PRINTED BY STRANGEWAYS AND SONS
Tower Street, Cambridge Circus, W.C.

INDEX.

- Abbott, Brothers, Pitts apary, Southall, 29; sections, 86, 159; honey-labels, 219; apiaries, 391; new method of fixing foundation, 72
- Abbott, C. N., his syrup-can, 158; on in-and-in breeding, 140; his wax-guide, 185; his wax-smelter, 48
- A B C for beginners, 40
- Adapting-board, 211
- Adulterate foundation, 307
- Adulterated honey, 129
- Adulteration, 333; of honey, 293, 329, 439, and wax, 315
- Afternoon of, an, 291
- After-swarm, 310, 391
- Aids to success, 50
- Alberti hive, 152
- Albany Heath, 185
- Alighting-boards, 191
- Alley, H., on queen introduction, 113; his cheap queens, 422; and Carniolan queens, 530; *Thirty Years among the Bees*, 576
- Alpough, Mr., his foundation fastener, 193
- Aluminium, 433
- Amateur carpenter, notes by, 534
- 'Amateur Expert,' his apary, 3; who is he? 51, 64; on third-class examiners, 76; jottings by, 224, 367, 422, 432, 508, 528, 538, 551; Carniolans, Italians, &c., 553
- Amulant apary in Belgium, 166
- America, product of honey in, 311; weather in, 120
- American Apiculturist, 536
- American bee-keepers, with the, 574, 600, 610
- American enamel cloth. See Enamel cloth.
- Ancient bee-keepers, 128
- Andrea, 243, 363; effect of, on a lawn, 308
- Andren, F. C., his apiaries in Minorca, 339. See Minorcan bees.
- Antenna cleaner of hymenoptera, 414, 579; functions of, 401
- Anterior legs of bees, 509
- Ants, getting rid of, 613
- Aphidian honey, 575
- Apary, demoralised, 41; establishing, 107; position for, *ib.*; locating, 237; a new enemy in, 325; space for, 362; help in the, 395; situation of, 400; strange visitants to, 553
- Apiaries, introducing fresh blood into, 30; isolated, 63; site for, 207; Mr. McNally's, change in locality, 512; class in schedules for small, 558
- Apiculture, report of some experiments in, 109, 476, 484, 565
- Apicultural terms, glossary of, 122
- Apis Europaea*, 122
- Apifuge, 1, 302
- Apiol, 310
- Apis dorsata*, 219; indica, *ib.*
- Apology, an, 170
- Appliance-manufacturing, 94
- Artificial combs, 432
- Artificial foundation, 168
- Artificial honeycomb, 391
- Artificial pollen, 85, 139
- Artificial swarm, 183, 221, 349, 429; making, 319, 351
- Artificial swarming, 159, 348
- Associations, organization of, 78; work for, 62; and their work, 559
- Atte vreat show, 352
- Bacillus, 517, 528; or bacine, 443
- Bacillus alvei, 400, 460; its propagation, 461; treatment of, 462
- Bacillus depilis, 219, 234, 307, 472; and minor, 284
- Bacillus minor, 136, 390
- Bacteria, and the germ theory, 600
- Balling the queen, 362
- Barbadoes sugar, 184
- Barecelona, exposition at, 381
- Bar frame hive, management of, 169; arrangement of, 266
- Barricades constructed by bees, 573, 580, 602
- Barricading, 591, 615, 616
- Bee, the coming, 58; and the honeymoon, 457
- Bee-department at the Royal, 314
- Bee disease, 117
- Bee-farming, success in, 498
- Bee-farm, locality for, 55
- Bee-farming, 94
- Bee-feeding, syrup for, 552
- BEES-FLORA:—
- Alois clover, 311; Anbrictia purpurea, 5; Bokhara clover, 160; Borage, 85, 207, 272, 300, 488; Buckwheat, 297; Canada thistle, 497; Catmint, 297; Chapman's honey plant, 497; Clover, 523; Cotoneasters, 85; Cotoneaster micropophylla, 195; Crocuses, 400; Echinops glolosa and ritro, 497; Echinops sphaeroccephalus, 321, 390, 422; Erchium (English), 322; Erica vagans, 529; Figwort, 207; Giant balsam, 502; Giant globe thistle, 508; Gorse, 136; Groundsel, 68; Heath, cross-leaved, 399; Heather, 362, 399, 415, 44, 472; Honey plants, 565; Hoya carnos, 121; Lamium (dead-nettle), 321; Linanthus Douglasii, 85, 322; Ling, 399; Medicago lupulina, 322, 333; Melilotus leucantha, 467; Mignonette, 322; Melilotus alibi, 167; Nepeta, 321, 390; N. Mussini, 272, 488; Mustard, 207; Parsley, 322; Phacelia, 207; Protea mellifera, 198, 310; Sainfoin, 343; Scrophularia, 322; Teucrium, 321, 390; Trifolium incarnatum, 85, 254; Trifolium minus, 322, 333; Trifolium procumbens, 333; Trifolium repens, 333; Wallflowers, 85, 400; Whitearads, 400; Winter beans, 85
- Bee-flowers, 122, 330, 497
- Bee garden, County Down, 501
- Bee-hive, damage to a, 393
- Bee-hives, long or short? 497
- Bee-house, 109, 155
- Bee-hunter, a, in trouble, 128
- Bee-keeper, accident to a, 212; in prison, 225; antiquated, 331; a young, 572
- Bee-keepers, to, 405
- Bee-keeper's Advice, 135, 155
- BEES-KEEPERS' ASSOCIATIONS AND SHOWS:—
- Bedfordshire, 189; Berks, 61, 140, 519; British, 1, 5, 15, 44, 86, 111, 175, 209, 222, 233, 260, 309, 325, 331, 352, 379, 463, 493, 526, 539, 555; Bury St. Edmunds, 313; Caledonian, 392; Cambridge, 209; Craven District, 285; Derbyshire, 114, 452; Devon County Agricultural, 343, 356; Essex, 100, 223; East Lothian, 452; East Stirlingshire, 452; Ebor, 264; Glamorganshire, 331; Glasgow International, 19, 20, 154, 176, 245; Gloucestershire, 111, 153, 176; Hants and Isle of Wight, 331; Herefordshire, 49; Herts, 492; Huddersfield, 421; Hull and District, 237; Hunts, 5, 44, 46, 579, 622; Irish, 19, 109, 152, 188, 257, 331, 466, 485, 493, 495, 552, 601; Kent, 32, 579; Lancashire and Cheshire, 73, 98, 165, 239, 377, 435, 451; Leicestershire, 61, 72, 128, 153, 170, 348, 368; Lincolnshire, 348, 601; Lowestoft, 222; Middlesex, 114, 222, 368; Monmouthshire, 237; Northamptonshire, 49, 165, 369, 495; Northumberland, 1; North-east of Ireland, 134, 463; North of Scotland, 219; Nottingham, 104, 223, 309, 331, 349, 369; Oxfordshire, 72; Royal Agricultural at Nottingham, 197, 233, 249, 331, 340; Shropshire, 123; Somerset, 98, 115; South-east, 222; Staffordshire, 164; Surrey, 463; Sutherland, 343; Teinoiden, 125; Warwickshire, 293; Waterford, 393; West Cumberland, 552; Wiltshire, 116; Wilts, 368; Windsor Royal Show, 558, 585; Worcestershire, 141, 166, 176; Wotton-under-Edge, 435, 601; Wrockwardine, 47, 477; Yarnton, 493; Yorkshire, 73, 240, 423, 590
- Bee-keepers' Magazine, 105
- Bee-keepers' Review, 105
- Bee-keeper's song, 555
- Bee-keeper's vocabulary, 175, 188, 246, 366, 379, 408, 422, 433, 529, 541, 550, 562
- Bee-keeping, 128; progress of, 4; alone, or with other pursuits, 32; teaching, in schools, 106; how to commence, 107; prospects of, 149; progress in, 241; in Russia, 322, 605; conducting, 378; investments in, 393; as a hobby, 183; time for beginning, 492; locality for, *ib.*; illustrations of, for children, 522
- Bee-master, of a century ago, 281, 292, 302, 309; a gentle, 320; out of harness, 43
- Bee parasites, 492
- Bee pasturage, 509
- Bees, do they select a home, before swarming? 10; selecting a home before swarming, 20, 497; how they extract pollen from flowers, 21; cruel laws as to destruction of, 33; stealing honey, *ib.*; what induced me to keep, 39, 50; old, 41; decamping, 55; best variety of, 55; Irish and Moorish, 77; in peach-house, 81; scouting, 94; moving, 94; in skeps starving, 95; natives of England, 121; in roof, 122; on the first flight of, in spring, 134; do they sleep? 135; dead, 135, 147, 161; a nuisance, 147, 338; killing each other, 190; confining to the number of frames they can cover, 163; for pleasure and profit, 168; proving a nuisance, 171; and blast furnaces, 184; dying in the midst of stores, 181; fixed in comb, 219; vacating hive, 219, 254; are they worth keeping? 221; best for all purposes, 227; collecting honey, 239, 294; at shows, 241; deserting skep, 243; benefit of, to agriculture and horti-
- culture, 253, 272; carrying out larva, *ib.*; dying, 266; improving race of, 272; damaged in transit, 289, 298; in skep, driving and transferring, 298; deformed, *ib.*; selling, 307; refusing a queen, *ib.*; are they a nuisance? *ib.*; immature, thrown out of hive, *ib.*; hanging out, 308, 319; lousy, 317; in Minorca, 323; impaled, 327; one pound of, 327, 572; to cover six frames, 327; swarming, *ib.*; management of, *ib.*; in a riddle, 335, 348; carrying pollen, 337; vacating hive, *ib.*; variety of, *ib.*; beautiful coloured, 348; number of, in a hive, 367; and monarchy, *ib.*; in Natal, 369; grub-from, 370; short of food, 374; in roof of hive, *ib.*; who should keep, 378; and bee-stings, 384; illegal interfering with, 415; de-lodging, *ib.*; travelling, *ib.*; recognition by, 418; do they mix honey in the cells? 422; getting out of sections, 423; some queer things about, *ib.*; on the raid, 425; and clover, 432; swarming on a cow's back, 435; rapidity of, in gathering honey, 441; in skep-building combs parallel to the entrance, 442; the battle of, 467; what they will do, 469; have they a memory? *ib.*; shiny, 472; best look on, 492; do they hear? 500; and pigeons, race between, 529; time for purchasing, 563; their sense of smell, 562; best age of, to go into winter quarters, 565; how they eat honey and pollen, 569; hunting, 589; as educators, 605; r. fruit, 611; defensive works of, 615; as food, 625
- Bee-shows, 75
- Bee-space in body-box, 68; between rack-and-frame, 243; in tiering-up cases of sections, 223
- Bee, stung by, a, 391
- Bee-stings, what becomes of that part left in the flesh? 426. See Stings.

- Painting hives, 97, 143, 179, 184, 559; inside of hives, 105, 124, 132, 143, 155
- Palestine, bee-keeping in, 8, 157
- Palestine bees, 113
- Paper quilts, 396, 499
- Parallel r. right-angled frames, 30, 54, 52, 67, 77, 102
- Parasites, 195
- Passage-way over the frames, 429
- Past, the, and future, 504
- Patent hives, 68
- Patent rights in sections, 67
- Pea-foot, 55, 57, 139
- Pect cage, 39
- Pellicles in cells, 417
- Percentages, 457, 468
- Perfect rest, 576
- Perforated separators, 207
- Perforation of flowers, 506, 594
- Pettitt, Mr., of Dover, his adapting-board, 211
- Phenol, 496, 601; in drink ing water, 160
- Phenolated syrup, feeding for winter with, 387
- Phenolating syrup, 441, 482
- Photographs of bee keepers, 106, 179, 327, 625
- Physiology of the honey-bee, 599
- Pipe-cover case, 421
- Piping queen, 318
- Pitts apiary, Southall, 29
- Planting trees and shrubs, 98, 562, 595
- Plants, 187, 441; to cover walls and fence, 195; cultivation of, 218
- Plenary root, 311
- Pollen, 136; masses, 22; food, 27; substitutes for, 57; gathering, 68, 347, 362; whence derived, 117; in combs, what should be done with, 159; chemical properties of, 212; cells clogged with, 231, and hie bread, 288; proportion of, carried, 289; the medium of introduction of bacillus alvei into the hive, 461
- Pollination of flowers, 504, 534
- Pollman, Dr., on the different races of bees, 121
- Porches, 204
- Porto Rico sugar, 184, 118
- Portraits of bee-keepers, 625
- Postal arrangements, 19
- Practical work in the apiary, 57, 63, 97, 111, 125, 137, 161, 185, 209, 245, 258, 269, 299, 319, 351, 375, 473
- Practical hints from Brother Jonathan, 119, 162
- Preparations, 5, 97; for summer, 212; for winter, 391, 395, 509
- Preventing sagging of foundation, 269
- Preventing swarming, 77, 91, 195, 196, 283, 372
- Prize-takers, 522; engagements of, 192
- Prizes, proposed subscription for, 11
- Propolised frames, 147
- Provincial Associations, 565
- Psychida, 395
- Quarterly conversaciones, 299, 353, 513, 526
- Queen, securing in a swarm, 28; getting rid of, old, 68; ascending to third storey, 89; preserving frozen, 95; should she be retained more than two years? 127; finding, 146, 491; clipping wings of, 218, 492; nursery, 219; droue

- rearing, 231; dead, 255, 289, 337, 348, 400; thrown out, 255, 317, 383; giving to parent colony immediately after swarming, 275; keeping laying, 289; half a, better than none, 306; presence of, 327, 339; laying powers of, 327, 359; rearing or providing, 349; missing, 337, 374, 491; superseding, 384, 491; failure in introducing, 408; will removing increase the honey yield? 413; how recognized, 419; doubtful, 458; age of, 482; barren, *ib.*; fertilised or not? 502; fertilised, 536, 518; balling, 562
- Queens, sending by post, 39; virgin, 60, 61; superseding, 94, 273, 316, 293, 420; doubtful, 243; records of, 273; young, 327; laying capacity of good, 35; rearing, 415; mating, 419; balled, 432; missing, 458; do they lay eggs in royal cells? 509; size of, 521, 568; probability of pure fertilisation of, 548; introducing, by scent, 557; late, 609
- Queen-ant, an old, 171
- Queen-brooding, 30, 18, 93
- Queen-cage, 604
- Queen cells, old, 255; destroying, 290; in hive, 307; preservation of, 432
- Queen-excluder, 94, 122
- Queen-excluding honey-boards, 211
- Queen-introduction, 115, 194, 200, 311, 384, 400, 420, 432, 438, 447, 456, 481, 523
- Queen-nurseries, 219, 250

THE BRITISH BEE JOURNAL

Communications to the Editor to be addressed 'STRANGWAYS' PRINTING OFFICE, Tower Street, Cambridge Circus, W.C.

[No. 289. VOL. XVI.]

JANUARY 5, 1888.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

BRITISH BEE-KEEPERS' ASSOCIATION.

The next Quarterly Conversazione will be held at 105 Jermyn Street, on Wednesday, 18th inst. Members wishing to introduce subjects for discussion should communicate with the Secretary on an early date.

A RETROSPECT.

About to commence the labours and duties of another year, it seems desirable to cast a glance at the work performed during that through which we have just passed, to note the experience that has been gained, and to recognise the position bee-keeping now occupies.

Although the past year can in no wise be compared with that which preceded it, when the magnificent exhibition of honey and bee-appliances was held in South Kensington, and when we had the unique opportunity of practising international courtesies to the delegates from the bee-keepers in Canada, yet the year 1887 has been productive of good and varied work, and considerable progress has been made.

Several most important exhibitions of the products of, and aids to, bee-keeping have been held during the year; the principal of which have been held under the auspices of the Royal, and the various Counties Agricultural Shows. The intimate connection between Agriculture, Horticulture, and Apiculture, has herein been recognised; and we have evidence that farmers and bee-keepers are becoming more united to each other, and that the production of honey in the future will not be merely a pleasant pastime to the few, but a useful adjunct to the other occupations and industries of the farmer. A noticeable exhibition was held at Bury St. Edmunds in connexion with the Suffolk Agricultural Society Show, which created much interest in that district. The bee department of the Royal Agricultural Show at Newcastle fully maintained the prestige which bee-keeping had gained at previous exhibitions of the Royal. The entries were more numerous than on any previous occasion. A series of lectures were also given in that district, which, together with the exhibition, has given birth to an Association in Northumberland. The example thus

shown by the Royal has been followed by the Lincolnshire, Hampshire, Norfolk, Glamorganshire, and others. Bee-keeping has also, by the action of the Association, found a place amongst the Co-operative body. The small exhibition of honey held in connexion with the National Co-operative Show at South Kensington has resulted in a comprehensive prize-list for honey and appliances being prepared for their next annual show, which it is proposed to hold at the Crystal Palace in the month of August.

The increased interest taken by bee-keepers in obtaining certificates for ability in the manipulation of bees is a hopeful sign, and has been a marked feature during the past year. The number of examinations throughout the country is steadily increasing. Nearly fifty candidates have presented themselves as anxious to obtain honours in the profession. Nearly thirty third-class certificates have been gained by successful competitors, one of these, we have much pleasure in mentioning, being a lady. A number of first and second-class certificates has also been awarded.

Considerable advance has been made in the perfection of bee-appliances; and although many of the improvements may be very minute the tendency of them is to make bee-keeping a more pleasing occupation, and, when connected with a knowledge of the management of the honey-bee, to render it more certain of success. We may also mention the greater attention which has been bestowed on the more gentle and humane mode of handling bees. During the year there has been a considerable demand for the Apifuge, a knowledge of the virtues of which is due to Mr. R. A. H. Grimshaw. This has been in a majority of instances a great success, and has proved of service in giving confidence to young beginners and to lady-bee-keepers. We have also heard much of, and can testify to, the value of the frames, sections, and crates invented by Mr. James Lee; but as these are scarcely yet launched on the public market it would be premature at present to do aught but mention them as inventions of the year 1887.

During the past year we have arrived at a more definite knowledge of the quantities and values of the honey and wax imported into the United Kingdom. This, when conjoined with the amounts re-exported to other countries, gives as the result that 1755 cwts. of foreign honey have been required to supplement the deficiency of production

to satisfy the wants of the British population; while in wax 20,108 cwts. have been required for the various industries in which it forms a part. To what degree these importations of honey and wax may be reduced depends on the energy and enterprise of the British bee-keeper.

We regret in this retrospect to have to notice that the year has not passed away without the loss of some who have in their time done the cause of bee-keeping good service. Amongst these we may mention Mr. Duncan Stewart, one of the most assiduous and energetic members of the Directors of the B. B. K. A.; and Mr. C. Fox Kenworthy, once Secretary of the B. B. K. A., and at the time of his death Secretary of the Middlesex B. K. A., a young man of great ability, and of singularly amiable and modest demeanour, who did much during the short time he was in office to revive the position of Middlesex amongst County Associations.

Amongst the features of the past year it becomes us to mention the visit of Mr. Cowan to the bee-keepers of Canada and the United States. This visit, we rejoice to say, has much gratified our Transatlantic brethren, and has cemented bee-keepers in both countries in a closer bond of interest.

The literature of the honey-bee has not been neglected during the past year. Mr. Simmins's *Modern Bee Farm* has been well received; Mr. Cheshire's work is now completed; a new edition of Mr. Cowan's *Guide-book* has been called for; and *Modern Bee-keeping* still maintains the high position it has always held in the estimation of bee-keepers.

The position of the County Associations, being a matter of the greatest moment to bee-keepers, has been dealt with in a separate comment.

The season of the past year has been peculiar; for some time the honey-flow was most plentiful, but it was brought to a stand-still by a long and continuous drought. This had a serious effect on the honey prospects of the southern portion of the kingdom, while in the northern parts of England and in Scotland the harvest was most propitious, and in many instances wonderful results were obtained.

In drawing these remarks to a close, we again desire to recognise the assistance we have derived from our numerous friends,—assistance which we trust may be continued towards us during the year on which we are entering, and we hope that the year 1888 may be one marked by prosperity and blessing to all bee-keepers.

COUNTY BEE-KEEPING ASSOCIATIONS.

Now that the organization of the British Beekeepers' Association may be regarded as complete, and the County Associations fulfilling in a more or less active manner the functions assigned to them, the *internal working* of the latter and their *individual condition* may be a useful and timely inquiry. The thought is now and then expressed that 'the work for which they were formed has in a great degree been accomplished.' Meetings have been held generally all over the county, the expert has been his rounds year by year, shows have been

held annually, and knowledge on the science of bee-keeping has been widely spread; the straw skep has been superseded, and the fact driven home that the old-fashioned bee-keeper has been left far behind. The question may now, therefore, not be out of season, and the consideration of it may throw light upon the more particular aims which the managers of County Associations should set before them.

That the spirit in the management of County Associations is on the decline there is evidence, and, had we the facts on which to speak more fully, we fear that the one instance on which we can speak with knowledge would not be an isolated one.

In an important county, and with a list of subscribers approximating to 300, we learn that, though its committee contains fifteen members, the business of the Association has been carried on by four only, two of whom have attended all the meetings summoned, and the other two have each attended once.

This, after due allowance made for inability to attend on the particular days fixed, and the difficulty of getting to the places appointed, cannot but be considered as unsatisfactory. In some other counties the circumstances, although differing, are not satisfactory. In one in the south of England all movement appears to have died out, while in another, more northward, the whole management seems to have fallen into the hands of the honorary secretary. That these are alarming symptoms of decline only very sanguine people can doubt, and to arouse attention to the malady and to seek to remedy it should, we think, be the immediate work of the Central Association. The present period of the year is well suited for the purpose of instituting a general inquiry into the working of the various Associations, and for the consideration of suggestions which might be applied during the ensuing season.

LANTERN-SLIDES.

We are pleased to find that Mr. Watkins, the Hon. Secretary of the Hereford Association, has devoted so much time and trouble in preparing such a selection of lantern-slides illustrating bee-keeping. Mr. Watkins has not only illustrated the natural history of the honey-bee, but has gone thoroughly into the processes and manipulation of the science in general. We notice many very interesting subjects, showing the various stages of bee-keeping, describing the modes of stinging, supering, extracting, &c., also a slide of a Swiss apiary, giving us an idea of our Continental friends' bee-hives.

The preparation of the slides is not quite satisfactory, some being rather out of focus, thus losing the crisp sharpness which is very essential for lantern work. The slides are generally too intense from over-development, consequently will not show a sufficiently bright transparent image on the screen. Had Mr. Watkins taken more care on these points, we could have pronounced them as a splendid collection. We should certainly recommend him to make another selection of transparencies to obtain a more perfect result.

AMATEUR EXPERT 'AT HOME.'

Readers of the *B. Bee Journal* will quite understand my feeling considerable curiosity about and a consequent desire to unearth (or smoke out) our genial correspondent, whom I had already met at our *Conversazione*. I therefore consulted 'the Sage,' whose kind offices as *cicerone* I was desirous of obtaining, for I hoped he would prove a 'jolly old buffer' (if he will pardon the expression) between 'A. E.' and myself, softening the impact and reducing the results of a collision to a minimum. My scheme, growing by contemplation, was advanced by the despatch of a tentative P. C. (post-card, not police-constable) on scout-work to ascertain if our friend would be at home. The defensive nature of the reply—just the monosyllabic 'Come'

times, when unusually facetious, taunts us Saxons with being 'land robbers.' After serving a youthful apprenticeship in the cleanest and prettiest town of 'West Barbary' he has to choose his future path, and hesitates between London and Canada, for several of his school-mates had emigrated and were sending home good reports from that colony. He, however, selects London, and (having started bee-keeping when six years old) it were perhaps as well he did so, or where might he not have been by this in the ranks of Canadian bee-keepers? Eight years' toiling hard at the bench, all his leisure filled in with mission and Sunday-school work, are cut short by an accident which necessitates two long spells and an operation in hospital. These tell on a constitu-

—was characteristic, we thought; it might mean anything, 'Come and welcome,' or 'Have at you.'

Express train from a London terminus took us to within four miles of where 'A. E.' had fixed his 'hive,' and upon that gentleman meeting us we were welcomed as bee-keepers *know how* to welcome their brethren.

The query, 'Is it to spy out the nakedness of the land ye are come?' being met by a reply that X-Traction was the means we were at home. Of course when we entered the house we 'uncapped,' but there was no 'sling' done, and the Formic-Aphidean process commenced. I question much if the umpire himself would not decide that it was impossible to determine which was Napoleon and which the Alps—which the ant and which the aphid—at the conclusion of the extracting. I leave you to judge, though, if I did not do well to glean what follows.

'A. E.' not forty, fair, and fairly fat, is—speaking as a poultry fancier—a 'Plymouth rock';* a Cornish man, with a Cornish name, and a tread-on-your-Cornish nature if you attack him. I can assure you he is able to 'hold his end up' in a dispute. Being a Celt he some-

times, when unusually facetious, taunts us Saxons with being 'land robbers.' After serving a youthful apprenticeship in the cleanest and prettiest town of 'West Barbary' he has to choose his future path, and hesitates between London and Canada, for several of his school-mates had emigrated and were sending home good reports from that colony. He, however, selects London, and (having started bee-keeping when six years old) it were perhaps as well he did so, or where might he not have been by this in the ranks of Canadian bee-keepers? Eight years' toiling hard at the bench, all his leisure filled in with mission and Sunday-school work, are cut short by an accident which necessitates two long spells and an operation in hospital. These tell on a constitu-

tion none too robust, and drive our friend into fresh fields of enterprise—his present business, which he boasts is three miles from 'Civilisation,' *i.e.*, from butcher, baker, chapel, and post. He has been a life abstainer from alcohol, tobacco (Ah!), and the razor. (Some may understand me when I say there has been either a land-slip or a hard frost in the polar regions.) The Band of Hope and the Mutual Improvement Society in the neighbouring town give 'A. E.' scope for his superabundant energy, and he affirms that his happiest hours are spent amongst children. Children, alas! when I looked round for the bairns he told me with a husky voice, 'Our five are where pain and sorrow cannot come.' 'A. E.' lives by activity, and 'jots' for pure pastime, as a safety-valve for the escape of exuberant fun.

* I don't infer he keeps this breed, but was born at Plymouth, where they are said to be favoured with thirteen months annually of rainy weather.

iron and stone, carve and paint, gild and paperhang, do moulting and bricklaying, and even work in wool—specimens of all these I saw—you will admit that he is not only a 'jack-of-all-trades,' but I can testify he masters them too. His literary work gives you a fair sample. Roses and fruit trees, hives and hennery, winter packing (mattresses of bed-ticking, rammed, just too hard I thought, with cork-dust, sewn and wadded down), quilts edged with scarlet binding to prevent fraying, hives painted different colours, roofs covered with canvas and well painted—neatness, neatness everywhere.

A 'grand promenade' for bees, under and in front of hives, is made by battering down into a hard, flat surface what are known as 'breezes,' i.e., the small cinders from a forge. This forms a sacrum and reservation, absorbing and retaining solar heat, thus providing the bees with a warm, dry alighting ground. The central bee-house, containing six hives, is flanked by two straw-hacked skeps, reminding us that a hackle, like charity, covereth a multitude of sins. Outside these are two 18-frame Abbott's Combination hives, beyond which are six 10-framed, double-walled, home-made hives. The house is surrounded by a six-acre meadow in which hives were formerly kept, but in summer time the cows objected, and Our friend takes great interest in his County Association, and has been county representative and local adviser for some years, lecturing at frequent intervals to both adults and children on our hobby. He was made 'A. E.' by the late Rev. H. R. Peel, who often met him on long trips with the bee-tenant when certified experts were unknown, yet expert work he never took unless as a stop-gap, when professionals could not be obtained.

Fruit gardens on all sides, amidst clover and bean-fields, give the bees ample pasturage for the early harvest, and amongst the surrounding woodlands trees—sycamores, limes, and oaks—will yield their quota of honey in their season. A stroll in the adjacent park showed us wild thyme still in bloom on the bosses of verdure provided by old tree-stumps. This adds its strong pervading scent to the larger bulk of honey gathered from other flowers, and often, as is the case with labiates, presents us with a puzzle-blend which defies us to brand the honey with its origin. The lanes at every junction open out into large stretches of close green turf, lightly suggestive of village-greens, and the hedges are so thickly covered with bramble-berries that we recognise another feeding ground. The bees have been here, and the blackberries show it; the oaks show it, too, for they are laden with acorns, a proof of maturation and insect (not wind) cross-fertilisation. At almost every step immense bushes are literally covered with crimson-scarlet fruit, and these, the seed-pods of the single rose, surely indicate insect visitation. The dazzling-shining lips vie with the autumn tints of the bramble-leaves, which run in a perfect gradation of colour, from bluish-purple through crimson, scarlet, orange, primrose, and lemon-green, into the pale-green and deeper shades of the still growing foliage. Here, too, are sloes and wild plums in fruit, whilst the masses of haws on the thorns testify that some one has had a good share of the hawthorn honey, and that we must expect a winter of snow-covered ground. Thus does Nature anticipate the requirements of the fruit and seed-eating birds, and prevent their extermination. So, reader, you learn the tone and subject of our talk as we stroll about, regretful at the close of another season, yet cheerfully hopeful in the future.

With something like a sigh we leave the park, the fine ancestral elms and oaks, the bee-gardens amidst rustic homes, decked with the graceful festoons of the virginian creeper, whose leaves gleam with all the intermediate tints, from deep bronze to a weird living scarlet, as though 'the early frosts of winter' had pierced Auctumnus to the heart, her life-blood dropping

from her breast upon the wreaths 'midst which she hid herself.

Long may 'Amateur Expert' and his good lady be spared to enjoy the grand gifts with which Dame Nature has surrounded their home! Long may his 'jottings' enliven the pages of the *B. B. J.*—EX-TRACTOR.

USEFUL HINTS.

NEW YEAR'S GREETING.—With the advent of another year we offer a New Year's greeting to all our friends and readers. May it prove a happy and successful year to the great fraternity of bee-keepers wheresoever scattered over the surface of this terrestrial globe. In these days of steam and electricity the term 'isolation' has become obsolete, and the interest in our antipodean brethren is as great almost as in our neighbours. Would that we could exchange a portion of our fog and cloud for a little of their superabundant sunshine!

PROGRESS.—Great strides indeed is the art of bee-keeping making in our day, and still must 'progress' ever be our watchword in every department of the science. *Apicultura floreat* amongst all 'nations, kindred, peoples, and tongues,' is the one wish of all our hearts whilst we earnestly strive to hold our own in the great world of apiculture. Great as the advance has already been, visions of future progress appear to us to loom in the future distance, as we read of English bee-farms with increased produce arising from the more perfect fertilisation by our bees, of the fruit grain and fodder crops of our at present sadly depressed agricultural interest. We must sow and water in hope, never forgetting that there is ONE, and ONE only, who can give the increase.

WEATHER—that universal theme of the Englishman—has, as we are told on all sides, become 'seasonable,' which at this time, we believe, implies severe frost and heavy snowstorms. The latter, we are truly thankful to say, have not visited us, although we hear from neighbouring localities reports of the action of steam-snow ploughs, clearing of roads, &c. Fifteen degrees of frost, kept up nightly for a few weeks, may be of great service to the land and to farming operations, and may also gratify the youthful yearning for skating pastime, and so we who would fain be spared such an ordeal must 'grin and bear it' in the hope that it may result in good to all, our bees not excepted.

THE STANDARD FRAME, established by the B.B.K. Association in 1882, as was to be expected, has met with unfavourable criticism at various times, but is now very generally adopted by all British bee-keepers. The point to which most objections have been raised is the length of the top bar, viz., 17 in. A short account of the establishment of the 'Standard' may, perhaps, interest our readers, reference being repeatedly made to it in the columns of the *Journal*. At the Annual General Meeting of the B.B.K.A., held at 105, Jermy Street on February 15th, 1882, a resolution was proposed and carried unanimously, 'That it is desirable that the B.B.K.A. do set forth a *Standard frame*, stamped by its Association and authority, with the view of bringing such frame into general use: its size and form to be determined by a Committee appointed for that purpose.' At the same meeting we read that, 'The following gentlemen—Messrs. C. N. Abbott, T. W. Cowan, F. Cheshire, J. G. Desborough, J. M. Hooker, Rev. G. Raynor, A. Neighbour, and Rev. F. T. Scott, were appointed the Committee to carry out the foregoing resolution.' On the 16th of March following this Committee held its first meeting at the Langham Hotel, when it was unanimously resolved: 'That the outside dimensions of the Standard frame be 14 in. long by 8½ in. deep, the top bar ¾ in. thick, the bottom bar ½ in. thick, and the side bars ¼ in. thick. These dimensions not to refer to anything outside the rectangle.' At a final meeting of the above Committee, held at South

Kensington on August 4th following, it was resolved, 'That the entire length of the top bar be 17 in., allowing $1\frac{1}{2}$ in. projection beyond the rectangle at each end of the frame.' This resolution was also carried unanimously. Also, on the same day, and at the same place, a General Meeting of the B.B.K.A. was held, at which it was reported by the Standard Frame Committee, 'That two meetings had been held, and it had been decided that the dimensions of the Standard frame should be in accordance with the resolutions,' as quoted above. This report, with its decisions, was accepted unanimously by the General Meeting, and a resolution was carried: 'That the work of the special Committee on a Standard frame be considered terminated.' Thus was completed, perhaps, the most important step of any taken by the Association for the advancement of bee-culture in this kingdom. *Pattern Standard Frames*, duly stamped and labelled with dimensions, were issued by the Association at 1s. each, and were freely circulated through the country. It will be noticed from the above account, that no *width* of the four frame-bars was sanctioned, or even proposed, by the *Frame Committee*. Upon what authority, therefore, is the width stated to be $\frac{7}{8}$ in. whenever the dimensions of the Standard frame are given? In Mr. Cowan's Book, p. 30, we are told 'the width of all the bars is $\frac{7}{8}$ in.' And Mr. Cheshire in *Bees and Bee-keeping* (vol. II., p. 53) says: 'The width on all sides being $\frac{7}{8}$ in.' In *Modern Bee-keeping* the width of the bars is omitted. It is true that the '*pattern frames*' were issued with bars $\frac{7}{8}$ in. wide, but there was no *authority* for this width. Would it not be well that this point, of width, and the length of the top bar, should be reconsidered by the general Committee? Our own feeling is that the outer dimensions of the rectangle, having been once established, and most extensively used, should remain unchanged, after 'the law of the Medes and Persians, which altereth not;' but that the length of the top bars—or, rather, of the lugs, or ears—and the width of the four bars, should *not* be defined. As the matter at present stands, there is an uncertainty, which, we think, might be removed without reopening the question of the size of the rectangle. As regards the question of standard one and two-pound sections, we are strongly of opinion that the imposition of such standards would be decidedly detrimental to the advance of apiculture.

INSERTING FOUNDATION IN SECTIONS.—There is a complaint in the *American Bee Journal* of the 14th ult., by Mr. E. S. Eden—after reviewing the different methods employed to fasten foundation into section-boxes—'that no one has invented a machine to do the work satisfactorily.' He goes on to say 'that, of the many machines invented, not one has given general satisfaction—that if foundation is fastened by dipping it into a melted mixture, or by pouring wax along each side, to attach it to the section, it will be found that the guide, or the wall to the top row of cells, will be destroyed, and the bees will refuse to draw them out unless they are short of room, leaving a very imperfectly-filled section. But if the foundation is fastened neatly they will draw the top row out equally with the rest, leaving the section filled in a superior manner. The plan of fixing foundation by pressure has also its drawbacks, as it is almost impossible to make the foundation adhere firmly, especially if the section is smooth and full sheets are used. Some have adopted the plan of heating the section and pressing the foundation upon the heated surface, but this plan has generally failed from the non-adherence of the wax. It is doubtful whether the plan of fastening foundation by pressure will ever be developed sufficiently to give general satisfaction. There are so many conditions that are absolutely necessary to procure the best results, such as temperature of the room, pliability of the foundation, warmth of the section, &c., before the work can be performed successfully. It is to be hoped that some one of the many thousand bee-

keepers will discover a plan that will give general satisfaction. Such a person would receive the thanks of every bee-keeper in the country.'

Let Mr. Eden rest assured that the plan has already been discovered, and patented, in the old country. Mr. James Lee's sections avoid every evil mentioned above; take full sheets of foundation, which are inserted while putting the section together in less time than any other section without heating, or smearing with melted wax without any machine at all; and from the foundation being stretched and tightly held in position, and the use of four-way section-boxes with slotted-dividers, the sections are worked and finished in the most perfect manner of any of which we have knowledge, after an experience of all kinds of section-boxes from the time of their introduction. We are informed that Mr. Lee has taken, or is about to take, out a patent for his invention in America as well as in England. Let our American and Canadian brethren take a note of this. Mr. Lee has also patented a brood-frame on the same principle as his sections, which, we feel well assured, will be the frame of the future, when it once becomes known. With one season's experience of these frames and section-boxes, we have not the slightest hesitation in pronouncing them *faciles principes* of any which have yet appeared to our knowledge.

WORK FOR THE MONTH.—Still we cry aloud, and say, 'Leave the bees severely alone during the present low temperature.' If necessity demands, supply candy, or Good's food, under the quilt, in mild weather, and in case of moisture flowing from the entrances a change of quilts—from damp to dry—is admissible, and, perhaps, a change of floor-boards, but all must be done as quietly and quickly as possible without jarring or disturbance of any kind. After this long confinement to their hives the least excitement will cause untold injury to the bees. If there be any suspicion of internal dampness it may be advantageous to raise the hive and floor-board an inch at the back and to wedge up the hive from the floor-board in front, sufficiently to allow the moisture to escape. We are supposing the hives to be on the 'right-angled system,' in giving these directions.

BREEDING.—In strong colonies the queens will now begin to breed, and the consumption of stores will increase daily. We are well over the shortest day, and in well-conducted apiaries the busy hum of the workshop, as well as of the hive will soon be heard in preparation for the impending campaign.

PREPARATIONS.—Hives, sections, crates, foundations, frames, &c., should be procured, and prepared for use whenever leisure affords an opportunity. As the spring months advance, the hives, with their colonies, will require all our attention in feeding, examining, uniting, and in other ways: hence, January and February afford more leisure, perhaps, to most, than any period of the year for preparing for the honey season. With milder weather bees, after their long confinement, will be eager for sanitary flights, which should be encouraged as much as possible, and on such occasions, let all be on their guard against the *tiss*, ever anxious for an insect meal after their long deprivation.

ASSOCIATIONS.

BRITISH BEE-KEEPERS' ASSOCIATION.

List of successful Candidates at the Second Class Examination, 1887, in order of merit:—T. Badcock and J. Palmer equal, W. Coxon, J. J. Shipman, T. Austin, R. Woodward, J. White, F. Wilshaw, A. J. Brown, Mary E. Eytton, and B. S. Rawson.

HUNTS BEE-KEEPERS' ASSOCIATION.

The annual distribution of the prizes gained at the recent show in connexion with the Hunts Bee-keepers'

Association took place at the Fountain Hotel, Huntingdon, on Saturday, the 24th December. Col. A. W. Marshall, treasurer of the Society, occupied the chair, and presented the successful exhibitors with their awards. There were also present Mr. C. N. White (secretary), the Rev. H. S. Budge, Messrs. J. Linton, J. Howard, J. Howard, jun., Allen, Bull, Allpress, Hobbs, &c.

The Chairman said that on the notice paper convening the meeting it was stated that Mr. White would find it incumbent upon him to resign the secretaryship of the Association at the end of the year. They would be all very sorry to hear that. He believed, however, that it would be informal to settle the matter at that meeting, because resignations could only be accepted at the annual meeting. The consideration of Mr. White's resignation, and the appointment of a fresh secretary, if they could not prevail upon him to alter his determination, would therefore be discussed then. Mr. White's object in putting the matter on the paper was to give due notice of his intention, so that his resignation should not be suddenly sprung upon the Association at the annual meeting. The resignation would cause a universal feeling of regret, and they could only hope that Mr. White's decision was not irrevocable.

The distribution of prizes, a list of which we give below, was then proceeded with.

At the conclusion of the distribution, Mr. White said that perhaps it would be as well for him to state the reasons which induced him to give notice of his resignation. He felt utterly unable to continue the secretaryship of the Association. He sincerely regretted this, but he really could not continue to bear the expenditure of time and money to which he had been subjected since the formation of the Society some five years ago. If all the members knew upon whose efforts the carrying on of the Association's work had depended, they would sympathise with him in his present action. It would have been utterly impossible to have carried on the Association so far had it not been for the assistance of the chairman of their meeting that afternoon. He really could not continue to hold office under this state of things any longer. Then there was another reason which had induced him to resign his office. The Association was originally intended for the benefit of the cottager class entirely, but now, when soliciting for subscriptions, he was frequently met with the question, 'What are you doing for the cottagers?' The fact of the matter was, they had done very little for the cottagers since the formation of the Society, and they were doing very little for them now. While speaking in this strain, he did not for one moment wish it to be understood that he intended to infer that the Association had not done any good since its formation. On the contrary, he believed that it had. Huntingdonshire could now boast of some bee-keepers who would not in a competition take a very low place amongst the bee-keepers of the kingdom. Then, again, there was the fact that the county now had manufacturers of bee-keeping appliances second to none in the kingdom.

A short conversation followed on the points which had been raised by Mr. White; those who took part in it being the Rev. H. S. Budge, Mr. J. Howard, and Mr. Hobbs. The proceedings concluded with a vote of thanks to the chairman.

The following is a list of the prize-winners:—

BEEES.—Best specimen of English bees, exhibited with their queen, in a unicomb observatory hive. C. N. White.

HIVES.—The cheapest and most serviceable hive on the moveable-comb principle, for general use, with arrangements for taking surplus honey. 1, 7s. 6d., J. H. Howard.

HONEY AND WAX.—Best 12 1-lb. sections of comb honey. 1, 7s. 6d. and silver medal, J. H. Howard, jun.; 2, 5s., A. Sharpe; 3, 2s. 6d., J. Linton.—Best 6 2-lb.

sections of comb honey. 1, 5s., E. Allen; 2, 2s. 6d., Rev. J. F. W. Trumper.—Best exhibit of comb honey (not sectional). 1, 7s. 6d., J. Linton; 2, 5s., E. Allen; 3, 2s. 6d., Mrs. Allpress.—Best 12 1-lb. bottles of run honey. 1, 7s. 6d., Rev. C. C. James; 2, 5s., E. Allen; 3, 2s. 6d., J. Linton.—Best sample of beeswax (in one cake, not weighing less than 3 lbs.). 1, 5s., Rev. C. C. James; 2, 3s., Rev. H. Gee; 3, 2s., E. Allen.—*Cottagers only.*—Best 12 1-lb. sections of comb honey. 1, 7s. 6d., B. Bull; 2, 5s., F. Whybray; 3, 2s. 6d., R. W. Allpress.—Best exhibit of comb honey (not sectional). 1, 7s. 6d. and certificate, Z. Hobbs; 2, 5s., B. Bull.—Best 12 1-lb. bottles of run honey. 1, 7s. 6d. and bronze medal, R. W. Allpress; 2, 5s., B. Bull; 3, 2s. 6d., C. Colbert.—Best sample of bees' wax (in one cake, weighing not less than 3 lbs.). 1, 5s., C. Colbert; 2, 3s., Z. Hobbs; 3, 2s. B. Bull.

NOTTS HONEY FAIR.

After a lapse of two years the honey fair in connexion with the Nottinghamshire Bee-keepers' Association was revived on Friday and Saturday, December 16 and 17, with encouraging prospects. Messrs. Morris and Place kindly lent their auction mart in Bridle-smith Gate, Nottingham, for the purpose of the display, and very considerable interest was shown in the proceedings by those interested in the work of the Association. There were over twenty exhibitors. The British Bee-keepers' offered a silver medal for the best six 1-lb. sections, a bronze medal for six 1-lb. jars of extracted honey, and a certificate for a bee-glass of honey, for which there was a keen competition. The judging took place on Thursday night, the awards being made by Mr. Henry Yates, of Grantham, and Mr. Godfrey, of Lambley. Mr. William Silver, of Bridge Gate, Retford, won the principal medal with some excellent sections. The bronze medal went to the Rev. R. A. McKie, of Farnfield, and the certificate to Mr. G. Caparn, of Newton, who exhibited a bell-glass of 75 lbs. of excellent honey. The arrangements have been efficiently carried out by Mr. F. W. K. Fisher, of Farnfield, the honorary secretary of the Association. Wax, of which there was a small supply, was selling at 1s. 8d. per lb. The exact quantity of honey staged was 207½ lbs. and of wax 13½ lbs. A comparatively small quantity of the honey staged was sold, considerably more than half remaining. Prices, which on the first day were quoted at 1s. and 1s. 6d. per lb., fell to as low a rate as 8d., 9d., and 10d., both for run and comb honey retail, and 6d. wholesale.

THE LANGSTROTH BOOK.—Concerning the revision of this book and its publication next spring, Mr. M. M. Baldrige, of St. Charles, Ills., writes us as follows:—'The following extract from a letter from Dadant & Son, dated November 30, received by the writer, may be of interest to all the readers of the *Bee Journal*, and so unknown to them. I take the liberty of putting it public, trusting no harm, but much good, will ensue in doing so. "The revised work of Father Langstroth will probably be ready by next spring, and, judging from the number of inquiring friends, we anticipate a ready sale for it. As soon as it is ready for the press, or rather for sale, the readers of the *Bee*-papers will be duly informed by extensive advertising. We have been delayed in the revision of the work by different causes, independent of our control, but we think we have now overcome all the obstacles, and that the balance of the work will soon be completed. The revision of Father Langstroth's book is certainly in the best of hands, and I sincerely hope that Messrs. Dadant will be able to give us the opportunity to peruse it by the time indicated.—*American Bee Journal.*

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal," c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, Kings Langley, Herts (see 2nd page of Advertisements).

* In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

A NEW ARTIFICIAL COMB.

[1407.] I have been successful in producing a new artificial comb. I made this invention two years ago, and the comb was subjected to a practical test on a pretty large scale last year, and again in the present year. My artificial comb is no work of fancy, but the result of continuous and careful observation of the bees suggested by a remark of Gravenhorst which I came across in the second and third editions of *Der Praktische Imker* (the *Practical Bee-keeper*), and which I find has been reproduced in the latest improved edition of this work.

This remark prompted me to make experiments, the more so as I was not satisfied with the contrivances generally employed for excluding the queen from a portion of the combs, my idea being that the queen should be able to move freely over all the combs in the hive, and yet be prevented from using certain combs for breeding. I constructed an entirely new artificial comb, different from any hitherto in use, and the workers completed it quite satisfactorily, and in accordance with my indications. Trials on a large scale have also proved most successful, and the large increase of honey harvested by me this season is mainly due to my having used these new combs. Many more tons of honey would be obtained if my combs were in general use. With my new combs my sole aim in future will be to let my bees gather honey only.

I shall be prepared to make my invention known at once if bee-keepers on their part are willing to compensate me for the outlay incurred and the time I have spent on these experiments.

In order to enable bee-keepers to manufacture their requirements of such combs for themselves, I have started a subscription to a pamphlet in which my experience, as also the manufacture of the combs and the mode of using them, shall be described. Any one who engages to buy from me such pamphlet at the price of 1s. 5d. (1s. 6d.) will in due course receive a copy post-paid, in case I can get at least a few thousand subscribers. The pamphlet would be posted to all subscribers on the same day.

Thus, I think, is the cheapest way for bee-keepers to take advantage of my invention, for which in that case I should not take out a patent. But no time should be lost if bee-keepers are desirous of having the new comb ready for use by next spring.

The pamphlet may be ordered by post-card or through bee-keepers' Associations, and the order once given remains binding. I will announce in the *Bee Journal* the date when payment is to be made, which will be when the pamphlet is ready to be posted.—H. KOERBS, *Teacher and Organist, Berka on the Ilm in Thuringia, November, 1887.*

From the *Deutsche Illustrierte Bienenzeitung*.

We have frequently expressed the opinion that artificial combs might possibly become of importance to

bee-keepers, as it would perhaps be possible to construct them in such a manner as to exclude the queen from the space reserved for the storage of honey, and thus to restrict breeding. This now appears likely to be realised. Mr. Koerbs, of Berka on the Ilm, in Thuringia, wrote to us a short time ago: 'Prompted by a remark which I had read somewhere, and after careful study in the apiary, I have succeeded, by means of a comb specially constructed by me, in dispensing with the separating board, as far as the obtaining of honey is concerned. The advantages I claim for my artificial combs are:

1. They are made of pure wax by means of the Rietsche press, and are not used by the queen for breeding, even if the combs are inserted in the brood-nest.

2. They are very durable.

3. The most delicate combs will stand the employment of full force in extracting the honey.

4. The honey is extracted very quickly, the operation scarcely requiring half the time it takes to empty other combs.

5. In bad seasons these combs remain empty, not being used for breeding, and there being, unfortunately, no honey to collect.

6. The bees do not carry pollen into these combs.

7. The separation of the honey compartment in the hive from the brood-nest becomes superfluous.'

Mr. Koerbs promises a good deal. What Dzierzon often imperfectly realised by means of his diamond rule, and others by means of a division-board, Vogel's canal, or by merely moving the combs together more closely, may now be obtained more easily and in a more natural way by the use of Koerbs' artificial combs. Mr. Koerbs has been known to us for a long time as the fortunate inventor of the frame machines which go by his name, nevertheless we were not over sanguine in regard to his latest invention. But as he offered to give us particulars of his invention if we would give him our word of honour not to divulge his secret, we complied with his desire, and asked for full particulars, which were readily supplied to us: and in addition we received one of Koerbs' artificial combs completed by the bees from which the honey had been extracted several times. How simple a matter it appears! It is, indeed, another case of the egg of Columbus, and it seems strange the idea has occurred to no one before. Nobody by merely looking at Koerbs' artificial comb, as put up by us, will see anything particular in it, but when you take it into your hands and have a little explanation given you, the importance of this invention becomes at once apparent. If this new invention should accomplish only half of what Mr. Koerbs expects it to do, we shall undoubtedly see a great revolution in the manufacture of artificial combs, as well as in bee-keeping generally.—C. J. H. GRAVENHORST.*

[We received the enclosed notice of a new artificial comb, with a request to give an opinion on it, and a promise to send us a sample comb if we would undertake not to divulge the secret. This we undertook to do, but pointed out that we thought British bee-keepers would look with suspicion upon the method employed to make the invention known, and suggested a simpler method. The inventor prefers now to keep the idea secret, so we give the opinion of M. Gravenhorst upon it, taken from the *Deutsche Illustrierte Bienenzeitung*. If, as there stated, the invention would be a valuable one, it would be a pity if some method could not be devised to bring it into the market other than the one of collecting 1s. 6d. from each bee-keeper previous to sending out the pamphlet. Why does not M. Koerbs sell his invention to some foundation manufacturer, and introduce it in that way, or take out a patent and charge a small royalty?—Ed.]

* We are indebted for the above translation to Mr. H. Dieck, the joint translator, with Mr. Stutterd, of Dzierzon's *Rational Bee-keeping*.

BEE-KEEPING IN PALESTINE.

[1408.] There is only one way to enter the 'land flowing with milk and honey.' According to mythology, Andromeda was exposed on the rocks lying out before the town of Jaffa to the seaside, forming a small harbour for little sailing vessels, and was delivered by Perseus from the sea monster going to devour her. It is wild enough the entrance to this town. I have been standing on the shore looking out for friends coming back from France and England, have seen them fighting their way through the angry sea, and exposed to the waves carrying the boats high up to the top and down again into a deep gulph of water hiding them from sight. Why don't they choose an easier way? The steamer can come no nearer for the rocks which abound here. It is always a terrific sight to see travellers and pilgrims landing. Yet after having travelled so many days and nights, it is only a mile on the raging sea to touch the Holy Land. It is here the prophet Jonas found a ship going to Tarshish, embarked for that place, and was seized by a tempest. Joppa of the ancients, now Jaffa, is the port of Jerusalem. It is here that numbers of bees are kept, both in the original way of keeping them, *i.e.* in clay pipes, and in Langstroth hives, kept only by your humble servant.

Although Palestine is acknowledged by many authorities to be the real home of the honey-bees, and although we never read in the Bible of bee-keeping, yet, very often we read of the 'land flowing with milk and honey' promised to Moses. Some writers on Palestine are mistaken when they mention wild bees as more abundant than the domesticated ones, because, in Psalm lxxxi. 16, the Lord promises honey out of the rock; this is only to illustrate the abundance in saying, 'Even out of the rock shall I fill thee with honey.' In no wise was it meant that the honey out of the rock was more abundant than the honey out of domesticated hives. Although it is possible run-away swarms were more secure from the interference of man before the invention of gunpowder, because they could not easily be had without breaking the rocks, yet certainly they did get some, or else it would not have been mentioned. Very likely the Canaanites kept bees in the same way as the Arab population of Palestine, partly their descendants. All Eastern invasions were followed by a retrograde movement, agricultural, architectural, industrial, &c. We know that the Canaanites had chariots and highways, but nowadays an Arab is astonished to see a chariot, introduced only about eighteen years ago from Europe; and, to use their own expression, it is a 'thing moving along with nothing but two horses in front to drag it.' They had oil-mills exactly the same as now. The invasions destroyed arts and sciences, whilst the weaker inhabitant of the country was always more or less abandoned, and continued in his primitive industry, thus carrying throughout more than thirty centuries household and agricultural implements without the least improvements, and in many cases carrying the very name throughout all the generations, notwithstanding the change of languages from the Canaanites, Hebrews, Greeks, Romans, Arabs, Latins to Turks and Arabs again. Go to an Arab village, and you will find women grinding at the mill, either alone or as illustrated in Matt. xxiv. 41, 'Two women shall be grinding at the mill.' The mill is small, and can easily be transported. Two women sit down on each side of the mill (the upper mill-stone having a handle with just place enough for two hands) thus driving the mill, and singing a monotonous, solemn song of their departed loved ones and friends. It is to be concluded that the aborigines of this country kept bees in the same way as the inhabitants now do, by comparing the above.

Honey was always abundant in Palestine. I mean real bees' honey, gathered from flowers of all kinds abounding in the land, the almond, pear (our largest

crop), the orange-blossom, and the cactus; and in summer time when everything seems dry, the sesame (from the seeds of which the oil of sesame is produced, and used to a great extent in the country), and the labiate flowers, from which still the very highly flavoured and high-renowned honey of Hymettus was gathered from thyme-blossoms. Though some travellers tried to illustrate the fact of honey flowing from the trees, it is in no way common, for the want of trees or forests; and in the case of Jonathan, I Sam. xiv. 25-30, the honey was not dropping from the trees, but was flowing upon the ground, according to the new version; and, furthermore, Jonathan dipped his rod in a honey-comb, thus it was no honeydew, and he said: 'My father hath troubled the land; see, I pray you, how mine eyes have been enlightened because I tasted a little of this honey. How much more, if the people had eaten freely to-day of the *spoil of their enemies* which they found?' The Israelites came on the encampment of the Philistines, and suddenly fell on them. They overthrew everything, and the honey, kept in jars or he-goat skins then as nowadays, was overturned by the frightened cattle and soldiers, and was *flowing upon the ground*. The honeydew is only found in some trees, but in no locality that I know of will it yield honey enough to give anything more than a taste to bees in search of water or pollen during the intermediate months of the honey flow. In the Jordan Valley no bees are kept, because the nomadic Arabs only live here, and never trouble themselves in their wanderings with bees.

I dare say, except orange-trees and cactus-plants introduced here, the other honey plants have always been here, and the country yielded honey in quantity sufficient to form an article of export (Ezek. xxvii. 17). Honey was translated from the Hebrew 'dabash,' the real old name for honey. The Arabic word for honey is 'assal,' whilst a treacle made of the juice of grapes and boiled is called 'dibs' or 'dibes' in Arabic, wherefore many writers suppose that the honey so often mentioned in the Bible was not bees' honey but this dibes or grape-treacle; but when we read in Judges, xiv. 8, 9, that there was a swarm of bees (daburim) and honey (dabash) in the carcass of the lion, and that Samson took thereof in his hands and went on eating, it leaves no doubt as to the identification of 'dabash' with honey, and can therefore be applied to most other instances of 'dabash' as bees' honey, excepting a few cases, as in Job, xx. 1. 'Brooks of honey' were most probably meant for the grape-treacle, as can easily be understood if you bear in mind that grapes still are pressed out in pits cut into the rock, and flowing from one pit to another for purification, which was the method used thousands of years ago, and certainly never applied in the use of honey, because of robber bees and the thickness of honey too much would thus be wasted. The thinner treacle can easily be taken out of the rock again without much waste. And again, this 'dabash'—bees' honey—was collected by the bees (daburim), and not the 'nets,' as suggested by some: hornets are now called 'dababeer' plural, and 'dabur' the singular Arabic. The mixture of the two names is comprehensible when we remember that the root of the word, 'dabr,' signifying 'the buzzer' or 'buzzing,' was given to all Hymenoptera and Neuroptera, and was only distinguished later when civilisation came in, and Arabs called the common fly 'dibaan,' the hornet 'dabur,' and the bee 'nahlé,' so with the sweets 'dibs' or 'dibes,' the grape-treacle, and 'assal' honey.

In almost every village of Palestine and Syria bees are kept, and, with a very few exceptions, they do not keep such numbers to depend upon them for their living, but simply a few hives placed one on the top of the other, having an arch built over them or some protection intended to keep away the hot sun rays, which in summer time would melt the combs but for the

protection. The clay pipes are very cool as long as they are kept in the shade, but as soon as exposed to the sun become fearfully hot. In winter time the accumulation of the hives keeps them warm in the first place, and again nature helps itself, for any swarm unable to winter is destroyed in the course of the autumn by different enemies abounding here as in all other countries. The hornets, the wax-moth, the tellio-aganide, and gecko abounding here, and the bee-eater, being the most dangerous ones to be named.

In general, bee-keeping is carried on in very primitive and negligent ways in some respects, as weak swarms are never cared for, all such swarms are left over to themselves. The good swarms with plenty of food and bees only successfully pass the winter, thus establishing a good stock on one hand, whilst on the other weak swarms could be united, thus constituting a strong one. The only work performed is in the swarming season, when swarms are watched for a few weeks in April and May, and hived into clay cylinders. The back covers are put on after hiving, and besmeared with wetted argillaceous earth. The interior is rubbed with citron-leaves, and the small flying hole stopped with a few herbs for a day or two. They are then released, and not again looked to till the honey-crop. In some localities honey is taken twice, gathered from the early flowers and in September. The more general honey harvest is the September crop. The covers are then hastily broken open, a few puffs of smoke from the pitcher-smoker (and it is a pitcher with a hole in the bottom, filled with manure: some burning coals are put into it, and by continual blowing the smoke is kept going) are blown on the bees, a comb or two of honey is cut out and put away, the cover is immediately replaced, and the bees are left to themselves for a whole year. In such apiaries the moth is the worst enemy, destroying numbers of bees yearly. In the watered localities or such as afford good food for the carnivorous hornets the bees suffer greatly by them. They are the only enemies against which the inhabitants use their skill; they burn heaps of manure in front of the hives, keeping up a smoking for several weeks, from September to the beginning of November, which keeps the hornets out and the bees in.

The Palestine bees are good honey-gatherers, and the queens are very prolific and beautiful. It is not rare to have colonies yielding upwards of 100 lbs. for a single crop, though it is not the average. This is for bees handled in Langstroth hives—our system. Excepting during the orange-blossoming in April, our bees can be handled without a veil, the strong perfume at that time filling the air renders them fierce. Have any of your correspondents any experience as to the reason why bees are fierce, influence of weather, scent of flowers, &c? With us the east winds render the bees angry, and the strong odour of orange-blossoms makes them fierce.—PH. J. BALDENSPERGER, *Jaffa, December 7, 1887.*

BLE-HUNTING IN CANADA.

[1409.] In a recent issue of your paper, one of its readers desires to know whether Mr. Cowan went 'bee-hunting' while in this country, and expresses the hope that he will give an account of the exciting sport, if he did engage in it. I doubt if Mr. C. went bee-hunting while here in the sense your correspondent looks upon it. If he did not hunt bees, he hunted bee-keepers, and threw all his energy into the work. He reminded one of a chased ostrich striding across the country with its wings up. I do not know to what extent *bee-hunts* are now indulged in in other parts of this continent, but I know they have gone out of fashion in this section of Canada, and I hear little or nothing of them from other parts of America. I have often wondered why this is so, and have come to the conclusion that the altered

condition of things makes the chances of success much less than they were years ago. If bees that made their homes in the hollows of large trees in the early history of this country were escaped swarms, and the offspring of escaped swarms from the primitive apiaries of early settlers, they must have been a much hardier race than those now generally kept. If this was not the case, there would be a hundred 'bee trees' in the country now for one there was thirty years ago.

Thirty years ago there might be found in every settlement a skilled and successful 'bee-hunter,' who rarely failed to bring home his buckets full of honey from the woods with every returning autumn, but I have not known of a bee-tree to be cut down for the last ten years, and yet there must be a hundred swarms that take to the woods now for every one there was thirty years ago. I think the inference to be drawn from this is that the black bee of former years, being acclimatized, survived the winters better than the Ligurian crosses that now prevail. There may be still another reason in the altered condition of the country. In those earlier days the greater part of this province, at least, was a dark, unbroken forest, with here and there the light of day let into it by the early settler's little 'clearing' that surrounded his 'log shanty,' or more frequently a series of such openings made by bands of pioneers who took up their 'locations' in the same neighbourhoods, becoming the nucleus of settlements long since extended to meet other settlements at a greater or less distance, till ultimately becoming broader and wider they organized themselves into municipalities. So the settlements grew into town-ships and counties, and the original forest diminished as they grew, till to-day many of the farms have not enough of the original timber standing upon them to supply their owners with fuel. Thus the face of the country became denuded of its timber and more exposed to the influence of wind and weather, materially altering the climate of the country.

I can well remember over thirty years ago spending two winters taking out timber in one of the most magnificent pine-forests in the country. The temporary homes of the workmen were rudely-constructed log-cabins, the interstices between the logs being stuck full of chips and moss taken from the dead trunks of fallen trees, and daylight streamed in through many an opening in the walls. To enjoy oneself through a Canadian winter in such a home will seem almost incredible, yet I look back on those two winters spent in the woods, remote from the permanent habitation of man, as amongst the pleasantest and most enjoyable of my life. It is true, it was sometimes cold, but not a breath of wind stirred the air. The solemn stillness of the place was broken only by the sound of the woodmen's axes, or the gentle sigh of the wind as it passed through the tops of the stately pines and bent them over in a dignified bow; but its influence was never felt below, no matter how it raged above. When snow fell it filtered down through the canopy of pine needles, and fell as dry and as fine as flour. There was no broken time from stormy weather to the workmen in the woods in those days.

A hollow pine was the favourite home of the bee. These nests were usually ten or more feet from the roots of the tree, and at the top of the cavity. The entrance to it was, generally speaking, a small knot hole or 'punk' hole. These cavities were always dry, and not usually more than from six to ten feet long. There was certainly no upward ventilation, for the tree was invariably a solid body above the nest, while the outer shell was intact, except the aperture that served the bee as an entrance place. From the quantity and condition of the combs found in many bee trees it is clear they had been occupied for years, which would go to prove that the conditions under which the bees existed were favourable to them. That they cast swarms which took possession of other trees is also obvious, for they were frequently

found in places many miles away from settlements where bees were kept.

It is said the honey bee is not a native of America. If this be so, the early importations into these parts must have been a hardy race, for they adapted themselves to their surroundings, and survived the rigours of the climate, in a way that is surprising. Whether they have become extinct in the woods, I know not. It is certain their progeny exists in our apiaries to this day. I think, however, the changes they have undergone by being crossed with other races have lessened their 'staying powers,' or the changed condition of the country has removed the protection necessary to their existence. I believe that most, if not all, the swarms that escape to the woods now-a-days perish through the winter. If it was otherwise, we would hear more of bee-hunts and bee-trees than we do.

In 1857 I became acquainted with a Scotchman who was an expert and successful bee-hunter. The first honey I saw in America was with this man. I went to his house one day when he showed me two tubs and several buckets filled with comb and honey—the result of the previous day's work in the woods. He had a barrel of vinegar which I tasted, and my recollection is it was very good. He told me it was made from the honey refuse. I enjoyed the acquaintanceship of this man until he was accidentally drowned. He was the most successful bee-hunter I ever knew. His *modus operandi* was to put some honey into a tin box, and upon the honey he poured a little oil of aniseed. With this he would go into the woods. Arriving at the place where he intended commencing operations he uncovered the box, set it upon the ground, and seated himself on a log hard by. Here he waited till a bee came along, and filled itself with honey from the box. When it took wing he watched and followed the 'bee line' for some distance, when he again uncovered the box, set it down, and waited for other visitors. If the second visitor struck off on the same line as the first, he felt certain they belonged to the same colony. He then moved on, repeating what he had done before until he came to the tree, which his practised eye generally enabled him to find. It sometimes happened that the bee when released would fly in the opposite direction to that of his former visitors. If its flight was on the same line as these, he knew he had passed the tree, and would retrace his steps till he came upon the tree he sought. This man told me he rarely ever got his first bee more than two miles from its home, which is, I think, some evidence of the length of their flight. The tree having been found and marked, he returned home for the necessary assistance to fell it and take away the stores. This sketch of how bees were hunted in those days may afford some satisfaction to your correspondent on a subject in which he appears interested.—R. MCKNIGHT, *Owen Sound, Ontario, December 19, 1887.*

MARKET PRICE OF HONEY.

[1410.] There are two points which have frequently been alluded to of late in your columns, but, so far as I know, without any practical result. The first is that many bee-keepers are unable to find a market for their honey. The second is the suggestion that you should publish the market price of honey. The latter, in my opinion, you have hitherto been unable to do, from the simple fact that up to the present time there is no such thing as a market price for *British* honey. We must then direct our attention to finding a solution of the first point, viz., 'How to find a market?' and it is with regard to this that I wish to make a suggestion, viz., Let us have have periodical (say, monthly) auction sales of British honey in London. If bee-keepers could combine, so that a fair quantity of British honey could be offered for sale at one time, this could be managed. It is with a view of eliciting the general opinion and estimating

the amount of support which would be accorded to such a plan that I invite replies from bee-keepers and dealers to the following questions:—

1. What amount of honey (extracted or run) are you prepared to offer for sale now and from time to time?
2. Are you prepared to assist, by making the sales known to possible purchasers or friends?
3. What day and what hour would be most convenient to you?

Bee-keepers will naturally want to know what expense they would incur on the honey they might offer for sale. I think it probable, if sufficient promises of support were received, I could arrange for a charge of five per cent upon the selling price or limit, to include brokerage and warehouse charges. There would also, necessarily, be a small charge towards cost of advertisements announcing the sale and postage. Beeswax might also be included in these sales. My premises being near Mincing Lane are suitably situated for London buyers and the trade, and I shall be pleased to place them at the convenience of bee-keepers if they think well of the above plan.—HERBERT P. FATT, *Proprietor of the British Bee-keepers' Stores, 6 George Yard, Fenchurch Street.*

SCRIPTURE TEXTS.

[1411.] In answer to R. R. Godfrey's 'Scripture texts,' I sometime ago wrote them all out and found sixty-one of honey and honeycomb, three of bees, two of wax, and one hornet. I have two corrections to make in his list. Instead of Deut. xx. 9 it is xxvi. 9, 15. Also instead of 2 Sam. xviii. it is xvii. 29. The undermentioned are the additional ones:—

- Honey.*—2 Chron. xxxi. 5.
Honeycomb.—Prov. xxvi. 7.
Bees.—Deut. i. 44; Isa. vii. 18.
Wax.—Ps. lxxviii. 2, xxvii. 5.
Hornets.—Deut. vii. 20.

F. M. SPAULBING, *Rusthall, Tunbridge Wells.*

[Mr. Godfrey has pointed out the above corrections. Mr. J. A. A. Wood, of Newport, Isle of Wight, has indicated one of the above corrections, as also one of the additions.—Ed.]

WINTER PACKING.

[1412.] My plan of packing is more simple than 'Amateur Expert's' of December 29, page 568. I neither use chaff, cork-dust, nor quilts, having calico cover on and observatory feeder. I take my floral shading, the extra strong brown which I get from Sutton & Sons of Reading, and instead of hanging it up for the winter I pack it between sides of hive and on top of frames and fill up to top. I have a few squares of heavy plate-glass and I put them on to keep all down tight. The only fault is that is too warm; as soon as the temperature is fifty degrees my bees come out and have a good airing and cleansing flight. I may say that my shading is always dry, no mouldiness or damp. You see by my plan I don't require a sewing machine and am independent of help. Don't think I am a bachelor; I have a family hive. In conclusion, Mr. Editor, the *Bee Journal* gives me honey all the day. Wishing you a happy new year and success to the *Bee Journal*,—T. H.

[Be pleased to forward the communications mentioned.—Ed.]

DO BEEES SELECT A HOME BEFORE SWARMING?

[1413.] We have always regarded the statement, frequently made, that before leaving the apiary, if not before leaving the hive, bees have a new home selected if not fitted up, as a tradition that might, and again might not, have a basis of fact. We had an opportunity last week to see for ourselves, or rather to get our

information from first hands, and under circumstances that left no opportunity for mistake.

On Sunday Mr. Vance, the manager of our creamery farm, discovered bees clustered under the window-sill of his bedroom. There were but few of them, probably half a pint, and they seemed to go in and out of a very small crevice where the weather-boarding had shrunk from the sill. He concluded this must be the traditional committee of investigation appointed by whatever power rules in the bee-hive, to find out whatever *good* lay before them and report. The committee stayed all Sunday forenoon, and spent the night and the next forenoon. The bees were Italians of a brighter and better colour than any in our apiary, and hence were clearly strangers. The next afternoon, while Mr. Vance happened to be watching them, a large swarm of bees of the same colour came in from the north-west and immediately began to cluster and enter the aperture in the siding. By prompt and efficient use of the smoker they were driven out, the hole closed and the bees clustered on a tree and were hived. We know of no bees of the quality nearer than nine miles to the north-west.

This seems to us a demonstration that bees select their home. This committee had evidently reported a land of promise near the alsike, white clover and linden, and had sent back a good report of the land as well as guides to bring on the colony. There seems to have been some misunderstanding, however, as about the same number of bees remained clustered on the spot after the swarm was hived, and remained there till Thursday, evidently supporting themselves by foraging in the fields till we took pity on them and allowed them to go to their chosen home.

The same day another investigating committee selected a similar place in a neighbour's house, and the next day one of his neighbours had a swarm of bees come off and leave. He followed them directly to the spot where the committee had all things in readiness.

What now is the governing supreme power in the bee-hive? It is certainly not the queen. She is simply the mother-bee, and at the time the swarm leaves the hive may be but an infant of a day. Nor is it the drones, who are born to serve a brief purpose and then murdered. In the case mentioned there is a search for a location, the communication of intelligence to the parent colony, and uniformity of action on the part of the swarm. Now, who appoints this committee, and in what way is their report received and unanimously adopted and acted upon?—*Iowa Homestead.*

HORTICULTURE AND APICULTURE.

[1414.] The true horticulturist, like the successful bee-keeper, is an enthusiast. I need not remind any one who plants trees and grows fruits of the genuine pleasure that thrills the soul when nature responds to his intelligence, thought, and careful direction? He lives in a world of his own. He needs no other intoxicant to complete his happiness. Horticulture is one of the fine arts; it requires the skill of a master. It is just as impossible for the thoughtless, brainless elod-hopper to reach the highest round in the ladder in propagating fruit, as it is for him to appreciate it after it is grown. But after all man's skill in planting, after ransacking the earth for improved varieties, after propagating, grafting and hybridizing, he must rely mainly upon Nature's methods of fructification. The favouring winds and industrious bees are needed to fertilise the bloom to insure a harvest of fruit. As a means of accomplishing this end, there is no question but that the bee is of great service to the grower of fruits; no other insect is multiplied in such vast numbers so early in the spring when their agency is so much needed to fertilise the orchards and small fruits.

If the winds were the only means of carrying the

pollen from flower to flower, how often would perfect fertilisation fail from too much or too little wind during the brief opportunity when the bursting buds are sighing for the life-giving dust from the neighbouring flowers.

Not only is honey provided in the delicate chalices to entice them, but the pollen so essential to the plant (and just as essential to the bee in furnishing the proper food for its young), is placed in close proximity to the nectar, so that in getting either, the bee is unwittingly carrying the dust from flower to flower, or working out the wise plans of Providence as relates to plants, and catering to man's pleasurable tastes at the same time. The drop of honey is placed then in the flower not because it is needed to perfect the flower or fruit, but to tempt the bee to brush its hairy legs against anthers, and distribute the golden dust. So the bee introduces itself at once to the horticulturist as his friend. The latter ought to meet it half way and acknowledge its two-fold service. It does him a service while on its daily rounds in search of food for itself and young, and again by storing up for his benefit the liquid sweets which it does not need itself, and which ungathered vanish like the morning dew, like the manna which the Israelites ate of—the ungathered portions melted 'when the sun waxed hot.'

What, then, is there to hinder these two vocations from going hand in hand, since each is helpful to the other? They ought at least to be on friendly terms. Each furnishes inducements for the other to exist.

But, aside from these considerations of the healthful diversions and pleasing variety of mind, and returning again to the utilitarian side of the question, the horticulturist will find it profitable to pursue the study and practice of this delightful branch of entomology. The habits and instincts of this 'pattern of industry' are ever interesting, and the business quite as remunerative as raising tender fruits in an 'iron-clad climate.' This pursuit, once entered upon, possesses charms of its own. No other stimulus is needed to follow it than the fascination of its own creations.

A great deal has been said about bees injuring fruit—some fruit-growers having charged that they puncture the ripe grapes, suck the juice, and destroy the crop. But from the physical structure of the bee this is said to be impossible by scientific entomologists. It has no jaws like the hornet; it is made to suck, not to bite; and on close observation, and after repeated experiments, it has been found that where bees are discovered helping themselves to ripe fruit, that the skins had been ruptured by the weather or from over-ripeness, or that hornets or wasps or birds had first been the depredators. After the skin has been broken from any cause, if there is a scarcity of honey, the bees, always anxious to be doing something, will endeavour to get a share of the plunder. Therefore, as to bees injuring fruit, I, as their attorney, shall claim to the jury that the charge is not proven.

In dismissing this subject, which to the lover of fruits, flowers, and bees is always a source of infinite delight, I cannot refrain from quoting a few lines from 'The Planting of the Apple Tree,' by that venerable sylvan poet, our own Bryant, who saw so much of future hope and promise as he sifted the soft mould about its tiny rootlets:—

'What plant we in this apple tree?
Sweets for a hundred flowery springs
To load the May-winds' restless wings;
When from the orchard row he pours
Its fragrance at our open doors
A world of blossom for the bee.'

—EUGENE SECOR, *Forest City, Iowa* (extracted from the Address of the President of Michigan Bee-keepers' Convention).—*American Bee Journal.*

PRIZES.

[1415.] I have been thinking that if some substantial prizes were offered at our shows it would give a fresh

and increasing impulse to bee-keeping. For instance, think of the thousands of people who keep dogs, fowls, pigeons, canaries, &c., mainly for competition and to win prizes at shows in different parts of England. Men compete for prizes at athletic sports who would not take any interest in them if it were not for the competition they caused. I believe we as bee-keepers would all be benefited if something were done in this direction. In this town (Ipswich) we are going to have next year the Agricultural Show, when thousands of people will visit it from all parts of the country, and if a good number of bee-keepers exhibited their honey they would have an excellent opportunity of selling a large quantity, increasing the demand for English honey, improving bee-keeping in our rural districts, and taking prizes worth having which would well repay their trouble. We are living in an age of keen competition, and if we wish to succeed we must keep up with the times, and not leave a stone unturned to make bee-keeping a paying industrial enterprise.

In conclusion, I propose that a subscription be started for obtaining money for the prizes, and I am willing to give a donation and join the subscription list if started. Hoping this may meet with my fellow-bee-keepers' approval.—J. CHURCHYARD, 333 *Chevalier Street, Ipswich.*

WHAT DO BEES USE IN WINTER WHEN THE POLLEN COLLECTED BY THEM HAS BECOME EXHAUSTED?

By PASTOR SCHÖNFELD OF TENTSCHEL.

Any apiarist, with however slight a knowledge of bees, is aware that they require a certain quantity of nitrogenous food, not only for the purpose of supporting life, but also for the maintenance of the brood. The natural food of bees, of course, is honey and pollen. If, therefore, for some reason or other, there is an absence of pollen in the hive in winter, which unfortunately is but too often the case in districts without bee-pasture late in the summer, when there has been a continuance of breeding till late in the autumn which has exhausted all the pollen collected by the bees, or when unfavourable weather during the last few weeks in autumn rendered the storage of it impossible, the bees have entirely to content themselves with honey as food for themselves and their brood during the succeeding winter. But according to the valuable investigations of Erlenmeyer and Dr. von Planta (*Nördlinger Bienenzeitung*, 1879 p. 5), the average total quantity of nitrogen in ten different samples of honey was only 0.1762 parts in 100 parts of dried honey. It is quite clear that so exceedingly small a percentage of nitrogen is altogether insufficient to maintain a colony in a normally healthy state during the winter, and still more so to enable healthy brood to be reared from the middle of January till the month of April, during which time breeding not infrequently takes place. As although, old bees during the first three months of the winter when their vital energy is considerably reduced, are able to dispense with pollen, and from instinct, perhaps intentionally, discontinue its use even if present in large quantity, in order to make it possible to lower the vital process, so absolutely necessary in our climate, yet as soon as the impulse for breeding is aroused and the preparation of chyle demands the full use of their vital power, pollen becomes indispensable to them and the brood. This is proved by the eagerness and hurry of bees in search of pollen, as soon as their first excursions to cleanse themselves have taken place in spring, by the enormous consumption of pollen while breeding is on the increase, by the diminution or complete cessation of breeding if pollen-gathering is impeded by continuously unfavourable weather, by the remarkably favourable results obtained by Heath bee-keepers, who feed their colonies stimulativey on honey preserved in casks into which it is pressed, together with the combs, which honey, on account of its high percentage

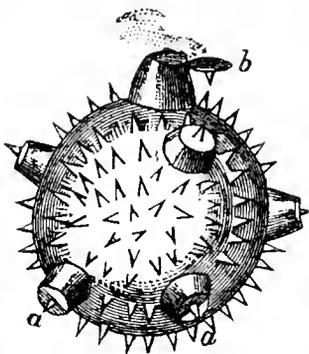

of pollen and nitrogen, ought not, as is usual, to be classed as a stimulant, but as nourishing food; and lastly, it is proved by the bees becoming ill and dying, if compelled for any length of time to rear brood or to construct combs in the absence of pollen. (Von Berlepsch, *Nördlinger Bienenzeitung*, 1854, p. 241.)

But how can these notorious facts be made to agree with the equally well-known fact that very many colonies without possessing a single cell of pollen are able to live through the whole winter, and to rear perfectly healthy brood for a period of from eight to ten weeks? Does not this forcibly suggest to us that inside the hive there must be another source from which bees are able to procure the indispensable nitrogen, though the quantity obtainable may be but small? For no physiologist who is acquainted with the nature and life of the bee will for a moment admit the common assertion which is repeated over and over again, that when bees are compelled to live upon honey exclusively the nitrogen stored up in their body is used as a substitute for weeks or even months in the absence of pollen, just as the bear is said to feed upon its own fat during its long sleep in winter. Chemical change takes place in the body of the bee so very rapidly and energetically, that without food in the shape of honey starvation would result within thirty-six hours: on the other hand, the consumption of the raw material—honey and pollen—in the preparation of chyle for the brood is so large, that when pollen is wanting, a supply of the requisite albuminous constituents of food from the body of the bee for weeks or months is a matter of impossibility. The quick and short-lived bee can only for a short time draw upon its own body for the failing nitrogen, inasmuch as chyle is not an extract from its blood but a product of its stomach.

Starting with the fact of bee-keepers frequently making the experience, that second swarms of young and strong bees with a young and vigorous queen and splendid new combs often survive the winter in a worse condition, and with greater loss in population, than colonies with old comb, even if possessing sufficient honey, stored in the proper place in the hive—a fact which is generally explained by saying that old combs are better for keeping bees warm: and having had my attention directed to the very large quantity of whole and undamaged pollen-grains, which during my experiments concerning the question of brood-cell cappings I discovered in the cell-walls and the membranes left behind by the nymphs, but principally in the margins of cells of old comb, and in equally large numbers in the excreta of the larvae at the bottom of the cells, I arrived at the conclusion that in these pollen-grains, as in other nitrogenous matter mixed up with them, the bees have a sufficiently abundant source of this (to them) indispensable substance; and as in making brood-cell cappings they are obliged to gnaw down the cell-walls and to masticate the wax and work it up, and likewise, in cleansing the cells have to remove from the bottom of the cells the excreta of the hatched larvae, they become aware of the presence of the pollen, which is thus rendered accessible to them.

And the percentage of nitrogenous matter which these excreta contain is very high, seeing that they are largely mixed with unbroken pollen-grains, as mentioned above. The exterior membrane of pollen, called the exine, is known to possess a great resisting force. Besides, the stomach of the bee, much less the stomach of the larvae, is unable to make all pollen-grains discharge their contents of protoplasm. For the discharge of the protoplasm in the natural way takes place, in most cases, not by the exine simply bursting, but through special valves in the exine, which remain closed as long as the pollen is kept dry. In my last article I gave a sketch of an unbroken pollen-grain from a pumpkin blossom to which I have to direct attention once more. It shows the lids of the valves. When the pollen-grain is moistened, the proto-

plasm swells and raises the valves, as shown in the figure at *a* until at last the lids fly back, and the protoplasm discharges itself as seen at *b*. But this mechanism often

fails to act in the stomach of the bee, and the pollen then remains closed and is of no use to the bee. This is proved by the large number of whole pollen-grains frequently found in the rectum of bees.

After these observations there appeared to me some justification for my conjecture that bees, in case of need, seek to obtain the nitrogen they are in want of from old comb and the excreta of larvae, the more so as it is well known that when pollen is wanting during the time bees are in full flight, they have recourse to various substitutes, such as dust from blighted barley, from clover seed at thrashing time, and charcoal, and rust from willow leaves, &c. &c. (Von Berlepsch, *Die Biene*, 1869, p. 135.) It therefore became necessary for me to ascertain by experiment, whether my conjecture was correct or untenable.

For this purpose I made two small trial colonies which I kept without food for two days, in order that any pollen the honey stomach and the chyle stomach might contain should become digested, and the husks be carried into the rectum. Thirty hours later trial colony A received a small comb quite recently constructed, with brood, from one to three days old, and two empty combs also recently made, with a supply of solution of sugar, all the three combs being without a trace of pollen. Colony B received two old black combs with solution of sugar, and in addition one new comb with brood, one to three days old, likewise without pollen. The colonies were then placed in a dark, dry cellar. If, at the end of four days no pollen was found in the rectum of the brood from colony A, while that of the brood from colony B contained pollen, this would prove conclusively that the bees in hive B had obtained nitrogenous food from the black combs. The experiment unfortunately gave no result, as at the end of four days it was found that both colonies had torn out and sucked all the brood. Nevertheless, this experiment strengthened my supposition that I was on the right track to discover the unknown source from which bees obtain nitrogen, having found out that the chyle stomach of the bees from colony A contained only perfectly pure and clear chyle, while among the contents of the chyle stomach of bees from hive B there were numerous pollen-grains, pollen-husks, and a great many small black bodies, which could only have been derived from the black combs. I therefore made preparations at once for a second experiment, determining to place the trial bees in the middle of the brood-nest of a colony that was at perfect liberty to fly out. I took a newly-made comb, perfectly free from pollen, and containing some brood one to three days old, adding the necessary food, consisting of a solution of sugar, and surrounded it on all sides with wirework, between which and the upper edges of the cells a space was left of half centimetre, so as to allow the bees to move freely on the comb, but in order to prevent their being fed through the wire-

work by the other bees in the hive I fixed a second cage of wirework over the first, leaving a space of one centimetre between them. A black comb, in the middle of which a piece of brood one to three days old had been inserted, was protected in the same way, and then the two combs were placed in the brood-nest of a strong colony after a sufficient number of workers from the first trial colony A, which had already been seven days without any supply of pollen, had been driven into the cages through an opening arranged for that purpose, so as to have the combs well covered with bees. In this way the brood was attended to, and the examination four days later showed the stomach and rectum of the brood in the black comb to be full of pollen-grains, pollen-husks, and those small black bodies mentioned above, while the same organs of the brood in the other comb contained only pure chyle.

This seems to prove that in the absence of collected pollen bees are able to find a substitute in the nitrogenous matter contained in old combs and the excreta of larvae. I make use of the word 'seems,' because the trial bees in their prison, although in the middle of a brood-nest, were, nevertheless, somewhat in a state of distress. But needs must when the devil drives, and I, therefore, do not judge with certainty of the behaviour of colonies which enjoy perfect freedom by the conduct of bees in confinement. It is consequently necessary that a final experiment should be made. Which of my colleagues will assist me? Who will take the trouble, about the end of October, when all gathering has ceased, to establish a trial colony with combs as new and white as possible, but without pollen, and who will put up a similar colony with very old combs, likewise without pollen?

The honey for these colonies had best be given in drone-combs, which never contain any pollen, and the most suitable place in the hive for these small colonies would be the division for the storage of honey, provided with special entrances in order that the bees may enjoy the necessary warmth and commence breeding next spring before the opening of the honey season. The greater the number of trial colonies established the more reliable will be the result obtained.

Whoever is kind enough to set up trial colonies as described will oblige by sending me about the end of February or beginning of March a small piece of brood-comb ready to be sealed, without, in the first instance, mentioning whether it has been taken from a colony with new or old combs, in order that I may commence my examination unprejudiced by any pre-conceived opinion.

Should any Bee-keepers' Association be willing to take this matter in hand I should be pleased if they would communicate with me.—Translated from *Gravenhorst's Deutsche illustrierte Bienenzeitung*, September, 1887.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication. All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

Rev. J. DAVIES.—*Deserted Skeps*.—In all likelihood both colonies became queenless, more especially the one in which you found two clusters of dead drones. On the last occasion, when you noticed these skeps with apparently strong colonies, judging by the number of bees round the entrances, did you observe any chips of wax on the alighting-board? From your description of the condition of the skeps, it seems improbable that they have been tenanted by the rightful owners for some time. If the capped brood found in one was alive, the desertion must have been recent. Bees finding themselves queenless in

the late autumn, will desert to another hive. Would it be inconvenient for you to transfer all you may have in skeps to bar-frame hives in the spring? The actual condition of a colony can be ascertained with so much greater ease.

W. A. T.—*Moving Bees to Heath Two Miles Distant.*—If there are no extensive woods between you and the heath your bees would most likely find their way to it. The heath is not so good a honey-plant as the heather so frequently mentioned in our pages. Unless your bees have really no forage within a mile or two of home at the time the heath is in bloom it would not be worth while to move them, considering the risks. If you would like to see a piece of real heather, send your name and address to the Editor.

C. A. J.—*Murmuring Noise in Hives.*—*Apis mellifica*, like the genus *Homo*, is at times compelled to indulge in exercise to keep warm. This explains the noise you refer to, which is by no means unknown.

MALTA.—1. *Wax-moth in Frame-hive.*—From your description there is no doubt you have wax-moth. Keeping all frames well covered with bees is the best preventative and cure. Any combs not in use should be well fumigated with burning sulphur, and either kept in paper or hung in a cupboard where there are plenty of spiders, who will catch any moth that attempts to alight on the combs. A slight brush will remove the spiders' webs before returning the frames to the hives. Put new quilts on; burn the old ones. Carefully clean out the hives at the same time. 2. *Crooked Combs.*— $1\frac{3}{4}$ in. is the extreme distance that should intervene between the centre frame and that next to it. If you cannot put a starter of either foundation or comb, melt some wax, and run a streak of it along the centre of each top-bar and side bars. Take care your hives stand level. 3. *Hornets, to Destroy.*—You will find (p.9) an interesting communication from Palestine, in which reference is made to the native method of dealing with these pests. 4. *Bee-keeping in Malta.*—Can you favour us with any particulars concerning the present state of bee-keeping in Malta? if so, it may afford pleasure to many of our readers.

J. FITZGIBBONS.—*Moving Bees.*—You will doubtless find sufficient information on pages 39, 149, 210, 409, and 478 of the volume for 1887.

DOUBTFUL.—*Combs from foul-broody Hives mixed with others.*—Spray ALL your combs with a solution composed of salicylic acid one ounce, borax one ounce, water four pints. As an extra precaution, repeat the operation three or four times between now and the time you will be returning them to the hives in spring. If you can identify those from the diseased hive, give them extra sprayings.

C. D.—*Unsealed Brood.*—It is to be hoped that no serious mischief will be the result of the presence of the unsealed brood. The bees cannot be disturbed at present. As a counter-attraction candy can be given to them below the quilt.

E. W. SHOTTER.—*Bibliography of Bee-Keeping.*—The enumeration of the books on bee-keeping that would be 'worth securing' would fill a large portion of our space; the catalogue of the library of the B.B.K.A. (a copy of which we have forwarded to you) would render you great assistance in this, and would furnish you with the titles of the best and most precious works that have been written in the English language on bees and bee-keeping. Thomas Wildman's *Treatise on the Management of Bees* (1778) would be worth about 8s. 6d. This is the third edition of Wildman's *Treatise*: the two former were published in 1768 and 1770. The book is not often met with.

Communications to the Editor to be addressed 'STRANGWAYS' PRINTING OFFICE, Tower Street, Cambridge Circus, W.C.

[No. 290. VOL. XVI.]

JANUARY 12, 1888.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

BRITISH BEE-KEEPERS' ASSOCIATION.

ELECTION OF THE COMMITTEE FOR 1888.

The following members have been nominated in accordance with the amended form of rules as passed at the last Annual General Meeting, each member being nominated by two members of the Association:—

- Rev. E. Bartrum, D.D., Wakes Colne Rectory, Halstead, Essex.
 E. H. Bellairs, Esq., Christchurch, Hants. Hon. Secretary of the Hants Association.
 Hon. and Rev. H. Bligh, Hampton Hill, Middlesex.
 Captain W. Bush, R.N., Southleigh, Stevenage.
 Captain C. D. Campbell, Box Grove, Guildford.
 Rev. E. Clay, Great Kimble, Tring.
 Thos. W. Cowan, Esq., Comptons Lea, Horsham.
 J. Eastty, Esq., 86 Grange Road, Bermondsey.
 Rev. R. Errington, Clewer Rectory, Windsor, Hon. Secretary of the Berkshire Association.
 J. M. Hooker, Esq., 76 Tyrwhitt Road, St. John's.
 H. Jonas, Esq., 64 Redcliffe Gardens, S.W.
 Rev. F. G. Jenyns, Knebworth, Stevenage.
 W. Lees McClure, Esq., The Lathoms, Prescott, Lancashire, Hon. Secretary of the Lancashire and Cheshire Association.
 Rev. G. V. Oddie, Aston, Stevenage.
 Rev. Geo. Raynor, Hazeleigh Rectory, Maldon.
 Rev. F. S. Selater, Drompore Vicarage, Maidenhead.
 Rev. F. T. Scott, Hartlipp Vicarage, Sittingbourne.
 Rev. J. L. Seager, Stevenage.
 Dr. G. Walker, Lingfield Road, Wimbledon.

Four of the above named are unable to serve on the Committee, the remaining fifteen therefore stand elected for the ensuing year.

SUBSCRIPTIONS, &c.

Subscriptions for the current year become due on January 1st. It is hoped that members will forward the same at the earliest possible date, and, further, use their best endeavours to induce their friends to become Members of the Association. Post Office Orders to be made payable at the Kings Langley Post Office. Cheques to be crossed 'Bucks and Oxon Bank.'

QUARTERLY MEETING AND CONVERSAZIONE.

The next Quarterly Conversazione will be held at 105 Jermyn Street, on Wednesday, January 18th, at six o'clock. Members wishing to introduce subjects for discussion, or to submit new, improved, or interesting appliances, are requested to communicate with the Secretary not later than Saturday, the 14th inst. Mr. R. A. H.

Grimshaw will read a paper on 'Specialization.' County Representatives will meet at 149 Regent Street, at four o'clock. The Quarterly Conference of the County Representatives with the Committee of the B. B. K. A., will take place at 105 Jermyn Street, at five o'clock.

GENERAL MEETING.

The Annual General Meeting of the Members will be held at 105 Jermyn Street, at 3:30 p.m., on Wednesday, February 8th, the Baroness Bardett-Countts, President of the Association, in the chair. Notices of motions for this Meeting must reach the Secretary not later than Saturday, January 2nd.—JOHN HUCKLE, *Secretary*, Kings Langley, Jan. 7th, 1888.

THE WINTERING PROBLEM.

In the December number of our contemporary, the *Record*, we notice the details of an interesting experiment in wintering, viz., burying a frame-hive, containing a colony of bees with a proper supply of food, in a shepherd's hut, which is dug out of a hill-side, the door of the hut being blocked up with sods of turf to a considerable thickness. Prior to depositing the stock, it was weighed, and the condition of the bees as to strength and stores carefully noted. It is intended to unearth them at the expiration of five months from the date of their being placed in the hut, when the hive will again be weighed, and full notes taken of the state in which it may be found. We trust success may attend the experiment.

The theory that if bees can be maintained at an equable but low temperature of about 40° to 45°, it will tend to conserve the life of the workers during the winter months, and so enable the stock to commence spring strong in numbers, is, no doubt, worth consideration, *i.e.*, that an excitement during the winter, even although it be a cleansing flight, is the occasion of a depletion in numbers. To decide whether it would be a commercial success to incur the outlay necessary to provide a suitable cellar, and also the annual expense of moving the stocks into and from the same, is a question that nothing short of an experiment on a large scale, extending over several years, can solve.

Our Canadian friends are, by force of circumstances, obliged to carry out elaborate arrangements in order to prevent their bees being frozen to death. But they certainly seem to have the advantage of us in the numerical strength of their

colonies in the early spring. The questions that arise in our mind at this point is, Can this greater numerical strength be the result of the bees being so long confined to their hives, and general inaction consequent on the temperature being low and varying so little? Also, is such a colony (numerically strong through the prolonged survival of the old bees) not more liable to a sharp attack of 'spring dwindling,' through these old bees all dying off about the same time?

In such a variable climate as ours, and one alternating with such rapidity, it is impossible, while bees continue to be left on their summer stands, to avoid a considerable loss of the old bees during the sudden changes of our English winter, which not infrequently in the neighbourhood of London has a temperature varying from 20° to 50° Fahr. within sixty or seventy hours. Such variations effectually prevent our bees, as at present wintered, remaining dormant. Raising the body-box containing the brood-nest some distance up from the floor-board by means of an eke is practised by some eminent apiarists, and considerable success is claimed for this system. In some cases a doubling-box, of the usual depth of a standard frame, is recommended. Such an arrangement will, of course, effectually prevent the dead bees blocking up the passage-way under the combs. In the autumn of 1886 we inspected a stock that had been sadly neglected. As a swarm of that year they had been placed in the box super without foundation, but with empty frames in the hive proper. The bees (nearly pure Italians) built their combs in the super, and continued them about five inches down into the hive, as no frames had been placed under the super except at the ends. The colony never became strong, and had not more than six pounds of stores at the date of our examination. The owner gave no additional supply of food, although strongly advised so to do. No extra packing was given, yet in the spring there certainly was not a wineglassful of dead bees on the floor-board. The colony prospered in the early spring, and would, doubtless, have given a good account of themselves if the season had been a normal one. At the end of March, 1887, they still had quite two pounds of stores, a fair patch of brood, and a general healthy appearance.

Would this neglected colony have wintered as well if they had been in the hive body, instead of the super, which, by the way, had no upward ventilation, as it had a wooden top tightly screwed down? We are inclined to think not, because this hive was the only one in the district referred to that did not lose a large number of bees during the time the snow lay on the ground. They took no flights during that period. Is this to be accounted for by the fact that the very free circulation of air through the body-box and around the outside of the super really induced an almost complete hibernation, with a consequent saving of bee life?

Mr. Simmins, in his *Modern Bee Farm*, expresses his preference for all floor-boards to have a two-inch auger hole through the centre, as providing free ventilation and a ready means for the removal

of dead bees, and that hives of twelve-frame capacity have an empty hive-box under the one containing the bees and their stores. In long hives, he further recommends making the swarm comfortable, with quilts and cork cushion, on a few frames at the back of the hive, having no division-board in front, but merely empty frames, covered by a thin, porous quilt. He states that a colony so wintered will be much stronger in spring than one in a single-storey hive, and confined to a few frames by division-boards, especially by the front one. Is this departure to revolutionise our system of wintering? We shall be glad to receive reports from any of our readers who may give it a trial either in part or in its entirety.

The question is not, With how little care can our bees survive the winter? but, Would a system which provides for a free circulation of air within the body of the hive conduce to the greater strength of our colonies in spring, and a consequent anticipation of the date when such colonies would be in readiness for the honey-flow?

Foreign.

UNITED STATES.

The Annual Convention of the North American Beekeepers' Society took place at Chicago on the 16th, 17th, and 18th November. Dr. C. C. Miller, the President, took the chair, and there were present a great number of the leading bee-keepers. The *American Bee Journal* gives a very full account of the papers read and the discussions, and from it we are able to give our readers a summary of those parts which we consider would prove interesting to them.

Mr. J. A. Green read a paper on 'The Production of Comb and Extracted Honey in the same Apiary.' He said that 'in bee-keeping, as in other occupations, the greatest average success will be gained by making a specialty of it, even though an occasional season, such as that just past, may bear hard on some. Yet this principle may be carried too far. We have already bee-keeping as a specialty, divided into the sub-specialties of honey-production and the rearing of queens and bees for sale, while some insist that honey production should be divided, and a specialty made of either comb or extracted honey.' He thinks, although in some places comb-honey cannot be profitably produced, and in others it will not pay to work for extracted, in most cases a judicious combination of the two will give the best results.

In working if you have some colonies that do not produce nice-looking comb-honey, pinch off the heads of the queens as soon as convenient, but in the meantime take their honey with the extractor. Poor extracted honey can be sold for manufacturing purposes, but poor comb-honey is hard to sell anywhere. If honey comes in faster than bees can build comb for it, a few empty combs distributed among the best colonies will pay an enormous profit.

In working for extracted honey a large number of extracted combs are wanted, at least one set for each colony. When the honey-flow begins give each colony a set of combs. Bees will begin to work sooner in empty combs than in empty sections. After the bees are well at work above, remove the extracting combs from as many colonies as you want to work for comb-honey, and give them sections. Tile up the supers of partly filled combs over other colonies, and this will ripen the honey which will be much finer than that usually produced.

Whether for economy or excellence of quality there is no way of producing extracted honey equal to that of giving the bees plenty of room in which to store it, and then plenty of time to ripen it.

Towards the close of the honey-flow, instead of putting on more sections, which are not likely to be finished, take the sections from a part of the colonies and put them on the others to complete, and give those from which they were taken empty combs instead. The advantages of this system are: First, getting the bees started without delay; second, your comb-honey is nearly all No. 1, and the extracted honey is the finest that can be produced; last, and not least, you are rid of nearly all the trouble and expense of unfinished sections in the fall, and having few now you have few in the spring, and this is the reason why the comb-honey is finer. Honey stored in combs built the year before is never equal in quality or appearance to honey in newly-built combs.

On being asked by F. Wilcox how much more extracted than comb-honey was produced, Mr. Green said if first-class honey about twice as much, but if such as is usually produced three times as much. In answer to Dr. Miller, he said that he secured a poorer class of honey by using drawn combs in the sections. Honey is more inclined to leak when stored in old combs.

Mr. Betsinger said that it was more inclined to granulate, because any comb or vessel that has once contained granulated honey will cause the granulation of any honey placed therein.

President Miller introduced the subject of 'Legislation for Bee-keepers.' He said as a man could not farm without land he could not keep bees without pasture, and believed that legislation securing to each bee-keeper a certain amount of territory was desirable, although it might not be feasible.

Dr. Mason concurred, and F. Wilcox suggested that bees should be exempt from taxation, and that licenses should be granted giving the right to a certain territory.

Mr. H. R. Boardman considered small bee-keepers needed protection more than large ones.

Professor Cook thought if there were a large number of specialists all over the country such legislation might be advisable; but these were few and scattered, and he thought that reasoning would be the better plan with any one coming to set up bee-keeping close to him, and pointing out that coming so near meant disaster to both.

It was voted that in the present stage of bee-culture legislation was neither desirable nor feasible.

Mr. Thomas G. Newman read the next paper on 'Objects and Methods of a thorough Organization of the Bee-keepers of North America.' He said he desired to inspire them to undertake a 'progressive step' in the direction of organization. The pursuit of modern bee-keeping is in its infancy, yet at the present day its devotees in North America number 300,000 persons, and its annual product of honey amounted to 100,000,000 of pounds, and its value about fifteen million dollars.

Some of the principal wants were: A systematic encouragement of bee and honey shows at fairs, providing bee-tents at bee exhibitions, inaugurating a system of education of bee-keepers, and by certificate or otherwise guaranteeing to those who wish to hire assistants that they possess a practical knowledge of the business for which they are wanted.

The constitution of the Society should be amended to make it a representative Society; this would not be difficult to carry into effect, and he proposed a number of rules and bye-laws, thirteen in number. These are in the main taken from the Rules and Regulations of our British Bee-keepers' Association, the working of which we explained to Mr. Newman when at Chicago, and full details of which we wrote out at his request. The proposed constitution would alter the name of the

Society to 'The Inter-National American Bee-keepers' Association,' and is to include all of the United States and Canada. Any state, district, territory, or province, can become affiliated on payment of five dollars a-year; the presidents of these to be *ex-officio* vice-presidents of the Inter-National. Experts are to be examined by an expert committee and certificates awarded. Two medals are to be given to each affiliated Society as prizes for honey shown by its members, and they shall be entitled to the privileges of the Honey Company, which it is proposed to form in connexion with the Society. Delegates are to be appointed to attend the annual meeting of the Society.

The proposed organization differs from ours in having a Honey Company in connexion with it, otherwise it is very similar; and we are glad to find that our Society has been taken as a model, and hope that the Inter-National may be as successful and as useful as ours has been. A change is not made in a day, and it will, of course, take some time before it can equal ours in efficiency, but we welcome the step as a progressive movement.

On the motion of Dr. Mason the consideration of the subject was put into the hands of a committee consisting of Professor A. J. Cook, W. Z. Hutchinson, and A. I. Root.

Before the close of the Convention the Committee reported that they had given the scheme all the thought and consideration it was possible in so short a time, and while thanking Mr. Newman for the great labour and thought bestowed on the subject, in view of the somewhat intricate and involved plan proposed, they recommended that the consideration of the matter be postponed for one year, at the end of which they would be better able to present a report commensurate with so important a subject.

The next subject was introduced by Mr. A. I. Root, on 'Foul Brood, how shall we treat it?' He said as soon as foul brood appeared in his apiary he began burning all the colonies affected. After burning forty colonies he found that in nearly every case the colonies adjoining the stand of the destroyed colony became affected, so he began to look out for another cure—spraying with phenol after tearing off the cappings with a wire-hair brush in such a manner as not to injure the healthy brood. This treatment does not always cure the disease, but it prevents its spreading to other colonies. With a small apiary he would burn up the 'whole business' if he found it infested with foul brood.

N. N. Betsinger said there are certain conditions that will bring about foul brood. He can produce it in ten days and can cure it in the same length of time with salt. Mix it with sawdust, put it into a keg, add water and keep it in the apiary where the bees have access to it.

Dr. Mason said he had known many who had tried salt and failed.

Professor Cook said odour was not a sure test, but the elasticity or rosy mass was.

B. T. Davenport had had trouble from 'dry' foul brood. The larva will break in two when attempt is made to remove it, but there is no ropiness or elasticity. The trouble is greater with dark than with Italian bees. He has cured it by change of queens.

The next paper was by Mr. C. P. Dadant, on 'Comb Foundation, its Manufacture and Use.' To make good foundation pure wax must be produced. Compounds of wax and paraffine or ceresine have been tried and will not do. They melt at a lower temperature than wax and endanger the safety of the colony. Paraffine and ceresine are detected by their lighter specific gravity, and tallow, which is a frequent adulterant, is noticed by the greasy and dull appearance of the cakes. Such wax should be rejected. After selecting the wax it is

melted and kept hot for twenty-four hours or more to allow impurities to settle. The sheets are made by dipping damp boards, and are thick enough to stretch in the rolls when moulded. In this wax all the inequalities on the surface are eliminated out, and from the pressure all moisture is driven off. In this branch of industry, as in all others, practice is required to acquire skill and speed in manipulation.

J. A. Green used 1500 sections one year, filled some with old and others with new foundation. Those with the new foundation were finished first, and those with old foundation completed last.

In reply to a question by Mr. Root, R. R. Murphy stated he had tried starters only, and found sections furnished with them were last finished.

F. Wilcox could not understand how Mr. Doolittle can secure and use natural comb, as he advocates.

R. R. Murphy puts on an upper storey in the fall and allows the bees to build combs in the frames, then extracts the honey and uses the comb next year.

J. Heddon prefers foundation to drawn combs, as it is quicker finished and looks better.

A. I. Root said that in using combs the cells are deep, and the honey does not ripen so quickly as when the cells are filled as they are drawn.

W. Z. Hutchinson preferred combs as it induced the bees to store the honey above instead of in the brood-nests. With him they commence to work in the supers when combs are used, and finish the honey sooner.

An essay on 'Production of Extracted Honey for Table Use' was read by T. F. Bingham, in which he stated that honey, like other non-crystallised saccharine substances, had a tendency to absorb water and undergo fermentation. If the honey was thick its changes are slower, but if thin they are more rapid. The honey should be left a long time in the hive of a populous colony before extracting, and then put up in neat two-pound bottles. If extracted late in the season it should be kept in a clean pine-barrel, bunged tightly if stored in a cool place. When taking out the honey he removes one or two inches of the surface honey, so as to avoid mixing that which has been in contact with the air with that which has not. The surface may be soft and foamy; this could be used for making into vinegar, the remainder melted in a water-bath and put into glass jars in a cool place. It will remain clear a long time, and will be as fine as if just taken from the combs. If only such honey were offered to the public, the market would not be *overstocked* and the *prices* would be satisfactory.

In the discussion most of the speakers advocated tin for storing instead of wood.

At this time Professor A. J. Cook, of Agricultural College, Michigan, took occasion to speak of the recent enjoyable visit to America of Mr. Thomas W. Cowan, the distinguished editor of the *British Bee Journal*, who had called on so many prominent apiculturists of the New World. The Professor said that it had never been his pleasure to meet with one so familiar with everything connected with bee-keeping, and with every person of any reputation as a bee-keeper. That, in the future, this visit of Mr. Cowan's would often be referred to, by those who were so fortunate as to meet him, as being one of the brightest events occurring in the history of progressive American apiculture. In view of the many resulting benefits, and the pleasant and profitable recollections following such a visit, the Professor moved that the thanks of the Society be tendered to Mr. Cowan for his visit, and that he be elected an honorary member of the "North American Bee-keepers' Society." The motion was seconded and carried unanimously.

Immediately after this Professor Cook spoke about the Rev. L. L. Langstroth, and said that the Society could not do itself more honour, and express its appreciation of his efforts, than to forward a goodly purse to Mr.

Langstroth, who, in his long-continued sickness, would receive it with much grateful appreciation. It was resolved to make a collection and add it to the amount remaining in the treasury, and after paying all the legitimate expenses of the Convention, to send the whole of the balance to Mr. Langstroth.

(To be continued.)

CANADA.

I have just returned from the North American Bee-keepers' Association which met at Chicago, November 16, 17, and 18. Canada had but one representative. The season has been a severe one for bee-keepers throughout America, reports from about forty bee-keepers show the following results:—Number of colonies in spring (1887), 3761; number of colonies in fall (1887), 4342; number of lbs. comb honey secured, 33,290; number of lbs. extracted secured, 28,100; number of lbs. beeswax secured, 1136; number of lbs. fed back, 10,260. This shows an average yield of about 6 lbs. of comb honey and 6 lbs. of extracted honey per colony after deducting the number of pounds fed back. Amongst the reports there is only one from Canada, my own, which is:—Spring count, 39; fall, 48; lbs. of extracted honey secured, 3100; lbs. fed back, 200; lbs. of wax secured, none given, as it has not yet been rendered.

From all reports it is however safe to say we have been more fortunate than the bee-keepers of the United States, and throughout the entire American continent the markets will be entirely free of honey long before next year's honey crop will be harvested in even the more southern parts. The prices secured at present are very much above what they have been for some years, especially so in the United States, and for comb honey we are looking hopefully forward to keeping the prices up for the future.

Mr. Cowan's visit to us has been during an exceptionally poor honey season, and we have regretted our inability to show him what honey flows we have, and what honey exhibits we can make. His visit to Canada has been, to those with whom he has come in contact, one of the bright spots of a season which to so many, especially those who depend upon the profits of their apiary, has been a rather depressing one. We all feel that we owe Mr. Cowan a debt of gratitude for his visit. His unselfishness in caring for and carrying about a heavy microscope, and labouring for hours to show to us new wonders in regard to the structure of the honey bee, and creating in us a higher interest in apiculture, cannot soon be forgotten. The information which he possesses as to bee-keeping in all parts of the world and past ages has also been of interest to us; and, as will be seen by past numbers of the *British Bee Journal*, we have attempted in some small measure to show Mr. Cowan our hearty appreciation of his kindly visit amongst us. The North American Bee-keepers' Association, by a unanimous vote, passed a resolution thanking Mr. Cowan for his visit, and the great trouble and expense he had gone to in visiting us, regretting his inability to remain and be with them at their meeting.

One point which must have struck Mr. Cowan very forcibly, and does us in a measure, is the fact that we keep our bees, first and foremost, for the profits which we may derive from them financially; all else is secondary. We, in a measure, appreciate the study of the bee, but not as leading British bee-keepers do. From what I can learn their motives are different to ours, and few of us can devote our labours to apiculture, its spread and study, aside from financial return. This must be the case in every new country, and our struggle for money, or, in other words, the means of subsistence, debars us often from other pleasures and studies which would be quite as much in accordance with our inclinations. The structure of the bee as revealed by the microscope is

therefore something new to most of us, and this more intimate study of the bee, for which such are indebted to Mr. Cowan, will awaken interest in a new direction, and give us ever after keener enjoyment from the source from which we must derive our means of subsistence.

FRANCE.

The annual Bee and Honey Fair, which is held at Chartres on St. Andrew's day, has, this year, been a complete success, and several transactions of considerable importance are known to have taken place. Bee-keepers came in from the surrounding districts in large numbers, and, after having attended the annual general meeting of the Bee Association, repaired to the 'Café Bordier,' Place des Halles, where, for the convenience of intending buyers, the names of those who had either honey, bees, or implements to sell, were exhibited in a large frame; and it was noticed that many were those who made notes of what there was to be sold and of seller's name and address.

Bee-keepers are again reminded that applications for exhibiting in the great forthcoming exhibition of 1889, must be sent in before the 1st of February next, addressed to the 'Ministère du Commerce,' or 'Avenue de La Bourdonnais, au Champ de Mars, Paris.' In again repeating this information, the *Apiculteur* of that city suggests that, as far as possible, Bee Associations should not exhibit individually, but rather collectively.

ASSOCIATIONS.

GLASGOW INTERNATIONAL EXHIBITION.

We would desire to direct the attention of bee-keepers in England and Ireland to a letter from Mr. E. Mc'Nally, who, with his brother, John, has taken measures for the proper representation of the honey industry at the Glasgow International Exhibition, which will be held during the present year. He is anxious to get the names of manufacturers who use honey in their goods, and any information which will assist him in making the special classes interesting and instructive. Mr. E. Mc'Nally's address is 'Main Street, Rutherglen.'

IRISH BEE-KEEPERS' ASSOCIATION.

The Committee met on 3rd inst. Present—Mr. Gillies in the chair, Rev. P. Kavanagh, Messrs. Sproule and Stanford, and the Hon. Secretary. The drawing up of the annual report for 1887 was referred to a sub-committee, and arrangements were made for having it printed. Additional steps were taken with respect to the Association's standard hive, in order to ensure its being sent out perfectly complete.

LECTURE ON BEE-KEEPING.—Mr. R. A. H. Grimshaw, of Horsforth, near Leeds, gave a very interesting lecture on 'The Wonders of Bee Life,' in the schools of St. John the Evangelist, Walton-on-the-Hill, near Liverpool, to a large and appreciative audience on Tuesday evening 3rd inst. The chair was taken by Mr. E. Bird, Esq., J.P. The lecturer traced, in a most amusing and instructive manner, the various stages of growth, with the anatomy, habits, and customs, and use of these wonderful creatures and held his audience from first to last thoroughly interested. It was particularly noticed that the younger members of the audience were kept amused and instructed from first to last, the lecture lasting one hour and twenty minutes. After several interesting questions were answered by the lecturer, which were put by two bee-keepers, Mr. E. Fowler and Mr. J. A. Bally, and some clever diagrams explained, a hearty vote of thanks to the lecturer was proposed by Mr. J. A. Bally and seconded by Rev. F. B. Plummer, B.A., and suitably responded to by the lecturer.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal," c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, Kings Langley, Herts (see 2nd page of Advertisements).

** In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.*

OUR HONEY IMPORTS.

The value of honey imported into the United Kingdom during the month of December, 1887, amounted to 4817. [From a Return furnished by the Statistical Department Her Majesty's Customs to E. H. Bellairs, Wingfield House, Christchurch.]

HIVES AND THEIR MANAGEMENT FOR COTTAGERS.

[1416.] The first question a cottager must solve is, 'What hive shall I use?' and we who endeavour to carry out the primary object of the existence of the British and County Associations, viz., the bettering of the condition of the cottager by urging him to adopt a more humane and more profitable system of bee-keeping, should, if we intend to assist him, have put to ourselves and solved this question, 'What hive shall I recommend?'

It has frequently been stated that almost anything will do to put bees into. That is quite true; bees may be kept in almost anything in which combs may be built—straw-skep, box or bar-frame hive. I have even seen stocks in old casks, wooden and zinc pails, and have taken from them for the owners a nice lot of honey. But although almost anything may be used and a nice surplus obtained, both the pleasure and the profit are much increased if the bees are kept in suitable hives, well and accurately made, and whether straw skep, box or bar-frame hive, well painted. The best and most economical materials for hive construction are certainly straw and wood. It would, I think, be a pity to banish the straw skep from modern apiaries, for it has a rustic appearance which is greatly valued by many old and some advanced bee-keepers. Personally, I should not like to see my apiary without a few stocks in straw skeps, because I like to see that most pleasant (sometimes most annoying) of all sights to a bee-keeper—bees swarming. Hence nothing would induce me to entirely prevent natural swarming from skeps.

The object of this article being to assist the cottager I shall be glad, with the Editor's permission, to more fully explain at a future time any part I may not make sufficiently clear.

In the first place, I must recommend the beginner straw skeps worked on the system explained below, or if it is his intention to become possessed of bar-frame hives I should say commence with the 'Champion Cottager.' This is a hive which I have designed with a view to its being used on the fixed-comb principle, as when skeps are used, and for the production of sections or run honey. When the fixed-comb system has been given up this hive will not have to be discarded as useless, but may then be used permanently as a section-crate.

Somersham Skep System.

The Hives.—Two kinds of hives are used, and these I term *stock hive* and *super*. Both should be closely and neatly made so as to fit accurately either above or below

each other: and they are exactly alike in every respect except depth, the stock hive being ten inches and the super six inches without the crown-boards. The outside measurement is exactly fifteen inches across, while the crown-board is sixteen inches across, half an inch thus projecting all round. The crown-board is made of two pieces of light wood about half an inch thick, securely fastened across the grain to prevent warping, the upper half being bevelled half an inch, so that the rain running down the side of a super will fall on the level of the lower hive and drop from the projecting half inch of the lower half of the crown-board. The floor-board is similar to the crown-board, except that a piece about six inches wide and three inches deep is cut out of the lower half to give the bees access to the hive through a hole $1\frac{1}{2}$ inches wide by six inches long, cut in the upper half about three inches from the edge. A piece of wood projecting about four inches is then nailed under to act as an alighting-board, and form the floor of the passage into the hive. The object of this arrangement is to allow the bottom edge of the skep to remain perfectly level all round. This is not the case when the entrance is cut out of the floor-board, as that part of the skep immediately over the entrance is sure to fall by pressure above and will then fit no other part of the floor-board. The hole in the crown-boards of this kind of hive now in use in this district is two inches wide and eight inches long. This hole is apt to give a little trouble, though the immense advantage it gives over a small circular hole should be more than compensation for it. I now, therefore, recommend what I have found to give little or no trouble, viz., six holes eight inches long, $\frac{3}{4}$ inch wide, $\frac{3}{4}$ inch apart and running parallel in the centre of the crown-board.

Management.—For each swarm there should be provided one stock hive and at least two supers, a floor-board and cover—an earthen pan if not too heavy. First give the outside of the hives at least two coats of light-coloured paint: if white is used the combs will be less likely to give way when the hive is exposed to the full rays of the sun. In very hot weather it is advisable to shade the hives a little. The bottom edge of the skeps and inside for about an inch from the bottom should be painted. The edges and about two inches of the floor and crown-boards should also be painted, so that the rain may not draw under. This would happen, and the edge of the skeps would soon rot if it and that part of the crown-board and floor-board where it rests were not painted. Having got the hives well painted and thoroughly dry, a swarm headed with a young queen should be obtained. It should weigh about four pounds.

Although the hive is ready we have not considered the site. An open space facing the south should be chosen when practicable, and with the path running behind the hives. Now clear away (and keep away) all weeds and make the ground firm. Four or eight bricks will make a sufficiently good stand, but the one I should prefer, where sleepers can be got, would be two laid side by side with the soil made slanting up to the top edge of the front sleeper, so that heavily-laden bees falling in front of the hive would easily get into it. The stand should be set as level as possible and then the floor-board should be placed on the spot the stock will occupy. This must be made perfectly level both ways by means of a spirit-level, which may be obtained for a few pence, and should always find a place in every apiary. This done, raise the back of the floor-board half an inch, because the combs should be built across the long holes in the crown-board, thus allowing the bees access to the supers from between all but the outer combs.

Having stopped the holes in the crown-board with a piece of cloth the swarm may be put in (hived in if got from a neighbour) and the hive then placed mouth downwards in front of the stand, not on it. Put a stone

under the edge of the skep, and so let it remain until the bees have clustered in it. Then lift the hive carefully so as not to disturb the cluster and place it with the holes in the crown-board pointing east and west. As the entrance which points to the south is half an inch lower than the back the combs will be built from front to back across the holes. The swarm need not now be touched again for a week or ten days, unless the weather should be unfavourable for honey-gathering, in which case it should be fed with dry sugar.

If the weather be fine for a week or ten days a good swarm will have built combs nearly half way down to the floor-board, and unless super room is given every comb will be clogged with honey almost as fast as the comb is built, with the result that the hive, if left alone till the end of the season, would contain a lot of honey and a small quantity of bees. To super, place on the stock-hive, after carefully removing the cloth in the holes, so that the tender combs are not broken, a six-inch super with the holes in the crown-board pointing east and west. The super must be made secure so that there is no escape of heat. These operations are best done in the evening, the bees being kept down by a puff of smoke, or by smearing the edges of the holes with a feather which has been dipped in carbolic acid. If the swarm be a good one, the season early, and the district a good one for bee-pasturage, the bees will quickly take to the super, and when it is about three-parts filled it should be raised and another placed between it and the stock-hive. Both these supers will most probably be filled with delicious honey, while the combs below will be one mass of brood. If the bee-keeper prefer to have no bother with feeding he might be content with one super, when the stock-hive would as regards bees and honey by the end of the season be in a condition to winter successfully. When, however, it is found that after taking off the supers there is not sufficient food in the stock-hive to last the winter, syrup should be given as described in this *Journal* and the various bee-books.

The swarm will be termed a stock the following spring, and the treatment it will require will be similar to that recommended for the swarm. But as our object in the spring will be to prevent swarming, the super should be placed on the stock-hive early, that is, when the hive is well filled with bees and when honey-gathering in quantity has commenced. But it must be borne in mind that the super must not be allowed to get more than three-parts full before it is raised and another is placed between it and the stock-hive. The upper super will be first completed and may then be removed, and the remaining one treated as was the super, first placed on the stock-hive. Thus treated the stock will most probably give a large surplus in the supers, and swarming will be prevented. If there should be a fear when the supers are on that a swarm will issue raise the stock-hive and supers bodily and place under all on the floor-board an empty super. This will be used as a brood-chamber, and at the end of the season the combs should be cut out and melted in order that the super may be ready for use the following season.—C. N. WHITE.

(To be continued.)

GLASGOW INTERNATIONAL EXHIBITION, 1888.

[1417.] As the season of 1886 proved to be a most interesting one in connexion with the honey exhibition in England, so the present year (1888) promises to be an eventful one in the history of Scotch bee-keeping. A year ago when the proposal to hold a Grand International Exhibition in Glasgow was introduced, I put myself in communication with the executive, and urged the importance of having our national industry duly represented. This suggestion was generously agreed to, and the name of

Mr. R. J. Bennett, the energetic secretary of our Caledonian Apian Society, was added to the list of directors.

At the annual meeting of this Association the whole subject was fully considered, but it was felt that the great expense necessary, and at the same time the fact, that no awards were to be offered, would debar many from coming forward during the full period of six months which the exhibition is expected to be open. Mr. Bennett had, however, arranged to get up a two-weeks exhibition during the month of July, to be held about the time when the annual show of the Caledonian is held which happens this year to be also in Glasgow.

This, however, still left the three sections granted us, viz., honey, honey goods, and apian appliances, unrepresented during the remainder of the exhibition. At this stage I consulted with my brother, Mr. John D. McNally, Springburn, who, like myself, lives convenient to Glasgow, and we finally agreed to apply for fifty square feet of space for two sections, viz., honey and honey goods, with the intention of getting up one or two cases, which we estimate will cost over 30*l.* each, exclusive of exhibits.

We have now secured the necessary space for one case, and the other is under consideration. It is expected that the Exhibition will be opened in May by H.R.H. the Prince of Wales, and already we have secured samples of honey from England, Ireland, Scotland, &c., and are still open to purchase special samples so as to fully illustrate the varieties and high qualities of British honey. In taking this matter in hand, it is only right to mention that neither my brother nor myself make bee-keeping part of our profession, others in our family do, but are too far resident from Glasgow. It is only an earnest desire on our part to see our 'hobby' getting more popular, of seeing new outlets opened for the sale and use of honey, and, at this particular stage, to show that honey is, and can still be classified, as one of our important food productions, which has encouraged us to make this venture, which we are hopeful will eventually meet the object we have in view. We are anxious to get the names of those manufacturers who use honey in their goods, and any information as to articles which will assist us in those special classes, in making them as interesting as possible.

At a later stage we hope to submit the extent of our exhibits more fully, meanwhile will be glad to get all the information possible.—E. McNALLY, *Main Street, Rutherglen.*

COUNTY ASSOCIATIONS.

[1418.] Your article on page 2 should make every office-bearer of any such association hasten to set his house in order, for there is no disguising the fact that some of our County Associations are far from being so prosperous as they might and should be. I have just been looking through the Reports of the Affiliated Associations for 1886, and I have found one that ought to prosper amazingly, viz., Leicestershire, for they offer 'a sure market for honey' as one of the advantages of membership. I must join that, I think. Why, Mr. Editor, the bee-keepers' millennium must be at hand.

The objects of the Hertfordshire B.K.A. deserve recapitulation:—'To teach the residents of the county a more humane and profitable system of bee-culture, and the increase of the home supply of pure, wholesome food among the labouring classes.'

Is it not possible that, if our different B.K.A.s had been satisfied with this pithy extract from our Hertfordshire friends' report as their text, and then worked up to it, that you would never have felt the necessity of laying on the rod of correction. Have we not one and all promised too much and done too little? I am much afraid the profits of bee-keeping have been made too

prominent a feature when recommending the modern system, forgetting that many of our hearers would, through their own inattention, fail to get any profit. Would it not be well to at once adopt the lines laid down by the Hertfordshire B.K.A., and do our best to show *all* how they may, at a comparatively small cost, become possessed of a good, wholesome table delicacy, leaving the *few*, who eventually prove successful, to be helped according to their various necessities, and encouraged to make a business of it? Even of the few who succeed, there will be many who cannot manage more than perhaps six colonies. Such should have no difficulty in disposing of their surplus locally, either by their own efforts entirely or with a little assistance from the local secretary of their association. I have great faith in the idea propounded in the last paragraph but one of your remarks on 'Keep your colonies strong' which appear on page 509 of the 1887 volume, and I propose inviting all members in my province to communicate to me particulars of their wants, and also any of surplus they may have for disposal, with a view to making our M.B.K.A. more useful. Will any one kindly discuss the present status of our Associations, and suggest useful remedies?—W. M. GRAHAM, *Provincial Secretary of the Middlesex B.K.A., Lutyners Lodge, Lower Edmonton.*

COUNTY ASSOCIATIONS.

[1419.] The county association of which I am honorary secretary, has not begun to fill the place it was intended to take amongst the bee-keepers in its radius, therefore it is, to say the least, discouraging to read the remarks under the heading 'County Bee-keeping Associations' on page 2 of your issue of the 5th January, 1888.

If the committee of the B. B. K. A. consider their organization perfect, by all means let them come and assist their country cousins, but do not let their organ write or call *stinking fish* when it is not in a position to know what many of the county Associations are doing. Instead of the old-fashioned bee-keeper being left far behind, we have those amongst us, *lately unearthed*, bee-keepers who have been bee-keepers long before the *Journal* existed, and who are (as far as is generally known) a long way ahead of the recognised *savants* in the successful management of apiaries.

Out of the list, 'approximating to 300 subscribers,' how many were bee-keepers? I am quite ready to acknowledge that the subscriptions of non-bee-keepers are valuable to treasurers of county associations, but their interest will not continue; and my aim is and will be to get bee-keepers throughout the county at as short distances apart as possible to work their districts up: by this means I believe county bee-keepers' associations will prosper. These district workers will be a great assistance to county secretaries, but at the same time they will give him more work, as there will be more shows to organize and more honey to negotiate the sale of.

What will all this lead to? I would venture to assert an honorary treasurer in every county, with a paid secretary; is not this the experience of floral, horticultural, and agricultural shows?

My committee consists of eleven members, they have been called together twelve times, and have put in eighty-two appearances. I have no record of their attendances at shows, but this would add materially to the time the committee have given to the cause. Please do not make our work harder by writing about alarming symptoms of decline, but rather, I would suggest, in every issue impress on your readers how intelligent bee-keepers could assist the cause by joining their county association, and bringing before its working head the

way in which he could best benefit their particular neighbourhoods.

As an association we are ready to send out lecturers in the winter, experts or advisers in the spring and summer, and to arrange for the sale of surplus honey; in return we ask that bee-keepers in each district will get so many subscribers that the association is not put to a large money cost.—W. LEES McCLURE.

MEMS. BY 'WOODLEIGH.'

[1420.] As regards the statement of the 'Iowa Homestead' about bees selecting a home before swarming, I can endorse it somewhat. There is a village called Peasemore about two miles from where I live in a 'bee line.' Now, nearly all the stray swarms from our part go straight off in a direct 'bee line' for Peasemore. The only conspicuous object in the village is the church spire. Now, bees have tenanted the said church roof, also the tower, many times, but rarely live through the winter. One would suppose that scouts or spies had investigated the district for a suitable spot in which to start a new colony, or why should bees start off in a particular direction as soon as out of the hive if there was no preconceived plan decided on before the swarming took place. Nine miles seems a long distance for bees to travel, and a longer distance for scouts to go in search of a *dulce domum*, but I can vouch for a swarm of bees flying six miles in a bee line. It happened some years ago, and the man who rode horseback after them told me himself. His master, a farmer, kept a large apiary in those days of 100 stocks, and a man used to have to attend to them, and a very busy time he had in May and June, during swarming time, as they were all in straw skeps. The swarm in question, a very large one, came off just as the farmer returned from the fields on his horse. The beeman says, 'Maister, they means off.' 'Here, George,' says the farmer to his factotum, 'take a hive, jump on my horse and follow them.' George followed over hedges and ditches, through fields of waving corn, across commons of gorse, still keeping them well in view, till weary of wing they settled in a piece of wheat. Here George hived them, gave his horse a rest, borrowed an old woman's apron, tied them in, and trotted back home with them. Evidently, if this particular swarm had selected a cavity in some wall they never reached their intended destination.

I notice 'Mr. T. H.' considers his winter packing more simple than friend 'A. E.'s,' and as I consider my system more simple, more economical, and more utilitarian than 'T. H.'s,' I give it for what it is worth. I buy some cheap unbleached calico at 1½d. or 2d. per yard, and form it into bags 20 or 21 inches wide. The sewing-machine comes in handy here, as a dozen or two bags or cases can soon be run up together, leaving one end partly open. Now take your clean wheat-chaff with dust sifted out, and about half fill your bags, or, as my little girl calls them, the pillow-cases, then finish the sewing up. Here you have a wrap that you can mould to your frames, and long enough to lap or hang down to the bottom of the hive behind the frames or dummy. I always use two or three quilts of hemp carpet, then the chaff pillow or cushions over them. Then if a lump of candy is required by the bees, what is more easy than to roll back the cushion, place your candy over feed-hole, and replace your cushion, retaining the heat of the hive, and causing no disturbance to the bees. Then in spring, during feeding time the cushion will cover the feeding bottle by lapping over it and reaching the outsides or ends of frames, thus retaining the heat when most needed for the well-being of the colony. Then later on, when the crates or sections are on, their winter cushion still holds its own and mounts the upper deck, keeping the super warm and comfortable, and preventing the chill night air and lower temperature driving the bees

out of the sections down to the brood nest below for warmth.

Anent the mention of honey in the Old Testament, Genesis, chap. xliii. ver. 11, one would think the Patriarch must have been a bee-keeper on a large scale, as we find him possessed of *honey* a long time after the *corn* was all consumed, and we should expect the famine was caused by drought, consequently herbage and flowers suffered equally with cereals.—WOODLEIGH.

KOERBS' NEW ARTIFICIAL COMB AND CELLS.

[1421.] I have read about Koerbs' new artificial comb with great interest in yesterday's *Journal*. I *guess* he does away with the *mid-rib* as then the queen would not have a place to deposit her eggs; and if he makes the cells *right through* the combs the whole of the honey could be extracted at one operation without having to take them out and reverse.—J. HALL, *Station Hill, Wighton, Cumberland, January 6, 1888.*

A NEW ARTIFICIAL COMB.

[1422.] Is it possible that the comb invented by Mr. Koerbs, an announcement of which appeared in your valuable *Journal* of the 5th inst. (No. 1407), may simply turn out to be combs with cells of a yet larger size than such as are built by the bees for the purpose of raising drones? We do not find pollen deposited in drone-comb, therefore, is it not probable that foundation with cells somewhat larger still would readily be drawn out by the bees which, from their size, would be avoided by the queen when depositing eggs, but which would be utilised by the workers when storing honey? Such is, perhaps, not improbable. May I suggest the use of foundation with cells measuring $\frac{1}{4}$ of an inch in cross section. Should the queen deposit eggs in these the size might be somewhat increased.

The matter could be easily tested, but the cost of machines for impressing foundation for experimental purposes would be greater than most bee-keepers could afford. I should, however, be glad to contribute my share towards the cost if a few bee-keepers could be found to unite for this purpose.—T. M.

NEW ARTIFICIAL COMB, &c.

[1423.] After reading article on (1407) p. 7 of last week's *Journal* on 'A New Artificial Comb,' I said to myself, What a simpleton I have been! Why, for the last two years I have had combs, and newly drawn out at that; that the bees would not breed in or store pollen; they would use them for nothing but honey, even when placed in the centre of brood-nest, and for that very reason I threw them all into the melting-pot. I thought to myself now, If I had but got them by me now how useful they would be. The thought then struck me, Had I cooked them all? I went straight away to the honey room and pulled down (empty) comb after comb in hopes that one had escaped the melting-pot. I had almost given it up as a bad job, when well nigh the last comb had been removed I came across one, but much damaged. However, I have cut out a sample large enough to show what it is like. Now, the thought never struck me of making comb-foundation after the same pattern until I read the above article. I set to work straight away and made a sample foundation, which I think will fill the bill to a T. Now I don't say that the bees would not breed in them if all the combs in the hive were of the same pattern (for they will do some very curious things sometimes), but I am certain that if they had a fair amount of ordinary worker and drone comb in the hive to breed in they would not use these said combs for anything but honey.

I write this simply to show that the discovery is not new (that is, if Mr. Koerbs' discovery is the same as mine; I don't know whether it is or not), although I had not taken advantage of this discovery until reading the article above referred to. I have sent samples of both comb and foundation, with explanation, to Mr. A. Neighbour by the same post as this. I have no doubt Mr. N. will show you the same upon application; he also will inform you whether he is disposed to patent it or not, or whether he intends making it for sale; if he does we can soon get a mill cut for making it. I have also sent him a sample of new comb-foundation, which perhaps he will show you, invented by me, which I think will do away with wired frames and wired foundation. It has other advantages which, if it turns out as I anticipate, will make a revolution in bee-keeping. I am getting up a new section case, which I think will be welcomed by many. Mr. N., no doubt, will send a description (when ready) to the *Journal*; if he does not I will. Yesterday (Sunday) was a splendid day for the bees. I walked through the apiary and put them through the roll-call, and they all (60) answered to it. Of course I never opened them, but if we get such a nice day sometime this week I shall remove all the covers and chaff-cushions to give them a good airing in the sun.—WALTER MARSHALL, *Messrs. Neighbour's Bee Farm, Buncefield, Hemel Hempstead.*

[We received the above communication too late to allow an opportunity of seeing the samples referred to; but if there be any merit in the discovery we are pleased to give our correspondent the credit of priority.—Ed.]

HONEY SCRIPTURE TEXTS.

[1424.] 1403, and 1411, on 'Scripture texts,' still need a little clearing and addition. 'Honey' is named fifty-two times in the Old Testament and four times in the New. 'Honeycomb' is named eight times in Old Testament and once in New Testament, making sixty-five times in all. 'Sweeter also than honey and the honeycomb' should surely be reckoned once for each word, &c.

I add the whole of the passages naming 'honeycomb' for clearness.

1 Sam. xiv. 27. Psa. xix. 10. Prov. v. 3, and xvi. 24, and xxiv. 13, and xxvii. 7 (not xxvi. 7). Cant. iv. 11, and v. 1.

Add for 'Bees' Judg. xiv. 8, and Psa. cxviii. 12, making four occurrences.

Add for 'wax' Psa. xxii. 14, and Micah, i. 4, making four occurrences.

Add for 'hornet' Exod. xxiii. 28, and Josh. xxiv. 12, making three occurrences.

'Stingeth' (but, like an adder) Prov. xxiii. 32, and 'Sting' 1 Cor. xv. 55, 56.

'Swarm' is mentioned only in Judg. xiv. 8, in connexion with bees.

It is worth noting that no queen-bee is mentioned: while their undesirable tenacity of pursuit is the point of Deut. i. 44. Their order and industry are not referred to, but the ant instead is the entomological pattern for us in these respects.

Qy. 1. Is it because bees sting so readily?

Qy. 2. Do all bee-keepers, if so, learn the implied warning?—E. C. P.

HOW BEES EXTRACT POLLEN FROM FLOWERS.

[1425.] In regard to the visitors of *Asclepias cornuti* (common milkweed) Dr. Hermann Müller observes that they 'slip upon the smooth parts of the flower until the foot enters the wide inferior part of the slit, in which it at last gets a firm hold.' Mr. T. H. Corry describes the insect

as grasping the back of a nectary, and plunging its proboscis into its cavity, 'endeavouring at the same time to get a firm and sure foothold on the unstable flowers,' until the insect at length places one of its feet into the wider part of an alar fissure.

Having collected insects on the flowers of six species of *Asclepias*, I regard the normal action of the most common and most efficient to be that they hold on to a flower, or several flowers, in such a way that their feet go down below the angles of the alæ, and when the legs are drawn upwards they are caught between the strongly projecting hoods and guided by them over the entrance of the stigmatic chamber, which occupies the narrow interval between their bases. Of native insects, the most common visitors I have observed on *A. Sullivantii*, are humble bees (*Bombus separatus*, *B. Pennsylvanicus*, and *B. scutellaris*) and *Danaus Archippus*. The feet of humble bees reach down as far as the basis of the petals, and I have often found the pollinia fastened upon their tibial spurs as well as on their claws. I have also found pollinia of this species on the spurs and claws of *Danaus Archippus*, and high up on tarsal hairs of *Prionyx Thomas*.

In a similar way a specimen of *Scolia bicincta* shows pollinia of *A. cornuti* on the tarsal hairs. However, the gynostegia of these species are so large that the feet of many visitors will not reach far below the angles of the wings, and when this occurs the claws are the only parts which are readily caught. The importance of the hoods in guiding the legs of insects over the angles of the wings is more apparent in the smaller flowered species, since the more delicate wings catch hairs which are not only very fine and short, but which are also situated much higher up on the legs. Thus hive bees caught on *A. Sullivantii* and *A. cornuti* show pollinia only on their claws and pulvilli, but they have the pollinia of *A. tuberosa*, *A. incarnata*, and *A. verticillata* scattered upon the hairs of the tarsi. A specimen of *Argynnis Cybele*, which I caught on *A. cornuti* has pollinia of this plant on its claws, and pollinia of *A. tuberosa* on the tarsal hairs. . . .

H. Müller, who supposes that the whole foot enters the stigmatic chamber, says: 'When the insect tries to draw its foot out in order to proceed further, the diverging claws are caught by the apposed edges of the anther-wings, and guided upwards in the slit so that one or other of the two claws is brought without fail into the notch in the lower border of the corpusculum and there held fast.'

On the same subject Mr. Corry says: 'When the foot reaches the superior end of the alar chamber in which it has been guided, one at least of the two hooked claws upon it, or some part of the foot in the case of Diptera, must easily enter the hollow cavity of the corpusculum, which lies in such a position that this result is inevitable.'

The importance which these authors attach to the view that the whole foot enters the chamber, in my opinion, rests on a misunderstanding of the mode of insertion of the pollinia, and has led them to overlook the precision with which a corpusculum comes to be fastened to a hair or claw. The corpusculum is placed so nicely at the top of the wings that its cleft is fairly continuous with the slit between them, and I cannot conceive that the contrivance works normally unless the particular part, *z. e.*, a single claw, hair, or pulvillus, to which the corpusculum becomes attached, is caught between the wings and guided by them into the cleft.

Believing that all processes are caught as the leg of the insect passes over the angle of the wing, I suppose that only a single process is caught, and that a claw is caught in exactly the same manner as a hair or spur. In a careful examination of the feet of 116 hive-bees which were killed by being caught on the flowers of *A. Sullivantii*, I have found that, with but two exceptions, when a foot was held by the wings, only one claw was

between them, the other being free, or less often the pulvillus was held between the wings and both claws were outside.

When first withdrawn the pollinia lie in the same plane. In a few minutes the twisting of the retinacula brings the pollinia into nearly parallel planes, but the upper ends are still separated by quite an interval. According to the authors to whom reference has been made the pollinia are inserted by the corpusculum. From the analogy of observations made on the movements of the pollinia of some Orchidaceæ some advantage might be looked for in the slow movement of the pollinia of *Asclepias*. Indeed, Mr. Corry, who has observed this phenomenon in *A. cornuti*, states that it is of advantage, although he fails to show it; and I think it impossible so to do on the supposition that the pollinia are introduced by the corpuscula. He says:—

‘Some considerable time, moreover, must elapse after the pollinia are extracted before the corpuscular appendages are so far dried that both pollinia of the same corpusculum can be introduced through the fissure into the alar chamber, and in the meantime the insect has had time to reach another flower or plant.’

On another page he observes: ‘If the movement did not occur on the part of the pollinia, their broad surfaces would lie at right angles to the alar fissure, and their insertion into it in this position through the notch would in consequence be rendered a much more difficult, if not an altogether impossible operation, or else the pollinia in being slipped in would become folded in the opposite direction, and the less curved border which emits no pollen tubes would be first inserted into the fissure.’ But what is to prevent this consequence before the movement takes place? Whatever might happen there is obviously nothing to render the introduction of the corpusculum itself more difficult before the movement occurs than afterwards, so that the slowness of the movement is hardly an average under this view. If the corpusculum were very slender or flattened so that a thin edge could be presented to the slits, there would be no difficulty in understanding how it could readily slip into the stigmatic chamber; but it is a rounded body, and is relatively large in comparison with the entrance to the cavity.

Of course, if the whole foot of an insect commonly enters the stigmatic chamber, it is not hard to understand how the corpusculum should go in with it. But when the corpusculum is fastened to a hair which is directed outward and downward from the leg of the insect, and which is often so short that the corpusculum is fairly in contact with the leg, the difficulty increases.

In the examination of the feet of hive-bees killed on the flowers, I have failed to find a single case in which a corpusculum was attached to that part of the foot which was held between the anther wings. In my opinion, therefore, the structure of the corpusculum is so far from facilitating the introduction of the pollinia that it prevents the part to which it is attached from being again caught in the slits, and until the movement occurs the corpusculum with its two pollinia will pass over the entrance to the stigmatic chamber without being injured.

After the movement occurs, if the corpusculum be examined from one side, it will be observed that the retinacula project outward and downward. Since the parts to which the corpuscula are attached themselves project outward and downward, the retinacula finally stand nearly at right angles to the leg of the insect. The retinaculum near the point where it joins the pollinium, is bent rather suddenly, so that the pollinium appears to be flexed upon it. This flexure, which Mr. W. H. Leggett has called the knee, is very prominent.

There is quite an interval between the knees, and the membrane of the retinaculum of the knee is expanded transversely to the plane of the pollinium. Robert Brown has observed in *A. purpurascens*, that the part of

the retinaculum extended between the knee, and the pollinium remains attached to the latter when it is found in the stigmatic chamber. This expansion of the membrane serves to prevent the withdrawal of the pollinium after it has been inserted into the cavity, and when drawn against the closely opposed edges of the alæ in the upper part of the stigmatic chamber, facilitates the rupture of the retinaculum.

Judging from the structure of parts which are readily caught between the anther wings nothing could be more natural than for one of the knees to slip into the entrance to the stigmatic chamber, and the movement is intended to turn them into such a position that this will occur. When, therefore, the movement has taken place, and the insect draws its leg over the angle of the wings, the corpusculum with the claw or hair to which it is attached, passes on without being caught, while one of the knees of the pollinia readily enters the stigmatic chamber, and the pollinium enters with it. When the knee has reached the upper part of the cavity, and will go no further, the retinaculum is torn across and escapes, leaving the pollinium in position to effect fertilisation.

In repeated trials at artificial pollination of the flowers of *A. cornuti*, *A. Sullivantii*, and *A. incarnata*, I succeeded three times in the case of *A. Sullivantii* in separating the pollinium from the retinaculum without withdrawing the latter from the slit, and thus was enabled to insert a pollinium, and to draw out a corpusculum at the top of the alæ with its two pollinia by the same movement. But in all other cases a pull that seemed sufficient to break the retinaculum freed it from the slit so that the corpusculum at the top remained intact. Accordingly I have seen no difficulty on the supposition that the pollinia are introduced by the knees, in the observation of H. Muller, who says:

‘In several flowers which I dissected, the corpuscula and pollen-masses were still in their places, though pollinia, which must have come from other flowers, had been inserted into the stigmatic chamber.’

In a number of cases observed by me on *A. Sullivantii* the movement which turns the knees toward the flower is completed in about seven minutes, though it has proceeded sufficiently in five minutes to turn the flexure far enough to render insertion quite likely. With the view of pollination stated in this paper, the slow movement is plainly of advantage, because a knee can hardly be caught by the wings until it has occurred.

Now, since only one pollinium is inserted into the stigmatic chamber, there is an economic disposal of the pollinia. The interval between the flexures is so great that only one of them can be caught, while the other passes by the slit uninjured. There are, therefore, two chances of a pollinium being transferred to another plant. If both pollinia were left at each act of pollination, there would be but one chance of cross fertilisation. Moreover the chances of cross-fertilisation would be reduced from the fact that the stigmatic chambers would be more nearly filled by pollinia from the same source, while if they are introduced singly, there are more chances of a chamber receiving a pollinium from a distinct plant.

As two pollinia are fastened together, there would be but one chance of pollination occurring if the pollinia were inserted by the corpuscula, while there are two chances of a knee being caught. When a pollinium has been removed the broken retinaculum may be caught in a slit, and remove a second corpusculum with its two pollinia. When this combination of two corpuscula and three pollinia is drawn over the angle of the wings, there are three chances of a pollinium being caught. Whenever a pollinium is removed two new pollinia may be substituted for it, and a large combination of pollinia may result arranged either in a unilateral series or dichotomously. In either case the chances of the insertion of pollinium equals the number of pollinia in the combination,

If the foot to which the first corpusculum of the combination is attached must enter the stigmatic chamber, of course there would be but one chance of pollination taking place without regard to the number of pollinia. Such an accident would be likely to destroy the whole combination. As already observed, on the large flowers of *A. Sullivantii* and *A. cornuti*, the shorter hairs on the legs of insects are not readily caught, so that the number of parts to which the corpuscula may be attached are reduced to the minimum.

For instance, the only parts of the leg of a hive-bee which can remove the corpuscula of these species, are the two claws and the pulvillus. The leg will thus remove three corpuscula, and since these bodies render useless the parts to which they are attached, the broken retinacula not only take the place of the parts disqualified, but increase the number of parts to which the corpuscula can be attached. By means of these combinations, therefore, the leg of an insect has its capacity for carrying pollinia greatly increased. . . .

Finally, I have seen the pollinia of *A. Sullivantii* introduced into the stigmatic chambers in the manner described. The pollinia and the entrance to the chamber in this species are very large and are easily seen, and hive-bees move so slowly in effecting pollination that, after a knee is caught, one can see the pollinium slowly disappear between the wings, so that there can be no doubt as to the manner of insertion. Commonly, however, the insertion of pollinia occurs so rapidly that it is impossible to see how it really happens. After a pollinium has been introduced into the chamber, hive-bees always have difficulty in breaking the retinaculum, and they lose their lives on account of this as well as on account of the difficulty in drawing their claws through the slit. When a foot is held by a retinaculum the pollinium is found in the chamber, with every indication that it was introduced by the knee.—PROFESSOR CHARLES ROBERTSON, *Blackburn University, Chicago, Ill.* (*Botanical Gazette.*)

THE BLUNDERS, ACCIDENTS, &c., OF A NOVICE.

[1426.] Twelve months ago last Michaelmas we decided to 'go in' for bees in a small way. A hale, drooping old man, who had drawn the sickle and swung the scythe for fifty harvests, and flung the flail for fifty winters, now in his eighty-fourth year, offered us four straw hives for 24s. Bargain was struck, and night fixed for removal; and, forsooth, this first step was a step in the dark, for we knew absolutely nothing about bees—had never heard of bar-frame hives.

In our ignorance we made what we considered a good bee-house, capable of accommodating eight colonies in straw hives. This was firmly fixed in the ground, facing south, and fully exposed to the strong winds that swept with such great force athwart this flat part of the country.

The night for removal was very dark. We joined the old man, son, grandson, donkey and cart, and soon arrived at the old stand. With the lantern the old man led the way, and cautioned us not to talk, or nothing could be done. Superstitious old man, as we shall see.

About the hive entrances there was quite a hubbub, as if the bees had been disturbed. The clothes were spread, donkey and cart at the garden gate, 'we four' ready for action, but after looking under one of the hives it was decided to leave them till another night, for the bees covered the board. Just at this moment the old man exclaimed that they were about his noddle, and fumbled about, expecting every moment to feel the dreaded stings.

'We four' went the following evening. The donkey stayed at home. The bees were quiet. The father and

son carried two, and the grandson and I two; their two on the old stand, our two slung on a pole.

We had a mile to carry them. Half way we halted; my pole end rested upon railings, my companion's perilously upon the end of a stick. The pole slipped, and the heavy skeps went suddenly to the ground. No damage was suspected, so you may imagine our feelings when it was found that the comb in the hive which struck the ground first was all broken from its holding. The hive was lifted in the cloth and put upon its new stand, and left till the morrow. But before leaving the bees the hale old man of eighty-three said, 'Now yow must talk tu 'em, tell 'em thair yars, an' that yow'll be a good master tu 'em.' We did as he bade, of course, there and then, and they *hure* stayed with us, although, like us, they have had new experiences. As we were walking home, the old man had other and stranger things to tell us about these mysterious little 'critters.'

'It's many years sin we bought our fust skip. We got 'em fro Mrs. K—, an' forgot to talk tu 'em, an' tell 'em tha was ours. We had bad luck wi' them lot. Not long arter Mrs. K— died, an' wen her funeral was passen our gate, we was reminded of the bees, an' went down an' loked at 'em. Bleeve me bor, wen we got there them bees was awready awasten, and wen we tand up the skip nearly all the bees was dead.'

We suggested that the bees might have died from want of food.

'Oh, no, tha din't! no, no; tha had plenty t' ate, but we din't talk tu 'em bor, that was the reason. The next skip I got fro Mrs. B—, an' wen I got em' hum I land over 'em an' mapp'd on the skip wi' my finger, an' told 'em tha bloug'd tu me, an' bor, them bees done well, an' I never bought no more. An yow mussen't ha no words about 'em, du tha *can't* stop wi' ye.'

We were anxious next morning to get to the ill-fated hive. It was a complete wreck—honey running, dead and dying bees, and what to do? We scarcely know what we did. Knew, however, that all the bees were lost, a few pounds of honey only saved.

Not many weeks had passed when, during a cold and windy night, our new bee-house was blown over on its back, where it lay till the morning, and each of the three hives upset. All were made more secure than before, and no further inconvenience or loss resulted.

A farmer friend, who was the only one in the village at the time who had modern hives, when passing one day, intimated that our hives were disgraceful old things, and that we must not expect much from them. He advised Cowan's *Guide*, which we immediately procured, and went through and through with the greatest avidity. We became fascinated, ordered one of Walton's 10s. hives, had it fitted ready for a reception.

In driving for the first time we were very successful, cut the old skep in twain, and gave the best comb to the bees in the new hive. But whether from want of a more prolific queen, or experience on our part, we know not, at the end of the summer they had not stored enough for winter, which necessitated feeding, and to strengthen them driven bees were mited.

Late in May both the remaining skeps showed signs of swarming, and clustered about for many days—one of them for weeks. We watched them constantly, and with absorbing interest. The first swarm issued and clustered very awkwardly round the lower part of the trunk of a pyramid pear-tree, just near the bee-house. With much difficulty we succeeded in getting them into a straw hive, and in the evening placed them upon the stand near their old home. Being our first swarm we were delighted at having secured them.

Next morning, when amongst the fruit trees, we heard such commotion in the air, and sure enough there was another (?) swarm out. We hastened to the spot, regarding nothing but the bees. It was soon evident they meant flight, and forthwith, in a direct line, made for

an old willow-tree in the next meadow. We followed, determined not to lose them. They must have selected this place before swarming, as will appear more evident presently.

A ladder was procured and a skep, and we tried all ways to get them out of the tree, but to no purpose; we had to leave them in the end, though most reluctantly. We returned, therefore, disappointed, to find—what? Why, that the very bees which had given us so much trouble and delight the day previous were the same bees which had reissued without provocation and gone to the tree. We have reason to think with 'Iowa Homestead' (1413) in this week's *Journal* that bees do select a place before swarming.

At the back of our bee-house is a hedge and not long before our second swarm issued a score or so of bees were observed hovering about one place. We guessed then that the bees were selecting a place to cluster, which proved true, for soon after a swarm came out with a rush and went direct to the spot over which the few had hovered, and in a few minutes they were all clustered upon a slender thorn twig. As if to recompense us for the loss of our first swarm, the same day our attention was hurriedly directed to some bees which were clustering near the ground not far from the bee-house. With a straw hive we hastened to the spot, and quite a curious phenomenon presented itself,—a cast, undoubtedly, and all clustering upon a common nettle. The skep was placed over them, and in five minutes most of them were safely hived.

We knocked together a hive to take standard frames and drove the bees from the hive whence the lost swarm had issued and stood them where the old hive had been; but they resented, though dry-sugar feeder and full sheets of foundation seemed all that were required for their comfort. They left; how and whither we never knew, but think they went to the other hives.

We did not move the hive, however, and about this time we left and were away about a month. It was August, a month when most of us would rather be at home, the time of harvest and of fruit. It was especially hard to leave the bees, for some might get lost—a flight or two perhaps. But we had no thought of gaining a swarm, which, to our amazement, was only too true, for we found on returning that the frame-hive which we had left empty of bees, but with sugar and foundation still in, was full of wasps. Here was a job. The store they had stolen who could tell? For hours we waged war with those yellow thieves, and, as we thought, killed nearly all of them. They were troublesome, however, till late autumn. Faint heart never won fair anything. We began to take the *B. Bee Journal*, which has been a pleasure and profit to us to this day.

Driving bees is a novelty here, but having been begun we hope the days of the sulphur-pit are numbered; of the old straw hive we cannot hope so much. The apathy of the cottager, speaking generally, is extraordinary; they are for the some part thriftless, sensual, poor. After work the pipe and the pint seem the only attractions.

We had little difficulty in obtaining the consent of cottagers to allow us to drive their bees. Altogether during the autumn we drove eighteen lots and introduced them after uniting into modern hives.

Wishing to get rid of our new bee-house we changed it for a skep of bees, which is the only stock now that is not in a bar-frame hive. Through autumn we had five feeders going (syrup), and had united in the five hives eighteen lots of driven bees. The most united in one hive were five lots, which is our best, and are wintered on eight frames.

We had great difficulty in driving in every instance where cross sticks had been used. Late in the autumn we drove to a neighbouring village with the intention of driving ten out of fifteen colonies. The comb was so

firm with the sticks that at the end of half an hour many bees were left in the first hive, and at the end of the third we were almost fagged out and disgusted. No. 2, which was placed on its old stand after being driven, was a disappointment, for just afterwards when we turned up the hive not a bee was left. They had forced their way into the adjacent hives only to meet their death. We could not wonder, for the hives stood all in a row not an inch apart.

The other hives were brought home here and driven with perfect ease. Let us caution any readers who from inexperience may be tempted to draw the cross-sticks out of the straw hives before driving. They are generally so firm that in pulling them there is great danger of breaking the comb from its holding and thereby crushing and impeding the exit of the bees.

Now perhaps some one will be good enough to assist us over a difficulty. It was our fault that father made an observatory hive in the autumn, which does not take a standard frame. The top bar is just fifteen inches, and as we found it necessary to transfer the bees to another hive prepared for winter we found the frames only just long enough to lie upon the inner walls.

After transferring we united three lots more of driven bees to them, making five lots in all in the one hive. It was necessary to take two unfinished frames out now and give them finished ones, which we did. So now they have six top bars fifteen inches and two seventeen inches long. As this is our strongest stock we wish to transfer them in spring into a storifying hive.

We have made a capital hive four-storey, and we want to know how to proceed so that the short top bars may be replaced by standard frames. If a change can be made we have enough of the latter unfinished. Supposing frames *can* be changed will it be wise to storey when we have no finished frames of comb for use in the second, third and fourth storeys? To-day (Saturday) the bees have been out in large numbers; their first duty was to bring out all the dead, which they carried quite away. We allowed the sun to shine upon the quilts awhile and ventured to peep at the stores, as there was some doubt.

In conclusion, we are sure that our worthy Editor will agree with us in thinking that, whilst Guide-books are good and indispensable, there is no school like experience. Our blunders, accidents, and disappointments, have not in the least diminished our interest. We have a larger hope than at the first. We are satisfied that the step from the straw skep to the modern bar-frame villa was progress, and having started, our watchword ought, can, and must be still, Progress.—F. GOODRICH, *Methwold, Norfolk, January 7.*

THE PRICE OF HONEY.

[1427.] Mr. C. Howes [1406] pays me, I think, a very poor compliment in thinking that I do not take the trouble to read carefully what has appeared in the *Journal* from the pens of several writers to whom he refers, 'Mr. Useful Hints,' Messrs. Godfrey, Simmins, &c. Evidently Mr. Howes still labours under the same delusion that in this district we possess the same advantage as he enjoys. Let me undeceive him again, once for all, by telling him that we have no market or other place within twenty miles at least, nor do I know of any such a place anywhere where 'honey vendors' have a chance of standing side by side with their several 'gets-up,' as he calls them, therefore we have no chance of showing any superior 'get-up' in our goods for sale, neither do I rush into the market to sell at a low figure just because others do. I have sold none for less than 8*d.*, more for 10*d.* and 1*s.* per section; but it has been a very difficult matter to do. I, however, cleared out my last about a month since at 8*d.*, not a great price after waiting three months, and then had to go to

London do to it. I have found two or three markets for another year by doing so, which is some small consolation.

I am very pleased to receive any hints on any subject, but I flatter myself that I have a little common sense not to put the 'sulphur pit' honey on the same level as extracted. It is not I, but the uneducated public who do it. There is no chance of comparison. Honey is honey, that is all they know, and if you try to explain and endeavour to show how and why the difference, they only look at you in blank amazement, as much as to say, Do you think me a fool not to know honey?

No doubt, if the B. B. K. A. were to publish some leaflets on the different qualities of honey, it would have a most salutary effect.

Mr. Howes next refers to 'our great masters,' trying to increase the number of bee-keepers in this country, yet advocating the 'down-grade' in the price of honey. I do not see this; I do not think they trouble much about the price of honey, they are generally great producers or manufacturers of bee-furniture and appliances generally; if they seek to push and extend their business it is no more than they have a perfect right to do. If bee-keeping is to be a paying industry, it must be conducted on ordinary business principles of profit and loss, and consider time as money spent in its cultivation. This, I think, is where the mischief arises to a great extent, men with their regular salary, and clergymen to a large extent, as if they had just begun to realise the advantage or wisdom of acting on a celebrated bishop's advice to his clergy, 'Keep bees, Keep bees,' have gone in for many things latterly, fruit, vegetables, bees, and photography. Another reason is the middle man, who advertises for honey at 6½d. per lb., this also tends to make a false impression and lower the price, while the middleman makes his thirty and over forty per cent profit, so that the consumer is not in any way benefited by the low price the producer gets. What then are bee-keepers to do? In the first place (if it is not practical for the B. B. K. A. through county associations to assist bee-keepers to sell their honey, which I submit they could without much difficulty), let all bee-keepers refuse to sell their honey to those middlemen and look out for the retail seller who supplies the consumer direct, thus dividing the profit between two instead of three parties. Considering the uncertainty of the weather season, honey cannot in many districts be produced at 6d. per lb. if time has to be paid for in producing it, as it clearly should be, or else those who have to give all their time to it had better look out for even a chimney-sweep's business, where he can get his time paid for. There are but very few businesses one can combine with it, to work either successfully; even at this season, I find every day brings something to do, or to be looked into.—*SHERBORNE, Dorset, January 4, 1888.*

POLLEN FOOD.

By PASTOR SCHÖNFELD OF TENTSCHEL.

In my last article I endeavoured to prove that bees are unable to prepare for any length of time the chyle required for the nourishment of the brood, unless they have a supply of nitrogenous food, and that, in the absence of collected pollen, from some reason or other at the commencement of breeding they extract it from old combs which contain an abundance of it. All practical apiarists will have concluded from this that it is well to insert one or two old combs in the neighbourhood of the winter quarter of the bees when a colony is without pollen at the end of the season, and when there are only new combs in the hive. By this simple and easy expedient such a colony is very materially assisted in the preparation of the necessary chyle; without it, indeed, the bees would be unable to subsist, for as the brood require albuminous food to build up their body, so the bees require it for their maintenance. It is quite

incorrect to suppose that a colony without pollen is able to survive the winter in a perfectly healthy condition as long as it has a plentiful supply of honey. During the whole winter it is impossible to find a single bee the intestinal canal of which is not full of particles of pollen, being an undeniable proof that pollen is an indispensable food of bees. Bees found without particles of pollen always, and without exception, belong to a colony which had no pollen, and only newly made combs at the beginning of winter, but such colony would hardly survive the winter. How indispensable albuminous food is to drones I learnt last summer. It is a well-known fact that queens and drones do not consume pollen, but only honey which they take from the cells, the necessary albuminous food being supplied to them in the chyle with which they are fed by the workers. In order to find out how long drones are able to live, if merely fed on honey, I made the following experiment: I took two combs, containing about 2-300 grains each of freshly gathered honey and surrounded each comb with wirework, a space of ½ centimetre being left between it and the upper ends of the cells, so as to enable any drones on the combs to move comfortably in every direction. One of the two combs was protected by a second screen of wirework, a space of 1 centimetre being left between the two, so that any drones on this honeycomb would be compelled to exist upon honey alone, as they could not possibly receive food from the worker bees on the outside, while the drones on the first honeycomb were not prevented from receiving chyle through the grating.

During a week of cold and rainy weather in June, when the drones showed no particular inclination to leave the hive, I took 200 drones from one large colony, dividing this number equally between the two honeycombs, described as above, and then placed the two combs in the middle of the brood-nest, where I watched them carefully. In the evening of the fourth day the drones in the double cage which could not be fed by worker bees from without, were in such a feeble condition that they seemed to be unable to live much longer. In fact, on the fifth day all were found dead, except four, which were just able to move. The drones on the comb which the workers were able to supply with chyle, remained in perfect health, and flew off briskly when I liberated them a few days afterwards.

What had caused the death of those unfortunate 100 drones which in all respects, save one, were in exactly the same position as the surviving drones on the first comb? Surely it was the want of nitrogenous food alone. Worker bees, subjected to a similar test, remain alive much longer than drones—for though the latter appear most phlegmatic, they are in reality very sensitive creatures—if it were possible to keep worker bees in confinement as long as they are able to exist without nitrogen. In any case, my experiment on drones should be an inducement to bee-keepers to satisfy themselves, more than has hitherto been done, that their colonies are not in want of pollen at the commencement of winter.—*Translated from Gravenhorst's Illustrirte Bienenzeitung, December, 1887.*

Echoes from the Hives.

Honey Cott, Weston, Leamington, January 9th, 1888.—On the 13th and 14th of December a few stocks were having what I might term a partial flight, but the majority were quiet, with, perhaps, just a single bee or two going in and out; after this all were quiet till about the 29th and 30th, when the sun was shining quite warm during the middle of the day, and fetched out the bees from stocks that are in half-inch makeshift hives, but it has been reserved for the four last days of the week just passed for the bees to have grand flights every day, so much, that any one might almost say they were swarming. They look remarkably

clean and healthy. I have scattered some nice clean straw among the hives, which I believe has saved the lives of many bees, as it saved them from the damp ground.—JOHN WALTON.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of persons interest will be answered in this column.

C. WHITING.—*Uniting.*—March will be soon enough to unite. Move the colonies near to each other, and feed both if necessary. When uniting remove the queen from one hive and place its combs alternately with those of the other, at the same time throwing in a little smoke. The evening is the best time for uniting.

H. SCHWARZ.—*Nuclei, Swarming, &c.*—Your proposed plan would not work well, since each hive would suffer from a cessation of breeding for at least fourteen days in the midst of the honey season. The usual plan of rearing queens in nuclei is far better; but if you object to the trouble, when the honey season is over—say about the end of July—remove the old queen from each hive, and allow the bees to raise another. The smallest nucleus we advise you to use is one containing three standard frames. To secure the queen in a swarm shake the swarm on to a sheet, and with a carbolised feather direct the bees to the entrance of an empty hive, raised slightly in front, preventing them from crowding in too hastily, when you will easily discover the queen as she leisurely marches in. This should be done in the evening.

W. H. JENKINS.—*Honey Leaflet.*—The B. B. K. A. have issued a leaflet entitled, 'Honey as Food,' which may be procured from the Secretary, Mr. J. Huckle, Kings Langley, Herts.

SHERBORNE.—*Holy Writ.*—The questions raised by you in your letter respecting the authenticity and inspiration of the Scriptures are beyond the limits of discussion allowable in the *Bee Journal*. If your letter appeared in our columns it would most probably give rise to a very wide, perhaps angry, and altogether useless controversy, which is much to be deprecated. Our views are dissimilar to yours, but to rebut your opinions would be going beyond our *crepida*.

R. CHAPMAN.—*The Best Frames.*—We should advise you to give frames of both the makers mentioned a fair trial, and report to us the result at the end of the season. Both the kinds of frames have special merits.

CHARLES WADE.—*Crooked Combs.*—When the weather will admit lift the frames, on to which the combs have been irregularly built, bodily out of the hive by means of two pieces of lath placed beneath the ends of the top-bars. Lay two pieces of tape on the transferring board, and lay the comb upon it. Straighten the combs by cutting down to the mid-rib and press it flat, the convex side will compress sufficiently; lay a frame round the comb, and tie it on tightly; keep the mid-rib in the centre of the top-bar, and be sure to keep the comb close up against the top-bar. Preserve all the brood, and keep it out of the hive but a short time. The drone-comb can be discarded. As each frame is finished return it to the bees in the hive. After two days examine the hive, and if the combs are firmly fixed, remove the tapes. If any have slipped tie them on again more firmly. The bees will repair all damages.

THE BRITISH BEE JOURNAL

Communications to the Editor to be addressed 'STRANGWAYS' PRINTING OFFICE, Tower Street, Cambridge Circus, W.C.

[No. 291. VOL. XVI.]

JANUARY 19, 1888.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

'THE PITTS' APIARY, SOUTHALL.

We could scarcely have selected a more unpropitious time for visiting a bee-garden than a recent Saturday afternoon, and when we saw the locale of 'The Pitts' it was a double source of regret that a season of 'ethereal mildness, gentle spring,' was not chosen. Messrs. Abbott Brothers have hit it to a T (or, rather, two T's) in fixing upon the Old Gravel Pits as the groundwork of what they consider a *beau idéal* apiary should be.

In a snug excavation, many years old, now covered with rich vegetation growing rankly on its gravelly sides, and sheltered from strong winds, are seen bifurcating canals filled to their margins with fresh, green watercress (what magnificent drinking fountains for the bees!), whilst 'the pitts' are belted along the eastern side with willows (what early pollen!), recalling visions of spring.

'Behold, yon bordering fence of willow trees

Is fraught with flowers, the flowers are fraught with bees.'

Tangled brambles, too, are there in plenty, so that there is food and drink, at least, at hand, eked out by whatsoever the bees can forage out in the adjoining meadows, for in the magnificent country between Hanwell and Southall, some ten miles from London, lies this bee-garden: indeed, there should surely be considerable surplus honey gathered in this locality.

We do not exaggerate when we say that there is no sight in these islands to equal, from a bee-keeper's point of view, the one before us this dismal, dark December day. Here are seventy new hives filled with new frames; the frames are filled with new comb, the combs 'all fraught with bees'; hives of white and hives of red alternate with others of blue, green, orange, and slate colour, these colours being so arranged with regard to each other that each one is in juxtaposition with others bearing the greatest contrast to it. The hives are arranged in what gardeners call 'quincunx' form, *i.e.*, straight lines are seen from whatever point one stands at, instead of a confused, disorderly medley. Messrs. Abbott Brothers' idea in establishing this bee-garden is that they may be able to supply at a moment's notice any reasonable number of perfect

hives in thorough working order, their intention being to use wired foundation throughout, so that there may be no risk of breakdowns in transit; all that remains, therefore, for the purchaser to do on receipt of his hives, supposing the season be suitable, is to uncork the bees and put on sections. The hives at present in use are of the Gayton type, and very pretty they look. We shall be glad to revisit 'the pitts' on an insect hunt in due season, for by repute, and to all appearance, the place is a true home of rarities amongst the Lepidoptera.

USEFUL HINTS.

WEATHER.—A variation of 45°—from 15° to 60° Fahr.—in the course of a few days, maintains the character of our climate for fickleness. And now we have day after day of densest fog in most parts of the country. Saturday, the 7th inst., and the three following days, were days of brilliant sunshine, while the thermometer at mid-day in the open air stood at 60°.

CLEANSING FLIGHTS.—The bees were only too willing to take advantage of weather so unusual, and the apiary resounded with the pleasant hum of a bright day in June. After many weeks' confinement a thorough cleansing flight was obtained, and the health of the colonies thereby has been improved and assured for the future.

MANIPULATION.—So great was the inducement to examine several colonies, of whose condition we felt rather uncertain, that we took up our carbolised cloth, stripped off the quilts, and inspected the combs one by one, only to find that the bees were flourishing, and the hives dry, snug, and cosy, beneath enamelled cloth and other quilts. All were breeding, and the queens with distended abdomens, as in the summer months. Notably one colony, formed in the autumn from condemned bees, to which an imported Italian queen had been given, possessed four frames of sealed brood, together with eggs and larvæ. Such a proceeding, on the 7th of January, is without a parallel in our records of nearly half a century. The murmur of the bees, their flitting around in the sunshine, the feeble crawling over the brood combs of the newly hatched, and the short flights of others, for the first time trying their tiny wings, are things to be noted and remembered.

As quickly as possible the hives were closed, the quilts returned, and the hive-covers turned up towards the sun for an airing, and we trust that these colonies will be found none the worse for so untimely a disturbance when the honey season comes. *But* it behoves us all to remember that there is time enough yet for winter storms to reassert their rule. On January 18th, 1881, we experienced in this country a snowstorm of such violence that it might well be termed a hurricane, and to which our meteorological records contain no equal. So that it is

well to bear in mind the uncertainty of our climate, and not to 'cry before we are out of the wood.'

QUEEN-BREEDING.—It either is, or ought to be, the object of every bee-keeper to obtain the most hardy and prolific queens; indeed, there is no truer motto than that adopted by one of our principal firms of caterers in bee-appliances, viz., *Nihil sine Regina*. How many tons of honey have been lost by allowing effete and worn-out queens to remain over colonies until the honey season has passed away, and the bees have dwindled and died! There can be little doubt, too, that hives in such condition are meet receptacles for the germs of foul brood. That what is termed in-and-in breeding has a tendency towards depreciating the good qualities of queens—such as fecundity, longevity, energy, and so forth,—is generally admitted. But are we making any effort to procure the fecundation of our queens by drones of fresh blood? Certainly we are not if we allow fecundation in the same apiary in which the queens are bred, since in that case a young queen may, and probably will, mate with her own brother. It is true that our best strains of cattle, sheep, and pigs, have been raised by a constant succession of in-and-in breeding, but mating brother and sister, or parent and child, has always been avoided; and although the highest perfection as regards shape and development of particular point, has been reached in this way, yet it cannot be denied that fecundity has been impaired. Ask any farmer who has tried breeding pigs, for instance, from the higher class of pure bred prize-winning varieties, and he will tell you that their produce is very small in number. In our own experience the farrows have consisted of from three to five in the best and purest breeds, whilst these same breeds when crossed with entirely new blood have produced farrows of from ten to fifteen. And our belief is that the same rule applies equally in the case of bees. Hence the amount of benefit derived by English bee-keepers from the introduction of the Italian and other foreign races of bees into this country, can scarcely be estimated. The hybrids are acknowledged on all sides, both at home and abroad, to be the best bees, which at once proves our point; and our object in introducing the subject is to suggest a remedy for this in-and-in breeding, by which we mean the mating of queens in the same apiary in which they are bred.

There are various ways by which fresh blood can be introduced into our apiaries. Imported queens of the various races may be used, but the expense is considerable. English-bred queens of these races may be obtained from trustworthy breeders at home, but here there is some doubt as to the possibility of obtaining the pure race; in all cases, nevertheless, fresh blood will have been obtained. But there is another, and a very simple method, which we do not remember to have seen recommended in this country, viz., exchange of *virgin queens between apiarists living at a distance* of not less than eight miles from each other, or of sending such queens to a greater distance, solely for the purpose of fecundation. If it be an object to keep pure races only, we find greater difficulty, but even thus, by giving a little more time to the work, and by practising the Köhler plan, we can obtain our object under the exchange system. We will suppose, for illustration, two apiaries situated at a distance of ten or more miles from each other, one consisting entirely of black bees, and the other of Italians, in both a fair quantity of drones being tolerated. If the virgin queens are sent from each of these apiaries to the other, and introduced to nuclei, or to colonies which have just swarmed, in a few days they will have mated and can be returned to their owners. The worker progeny of such queens will be hybrid, but their drone offspring will be pure, and consequently there will be no danger of contamination to either race if the hybridised queens are not used for queen-breeding—always supposing that both apiaries are sufficiently

isolated from other races. If only we could obtain the privilege of sending queens by post, a virgin queen, with a dozen attendant workers, could be forwarded, in a Peet or Benton cage, to a distant friend for fecundation, as easily as a letter is now transmitted, and returned in the course of a few days. That such a system would be largely and beneficially carried out, simply with the object of infusing fresh blood, independently of breeding the pure races, we have no manner of doubt. Or, again, supposing a breeder of queens for sale, who would, for a small consideration, receive virgin queens for fecundation by drones of any specified race, how great would be the convenience and advantage to most bee-keepers, and how great the saving of time and trouble! Without interfering with honey production—comb or extracted, with or without increase of colonies—by the above means we might annually introduce fresh blood into our apiaries, to any extent desired, and at little expense. The manner of proceeding we recommend is that stated in 'Useful Hints' (vol. xiv., p. 162, *B. B. J.*) under 'Preventing After-Swarms,' in which, when a natural swarm issues from a honey-storing colony, the swarm takes the position, and continues the surplus storage of the parent hive, the latter being placed beside the former for use as a nucleus (or otherwise) and for raising a queen. In this parent colony the queen may be allowed to hatch, in accordance with nature's law, and forthwith be transmitted for fecundation to some distant apiary, and afterwards returned to her hive. Or if the ordinary plan of natural swarming be allowed, the supernumerary queens—of which there are often from two to six with each swarm—may be secured from the after-swarms, and treated in a similar manner, for superseding old queens, or for any other purpose. A change of blood may be obtained also by purchasing virgin queens from the breeders, and introducing them into our own apiaries. For such lower prices should be charged than for fecundated ones. In artificial swarming, the plan may be carried out by giving a frame of brood to the colony during the absence of its queen. Under present postal regulations we have successfully carried out this plan, by sending by rail the virgin queens in the boxes from which we had taken imported Italian queens, but time occupied in transmission is more than it would be in remitting by post. May the Post-office authorities soon be induced, by our incessant importunities, if by no other means, to grant us the boon of sending our queens through the post. Young queens, weather permitting, will generally mate about the fifth day of their age; it is evident, therefore, that they should be despatched on these excursions as soon as possible after emerging from the cell.

HOR OR COLD?—We are indebted to Messrs. Carr and Raitt for complying with our request that they would give their views on the subject of 'Parallel v. Right-angled Frames.' Their pertinent remarks, given in the last issue of the *Record*, should be read by all who are interested (and who are not?) in this controversy. Their views, after a fair amount of experience, we can fully endorse, especially in regard to the advantages of tiering up over lateral extension, for either extracted or comb-honey, and free passage for the bees.

We still hope to have the experience of other practical apiarists on this subject, which appears, in our little world, to be assuming the position of the old controversy of 'Broad v. Narrow gauge,' in the railway world.

The truth of the old proverb, that 'habit becomes second nature,' will account for the variety of opinions as regards the use or difficulty of manipulation under either system. To ourselves manipulation is far easier and more pleasant with frames ranging from back to front than when placed transversely. Our rule is never to stand before the entrance to a hive when manipulating; but how to avoid doing so, in comfort, with transverse frames, we know not, since reaching over the whole

length of a fifteen or twenty-frame hive, well tenanted with angry bees, or even crossing the arms from side to side, is certainly not a pleasant operation.

With frames at right angles we always work from side to centre of hive, changing position from one side to the other, which causes the minimum of disturbance to the bees and facility in handling the frames. Mr. Godfrey's experience—that in roofs of houses, or other buildings, bees build their combs from rafter to rafter, or joist to joist—is exactly what we should have expected, even when such combs cross the entrance; but we do not think they do so in order to avoid draft—since in such situations this would simply be an impossibility—but to obtain a solid foundation for their combs.

But we are strongly of opinion that, given a hive, with perfectly horizontal base and roof, tenanted by a swarm large enough to fill, or nearly to fill it, with an entrance on the south side, we shall find that the bees will range their combs from back to front.

SECTION-RACKS.—We are often asked which is the best way to range the section-boxes on the hive—whether parallel, or transversely with the combs beneath. Our own plan is to place them transversely, but we do not think that it makes the slightest difference if placed the other way, if a full bee-space is left between brood-combs and sections. From a trial last season of Heddon's honey-board we are inclined to think favourably of it, and hope to give it a more extensive trial in the coming season.

MANIPULATION, FEEDING, AND OTHER WORK.—Manipulation must only be tolerated in cases of dire necessity, such as dysentery, starvation, &c., when a change from wet to dry hive, in a warm room, or out-of-doors in a temperature of 60°, will prove of advantage. In such case moderate feeding with warm syrup will also do good, but otherwise candy should still be given. Keep all hives well and warmly covered, with dry quilts, winter packing, and sound roofs, and let there be no disturbance of any kind. Continue to prepare hives and sections in anticipation of the good time coming.

Foreign.

UNITED STATES.

THE ANNUAL CONVENTION OF NORTH AMERICAN BEE-KEEPERS AT CHICAGO.

(Continued from p. 18.)

Professor Cook gave a lecture on 'The Legs of the Bee,' which we hope to reproduce in full, together with illustrations, which the Professor has kindly offered to forward to us.

Mr. T. G. Newman introduced the question of 'The Best name for Extracted Honey.' Thirty-three names had been suggested, some of them very peculiar ones, such as 'Divorced Honey,' 'Cycloned Honey,' 'Loose Honey,' 'Honeysein.' None of them appeared as good as 'Extracted,' and the meeting voted unanimously that no more appropriate name for 'Extracted Honey' can be selected than its present one.

Mr. J. H. Martin's essay on 'Cost of Production of Honey' was next read. He said, in computing the cost of production, the figures should show the cost for several years. He found the cost in his bee-yards has varied from 2 cents to 50 cents per pound. He values his bees at 5 dollars per colony. In 1886 he had 200 colonies, valued at 1000 dollars; empty combs, hives, fixtures, &c., 300 dollars; hired help, rent of apiary, &c., 72 dollars; his own labour, five months at 30 dollars a month, 150 dollars; total expenses, 300 dollars. He secured 10,000 pounds of honey at a cost of 3 cents per pound. In 1883 the cost was 2 cents per pound. In 1882 it was 50 cents per pound. This year the yield is 6000 pounds at 4 cents per pound. If comb honey is produced the bee-keeper prepares his own crates, sec-

tions, &c., three months more time should be added and 50 per cent should be added to the cost, making the cost of comb honey at least 10 cents per pound. He thinks an expert ought to manage 300 colonies in one yard, with little or no help.

The next was an essay by Mr. G. M. Doolittle on 'Honey Production—Its first cost, and how much the Bee-keeper should obtain for his Labour.' He considers a bee-keeper's time is worth more than that of the man who cuts wood, carries the hod, or breaks stones upon the highways, men whose working value is 1½ dollars a-day. Bee-keeping requires study and brain-work which should be paid for. After carefully considering the position, he believes that 45 pounds of comb honey per colony is as a rule an average crop. Allowing that a man can manage 100 colonies of bees he will get 4500 pounds of comb honey as the result of a year's labour. This is not clear gain, there is interest on his 35 dollars, taxes, 4 dollars; sections, 25 dollars; foundation, 30 dollars; shipping, 40 dollars; double interest on 200 dollars invested in hives, which would be needed to keep them in repair; rent of shop and land, 30 dollars; carting honey to railroad, 11 dollars; making a cash outlay of 200 dollars a-year. Taking a hod-carrier's wages at 1½ dollars a-day, or 301½ dollars for 313 working days, and this added to the 200 dollars gives the actual cost at 591½ dollars, or a trifle over 13 cents per pound. If one half more of extracted honey is obtained the cost is 8½ cents as the cost of a pound of extracted honey. He says whoever sells for less than these figures works for less than 1½ dollars a-day.

A paper on 'Price of Honey—how to control it' was read by M. M. Baldrige, in which he advocated the bee-keeper to fix the price and sell only to consumers. Honey in small sections should sell at 15 to 25 cents per pound. He proposes to sell to consumers through retail agents, supplying the growers with a can of honey and giving them a commission of 10 to 20 per cent, as they would have no cash invested in it. It should be constantly kept on sale and in sight every month of the year. The money may be collected every month, so that there would be little risk of bad debts. The distant markets should be supplied through agents, who would also receive a commission. In this way it would do away with the necessity of more than one wholesale supply house in each state.

On the question of statistics it was resolved that a committee of three be appointed by the President to use their influence in securing the placing of bees and honey upon the statistical list issued by the Government. Professor A. J. Cook and Dr. Mason were appointed.

Reports were then read from the Vice-Presidents from Ontario, Florida, Iowa, Pennsylvania, Georgia, Indiana, Vermont, and Quebec.

Mr. W. Z. Hutchinson then gave a short address on 'The Production of Comb Honey.' He said: To produce comb honey we must have populous colonies at the beginning of the honey harvest, and to secure these breeding must go on rapidly and uninterruptedly for two months previous to the honey harvest. Aside from food in abundance, *warmth* is one great requisite for breeding. The heat from a colony of bees is sufficient; the difficulty is that it is lost by radiation. To prevent this loss pack the colonies when taken from the cellars, and allow the packing to remain until time for putting on the supers. He packs by putting on an outer case and filling between with sawdust. Uses supers one tier high, the sections being filled with foundation. Although straighter combs are obtained by using separators, he can secure combs that are straight enough without them.

Mr. Heddon then took up the subject of 'Hives and Fixtures,' and at the request of several members gave a description of the construction and working of his hive, in which he said by reversing it the bees would

completely fill the frames with comb, while the screws holding the frames tight enabled the bee-keeper to shake out the bees. The break-joint principle of his honey-board prevented the building of brace combs.

Mr. Betsinger said he could shake bees from a Langstroth hive quite as quickly as they can be shaken from a Heddon hive.

Mr. Eugene Secor, in his essay on 'Bee-keeping alone, or with other pursuits,' advocated the combining something else with bee-keeping. He did not believe in specialists in bee-keeping any more than in hog-rearing. He believed that bees ought to form part of the surroundings of every ideal rural home; not only because it adds to the beauty of the landscape picture, but because, in the economy of nature, bees are necessary to the perfect fertilisation and fructification of the vegetable kingdom, and that object can be best attained by the proper distribution of the means to accomplish the end sought. If bee-keeping were in the hands only of specialists, some localities would be overstocked. The man who knows only one thing is a one-idea man. His capacity for enjoyments in this world is also limited. His horizon is narrow, bound by a single thought. It produces and develops a man to know more than one thing. All who have given the subject a thought know that the massing together of large numbers of either animals or men, soon develops disease and death—Nature's remedy for restoring the proper equilibrium of life. Who shall say that foul brood is not Nature's punishment for overstocking, and a gentle hint to more widely distribute the bees which she intended to act as marriage priest to all the plants in her flowery kingdom? In his judgment 100 colonies in one yard come very near the limit of profitable increase. Dairying or stock-raising could be combined with bee-keeping. In this case the increase of bee-pasturage will also increase his available food for stock and *vice versa*. Raising fruits, such as strawberries, raspberries, and gooseberries, apples, and plums, are also recommended, as well as the keeping of poultry, either of which, combined with bee-keeping, could be managed successfully by an energetic and suitable person.

Mr. Heddon stood up for the specialist, and said that taking one year with another the advantages were all with speciality.

Mr. Root thought it better that the eggs should not all be in one basket, especially in a bad season.

Of the bee-keepers present, on the call of the President, twenty-five stood up as specialists.

Mr. R. L. Taylor next read a paper on 'Wintering Bees in the Northern States.' He attributed the heavy losses in wintering to allowing the bees to retain their honey, which was frequently unfit for them. When he winters out-of-doors he gives full hive-entrance and ventilating without draught. He gave several instances of bad wintering of bees traced to bad food, and recommends that all honey should be removed, and the bees fed up on syrup. In 1879 he had fifteen colonies, and fed each with sugar syrup. Wintered out-of-doors, and in the spring, one pint cup would have contained all the dead bees from all the colonies. He began the disastrous winter of 1880-81 with sixty colonies, thirty were fed with a limited amount of sugar, and of these sixteen survived; of the thirty not fed only three survived. In 1884 he gave all his 200 colonies empty combs and fed them on sugar. The result was that although all other bees in that part of Michigan, with but few exceptions, perished, there was not one of his in a normal condition; but, so far as he could judge, wintered perfectly. Next year his loss was 12 per cent, on stores partly honey and partly syrup. In 1886-87 he had 400 colonies, two-thirds had honey stores, the remainder were supplied with sugar syrup. There was a marked difference between the two, those on sugar stores were the picture of comfort and contentment, quiet, closely

clustered, not easily disturbed, not a diarrhetic sign, and only now and then a dead bee dropping out of the cluster. Those on honey stores were uneasy, not closely clustered, easily disturbed, dying by the thousand, and many of the hives bearing unmistakable signs of disease. Colonies with plenty of good stores always winter well, while those with stores of a doubtful character winter more or less disastrously.

Mr. McLain then gave an interesting account of his practical accomplishments and experiments in scientific bee-keeping during the past year, referring to the interest displayed by the United States' Department of Agriculture in the valuable and rapidly increasing industry of bee-keeping and the honey product.

The last essay was by Mr. D. A. Jones on 'Establishing out apiaries.' He said there were some localities where 500 colonies might be kept, and others where 100 to 200 colonies would overstock them. He considered 100 to 200 as many as could be profitably kept in one apiary. Instead of increasing at home he would establish out apiaries, commencing with fifty colonies. One man is required at each place during the season of five months. He has himself located one from his home apiary one and a half miles north-west, the next four miles north-west, then one seven miles to the north-east; next one five miles north, one six miles north-west, and one ten miles north-west, with sometimes smaller ones between. From personal experience he considers that in good localities, from two to three miles is far enough apart. If the locality were suitable he would prefer to have them so that he could visit them all by driving the shortest possible distance. With a good practical foreman to visit the yards and see after them, as much can be realised from the out apiaries as from the home ones. Often they bring in a better return, because they are selected on account of their fitness, while the home apiary may only be tolerated because of its being your 'home' rather than the most favourable place for an apiary. Almost any number of apiaries may be managed in this way, if the owner is thoroughly practical, and will devote his entire attention to the business. He believes that all such apiaries should be managed both for honey and increase, unless the sale of bees is impossible.

It was decided to hold the next Convention at Toledo, with Dr. A. B. Mason as President.

KENT BEE-KEEPERS' ASSOCIATION.

The annual meeting of this Association was held, by the kind permission of the Royal Society for the Prevention of Cruelty to Animals at 105 Jermyn Street, London, on Thursday, the 12th January, at 5 o'clock in the afternoon.

The attendance of members was meagre in the extreme. Mr. J. M. Hooker, by unanimous consent, occupied the chair. The minutes of the previous meeting were read and confirmed. The Report of the Council for the past year touched upon the chief events occurring within that period, and adverted to the improved financial position as compared with previous years, the accounts showing the balance on the right side. The addition of forty-five new members had been made; on the other hand, sixty-five had withdrawn, removed, or allowed their connexion to lapse. The remarks upon the condition of the honey market were decidedly hopeful, and calculated to allay the anxiety which we have sometimes expressed. The season of 1887, like that of 1886, was not regarded as a favourable one for the county of Kent, the spring having been marked by too long-continued easterly winds. The Association held its annual exhibition at Ashford, and although its extent showed some decline, the classes appropriated to cottagers showed a marked advance in every way. Attention was drawn to the sparse attendance at the Council meetings which had been held, and

the hope expressed that by a careful selection of the localities in which the meetings might be held, an improvement would possibly result. A feature in the work of the Association during the year was the instituting of a competition for the best-managed cottage apiary, the result of which was so completely satisfactory that it will probably be adopted as a regular practice.

The usual recognition of the services of the officers and Council was observed, votes of thanks being accorded to them, as was also done to the Royal Society for the Prevention of Cruelty to Animals for the privilege of holding the meeting in their Board-room. The election of the Council, into which six new names were introduced, and the re-election of the Hon. Treasurer and Secretary, was performed. The choice of President for the ensuing year fell upon the Right Hon. Earl Stanhope, and the representatives to attend the Quarterly Conferences of the British Bee-keepers' Association were Mr. F. H. Cudd and Mr. Garratt, the Hon. Secretary of the Association.

The proceedings were brought to a conclusion by the drawing for three prize hives for cottagers, of whom there are ninety, resulting in the favour of Richard Wilmshurst of Kilndown, Gondhurst; Frederick Dean of Lamberhurst; and George Bowers of Bette-shanger.

CRUEL PUNISHMENT FOR DESTROYING OR INTERFERING WITH BEES.—In the territory of Lauenburg and Bütow, which was ceded by Poland to the Elector of Brandenburg in the year 1657, and incorporated by him with Pomerania, bee-keeping at that time was carried on very extensively under the protection of an edict which dated from pre-Brandenburg times. This edict contained some very severe and even cruel punishments. Paragraph 16 states that 'any one who wilfully takes bees belonging to others, or unlawfully deprives them of their honey, shall be condemned to death on the gallows.' Bees at that time were kept in decayed trees in the forests. A still more severe punishment was exacted in the following paragraph, viz.: 'Whosoever destroys an entire colony of bees, no matter whether they belong to himself or to anybody else, shall be handed over to the public executioner, who shall take out his entrails and wind them round the tree in which the bees were wilfully destroyed, and shall afterwards hang him on the same tree.' Thus protection was afforded to bees by this paragraph even against their own masters. There are other offences mentioned in this edict that were also punishable by death, minor offences by fines or otherwise.—*Translated from the 'Gartenlaube'* xi. 1857.

BEES STEALING HONEY.—A gentleman of this city who keeps bees, and has always been touched with their simple, hard-working, honest ways, has recently had that sentiment very severely tried. He had taken a large amount of honey from his hives, and put it into a small house in his yard that he provides for such storage. There were thirty-two pounds of it. He neglected to close the door, however, and the honey was left in the open boxes just as it came from the hives. Business called the amateur away for a couple of hours, and when he returned he went with pleasing anticipation for his honey. He found, however, that somebody had been there before him. Through the open door was to be seen a black mass, which seemed like all the bees in the Sutte of Rhode Island, if not in the country. They were gathered about the honey, and were making the most of their time in carrying it off to spots more convenient for their own use. After entrance was gained, it was found that more than twenty-five pounds of honey had been abstracted within the two hours that he had been gone. The worst of it was that the honey had been diffused so generally by his bee neighbours. It would be interesting to know how the intelligence was spread so quickly for so great a distance.—*Detroit Free Press, January 14, 1888.*

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal," c/o Messrs. Stangerways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, Kings Langley, Herts (see 2nd page of Advertisements).

* In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

VIRGIN QUEENS—CONSANGUINITY.

[1428.] Many have been the disappointments experienced by, I may say, all bee-keepers in the British Isles at the almost insurmountable difficulties presented to them on their endeavouring to keep a certain variety or varieties of bees distinct. It is, without doubt, next to an impossibility to breed a certain race or perpetuate a certain strain of bees in these islands with a certainty of true mating. In what county of England can we go at the present time where it can be guaranteed that there are not colonies of bees within two or three miles of any position we like to take in that county? I venture to say there is not one. True, there may be a few isolated places where apiaries are few and sufficiently distant from each other that a desired cross may now and then be made between drones and queens of one's own apiary; but even in these isolated places, if strict search were made, stray colonies could be found, perhaps high up in the church steeple, or under the eaves of the roof of some house, or maybe in the hollow trunk of some patriarch of a neighbouring copse or hedgerow, where, owing to the vigilance and jealousy—they are very jealous of an outsider even looking in—of the game-keeper, an *entrée* is exceedingly difficult to satisfy oneself that such a colony is existent or non-existent.

These views will be supported by many a disappointed apiarist who has given a long price for a queen of a certain variety only to find in the end that her progeny have become mongrel breeders—albeit mostly the best honey-gatherers—and in two seasons a pure bee of the variety introduced is not to be found in any of the hives, but nearly all the other colonies in the apiary have received a taint of the fresh blood introduced, the bee-keeper in the meantime can console himself with the reflection that he has provided all his neighbours for miles around with a, perhaps, advantageous cross to their stocks, or *cave versa* according to the qualities of the bee introduced.

Where the Italian race has been introduced into a district—and where has it not, more or less?—the original black race has been improved—I hope in this matter I shall not bring down any very rabid controversialist upon me very strong—and, I may add, superlatively improved. I will not include districts above latitude 54°, as there I do not find so great an improvement in the bees by such an introduction: perhaps in course of time climatic influences will not have so marked an effect on them. This no doubt will account for so varied an opinion expressed by many as to the policy of introducing Italians to their apiaries.

I have been turning over a file of the *British Bee Journal* for 1886, and comparing the tabulated statements made by many bee-keepers who have introduced Italians into their apiaries. In by far the majority of cases the advantage gained is very marked: not that the superiority shows itself in so decided a manner with the pure Italians, but when the stocks have become hybridized the amount of honey gathered shows a most

important gain, especially in the first cross: my own experience of the superiority of such a cross I have frequently expressed before. The large returns per hive now obtained in comparison to those of a few years ago are in a great measure owing to the knowledge now in the possession of many apiarists as to the method of manipulating their stocks, and in taking advantage of every advantageous trait in the bee's character, and utilising it for their own profit. But we must not flatter ourselves that this is entirely the result of our own or others' practical knowledge; a great deal of this is the result of the introduction, not entirely of a fresh race, but the intermingling of fresh blood—a judicious crossing. In animals the advantage of so doing is very marked, and I think, although our little dependants are only insects, the same rule applies to them. Would a dairy farmer, in order to obtain a larger return of milk, keep a race of pure bred cows? He would, without doubt, choose cross-breds; in like manner no poultry keeper would expect a larger return of eggs from pedigree fowls, but would mate these with another variety—that is, introduce fresh blood to his yard. Such are the lines upon which all stock-keepers work who depend upon the produce from their stocks only.

We here see the advantage of having those among us who, through the peculiar situations occupied by their apiaries, are enabled to keep the different varieties distinct, breeding a true race, that they may in the course of trade spread abroad the advantages gained by the introduction of fresh blood to their customers' stocks. But in introducing this blood to our stocks the variety introduced must be taken cognizance of. It would not do for a dairyman to introduce, we will say for example, a wild Chillingham bull into his farmyard: if he did, deterioration instead of improvement would ensue. He must choose a variety which will correct the failings exhibited in his particular stock, that is, if a richer milk is required, his cows being deficient in that quality, although perhaps large producers, he must introduce a variety that are pre-eminently renowned for that richness, and perhaps a subsequent cross to correct any reverting to a loss of quantity that may take place in such cross that he may obtain both quantity and quality. We bee-keepers will be bound to work upon these same lines, gradually working out the shortcomings of our colonies by the introduction of correctives in the form of other varieties or strains.

It is becoming absolutely imperative that we obtain a maximum return from our colonies with a minimum of expense. Every advantage that can be gained by a low rate of expenditure is a point gained towards success; but such an expenditure must not be made simply because it is very small, as often the dearest turns out the cheapest in the end; the price must be governed by the results and the profits deduced from this.

In the above particular I note that the Americans have got just a little ahead of us by the trade that is springing up in virgin queens, and also the despatching virgin queens, in nuclei, for fertilisation to some distant apiary, which afterwards are returned to their owners mated.

We will first take the case of the trade in virgin queens. These, as all queen-breeders are aware, can be produced at a very low cost, as all the time, trouble, and anxiety of pure fertilisation is avoided; fresh blood can be introduced by these means at a minimum of cost.—W. B. WEBSTER.

(To be continued.)

KOERBS' NEW ARTIFICIAL COMBS.

[1429.] It is with very considerable diffidence that, for the first time, I send you a communication, though I have long been a practical bee-keeper, and (I hope I may say without conceit) have experienced some gratifying

successes. But upon carefully considering M. Koerbs' letter (1407) and the subsequent article upon the subject, I have a curious conviction that I have stumbled upon precisely the same principle in the construction of new combs. And though I do not for one moment desire to attract any reflected honour, and am not, just now, guessing Koerbs' principle and applying it to myself, still it is strange that the description of the advantages claimed (in 1407) are precisely similar and equally applicable to that of the combs I have been experimenting with lately. Unfortunately the honey-flow ceased rather too early last season for me to have arrived definitely at the fact that the queen would not breed in these combs and other perfectly reliable results, but the publication of M. Koerbs' perfected invention has hastened my action in a rather premature manner, for I had not intended applying for letters patent until I had proved without doubt the actual fact of the non-breeding of the queen in the new combs. Still, now that the subject is mooted there may be a possibility of some one 'stepping in' before me without having arrived at any proof at all; hence my present action.

It is certainly rather unfortunate for me that I did not put my scheme into action earlier in the season, but the honey harvest came so abundantly upon us, all at once, that every moment was occupied in immediate requirement and work in the apiary, leaving no time for experimenting with queens. Still, I feel very confident from the vague descriptions we have to hand that M. Koerbs' invention must be very similar to my own, which is simplicity itself, and I wonder why and if it has never previously been thought of. The principles may, however, be entirely different.

I may say I should not have written this explanation at all, but I see in your last issue several correspondents are taking up the matter; and, in common with your correspondent Mr. W. Marshall (1423), I write in self-justification, and without in any degree laying claim to an invention which will revolutionise bee-keeping, but a simple matter which will, I confidently hope, be of practical utility, and also to show that others are keeping an open eye and to save some of the credit for all new ideas from going abroad, for it will be very useless to say after we all know M. Koerbs' process, 'Why! I thought of that long ago.'

I may say, in conclusion, my principle is entirely confined to the production of honey and is not intended for use in the brood-nest.—W. G. PREECE, JUN., *Local Hon. Secretary, Salop, L.S.*

THE NEW ARTIFICIAL COMB.

[1430.] *Re* Artificial Comb, as mentioned in last week's *B.B.J.*, I think, if it is tried, you will find if a comb foundation is made of cell bases a size larger than drone comb it will be similar to what our German friend wants 1s. 6d. from each bee-keeper for. I intend trying such a base this season.—W. ROBINSON.

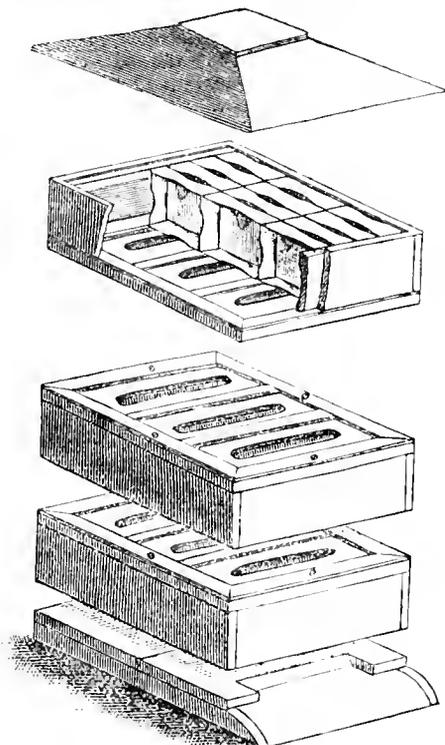

HIVES AND THEIR MANAGEMENT FOR COTTAGERS.

(Continued from page 20.)

'COTTAGER CHAMPION.'

[1431.] This hive is designed for the use of the cottager who intends adopting bar-frame hives when he shall have had sufficient knowledge of the management of his bees to warrant him in turning to that more modern, more interesting, and more profitable method of bee-keeping. It is also recommended to those bee-keepers who may not feel inclined to adopt the bar-frame hive, but who prefer something more modern than a skep in which to keep bees on the fixed-comb principle.

Description.—The hive, in reality a section crate, consists simply of four walls with a reversible lid. The wood, after planing, should be $\frac{3}{4}$ in. thick. The inside dimensions are $14\frac{1}{2} \times 14\frac{1}{2}$ in., and the outside 16 in. The sides are $4\frac{1}{2}$ in. deep. The lid is 16 in. square, and clamped to prevent warping. Upon this lid, on one side only, a rim 2 in. wide and $\frac{1}{2}$ in. thick, is nailed round, leaving a recess in the centre 12 in. square. Two pieces of wood, $\frac{1}{2}$ in. thick and $\frac{3}{4}$ in., full, wide (latter face

downwards), are nailed along the grain of the wood $3\frac{3}{4}$ in. from the opposite inner sides of the rim. These afford rests for the centre row of sections and the bottom corners of the outer rows, and they make three spaces or recesses $3\frac{3}{4}$ in. wide and 12 in. long. In these recesses running parallel with the section rests are holes through the lid $\frac{3}{4}$ in. wide and 12 in. long. There are two of these holes in each recess $\frac{3}{4}$ in. from each side, so that when a piece of excluder zinc $12 \times 3\frac{3}{4}$ in. be dropped in, it just fits, and the bees have access from below through two rows of holes in each recess to the super above whether for sections or fixed combs. (Only one hole in each recess is shown in the illustration.) The lid is secured to the body of the hive by four screws, one in the centre of each side. As I set my hives perfectly level both ways, and always recommend that plan, provision in this hive is made for guides. (Skeps are an exception to this rule on account of the difficulty of fixing guides.) The under side of the lid is marked with ten saw-cuts across the grain of the wood, which will be across the holes as guides for the fixing of narrow or deep pieces of foundation. The bottom two in the illustration are fixed as described above, while the top one is shown with the lid reversed, and in use as a section-crate. When used as a section-crate it will be noted, from the dimensions given, that there is a space between the ends of the outer rows of sections and the inner side walls. This is filled with blocks, which slide in. On one side, as shown in the illustration, there is a $\frac{1}{2}$ in. recess, permitting bees to pass round the ends of the

sections. If this facility be not preferred, by reversing the block a plain side is turned to the ends of the sections. The roof recommended is a plain 'Simmins.'

Floor-board.—The floor-board is 16 in. square, nailed on side pieces projecting 4 in., and that much rounded. A piece $1\frac{1}{2}$ in. deep and 12 in. long is cut out of the front of the floor-board. Under this, and between the projecting parts of the side pieces, is nailed a piece of thick wood which has also been rounded to correspond with the ends of the side pieces, and to throw off the rain. A rim $\frac{1}{2}$ in. thick and 2 in. wide is nailed on the sides and back of the floor-board (not shown in illustration), this allowing of inverting if the bee-keeper wishes to practise it.

Management.—Having chosen the site and provided a stand as already recommended, preparations should be made for a swarm. Three bodies, floor-board, and roof should be provided, and they should be well painted, not only the sides but the edges. The swarm should be allowed to cluster in a skep, and it may be then, or in the evening, brought near to the stand prepared for it. Now place the floor-board on the ground in front of the stand and upon it a body prepared with starters of foundation, and with sheets of excluder zinc in the recesses on the lid. Upon this place a super, which may be prepared with sections, or with guides of foundation exactly like the first. The upper body—super—should now be covered carefully with cloth and the roof placed upon it.

The swarm should then be thrown on the ground in front of the entrance, and the bees urged in by smoke or a feather dipped in carbolic acid. When the bulk of the bees have entered the whole arrangement may be lifted into position and the top of the super tested with the spirit-level, to be sure that it is perfectly level both ways. A good swarm will not be provided with sufficient accommodation in the lower body, which I will term the brood-chamber, and therefore a good proportion will go into the upper body, the super, while the queen, full of eggs, will be kept by the excluder below.

When the bees are thus forced into the super, storing, if necessary conditions are favourable, commences at once, and continues so rapidly that more room will soon be needed. (The progress of the work is seen through a circular window in one side.) The extra super room, if it is decided to give it, should be a similar super placed between the one already on and the brood-chamber. If, however, one super is all that can be expected or is cared for, instead of giving more super room above the brood-nest a body should be prepared with wide starters and placed under the brood-chamber. When two supers are used this is how the first taken off should be served when emptied.

In either case the swarm will then have a partly filled super and two body boxes for brood-chamber, and it should be the bee-keepers' endeavour to get these two bodies filled with combs and have a strong stock well supplied with food by, say October 1st, when a farewell should be taken of them as far as interference is concerned until early in February, when on a very fine day a slight examination to see how the food is holding out may be made. A thorough examination should be made on a really warm day on or as near as possible to March 1st.

When brood-rearing has progressed satisfactorily it will be a great advantage to change the positions of the boxes; that is, the upper box may be put on the floor-board and the lower one upon it. This operation would, as a rule, take place in this district, where we are surrounded with orchards, early in April, if not earlier.

When supering, if the two bodies have been so managed as to contain little but brood and bees by the commencement of the honey flow, excluders between the brood-chamber—now consisting of two bodies—and the super are not necessary.

There are many ways in which a stock in these two boxes may be manipulated to the advantage of the bee-keeper. For instance, if from neglect to give sufficient super room there is a quantity of honey stored in the upper section of the brood-chamber, it may be inverted and placed on the floor-board, that the honey may be taken from it to the super (of course in inverting the combs must be kept in a perpendicular position). When the honey has been removed from the inverted chamber it should be restored to its previous position, but remain on the floor-board.

Again, when the time for supering has arrived the bees may be driven from the body containing the least brood to the other, and then having placed upon that single body excluders a sectional or other super would be taken to at once. One caution is necessary when the stock is thus treated, the bees will be cramped for want of room in a few days by the rapid storing in the super and the increase of the population, and it will be probably advisable to place a body of starters only on the floor-board before giving a second super, or swarming may take place, but for sectional work the bees should be crowded as much as possible without causing swarming.—C. N. WHITE.

FRUIT CULTURE AND APICULTURE.

[1432.] Speaking superficially we are decidedly in favour of the two going together. We can testify to the unalloyed pleasure experienced when labouring amid some hundreds of pyramid fruit trees. And it was our daily and irresistible pleasure too, last summer, to leave awhile the hoe, and lie or sit opposite the hives. The experience was so charmingly new to us.

The bees were ever visiting the profusion of thorn, cherry, plum, apple, pear, and raspberry blossom. The great advantage of being always near the bees cannot well be over-estimated. Especially is this so during the swarming season. But there appears to be one drawback, viz., wasps; and it would be a considerable gain to some of us if any effectual means were known of preventing or destroying these very troublesome and annoying insects.

The summer before last, when we had no bees, wasps were not so troublesome, nor half so numerous, as they were last summer. Wherever bees were kept there were the robber wasps, and the pickle bottles with sugar and water as counter-attractions. The latter, however, seem to entrap as many bees as wasps.

But last summer the wasps were not only exceedingly annoying to the bees, but the fruit of every apple, pear, and plum tree was attacked and seriously damaged. So general was the destruction that we had to gather all the fruit ere it was ripe, or lose it altogether. Not a single pair was left to ripen.

We frequently found three or four wasps inside an apple or pear. And of course, when the fruit was all gathered the wasps attacked in greater force the bees.

We were glad, however, to find that our bees were quite equal in fighting capacity to the wasps. We had the opportunity of watching scores of combats, and it was very seldom that the bees lost their lives in battle. Generally they would fight and fly again. After, when we lifted the roofs off hives, the severed bodies of wasps lay scattered about the quilt, and just as often the bees seized the opportunity of lugging their victims off the premises. And yet how daring and cunning is the wasp, how she watches her opportunity to enter the hive, and, though often repulsed, at last succeeds. We object to this wholesale depredation, and shall be very grateful for any information of means of prevention. I suppose we must follow the wasp line till we reach their nest, and there put an end to them.

On the 7th, 8th, and 9th, our bees were much on the wing. The weather was remarkably mild and bright between the morning and evening mists. Many of the

bees returned home after sundown, which to us was rather a surprise. To many the pleasure was very brief. On the morning of the 10th, scores of them hung with the grip of death upon wood and stone, white with the prevailing fog.—F. GOODRICH, *Methwold, Norfolk, Jan. 14th.*

FOUL BROOD.

[1433.] Foul brood is not a thing of yesterday, and was in existence in Ireland long before the introduction of the bar-frame hive or Ligurian bee. Of late years bees have been going to the bad in the old skep, and died out in many places, due in part to the sulphur-pit, and the survival of the unfittest which was kept as a stock; but in many cases, also, to the foul brood. On making inquiries of many as to the condition of the hives on the death of the stocks, they had plenty of honey, and the wonder was, why they had died. I saw combs thrown out of hives that had foul brood most decidedly, though I did not know it then; but know it too well now, having got it from a skep apiary of several hives that died right out of the same. Being hardly a mile from this, my bees brought it home through robbing the deserted hives. An error of mine may act as a warning to others. I extracted and fed back the phenolated honey to infected hives (had then but two), gave it driven lots in autumn, and fed it to others besides, with the result of sowing the disease broadcast, so that out of thirty-five hives I had but two clean the following spring. Through doubling up weak and dwindling stocks, and then treating all infected hives as swarms, placing a new clean queen at the head of each I got a good many into a healthy state again; boiled down old combs and burned the frames. If the queen is infected no cure can be made until she is superseded, for though the phenolised syrup may be freely used the source of the disease is there still, for though you may cure it in one part of the hive it will break out in another. Many would advocate stamping it out by destroying the whole lot. That to my mind is very wasteful, as with care, and a good deal of trouble, you can get them clean again; and if a good season get a little honey too, with carefully disinfected hives, but with new frames and quilts I do not think there is much danger of an outbreak in the same hive again. I have them in use, and the stocks are now well.

Camphor I found of no use against foul brood.

To show how widespread this disease is, and how little is known about it in Ireland in its southern counties, I was made a present of a skep some time since from a place where foul brood was said to be unknown, and it was simply rotten with it. Died out in one month.

A diseased stock may be cured by treating it as a swarm in May if you have a young and clean queen to put at the head of it; place in a clean or thoroughly disinfected hive, and feed with phenolated syrup while comb-building, and I would consider a cure assured. Some may differ, and if a better way is shown no one will be better pleased than yours, truly,—JOHN J. SMYTH.

COUNTY BEE-KEEPERS' ASSOCIATIONS.

[1434.] In your article on page 2 of this year's *B.J.*, under this heading, there are still some remarks that I think should not pass without notice.

It will not be conceded that the County Associations have already accomplished the work for which they were formed, and I am glad to see that Mr. McClure (the energetic Hon. Secretary of the Lancashire and Cheshire Association) takes exception to this statement in a very able manner in his letter [1419]. He naturally is surprised to find such gloomy and discouraging remarks in an editorial of the *B.B.J.* I may say that although this is the recognised organ of the B.B.K.A., the Committee are in no way responsible for the article in question, and

do not in the least share the desponding feelings of the writer. Considerable progress has been made by some of the county Associations, the quantity and quality of the honey exhibited, the number and keenness of the competitors, the able management of the exhibitions, the questions asked by visitors anxious to commence bee-keeping, and the general interest taken, all tend to show this. Still, much remains to be done.

I have, during the last season, had many opportunities of noticing all this at the exhibitions where I have attended to act as one of the judges, and I think the B.B.K.A. has much reason to be satisfied with the efforts being made and the success achieved in most counties. Depend upon it that where there is this decline and want of interest there is something wanting in the organization and management.

One Association not having fulfilled the conditions of affiliation, is not acknowledged by the B.B.K.A. No general meetings have been held, no Committee of Management has been appointed, and no report and balance-sheet have been issued for several years. Under these circumstances it would not be matter of surprise if such an Association was on the 'decline.' This state of things exists in one of the best honey-producing counties in England, where there are some of our most enthusiastic and successful bee-keepers living. They are ready to support and subscribe handsomely if an Association can be properly organized and affiliated to the British. Surely some effort will be made before another season to place this Association upon a proper footing.

There are other Associations in which parts of counties only have been properly worked, and this must be the case in large counties unless they are subdivided into districts, each having its district Secretary and its local adviser, who should hold a third-class certificate at least, working with and under the county Hon. Secretary. By this division of labour the work would be easier, and, at the same time, thoroughly done, and all bee-keepers could be reached. Where the counties are thus subdivided, the number of members would be increased, the entries at shows more numerous, the different districts vying with each other in friendly rivalry for the credit of a particular part of the county. The district Secretary should arrange for periodical meetings for the friendly discussion of all matters connected with bee-keeping, lectures, and local exhibitions. Prizes should be offered to cottagers for the best-managed apiary in each district much in the same way that Horticultural Societies give prizes for the best-managed garden.

A county subdivided in this way can be more economically worked, the travelling expenses of the expert will be saved, and the advice given at the time it is wanted, which is not the case where there is only one expert for a whole county.

Several counties have not yet started Associations. In some instances members are ready to be enrolled, and are only waiting to find honorary secretaries among the clergy or persons well known and respected who have time, and who will volunteer their services, and throw some energy into the work of formation. The Secretary of the B.B.K.A. will be very glad to give advice and assistance in this work.

The county Associations were formed with the object of assisting the British in spreading the knowledge of the humane and scientific method of bee-keeping, of teaching the agricultural and other labourers how they could occupy their leisure time in an interesting and profitable manner, and so improve their condition. Surely you, Mr. Editor, do not admit that even in the most prosperous county Associations 'the work for which they were formed has in a great degree been accomplished,' and that there is not much more to be done before any appreciable number of cottage bee-keepers are taught that they can keep bees in such a way, in their leisure hours, that they may pay their rent out of the profits

derived from bee-keeping?—JOHN M. HOOKER, 76 Tyndal Road, St. John's, S.E.

[The object of the institution of the British Bee-keepers' Association cannot be said to be accomplished until the great object to which the late Rev. H. R. Peel devoted himself with so much earnestness—viz., that an Association should be established in every county of England and Wales—is effected. That gentleman took the trouble to publish in the columns of the *Bee Journal* a map with the counties marked dark and light—the dark indicating where no Associations were formed, and the light where they were. A reference to this map will at once show how matters have progressed, or retrogressed, since his time. Many that were then light should now have to be made dark, and a few the reverse. A great advance has been effected by the division of counties into provinces, and the provinces again being subdivided into districts. But failing secretaries (see in a recent number Mr. C. N. White's reasons for his resignation of the Hon. Secretaryship of the Hunts B.B.K.A.) have sad reminiscences of the *vis inertiae* of bee-keepers yet to be overcome before the desire of Mr. Peel can be realised.—ED.]

COUNTY ASSOCIATIONS.

[1435.] Mr. W. M. Graham (HHS) is probably not far wrong in thinking that County Associations have 'come and all promised too much and done too little.' I have been connected with two Associations, of both of which this was certainly true; and I quite agree with our Editor in thinking that the time has now arrived when 'the internal working of the Associations and their individual condition may be a useful and timely inquiry.'

I trust that the matter will be freely and fully discussed in the *Journal* and at the quarterly meetings of the Central Association, and that some of the County Organizations will thus be induced to reform their modes of procedure. Like all other public bodies we must learn from experience, modify our rules and action accordingly, and move with the times. There is still much good work to be done. There is ample room for more lectures in winter, as well as shows in summer; but both the lectures and the shows should be 'up to the times.'

Then, again, certificated experts could still do important work in most counties, and every intelligent amateur who has a little spare time could become an apostle of advanced bee-keeping. The fact is, many of the older bee-keepers have fallen out of the ranks or lost their enthusiasm, and the time has come for rousing up and re-organizing the younger men.

Bee-keeping is now such an important industry that it is well worth while to take this matter seriously in hand, and to try to put our local machinery in gear again. In the part of the country where I recently lived, we never did so well as when there was a metropolitan show, which was something to look forward to and prepare for, as well as a rallying point for our best workers, who brought back from it a stock of knowledge and a fund of enthusiasm that helped most materially to keep things moving in our shire. Then we had our own local shows, lectures, and experts; now we have neither. At our shows honey producers sold their surplus stock, and local hive-makers booked their orders: they could still do so, I feel convinced, if things were properly managed. The practical lessons conveyed during the manipulations were invaluable, because they carried conviction to the minds of the sceptical, and taught those who could not or would not read. But deaths, removals, and changes of circumstances, thinned the old ranks; depression of trade and agriculture reduced the subscriptions, and a little want of discretion in management put the finishing touch

to what was at one time a flourishing association—the result being debt and temporary despair. There is hope yet, however; and a time of revival is, I trust, at hand. It will help us in re-organising, and others also probably, if bee-keeping friends will tell us candidly, during this discussion, the secrets of success and the causes of failure.—AN OLD BEE-KEEPER.

THE PRICE OF HONEY.

[1436.] On page 27, 'Sherborne,' lamenting the low price of honey, is allowed to take occasion to have a fling at the clergy. As far as I can understand his meaning from the construction of his sentences (and I am in doubt between 'I' and 'the uneducated public' whether I am not one of the latter), he attributes the 'mischief' in part to 'men with their regular salary, and clergymen to a large extent . . . going in for fruit, vegetables, bees, and photography.'

Now, clergymen have not a 'salary' in the ordinary acceptance of the term, but an income given to them originally by those who had it to give; and it is not regular in one sense, viz., that it does not maintain its level, but is on what 'Sherborne' calls, a 'down-grade,' to an extent which he is evidently unaware of, and which, if he understood or believed it, I am inclined to think would not distress him. From a pecuniary point of view—if one is not too nice as to the use of the words 'salary,' 'business,' and suchlike—very likely the information he gives us as to the superior importance of chimney-sweeping is quite correct. It seems to be attributed to 'Sherborne' that he does not 'read carefully,' &c. Has he observed the many names of clergymen on the list of the committee of B. B. K. A.? and does he think that one of the objects of these gentlemen is to lower the price of his tempenny sections? Would he be surprised to hear (I expect he would) that the interest of many a clergyman who keeps bees is quite the other way through diminution of salary? and will he give others credit for having for years, with the secretary and perhaps his assistant, done *nearly the whole* of the work of their County Associations, till they feel bitterly the wrong of such a 'foul' blow, as that which 'Sherborne' has delivered, and clergymen to a large extent?

I see, sir, that you have had to sit on this same individual anent 'Holy Writ.' Whether or not he used the word 'holy' I am unaware, but one is astounded that he should have attempted to introduce such a subject to your columns, and one feels more than it is well to say; so I will only add that if you had but 'deled' that unhappy expression you would not have been troubled with these lines by—CLEMENS.

IMPRESSED FOUNDATION.

[1437.] I see in *B. B. J.* Messrs. Neighbour have invented an impressed foundation. I have made foundation for some time with thread or twine embedded, also thin strips of wood—which foundation is *unbreakable*—also foundation on paper base. The idea of embedding other material than wire is mine.—GEO. STOTHARD, *Walsby,* January 13.

FOUNDATION v. WORKED COMBS.

[1438.] Instead of replying to my query, as to his experience of tying clean combs, Mr. Saddler asks a question and refers me to the practice of another correspondent; this may be a reply, but is scarcely an answer. Further, I did not write concerning the replies to Query No. 2, but to Mr. Saddler's strictures thereon—which I am glad to hear were not meant to be uncourteous.

By the method advised of extending the brood-nest by the insertion of foundation, at least three examinations

are necessary in place of one where a comb would be used in which food could also be supplied in its most available form; further, to work out the foundation an additional strain would be imposed on the colony (and therefore an increase of food) whose every effort might otherwise be employed in raising brood at this critical time, which may be in April or May, according to the latitude of the stock, or the forwardness or the reverse of the season. It is further advised that the frame of foundation be placed in centre of brood-nest, when, should a cold snap occur, the bees and brood will be divided by a comparatively cold wall of wax and air-space on each side, which if they fill, other portions of the brood must be consequently depopulated. Now had a frame (with stores) warmed to the temperature of the hive been placed on the outside of the brood-nest, the colony would be comfortable in any weather and could be left safely until it was practicable to divide the brood-nest by additional combs.

An easy and safe method of storing combs is to fill the body of a hive that will 'tier up' with frames, give the bottom board a strong dressing of carbolic acid, double on another hive body—*de novo*—until the ceiling is reached if your combs hold out. Place on cover, close up the single bottom entrance, and all is secure from mice, moth, and foul brood; at least, that is our experience in dealing annually with about three hundred combs, if packed in Edey's doubler.—JOHN EDEY, *St. Neot's.*

CHILIAN HONEY—SUCCESSFUL WINTERING.

[1439.] A few weeks back you referred to the import of Chilean honey. It occurred to me that my father, having at one time imported the article, could give some account of the use made of this honey, and I wrote him accordingly. In reply he says, 'The Chilean honey of which I formerly got consignments was mostly sold in Liverpool through a broker. The few parcels that came to London were given to my drug-brokers, who took samples and submitted them to the wholesale confectioners. The latter relied upon their being given impartially by the brokers, and made offers which were submitted to me. I afterwards received a contract of sale.'

'Or the brokers advertised the honey for sale by public auction, when they exhibited samples at their offices for intending buyers to examine. Chilean, Californian, and Cuban honey comes generally to Liverpool, has every appearance of rough handling and of wanting a great deal of civilisation yet. It is not likely that any methods exist in those countries by which you could learn anything. These outlandish honeys are at present (after the season) unsaleable, and only worth 25s. per cwt., whereas British honeys might still be sold at 60s. The principal season is two months before Christmas, and the principal buyers are the wholesale confectioners and cake-manufacturers. They absorb the whole import, the difference in price between British and Chilean being so great. The rough quality of the latter is quite sufficient for the common cakes. These articles are generally sold for cash in fourteen days and usually through a broker, who acts as an impartial middle man.'

With regard to successful wintering, I am of opinion that the size of the hive is of little consequence in the matter; the main point being that there is only *one* opening to the live. I don't know if any one has ever tried having the entrance at top of the hive, but probably even in such a case the bees would winter well enough.

The great danger is to have ventilation as usually understood, viz., in at one hole below out at another above. With a quilt of double or treble felt, or thick chaff cushion, there is, of course, no ventilation to speak of, any more than there is through our plaster ceilings.

Gases do find their way out, but by no means as fast as generated, and when a stock is packed for the winter with propolised top covering their abode may be practically considered as air-tight above. Anyway they will do their best to make it so, and no one has ever given an instance in which his bees have left a hole above unpropolised for ventilation.

My bees enter below the floor-board through a 9-inch opening $\frac{3}{4}$ -inch wide. The alighting-board is underneath also, and is always dry. No rain can blow in, and robbers have no chance of entering and a poor one of even alighting. It is known that a roof by itself placed above plants will keep off frost, for the reason that the colder air is always descending, I suppose. Thus the floor-board keeps the frost from the entrance in my hives, being a roof to the alighting board. Though I consider this plan much better than having a direct opening in the side of the hive, I am unable to say yet if there is any marked effect, advantageously or otherwise, on the colonies. The only decided point noticed so far in comparing the two plans are: on frosty days there is distinct buzzing at each floor entrance, none at the side entrances. Looking in at the top I find the colonies with floor opening down low, some bees on the floor-board at times, the others close up against quilt.

The bees with side entrance come out in great numbers on warm days, the others only sparingly. I may also state that the driven bees put on empty combs reared brood to end of November over the floor-holes, and there is no sign of mortality so far. I shall be pleased to report further if the matter is of any interest. My winter packing is ticking, two felts, wood in pieces, and, as extra precaution against frost, four straw bottle covers. The latter are cut loose at the top and make a neat covering, and can easily, if wanted, be strung together as a mat. The two felts are laid together, and then, with a round tin canister having one or two notches filed in the edge, two neat circular bits of felt are cut out of the middle of the quilts. These are stitched together and a loop of string attached, over the quilt-hole, fits the hole in the centre bit of wood, which is covered in feeding time with gauze. By removing a straw bundle and pulling up the felt bung one can get a hasty glimpse of the condition of the nest.—SILKE.

SAFE ARRIVAL OF TWO STOCKS OF ITALIAN BEES IN INDIA.

[1440.] Mr. A. G. Nicholson, Hawthorne Estate, Yercand Sheraroy Hills, Madras Presidency, India, writing to Messrs. Geo. Neighbour & Sons in December last, acknowledging the receipt of two stocks of Italian bees, says: 'You will be glad to hear that both stocks you sent me have arrived at their destination in perfect condition, in spite of many bees having died, but then we had terrible storms to start with and very hot weather. I was greatly surprised to find both hives full of brood, and in one the queen actually continued depositing eggs whilst I held the frame of comb in my hand. I am, as you may imagine, greatly pleased with the success so far, but they are having a trying time just now, for we have been having days of pouring rain and Scotch mist ever since their arrival, and the time for flowers will not begin before April next.'

These two stocks of Italian bees were sent on November the 4th, by order of the Indian Government, in the steamship *Pekin*, and I shall endeavour to prevail on Mr. Nicholson to let me know their future condition, so that I may report the same to this *Journal*.—ALFRED NEIGHBOUR, *London*.

WHAT INDUCED ME TO KEEP BEES.

[1441.] 'Will you accept of a hive of bees?' I must confess that I have a very great weakness in always

trying to please: as the questioner was a lady I said, 'With pleasure.' So in due time I received—'none of your new-fangled notions about bar-hives, observatory-hives'—a skep with a strong lot of bees; but this was an extraordinary hive, an old skep which I presume had been used in a case of emergency. It was a very crazy sort of thing, very rustic; one skep on the top of another, and a large bell-glass on the top with a cosy over. I don't believe that ever a tom-tit would approach within a few yards. Talk of strong stocks, there was almost a swarm in the bell-glass.

I have given a minute description because I wish to refer to it again, and see what lesson we may learn from it. I got a covered stand and put the skep on facing south. My neighbours and friends called out in passing, 'I see you are going to keep bees.'

Just to digress for a moment.—A minister once overheard a conversation which was carried on so that he might hear,—this occurred on the platform, —'Do you know the reverend gentleman?' 'Only that he once kept a shoe-shop.' The reverend gentleman was called upon to speak, and he said that he had heard that he once kept a shoe-shop, 'I can assure you, Mr. Chairman, I never did keep a shoe-shop, but that the shoe-shop kept me.'

Within a few days a lady brought me a *Parish Magazine*. She said, 'Here is something that may be of service to you, as there is an article about bees.' I was very glad, because I knew nothing whatever about bees, only that they stung and gave honey; my wife appeared to know a great deal, as her father kept bees for many years. I soon found out that he belonged to the old school—honey and brimstone. I found the article, and something like a parson with a veil on; the article was about quieting bees, my wife's father knew all about that.

I read it more than once, then I got excited and wished to know more about the dear bees. Now I must go in for a bar-frame hive. I sent for one, and all fitted up with foundation, &c. I got a letter from the Station Master that it had arrived. I shall never forget the misery I was in at this time; a day or two before the arrival of the hive a lady friend called and told me that the bar-frame hives would not answer. Her brother had had several, but the bees all died in them; and that his place was much better than mine as it was high and dry. My dear half gave me no rest: 'Oh! send the hive back, and get the man to allow you something; and suchlike. I still had a besetting sin in that line of bees-keeping me, or at least that they would pay their way. Well, I painted the hive a nice green colour, and was careful to leave the opening same size as the skep. I had to do nothing now but wait until my bees swarmed.

Coming from church one Sunday morning I met a man who worked for the lady that gave me the hive; he had his shirt-sleeves rolled up. I said, 'Whatever are you going to do, and on a Sunday?' he said he had been sent for to go and hive a swarm of bees. What a chance for me, only that it was Sunday! That besetting sin again got the mastery, and I went to arrange to have them. I had not to ask twice. Two men brought them, a skep full as full could be of bees; it happened that two hives had swarmed at the same time, both on the same bough about three feet from each other, and the men put them all in, or tried to do so. Here was uniting. I was quite ready for them when two men brought them. I had got a platform in front of the hive, and covered with a white table-cloth. The men said, 'There they are.' I said, 'I want you to throw the skep down, and then take it up.' 'No fear; you do it yourself,' said one of the men. He added, 'You nor no other man will ever get them into a thing like that; how can you expect it?' My master once tried it, but he soon fired off. I had no other alternative than to commence without help. The man undid the cover, and then I dumped them on to the platform, about half of the bees fell out. I was

very glad I did not get stung. 'Now then, look; just as I told you,' chimed in one of the men; 'they will never go into such a thing as that.' The bees ran here and there. I was glad it was getting rather dark because they did not fly. I could see the bees clustering in front of hive up to the very top. Just then my wife called me in to supper. She said, 'How long will you be in getting the bees into the hive, as it is getting very cold?' I said, 'You had better go to bed.' 'Ah!' she said, 'you told me they would all be in in the course of half an hour.' When I got to the hive most of the bees had found their way back into the skep. I had to commence again. This time I got a brick and placed it in the centre of the white table-cloth, and I soon bumped them out; they hissed just like an egg in a frying-pan.

Necessity is the mother of invention. I had no smoker, so I got all the brown paper I could, and a box of matches. The paper smoked away very nicely, and I kept getting them in; about half of them were in when it struck three o'clock. I was very cold and chilly. I then and there promised that if ever I again got another swarm I would have a smoker. About six o'clock I heard a door open, and then a voice twitting me, 'Why, have you not got them in yet?' Then my wife came to look at the bees, and then she looked at me. Oh, what a lecture I got on bee-keeping! Her father never had any of those foolish things; just nice, comfortable skeps, and at the end of the season used a very small piece of brimstone and took the honey and got 1s. per pound. How humiliated I was! My wife said, 'Just look, they come out as fast as they go in.' At eight o'clock I gave it up for a bad job. Friends came to see my success; alas! they saw thousands of bees clustering outside. I was very like Job; you may be sure they gave me a lot of comfort. I wrote to a friend stating that I had put the bees on six frames according to directions. I got a reply, and what a relief!—'Give them all the frames.' Oh, how happy I felt! It was only the work of a few moments to remove dummy, and then to my relief they scampered in; but it was strong work on account of the narrow doorway; still, a great many refused to go to work, just basking in the sunshine. I wrote again. Reply came, 'Put sections on.' I was very thankful for this piece of advice; it was worth 6s. 8d. You may be sure I put them on within twenty minutes. There was not a bee outside—I mean basking in the sun; there they were in the sections looking through the glass. Next day I could see honey. I felt like Columbus now, repaid for all the worry and trouble. And there was a great change in my appearance, especially my head; if Barnum had been about I would not have been safe in nine days. I took twenty-two pounds of honey from the hive; if I had known then what I do now I could have had fifty pounds. My friends came again this time; they said, 'Who would have thought it?' others, 'I could not have believed it!' I shall never forget when I took the honey into the house. My wife opened her eyes and looked at the honey, not at me, and said, 'Well, well,' and ran for some dishes.

I wrote to friend Huckle, and I soon got a wrinkle or two from *Modern Bee-keeping* and Mr. Cowan's book. By the time I had read these books I really had got bee-keeping on the brain. I found that I had done all things which I ought not to have done and left undone the things which I ought to have done.

(To be continued.)

HONEY AND MELLA.

Has the taste for honey died out in this country, or has it been hobbled by the atrocious imitations and adulterations with which, in a time of scarcity, the market has been flooded? It is doubtful which, for the introduction of sugar and the subsequent removal of the sugar tax has decidedly told its tale upon the demand,

honey being used where sugar is now for domestic use or confection. The tax upon mead and metheglin, our rare old ancestral honey beverages, stopped their manufacture in a great measure, and with the consequent decrease in the demand followed the decrease in the supply, until the reaction went, as all reactions do, too far, and then the supply of real honey became deficient, insufficient even for the reduced demand; consequently fictitious manufactures, that a bee had never known, found a sale as the genuine thing, and the taste for real honey died out.

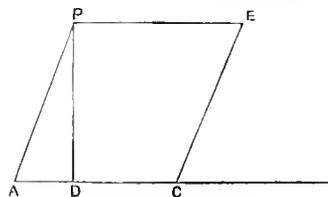

Now there is another tide of reaction setting in, and a demand for real honey is greatly on the increase. Medical men prescribe it as a health-giving diet for children, and especially invalids, or others; and beverage-makers, in their quest for 'something new,' are inclined to go back to 'something old,' and take up the honey drinks again. All this means a renewed supply, and that of the genuine article only, wherefore there seems to be a wide field for the cultivator and collector. Great Britain can supply many thousand times more honey than it does, and ladies would find bee-keeping a very lucrative home employment, and a very pleasant and interesting occupation.

The British Honey Company Limited (17 King William Street, Strand; dépôt: Columbia Market, Shoreditch) have sent us some samples which are truly delicious, and should be found on every breakfast or tea-table where cheap and nasty jams are now too often to be found.

The same Company manufactures an effervescing, non-intoxicating drink which they call 'Mella.' It is rather too sweet for ordinary drinking, but it is by no means insipid, and the honey is there in full flavour.

The adulterations of honey to increase bulk and profit are perhaps more numerous than samples of fictitious honey, and they are as bad and injurious as any can be. Without going into the methods of their detection, it must suffice in this article to enumerate those more generally met with, and not a trace of one of them can be detected in the honey sold by the British Honey Company. Amongst them starch, potato, wheat, and cane-sugar, are the least injurious; chalk, hydrated sulphate of lime, and pipeclay taking a very bad position, and being very commonly found. The starch is not only added for the sake of creating weight and bulk, but to 'improve' the colour of dark honey, and to correct an acidulous taste which old honey sometimes acquires. No doubt the chalk, &c., are used for the same purpose. The wax is often simulated with the aid of hard mutton suet and starch.—*The British Journal of Catering, December.*

GEOMETRICAL CONSTRUCTION OF THE CELL OF THE HONEY-BEE.—In the *Proceedings of the Royal Society* Professor H. Hennessey describes the geometrical construction of the cell of the honey-bee, and gives a figure

and method by means of which the lozenges comprising the cell can be obtained. On a straight line take a part A D, and mark off DC=2 A D. From D draw a line at right angles to A C, and with a radius AC=3 A D cut off D P. Draw a line from A to P, then A P and A C will form the sides of the lozenge A C E P. From this the two remaining lozenges and the six trapeziums can

be obtained. The triangular pyramid which terminates the bee's cell may be inscribed in a sphere whose diameter is three times the size of one of the edges of the pyramid.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication. All queries forwarded will be attended to, and those only of persons interest will be answered in this column.

H. WRIGHT.—1. *Lee's Frames.*—You will be able to procure Lee's frames from Messrs. Neighbour; but we believe the machine for making them is not quite perfected. When the frames are ready will be announced in our advertisement columns. 2. *First Swarm.*—In the case of a first swarm, it is the old queen that leaves with the swarm.—3. *Camphor.*—Bees do not object to camphor. 4. *Excluder Zinc.*—It is not necessary to use excluder zinc under sections. The bees object to it. Allow not less than one-fourth of an inch, and not more than three-eighths between rack and frame.

S. J. S.—Mr. James Lee's address is 43 Glycena Road, Lavender Hill, London, S.W.

H. C. SCHWEIZ.—1. *French Works on Bees.*—*Elevage des Abeilles* by M. Georges de Layens. *Les Abeilles* by V. Rendu. *Les Abeilles* by Maurice Girard. 2. *Italian Works on Bees.*—*L'Ape e il suo Governo*, by Dott. A. Dubini. *L'Ape Italiana*, by F. de Jorio. *Manuale: Apicoltura in Italia*, by Cav. L. Sartori and Cav. A. de Rauschenfels. These may be procured through Messrs. Dulau, Foreign Booksellers, Soho Square, London.

C. M. R.—1. *Old Bees.*—It is most probable that your bees were old and queenless, and consequently died out. 2. *Condemned Bees.*—For treatment of condemned bees, consult Vol. XV., pp. 329, 341.

WELSH NOVICE.—1. *Utilising Slag Heap.*—Try borage, mignonette, wallflowers, or stocks. You give no idea whether there is any soil at all among the slag. 2. *Feeding Stocks short of food during January.*—Flour candy, pushed quietly below the quilt, is the only food permissible.

A. NICHOLLS.—1. *Preventing Loss of Swarms from Skips.*—If you increase the size of your hives by adding ekes below and supers above, you may safely leave them from week to week. 2. If your bees require feeding, give them candy or barley sugar.

W. CHESTER.—The honey in the unfinished sections should be extracted when convenient, and given to the bees to lick out. They may for this purpose be placed behind the dividers, on the lower edge of which an entrance must be made to give access to them. Then wrap them up warm and dry, so that they may be ready on the arrival of the honey-glut.

E. A. GIBSON.—It is not easy to say what caused the bees to desert the hive; but the hive having been deserted, the inmates of the neighbouring hives found it impossible to resist the temptation of plundering. This temptation passed from one hive to another till the whole apiary became demoralised. Robbing is generally accompanied with fighting.

SHERBORNE.—*Holy Writ.*—Your letter received, with thanks. We must respectfully, but firmly, decline its insertion.

THE HONEY-PRODUCING INDUSTRY.

THIS department of Bee-keeping has attained such important dimensions, that Honey in its various forms is now recognised as a staple article of commerce. There is hardly a Grocer or other dealer in the large towns of the country, who is not becoming aware of the value of the same as a medium of profit; and it is now common for the Wholesale Dealer to come to the large Apiary and make his purchases, just as he would buy any other commodity; and notwithstanding, small Bee-keepers sometimes complain they cannot sell. The fault is mainly their own, in holding out for a high price on a quantity too small for the dealer to trouble with. The large holder, on the other hand, being well known, and having greater facilities, disposes of his entire crop to one party, often before it is removed from the hives. Consequently the demand has exceeded the supply, and an unlimited field is open for the profitable investment of capital in developing this industry, when under efficient management.

Relying upon these facts gleaned from personal experience, as well as that of other large holders, the present proprietor of the Great Sussex Apiaries is making arrangements to develop his entire business into a Limited Liability Company, for the purpose of very largely extending the honey-producing department.

The district is entirely free from any possibility of interference from the dark honey produced in some localities by aphidean pests. At one of the apiaries, very favourably situated in a hollow at the junction of several fertile valleys, many acres have already been sown for the benefit of the bees with honey-producing plants; while many acres more can be sown in like manner at little expense.

It is also intended to make mutual arrangements with neighbouring land-owners for the same purpose; as also to rent land for the double object of producing both honey and hay from the same crop. Other apiaries will be established from time to time in suitable locations, so that nothing will be wanting to make this the most complete and extensive business of the kind in either Europe or America.

The Queen trade, as also the Factory, will all continue under Mr. Simmins' personal supervision, and it will be his utmost endeavour to give satisfaction to all who may become interested either as Customers or Shareholders. A complete Prospectus, with full particulars, will shortly be ready; of which due notice will be given.

Special Prepaid Advertisements.

Exchange Column.—Sales of Honey and Second-hand Goods.—Intended to aid Bee-keepers in the disposal of Bee-produce and Appliances for which they have no further use. Terms: Twelve words and under, Fourpence; for every additional Three words, One Penny extra.

No reduction made for continuous insertion.

Now Ready.

SIMMINS' NEW BOOK.—'A MODERN BEE-FARM, AND ITS ECONOMIC MANAGEMENT.' Popular Edition, limp cloth cover, 3s. 9d. Special Edition, stiff covers, 7s. 6d., post free.

The Special Edition includes Photos of the Author's Domestic Hive; his Home Apiary, and another covered Apiary; also one of Queen and Workers on a Comb. Of the Author, Rottingdean, Brighton; NEIGHBOUR & SONS, 149 Regent Street, London; and J. HUCKLE, Kings Langley, Herts.

BEE-KEEPING, Plain and Practical: How to Make it Pay. By A. RUSBRIDGE, 1s. 6d., post free, 1s. 8d. Address J. HUCKLE, Kings Langley, Herts. A 1253

THE MANAGEMENT OF STRAW SKEPS. Designed to teach the Cottager how to obtain the best results at the least possible cost. By attention to its teachings, Cottagers will be enabled to make their Bees a more profitable source of income than hitherto. Price One Penny. Six copies and upwards, post free. J. HUCKLE, Kings Langley.

ADVERTISEMENTS for Leicestershire Bee-keepers' Association's Report should be sent to EDWIN BALL, Waltham, Melton Mowbray. Members residing in County, 10s. per page; others, 20s.

WANTED.—Copies of *British Bee Journal* for January 7th, 1886, and Nov. 1873. Full price given. Apply J. HUCKLE, Kings Langley, Herts.

FOR SALE.—50 lbs. of best Extracted Honey at 6d. per lb. Address T. BARNETT, Ross, Herefordshire. B 88

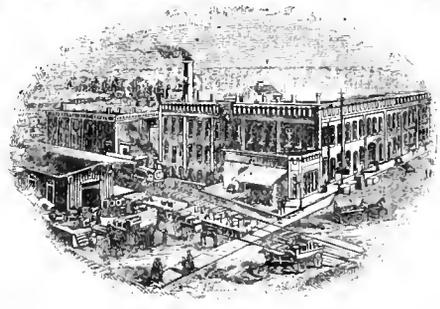

ADVERTISEMENTS for the Kent Bee-keepers' Association Report should be sent to the Hon. Secretary, Hoekenden, St. Mary Cray, by Saturday the 21st instant.

ADVERTISEMENTS for Derbyshire Bee-keepers' Association Report (1000) received at W. T. ATKINS, 6 North Street, Derby. 10s. per page.

FOR SALE.—12 dozen 1-lb. Sections (glazed), 8s. per dozen, or 90s. the lot. Address WOODLEY, World's End, Newbury. B 89

AMERICAN SECTIONS BY THE MILLION

LARGEST BEE-HIVE FACTORY IN THE WORLD

WITH FLOOR-ROOM SPACE OF OVER AN ACRE.

The cut, taken from a photograph, represents our bee-hive factory where we annually turn out about 20,000 hives and 3,000,000 sections, besides enormous quantities of bee-supplies of every description. Dealers before ordering elsewhere should correspond directly with us. We are prepared to quote better prices on sections in quantities than we have ever quoted before. We are also publishers of *Gleanings in Bee Culture*, with a circulation of 7674 subscribers. A sample copy of our journal and our 40-page price list sent on application to **A. I. ROOT, Medina, Ohio, U. S. A.**

THE BRITISH BEE JOURNAL

Communications to the Editor to be addressed 'STRANGWAYS' PRINTING OFFICE, Tower Street, Cambridge Circus, W.C.

[No. 292. VOL. XVI.]

JANUARY 26, 1888.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

A COTTAGER'S BEE JOURNAL.

It must be apparent to all who have noted the successive changes which have taken place in the issue of the *British Bee Journal*,—from monthly to fortnightly, from fortnightly to weekly, from its price at sixpence to that of twopence per number, the constant aim of the respective proprietors to produce a journal which should be the full exponent of the developments of a progressive industry, and the faithful reflection of all those improvements which are constantly being brought before the public in the various appliances which tend to the more perfect and profitable management of the Honey Bee, and which should be able to give sufficient reports of the meetings of the County Associations.

But we have oftentimes been much exercised in our minds whether our *Journal*, in its present form and at its present price, has reached the hands of those for whose benefit the British Bee-keepers' and the County Associations were more particularly instituted, viz., the Cottagers and the Agricultural labouring classes. Again, in the annual reports of the various County Associations mention has constantly been made of the trouble and difficulty experienced by the Secretaries in regulating the circulation of the *Journal*: and great has been the trial of their patience at the absence of regularity in forwarding the *Journal* from one member to another. We also have in some measure been dissatisfied with ourselves, and have felt that the object of our mission was not accomplished till the *Journal* was published at such a price as should render it accessible to bee-keepers of every class and grade. The difficulty which we have felt we have had to contend with has been how to produce a journal containing the information appertaining to an industry which is ever extending its borders, the exposition of the constant novelties in appliances, the communication of the increasing knowledge of the physiology and habits of the honey-bee, and the reports of the various Associations, and at the same time to bring the teachings of the *Journal* to the homes and hearths of the cottager and artisan.

To perform with satisfaction these *desiderata*, it has been suggested to us by many friends and members of County Associations to retain the *Bee Journal* in its present fulness and form, and concurrently to issue monthly a summary of the useful and practical portions of the *Journal* at a price which should bring it within the means of the humblest bee-keeper. This suggestion we have much pleasure in adopting, with the hope that it will be for the 'encouragement, improvement, and advancement of bee-culture in the United Kingdom, and for the bettering the condition of cottagers' and others; and also that it will be the means of relieving in some degree the hard-worked Secretaries of County Associations of the anxiety they have felt with regard to the circulation of the *Journal*, and of giving facilities whereby the various Associations could send out notices of meetings and other information to their members at more frequent intervals than can now be arranged, and with less trouble than now devolves upon the Secretaries.

We propose, then, on or about the 1st of March, to issue a Cottager's *Bee Journal*, which will contain those portions of the weekly *Journal* which are most general and serviceable. The price will be 1s. 6d. a-year, or three-halfpence per number, 2s. post-free. At this price we hope to give sixteen crown quarto pages—nearly equal to the size of the *Bee Journal*. We propose to make special arrangements with the Secretaries of County Associations.

The price we have every reason to believe will come within the means of those whom we most desire to reach, who will thus be able to have their own paper, at the beginning of every month, without the trouble of having it passed from member to member. This will be found to be the cheapest printed bee paper,—cheaper even than those published in America. We trust that the secretaries of the various County Associations, who will find this mode of publication a great assistance to them in their work, will give us their heartiest assistance in making this 'new departure' a success; and for this purpose we might suggest that the *Journal* in its new form should be given to every cottager as an inducement to become a member of the Association. We shall be pleased to receive any practical suggestions which will enable us more readily and completely to meet the requirements of the Cottager.

It will be a great source of pleasure if by this endeavour we as journalists are enabled more

effectually to fulfil the object of the existence of the *Journal*; and we feel we may confidently depend upon the assistance of those who have in time past supported us, so that a fresh impetus may be given to the cause we all have at heart.

HUNTS BEE-KEEPERS' ASSOCIATION.

We very much regret to hear that the Hunts Bee-keepers' Association are about to lose the services of their Secretary, Mr. C. N. White, of Somersham. For five years Mr. White has been most assiduous in the performance of his duties. In his capacity of expert he has visited every portion of the county, and given lectures on bee-keeping to the cottagers and villagers; and he has spent more than one vacation in tours through various districts with the object of spreading a knowledge of the management of bees. The demands on his time have now become too great, and he is obliged to resign the post, the duties of which he has so efficiently performed. It is sad to think that a gentleman, so enthusiastic and capable, is obliged to retire from the scene of his labours, baffled and disappointed. Could not the services of Mr. White be still retained? Could not the county be divided into provinces, and the provinces into districts, giving Mr. White the superintendence thereof? We trust that some such arrangement will be effected, and not allow Mr. White to fall back into the ranks.

ASSOCIATIONS.

BRITISH BEE-KEEPERS' ASSOCIATION.

Meeting of the Committee held at 105 Jermyn Street, on Wednesday, January 18th; present, the Hon. and Rev. H. Bligh (in the chair), the Rev. Geo. Raynor, Captain Bush, Captain Campbell, the Rev. Dr. Bartrum, the Rev. F. S. Selater, the Rev. J. L. Seager, J. M. Hooker, H. Jonas, W. O.B. Glennie (Treasurer), and the Secretary. The minutes of the last meeting having been read and confirmed, the Secretary presented the statement of accounts for the past year. After some consideration, it was resolved that the same be adopted and printed as usual. Attention was called to the fact that whilst the Association had fully maintained its position in all other branches of its work, the income from subscriptions had decreased.

The advisability of the Committee altering their day of meeting was considered, and the Secretary was instructed to write to each member of the Committee requesting him to name the most suitable day, or days, of Monday, Tuesday, or Thursday, for him to attend with the view of fixing the meetings in future so as to enable the majority to attend.

The consideration of the Committee's Report and the business of the General Meeting occupied the remainder of the meeting, which was followed by the usual Quarterly Conference with the County Representatives. There were present, Mrs. Curry and Mr. W. B. Webster, Berks; F. Cudd, Kent; Rev. W. E. Burkitt, Wilts; W. Lees McClure, Lancashire and Cheshire; W. M. Graham, Middlesex.

The representatives reported that two subjects had been considered at their preliminary meeting:—

(1.) The advisability of some modification being made in the existing arrangements for the third-class examination of candidates for certificates in practical work.

(2.) The desirability of some facilities being given to the County Associations whereby the *Bee Journal* might be more largely used by them, and further whether there was any probability of the price being reduced to one penny.

In regard to the latter point the Committee pointed out that they had no power in the matter, but they had no doubt but that those who conducted the *Journal* would do their best for the Counties.

The former recommendation was discussed at some length, the majority being of opinion that the present system was not too severe so far as the requirements of the knowledge of the work, but that the system might be much more simplified. The Committee promised to give the matter their best consideration, and in the meantime they would be glad if the representatives present, and others, would send their suggestions on the subject in writing to the Secretary.

The first Quarterly Conversazione of the new year was held at 6 p.m. Among the ladies and gentlemen present were the Hon. and Rev. Henry and Mrs. Bligh, Mr. Hooker, Mr. Glennie, Mr. Lyon, Mr. Grimshaw, Captain Campbell, the Rev. G. Raynor, Mr. Webster, Mr. Leigh, Mr. Baldwin, Mr. Haviland, Mr. McClure, Mr. Wm. Graham, Mr. Henderson, and others.

The Chairman (Mr. Glennie), in opening the proceedings, said he would not detain the meeting by any preliminary remarks, but as Mr. Grimshaw had kindly undertaken to read a paper he would at once call on that gentleman to give them the benefit of his ideas, which could not fail to be entertaining and instructive.

Mr. Grimshaw said that he had entitled the subject of his address 'Specialisation,' and he begged that the meeting would favour him by freely discussing and criticising the opinions he was about to lay before it.

SPECIALISATION.

It seems strange that it now becomes a question, debatable *pro* and *con*, I admit, but still an open question, whether it is advisable at this stage in bee-keeping knowledge to centralise our studies, our experiments, and our energies, into given grooves and channels in order that our science may continue to develop with the same giant-like rapidity which has distinguished it during the recent past.

There are rivers of thought which widen and deepen their channels by the aid of the numerous streamlets whose contents they are constantly absorbing. There are also other watercourses which spread themselves out over barren stretches of almost profitless waste, which divide, and again subdivide, their flow until, if travellers tell us truly, their floods become so absorbed amongst the sandy and muddy detritus or residuum that they are entirely wasted.

What applies to one science may apply to another, and if it be found requisite for students in other sciences to *specialise* their energies after reaching some common given point, it is necessary for the bee-keeper also to well consider the matter, whether he can add to our present store of knowledge, and advance the science, without this specialisation. Like the veins on a leaf, or the ribs on a bee's wing, bee-keeping has divided itself and ramified into so many channels that we are beginning to feel the necessity for specialists and authorities who have made particular branches distinct and undivided studies, and whose word becomes a dictum. As we stand at present, we see in Great Britain, Canada, America, and Europe, many brilliant lights amongst bee-keepers, whose opinions differ as we read them, week by week, in the columns of nearly every journal, so that one feels constrained, when asked for advice, to recommend the novice to subscribe to but a single journal, and follow its teaching alone; and there sometimes exists a little feeling of delicacy in suggesting even this course.

Clever doctors are quite at variance with each other as to the treatment their patients require, and though we cannot but warmly thank them for their best prescriptions, gratuitous and at great trouble, we have but to look into that *foetic* column, the part of our journals devoted to 'the selected query,' and glance at the answers, to see the necessity for specialisation. The distinctly conflicting nature of the advice in some places, given by men of light and leading for the guidance of the subscribers to the periodicals, is symptomatic of the want of specialisation; the confusion of their readers is a development of this, and the tyro in bee-keeping becomes discouraged and disgusted with the whole thing. The queries are sent out to well-known bee-keepers, they answer according to their individual predilections, but it requires an expert in the business to sift out the real truth, and best proceeding out of the matter of their replies. Often there is direct variance amongst the replies, and then the reader's difficulty is at its height, for, amidst it all, he feels how much they are trying to do for him, and how grateful he must be, and is, for their efforts.

The directions which efforts towards specialisation should take are almost self-evident. On the subject of foul brood and dysentery, there is room for years of study, and by getting periodical information from those who are devoting attention to this branch (of this kind of information by the way we have the exceedingly interesting translations of Pastor Schönfeld's articles on brood-food), the bee-keeper, by means of his journal, would get to know exactly what to do, and when to do it, in both the prevention and cure of this disease. Queen-raising and mating affords another deeply interesting route for investigation and experiment; we may thus learn from specialists the disadvantages of permitting any black drones in our own apiaries, and also the combinations of varieties required to produce the best all-round bee, the bee of the future; one which shall work early and late, swarm little, winter well, give clear white capings, and withal, 'keep its temper,' thus giving us another reason for looking to it, as we are told to go to the ant.

Another special study well worthy the attention of the highest intellects amongst bee-keepers of to-day, as it has engaged the minds of many in the past, is the botanical aspect of bee-keeping, the practical part of this being, of course, what, when, and where to plant forage, with its respective values as cattle-fodder. The *rationale* of the hive, the why and wherefore of the best systems of hanging frames, wintering, obtaining the best sections, or combs for extracting, these are, both theoretically and practically, advantageous lines of research; but particularly interesting would be a study of the different kinds of honey, with their respective worths as food, their various flavours, and medical properties. For the specialist in bee anatomy and physiology there is the widest and most delightful field for observation and thought in such enchanting vistas of light, as the voice, sight, hearing, smell, taste, memory, instinct or reason of the bee, its homing power, the uses of the different limbs, wings, head, antennae, jaws, eyes, and what not; for, depend upon it, there is much more to learn yet about all these than we already know.

Specialisation I hold to be the future watchword of those who aspire to become advanced bee-keepers. When I say advanced bee-keepers, I do not wish to class them with cynical scoffers, whose claim to be advanced is merely a question of the calendar. We know of Mr. Webster's discovery in borderland, the advanced apiarian who 'ken'd mair aboot bees than onybody,' and some of us can perhaps call to mind others of the same class, who sneer at science till it offers them some gem for the mere trouble of picking up, just as some despise the physician's science until they are seized with illness, or others who despise religion until they hear 'the old Reaper' sharpening

his scythe. Let not the specialist in bee-keeping be dismayed or disheartened by sceptical scorn, but let him take heart of grace from the knowledge that the mocker himself uses hives and appliances, and also follows the instruction of the scientific bee-keeper of the past, just as in the future he will follow those of to-day.

I am prepared to admit that the honey farmer, pure and simple, must generalise to some extent, and take only a digest of the information provided for him in the bee-literature of the day; this, coupled with his own experience, may perhaps keep him in a line with other honey-farmers, but as a thorough student of bee-physiology, the bee-keeper cannot long continue to cull the sweets from various flowers, from various chaliccs of study, the nectar-tubes become too deep for good to be drawn from all, and he will be forced eventually to take a lesson from the worker-bee herself, concentrating his attention on one exclusive source for a given time, if he intend to gather or diffuse any appreciable amount of intellectual nectar, and he will find he cannot keep pace with the latest information and most recent discoveries, and still be able to contribute to the sum of knowledge already possessed, unless he select one particular branch of apiculture, devoting to this the whole of the time and energy he has hitherto given to the entire subject.

If we do not specialise our work, we shall, I believe, drift to one side like logs, or become mere milestones, marking the advances made by others, who, wiser than we, selected one science, and then again one branch of that science, wherewith to develop and recreate the mind. By-and-bye, as one broad route is travelled and explored it becomes crowded with fellow-workers, the forward movement is again arrested, unless they decentralise and diverge along what seem at present only dark, tortuous alleys; but these open and expand the further they are explored until specialisation again becomes necessary. It is so with the chemist, the surgeon, the physician; in law, in art, in music; and also in our varied trades and manufactures. Finally, it is so in the home of industry, the hive itself. If excellence is to be maintained and continued, subdivision of effort, in other words specialisation, has to be resorted to. In my mind, it is not now a question of whether specialisation be necessary or not (it goes without saying), but whether the time has arrived when we must resort to it; and this, as far as regards bee-keeping, I hope to hear discussed—discussed I hope to advantage.

The Chairman congratulated Mr. Grimshaw on his very able paper. The subjects touched upon were no doubt open to a great amount of consideration and interchange of thought and opinion amongst bee-keepers, and he hoped that members who could throw any light thereon would kindly express their views, and thus assist in the elucidation of many mysteries in connexion with bee-keeping. Mr. Grimshaw had referred to some points upon which investigations were already being made by specialists, who had been good enough to lecture at the meetings of the Association from time to time; for instance, Mr. Cheshire had discoursed ably on foul brood. The subjects of wintering bees and honey as food had also been dealt with in the same way.

The Rev. G. Raynor thought they would all agree on the advantages of specialisation. It was impossible to arrive at anything like perfection in the different branches of the science of apiculture without specialising. It was well known that a 'Jack-of-all-trades' never excelled in any particular line. He was not surprised that experimenters had arrived at different conclusions. Such results were always occurring, no matter what the subjects were. In regard to bee-keeping, there was plenty of room for difference of opinion. As a cure for foul brood some people used salicylic acid, whilst others preferred camphor, and various other remedies. His experiences showed that the cheapest and safest cure was to destroy

the diseased stocks and their appliances. His apiary had never suffered from it, but he had seen a good deal of it in the apiaries of others, who had lost more than they gained by attempting to cure the evil with specifics. As to queen-raising, the great obstacle to breeding any race pure was the difficulty in making the queen pure. That could be insured by specialists, but in an apiary conducted on general principles it was troublesome to manage, and required a thorough knowledge of the subject. The greatest advantages accrued from the introduction of fresh blood into an apiary. They were well aware that in the breeding of cattle the diffusion of fresh blood was considered all important—the same applied to bees. Until the foreign races of bees were brought to England they had been breeding in-and-in for many centuries, which had resulted in a loss of vigour; and if that system had been continued, they would never have been able to take 200 lbs. per colony, as was the custom in the present stage of bee cultivation. He advocated the transmission of virgin queens a distance of at least ten miles from the apiary in which they were bred, where they should be introduced in a strange apiary in order to be mated with fresh blood, and then returned to the original home. By this means vigorous stocks would be ensured. He heartily thanked Mr. Grimshaw for his interesting paper.

Mr. Baldwin dissented somewhat from Mr. Raynor's view as to the desirability of killing the bees to destroy foul brood. Mr. Cheshire had thoroughly investigated the subject and shown beyond doubt that, if properly treated, however bad the disease may be, it was possible to thoroughly cure it. Perhaps, however, Mr. Raynor's advice was the best in the case of unskilled persons. He thought the object and aim of introducing new blood would be best served if bee-keepers would exchange young fertile queens. The capping of sections was a most important matter, and he would be pleased to see the bee that could give good white capping, thick enough to prevent the sections from 'weeping,' but not too thick to displease judges. The bee that he had found to give the best capping was a cross between the Ligurian and black bee, or a cross between the Carniolan and black bee. Carniolan capping was exceedingly thin, and not suitable for sending distances, low temperature or dampness causing it to 'weep.'

Mr. Lyon said a few words in regard to the modes of transmitting bees from place to place, which subject was discussed at great length by the Chairman, Messrs. Baldwin, Graham, Webster, Raynor, Sambels, Hooker, Haviland, Lyon, and Grimshaw.

Mr. Webster was strongly of Mr. Raynor's opinion as to the necessity of destroying hives containing foul brood. In cases where the bee-keeper thoroughly understood the disease the circumstances were different and a cure might reasonably be attempted.

Mr. Sambels was of the same opinion as Mr. Raynor with reference to the stamping out of foul brood by total destruction of the stocks. That was the best advice to inexperienced people. If he (the speaker) had large apiaries he should do his utmost by means of the doctoring system rather than condemn a number of hives to the sulphur pit. His bees had never been troubled with the disease, but he had had experience of it in the apiaries of neighbours.

Mr. Hooker considered that no bees were so good as the old English bees for sealing honey-comb. Crosses were no doubt more vigorous and produced more honey, but for satisfactorily sealing comb black bees were the best.

Mr. Haviland said with regard to Mr. Raynor's remarks, that few bee-keepers had time to attend specially to the breeding of bees, which involved the expenditure of considerable time and money. The first cross was generally considered very vigorous, but breeding from the crosses produced speedy degeneration.

Mr. Sambels approved of the frequent importation of fresh blood. Instead of breeding crosses he thought it better to keep to one breed, but obtain fresh blood. That principle applied well to fowls and other animals.

Mr. Grimshaw differed from Mr. Haviland somewhat. In-and-in breeding no doubt caused an inferiority of race. The first cross was no better than either of the original ancestors, but this should be crossed with a bee whose good points it was desirable to secure, and by so crossing and inter-crossing with bees possessed of specially good qualities the result would be what he would call the bee of the future—containing a maximum of good with a minimum of bad points. Some races had extra long tongues, some wintered more successfully, whilst others gave better cappings. His object in writing the paper on 'Specialisation' was to cause bee-keepers to think on the subject, and decide for themselves what particular line they would take in specialising their studies. Generalisation did not forward the science of apiculture at all.

Mr. Graham said a gentleman whom he knew, and who had made a special study of breeding, advocated that a start should be made with a black bee as the original queen, introducing yellow blood by means of Carniolans or Italians. That product might be allowed to last for three years, after which fresh blood should be introduced according to circumstances. If vigour should be found wanting introduce the black species; if the stocks were not prolific or not good honey-gatherers yellow blood was required.

Mr. Baldwin was afraid a great deal of mischief was done by what were known as condemned bees. He believed that many stocks given up to be driven contained foul brood. He had found straw hives so diseased that he had refused to take them, and it would be impossible for him to say that he had never unconsciously driven from hives containing the disease. Generally cottagers would insist on the combs being left in the hives, and in such cases persons of the greatest experience would have a difficulty in recognising foul brood.

The Chairman said they were all much indebted to Mr. Grimshaw for his able and valuable lecture. While agreeing with that gentleman's remarks, he must add that most bee-keepers were obliged to go in for generalisation. But there were scientific gentlemen, members of the Association, who had both time and opportunity to devote to the specialities of apiculture; and if they would each study one particular branch of that industry, and give to the bee-keeping world the results of their labours, in the same way as physicians and physiologists assist one another, the cause for which they met would be advanced to an incalculable extent. He proposed a vote of thanks to Mr. Grimshaw.

Mr. Sambels heartily seconded the motion.

The Rev. G. Raynor then proposed a vote of thanks to the Chairman; which was seconded by Mr. McClure, and acknowledged in graceful terms by Mr. Glennie.

Mr. Grimshaw expressed his thanks, saying that he had been honoured by a patient hearing, and also by the interesting conversation which had ensued after the reading of his paper. He would at all times be proud to do his best towards assisting the Association by the introduction of subjects for thought and discussion at the quarterly gatherings, and he hoped they would have the benefit of many fellow-labourers.

HUNTS BEE-KEEPERS' ASSOCIATION.

The annual business meeting in connexion with the Hunts Bee-keepers' Association was held at the 'Fountain' hotel, Huntingdon, on Saturday afternoon. In the absence of the President (the Earl of Sandwich) the chair was occupied by Col. A. W. Marshall, J. P. (vice-president). Amongst those also present were the Rev.

C. G. Hill, Rev. C. C. James, Mr. J. Howard, Mr. Z. Hobbs, Mr. C. N. White (honorary Secretary), &c.

The Chairman, in presenting the financial report for the past year, expressed the pleasure it afforded him to be able to give them a more favourable account of the Association's finances than he was in a position to do last year, when there was a balance against them of 5*l.* 3*s.* 4½*d.* The receipts during the past year had amounted to 26*l.* 0*s.* 4*d.*, and the expenditure to 26*l.* 4*s.* 8½*d.*, leaving only 4*s.* 4½*d.* due to the Treasurer. On the motion of the Rev. C. C. James, seconded by the Rev. C. G. Hill, the Report was adopted.

Mr. C. N. White presented the annual report of the Association. It was as follows:—

'The record of 1887, which is now presented to the Association, is, I feel sure, one upon which we may congratulate ourselves. The number of subscribers now far exceeds that of any previous year, and the balance-sheet which the Treasurer is enabled to present will give more general satisfaction than, at the beginning of the year, the most sanguine of us anticipated.

'In addition to defraying the ordinary expenses, the Committee have paid 3*l.* 15*s.* towards the expenses attending the Great Exhibition, which, as representing the bee-keeping industry in England, was held in London in 1886. Mr. Linton, one of our representatives to the British Bee-keepers' Association, has also very generously paid the sum of 2*l.* 7*s.* 3*d.* to the same fund. Thus have we taken a worthy part in an exhibition which has done much to make a valuable bee-product more extensively known and probably more generally sought after.

'Now, although it is undoubtedly gratifying to be able to present such a satisfactory balance-sheet, there is cause for regret, as many old subscribers have intimated their intention of withdrawing their names from the list of members. This action on the part of some of our friends evidently suggests the necessity for reviewing the past, with the idea of securing more general sympathy and support in the future. And here, as a means to that end, I would again emphasise the importance of endeavouring to find a means of assisting members in the sale of their produce. I feel convinced that it is to the attainment of this object that our efforts must be mainly directed.

'Acting again in the capacity of honorary expert, I have visited most of the members requiring advice. I have also delivered a lecture at Hemmingford Grey, where fresh members were obtained.

'The Annual Show was held on July 26th, at St. Ives, in connexion with the Agricultural Society's Show, and to this Society we are indebted for the space for our tents and a donation of 3*l.* to the prize fund. Considerable improvement in the quality and appearance of the exhibits has been noticed in previous years, and this exhibition was no exception to the rule. The judge appointed by the British Bee-keepers' Association, the Rev. F. G. Jenyns, of Knebworth, reported that the show was a success, and had rarely, if ever, been surpassed in the history of the Society. The cottagers' exhibits were more numerous than in previous years, and were specially complimented by the judge, who pointed out the non-sectional exhibit of Mr. Z. Hobbs as the best of its kind in the show. The silver medal was awarded to Mr. J. H. Howard, jun., Holme; the bronze medal to Mr. R. Allpress, Fenstanton; and the British Bee-keepers' Association certificate to Mr. Z. Hobbs, Little Stukely.

'Copies of the *Bee Journal* have been sent round to thirty-seven members weekly, but very few have been returned.

'In concluding this report, I regret feeling compelled to surrender the official position which I have held since the formation of the Society in 1882, but I trust that, with the kind assistance of the Agricultural Society continued, and the hearty co-operation of the bee-keepers

and their friends in the county, our work will be carried on with vigour and success.'

The Rev. C. G. Hill moved, and Mr. Howard seconded, the adoption of the report, and the motion was carried unanimously.

In the course of a conversation which ensued on the present condition and future prospects of the Association, the Rev. C. G. Hill threw out a suggestion with regard to the Society's meetings. Huntingdon, he said, ought not to be always the place in which the meetings of the Association were held. To bring the objects of the Association thoroughly home to the minds of the cottagers it would be necessary to form smaller areas in which meetings might take place. If, for instance, the various polling districts were taken, honey might be exhibited in those districts, and a number of prizes could be apportioned to each. That, he believed, would greatly tend to popularise the Association, and would carry out its principal objects in a more effective manner.—Mr. White pointed out that the chief objection to that plan would be the additional expense it would entail, and this the Association would really be unable to bear under the present circumstances. Prizes might certainly be given to local centres, but it would be a great pity to adopt any scheme which would in any way tend to do away with the annual central show.

On the motion of the Rev. C. G. Hill, seconded by the Rev. C. C. James, Lord Sandwich was unanimously re-elected President. Mr. Marshall was then thanked for his past services, and also re-elected. The Rev. C. C. James suggested the advisability of having a paid secretary, but Mr. White pointed out that the funds of the Association would not permit of this. For himself, he added, he would at once say that he could not consent to receive payment. That was not the idea which possessed him when he first undertook the office. The secretary should be a gentleman who had more time at his disposal than he had.—The Rev. C. C. James was then requested to accept the office, but this he declined to do on the ground that he had not sufficient time to devote to the work.—It was found impossible to make a definite selection of a successor to the retiring Secretary, and, Mr. White consenting to continue the duties in the meantime, the matter was left to the next meeting of the Association on April 25th.—Mr. J. Linton and Mr. White were appointed as representatives to the British Bee-keepers' Association, and one or two alterations were made in the composition of the Committee.

WROCKWARDINE BEE CLUB.

The annual meeting of this Club was held in the Boys' Schoolroom, Wrockwardine, on Tuesday, the 17th inst. The report of the hon. treasurer and secretary (Miss M. E. Eytton) showed the Club to be in a flourishing condition, both as regards funds and members. Nine new members have joined during the year, and the Club now numbers thirty. Great interest has been taken in the examinations held by the B. B. K. A., and during the year five members, three of whom are cottagers, succeeded in passing as third-class experts. Of these five, two have also been successful at the examination for experts of the second class. Several of the members were exhibitors at the County Honey Show, and succeeded in carrying off four prizes in all. The Club Show, held in September, was a most successful and encouraging exhibition, and altogether the members may fairly congratulate themselves upon their advance during 1887. This prosperous state of affairs is chiefly due to the unflinching interest and fostering care of their indefatigable hon. secretary. The following were elected as officers during the next year:—President, the Hon. Mrs. R. C. Herbert; hon. secretary and treasurer, Miss M. E. Eytton; assistant-secretary, Mr. John Palmer.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the Literary Department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal," c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, Kings Langley, Herts (see 2nd page of Advertisements).

* In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

VIRGIN QUEENS—CONSAQUINITY.

(Continued from page 31.)

[1442.] The mother being of a pure variety the drones are, according to the ideas of many, pure also, but in this particular I am not a believer. If the drones of a pure, say Italian, mother mated with a black drone are examined they will be found, as a rule, much less decidedly marked than those produced from, say, the same queen's sister who is purely mated. I should like bee-keepers to pay particular attention during the coming season to this fact, which apparently shows, although it is a subject that requires further investigation, that there is an influence produced upon the drone progeny by the mate of their mother. This theory is supported by several very advanced bee-keepers of the present day both here and in America.

Presuming that the drones are entirely of the same blood as the mother, we, by increasing the opportunities of drone production, accomplished by providing plenty of drone comb in the brood nest, introduce fresh blood to most of our other stocks. Especially will this be found beneficial where certain queens are allowed to fly at the same time that these particular drones are on the wing. I have thus shown how by purchasing queens at a minimum cost, that is as virgins, a change of blood can be introduced into an apiary with a result as beneficial as would accrue by introducing a fecundated queen at the usual almost prohibitive prices charged for them.

Another advantage is also gained, inasmuch that virgin queens will be accepted by queenless stocks with much more favour than fertilised ones.

It is of little use paying so much money for purely fertilised queens when it is so exceedingly difficult to keep a distinct variety from becoming hybridized. Again, what is the use of the honey producer, who desires the largest crop obtainable, wasting precious time at the busiest season of the year watching or assisting the pure mating of his queens? It is so much time thrown away with a very questionable result. It is true that some of these virgin queens may be mated with drones of an undesirable character, but by supplanting all worthless queens, which every bee-keeper must do to ensure success, the risk of such a *mésalliance* is reduced to a minimum. The chances of such mating also holds good with the daughters of purely fertilised queens; it is only the purely fecundated queen that will produce offspring true to the variety which more often than not are characterised only by a certain regular colouring. It is also not the pure race that produces the largest crop of honey, but the hybrid.

Many, no doubt, will say that the same advantages are gained by purchasing a purely mated queen. I answer, to a certain extent they do, but if three virgin queens can be purchased for the same price as one fertilised queen a great gain is obtained, inasmuch as the three colonies presided over by the latter, will produce three times as many drones as the colony headed

by the former to improve, by crossing, the other stocks in the apiary.

Virgin queens can be produced and delivered into customers' hands at an earlier date than fertilised ones, so that the advantage of having an infusion of fresh blood will be felt during the current season in those stocks where the same are introduced. A queen of the current year will not, as a rule, produce so many drones as one of the previous season, but her adaptability to be moulded into a form desired by the bee-keeper can be easily taken advantage of by supplying an extra amount of drone comb in the brood nest, this, if the colony be well crowded will always facilitate the production of an almost unlimited supply of drones; whereas, in many cases, fertilised queens of the previous year cannot be obtained until after the natural desire on their part to produce drones has very much abated.

The next point that presents itself to me is that of temper of the workers. It is a well-known fact, but very often exaggerated, that hybrids between English and Italian varieties are somewhat irritable, this characteristic no one seems clear as to how or from which parent it emanates; there are without doubt some grounds for such an assertion. It will be quite foreign to these lines to inquire as to the why or wherefore; it is there, but can be easily eradicated by gradually weeding out those queens which produce such vicious progeny. A cross between an Italian mother and a black drone is but rarely imbued with this temper, it is the opposite cross where it is so self-evident; even this drawback is gradually being eliminated by the system advocated above, practised by all queen-breeders of any note.

Virgin queens can be forwarded to recipients by the ordinary means with as little chance of damage as fertilised ones; in fact, theory would lead one to suppose that less damage would be the result, and no doubt it is so; numbers are in America sent through the post without suffering any deterioration.

Sending Virgin Queens to other Apiaries for Fertilisation.—A change of blood can be obtained by these means which will be found very advantageous to those who, having friends living at a distance, not under seven or eight miles, are willing to allow a nucleus hive or hives to stand in their apiary, or even to be placed in a corner of their gardens if they are not bee-keepers, that the queens may be fertilised by drones issuing from hives in the neighbourhood. There are just a few difficulties to be surmounted with this plan. One of the first that presents itself to my mind is that now and then a queen gets lost on her wedding trip; this would often be a source of annoyance to the person who has them in charge, although he may be quite ignorant of the cause; but here and there would be found some, especially novices in queen fertilisation, who would perhaps cast a certain amount of blame upon the shoulders of the would-be friend if he received his nucleus back minus the queen.

If a nucleus hive had to be sent by rail the item of carriage would be quite a consideration. It would not answer to send the queen with a few workers in a travelling-box or cage, as the recipient would have either to provide a nucleus hive or else introduce her to a fresh stock, from which the queen would first have to be removed. One, I think, would very seldom find a bee-keeper so obliging as to do this. Then again, the chances of successful introduction would have to be taken into consideration, as well as a second introduction when the queen was to be located in her permanent domicile.—W. B. WEBSTER.

(To be continued.)

VIRGIN QUEENS.—QUEEN-BREEDING.

[1443.] In last week's issue both 'U. H.' and Mr. Webster offer food for thought relative to above,

and we may well consider if we have hitherto made the most of our opportunities in these directions.

During the last two or three seasons we have exchanged virgin queens with other bee-keepers (at one time as many as eighteen were obtained from one hive), have successfully introduced some, and when fertilised again distributed them. Whether owing to less care being taken in introducing, or other causes, many more failures were met with than with fertile queens; but as virgin queens can be produced at from one-fourth to one-tenth the cost of the former, this is not of so much consequence; our practice being to smoke the nucleus and let the virgin queen run in and take her chance. While on this subject, there is one other matter connected therewith worth attention. We are not aware the practice has been followed by any but ourselves, *i.e.*, sending queen-cells and frames of eggs of the different varieties for the purpose of raising queens therefrom; the former has only been partially successful, perhaps the shaking, &c. of the immature princesses during transit had much to do with this, and extremes of heat or cold.

On the other hand, frames (wired) containing eggs of the various Eastern races and of Carniolan queens, &c. have been almost invariably successful when subjected to proper treatment after arrival; and as one frame may contain eggs from queens imported from two or three different countries the plan may be worthy of fuller development. Of course it is generally necessary that bees (say one pound or under) accompany to act as nurses, although there is not much doubt that given suitable weather a parcel containing eggs would be safe after a few hours' travelling in the mail-bags.

During the past five years we have handled and raised a considerable number of queens of various races, also natives, and can fully endorse the remarks of 'U. H.' on the value of fresh blood, whether native or foreign, when introduced to apiaries where in-and-in breeding had been allowed.

Referring to postal arrangements, it appears hopeless to expect that until other weightier matters—such as an excess of *3½d.* being charged per letter to the Australian colonies over that of our neighbours, of circulars being posted by the ton in Belgium for redelivery in England, &c., &c.—are satisfactorily adjusted, that we shall be able safely to drop our surplus queens in the letter-box. Perhaps half-a-dozen so posted may be safely delivered, but the seventh will bring an official notice that 'Live bees are not allowed by post,' and the parcel (after a week's rest) will be delivered personally to the sender.—*JOHN EDEY, St. Neots.*

PREVENTION OF INCREASE.

NUMBER ONE.

[144.] Prevention of increase of colonies of bees does not mean to prevent the increase of bees by any means, as this would be exactly opposite what we do to gain the best results, for no bee-master ever had too many bees in a hive. Its object is to prevent swarming in a measure, but more especially increase in numbers of his colonies, which is always done at a loss of surplus honey and expense of new hives, combs, and reducing the season's profit. My plan is no theory, but the result of five years' experience with one hundred colonies of bees.

It is as follows: As the preparation begins when bees are set out, I will begin with April 1. In the first place I will say I use the Langstroth hive 16½ inches wide, allowing 1½ inches from centre to centre of combs; brood-frames 9 inches deep, thus it will be seen that I have a broad, shallow hive, which I find the best, all things considered, for profitable bee-keeping, and as I am a specialist at bee-keeping, have been obliged to make it pay. I strive

to keep queens that will fill ten combs with brood; this hive will certainly give room for the most prolific queens, which if crowded in a small hive are too willing to swarm out. Then again, if we contract too much, we shall crowd pollen into the sections. This size of hive obviated these troubles.

My belief is that the bees control swarming, and that the queen is always opposed to swarming. It is, therefore, the bees we must please. Knowing just what they require we may proceed to manipulate them to the best possible advantage.

First, then, in early spring, when set out, allow one day's flight for them to mark their location, then examine every colony, taking away all combs not densely covered with bees; then crowd with division-board, being sure they have abundant stores; cover up warm above and pack warm at sides of hives to hold the heat of cluster and hasten brood-rearing; leave entirely alone twenty-one days, when young bees will begin to hatch; then examine once a-week, adding the combs as fast as young bees emerge to cover them.

The combs should be added to outside of brood-nest, one at a time, as warm weather advances, until all are in. Young bees will now hatch as fast as the queen can fill the empty cells with eggs; the swarm is now a rousing one, and the hive packed full of bees, brood in all stages, and honey (the old stores) mostly consumed.

It is now June 1; clover begins to yield, and we see the combs begin to whiten. This is the proper time to place on a super filled with sections, having starters in them, which will be taken possession of immediately, and honey will be stored rapidly, and if left in this condition swarming would be the result. We watch the super, however, and before it is quite full we raise it up and place an empty one under it, always adding extra room before quite needed, and if the hive is standing in the sun a shade-board is placed upon it. Managed in this way throughout the season swarming is scarcely ever thought of, and not one colony in twenty-five will cast a swarm, as all the energy of the bees is bent upon honey-gathering. The strength of swarm is kept up by the queen having all the room she can fill; consequently, the white honey all goes into sections. But should a swarm issue we proceed at once to profit by it, and hive them so that no time is lost for work in the sections. This we accomplish as follows: As soon as all the bees are in the air we turn the hive clear around, so that it faces the opposite direction from what it did; setting it just off the stand.

We now place a new hive on the same stand as the old one occupied, and put seven combs or frames with foundation in it. Take three combs of brood from old hive and put in also; then place the super, or supers, as the case may be, on the new hive, and hive the swarm back in it, letting the old hive remain until towards evening. At that time all the flying force will be back in the new hive on the old stand. Now open old hive and shake and brush all remaining bees down in front of new hive, when they will all run in. We now have all the bees of the swarm, and all left in old hive on new stand. That colony is now done with swarming for the season. There is a strong field force, no combs to build, or supers of unfinished sections to fill up. The bees have gained a new impetus by swarming, and the work goes on rapidly; no loss of time, no increase, and a double surplus will be taken.

We now return to the old hive, which is taken into honey-house, queen-cells cut out, honey extracted, and the brood given to stocks not overflowing with bees, to nucleus, or to artificial increase (if we wish such), or still better, held over till next day and a swarm hived on them and treated the same as was the one the day before, as regards supers, &c., and so on to the end of the season; when we find we have had half-a-dozen swarms, and yet only our one hundred stocks in the yard in the

fall, the original number in the spring. Following up this method during the season, an extra yield of comb-honey can be secured, fully as much, I believe, as of extracted.

After July 10, the supers can be contracted to the close of the season, leaving few unfinished sections to carry over. These latter can be extracted and combs kept for the next year. Should I wish increase I should manage my apiary as above until after clover and bass-wood bloom, then divide and let them fill up on fall flowers. — E. A. MORGAN, *Columbus, Wts.* (*American Apiculturist.*)

WHAT INDUCED ME TO KEEP BEES.

(Continued from p. 40.)

[1445.] I got another bar-frame hive. I knew all about what ought not to have been done. Had another strong swarm this time from the skep which the lady made me a present of. This time I gave the six frames and left the opening full width and a feeder on. A few days after I gave the ten frames, and when I was satisfied that they wished to work above I put on the large bell-glass which I got with the skep. It was about half filled with honey when I got it; I thought it would look very nice as an ornament when it would be full of honey, but I counted my chickens before they were hatched; in a few days all the furniture had disappeared, they had taken it down below.

I caught a severe cold the night that I kept my bees company, which turned to bronchitis. I gradually wasted away for three months. I had a daughter at this time troubled with a short cough; I knew well what that meant. We took our walks together, thinking that soon we must be parted from those who are very dear to us. Just at this time I thought I would send to friend Huckle for the leaflet 'Honey as Food and Medicine.' There was not much medicine that I could see about it, but I saw it was good for food. I had my bread cut very thin, then spread honey on it, and made a sandwich of it. Before twenty-four hours I began to feel a different man. I got my daughter to take some; her cough has left, and we are now in as good health as any person could wish, and I thank God for it. Calling upon a bee-keeper a few days ago I found his wife had the bronchitis; her case was worse than mine. I told her of my cure. She tried it, and is now able to go about as usual, although seventy years old. People looked at me and said, 'Why, you are quite well!' 'Oh, yes! the honey has done it.' I was soon sold out, and not less than 1s. per pound, some more. One thing I know; I shall always try to keep 100 pounds of honey per year for home use. Once let the value of pure honey be known, and then our friends may do better than they have ever done before, both for themselves and to benefit their fellow-creatures. I hope that some who read these few lines and who have the bronchitis will just try it, and write a few lines respecting their cure and send them to the Editor for publication. Eat the bread very, very slowly, don't wash it down with tea or coffee. I believe in God's providence, and here we have one of His good gifts.

I have got a long way from the hives. I must now get back. Well, I was so delighted with my bees, just to think what good creatures they were. I had a great many visitors coming to see the bees working—indeed, it was becoming almost like a show; every person that came to the house must see the dear bees that I looked upon as having under God's providence saved my life. A very sudden stop was put to my peeping. It is the last feather that breaks the camel's back, and so I suppose that they had put up with my prying until they were determined to resent it. A young man wished to look. I lifted the top, and in a moment the bees lifted me. We ran (I know some bee-keepers will say 'What

cowards!') into a shed a few yards off, but the bees followed us. The young man managed to get behind me in a stooping position in one corner. The bees placed their stings into my face as if it were a pin-cushion, and it resembled one for a few days afterwards. At last I said, 'We must run for it, and we did run. When we had got out of harm's way he drew the stings out and pressed his watch-key on them to get the poison out.'

Now all this can be avoided. We all wish to learn as much as possible about 'our bees.' Thanks to Abbott Brothers of Southall, London, for their cheap observatory hive, Messrs. Neighbour & Sons, Regent Street, London, and others, we can now see what is wanted; before we were still partly groping in the dark. We get one lesson respecting our frames hanging true. How many of us have found our frames near each other at the bottom of hive, and consequently the next space further off than it ought to be? I now do the following. Place a piece of wood between each frame one inch in length and $\frac{1}{2}$ th of an inch square, keeping them about one inch from hive side, and resting on bottom of hive. Again I have found the bottom bar bent so that it touched bottom of hive. This is very annoying to the bees. I now have a piece of cork about a quarter inch deep and glue it on centre of bar. We can hardly expect our hive-makers to do this work for us, as they put everything in our way for as little money as possible. We have also gone a step further in the observatory hive. We can now see our bees feeding, piercing their candy, and making it like a beautiful piece of coral work. Thanks to the Productive Tin-plate Worker Association, Masshouse Lane, Birmingham, for their Excelsior bee-feeder. How pleasant for an invalid to see all this when he cannot get about.

Now to return to my skep which the lady kindly gave me. With one skep being on the top of the other the bees got in between the skeps and came out same way, as well as others using the bottom entrance. Query: Can something not be done with our bar-frame hives? It would save the bees a great amount of travelling up and down in the hive; I mean just when the honey is coming in freely.

And now, in conclusion, I am glad to say that I have never seen or heard any of the hobgoblins or will-o'-the-wisps in my hives. Cleanliness is next to godliness. Commence this season well. Begin by getting at least one new hive, and do not omit to order an observatory hive. Paint it well outside with four coats of good oil-paint, and paint the inside with Mr. Cowan's prescription. When there is no smell from the paint then commence to put the bees in, and treat every hive in the same way. To beginners, Don't be alarmed by all the thousand and one things you read about. I quite expect to hear of the Hessian fly or the Colorado beetle being found,—almost anything, but I am quite prepared for anything in that line; nothing will deter me from keeping bees. Bee-keeping is with me a great pleasure; indeed, I may say they contribute to my happiness as well as the pocket. The *Bee Journal* I prize very much, although we do get unpleasant things to read about, such as damp hives, mouldiness, and that other thing, &c. If you are determined to have 1s. per pound for your honey, get the bronchitis.—T. H.

NOTES ON BEE-HIVES—SECTIONS.

[1446.] During the season of 1887 I have made a number of experiments in order to find the best method of securing sections filled evenly and entirely. I have had colonies worked upon the various lines indicated in the issues of the *British Bee Journal* for the past two years, and will here just say the method which has given the most perfect result. The four inner faces of the sections have a small groove into which the foundation is placed at the time of setting up the sections. This foundation fits rather loosely in

order to allow for a slight expansion upon being treated with the heat of the hive. I find the bees fix the four edges of the foundation to the sides of the sections 'first thing they do' invariably. I use Dadant's thin foundation, which I import direct from their establishment in America. After this is worked out, the so-called fish-bone cannot be detected, and I have never found this foundation to fail, break down, or be removed or destroyed by the bees. Dadant's extra thin foundation I fix all round with molten wax by means of a sable-hair pencil, afterwards scraping the surplus wax away with the point of a penknife. When foundation is fixed by either of the above methods I have had 100 per cent of finished sections without a single pop-hole.

The grooves can be easily made by means of a small plane, or a small circular saw. I cannot bear the appearance of a line of wax showing upon the outside of the section, as is the case with the Lee section and the one figured by Mr. Simmins in his *Modern Bee-farm*.

For all practical purposes, appearance, &c., the very best section is the four-piece pin-dovetail section. Those I import from Mr. Heddon have their faces beautifully smooth, and the wood is nearly as white as milk. By means of slotted dividers I have not obtained more than 80 per cent of sections free from pop-holes when the ordinary one-piece sections have been used in the cases of two-ways and four-ways respectively, and the most approved section-cases have been used, the defects being caused by the wood corners of the one-piece sections. My best results have been made by using wide frames, as illustrated in Heddon's *Success in Bee Culture*, the wood of the sections being quite free from traces of propolis, &c., and the sections evenly and entirely filled. I have come to the conclusion that a vertical unobstructed passage is what is required in order to have the corners filled, and that this is almost impossible with the one-piece section with two bee-ways, or even four bee-ways, to secure entirely filled sections every time owing to the wood corners. I have most carefully tested the new patent Heddon hive with reference to sections, and find it unsurpassable for this purpose.—T. BONNER CHAMBERS, F.L.S., *Tref Eglweys, January 18*.

HONEY LIQUORS, CONFECTIONS, &c.

[1417.] Mr. E. McNally, of Rutherglen (1417), will probably get the information he requires as to the names of manufacturers who use honey in their goods, if he communicates with the Hon. Sec. of the Berkshire B. A. I remember they had an exhibition at Reading some years ago, at which such articles formed a very prominent feature. A reverend gentleman, whose name I forget, took great interest in the matter, and did much to bring the many uses of honey before the public.

The Dorset B. A. also had a stall at their shows for some time for the sale of confectionery, drinks, &c., in the manufacture of which honey was used. I tasted many varieties and found them excellent. The biscuits made by Messrs. Huntley & Palmer, of Reading, and called 'Honey Drops,' are so good that I do not like to be without them. They are sold in tin boxes at 1s. per box.

There were many announcements in the *Journal* a few years ago giving such information as Mr. E. McNally now wants. If he fails to get the information from other sources I dare say he can get access to a file of bound volumes. The report of the B. B. A. exhibits at 'The Healtheries' will be especially useful to him. Mr. W. H. Dunman, of Dorchester, late Hon. Sec. of the Dorset B. A., and Mr. W. N. Griffin, of Reading, late of the Honey Depot, Freshford, Somerset, could probably give much acceptable information on the subject.—WEST COUNTRYMAN.

WHO IS 'AMATEUR EXPERT'?

[1448.] This is a question which none of us would have thought it necessary to ask as long as that *nom de plume* attached itself only to the pleasant chit-chat and friendly criticisms which have appeared from time to time in the pages of the *British Bee Journal*. Lately, however, under cover of the same fictitious name, an attack has been made in the columns of a *Canadian Bee Journal* which will naturally incline us to ask, 'Is this the writer in the *B. B. J.*, whose letters have crossed the Atlantic? Are the two "Amateur Experts" in reality one and the same man?' As chairman of the Board of Examiners of the B. B. K. A., I am perhaps in a better position than any one to refute this attack which is made against those who conduct the examinations for the third-class certificates of the B. B. K. A. 'Amateur Expert' says that the candidates are required to find the queen in ten minutes by examiners who would probably take ten hours to find her, or words to that effect. We can only interpret this to mean that these examiners are incompetent men, and I think it due to the British bee-keeping public that I should say that this is altogether a false charge. Although as chairman of the Board I have signed nearly all the diplomas to examiners which have been issued, I have never acted in the capacity of third-class examiner myself, and have therefore less hesitation in saying that the examiners have always been chosen from those who were known to be most competent, nor have any been appointed about whom the Board felt any doubt as to their fitness.

May I be allowed to give this advice to those who use a *nom de plume*: Do so as long as you please, if protected by its shelter from the public gaze you feel more confidence and can write better for the good of the community at large; but when you think it necessary to make attacks which are more or less personal—use your own name!—HENRY BUGH, *Hampton Hill Vicarage, January 19th*.

PARALLEL v. RIGHT-ANGLE FRAMES, &c.

[1449.] Having read a good deal of the correspondence on the above subject, I should like now to give my experience and the result. I use some long hives with the frames parallel, and some hives with ten frames. I can turn either side to the front, as my entrances are all sunk in the floor-boards. In 1886 I wintered fifteen stocks on the parallel, six on the right-angle, and last spring I had one queenless on each system, and one rather mouldy on each system. I have not lost a stock for several years, except one I tried to winter as an experiment on the right-angle in a half-inch hive, which died. My four best stocks last year on the parallel system gave me, as near as I can say, No. 1, hybrids, 53 lbs. and 91 sections; No. 2, Ligurians, 101 lbs.; No. 3, blacks, 56 lbs. and 41 sections; No. 4, hybrids, 91 lbs. The four best on right-angle: No. 1, blacks, 68 sections; No. 2, blacks, 66 sections; No. 3, hybrids, 46 lbs. and 14 sections; No. 4, blacks, 32 lbs. and 21 sections, which leaves me in favour of parallel frames. I have not found any difference in the healthiness of either system. I prefer manipulating parallel frames. I was pleased with my Ligurians beating all my others but one, and they the No. 1, hybrids, which I should have said were two lots wintered in a fifteen bar-frame hive, and having a queenless stock. On May 28th I took one queen away and united the others, they giving the 53 lbs. and 91 sections.

If it will interest the readers of the *Bee Journal*, I will explain how I managed the Ligurians, which are a mile from home. Wintered on nine bars. On January 20th I found entrance stopped with dead bees. April 5th, examined and gave 1-lb. cake of candy on top, and two pounds of dry sugar in dummy

at back; in May gave 2 lbs. of liquid food. June 10th, doubled to twenty bars, putting the stock at the top, and five bars of comb and five bars of foundation in the bottom hive. June 16th, gave ten more bars of foundation in the centre. June 29th, gave five more bars of comb and five bars of foundation under top box, making four storeys high. July 29th, took top box, ten full bars. August 15th, took nineteen full, one empty, leaving stock strong and plenty of honey.

I am now going to give the Carniolans a trial, having received one of Mr. Benton's selected queens, and successfully introduced her, October 4th, on Mr. Simmins's principle, as I have done several before. On November 26th young Carniolans were out, on December 16th a lot were out, and on January 8th and 9th all the bees had a good cleansing flight.—*LIGUSTICS.*

PARALLEL *versus* RIGHT-ANGLED FRAMES.

[1450.] We are invited by the writer of 'Useful Hints' to the *B. B. J.* to publish our experience in regard to the above question, *i.e.*, whether frames should be hung parallel or at right angles to the entrance. We can scarcely claim to have any experience in the matter, as we have never worked a single stock on the parallel system. Our objections to it are rather theoretical than practical. But so thoroughly convinced are we of its demerits that we have never even considered it necessary to test it. We could tolerate it, and even recommend it as perhaps the best arrangement for wintering weak stocks, and we have frequently practised it so far, keeping the bees on a few frames well back from the entrance, and chaff packed. It may work well also in building up stocks in spring, since it is unquestionably the warmer system. But when our stocks come to full strength we could not tolerate it. It would be impossible for the bees, of what we call strong stocks, to get jostled past each other in the limited passage afforded by a comb hung across the entrance. Under the right-angled system the bees have all their streets opening clear out to the country, in our case ten in number, not counting those at the sides. Under the other system every passenger has to burrow under or scramble round *each* of the ten or eleven combs the hive contains before reaching the back. And so, of course, with the ventilation. Only in one way could we tolerate it, *viz.*, by propping the hive from the floor-board so as to give entrance all round. Our *great difficulty* in bee-keeping has been, and to some extent still is, not to get stocks strong, but to *keep* them strong, which means during the honey season to *prevent swarming*. This we can almost certainly do under the system we prefer, but we would consider it a hopeless task under the parallel system.

While acknowledging that we have never given the latter system a season's trial, we should like it to be understood that we are not strangers to it. We have handled for others many hives on the combination principle; but in no case did we ever find one that could compare in results with our own.—*W. R.*

So far as actual experience in working hives on the parallel system goes, we are only a little in advance of 'W. R.' We have in our apiary but one stock of bees with frames so hung, and this is one of two 'long-idea' hives presented to us last year by a friend who was reducing his stock. Our experience, therefore, of parallel frames is too limited for us to speak with authority for or against them. At the same time, we have seen enough of the combination principle in the hands of others to be quite sure we shall never adopt that plan. Tying-up recommends itself, both in theory and practice, over lateral extension so unmistakably that we shall never give the latter a trial. As to hanging frames parallel to entrance, it has something to recommend it,

so far as actual manipulation goes, because, no doubt, it gives some advantage in having lateral space in the rear, when hives are made to accommodate more frames than are in use by the bees.

It is also hardly likely that we should be much troubled by bees jostling past each other, as our colleague suggests, because we could not tolerate a hive for our own use wherein a free passage and free ventilation all round could not be readily given in hot weather. Seeing that the question has been put to us, and that we have a couple of these hives on our hands, we shall give the matter some attention; but, while endeavouring to keep an open mind regarding it, we have a strong conviction that we shall prefer to work with frames at right angles to the entrance in the future as we have in the past.—*W. B. C. (The Bee-keepers' Record.)*

COUNTY BEE-KEEPING ASSOCIATIONS.

[1451.] Your article under this heading has presumably produced the effect which was intended, and as far as comment upon it has gone it has been fully justified. As a County Secretary of many years' standing I thank you for opening your columns to a discussion which I trust will not be closed until the committee of the British Bee-keepers' Association admits that its future position in the world of bee matters requires it to give its aid in elucidating the questions commented upon.

It was not a little remarkable that coincidentally with the appearance of the article the intimation of Mr. White's retirement from the honorary secretaryship of the Hunts Bee-keepers' Association, under circumstances so closely resembling those indicated in that article, should have appeared. Simply stated, his resignation is owing to the lack of assistance afforded to him in the management of his Association.

I have carefully read the observations which have been made by your several contributors, and there are a few that I should like to remark upon. Of Mr. McClure (1449), I would ask, Why is it that the County Association, of which he is honorary secretary, 'has not begun to fill the place it was intended to take?' and what hitherto have been the aims which have so long prevented it from beginning to fill that place? Surely during the time that it has been in existence it has done something more than form an organization? If not there is at once good ground for the suggested investigation. Replies to these would in all probability afford additional justification for the article, but possibly not from exactly the same quarter as the writer expected. Mr. McClure brings into strong contrast the character of his committee with the one described in the article referred to. Could it but be known how such attendances were secured, and how to ensure their successful application in other counties, one of the chief causes of anxiety would be overcome. It is to be sincerely hoped that the enthusiastic hopes which Mr. McClure indulges in may be realised, and that he may soon see the bee-keepers of his county working their districts up and these workers greatly assisting the County Secretary. The conclusion to which Mr. McClure is led, in reference to the ultimate position of the County Secretary, is the same which I foresaw many years ago, and which I communicated to the *B. Bee Journal* during the time it was in the hands of Mr. Abbott; and it has been a matter of surprise to me, as it must have been to many others, that the voluntary efforts of a few devoted men filling the post of honorary secretaries in each county have so long supported and maintained the position of the respective Associations as has been done. The enthusiasm of one individual may do much; but can that enthusiasm be depended upon to continue if the objects on which its aim is fixed are uncertain and indefinite? I venture to assert that we do need some stimulus that shall rally the energies and direct the efforts of those who are interested

in the welfare of County Bee-keeping Associations, otherwise we shall find our ranks thinning, and the Associations assuming the character of which America supplies the type.

Turning to Mr. Hooker's contribution, I note he speaks of the considerable progress which has been made by some of the County Associations, the able management of exhibitions, the questions of visitors, &c., but concludes by saying, 'Still, much remains to be done.' Further on he attributes the decline, if such is shown, to 'something wanting in the organization and management.' This may be the very point and centre of the enquiry; and if so, the consideration of the matter by the Committee of the B. B. K. A. as suggested should be productive of great benefit at the present juncture.

Mr. Hooker does not leave us to find a remedy for the state of things complained of, but lays down an excellent programme, upon the carrying out of which he foresees a new period of prosperity. But can we at this period count upon a re-awakening of enthusiasm with which to produce so desirable a result? I fear not. In our Association we have local honorary secretaries, and it may be taken for granted that the best appointments possible have been made. The result is seen in district branches being formed on precisely the same footing, but showing very different degrees of energy and interest. For this inequality many circumstances must be brought into account, but rarely, if ever, does it happen that a complaint is formulated, or even a hint given, that any locality was prepared to furnish a better local secretary. Should the fault of the condition of things be attributable to the County Secretary? A simple remedy may be found by the members at the annual meeting replacing him by some one better fitted to carry out the duties of the office. I do not thrust myself into the controversy in any feeling of alarm, but solely with the object of furthering the inquiry which has been opened out, viz., What is the state of the *internal working* and the *internal condition* of the County Bee-keeping Associations?—JESSE GARRATT, *Hon. Secretary K. B. K. A.*

MARKETS FOR HONEY.

[1452.] Your correspondent 'Sherborne' must be one of those 'Peculiar' as no fellow can understand; he is pecking at all around, and himself too, but the latter fact need not, I think, concern any one but himself.

I feel sure correspondents and readers alike are not unmindful of your ever readiness to give space for all such matter communicated that is interesting and calculated to assist us on the path of learning; further, your liberality for giving broad gauge to fair and honest criticism is widely acknowledged; to say the least then, it is not generous on the part of any one to desire to force intrusive matter into your columns. Hence, I have ventured to thus express myself, not that I fear you would deviate from the course you have hitherto followed, and which is, I believe, so generally appreciated and has landed us with our fifteenth volume, but to record my warmest thanks and approval of the manner you conduct the *Journal*, which to their clear of dissensions is, at times, doubtless a difficult task.

Permit me through your medium to tender 'Sherborne' my thanks for his useful hints on the question of the price of honey, and to congratulate him upon his great success after his efforts of obtaining what, under present circumstances, may be considered so fair a price for all his honey, and having also found, too, two or three markets for another year, which, as he says, is some small consolation to him (I should feel it a very great

consolation.) Now here is a grand opportunity for 'Sherborne' to help those around him who may be less able to help themselves by letting such into the secret, say, of where *one* of the three markets may be met with. I don't for a moment doubt he will wish to monopolise all three markets, and it would be an excellent example.

Nothing like persevering oneself. 'Sherborne,' to be discontented and to find fault with others for their non-success in finding a ready market for your honey surely is of no avail. Vast is the advantage gained by careful study of the various articles put before us week by week in the *Journal*; few less in importance, perhaps, than some which have appeared of late in reference to the system by which such enormous stocks have been produced in so short a time, and the great yield of honey obtained. I have a statement before me, given by a member from the Uleby district of Lincolnshire, telling me how he worked up his stocks last season to an enormous size, and the great yield of honey consequently obtained, and the fact was fully demonstrated. I admit I have never yet been able to accomplish such great things, but I nevertheless readily admit they are accomplished, and right glad am I to know it.

A happy outpour, whether 'Sherborne' intended it or not (January 12, page 27), the *very trade*, forth it goes,—bee-keeping and chimney-sweeping. I never once thought of the combination, and I have long, too, been casting about to find a trade or business that necessitated little brain and labour to which that of bee-keeping could be linked with a prospect of its being profitably worked. The callings of the chimney-sweep are, as a rule, at early dawn, thus leaving the clear day for bee-calling. What trade could be better fitted? How great and good things may result from a slip!—R. R. GODFREY, *January 23.*

ECHOES FROM WILTS, 850 FEET ABOVE SEA LEVEL.

[1453.] As my experience for last week must be different to many, I send you the following report:—

January 9th.	Lowest night temperature by Negretti and Zambra, 1 ft. from ground, 39°	At 1 p.m., 80°	in sun.
January 10th,	Lowest 12	At 1 p.m., 82°	in sun.
" 11th,	" 37	" 76°	"
" 12th,	" 35	" 70°	"

This being the case, bees from all hives flying as in May, and cleansing themselves. At 10 a.m. on 9th removed all doors, slides, and covers, and exposed to sun and air. Bees at once set about cleaning out *débris*. In the middle of the day I helped them with a bent wire. Total dead from twenty stocks less than $\frac{3}{4}$ pint. Lifted *corners* of quilts only, and saw evidence of abundance of store for the present. Found all hives warm and dry, and floor-boards very clean. Knowing that food was not required to be given, I resisted the temptation of spreading frames to look for brood.

My stocks consist of four good skeps and sixteen bar-frames, the latter packed up at the end of October, with from six to ten frames well stocked with sealed food (*mostly* honey), and well covered with bees. I use American cloth quilts, two thicknesses of house-flannel, and over all 3-in. tray of chaff or cork-dust. All my hives have the entrance extending *full width* of hive. When I packed up, I removed all *wood* slides and substituted others of coarse perforated zinc, with entrance in centre $\frac{3}{4}$ in. wide, and never had floors so dry and clean. This time last year several of my hives were buried 3 ft. deep in snow.—W. E. BURKITT.

S. CORNEIL.

The subject of this sketch was born of Irish parentage in the township of Ops, County of Victoria, and Province of Ontario, April 7th, 1836. He worked on the farm until he was nearly eighteen years old, going to the common school in winter. He was big and strong for his age, and being the eldest of the family, and the only help his father had, got plenty of hard work. For some time before he left the farm he could take a man's place at most kinds of agricultural labour. He was always ambitious to excel, and won two prizes at ploughing matches before he quitted farming.

From childhood he was a voracious reader, and received many a severe scolding from his father when he was found reading a book while his team was feeding. His father belonged to the Episcopal Church. During a religious revival young S. expressed a wish to join the Methodists. This displeased his father, who told him he might do so if he pleased, and could continue at home, but must do no more farm-work. Learning that an examination of teachers was about to be held at Peterborough, young S. determined to attend it and try for a certificate. Peterborough was eighteen miles distant, but our hero set off with a brave heart on foot. He got a friendly lift part of the way and arrived in good time to undergo the ordeal. He succeeded in obtaining a certificate, and found himself in 1853, at the early age of seventeen, a legally qualified school teacher.

He did not, however, take a school at once. His father, having relented, sent for him to come home again, which he did, and worked on the farm for another twelve months. He then went to the Normal School for a session. He commenced teaching towards the end of 1854, and continued at it steadily for about thirteen years, until June 1867. He married early in life, so much so that statute labour could not be exacted of him until some time afterwards because he was under twenty-one. The third year of his teaching he obtained 400 dollars a-year, which was considered liberal wages in those days, and continued to get as good salaries as were paid to common school teachers at that time, but as the years rolled on and his family increased faster than his salary, it became necessary to look out for more lucrative employment.

He decided to go into the insurance business, at which he has now been working for upwards of twenty years. During his career as a teacher he had the schools in Omemeo, Balyduff, Cavanville, Milbrook, and Ashburnham. He has resided in Lindsay for nearly twenty years. While attending the Normal School he was greatly benefited by the teachings of Dr. Ormiston. It was not so much the information that was imparted, as the mental impetus given, that was of value. Young S. at that time acquired a fondness for the study of natural science, which has never since died out. Before he desisted from teaching, Mr. Corneil had obtained the highest certificate County Boards had the power to grant, viz., first class, grade A, permanent. It is still in force, so that if insurance fails, and bee-keeping goes to the dogs, he can resume that

'Delightful task! to rear the tender thought,
And to teach the young idea how to shoot.'

Mr. Corneil has been successful in the insurance business, his receipts having averaged not less than \$1800 a-year, but as he latterly remarked to the writer of this sketch, 'It has never stayed with me, and I suppose it never will now;' a condition of affairs in which he is by no means alone. He has been twice married. His first wife, a native of Edinburgh, died in 1858. He married again in 1859, his second wife being a daughter of the late Christopher Knowlson, of Omemeo.

In 1875 Mr. Corneil bought his first stock of bees. It cost him ten dollars, as it stood in his garden ready for business. He did not then know a worker-bee from a

drone, and had no idea of ever keeping more than three or four colonies—just to supply honey for his own table. He determined, however, to read up on bee-keeping in the winter, when he had more time. He got *Langstroth on the Honey Bee*, and *Quinby's Mysteries of Bee-keeping Explained*,—those old-timed standard books, to which many of us owe so much. He also read the writings of Mr. Quinby in the *American Apiculturist*, getting the back numbers for the purpose of tracing up every item of apicultural information. He was thus peculiarly a disciple of Quinby's, and naturally contracted a preference for the closed-end frame which was used by the great New York apiarist. After reading up on this fascinating pursuit, Mr. Corneil could not be satisfied without having the latest improvements. This meant outlay of money, and to recoup this expenditure, he bought more hives, and went more extensively into bee-keeping. Thus, from less to more, he got into it as a business. When he left home to attend the Colonial and Indian Exhibition a year ago last summer, he had 212 stocks of bees. In preparing them for winter, they were doubled down to 180 to avoid sugar-feeding, and make the apiary self-supporting. They were packed and prepared for winter as usual, but, unfortunately, the bees had gathered a large quantity of honey-dew. About half-a-dozen stocks which were given sealed comb, filled early in the season, were clean, bright, and strong; but wherever there was a considerable store of honey-dew, the bees were either sick or dead. On the first of June of last year, 122 colonies out of 180 had succumbed. Nothing daunted, however, Mr. Corneil went vigorously to work to repair his losses, and, though the past season has been an exceptionally unfavourable one, he has 105 colonies in winter quarters; 64 packed on their summer stands, and 41 housed in the cellar. Mr. Corneil is now an authority on honey-dew, and strongly advises extracting it, and feeding sugar to take its place.

The subject of this sketch is one of our foremost Canadian apiarists, and in the scientific branches of bee-keeping is probably 'the noblest Roman of them all.' He is a careful experimenter, a patient investigator, and arrives at his conclusions logically. He wields the pen of a ready writer, and his articles are always interesting, instructive, and to the point. He has filled the highest offices among Ontario bee-keepers, having been President of the Association in 1884, and one of the four commissioners to England in 1886. In the last-named capacity he rendered invaluable service as book-keeper and accountant, performing a lot of hard work, at late hours, in keeping the cash balance up to the mark.

At the present time Mr. Corneil is experimenting with a straw hive, which he hopes will prove 'just the thing' for out-door wintering in this climate. It is a model of neat workmanship, thanks to the mechanical ingenuity of his son, whom the writer watched one day last winter dexterously weaving in the layers of straw, making a very compact, nice job of it. This hive is designed so as to have the sheets of comb built transversely and converging to the centre, where it is meant to secure a vacant space large enough to admit of the bees forming one solid cluster, instead of being in *strata* between combs. It is believed that, on this plan, bees will hibernate more perfectly, and winter better, than on any other at present in use.

Mr. Corneil has never aspired to municipal or political distinction. But before the change from the Local Superintendency to County Inspection, he was Local Superintendent of Public Schools in Ops for several years. He is now, and has been for the past nine years, a prominent member of the Lindsay Board of Education.—W. F. CLARKE, *The Canadian Bee Journal*.

[Many of our readers were brought into contact with Mr. Corneil when acting as one of the Commissioners at the Colonial Exhibition; they will be pleased to read the above interesting memoir.—Ed.]

Echoes from the Hives.

Kilmington, Arminster, Devon, January 23.—We have been having dense fogs here for the last week or two, but the glorious sunshine has come out at last. On Sunday, the 22nd, my bees were taking advantage of it, and were coming out of their hives for a cleansing flight. One would think they were swarming; you could hear their joyful hum for some distance away. They look as if they are in a very healthy state. I have twenty stocks of different sorts, and they have passed the winter all well so far. I cannot complain with what my little-pets did for me last year. I took about 500 pounds of honey, which I think is exceedingly well for this part of the country, and, better still, I found a good sale for it; so I think you will agree with me that I have been remarkably lucky. I take the *Bee Journal* weekly, and I find it gives me a good bit of useful instruction, and I strongly recommend it to all other bee-keepers, and then, if they would follow its instructions, we should not so often hear them complaining about their bees not paying them which I often hear as I go about. So I just tell them the results that I have met with since I commenced bee-keeping. They cannot understand getting fifty pounds of honey from one hive of bees until I explain it to them and persuade them to try it. I now wish my fellow-bee-keepers a prosperous year for their little pets. —J. W. SANDERS.

Blind Lake Apiary, January 23.—To-day very bright sun; bees having a thorough cleanse, pouring out as if about to swarm. Their cheerful hum is delightful; they are bringing out their dead amongst them. I observe some dead grubs after two or three nights of sharp frost. I have given my opinion to several bee-keepers that we are to have a damp, mild winter and a damp summer. Look out for early swarms, plenty of bees, but small honey harvest. Shall be on the look out for reports from our 100 and 150-pounders this season. I hope they may get them, but am afraid the season will be against them. —SHERBORNE.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

H. NEEVE.—*Sample of Pea-flour.*—The pea-flour is just the thing for the purpose you name. A sprig of heather has been sent you.

R. F.—1. *Best variety of Bees.*—A hybrid bee as the result of a cross between a black queen and either a Carniolan or Italian drone gives better results as an all-round bee than the pure black or Italian. 2. *Addresses of large Consumers of Honey.*—We have no knowledge beyond that appearing in our advertising columns. 3. *Locality for large Bee-farm.*—This is a matter we cannot help you in without a great expenditure of time and money. We should recommend you to look round and try to discover where bee-forage would be naturally abundant, and then go to work there cautiously—*very cautiously*, unless you have more experience than your questions lead us to suppose. 4. *Present Value of Comb and Extracted Honey.*—This entirely depends on local requirements, the quality of the honey, and, last but not least, whether you know how to put it on the market in an attractive way. 5. *Slotted Dividers.*—We must refer you to page 531 of *B.B.J.* for 1886.

WOODSETTON.—*Deserting Hive.*—The condemned bees, being not more than a mile from home, returned to their old locality, with the exception of the handful or two which remained with the queen. These, being insufficient in number to keep up a sufficiently high temperature, perished from cold.

T. M. D.—*Decamping.*—The bees from the centre skep (full of honey) having lost their queen, joined the other colonies on the fine day you mention. Or it might be that, being a weak colony, it was attacked by the other bees, and, its queen being destroyed, united with the marauders.

J. W. P.—*Granulated Honey.*—The sample of honey forwarded is very good, with a nice rich flavour. The season of the previous year was very peculiar, being free from rains, and therefore a dry atmosphere, honey when extracted very quickly granulated. Many apianians found that the honey gathered from fruit granulated in less than eight days, and that from clover in fourteen days. Honey from rape, mustard, and plants of that genus, candies very quickly after extraction.

SHERBORNE.—You would much oblige by adhering in your communications to bee-keeping, pure and simple.

MALTA.—*Wax-moth.*—Strong stocks are the best defence against the wax-moth. If hives are kept strong, having a fertile queen, the moth need not be feared, as it would have little chance of effecting an entrance. As a preventive, care should be taken not to leave old combs about, or allow them to be in hives where moths can enter. Sulphur will destroy the eggs of the moth.

Captain H. H. has just started bees on humane principles at Malta, and being a novice, would be glad if any bee-master passing through would call on him and give him advice at 86 St^a Britannica.]

AMERICAN SECTIONS BY THE MILLION

LARGEST BEE-HIVE FACTORY
 IN THE WORLD

WITH FLOOR-ROOM SPACE
 OF OVER AN ACRE.

The ent. taken from a photograph, represents our bee-hive factory where we annually turn out about 20,000 hives and 3,000,000 sections, besides enormous quantities of bee-supplies of every description. Dealers before ordering elsewhere should correspond directly with us. We are prepared to quote better prices on sections in quantities than we have ever quoted before. We are also publishers of *Gleanings in Bee Culture*, with a circulation of 7674 subscribers. A sample copy of our journal and our 49-page price list sent on application to
A. I. ROOT, Medina, Ohio, U. S. A.

Special Prepaid Advertisements.

Exchange Column.—Sales of Honey and Second-hand Goods.—Intended to aid Bee-keepers in the disposal of Bee-produce and Appliances for which they have no further use. Terms: Twelve words and under, Fourpence; for every additional Three words, One Penny extra.

No reduction made for continuous insertion.

NOW READY.

SIMMINS' NEW BOOK.—‘A MODERN BEE-FARM, AND ITS ECONOMIC MANAGEMENT.’ Popular Edition, limp cloth cover, 3s. 9d. Special Edition, stiff covers, 7s. 6d., post free.

The Special Edition includes Photos of the Author's Domestic Hive; his Home Apiary, and another covered Apiary; also one of Queen and Workers on a Comb. Of the AUTHOR, Rottingdean, Brighton; NEIGHBOUR & SONS, 149 Regent Street, London; and J. HUCKLE, Kings Langley, Herts.

BEE-KEEPING, Plain and Practical: How to Make it Pay. By A. RUSBRIDGE, 1s. 6d., post free, 1s. 8d. Address J. HUCKLE, Kings Langley, Herts. A 1253

THE MANAGEMENT OF STRAW SKEPS. Designed to teach the Cottager how to obtain the best results at the least possible cost. By attention to its teachings, Cottagers will be enabled to make their Bees a more profitable source of income than hitherto. Price One Penny. Six copies and upwards, post free. J. HUCKLE, Kings Langley.

ADVERTISEMENTS for Leicestershire Bee-keepers' Association's Report should be sent to EDWIN BALL, Waltham, Melton Mowbray. Members residing in County, 10s. per page; others, 20s.

WANTED.—Copies of *British Bee Journal* for January 7th, 1886, and Nov. 1873. Full price given. Apply J. HUCKLE, Kings Langley, Herts.

FOR SALE.—50 lbs. of best Extracted Honey at 6d. per lb. Address T. BARNETT, Ross, Herefordshire. B 88

OFFERS Wanted for 6 dozen 1-lb. Sections of Clover Honey. Address J. CRAIGS, Gilling, Richmond, Yorks. B 90

FOR SALE.—40 lbs. best quality Honey in 1-lb. Glass Jars. 9d. per lb. Apply M. COLEMAN, Throcking Hall, Buntingford, Herts. B 91

FOR SALE.—*British Bee Journal*, 1886-87, unbound, perfect. What offers? Address JENKINSON, 6 Lapston Road, Millom, Carnforth. B 92

FOR SALE.—New Vertical Engine, suitable for Driving Circular Saw. Cheap. Crankshaft and Fly-wheels. Address A. GREEN, Selston, Notts. A 93

ADVERTISEMENTS for Derbyshire Bee-keepers' Association Report (1000) received at W. T. ATKINS, 6 North Street, Derby. 10s. per page.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

PRACTICAL WORK IN THE APIARY.

This month is usually considered one in which the bees should be kept quiet, and the bee-keeper will do well to do so when they are well protected from rain, snow, or cold. Some of our friends may not, however, have taken the necessary precautions in the autumn to pack their bees up snugly or provide them with sufficient food, and therefore a few words of caution may not be out of place. In many hives brood-raising will have commenced, and it is such colonies more than any others that would be likely to suffer most from the cold weather which we may yet have. Every precaution should be taken to prevent the escape of heat from the hives, for heat is necessary to existence, and if it escape the bees must generate more, at a great cost to themselves, or die; and if this heat-producing process is too severely taxed they exhaust themselves, wear out, or become diseased.

Should the bees be short of food from any cause, that in a liquid state should on no account be given them. A cake of candy pushed in under the quilt is the best method of feeding now. The candy is made in the following way:—Put into a tin saucepan about three-quarters of a pint of water, and let it boil, then while boiling gradually stir into it six lbs. of white lump-sugar; keep it boiling until it is quite clear and every particle of sugar dissolved. During the whole time the boiling syrup should be stirred to prevent its burning, as burnt sugar is not only injurious to the bees, but its presence in the syrup will prevent the syrup from granulating or setting hard, and no amount of boiling would produce candy such as we require for bees' food. If the syrup is boiled too much the candy will be too hard and the bees will not be able to use it; if, however, it is not boiled enough it would be too soft, and in this case would absorb moisture more rapidly than the bees could consume it. This would cause it to run down inside the hive, and would be detrimental to the bees. To know exactly when the boiling should be stopped the syrup must be tested. This can easily be done by first dipping a finger in cold water, then into the boiling syrup, and back again into the water. No fear need be entertained of burning the finger, provided it is not left in the boiling syrup too long. If the syrup has been boiled enough the coating on the finger will be crisp and

brittle. There may be some who will not have the courage to dip their finger into the boiling syrup; for these the next best way of testing is to drop a little on a cold plate. If this sets on cooling tolerably hard, and is only just sticky, it is done enough; if too hard and quite dry, it is done too much; and if it does not become hard at all and is very sticky, the boiling must be continued. When the proper consistence is obtained take it off the fire, place the saucepan on a cold stone and commence stirring. After a time it will be noticed that the syrup begins to lose its clear appearance and becomes opaque, owing to the granulation of the sugar. The stirring must be kept up until the mass becomes white and rather stiff, when it is ready for pouring out. The candy can be poured out into saucers, into which tissue or other very thin paper has been placed to prevent its sticking to them. When cold it will be ready for use, and can be put under the quilt just as it comes from the saucers, the flat side being placed on the frames.

If the bees are short of pollen, a substitute may be given to them, and this can be incorporated with the candy. We have always used lentil-flour, but as it is more expensive than pea-flour, the latter is more generally used, and even wheat-flour will do if the others are not at hand. One and a half pounds of the flour should be stirred into the syrup when it is taken off the fire, and when poured out into saucers and cold it will be what is known as 'flour candy.' This will be useful to the bees until the weather is sufficiently warm to feed them with liquid food. We should, however, not recommend giving bees flour candy so early in the season, and should prefer to wait at least another month or six weeks, as the probabilities are that the bees have plenty of pollen in their combs to keep them supplied with what they may require for the present. We must bear in mind that flour candy inclines to stimulate the rearing of brood, and we do not want much of that just yet, for the exertion of tending and nursing brood is exhaustive, and is apt to wear out the bees. Thus it is that at the time when we require most bees to nurse the larger quantities of brood later on we find our hives suffering from spring dwindling. If bees are fed now it should only be as a last resource and for their preservation, because the bee-keeper has neglected to do so in the autumn, but they should on no account whatever be fed for stimulation.

See that there is no draught through the hive, and by this we do not mean that the entrances should be closed so that hardly a breath of air can enter. Leave the

entrances open the full width, but see that all is close and tight at the top, that the quilt fits properly, and that there is no means of escape for the warm air by any accidental opening at the top. We use chaff round our hives, and consider it one of the cheapest and best of winter packings, and over the frames we have a sheet of unbleached calico, on which we place a chaff box. This plan we adopted in 1875, taking the hint from an American writer, and utilised for this purpose the supers we formerly used, which came in splendidly. The box has four sides 5 in. high, but has neither top nor bottom. On the bottom is tacked a piece of unbleached calico, and the chaff is poured in lightly when the box is in position on the hive. The calico is not stretched, but is a little loose, so that it may adjust itself over a cake of candy placed under it, while at the same time the edges of the box resting on the top of the hive prevent any escape of heat. This principle can be applied to any kind of hive, and we recommend it in preference to anything else as being both simple and efficient. Empty close-sided section-racks can be used, but if we were making boxes—especially for this purpose we should only make the sides about 3 in. deep, as this we find quite sufficient.

MICE IN THE APIARY.

We have recently had complaints of damage done by mice in hives. They are a great pest in an apiary at this time of the year and often effect lodgments when ingress is thought impossible. They are more troublesome in proportion to the coldness of the climate. Wax is a non-conductor of heat, and besides enjoying the heat generated by the bees, the honey and pollen furnish food, and the comb a comfortable bedding. Skeps are more frequently attacked than wooden hives on account of the deeper entrances of the former. It is almost incredible through how small a space they can crawl, and yet there is no valid reason why they should get into frame-hives if properly constructed, even when the entrances are open the full width. We have always recommended long and shallow entrances, at least 8 inches long and not more than 1 inch deep. With such entrances we have never been troubled by mice, but there are some hives in which the entrances are $\frac{1}{2}$ inch or $\frac{3}{8}$ inch deep, through which it is possible for mice to crawl. It has been recommended in order to prevent mice getting in to reduce the size of the entrance by drawing the slides closer together, but this is only a partial remedy and is frequently of very little use, as they are too knowing to be balked by such an arrangement. They are quite strong enough to push the slides aside and so get through. In such hives we should recommend the use in front of the entrance of wire net four meshes to the inch, and placing this close against the hive behind the slides so that these will keep it in position. This would not interfere with ventilation, and the holes would be large enough to allow the bees free passage to and fro.

A very simple trap was recommended some years ago in the *Journal* which we found very useful in destroying mice in the garden. It is made of two bricks and two sticks. The sticks are driven into the ground four and a half inches apart, and stand four inches above ground. A saw scarf is cut into the top of each. A piece of

thread about six inches long is then drawn through a soaked pea, and a knot tied at each end. The thread is slipped into the saw-marks on the top of the sticks, leaving the pea in the middle between them, and the brick is placed leaning on the thread, with the pea sufficiently under it to ensure the destruction of a mouse if he attacks the pea, as in doing so he is almost certain to bite through the thread and let the brick fall upon him. Such a trap would cost next to nothing, and is easily baited.

THE COMING BEE.

Both in this country and across the Atlantic much attention is now being directed towards the intercrossing of the different varieties of our honey-bees with the object (as suggested by Mr. Grimshaw in his paper on 'Specialisation') of arriving at a combination possessing admirable qualities, a maximum of good points with a minimum of objectionable ones. As a knowledge of disease is half its cure, so a knowledge of what we require in the future bee will in a great measure assist us on the road towards its attainment.

In the first place, we require points in the queen which can only be recognised in her progeny, or can but be guessed at in her ancestry, as the amateur queen-raiser now proceeds to work. When a mother-bee is found, whose progeny yields him the anticipated desirable qualities, he devotes her powers to queen-raising, never thinking, it may be, that in the mating of his young queens these particular characteristics may become all changed. In time the good points become eliminated, and he is recommended to introduce fresh blood, believing at the same time he is improving the race; so he is in a direction which is not beneficial. The introducer of foreign queens of to-day certainly does not know what he is getting. Does he know what he requires? In point of fact he does not need pure races; if he got them he could not keep them pure, and they would interest in the direction of giving him an ultimate production, having all the undesirable and few of the admirable qualities his bees should have in order to make them pay. He works by the queen, in short, instead of by the drone, and we are of the opinion that even the special queen-raiser cannot afford to do this.

By a *festina lente* process such specialists as Mr. Simmins, for example, may at length put us in possession of an insect which will in a great measure arrest the somewhat random importation of queens from countries now sending us queens of undoubtedly mixed ancestry, having, we admit, many admirable recommendations, yet these are frequently more than counterbalanced by undesirable qualities,—fickleness of temper in the progeny, constant tendency to swarm and build queen-cells, besides quite revolutionary ideas with regard to the hours of labour; bad winterers to boot, who only require a variation of a few degrees in temperature to excite them into cleansing flights at times when such a course means certain death.

We must not forget, too, that the importation of queens means the impoverishment in pocket of the bee-keepers of our own country to the benefit of those abroad; and, whatever be our individual notions on the subject of fair and free trade, we cannot close our eyes to the fact that we are morally bound, *ceteris paribus*, to support our own countrymen, who are doing their utmost to forward our science and make a living for themselves by specialising their efforts in either queen-raising or by hive, section, or foundation making.

Then, again, we are of opinion that the imported pure queen *per se* is only required by the special queen-raiser; scarcely at present by the ordinary bee-keeper, unless he

determines to destroy his native drones, and use the imported mother more as a drone-producer with the object of thus getting his young queens (and those of his neighbours) fecundated by them. Are not many of us going the wrong way to work by encouraging the production of pure young queens of foreign blood from the imported mothers, whose purity of race from a breeder's point of view is gone immediately on being crossed with the drones of the neighbouring hives? The well-known theory of parthenogenesis shows us that the drone is 'only the son of his mother,' and the only sex which can be depended on to entirely reproduce in perfect purity the commendable characteristics of his kind. The worker is, of course, an admixture of unknown points in almost every case. It is admitted that our Ligurian is only pure so long as she is purely mated. Now we only require purity, in our opinion, in order that we can impurify it, so to speak, in any particular way we ourselves desire, crossing and intermixing the good points of the several varieties at our desire; that is, if it be conceded that by judicious crossing we can improve a race—a fact in animal physiology now unquestionable, except by the most obstinate. We contend, therefore, that the only safe way of doing this is by looking to the drone and not to the queen as our most important ancestor, for it is he only who is a pure representative of his parent, and who can perpetuate his species purely.

It is a well-understood fact in biology that a sex transmits its own characteristics to its progeny of the opposite sex, therefore (keeping in mind parthenogenesis), by the breeding of drones from the unfertilised queens and from fertile workers (about the virility of these drones, by the way, there is considerable doubt), but worker brood only after fertilisation. This axiom and the proof of the above assumed fact becomes doubly strong when applied to the insect world, doubly so at least with our bee—our worker bee.

The young of a Ligurian queen mated with a black drone is quite a different article from that produced by a black queen and a Ligurian drone. Precisely the same principle obtains in the vegetable world; the pollen of a white *viola* or pansy, fertilising, say, the ovules of a purple one, will produce seeds the flowers from which will almost certainly be purple, having a few white markings. *Per contra*, the pollen from the same purple flower used on the stigma of the same white *viola* gives us, as a result, flowers of white ground with purple markings,—a very different thing.

Let us imagine how a queen-raiser would proceed, if intent upon raising a variety of his own, to approach as near as possible his notion of perfection. He will, as a basis, use, perhaps, our own bee for the production of black queens, as pure (!) as they may be after the intercrossing of recent years. He next imports a Ligurian, or some select foreign queen, and compels drone-raising, destroying his black drone brood and trapping such black drones as are raised in spite of his precautions. The black queens meet Ligurian drones, which transmit the good points of the Ligurian to those possessed by the native bee, these appearing in the worker young, which do not turn out to be the terrific demons so often the dread of the incautious experimenter. Next, he will probably select an imported Carniolan queen, supply her with drone comb, carefully excise or squeeze all queen-cells (and, at any time, the queen of chance swarms will be destroyed, sold, or sent away). He thus gets a second cross containing the characteristic admirable qualities of the three races. An imported Cyprian queen gives us a third cross with the good points of all four varieties. The queen-raiser has now obtained his standard stock, which he can keep fixedly pure and fresh by occasionally introducing a virgin black, Ligurian, Carniolan, or Cyprian queen. Such a mother is not allowed to be a queen-raiser, but, as before, produce as many drones as possible, such introduction being made by the queen-

raiser in exact measure as he wishes to increase or perpetuate some quality he notices to be on the wane in the progeny of his stock quality. To be able to purchase queens from such a man would be a boon, and be ten-fold better than importing and introducing queens by the bee-keeper himself.

The Rev. G. Raynor, at the recent *Conversazione*, opened a discussion advocating the posting of young queens to friends for fertilisation in their apiaries, and, no doubt, for the amateur who desires an infusion of new blood into his apiary the suggestion is a good one; we hope, however, to see 'in the good time coming' proprietary apiaries, where only one variety of bee is kept to which their own young stock queens will be sent for mating, and even the outside bee-keeping public may, perhaps, ultimately be allowed to partake in the benefits of having such sterling stock amongst us.

USEFUL HINTS.

WEATHER.—'And this other likeness too
Well behoves us all to view,
Namely, that to those who eat
Honey-comb, it seems more sweet
If a man, before the drop
Of honey, taste the bitter sop.

So, it falls that all men are
With fine weather happier far
If a little while before
Storms were spread the welkin o'er,
And the stark wind East by North
Lately rushed in anger forth.'

After storms, sunshine; after a winter of extremes we shall all rejoice in the gentle zephyrs and the glorious sunshine of spring and summer, when—

'Emicat omnis ager renovato flore rosarum,
Et passim viridi nube virescit humus.'

Do not those who fly to warmer climes and sunny skies, in order to escape the 'storms and stark winds East by North' of the English winter, fail to realise the full enjoyment of summer when it comes? In what country do we find the stalwart frame and ruddy countenance of the English yeoman? Where shall we find so many centenarians as in the British Isles? Where such thews and sinews as those of the Britons of olden time? We know that—

'Nottingham had archers good,
Derbyshire men are stern of mood.'

But what avail thews and sinews, skilled archers, and brave, stern men, in this scientific age of steam, electricity, dynamite, and what not? Progress! progress! we must go with the times. Compare the bee-keeping of the great Alfred's time—the 'Huniges taere'—with that of our own day of 'extractors' and 'extracted,'—no reflection on our supply dealers in a pecuniary sense. Now we have an extensive bee literature, witness our *Journal*, and woe be to him who neglects it, for he will assuredly fall behind in the race!

MONTHLY JOURNAL.—We sincerely congratulate our cottage friends on the announcement of a *monthly Journal* in addition to the weekly, and trust that county secretaries will do their best to insure it a full, large, and all but a free circulation. Eighteen-pence per annum should supply it, inclusive of the half-penny wrapper, to every cottage subscriber of 2s. 6d. to his county Association, leaving 1s. to the county funds. Surely this is a step in the right direction—a step long needed; and thanks are due to our Editor for venturing on the venture. May it repay him a thousand-fold!

OUT-DOOR WINTERING at present entirely prevails in England, and, in consequence, substantial, well-built, and well-painted hives are a *sine quâ non*.

CELLAR WINTERING.—We are by no means certain

that a system of underground, or partially underground wintering, in dry and well-ventilated storehouses, would not give better results than our present method. An equable, low, and dry temperature of 40° or 45° Fahr., at which the bees will remain quiet and semi-dormant, is a necessity of indoor wintering. It may be, and we are inclined to think that it will be, the future system in all large apiaries.

GRANULATED HONEY.—Virgil tells us that (out-door) ‘hives must have narrow entrances,’ and the reason he assigns is ‘that winter coagulates the honey with cold, and heat melts and dissolves it.’ Our present practice is to give wide entrances—as wide as the hive—both in winter and summer. When bees are crowded on as many combs only as they can cover, even with wide entrances and severest wintry weather, there may be no granulation, and there is no fear of sufficient heat being engendered to melt the sealed honey. But if the bees are not so crowded—if they cover five central frames only, and five outside frames of sealed honey—cold slabs are left in the hive, assuredly, with wide entrances, this will granulate, and probably with narrow ones also. Then comes the question, Is such granulated honey suitable food for the bees? The answer must be, No. We have repeatedly known bees to perish on such combs in the spring, even when the hives were half full of it. When only partially granulated they will consume the liquid portion and cast out the granules. But this liquid honey has become acidulated, and causes dysentery, hence in all cases of granulation it is best to remove such combs, melt them down, and feed on sugar syrup. It is quite possible that by indoor wintering granulation may be altogether avoided, and then entrances of any width may be allowed, or even the floor-boards may be entirely dispensed with. In out-door wintering our experience proves that bees winter far better in hives with double walls, and cork-dust packed, than in those with single walls; but if the latter are used, space should be allowed inside for cushion-packing outside the division-boards. Our own hives are mostly single-walled, but provided with an outer case, which admits of packing between hive and case—a system which affords great facility for tiering up, either for comb or extracted honey.

HIVE-MAKING.—Hives should be as simple as it is possible to make them, and free from all complications, if the object be profit. We advocate entrances the full width of the hive, capable of being contracted, or closed, by the Langstroth triangular blocks; and, in actual working, we find it more convenient to cut out the entrances from the hive fronts than from the floor-boards. All hives should take at least twelve standard frames. Simplicity should also be the rule in sections and section-cases. On hives such as described we recommend impervious quilts, both for summer and winter use, whenever storing is not carried on, with entrances half an inch deep, and kept at full width, except in cases of robbing.

STORED COMBS.—*Frames of comb*, and sections of empty comb stored for future use, should be occasionally inspected, otherwise moth or mite may destroy them.

REMOVAL OF HIVES to other locations in the same apiary should be made without further delay. In fine weather during this month bees begin to fly freely, and great loss of life may result if removals are postponed. Get all colonies, therefore, into the positions they are to occupy during the summer, and keep the apiary clean and tidy.

VENTILATION.—It is now generally acknowledged by all experienced apianists that bottom ventilation of out-door hives in winter is a most important factor in safe wintering. We have for many years noticed that those colonies which had free ventilation at the bottom of the hive came through the winter far better than those whose entrances were narrowed to the customary one, or two, bee passages. In severe winters few of the latter

survived, while we scarcely remember to have lost one of the former. But *upward* ventilation, even through chaff, should not be allowed unless the bees are crowded into the smallest possible space, when excess of moisture would seem to require pervious quilts. Accumulation of moisture must be prevented at all hazards, and we strongly recommend a space of at least four inches below the combs until spring work commences. All things considered, we are in favour of the natural mode of ventilation, viz., impervious tops, full bottom ventilation, not too much crowding, and perfect quiet and rest. Winter, let us hope, will soon be past. These notes are penned with a view to hive-construction, which must soon engross the attention of most bee-keepers in preparation for the coming season.

VIRGIN QUEENS.—We were pleased to read the very pertinent remarks of Mr. Edey (1443) in our last, on the subject of exchanging virgin queens for obtaining fresh blood. His plan of sending wired frames of comb, containing eggs of the various races, seems to us good, as well as simple, and easy of accomplishment. But we would limit it to *eggs* only, which at the normal temperature of swarming time, would suffer no injury from chill or shaking. Queen-cells, or larva, sealed or unsealed, would probably suffer from one or both. We like our queen-cells raised, and queens hatched in full and strong colonies, free from the smallest disturbance during incubation. In preference to sending virgin queens to a distance for the purpose of fecundation, an exchange of such queens *in toto* would obviate, in part, the introduction. This objection, however, really carries but little weight, since a virgin queen may be introduced to any queenless hive with very little risk if proper precautions are taken. Let the reigning queen be removed about noon from the colony to which it is desired to introduce a virgin queen, and on the following day at the same hour drive the latter into the hive with a few whiffs of smoke. If this method be practised during fine weather, when bees are at full work and storing honey, not one queen in a hundred will be refused. The hive must be queenless not less a time than twelve nor more than twenty-four hours—sufficient to allow the bees to discover their loss, but not enough to enable them to fully start queen-cells. There are various other methods by which such queens may also be introduced with very little risk of loss. At the late *Conversazione*, during a discussion on the introduction of fresh blood by the exchange or purchase of virgin queens from a distance, Mr. Baldwin is reported to have said that ‘he thought the object and aim of introducing new blood would be best served if bee-keepers would exchange young *fertile* queens’—a plan which would no doubt save trouble, and one which we have often carried out. But the advantage to be derived must depend in a great measure on the blood so introduced. We should not care to receive young and fertile queens from an apiary where in-and-in breeding had been carried on for years without any admixture of new blood. And this is a risk which we all have to run when making use of imported queens, many of which lack fecundity in a remarkable degree. If we wish to obtain a thoroughly prolific race of bees, let us breed queens from the most prolific mothers we possess, and procure fecundation at a distance from equally prolific stock. That we shall fail sometimes to attain our object there can be no doubt, but that is no reason for not using our best endeavours. From this simple practice of the introduction of fresh blood, great results have followed, and there is little doubt that still greater are in store for all who will systematically endeavour to practise it.

While closing our MS. for the press we have just seen, with unfeigned sorrow, the report of the sudden demise of our co-worker and esteemed friend the Rev.

C. F. G. Jenyns, by which our Association has sustained another severe loss. A true friend, an earnest worker, a most regular attendant at Committee, and an active member of the Board of Examiners—such a man can be ill spared from our already too greatly depleted ranks.

ASSOCIATIONS.

BERKS BEE-KEEPERS' ASSOCIATION.

The annual meeting of this Association was held at the Victoria Café, Reading, on Tuesday night, Mr. F. Cooksey in the chair, the attendance including members of the Society from various parts of the county.

The balance-sheet, presented by the assistant secretary (Mr. A. D. Woodley), showed a balance in favour of the Society of 12*l.* 12*s.* 6*d.* The assets, however, included stock valued at 22*l.* (in addition to 12*l.* outstanding subscriptions and amounts due), so that there was an actual cash deficit of 8*l.* 7*s.* 6*d.* The annual report of the committee stated that this deficit was due to a slight falling off in membership and subscriptions, while the working expenses of the Society showed no diminution. The Society was formed in conjunction with Buckinghamshire in 1879, the two counties being subsequently formed into separate Associations; and chiefly as a result of the Society's operations it was confidently asserted that where one stock was kept ten years ago ten are now kept, and that the production per hive has more than doubled, or, in other words, that for every pound of honey produced in 1879 there are now twenty. The Society's work was, however, by no means done, though in the future it would be devoted more especially to developing the use and demand for pure British honey. The Society was fettered in their endeavours by two obstacles—the undesirability of the Association undertaking the risk of traders, and the want of a means of communication between members themselves and members and consumers. At present the only bond of union was the circulation of the *Bee Journal*, which was costly, and answered its purpose very imperfectly, reaching not more than half of the members, and then only for a day or two. They had accordingly decided to consider at once the desirability of publishing a monthly paper devoted exclusively to the interests of bee-keeping in the county, and as an organ of the Association to be forwarded free to all members; and it was hoped, if this publication was decided upon, that it would be the means of strength and usefulness to the Association and that members would make full use of the opportunity it would offer them. The exhibition of honey, &c., at the Royal Counties' Agricultural Society's Show at Reading, arranged by the Berks and Hants Societies jointly, was a great success, nearly the whole of the honey staged being sold. The thanks of the Association are due to the Society and Local Committee for the handsome grants of money which enabled the show to be carried out at little cost to the Associations. The Windsor Show was also a success, while the Faringdon Show, although a good one, was not a financial success.

The Chairman having moved the adoption of the Report, Mr. Blow gave a practical address, insisting especially upon the utility of the shows, the importance of a visit from the expert to every member of the Association, and supported the proposal to establish a paper. Mr. Webster (Wokingham) was doubtful if the paper would be a literary or a financial success, although he would like to see it in existence. The Rev. V. H. Moyle advocated its publication. The Report having been carried, the Committee was appointed; Mr. Arthur L. Cooper, of Coley Avenue, Reading and Maidenhead, accepting the secretaryship in the place of the Rev. R. Errington, of Clewer, the pressure of whose parochial duties necessitated his resignation, and Mr. A. D. Woodley, of Reading, was reappointed Assistant Secretary. The Rev. V. H.

Moyle and Mr. Webster were appointed representatives to the Central Society. After other business had been transacted, the usual votes of thanks were awarded.

LEICESTERSHIRE BEE-KEEPERS' ASSOCIATION.

The annual meeting of this Association was held on Saturday, January 28th, in the Mayor's Parlour, Old Town Hall, Leicester. The attendance was rather thin, and no wonder, for the weather was bitterly cold. Mr. T. Carter, Mill Hill House, Leicester, was voted to the chair. The Report, after a short discussion, was accepted. The election of officers was then proceeded with, resulting in the re-election of Messrs. Carter, Meadows, Foxon, J. Cooper, Fosbrooke, Atkins, Johnson, Ward, Redshaw, and Rev. M. A. Thomson, and the election of Messrs. J. Clark, Shenton, Day, and Marriott, to serve on the Committee. The resignation of Dr. Emerson's treasurership was accepted, and the Secretary directed to ask Mr. Bickley to accept that office in his stead. The Secretary was re-elected, and a gratuity of three guineas voted to him. A special vote of thanks was accorded to him and Mrs. Ball for their services.

A conversation then ensued on the best methods of bringing the Association under the notice of the public, and the conclusion arrived at that a series of lectures be given and a general meeting be held immediately after. Mr. Meadows was deputed to open negotiations with a well-known expert.

A special vote of thanks was accorded the Leicester Agricultural Society for their liberality.

The date (February 25th) was fixed for next committee meeting, and the proceedings were brought to a close by vote of thanks to chairman.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to state on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to "The Editor of the British Bee Journal," c/o Messrs. Steamers and Sons, Torrey Street, Cambridge Circus, W.C. All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, Kings Langley, Herts (see 2nd page of Advertisements).

In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

VIRGIN QUEENS—CONSANGUINITY.

(Continued from page 48.)

[1454.] By the foregoing remarks with reference to sending virgin queens to distant apiaries to be fecundated, it is almost imperative that they should be sent in nuclei, as by such means there would be a minimum amount of trouble and risk imposed upon the receiver; but even in forwarding them thus, unless this person is expert in queen-rearing, there is a great chance of the queen, as well as the nucleus colony, being lost at the time of one of her flights, although preventive measures ought to be taken by the sender. In introducing virgin queens to a full colony no such risk is run, as an exodus of a full stock having brood is an unknown circumstance. The only casualty to be taken into account would be the one of her being alone lost on such an occasion. This is always risked by every bee-keeper at the time of the queen's desire for fertilisation; therefore it ought not to bear any weight against the present subject or argument.

I have before mentioned the cost of transit from and to the senders of a nucleus colony, which if sent by rail

would be a considerable addition to the cost of the queen. This would not be the case if a virgin queen were purchased and fertilised in the owner's apiary, as she could be transmitted through the post properly packed at the seller's expense, the same only being one penny. Looking at both sides of the question it must be quite evident to all that the plan best to be adopted in order to obtain fresh blood is that of purchasing virgin queens from known bee-keepers, if they can be obtained at a reasonable price and of the quality desired. I do not mean that only Italians should be selected as the change; any description or variety that suits the purchaser's ideas will come within the same line of argument. Even our frequently despised blacks (they ought not to be) could be renovated by these means, obtaining a queen or queens from some considerable distance of a well-known and reliable apiarist and introducing the same into the apiary. I have more specially dwelt upon the subject of Italians, as to the present time their qualities are more fully understood than any other variety of foreign bees. They have not been found wanting, as a most successful cross to our native blacks increasing the much-desired honey yield at once.

Consanguinity.—We now come to that portion of this article upon which all that I have written depends—consanguinity, or, as it is more commonly denominated, in-and-in breeding. We have not far to look to see the baneful effects of this system, which so strikingly present itself in such widely divergent subjects as man and plants. Among the lower order of animals as well as birds we see the same effect produced, in some cases in a more decided manner than others, according to the physical condition and circumstances in which the subjects are placed, hence those unnaturally fed or physically weak are more susceptible to its ill effects than are those where the constitution is physically strong and the surroundings in accordance with their various natural conditions. In my study of physiology as applied to the animal world, I have found that some birds in captivity are influenced to the maximum degree by the fourth generation. This I know is exceptional. In several experiments tried the Barbary dove was thus decidedly affected by its influence; but, in the case of some of the *Rodentia*, it was not perceptible in so marked a degree until the eighth or ninth generation, and even then was, in isolated cases, liable to variation. Not having given to botany so much attention, I cannot from my own experience write in so decided a manner upon this subject; but, from the writings of others and the collected experiences of farmers, seed-growers, and gardeners, the same effect is noted, but not quite in so marked a manner. Can we not then deduce the theory that the lower we go in the scale of living objects the less is it perceptible? The *animalcula* we know are less affected than the higher order of animals, and man commences to succumb frequently in the second generation. If, then, every living object brought before my reader's notice is so affected by consanguinity, may we not take it as an accepted fact that the *Insecta* are, in a more or less marked manner, susceptible to its influences; and as bees belong to this class, our particular attention must be, in the pursuit of the business of honey production, directed to preventive measures.

We will first note how the ill effects of in-and-in breeding are apparent in any subject that may come under its baneful influence, taking as an example the higher order of animals, and from such a description all way with a positive assurance come to the conclusion that the same effects will be reproduced in the genus *Apis*.

When mating very near relations, care is always taken that brother and sister are not so placed. This may be considered the worst form of consanguinity, and therefore even with pedigree animals it is always avoided. Father and daughter, or *vice versa*, is a degree removed, and the ill effects are less marked, and so on as a larger

proportion of extraneous blood is constitutional in the progeny. The ill effects are first seen in a debilitated condition of the offspring. This in the case of bees, upon whose robust constitution we depend for the success of our honey crop, would be a very serious drawback—in fact, a complete failure would ensue. Afterwards, and this is the maximum effect of consanguinity, barrenness, meaning total annihilation. I do not mean to assert that an apiary in the British Islands could be annihilated through the owner neglecting to introduce fresh blood, but each consanguineous cross militates the chances of a successful venture in bee-keeping, as it does in all stock-keeping and vegetal pursuits.

When bees are located within a certain radius of each other, and in an apiary such a radius is of the same extent, and covers the same district of each of the hives as the others, the chances of consanguineous mating of the queen are extremely probable, in fact, will most certainly take place, therefore it is of the utmost importance that occasionally a fresh strain or variety should be introduced into the apiary as a preventive measure. I think I have fully shown how such an introduction can be effected at a minimum cost.

The ill effects of in-and-in breeding among bees I have in several cases witnessed in a most striking manner. Two cases in point present themselves to my mind. An old lady, living in a valley where scarcely any bees were kept, gradually obtained less and less honey each season. At the end of, I think, the sixth, her bees were a complete failure. To this person I have paid as much as 6*l.* during one season for her swarms, honey, and wax; her usual spring count was from three to five hives. There is no disease apparent in the bees; each of her hives is in a similar condition of depopulation. When she had swarms the old stocks were invariably kept until the combs got too old; I had posted her up as to the age of queens. Another case, where the bees were kept in the middle of pine-woods, with plenty of heather in the district, they gradually lost their prolificness, and so ceased to pay. In both cases, I am quite confident, it was the result of in-and-in breeding. Several less decided cases have come under my observation. When debility asserts itself in a living object it is generally considered as a fit subject for the growth of the various diseases incidental to the different organisms, although this rule is not immutable. Being so, bees in such a condition would be more likely to become sources for the propagation of the germs of diseases than when in a robust condition. This is only a common-sense view of the subject, but it is, with all the foregoing arguments and assertions, well worthy the consideration of every apiarist. —W. B. WEBSTER.

COUNTY BEE-KEEPERS' ASSOCIATIONS.

[1455.] I venture to offer a few notes on the work and organization of County Associations, which are based on some years' active experience as a county secretary.

WORK OF THE ASSOCIATION.—It is convenient to consider this in the first place, apart from the question of organization necessary to carry it out.

1. Work for the benefit of all interested in bee-keeping. In the early days of Associations this was put forward as their chief aim, and people were asked to subscribe, not merely to benefit themselves, but to help others. Accordingly, manipulations in bee tents (which for a time paid their own expenses), winter lectures, and exhibitions of hives and honey at horticultural shows, were the main items in the programme. But as Associations progressed they began to offer substantial advantages to members in return for their subscription; and at the present time probably three-fourths of the members expect (and give up subscribing if they don't get it) some direct and real advantage to themselves as bee-keepers, and are not willing that part of their money

should go for the benefit of outsiders. Accordingly, manipulations at horticultural shows (which *now* do not benefit members) should be things of the past except where committees of such shows make a grant to cover all expenses; and the other work I have mentioned should not be undertaken except where the expenditure will be balanced by a direct benefit to members, or except, as in the case of lectures, there is the hope of gaining new members.

2. Work for the direct benefit of members. This should, I think, under present circumstances, be the first consideration; but of course if it is possible (as in *b. c.* and *e.*) to benefit the general public at the same time, so much the better.

(a.) *Experts' Visits.*—These have become among the most important items of work, and should on no account be left out. At the same time, it is impossible, if the bulk of the subscriptions are of the 2s. 6d. and 5s. class, to give more than one visit to members, preferably in the spring, or for that visit to be paid at any other time than on the organized tour. The idea, chiefly prevalent among well-to-do members, that in return for 5s. per year they are entitled at any time to a visit from the expert, who would perhaps have to travel twenty miles and spend a whole day at the one visit, should not be encouraged. It is most desirable to obtain the services of several experts in the county, each to work within a reasonable distance of his own home; this saves expenditure in lodgings and travelling. Experts must in nearly every case be paid, and will either be hive-makers or of the upper artisan class. There should be little difficulty in securing the services of intelligent and experienced bee-keepers of this class in various districts of a county.

(b.) *Lectures.*—As they cost but little, the lecturer being usually unpaid, lectures should be given in as many places as possible. They benefit the general public as well as members, and often result in the addition of subscribers. Admission must be free to the body of the room. My experience, both in this and other subjects, is that the value and attractiveness of any lecture is immensely increased by the aid of the lantern and a good series of slides bearing on the subject. Perhaps it is because I have been a photographer as long as I have been a bee-keeper; but I much prefer a photograph from nature thrown on the screen to a mere copy of a wood-cut, which may show the desired details with greater 'sharpness,' but lacks the attractiveness and fidelity of the natural photograph. This, at least, is my experience from having made and exhibited a large number of slides on many subjects.

(c.) *Summer Demonstrations.*—In our county these have taken the place of tent manipulations. Place—the garden of any member who has frame-hives and will issue invitations. Time—6 o'clock on a June or July (not later than the 15th) afternoon. Audience—all bee-keepers within walking distance. Protection—a screen of netting surrounding the hives and lecturer. Manipulations—any practical work which may happen to be required by the hives at hand, accompanied by practical explanations on the subject.

(d.) *Honey Fairs.*—One central one in the chief town well advertised by hand-bills distributed by hand to every house; managed in a business-like way by a business man; no charge for admission; held on market day, if possible in the public market hall; chief object in view, to sell honey. Our own Honey Fair is successful; thirty members (out of 105 paying subscriptions) sent 1½ tons of honey to the last one, and over half a ton was sold, nearly all retail.

(e.) *Hive and Honey Shows.*—There must be a curtailment of these, and I think it best to keep to one County Show in the year, and that one in connexion with the Honey Fair, so that members may at the same time send honey for exhibition and sale. This is one branch of

work where a good deal of members' money has been spent, partly for the benefit of the public. And now, I think, it is not well to spend money in prizes at Horticultural Shows, except where a grant is received to cover most of the expense.

(f.) *Circulation of a Bee Paper among Members.*—A most important item of work which is all advantage to members, but rather difficult to work for financial reasons. The *Bee Journal* has been almost out of the question, so the *Record* has been utilised, but now the cheaper *Cottager's Bee Journal* will much facilitate matters.

I am of opinion that a good deal of energy has been wasted in well-meant attempts to 'help the cottager.' My experience is that the average cottager is an ungettable individual, who, 'when he will he will, and when he won't he won't'—usually the latter; and that the best way of educating him is indirectly through the example of advancing bee-keepers around him. Cottagers' classes at shows have been a failure in their intention of stimulating improved methods, and a good many cottagers will cease to subscribe as soon as the Association fails to expend some 5s. or more on them in prizes, &c., in return for their 2s. 6d. subscription.

I will in my next consider the organization of Associations.—ALFRED WATKINS, *Herefordshire B. K. A.*

COUNTY BEE-KEEPERS' ASSOCIATIONS.

[1456.] The articles and letters on the above subject that have appeared in recent numbers point to the decreasing interest that is being taken in Association work by the executive of the various Associations. Perhaps, a few lines, even if pitched in a minor key, not to say in a pessimist vein, may throw some little light on some of the reasons why. Of the apparent declension in interest and working of the executive, some Hon. Secs. complain of the paucity of attendance by the members of Committee at the Committee meetings; and not without reason, for very often there is barely a quorum responds to the notice. Allow me to point out that in many instances it is a question of time and the attendant expenses causes a poor attendance. Take a case in fact. Probably, your Committee will be chosen from all parts of a large county to make it as representative as possible, and, say, the meeting is announced to take place in your county or other large town at 6.30 or 7 o'clock in the evening, an hour that suits the members of the Committee residing in, and in the immediate neighbourhood of, the town; but, probably, only a small minority are within easy distance, and the larger number reside in various parts of the county, engaged in various businesses and professions, some, perhaps, several miles from a railway (and that a branch line with only three or four trains per day). Now, probably, those country members of Committee are as anxious and as willing to attend as those living near, and have the success of their Association and the spread to profitable and humane bee-keeping as much at heart as those who, after business and living near, can always put in an appearance at the meetings. Now, the Committeeman from a distance has, most likely, to leave his home and business soon after the middle of the day to reach the town in time for the meeting, and, probably, the last train that would take him to within a few miles of his home leaves the town by 8.15 or 8.30 p.m., and the consequence is he must either leave the meeting before it is half over or lose his chance of reaching home that night, and the consequent discomfort of staying in lodgings and returning next day, with the chance of getting back again about the same time as he set out the day before. This, I think, is a very reasonable excuse for not always attending.

Then, on the other side, if the meeting is held at 2.30 or 3 p.m. to suit country members, the townsmen cannot leave business to attend. Another reason there is not

so great an interest evinced in the Association is the newness is wearing off, the new style of bee-keeping has become more general and the novelty is gone. Three or four years back my apiary was visited during the summer months by a large number of visitors for information, but during last season I had very few comparatively to what I had in previous seasons; and a still more cogent reason is the rapid decline in the price of honey, especially section honey, during the past year or two. We are feeling the depression as a body as much as any other industry, with, as a natural sequence, a diminished interest. If we could still make 1s. each for sections, our hopes would rise and our interest wax warm, and we should sing the praises and the profits of modern bee-keeping in as full a compass as of yore.—W. WOODLEY.

'WHO IS AMATEUR EXPERT?' (1448.)

[1457.] I have great pleasure in informing the Hon. and Rev. Chairman of the Board of Examiners that the 'Amateur Expert' of *The* (not 'A,' please!) *Canadian Bee Journal* is 'the original and only genuine' 'A. E.' of the *B. B. J.*

On page 713 of the *C. B. J.*, after describing 'Straw Sleps' and 'Bee-driving,' I said:—'A third-class expert has to drive a stock in this way: Capture the queen as she ascends and clean out the hive in ten minutes, or he fails to get a certificate—a feat that the examiner probably could not accomplish in ten hours. But there are examiners and examiners, and they all know when it is done well, if they cannot take the tools and show the non-successful how. Do you know the "fortunes of war?" I will tell you. "If you do or say such things you must make the consequences."'

As I *sinned* with my eyes wide open, I await my fate with calmness! I respectfully submit to my readers that I have done *some* of the examiners no injustice, and without wishing to 'add insult to injury' (?), I wish to assure Mr. Bligh that there are two opinions as to the fitness of some of those whom the 'Board' have appointed as examiners, just as there are two opinions as to 'pleasantness' of the chit-chat and the 'friendliness' of the criticisms that have appeared in the columns of the *B. B. J.* to which 'A. E.'s' *nom-de-plume* has been attached.

Our Committee in some matters 'go slow.' My quotation is from the *C. B. J.* for November 23rd. This arrived in England about the 8th of December. It has taken the rev. gentleman six weeks to sift it out and challenge it! And why after six weeks? Is it because I am at present at variance with the Committee, and have only recently given notice that I intend to carry a matter to the annual meeting of the B. B. K. A. because the Committee refuse to take what I consider a common-sense view of a very simple matter, that this question is now dragged in, on the score of 'abusing the plaintiff?'

Oh, 'A. E.,' how hast thou fallen! We had great hopes of you once; but alas! my unfortunate *nom-de-plume* is taken to task again! When Mark Twain takes his next 'tramp abroad' and calls to see me, I seriously shall have to take him to task about the iniquity of using a *nom-de-plume*. I do hope I may induce him to reform, as I may then think of reforming myself.—AMATEUR EXPERT.

DEATH TO WASPS.

[1458.] In letter [1432] on 'Fruit Culture and Apiculture,' Mr. F. Goodrich complains very much about the fruit-destroying and hive-robbing wasp. I have for the last few years lost on an average ten or twelve pounds of grapes from a large vinery by wasps; that is to say, if I did not take the trouble to bag them in muslin. But this year, having started bee-keeping, they (the wasps) tormented the bees so much I determined on

destroying their nests, and the best and simplest remedy is a powder named 'Death to Wasps.' It can be had through any respectable chemist, or from some wholesale chemist in Holborn, London, price 2s. 6d. Mode of applying it is by simply putting half a teaspoonful in the entrance to the nest, and in a few hours' time you can dig out the nest and destroy the larvæ without a single sting, as every wasp will be dead. There is sufficient in one box if one is careful with it to destroy twenty nests.—J. A. A. WOOD, *Watergate Nursery, near Newport, Isle of Wight, January 22nd.*

HOW TO DESTROY WASPS.

[1459.] In answer to the question asked by Mr. F. Goodrich, in his letter of January 14th, wasps may be almost entirely destroyed in any district by offering a reward of one penny for each queen killed in the spring. They will be found hunting along the hedgerows in the early spring, and can be easily caught with a butterfly-net. Boys will gladly undertake this work, and it is astonishing how soon a neighbourhood can be cleared of queens; after which you will see very few wasps, for at least one summer.—W.

BOTANICAL NAMES—HEATHER HONEY.

[1460.] As to botanical names, I suppose I did not express myself with sufficient clearness. What I meant to say was that our three late autumn honey-bearing plants were rosemary, *and* cirrhosa, *and* heather. Our almond-trees are, some of them, already white with blossoms, and the bees are having a little honey-flow all to themselves. This will last till the end of February, so that I think stimulating them is unnecessary for the present.

On the 6th of March, 1887, we transferred a few hives a few miles from here, and already found fresh combs of rosemary honey partly capped. The natives clear out the old combs from their cylinder hives about the 20th of February, preparatory to comb-building anew, so that were it not for the high winds that often prevail this would be a very fine climate for bees.

And now as to heather honey. It is considered very inferior here, and as the price would rule low, I would, like, with your permission, to propound the following:—

Query.—In a heather district where prices of honey are low—say 3d. or 4d. a pound—would it pay to set bees transforming it into wax-comb, and which would be the best method for so doing?—F. C. ANDREU, *Port Mahon, Minorca, January 11.*

[To produce combs you have only to put your frames closer together, say not more than one and a quarter inches from centre to centre. The frames should have guides to the top bar so as to induce the bees to build straight combs. These guides can be pieces of comb or strips of foundation half an inch deep. You need not wait to have the combs filled with honey, but as fast as they are constructed remove them, and any honey contained in them can be pressed out and given back to the bees, preferably at night. We have had bees build comb when the frames nearly touched each other, at one inch from centre to centre, but in this case our bottom bar was only three-eighths of an inch wide, so that the bees could go up between the combs, and the frames were brought from their normal distance apart close together by degrees. We can hardly think it will pay you to produce wax if you can get 3d. or 4d. a pound for the honey. Taking it at as low a figure as 15 lbs. of honey to produce 1 lb. of wax, this would make the wax cost you 3s. 9d. a pound at 3d. a pound for the honey, to say nothing of the time lost by the bees while making it, which would be otherwise employed in gathering. You would hardly get half the price of its cost to you

for the wax. It is therefore very much to your advantage to sell the honey at *3d.* or *4d.* a pound than convert it into wax.—ED.]

FASTENING FOUNDATION COMB.

[1461.] I think the difficulty referred to by a writer in your last *Journal* as to the fastening of foundation comb might be got over by making the sections with a slit along the middle of the top side, as in the bar-frames. The foundation comb could be then slipped through and turned over, dividing the lap so as to let one half turn one way and the other the other.—R. H. S.

ISOLATED APIARIES.

[1462.] In the *British Bee Journal* for January 19th, 1888 (No. 1428, page 73), Mr. Webster asks, 'In what county of England can we go where there are not colonies of bees kept within two or three miles, take any position we like in that county?' I am of opinion there is one county, and that is Hampshire in the New Forest. If he will take a ramble through the New Forest in the summer time it will repay him, for it is a lovely place for any one that has a week or a month to spare.

If Mr. Webster will start from the 'Compton Arms Hotel' at Stoney Cross, and take the main turnpike-road towards Ringwood he can have a nice walk of eight miles without finding a house along the road. The first house he comes to will be an hotel at Picked Post. After leaving Stoney Cross and walking for about two miles and a half he will come to a cross road: no finger-posts, but the road to the right hand takes him for about three miles to a gentleman's house called Broomy Lodge. There are the old straw skeps; I have no doubt: it was so fifteen years ago. If he take the left-hand road for one mile and half it brings him to Baulderwood Lodge. There, fifteen years ago, I saw about seventy old straw skeps; but it is in different hands now, so, perhaps, there are not any at all there now. Then, I think, he can get a distance of about four to five miles, and he will find several places through the New Forest of over two miles.

Let him take the Christchurch road to Lyndhurst or Lymington, he will in that direction, if he turns out of the main road through the woods, find a lonely keeper's house and the briarstone pit and straw skeps, and not any other house for miles.

The New Forest is noted for fine heather, chestnut, whitethorn, and the wild apple. I have known a swarm the first week in August gather fifty to sixty pounds of honey by the first week in October, and then done to death in the sulphur pit. How dreadful!—A. H. MILLER.

UNFINISHED SECTIONS.

[1463.] HOW BEST TO UTILISE THE PARTLY-FILLED SECTIONS.—In the report of the proceedings of the North American Bee-keepers' Convention at Chicago, I find the discussion on the re-use of comb built in sections to be filled with honey the next season. It is gratifying to know that the great majority of bee-keepers consider these combs of great advantage, by which they can obtain larger crops of honey, and of just as good quality, as by the use of foundation. I can hardly understand why some bee-keepers cannot obtain good honey in nice, white combs built in sections the year previous.

Some years ago it was a real perplexity to me to have a lot of unfinished sections in different states of completion, after the harvest was over, and I hardly knew what to do with them. I then tried in different ways to make use of them. Those nearly completed I sold at about half the price of sealed honey, and the rest was given to the bees for completion the next season, and of

which the bees made a bad job, as some of it was granulated, and some was sour, though they fixed it all up as well as they could, and finished them; but it was horrible-looking honey, the sides of the comb were very uneven, besides being of different colours. I was almost ashamed to offer it for sale.

USING PARTLY-FILLED SECTIONS.—After experimenting two or three seasons more, I discovered the right way, though I think I had lost considerable before by trying to make the bees finish nearly all the sections the same season, by changing them around among the hives. This was not only lost time for me, but also for the bees, or rather less honey for me. I now allow my bees to go above toward the close of the honey season, and let them have their own way about finishing the sections; but as soon as the honey season is over, I extract every unfinished section that I have, and let the bees clean them out, when they are ready for the next season. By this method I secured just as fine honey as I do with foundation starters, and a great deal more of it; and the cases with the empty combs are nicely put away, where no mice or dust can get at them. I am glad that there are more bee-keepers who can secure nice honey with these combs, as was shown at the late Convention in Chicago; that Mr. Hutchinson had the nicest lot of honey in Chicago; and that he, as we understand, uses the empty combs.

When I was ready to sell my honey, I have never been asked, 'Are your crates and sections clean?' or, 'Are the combs from last year?' &c. No, not any of these questions have ever been asked, but invariably, 'Is your honey white?' and on this *white* the whole question turns, in selling and buying. If I have my dark honey in ever so nice combs, crates, and sections, it is slow sale, and at a far lower price than white honey; even if the latter is less attractively put up. Of course it is best to have the honey in the best marketable shape, and everything else clean, and in its proper place.—C. THELMANN (*American Bee Journal*.)

COTTAGER'S HIVES.

[1464.] In the *Journal* of January 26 I read with great interest a most instructive and detailed article on the 'Champion Cottager's Hive,' by Mr. C. N. White. The hive so designated is presumably an introduction of Mr. White's, and is, I suppose, supplied by him to purchasers. In a spirit of friendly criticism perhaps he will allow me to make a few remarks as to the construction, form, and probable cost of the hive under notice, and its claim to be considered the Champion Cottager's Hive. In his introductory sentences he refers to it as a hive adapted to the wants of those bee-keepers who may desire to adopt the modern bar-frame system at a small initial outlay, and again in almost the same breath, as equally adapted to the wishes of those who, not desiring to give up altogether the old-fashioned skep or fixed-comb hive, yet require a sort of happy medium between the ancient and modern plans, and consequently welcome a hive made of wood, square, and having a top which is fixed or moveable at will and perforated for supering. It strikes one as slightly anomalous to describe an article as capable of adaptation to two such widely dissimilar methods of management. The boxes are of the standard size it is true, but from the description it is not clear how a standard frame could be accommodated, no provision apparently being made for hanging frames of any sort. Any deviation from the standard size of frame is much to be deprecated. It is the recognised national size, and is a standard round which all British bee-keepers rally throughout the world. Every appliance-manufacturer, Association, or individual bee-keeper, should regard any infringement with suspicion, and should consider as carefully as possible an institution in the bee world of such recognised value as the 'standard frame.' At the

same time it is not intended to reject all suggestions of improvement, but discourage so-called reform which is too often a change without being an advance. A hive which cannot take the standard frame forfeits its claim to be regarded as a frame-hive.

The Champion Cottager's Hive is a single-walled hive, and is on that account to be considered as inferior to the old straw skep in point of ventilation and in interior healthiness. This, perhaps, is a matter of opinion, but in fourteen years' experience, during which I have wintered bees in $\frac{1}{2}$ -inch and $\frac{3}{4}$ -inch single and double-walled hives, as well as skeps of all forms, I have proved to my own satisfaction that the double-walled hive with packing space is incomparably the best. I hesitate to cross swords with such a master of the art as Mr. Simmins of Brighton on any point of apiculture, but I am of opinion that double walls all round, and not on two sides only, are much to be preferred and offer no obstacle to the rapid diffusion of warmth during a spell of winter sunshine. As a medium between the ancient and modern bee domicile, one possessing some of the advantages and disadvantages of each, the Stewarton hive, holds the field against all competitors as yet, though like all the others, rather out of the reach of cottagers on account of the price. The great obstacle to the spread and development of the modern system of bee-keeping among the cottager classes is the first cost of the hive. The Champion Cottager's Hive first noticed, although cheaper, presumably, than any other, so far as I know at present in the market, is yet, I expect, too dear for the general run of artisan bee-keepers. When a good sound bee-hive, fitted with ten frames and a window-roof, and floor-board and cushion, double-walled, and painted, can be produced at a cost of 2s. or 2s. 6d., then will it compete successfully with the straw skep at 1s. 6d., and make good its title to the name of the Cottager's Champion, and then will the long-hoped-for day when every cottage garden possesses a bar-frame hive be near its accomplishment.—E. J.

THE STANDARD FRAME.

SHOULD THE 15 $\frac{1}{2}$ TOP BAR BE ADOPTED?

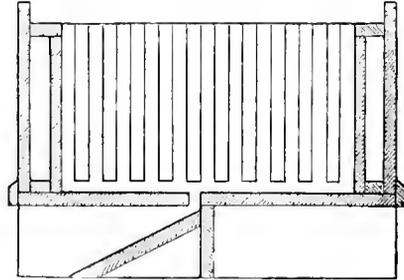

[1466.] Your esteemed writer of 'Useful Hints' of Jan. 5 states his views very clearly under the above heading. There is little doubt the Committee of the British Bee-keepers' Association, who in 1882 fixed on the size of the frame and also the length of top-bar, viz., 17 inches, at that time completed a most important step for the advancement of bee-culture. The size of the rectangle of the frame—14 × 8 $\frac{1}{2}$ outside—is all that could be desired. But I agree with 'V. H.' that this point of the length of the top bar should not be defined, and should be re-considered by the General Committee. Some of our veteran bee-keepers will perhaps say, 'On what grounds, then, do you think this alteration should take place?' It is a well-known fact that the manufacture of hives and appliances has been advanced in this way. At the annual shows of hives and honey, prizes are awarded to what the judges think the best, and the hive that gains the first place is perhaps bought by some local bee-keeper, is taken home as a pattern, and in a short time the district is filled up with the first prize hives. In 1882, and for several years later, prizes were awarded almost exclusively at our shows to hives ranging in price from three to six pounds sterling. They were most elaborate structures, 'having the most complete arrangements for summer and winter use, &c., &c.' At that date, no doubt, the 17-inch top bar would be the universal favourite. Within the last two years, however, matters have changed *in toto*: instead of these high-priced and ingenious hives carrying off first honours, prizes are awarded now to those that are ridiculously simple and cheap in comparison.

Competition may have something to do with this, but

the main reason is that bee-keeping is getting more to be recognised as a business and less as a hobby. Should the B.B.K.A. be prevailed on to reconstitute the Committee of 1882 that fixed on the standard frame I believe they would not be unanimous now in determining the length of the top-bar at 17 inches. All that is necessary would be to allow in competition the short and top-bar equal chances, and that the size of the rectangle of the frame remain unchanged.—WILLIAM McNALLY, *Glentuce, Scotland.*

HIVE ENTRANCE.

[1467.] I enclose sketch of new hive. There is nothing very new about it, except the alighting-board is fixed underneath on the slant. At the top of the slant a slot is cut, say, 6 in. long in the bottom-board, forming

the entrance to the hive, which I think is a great improvement on the present patterns. With this arrangement I think will be found the following advantages: Facility of hiving a swarm; bees have more control over robbers; they can come out in all weathers; young bees take an airing in safety; as the alighting-board is always dry; all dead bees, &c., brought to the hole fall out clear of the entrance. I would like some of our able bee-keepers' opinion on it, as I am only a new beginner.—W. CORKHILL.

NOTES ON BEE-HIVES.—SECTIONS.

[1468.] Respecting my note upon the above in the issue of the *British Bee Journal* of the 26th inst., I have received the following letter from Mr. T. B. Blow, which I think may be read with interest by some of your readers:—

'Welwyn, Herts, January 26th, 1888.

'DEAR SIR,—We have a patent on the thing you describe in the *Bee Journal*. We do not want to unduly interfere in the right of private individuals, but if there is any attempt to import a section with a groove all round the inside they will be stopped at the Customs. We shall be happy to send you a section to show you what it is. We may say that we shall have 50,000 in stock in a few days. We enclose you a cutting from the first proof of our new catalogue.—Yours truly, T. B. BLOW.'

Upon receipt of this note I at once wrote to Mr. Blow to say I had been using a groove all round the inside of sections during the past three years, and that I had mentioned this method of fixing foundation to friends upon various occasions, viz., to Messrs. Lee, Heddon, Neighbour, Howard, Simmins, Hewitt, &c., that I had a machine for turning them out, and had been doing so for three seasons; and asking Mr. Blow to say whether Mr. Howard's description (of using grooves for fixing foundation) appeared in the *B. B. J.*, or the *Record*, prior to his attempt to obtain a patent for this object.

The first season I used grooves my finished sections were not free from pop-holes owing to the wood-corners of the one-piece sections, but I had sufficient evidence to indicate that foundation could be fixed by this method, and that it merited further trial. In 1886 I cut out the wood-corners with my pen-knife and found a great im-

provement in the finish, but cutting away part of the wood of the section spoiled the shape of the section a little. Last season I used a number of $4\frac{1}{2} \times 4\frac{1}{2} \times 7$ to the foot, four-piece pin-dovetail sections, and now prefer this section to all others. But I should here state that my hives and bee-appliances are all fitted up regardless of cost, with the object of securing the best materials and apparatus obtainable. I suppose the sections I mentioned cannot be obtained here at the present prices of ordinary one-piece sections. I might add to my notes that I use Heddon's zinc-slotted queen-excluder, and also have a bee-space above and below the wide frames that contain the sections. I use shallow brood-cases, which are exactly similar to the surplus cases, and may be used as such, but these will require a separate description.

Some months ago Mr. S. Simmins wrote me to say he had tried grooves all round the inside of sections for fixing foundation, but it would not answer very well. I think this was owing to the sort of foundation which he used, or the style of section or the kind of section-case he experimented with.

I knew nothing about Mr. Blow trying to obtain patent rights until I received the above note. I have tried the grooves for fixing foundation in both the Glamafon Apiary and my bee garden at Tref Eglwys. My friend Nicholas Bennett, Esq., J.P., last year, whose ingenuity I have already noted in the *British Bee Journal*, kindly made me a present of a beautiful little plane for making grooves in sections, in addition to an apparatus for adjusting the groove to the centre of sections of any width. These appliances were similar to what he was already using himself, but I should confess they were only accepted as they were more neatly made than my own. I will add that I was constrained to mention this way of fixing foundation in sections through the remarks under 'Useful Hints' in your issue of the 5th inst. I might, of course, have written at least two years ago, but I prefer thoroughly testing a thing before giving or offering an opinion. I think it is only just to state that Mr. J. H. Howard, of Holme, Peterborough, has been in frequent correspondence with myself during the past three years upon the subject of grooves for sections and frames, and has sent me several samples of sections and frames with grooves all round, together with samples of his very excellent wax-foundation from his factory at Holme. Of course if Mr. T. B. Blow can justly claim a patent right for sections with grooves all round I congratulate him. I think, however, we might as well try to patent common needles and pins as to try to secure a patent right for the above, as so many factors are necessary to secure perfect sectional honey, and as British bee-keepers are striving to create a market for this industry, free from all hindrances. I should like to add that both Messrs. Neighbour and Howard have executed some orders for me in the highest state of perfection.—T. BONNER CHAMBERS, F.L.S. London, *Tref Eglwys*, January 27.

PARALLEL v. RIGHT-ANGLED FRAMES.

[1469.] It seems to me that your correspondents are making this a question of Tying *versus* Combination instead of the above. This does not seem right to the 'parallel' side of the question, because very many ten or eleven-frame hives are on the parallel system, and thus just as suitable for tying as any right-angle frame hive. At the present time the combination principle seems in disfavour, and if the question is confined to the use of parallel v. right-angle frames, the parallel will probably come out best. The majority of opinion seems decidedly to be, that (size of hives being about equal) the parallel is the most convenient to manipulate. The only opinion I have seen advanced against this is on account of the length of hive from back to front, but this is outside the question, as I have shown. The letters of 'W. R.' and

'W. B. C.' editors of the *Record*, are also outside the question because they have both taken it up as a question of combination *versus* tying. The argument of 'W. R.' that 'every passenger has to burrow or scramble round *each* of the ten or eleven frames,' shows that he has mistaken the question. In using parallel frames for a tying hive, here is how that argument would look. The laden bees instead of going up through the brood nest can at once go straight up the outer comb into the super. Altogether, I think this question resolves itself into one of convenience of manipulation, and I think that as such the parallel method is best.

If the question has been wrongly taken up by me and Combination *versus* Tying is meant, please give it its right name and prevent confusion.—GEORGE D. CLARK, *Kirklandhill, Dunbar*.

FRAMES.

[1470.] After nearly ten years' experience with frame-hives, I must say that for all-round purposes I prefer hives with frames at right angles to entrance. In my apiary (some 100 hives) I find the bees winter best on this system, and in the honey season the first stocks to start work in the supers are generally those with the frames at right angles. The American hives are almost all on this plan. The hives with frames parallel to entrance are, however, handy for some purposes in an apiary, and I should never entirely discard them. I find the generality of my customers prefer the parallel system.—G. STOTHARD, *Welwyn, Herts*.

EASY METHOD OF RENDERING WAX.

[1471.] For a while past my stock of wax odds and ends has been accumulating, because boiling down wax has always been the most disliked job in connexion with my bee-keeping, and the Swiss extractor is too expensive to be used by me. However, I have got out of the mess by the following plan which I can heartily recommend to those who have small quantities of wax. My wax was stored in a tin biscuit box. Through the bottom of this box I made a large number of small holes, then I got a dish wider and longer than the biscuit-box, and about four inches deep. This dish I filled almost full of water and then placed the tin box with wax above it, fixing the bottom of the box about an inch above the surface of the water. Then I placed both into a hot oven, and on going back an hour afterwards, was delighted to find all the wax melted and run through the small holes into the dish beneath. The dirt was all left in tin box above. On allowing the wax and water to cool I got a cake of beautifully clean wax, and with, as you will see, the smallest amount of trouble and no expense. I suppose if the combs were old and very dirty the wax might require to be run through again.

This method may have been mentioned in *B. B. J.* before, but not having seen it, I give it for the benefit of small bee-keepers. With best wishes for the success of your *Cottager's Journal*.—GEORGE D. CLARK, *Kirklandhill, Dunbar*.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

MICE IN APIARY.

QUERY.—I should be glad if you would advise me on the following point: In one of my hives I noticed today an unusual commotion, and at the entrance I found

small particles of comb. I wondered what made the bees carry out this comb, and being rather anxious about them I ventured to open the hive by lifting up the quilt. No sooner had I done so than a mouse ran out at the entrance. Suspecting this to be somehow the cause of the commotion I took out some of the frames, and you may imagine my astonishment when I saw that the combs had been nibbled away, and in one of them there was a hole more than three inches across. I followed your advice and left the entrances open the full width, but as they are only a trifle more than half an inch deep I cannot understand how a mouse could squeeze through. What do you advise me to? I have set a trap and hope to catch the rascal. I have not ventured to examine any of my other hives, but thanks to your instructions, which I have always carried out, they appear in good condition, and am anxiously looking forward to the spring when they will begin work.—A. W. B.

REPLY.—Your entrance is too deep and should not be more than $\frac{2}{3}$ ths of an inch. Leave the hive alone for the present, as you are more likely to do harm than good by disturbing the bees, but we should place a piece of wire net four meshes to the inch against the entrance. For more particulars consult our article on 'Mice in the Apiary,' page of the present number.—Ed.

J. G. SNOOK.—*Growing Heather*.—It is quite possible to grow heather or any other hardy heath in a private garden, providing the soil is suitable for its growth. If the soil is not naturally peaty the only alternative will be to procure as much peat as is requisite and plant good, strong, established clumps of heather, which will flower the first season. This operation should be done in February or early in March in order to get the plants thoroughly established before the hot weather sets in. If our correspondent put himself in communication with Mr. H. Dobbie, Nethersett, Norwich, he would, we feel assured, be pleased to give him all the information required.

WELSH NOVICE.—*Shale*.—The heap you mention might be profitably utilised by planting it with borage, golden rod, and French honeysuckle, planting the two latter round the base and giving the greater part up to borage. French honeysuckle and borage may be sown and golden rod planted in March. As borage is an annual it will flower this year. 2 lbs. of borage seed and 1 lb. of French honeysuckle will be sufficient, and the remainder may be planted with golden rod and broom.

A. CALPNEHEAD.—*Robbing*.—It is rarely that robbing begins so early as January. Are you quite sure that it is a case of robbing? If so, contract the entrance to about half an inch, and when the weather is mild enough for bees to fly, apply a little carbolic acid solution around it, and on the alighting-board.

C. A. J.—*Clipping Queen's Wings*.—The queen should be tenderly grasped between finger and thumb, in the left hand, across the thorax, and with a pair of sharp scissors the tips of both wings on the same side should be removed. The operation is very simple, but care must be taken not to injure the legs. The disadvantages are: (a) Bees often supersede clipped queens; (b) strictest watch must be kept at swarming time, or the queens, falling to the ground, will be lost. We should say that nine English bee-keepers out of ten disapprove the practice.

KINGSTON.—*Zinc Excluder*.—If a prolific queen with her colony is confined to eight frames under section-cases, with free access to the latter, it is probable that she will ascend and spoil sections. But much will depend on weather and income. A strong colony should have ten standard frames in the brood-nest. We are in favour of a modified Heddon honey-board (which we think Mr. Neighbour supplies) beneath

supers, but by no means use plain excluder zinc laid flat upon the frames.

J. A. A. WOOD.—*Pollen Gathering*.—The pollen your bees were carrying in was probably collected from the groundsel (*Senecio vulgaris*), which flowers freely in the winter whenever there is a spell of open weather.

LINCOLNSHIRE BILL.—1. *Doubling Boxes*.—The boxes will have to be made to correspond in size with the inside walls of the hive. 2. *Bee-space in Body-box*.—The bee-space is on every side of the body-box, no matter how many doubling boxes you have on. The size of doubling boxes is a matter of individual opinion. We prefer them to hold ten frames. This is the usual size, but many prefer a box of this size but much shallower, holding special shallow frames for extracting, from five to six inches in depth. 3. *Transferring Bees to Bar-frame Hive*.—Any warm day in April, but for a novice it is best to wait until three weeks after they swarm. 4. *Extractor for Loose Comb*.—Any extractor will answer your purpose if provided with a loose cage to hold the pieces of comb, this cage being placed within the cage of the extractor.

B. McD.—1. *Article on Sections*.—We have forwarded your thanks to Mr. W. B. Webster. The sheets of foundation are only fixed at the top. 2. *Spreading Brood*.—Do not attempt 'spreading brood,' it is a very risky operation even with an adept. 3. *Full Sheets of Foundation or Starters in the Brood-nest*.—In a heather district, where clover or early honey is of little or no value, we should use starters of about an inch in depth; but in other districts, where the early honey crop is a consideration, we should use full sheets.

H. M. B.—*White Super Foundation*.—The sample sent melts at much lower temperature than pure beeswax, viz., 40 F. We should not think of using it for foundation in sections, as the unmistakable odour of *Cera japonica* (earth-wax, used in the manufacture of candles) would taint the honey, and so spoil the sale of sections. We do not care for pure white foundation, the colour is not natural to beeswax.

W. J.—1. *Avoiding increase of Stock and getting rid of old Queen*.—Your plan would do. We should prefer placing swarm close alongside the stock to which it belonged until the new queen is laying well, then unite, shifting the hive that is to remain midway between where the two had stood. 2. *Patent Hives*.—There are plenty of good hives unpatented. If you are in doubt as to any particular hive, send particulars, and we will endeavour to help you.

H. J. A.—1. *Transferring to Frame-hives*.—Early in April if the weather is mild and bees flying freely. 2. *Getting Combs drawn out*.—Once your bees have got well to work in their new quarters you can from time to time introduce fresh sheets of foundation in the brood-nest, and if the bees are fed gently and regularly, they will draw same out if the weather is genial in about twenty-four to thirty-six hours. Remove that and replace with more foundation. Do not try to get too many done, as it is a considerable tax on them. Six per hive should be enough to make a good sheet for the doubling box.

W. A. T.—Your address was mislaid.

W. ROBINSON.—*Large Apiaries in Yorkshire*.—1, Rev. J. Challoner, Newton Kyme; 2, John Dixon, Great Ayton, Northallerton; 3, W. Dixon, Beckett Street, Leeds.

D. M.—No. It should be reboiled and mixed with fresh sugar. It is not sufficiently soluble for the bees in its present dried condition.

A QUERY.—Will 'T. H.' kindly say if he fastens the pieces of wood for keeping the frames a proper distance apart at the bottom permanently, or does he let them remain loose?—A. C.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

PRACTICAL WORK IN THE APIARY. QUEEN-REARING.

'I wish Mr. Cowan would write a leaflet, or in the *Journal* give a person who has not time to work scientific dodges a plain, easy way to understand of raising our own queens from an ordinary stock of bees (from frame-hives, of course). There is so much conflicting information, a few lines from him to tell an amateur how to start and go through with it would be a great service to many.—S. J. STEVENS.'

It is quite true, as our correspondent remarks, there is so much conflicting information respecting queen-rearing that it is often puzzling for an amateur or young bee-keeper to decide on the best and simplest plan. It is often thought that as queens are to be raised from common bees, any stock will do, but no greater mistake can be made. The queen is the life of the colony, and upon having a good one entirely depends whether the bee-keeper reaps the benefit of a good honey harvest or otherwise. Every one must have noticed that there is a great difference in the behaviour of various colonies. One will with difficulty be induced to take to supers, and will persist in swarming; another will do neither, whilst others again will be noticed to be eager in occupying all the space provided for them, build combs, collect honey, and not think of swarming. If we were to allow queens to be bred from such stocks, we should gain nothing by it, but, on the contrary, be the losers. Every bee-keeper should do his utmost to improve his strain of bees, be they even the common blacks, and this he is able to do by judicious selection of the colonies from which he intends to raise his queens. The secret of success in bee-keeping is, as we pointed out many years ago (*British Bee Journal*, Vol. II., page 186), in having young and vigorous queens at the head of colonies, and in constantly replacing them as they become worn, and we are pleased to find advanced bee-keepers are now beginning to adopt this plan.

As we are strong advocates of simplicity both in hives and methods, we will endeavour to give such instructions as will enable any bee-keeper to utilise what he may possess without the necessity of going to the expense of anything special for queen-raising. Presuming that the bee-keeper has several colonies of bees, he will have spare hives, and he must provide himself with a pen-knife and a few pins. Some recommend special hives for forming nuclei, and this may be necessary when hives on legs are used, but we prefer them without, and use our ordinary hives for the purpose, which can at any time be made

up to fill colonies, if we wish to do so. The inner boxes need only be used, and can have a second empty box put on the top to protect the feeder and over this a board for a roof. If the bee-keeper has only hives on legs he would do well to have a few make-shift hives, which he can easily make himself at a very trifling cost.

In selecting a colony from which to raise queens the bee-keeper must pick out the very best he has, one whose queen is in her prime and whose workers are industrious, good honey-gatherers, and not inclined to swarm. Although authorities differ on this point we prefer raising queens early in the season, so that they can have the whole summer before them, and thus enable the bee-keeper to form some idea of their good qualities before he puts them to real work the following year. The colonies we select must be very strong, and by stimulative feeding we can get the hive filled with bees and brood. All drone-comb should be excluded, frames containing any being removed, and others of worker-comb given in place of them, for this hive will only be used for raising queens, and no drones should be permitted to hatch. In this way we prevent the possibility of the queen mating with drones from the same hive, as it is obvious there would be none, since we have excluded all drone-comb and thus have prevented their production. In this manner we prevent that in-and-in brooding which is so detrimental if queens and drones are raised in one hive.

We commence by placing a frame of clean, empty worker-comb in the centre of brood-nest, which will be filled with eggs by the queen. Three days after this the queen can be removed, as well as any frames containing uncapped brood, except the one we introduced, and which now contains eggs. We remove the uncapped brood because we wish to make sure that the grubs, which are to be used for raising queens, receive the proper attention from the first. We have always insisted strongly upon this point, and have had ample evidence in our long experience of raising queens to prove that our practice is right.

Without entering deeply into the theory of the question, it is sufficient to say that it is based upon the discovery of Leuckart that the larvae of workers were weaned after the third day, by the gradual addition of pollen and honey to the food supplied them by the nurses; whereas those destined for queens receive the same food during the whole of their larval existence, without any admixture of pollen or honey; and further, that this brood food is administered in greater abundance.

The bees will commence queen-cells, and we can assist them by enlarging the mouth of any particular cell we wish them to start upon, in such a way as to break down the walls of the adjoining cells, especially those beneath.

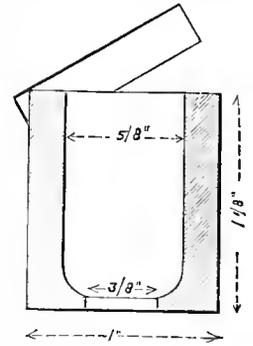

We generally cut off the edges of the comb, and get our cells started along these. They then usually hang down, so that they are more easily cut out. A large number will be constructed, and if we do not require

them all the earliest ones are selected, and the others destroyed. The bees should be gathering both honey and pollen in quantity when the cells are started and until they are capped over, otherwise they must be supplied with food artificially. In about eight or nine days from the time the queen-cells are started the bee-keeper will be ready to form his nuclei. We always use our ordinary hives for this purpose, and for several reasons do not recommend the small boxes sometimes used. The nuclei can be made up from any of the other hives having young bees. Two frames containing brood and honey will do for a nucleus, but three frames are better, because if these are well covered with bees the hive would be warmer, and there would be less risk of chilling. In taking the frames out of the hives take care not to remove the queen with them. Place the frame in the hive close up with division boards, and as all the old bees will return to the stock hive, shake or brush the young bees from one or two other combs into the nucleus, so that there should be as many as could well cover the frames, and be able to maintain the proper temperature. In this way form as many nuclei as you have cells to introduce. We then on the next day with a very sharp knife, cut out the queen-cells very carefully, so as not to damage them in the slightest degree. If the bee-keeper is not very proficient at this sort of work he had better cut out one cell at a time, and return the frame from which it was taken to its position in the hive until the cell is inserted in its place in the nucleus. There will then be less chance of the inmates being chilled or the cells damaged. In cutting them out leave a small piece of comb attached to each cell, and by this pin it to the side of one of the combs with its point downwards. The next frame is brought close, so that the cell hangs down between the two combs without touching them, they only coming in contact with the piece of comb attached to the upper part of the cell. The space is then closed up by the division board, covered with the quilt, and the bees fed gently with syrup. The nucleus must be watched to see if sufficient bees remain, and if too many leave give them more in the way already described. In from three to four days the queen will hatch, and in about a week or ten days after she will become fertilised. Before the queen leaves the hive for fertilisation, remove one of the combs, and replace it by another containing brood. Unless this precaution is taken, and there is brood in the comb, the whole of the bees may leave the hive with the queen when she goes out to meet the drones, and so there would be a chance of losing all. If brood, however, is given them, they will remain in the hive, because bees very seldom desert young brood. The queens may be left in these nuclei until they are required.

We have described the plan we prefer and have found the simplest and most successful (see our remarks in *B.B.J.*, 1883, page 2, Vol. XI.), but as an alternative one, some bee-keepers recommend instead of removing the queen from the best hive, and having the queen-cell started in it, to get the queen to lay eggs in some clean worker-comb, and then give the frame containing this to another hive. Of course the queen of this hive and all uncapped brood should be removed so as to make sure that the queen-cells will only be raised from the eggs we have introduced. Some bee-keepers introduced the queen-cells in a cage, Mr. Doolittle using one of wire: but the simplest thing in this way was one we saw in our journeying in America, and is used by Captain Hetherington. It consists simply of a block of wood $1\frac{1}{4} \times 1 \times \frac{3}{4}$ in., having a $\frac{3}{8}$ in. hole bored down to within $\frac{1}{16}$ in. of the bottom, and here the hole is reduced to a little under $\frac{3}{8}$ of an inch. The queen-cell is introduced into this, the point projecting below, and the tin lid closes the opening above. We give an illustration of this cage in section, so that the merest tyro can make one himself. It is placed between the combs, is kept in place by them, and the bees are not able to destroy the

cell if they are inclined to do so, but such an incident has rarely happened to us in introducing the cells in the ordinary way.

So far we have only considered the raising of select queens, and if we do no more than what has been described we must take the chance of our queens mating with drones from any other hive. But we can go a step further and select our drones. For this purpose we select our next best colony and use it for drone production. This hive must also be stimulated so that it is well filled with bees and brood on most of the comb. When we find this to be the case we remove one or two of the brood-combs from the middle of the hive and put in their place frames containing drone-comb. By feeding more rapidly the queen fills the drone-cells with eggs which will produce drones. As soon as the drones begin to hatch out it is just the right time to start the queen-cells in the other hive, so that when the young queens are ready to fly the drones will be in a condition to do so too. To further ensure a better chance of success we should prevent the production of drones in all our other hives, and have none others in our apiary but the selected ones. In this way queens are raised under the most favourable conditions, and are far superior to those started in nuclei with a small lot of bees, a plan frequently adopted by queen-breeders. Of course, by adopting this plan we must run the risk of the queen mating with drones from a distant apiary. Where a large number of queens are required the plan may be varied a little; but a description of this must be deferred to a future article, as well as the methods adopted for insuring fertilisation by selected drones.

SIMMINS' BEE COMPANY, LIMITED.

We are now about to have the question, Will a Bee Farm in England pay? put to a practical test, and we are sure our readers will concur with us when we say the first venture in this direction could not be confided to a more honest experimenter and withal a more competent man, than our respected correspondent Mr. Samuel Simmins of Rottingdean. During recent years he has attained a very prominent position as a queen-breeder; and we may say that having personally inspected his Rottingdean and Balsdean Apiaries it would be impossible to conceive places better adapted for this most interesting pursuit. In whatever direction we looked we found evidences of much thought and careful consideration. Mr. Simmins will continue to manage the affairs of the Company, it having purchased the sole right to use the name of 'SIMMINS' in connexion with bees, honey, and appliances, for the next twenty years.

Were bees and honey the only articles on which the Company proposed to rely for profit we should have some doubt as to its ultimate success; but as queens and appliances are to form a very considerable portion of the Company's business, thus utilising all hands during winter as well as summer, there seems to be no tangible reason why success should not crown their efforts.

We shall look forward with considerable interest to the first balance-sheet, when we hope to be able to congratulate the Company on having shown that there is money to be made by the development of our especial hobby into a national industry. In the meantime we have great pleasure in expressing our good wishes towards the Company, and our earnest desire that it may eventuate in success.

In Memoriam.

THE REV. C. F. G. JENYNS.

It was with a peculiar thrill of pain and regret that we read the concluding paragraph of the 'Useful Hints' of last week announcing the sudden demise of the Rev. C. F. G. Jenyns, Rector of Knebworth, Stevenage, Herts; and all who were acquainted with the deceased will readily join in the warm eulogium therein pronounced of his sterling worth and of his earnestness in the cause of bee-keeping.

The Rev. F. G. Jenyns was born on November 13th, 1827. He was educated at Bury St. Edmunds, after which he entered Emmanuel College, Cambridge. He there took a great interest in athletic sports, especially in boating and cricketing. He was in the College boat and in the University eleven. After leaving College, he obtained a curacy at Melbourn, Cambridgeshire, under the Rev. Mr. Selwyn, Professor at Cambridge. After serving the curacy for two years, he was appointed vicar of the same place, and here he remained twenty-one years. In the year 1874 he was collated to the rectory of Knebworth, Herts, the home of the family of the Bulwer-Lyttons, where he has been for the last thirteen and a half years. In the year 1856 he married Miss Rose Emily Bulwer, and leaves three sons and two daughters to deplore his loss. He died very suddenly on the 26th of January, and was buried on the 1st of February. The Committee of the British Bee-keepers' Association was represented at the funeral by Captain Bush, R.N., and the Rev. J. L. Seager; and amongst others present the following bee-keepers were noticed, Mr. J. P. Sambels, Mr. T. B. Blow, Mr. G. J. Buller, and Mrs. Maynard. The gentry from far and wide gathered to show their respect; and, notwithstanding the extreme severity of the weather, many ladies were present. In the neighbourhood of Stevenage there was probably no one more highly respected by all classes. He was a man of wise judgment and of great sympathy and kindness to all, both high and low. As a parish clergyman he had done a valuable work both at Melbourn and at Knebworth.

Mr. Jenyns joined the British Bee-keepers' Association in 1879, and was elected on the Committee at the election of 1884, since which time he has taken an active part in the work of the Association. He was conspicuous by the regularity of his attendance at the meetings, and by his impartiality as a judge.

In August 1884 he entered with great spirit into the controversy raised, in the *Times* newspaper, by the Hon. A. F. Leveson Gower, as to the position of bee-keeping as an industry in England. Mr. Jenyns' letter on that occasion was a valuable addition to those that were elicited from other advanced and experienced bee-keepers. His letter more especially embraced the work that had been performed by the British Association since its institution. The most interesting point was the means adopted to ensure that those employed as experts should be competent to instruct cottage bee-keepers at their own homes and in their own gardens.

Mr. Jenyns ever showed much interest in the educational aspect of bee-keeping, and at the quarterly *Conversazione* held on July 23rd, 1885, he read an interesting and exhaustive paper on that subject. In this he argued that bee-keeping should be introduced as a 'class' subject to elementary schools, and endeavoured to prove that as the tendency of bee-keeping is to make the man, so also it would educate the child, to be observant and accurate, to be prompt, ready, and provident, and to be

kind to God's creatures and attentive to their wants. His great aim was to make the study of bees and intelligent bee-keeping truly educational, and his earnest desire was to ascertain how that study could be most profitably promoted. And the conclusion he arrived at was that the Educational Department should move in the matter, so that bee-keeping should take its place as a subject in elementary schools; and not in those only, but also in the great middle-class schools and in the agricultural colleges of the kingdom—not merely as an educational subject, but as a profitable national industry.

At the instance, and under the auspices, of the British Bee-keepers' Association, and in continuance of the previous studies of Mr. Jenyns, he was induced to compile a work, entitled *A Book on Bees, their History, Habits and Instincts*. This was published in the beginning of the year 1886, with a preface written by our President, the Baroness Burdett-Coutts. This work was a valuable and welcome addition to bee-literature, the chief object of the work being to make bee-keeping interesting to young readers. Mr. Jenyns was most successful in the object he had set before himself. The work bore clear evidence of his special aptitude for making his subject interesting and intelligible to the young. Its style was lucid and simple, and the interest of the book was maintained from the beginning to the end. We consider that the work is a model of conveying instruction on the habits and structure of the bee. A cheap edition of the book has been since published, with a view to its introduction into elementary schools.

Mr. Jenyns evidently considered that his special mission was to interest the young in favour of bee-keeping, and therefore we were not taken by surprise in finding that at the Conference that was held at the Indian and Colonial Exhibition in connexion with the South Kensington Show, he selected as the subject of the paper he there read, 'The Promotion of Bee-keeping amongst the Young,' in which he strove to show that if we desire to promote bee-keeping amongst the working-classes, 'we shall do well to sow the early seed, which may afterwards bear fruit and so lead to intelligent and profitable bee-keeping on a much larger scale, and on a much wider field, than we had seen hitherto.'

We are indebted to Mr. Jenyns for the idea of 'local advisers,' the judicious carrying out of which has proved of such service to County Associations. Mr. Jenyns has officiated as judge on several occasions. The last time he occupied that post was at the Royal Agricultural Show at Norwich. He was one of the party who escorted the Princess of Wales and family through the Bee-department on that occasion. He was a member of the sub-committee for conducting examinations, for the duties of which he was eminently fitted. As Hon. Sec. of the St. Albans Diocesan Board of Education he possessed considerable knowledge of educational questions. Mr. Jenyns was also a great rosarian, and a painstaking recorder of meteorological facts.

In losing Mr. Jenyns we have to deplore the loss of not only one of the best and most successful of bee-keepers, but also of one of the most true-hearted and kindest of men.

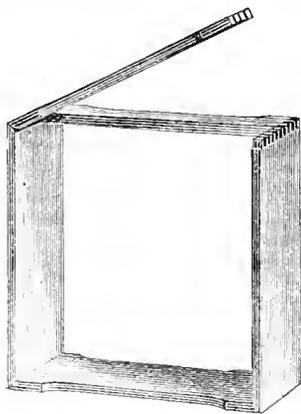

'EXCELSIOR' BEE-FEEDER.

We have received from the Co-operative Tin-plate Workers' Association one of their 'Excelsior' bee-feeders. In this feeder there is an inside circle, where the bees come up to the syrup-holder or tank. The syrup is conveyed from outside of the feeder by a tunnel. Inside of the syrup-holder is placed a cork float, which the bees get on to feed; there is also a bee-space between the outside circle and syrup-holder, the whole extending over six frames, and the spaces on each side of the frames

covered with a 9-inch circle of glass. When not in use for syrup or dry sugar, candy can be placed in the syrup-holder (and also on top of the frames as recommended in 'Modern Bee-keeping' and other works), and around the syrup-holder, and a quilt over the glass. On removing the quilt the bee-keeper can see what stores the bees have. If candy is required, the bee-keeper has only to take a penknife and lift up the glass and place the candy on. This feeder seems to be appreciated by the bees, if numbers be any criterion to go by. It is the warmest place in the hive, giving the bees air-space and a place for exercise.

A NEW METHOD OF FIXING COMB FOUNDATION.

Ever since the introduction of sections there has been wanting a better method of fixing comb foundation than is at present known. Messrs. Abbott Bros., in trying to meet the want, have invented a method (simple, but efficient) that leaves nothing to be desired. One glance at the little wood-cut will explain the whole thing; it is so simple that one wonders it did not occur to everybody years ago. The top of section is cut at an angle, with a cutter which leaves the top of cut larger than the bottom,

thus forming a dovetail for wax when inserted. The cut being left at an angle, and the right-hand half of the section being still unfolded, enables you to put the foundation in without the least trouble, then by closing the top half of section down into its place, a perfect tightening pressure is formed, which forces the wax into its place. Sections can be folded and waxed by this method at the rate of twelve a minute, no appliance whatever is required. We understand Messrs. Abbott Bros. have patented this new invention. (*See Advt.*)

ASSOCIATIONS.

LEICESTERSHIRE BEE-KEEPERS' ASSOCIATION.

ANNUAL REPORT.

Your Committee feel that they may very well commence their Report for the year 1887 with hearty congratulations, since the honey season in most parts of the county has been an exceptionally good one. The fact that one member (Mr. W. Brutnell, of Goadby Marwood, near Melton Mowbray) lifted 215 lbs. from one stock alone, clearly shows that Leicestershire possesses honey-producing capabilities favourably comparable with almost any county in England.

The annual show was held at Ashby-de-la-Zouch. There was, as usual, a good show of honey, the bulk of which was of first-class quality, but the number of exhibits was smaller than in the preceding year, probably owing to the difficulty of reaching Ashby from some parts of the county. No prizes were offered for collections of bee-keeping appliances; nevertheless, Mr.

W. P. Meadows, of Syston, Leicester, and Mr. C. Redshaw, of South Wigston, exhibited their complete collections for the benefit of the Association. For this act of liberality your Committee here accord them special and hearty thanks. The medals and certificate of the British Bee-keepers' Association were awarded as follows:—Silver medal, Mr. W. P. Meadows, Syston; bronze medal, Mrs. Ripon, Waltham; certificate, Miss Chester, Waltham. The judge, Mr. J. M. Hooker, was appointed by the British Bee-keepers' Association. He examined Mr. Windsor, of Netherscale, for third-class expert's certificate. Mr. Windsor's success has since been recorded in the *British Bee Journal*.

A second show, by kind permission and pecuniary assistance of the Corporation Committee of the Abbey Park Horticultural Society, was held in Abbey Park on August 2nd in conjunction with that Society. Acknowledgments are due to Messrs. Carter, Meadows, Clarke, J. Cooper, and others, for the able manner in which this show was managed.

It is hoped that the Abbey Park Committee may see their way to giving a larger grant to the Association, to enable it, during the next season, to carry out the arrangements more efficiently, and induce the members to take more general interest in the Show.

At a Committee Meeting held in May, it was resolved to employ an expert. Mr. George Munday, of Rutland Villas, Cavendish Road, Aylestone Park, Leicester, was appointed to visit the apiaries of the members in the spring. As a result, fifty new members were added to the Association. The expenses, unfortunately, more than covered the additional receipts, so that other arrangements for an autumnal visit had to be made, which it is hoped were little less effective. Mr. Munday visited 1250 hives, and as a large number of these were of modern make and under the modern system of management, there can no longer be any doubt of the beneficial influence of the Leicestershire Bee-keepers' Association. Furthermore, Mr. Munday saw large numbers of similar hives under the capable management of bee-keepers who still hold aloof from the Association, but who, nevertheless, must have derived, and be still deriving, considerable benefit from the teachings of the Association.

The Association has determined to send round an expert in the spring to visit members' apiaries. It must, however, be understood that the expert will not be able to examine more than two or three hives in each apiary, his time being limited; but he will give advice and information on special points if required. The services of the expert can be obtained at other times by special arrangements with him, with regard to payment for his time and travelling expenses. The address of the expert at present employed by the Association is Mr. George Munday, Rutland Villas, Cavendish Road, Aylestone Park, Leicester.

The condition of the finances of the Association is not very encouraging, nor is it very discouraging when it is borne in mind that there have been the extra expenses of the expert's tour and Abbey Park Show. Your Committee once more ask assistance in clearing off the debt. It may be here recorded that Mr. Bickley, to commemorate the Jubilee, offered to pay one pound towards liquidation of the debt, if nine others could be found to do the same. Are there any members still disposed to respond?

A larger number of exhibitors is very desirable. Intending exhibitors are requested to read the rules over very carefully. Competitors exhibiting for the first time are especially asked to give a little attention to the 'Hints to Exhibitors.'

OXFORDSHIRE BEE-KEEPERS' ASSOCIATION.

The annual meeting of this Society was held in the Clarendon Hotel on Wednesday afternoon, January 25th.

Lord Jersey presided, and there were also present: Revs. F. C. Dillon (hon. sec.), C. Stuges, Williams, and Neames; Messrs. Hitchman, Launchbury, Hancox, Cobb, Perry, Hayes, Taylor, Scrivener, Thomas, C. B. Anstey, Thomas, Hughes, C. Harris, &c. One lady bee-keeper was present.

The Secretary read the balance-sheet, which showed 6*l.* 1*s.* 10*d.* to the good.

The Secretary read the following Report:—‘Your Committee beg to present their sixth annual Report. They regret to find some falling off in the numbers of the Society, though in other respects its position appears very satisfactory. Fresh ground has been opened out by the circulation of the *Bee Journal* among the members, and the balance, thanks to the generous support given to the prize fund, is more favourable than it has ever been before. Under these circumstances your Committee trust that the work of the Society during the coming year will be effective, and result in bringing in a considerable number of recruits. The number of subscriptions received for 1887 was 116. Of those twenty-three were new members or old members whose names did not appear in the last report owing to their subscriptions not having been paid before the general meeting. As there were 136 last year, there are, therefore, forty-three members who have not yet paid for 1887. No doubt some of these losses are unavoidable, but your Committee hope that some may still be disposed to continue to support the Association. The Bee-tent of the Association does not seem to have been in as great request as in former years. No doubt it would be more sought after if the secretaries of flower-shows knew on what very favourable terms it could be secured, and they would, therefore, suggest to members and local secretaries that they should make its existence known to the secretaries of the flower shows in their neighbourhood and districts. It visited the following places last year, viz., Banbury (two days), in connexion with the Oxfordshire Agricultural Society; Headington, in connexion with the Church of England Temperance Society Fête, when the Association also held their annual show; and Swincombe. The spring tour was taken by Mr. Perry, and the autumn tour by Mr. Fextrell. It will be of great assistance to the Secretary, and save disappointment to members, if those who wish the experts to visit them, would be careful to send in the forms by the dates mentioned. The annual show was held, as stated, at Headington, in connexion with the Church Temperance Fête, on July 14th. The Committee were much disappointed in the number of exhibits sent, there being only forty-one entries. This was partly due, no doubt, to the fact that the great show of the British Bee-keepers’ Association was being held at the same time at Newcastle. In the honey class, there was a very good display in Nos. 3 and 5 for 1-lb. sections and extracted honey, but No. 4, for best supers of honey, found very little favour. Should it be decided to hold another show this year your Committee hope that members will do all they can to secure as many entries as possible. In accordance with a resolution passed at the last general meeting, copies of the *British Bee Journal* have been sent to each of the local secretaries for distribution among such members of the district as apply for them, and your Committee have reason to believe that this additional privilege has been much appreciated by many of the members. The hope expressed at the last meeting that some gentleman would come forward and undertake the post of local secretary for those districts which did not then possess one, has been realised, and the Committee are glad to be able to report that there is now a local secretary for each strict. In conclusion your Committee think that the satisfactory state of the balance-sheet justifies them in commending the appointment of an assistant secretary a small yearly salary. The Hon. Secretary is willing continue at that post, provided an assistant be found;

and your Committee are glad to report that Mr. C. Harris, who has previously held the post of local secretary for Oxford district, has consented to be nominated as assistant secretary. The Committee are confident that in him the Association would gain a most intelligent and energetic officer, whose work would soon make itself felt and bring a good return to the Association.’

Lord Jersey was re-elected President, the Rev. F. C. Dillon (Vicar of Enstone) Secretary, and Mr. C. Harris assistant secretary.

The following form the Committee for the year:—G. H. Morrell, Esq., Dr. Boyton, and Messrs. Salmon, C. Taylor, Crute, C. B. Anstey, C. Smith, and R. P. Thomas.

YORKSHIRE BEE-KEEPERS’ ASSOCIATION.

The Annual Meeting of the Yorkshire Bee-keepers’ Association was held at the Church Institute, Leeds, Jas. Dodgson, Esq., Skipton (Hon. Sec. of Craven Branch B.K.A.) in the chair. The usual official business was transacted and the accounts passed. The Committee regret to have to report to you the resignation from the Honorary Secretaryship of G. H. L. Rickards, Esq., who has so courteously and ably filled the position since the formation of our Association; the reasons given for this step being, that owing to the march of time our esteemed official did not feel himself able to do as much as he would like to forward the cause we have at heart, *i.e.*, the growth and prosperity of our County Bee-keepers’ Association. Suitable remarks thanking Mr. Rickards for his past labours, &c., were made by the Chairman and others, and a resolution was carried unanimously electing him an honorary member of Committee. Resolutions respecting the attendance of the Committee, &c., were passed, and interesting information as to the foundation of Branch Associations was given by Mr. Dodgson.

Mr. R. A. H. Grimshaw, of Horsforth, near Leeds, who was elected a year ago Co-secretary with Mr. Rickards, now remains the Hon. Sec. of your Association; and in presenting you with the annual report, he hopes he will receive the same kindly help given to his late colleague. He asks also that the sympathy and support of all who are interested in advanced bee-keeping be extended to the Yorkshire B.K.A., and especially does this appeal relate to those with whom the fruit and fodder-yielding capabilities of this ‘county of broad acres’ are subjects of importance. To these, amongst our friends, it is almost unnecessary to enlarge upon the enormous benefits silently conferred upon the community by the honey-bee as a plant-fertiliser (and, therefore, as a seed and fruit-producer), apart from its labours as a honey-producer.

During his year of office as Co-Secretary, Mr. Grimshaw has delivered six lectures (three at Leeds, one each at Uleskelf, Badsworth, and Walton, near Liverpool).

LANCASHIRE AND CHESHIRE BEE-KEEPERS’ ASSOCIATION.

ANNUAL REPORT.

In presenting the sixth Annual Report your committee are glad to say that in place of a debit balance they close the year with a small balance to their credit.

The shows that have been attended during the year 1888 are:—July 21st, Prescott and District Horticultural Society; August 4th, St. Mary’s Floral and Horticultural Society, Chester; August 20th, Huyton and Whiston Cottagers’ Horticultural Society; August 24th, Lancaster and District Floral and Horticultural Society; August 31st to September 3rd, Royal Manchester, Liverpool, and North Lancashire Agricultural Society, held at Old Trafford. The only one calling for remark

is the Show held at Old Trafford under the auspices of the Royal Manchester, Liverpool, and North Lancashire Agricultural Society, and your committee feel that the support of this Association should be given to this Society as the readiest means of increasing the usefulness of the Bee Association in the two counties. They have, therefore, made an offer to attend the Show of the Royal Manchester, Liverpool, and North Lancashire Agricultural Society, to be held at Lancaster in 1888, provided the Agricultural Society meet your Association with a grant. In making their report to their subscribers, the Agricultural Association refer to the assistance rendered them by your Association.

Of the 238 members referred to in the report for 1886, 19 have resigned; 63 have joined, leaving 282 members' names on the books, including 67 in the Artisan and Cottager List.

Your committee during the year have tried to work in conjunction with the Sandbach, Hawkshead, Poulton-le-Fylde, and Altrincham Associations, but no arrangements have been made to.

Your committee early in the year secured a room at 2 South John Street to meet in; this has proved very convenient.

The plan of having local secretaries has been found to work to the advantage of the Association, but many more are wanted throughout the two counties, and your committee ask the co-operation of members, so that no part of Lancashire and Cheshire may be further than five miles from an active local secretary.

The lectures given by Mr. Webster, of the British Bee-keepers' Association, in the spring, opened up a great deal of fresh ground to your Association, and will doubtless bring in fresh subscribers next year.

By the kindness of Dr. Walker, who is one of the examiners from the B.B.K. Association, candidates had a chance of getting third-class certificates at the time of the Show held at Lancaster; the two candidates who came for examination obtained certificates. With reference to this subject, your committee are glad to learn the Committee of Examiners of the B.B.K.A. are trying to arrange to make it easier for candidates to meet them; and it will greatly assist all parties interested if candidates for 1888 will send their names to the secretary by the end of June, or earlier where it is practicable.

On the recommendation of your representatives, the B.B.K.A. have arranged that county representatives shall meet an hour before the Conferences, so as to discuss and arrange for all matters of interest to County Associations to be brought authoritatively before the Committee of the B.B.K.A.

A large quantity of honey has been sold for members, and had more been sent it could have been readily disposed of. What is chiefly required is an attractive form of putting up, at popular prices, say—Jars at 1s., 1s. 6d., and 2s.

Foul brood being on the increase, your committee, early in the year, had phenol solution put up in a cheap form, but it was called for much more outside your own counties than in them. Members would do well to make very strict inquiries before purchasing any bees, and in every case the inquiry should be made whether foul brood exists at the apiary from whence the bees are bought.—WM. LEES McCURE, Hon. Sec., *The Lathams, Prescot, 31st December, 1887.*

Correspondence.

OUR HONEY IMPORTS.

The value of honey imported into the United Kingdom during the month of January, 1888, amounted to 467. [From a return furnished by the Statistical Department H.M. Customs to E. H. Bellairs, Wingfield, Christchurch.]

THE MONTHLY ISSUE OF *BEE JOURNAL* AND ITS ADVANTAGES TO BEE-KEEPERS' ASSOCIATIONS.

[1472.] I felt quite elated when I first heard whispers of there being a likelihood of the *B. J.* being issued in a form more compatible with the financial requirements of bee-keepers' Associations. For some considerable time past it has been the privilege of members of Associations to have sent them for their perusal (a time usually extending to from two to three days) a copy of the leading British journal in apiculture; but the difficulty of transmitting same from member to member soon became apparent, and for some lengthened period quite a failure in its distribution has been the result.

The *B. B. J.* at its weekly price of twopence was much too expensive for the Associations to send a copy gratis to each of its members, but the advent of the condensed yet practical stranger seemed all at once to relieve us from the cloud of failure, experienced with its more imposing congener.

There is little doubt that Associations will at once feel the great advantage thus conferred upon them, especially so if the practical portion only of the *B. B. J.* is transferred to the columns of its monthly echo. It is what the cottager or other bee-keeper requires; the right nail has been tapped upon its head, and now I trust to see it in a few months driven fairly home.

Many would-be members of B. K. Associations want to know what benefit they are going to derive from joining; if it can be pointed out to them that each month they will receive gratis for their own several uses a periodical devoted entirely to apiculture, they will be satisfied that a large amount of good will accrue, and then a visit or visits from the expert, free admission to all shows, meetings, conversaciones, &c., being added, their natural dislike to 'part' for a seeming myth will be overcome, and Associations will thus receive an impetus not felt for some considerable time past. Let us hope that these sanguine expectations of mine will be realised. I think they will.

Taking as a basis my own County Association (Berks) it will be found that for a not very significant amount above that paid for the weekly issue, the monthly *B. J.* can be sent post paid to each of its members to become their property for present use or reference. Unfortunately a few of the members of the committee of the Berks B.K.A. do not or will not see it in this light, they must have a journal of their own, although at the present time the funds are not in the most flourishing condition. A bee journal of their own, they say, will lessen the printers' bill. So it will, but not sufficiently by far to pay for a journal being issued from their own press of equivalent interest or such practical advantage as the *Journal*.

You, Mr. Editor, have the whole of the British Islands to draw your supply of 'copy' from; a county can but have a fractional portion of it, and a consequent diminution in its utility. Berkshire, I am aware, locates a goodly number of practical bee-keepers, but how many of these, although they may be stars in their profession, have the natural aptitude of imparting that knowledge in writing to others?

You have the control of numerous writers, men who have made their mark, more or less, in apiculture with the pen. Can any County Association obtain this control unless their funds are augmented to a condition far above any bee-keepers' Association at the present time? They cannot. Can they expect a man to expend his ideas in the columns of their paper, who, if these same ideas and writings were sent to another periodical, would command a marketable value? It is not a common-sense view to suppose they would. As a result, the matter produced in its pages will have to be obtained at the nominal sum of—nothing. In a bee journal, no matter how simple its

contents, it must in many practical articles be illustrated. Can they get draughtsmen and engravers to form these blocks for nothing? Will an editor (poor man!) work transcribing copy badly written, orthographically deficient, or almost in a state of printers 'pie' for nothing? You know, Mr. Editor, there is plenty of that sort of 'copy' sent in.

Philanthropy, I know, is a trait to be encouraged, but in these days of £ s. d., where each of us has to look around for the wherewith, few can be found to work day after day, night after night, without its equivalent in some form or other; and so, if the quality of the matter contained in this embryo journal is to be kept up to the standard, the promoters will assuredly find out.

By the articles of affiliation to the British Bee-keepers' Association the annual reports of Associations have to be produced to a certain standard size (ordinary 8vo.), that the different reports may be bound together in one volume; this journal, though of a different size, is to produce this report in its pages, and great satisfaction was expressed by the promoters that the item of a separate report would not have to be paid, as the first number issued could be almost filled with the same; rather dry reading for its recipients, and scarcely to be recognised as of practical advantage in the establishing or successful management of an apiary; therefore, as this must appear in the March number, would-be manipulators will have to wait until April for advice, or manage their bees blindfolded.

Financially, according to the figures of the promoters, it is a failure, as it will cost 7l. per year more than the monthly *Bee Journal*, replete with sound practical advice, if a copy were sent each month to every one of the members, and the annual report costing 6l. produced as usual, notwithstanding the very low price a printer has offered to execute the work and fill the editorial chair into the bargain. One principal idea of the promoters is to 'use the scissors' upon other journals; if so, the readers will receive the advice or news secondhand, and after a lapse of time, perhaps, sufficient to negative its effects.

The usual meagre attendance of Committee-men was the principal cause of the motion being carried, only four voted, three for and one (myself) against. Two of these three were promoters, the third being one who has been placed upon the Committee since the matter was brought forward.

I should not have troubled you with this latter portion of my letter, but publicity has been given to the meeting in these columns with but few particulars of it; my opposition was very, very faintly expressed.—W. B. WEBSTER.

A VOICE FROM THE COTTAGE.

[1473.] I am very glad to see that steps are being taken with the new year to bring the cottage bee-keeper again to the front, and also that a new and cheaper journal is promised him, although I cannot see how we can have a cheaper paper than the *B. B. J.*, or a more ably conducted one. There is one little improvement, however, I think might be made. I should like to see the *bonâ fide* cottager show himself in print; to hear a little of his successes and of some of his trials and difficulties. I have been a subscriber for a year now, and during that time I do not remember to have seen anything of him. I am afraid he is too much over-awed by the learned gentlemen who from week to week almost overwhelm with their stores of knowledge of all the mysteries of bees and bee-keeping that he is fain to hide his diminished head, lest, like some unlucky bee that we have read of lately, he should be snapped up by some tomtit in the form of some expert or other.

Now, Mr. Editor, I should like to know whom we are to include in the term cottager. I presume it would

include any working man of small means in an agricultural neighbourhood, whether working in his shop or on his bit of land, or as a day-labourer on a farm. In most villages there exists a class of small, working tradesmen—the village smith, the carpenter, shoemaker, tailor, &c., who in these times find it a hard job to make both ends meet, and would fain add to their little means if they only knew how. Several of our correspondents lately have been wondering what trade could be worked with bee-keeping. I venture to say that in most instances any village trade will work with it; for, as a rule, there is a garden, and sometimes a paddock (if the man keep a pony) where there are plenty of spare corners he might find to put a few hives in. It is in the interests of this class (to which I have the honour to belong) that I should like to say a few words. I am a smith myself, like Longfellow's 'Week in, week out, earning whate'er I can' (which is not much, I can tell you), and having a nice plot of ground at command, I thought I should like to keep bees. I thought over it a long time, but there seemed so much mystery about them that I was afraid to try. However, happening to be at a cottager's sale one day, and seeing some half-a-dozen skeps of bees for sale, I ventured to buy three skeps for a trifle, and that was my first start in the line, now four years ago. Naturally, like most other bee-keepers that I have met, I had a little touch of the fever, and, being of a studious turn of mind, I began to seek for information. Of course I turned to my nearest bee-keeping neighbour, who gravely asked me if I had told the bees they had got a new master. I gave him up as a bad job, and being near swarming time, I asked another, who kindly assisted me to hive my first swarm in a skep (I knew nothing of bar-hives then), properly dressed with beer and sugar, and wiped with elder-leaves in the orthodox way. But, like riches sometimes do, they took to themselves wings and flew away. That summer I went to the Royal Agricultural Show, and in my wanderings came across the bee-tent, and was very much interested in what I saw;—I can scarcely say in what I heard, for I could not make much out, except that you had only got to do this or that and you would soon get a fortune. One thing I did remember, however, and that was to get the *British Bee-keeper's Guide-book*, which I did, and then I really started to work in earnest. I found I had a great deal to learn, and it would be as well to proceed with caution; so, after a prolonged study, I ventured to buy a bar-frame hive, and by following instructions given, and a little advice here and there, I drove the bees from one of my old skeps and stocked my new hive. I soon began to find that I could not afford to buy even cheap hives, so began to burn the midnight oil in trying to master the theory and practice, and make my own hives and appliances, which I am glad to say I have succeeded tolerably well in doing. Of course I worked my own trade in as much as I could, and made some frames, rather novel ones, but they answer well. Up to now I have made a bee-house for skeps, ten bar-frame hives and frames, an extractor, section-crates—of an original character, a brick hive, fountain, &c., and almost all after seven in the evening. I would strongly advise cottagers as far as possible to make their own hives, because I believe by that means they will more quickly learn the science of bee-keeping, being necessarily compelled to study in order to ensure success.

A word or two on bee shows. I cannot see that they are of very great advantage to the cottager as at present managed. The information obtained at them, I am afraid, more often leads him astray than benefits him. He begins driving bees, and mousing them about before he has mastered even the elements of the science; and frequently, after wasting a lot of time and money, he either gives up in disgust or is compelled to make a fresh start. I should like to see a greater readiness on the part of the lecturer or manipulator to answer the

questions of the novice, and to give simpler lectures specially bearing on the first steps to be taken in bee-keeping, and not to bewilder him with elaborate manipulations. I think a little conversation with, or a visit to the apiary of a fellow-cotager more advanced than himself would be of more service to him, and stimulate him to try and do likewise. What we want is unity among ourselves, the desire and will to help one another, and to cultivate that fellow-feeling that would make us wondrous kind. There is one thing, too, that tends to depress the bee-keeper of small means, and that is, the constant changes that are continually taking place in almost everything pertaining to the profitable management of bees. It is utterly impossible for him to go in for buying new queens, expensive feeders, the latest hives, &c., for the simple reason that he cannot afford it. That our new *Journal* may be taken up heartily by the cottagers, and prove a boon to them and a success to all concerned, is the hearty wish of—A VILLAGE BLACKSMITH.

A CHAPTER ON SKEP MANAGEMENT.

[1474.] Some time ago I promised to send you some information respecting the use of skeps in this neighbourhood. The cottager here does not keep bees for a hobby, but for profit. The following is the mode of management, and some of it I have not seen in any other part of the country. First of all, I wish to draw your attention to two facts, viz., this part is not a good one for bee-keeping, because, being so high, it is very exposed and cold, and there is only one honey harvest, that the heather. All stocks are worked with this particular end in view, and that reason will account for the peculiar management in a great degree. We begin in the spring; the season opens about April as a rule, although bees have been known to 'bear' here as early as February 11th, but that is very, very exceptional. The stocks are fed when required by means of a drawer lined with zinc fitted under the floor-board containing a float of perforated wood. They are only scantily fed to keep them going. The only swarms are natural ones, and they come off during the last week in June or beginning of July, but sometimes extend into August, showing the lateness of the district. All swarms are hived into straw skeps and fed, if required, for about three days.

About August 12th, the time when grouse-shooting commences, all stocks and swarms are packed up overnight or after 6 p.m., and loaded up and taken to the moors. There they remain until the honey-flow commences. If the season is very dry, no honey is secreted in the bloom, and if very wet the bees cannot work; for instance, this last season for three weeks, although there was a perfect sea of bloom, yet it contained no honey whatever. Rain came, and five days was the sum total of the honey-flow, as after that the continual rain prevented any more being gathered, but during the five days mentioned each fairly strong-skep gathered upwards of 20 lbs. Well, to return, the hives are all set out and allowed to take their chance, no covering provided except a large sod. The hives are visited now and again, and if any seem to be short of room an 'ipper' or eke is added, and thus they remain until the end of the season, about September 14th. No supers are used.

Saturday following the latter date the hives are fetched home, and every one which contains over 10 lbs. of honey is taken. This is the part of the plan which I think peculiar to this district. All hives containing more than 10 lbs. are driven, and having previously considered how many are to be wintered, the bees are divided amongst them. Each hive is given a good whisk round and placed on its stand over one of the drawer-feeders, and fed up until the weight reaches 20 lbs. or over (30 lbs. of sugar will make 45 lbs. of thick syrup), and it takes only 20 lbs. of sugar to form sufficient

combs to nearly reach the floor-board and stores for winter, and therefore I can refute the statement that it requires 20 lbs. of honey to make 1 lb. of wax. All the combs, minus the little brood there may be, are put in a large press, having three sieves of fine brass wire mesh, and subjected to great pressure. The remaining blocks of refuse are boiled in water, and the wax extracted. I may here say the honey thus extracted is perfectly clear, and contains only a very small percentage of pollen.

For this plan the advantages are, very little trouble in management, all the honey is taken, new and clean combs are formed, no foul brood, and 20 lbs. of sugar only costs 3s. 4d., sufficient to winter one stock, whilst every 10 lbs. of honey is worth 10s. here. You now see the reason of this plan. The wax also obtained realises 2s. 6d. a pound. The only disadvantage is in the spring, on account of the extra amount of work. Many old bees are worn out, and there being no pollen stored, stocks are weak (but they winter better in skeps than in wood), and for this plan they are not required strong until August. This system has been carried out in this district for the last twenty years. A good stock in a favourable season will yield from 30 lbs. to 40 lbs. of honey, and on account of the honey-flow being so sudden and quick, the queen is soon crowded out, but when two or three lots of driven bees are added together and fed in September, a batch of new brood is hatched off before winter sets in.

I am sorry I cannot give exact account of income and expenditure, as I have mislaid some memoranda I made during last autumn.—W. ROBINSON, *Yorkshire*.

IRISH HONEY AT THE GLASGOW EXHIBITION.

[1475.] I think that Irish bee-keepers owe a debt of gratitude to Mr. John D. McNally and his brother for the exertions they are making to open up new outlets for the sale and use of honey by their scheme to exhibit samples from all parts of the world at the forthcoming Glasgow Exhibition (1417); and I am sure no pains and trouble will be spared by them to make their part of the Exhibition as attractive and interesting as possible. I received a large order for honey from Mr. John D. McNally in December, and I have been much gratified by hearing from him that he intends some of it to have a place amongst his Irish samples. He is still anxious to obtain anything in the way of a novelty, and any Irish bee-keeper who has anything of the sort likely to increase the interest in and attract notice to the Irish part of the honey show, will greatly further the good cause, and aid the efforts of the Messrs. McNally, by sending such to them. There is no doubt that something is needed to exceed the demand for honey if it is to be of benefit to bee-keepers; it is most disheartening to work hard all through the honey season, and after a grand honey harvest to find it next to impossible to dispose of the produce. I have quantities of first-class sections still on my hands, and the demand seems absolutely *nil*, so far as Ireland is concerned.—E. E. RUTHERFOORD, *Carlisleford, Co. Louth*.

AMATEUR EXPERT AND THE THIRD-CLASS EXAMINERS.

[1476.] Let me thank 'Amateur Expert' for acknowledging the authorship of the remarks made with regard to our Third Class Examiners in the *Canadian Bee Journal*. I know him well, and feel that I can appeal to him with confidence to set things straight if he has done us any wrong in this matter. My objection is not made to a *non-de-plume*, but to it being the cover of a grave charge. As to the charge I would bring forward the following figures. During the years 1884, 5, 6, and 7,

127 candidates presented themselves for examination. There were in all 18 examiners, and of these Messrs. Walker, Selater, Hooker, C. N. Abbott, Bellairs, Raynor, Seager, Blow, W. B. Carr, and Martin, examined 99 out of 127. The remaining eight examiners are all men whom I believe to be competent and quite capable of finding the queen in reasonable time, but without discussing their merits, we have here the fact that nearly four-fifths of the whole number were examined by men of whom no one would venture to hint that they were incompetent.

Has not the Examining Board reason to complain if, in a description, *not of one particular examination, but of third-class examinations in general*, it is alleged that to capture the queen is 'a feat that the examiner probably could not accomplish in ten hours?'

With regard to my 'slowness' I may say that I do not take in the *Canadian Bee Journal*, but the paragraph in question was shown to me on Wednesday, January 18th, and my letter appeared in the *British Bee Journal*, published the following Wednesday, January 25th.—HENRY BIRCH.

PREVENTION OF INCREASE.

NUMBER TWO.

[1477.] In preventing increase it is not necessary to prevent swarming; in fact, in working for comb honey I prefer to have the bees swarm, as I think they work better after the swarming impulse is satisfied. When the time comes for putting on the sections look the hive over carefully, cut out all the queen-cells, put on the supers and let them alone. If they go to work they will soon need more room. As soon as the first sections are finished take them off and replace with empty ones. With young queens this method will often prevent swarming, but when you put on the supers, if they have made preparation for swarming, let them swarm. Do not cut out cells and fuss with them, for they will not work while they are thinking about swarming. Have your new hive ready, and as far as convenient from the old stand. As soon as the swarm issues open the parent and remove all the combs but one to the new stand, bees and all, but be sure that you have removed every queen-cell. Put in one frame of foundation to fill the hive; take the super from the old hive and put it on the new one. By this time the swarm will be settled in your living-box. Now carry them to the new hive and run them in, as you now have all the bees and brood of the old swarm, except the one comb left at the old stand and the bees that are out in the fields; the latter will work with all the energy of a new swarm. Be sure and put on the super before hiving the swarm, and the bees will go into it with a rush and stay there. I never use any honey-board and am not troubled with the queen in the sections. I use the Langstroth frame. If I used small frames, and ten or twelve in a hive, I would leave two frames in the old hive instead of one. If they should swarm again in the course of two or three weeks treat them as before; if they persist in swarming supersede the queen. As to the frame of brood left in the old hive, leave it alone till you have bees enough to fill a hive; then unite the colony at sundown, remove the empty hives, put on the super, and the bees will go to work promptly. With this plan you will have only one new swarm out from eight or ten old ones, and still have them in the best condition for storing surplus. I think they will work with greater energy than when they are put back on the old stand.—JOHN H. RUPERT, *Wood-rock, Pa. (American Apiculturist.)*

PARALLEL V. RIGHT-ANGLED FRAMES.

[1478.] 'W. R.' states on p. 52 in your issue of the 26th January (1450), 'Under the other system (*i.e.*, parallel) every passenger has to burrow under or scramble

round each of the ten or eleven combs the hive contain before reaching the back.' This would lead one to imagine they were cramped for head room, or had a difficulty in passing under the frames; but it is not so, as all the hives I have seen on this system have ample space below for the bees to travel in any direction they like. And as regards ventilation, in my opinion it is better than the right-angle system. But I don't think there is really enough difference between the two systems to make any one change from one to the other. There is a good deal in what one starts with or takes a fancy to.—GEO. WHALLEY, *Mon.*

BEEES—IRISH AND MOORISH.

[1479.] I have just returned home to my bees after four months' absence in Morocco, and found all the hives looking well and the bees very lively, the weather being extremely mild for the time of year. On January 23 there were half-a-dozen good-sized clumps of yell w crocus in bloom, and the bees rolling about in them in great delight. These crocuses are not the ordinary kind, and blossom a little earlier; they have smaller blooms, and the petals curve back, giving the flower a star-like look. The ordinary crocuses were also beginning to bloom, and besides there were *Pyrus japonica*, wall-flowers, snowdrops in quantities, a few sticks, and anemones also in flower. I hope only we shall not have to pay for it all by-and-by with snow in March, &c. There is a great deal of furze in blossom, and to-day out walking I saw half-a-dozen bushes quite yellow with blossom. All this means that the bees are out a great deal, and I have got my usual 'starvation' panic on; so to ease my fears I removed the hive-covers the other day when it was quite hot at noon, and gave some more candy to the hives that had consumed their autumn allowance of it. Only one hive seemed at all damp, and to that I will give a dry quilt on the first good opportunity.

I had not much time to inquire about the bees in Tangier and its neighbourhood, but I should think at certain times of the year the yield ought to be large. I left about the middle of December, when the orange-trees were coming into blossom, and from what I heard I should expect a good yield of honey from that time till well on into summer, when the drought would probably check the honey-flow. I saw some bees in frame-hives, but I think they had 'established a funk,' and their owners showed a marked indisposition to interfere with them. I heard of one proprietor whose attempt to take some of his honey ended in his precipitating himself into his garden pond. And this in spite of veil, gloves, and smoker. It was plain to me that the bees were very aggressive, and as I had no protecting armour, I left them religiously alone after my first experience. I approached the alighting-board of one frame-hive cautiously, keeping well to the side, but when I was about four or five feet off a couple made for my face and neck,—and I fled!

I was unable to get a sample of the honey, but intended to bring you a few of the bees, which I proposed to entrap cunningly, but as my journey homewards was to be a long roundabout business I gave up the idea. I shall hope, however, to visit Tangier again next autumn, and will, if I have the opportunity, make good the omission. Anyhow, the bees are regular 'demons,' and I hope no one will improve (?) our home race by crossing them with Moorish. They are very dark-coloured bees, and I could see no bars on them. The Moorish bee-hive is a hollow tube of cork-bark. It is well to know this, lest one should sit upon or kick the (apparent) log of wood, which is just put on the ground at any convenient place.

On the high ground between Tangier and Cape Spartel I saw bees working busily on the beautiful tall

heath which was in bloom in November and December; but I also saw them working in indescribable numbers and with feverish energy on the vile, sticky compounds that the Moors devour as sweetmeats, and that are sold in quantities in the market-places and streets of the Moorish towns. As these sweets (?) are made with the most rancid butter that can be procured (no other suiting the Moorish palate) I confess I think some of the honey must be of curious flavour. The trays of sweetmeats were literally covered with bees, and the vendors did not attempt to drive them off. Probably it was safer to leave them alone, the Moorish costume leaving so much of the person exposed to insect attack.

One queer thing I noticed as to their pollen-gathering, the like of which I never saw at home. After breakfast, the day after my arrival at Tangier, I saw a lot of bees hovering round the Venetian shutters outside the windows. These were painted a most vivid green, and the bees, I soon saw, were working away at the paint and storing it on their legs as pollen. It was certainly extraordinary to see the big pellets of brightest emerald green. They seemed to get it most easily on the edges of the shutters and wherever the paint was at all lumpy, and at all these places the marks of 'nibbling' were very apparent. Of course I was not believed when I made my report, and I was met with the popular fallacy that 'bees hate paint'; but 'seeing is believing,' and there was soon an end of scepticism on the subject. The emerald-green was very patent on the bees' legs, and every day they were to be seen at work. But what, in the name of wonder, they were going to do with that arsenical-looking powder in the pollen-cells, I am sure I do not know.

I have been dutifully reading up the four months' back numbers of the *Journal* that accumulated in my absence. That box wasp-trap is, I am sure, a good thing. Cushions with centre openings I have used for three years, and find them most convenient. From the condition of the small amount of comb-honey I left in stock in the house last autumn, I am convinced that *light* should be carefully excluded if sections are to be kept without 'weeping.' Some half-a-dozen I left in a very close-fitting box with one side glass have oozed very much, and are quite unsaleable, but a couple of dozen that were in a less air-tight wooden box are in perfect condition. The same idea struck me last winter when I wrote to you about finding a hive, in which the bees had died out from queenlessness, with all the bars full of honey, and none of it granulated, though the weather was extremely cold and frosty, and some of the honey was from heather. The bars were all sealed of course, but the hive was very cold.

So far, bees have wintered well here, but the open weather will necessitate care in spring. Excuse this long yarn, but I have been so long absent I felt I must have 'my say' to you.—F. W. C., *The Mall House, Lismore, Ireland.*

COUNTY BEE-KEEPERS' ASSOCIATIONS.

[1480.] There are two important considerations affecting the work of Associations which the length of my last communication prevented me from speaking of. The first is the fact, patent to all engaged in active management, that the wants of members are in a progressive and transient state, and therefore the programme for one year will require modification for the next season, and in two or three years time may be quite out of date and unsatisfactory. The second is, that the amount of work which can be undertaken is sharply defined by the income by subscriptions, and that a serious proportion of income is unavoidably swallowed up by inevitable expenses (printing, postage, affiliation fee, &c.) which outsiders never reckon upon when estimating how many benefits can be given to a member in return for his subscription.

The difficulties of management are increased by undue expectations raised by such reasoning as that of the compiler of 'Useful Hints' in your issue of February 2, who remarks 'that eighteenpence per annum should supply the monthly *Journal*, inclusive of the halfpenny wrapper, to every cottage subscriber of 2s. 6d. to his county Association, leaving 1s. to the county funds.' This assumes that there is no other Association work to be considered, and, less clearly, that subscribers of 2s. 6d. are to be granted a boon denied to 5s. members.

The fact is, that the average amount received from, and therefore the average amount which can be expended on, each member, including the 2s. 6d. cottages, is about 5s. 9d., and that the following expenses per member are inevitable in an Association which already undertakes the usual honey show and expert's visit:—Printing, 1s. 6d. per member; stamps, affiliation fee, and sundries, 1s.; prizes at show, 1s. 3d.; spring tour, 1s. 6d.—total, 5s. 3d. It will be seen that it is difficult to add the free gift of even a monthly *Journal* to work already undertaken, but that the circulation of such a journal may be practicable, say, one copy to four members. My figures are based on our own balance-sheet; they may of course be different under different circumstances, such as a large increase of members.

Organization of Associations.—I will pass over the ornamental officers, as president and vice-presidents, without whose guineas it would be difficult to work. It may have been noticed that I have assumed that the average member joins the Association from selfish motives for the advantage he may gain thereby, and accordingly I have discussed the work of the Association from this standpoint.

In speaking, however, of those who assist in the management, I can safely assume that the average worker is willing to help from love of the cause and willingness to assist others: being but human, however, he on the one hand loses interest if he is not assigned some share of actual work and responsibility—attending committees to approve of others' work is not sufficient—and on the other hand, if the main burden and responsibility of the Association gradually falls upon him, and he has practically to manage a business for the benefit of others, a time comes when he feels he can do so no longer, and retires.

The Central System.—By this name I refer to the older organization of most Associations, by which no work was done except by the Central Committee; and as all work depends on personal energy, and no committee-man, however energetic, had power of action except when the committee were called together by the secretary, it naturally came to pass that everything depended on the secretary, and the Association became a business managed practically by him alone. It is on account of this weak point that a change becomes necessary, and that in the direction of power of independent action by workers in different parts of the county.

District System.—Under this plan the county is divided into districts, which should be defined by existing divisions—in our county the petty sessional divisions were found the most suitable. Each district is given into charge of a local secretary, who shall take charge of the work of the Association in his district and receive subscriptions. He should call a meeting of members in his district once a-year, and in our case we have entrusted the election of the local secretary for the ensuing year to this meeting. This meeting might be combined with a short lecture or discussion on practical points of bee-keeping. It is doubtful whether local secretaries or other unpaid officials should undertake much expert work, for it too frequently happens that members who receive such help begin to ask for it as something due to them in return for their subscription. For this reason I have doubts about the advisability of appointing local advisers in districts, but I cannot speak from experience.

Hon. Secretary.—This post will be more easy to fill under the divided responsibility of the District System, but the success of the Association will still depend upon the energy of the hon. secretary, who will in some districts have to fill the place of non-existent or useless local secretaries.

Treasurer.—On the one hand, it is well to have an independent treasurer, as it presses one more into active interest in the work; but, on the other hand, it creates extra work and expense in postage and remittance, if the treasurer should live at a distance from the hon. secretary; and I am inclined to think that if the hon. secretary would also act as treasurer, it is not much increase to his work, and enables him to keep an accurate list of members, to apply for subscriptions at the time of sending out other notices, and thus to get in money much more quickly.

Committee.—The local secretaries, with other officers, will constitute this body; but as they live widely apart, I think it is well to add the names of a few suitable members living in or near the town where committee meetings are usually held.

The rules of an Association should be as simple as possible, and not designed to cover every possible contingency. It is amusing to notice the space wasted in many annual reports on the 'Objects of the Association,' usually theoretical and not practical.—ALFRED WATKINS, *Herefordshire B. K. A.*

COUNTY BEE-KEEPING ASSOCIATIONS.

[1481.] Letter 1451 in your issue of the 26th January, 1888, asks some questions of me, or I would not further trouble you on the above subject.

In what way does Mr. Garratt want the Committee of the B.B.K.A. to move? Surely he might have given his views to his county representative that they might have been discussed at the meeting of county representatives. If the counties work together they will be an assistance to the British, and at the same time the counties, as a body, can point out many ways in which the British can assist them, but if each county goes with a separate proposal the Committee of the B.B.K.A. cannot give the time to consider them.

Why should not duly qualified county representatives, or County Honorary Secretaries, be *ex-officio* members of the B.B.K.A. Committee? I have written on, and named, the subject for twelve months and never heard any one speak but in approval of the suggestion. Why, then, at the coming annual meeting cannot a rule to meet the subject be proposed? I cannot attend the meeting, or I would have given notice of my proposition.

Will Mr. Garratt pay me a visit? I will then prove to him that no paid Secretary with ample funds at his back could cover Lancashire and Cheshire for bee-work. In the six years the Association has been in existence, in place of *paid*, our Association has had *unpaid* Secretaries, who have also had to consider the funds at their disposal.

My Committee have been advised by post-cards of the date, &c., of the next meetings a week before they were to be held, and the post-cards have stated the nature of the business requiring their attendance, and at all these meetings the accounts have been produced for signature by the Chairman, and the position of the Association to date been made known to the Committee. This is the simple way in which the Committee, to whom I am greatly indebted, have assisted me with their attendances.

After six more years with unpaid Secretaries, I am sure there will be new districts for an energetic Secretary to look up in Lancashire and Cheshire. Fortunately there is nothing uncertain or indefinite in our aims, and stimulus we must find in new districts.

Mr. Garratt's long experience differs from my very short one about the selection of *officers* in an Association; and if all would resign when they do not fill the requirements of the position they would confer a great benefit on bee-keepers in general, who prefer to let things drag on rather than hurt the feelings of some one who will neither act himself nor let any one else; but on this question of officers of an Association I could write more, but I have already trespassed too much on your space.—WM. LIES McCLEURE, *The Lathams, Prescot, January 27th.*

SECTIONS WITHOUT SEPARATORS.

[1482.] It might not be inappropriate, now that the time of preparation for the coming bee-season is approaching, to review the question of the disuse of separators as noticed in the *B. B. J.* and elsewhere during the past year. We find many have tried working without them, and results varied. The $1\frac{1}{2}$ in. wide thus worked has been a failure (see letters in *B. B. J.*, Nos. 1371, 1372, and 1380). The $1\frac{3}{4}$ in. not so. We may, in fact, consider them to have been a great success. Our first notice of this section is at the Hunts Agricultural Show (*B. B. J.*, August 11th, page 345). Mr. J. H. Howard, junr., here took a first prize and B.B.K.A. silver medal with his dividerless $1\frac{3}{4}$ in., and Mr. J. H. Howard, of Holme Apiary, with the same takes first place at the Cambridge and Isle of Ely Agricultural (same page *B. B. J.*) and, I understand, the first prize in the Cottagers' class was also awarded to the $1\frac{3}{4}$ in. sections. Concerning these, Mr. Howard writes, 'Nothing can beat dividerless $1\frac{3}{4}$ in. sections.'

Let us now turn to *B. B. J.*, page 465, letter 1321, and we find that in Co. Leitrim, Ireland, the largest recorded take of comb honey but one was taken by the open-sided $1\frac{3}{4}$ in. dividerless, viz., 160 sections. This one larger, 194, by 'An Old Bee-master,' letter 1354, was taken from a hive worked on the 'Simmins' principle; and as Mr. Simmins works this section without separators these may have also been the same. We next hear from the Isle of Man. Mr. Fryer writes (letter 1365), 'That his open-sided $1\frac{3}{4}$ in. worked without separators placed alongside his 2 in. looked better and weighed more, but that they were more easily injured in handling.' This applies to all open-sided sections, and will disappear when we become more accustomed to them; the close-sided $1\frac{3}{4}$ in. are safer in this respect; but in both we have a wide margin for unlucky knocks, extracting, and home consumption in the greater quantity of honey taken by them than by the 2 in.

We now come to America. We have it on the best authority that this section is increasing in favour in Canada, our friends there considering they take most comb honey by its use; but these sections were not quite level last year, nor were they at the Colonial the year previous. This can be explained by an indifferent and a bad honey year. It requires a strong honey-flow, such as we had for a short while this year here, to give quite level sections without separators. The same good authority says that in the States separators are in general use. Perhaps, the cheapness of extracted compared with comb honey, especially in the State of New York, has something to say to this; it won't pay to have to extract any section, and Brother Jonathan is willing to sacrifice quantity to get evenness of finish at all times. But we find Mr. Hutchinson at the Chicago Convention stating that he secures quite sufficiently even sections without separators (see *B. B. J.* about January 15th), and Mr. Heddon writes in the January *Gleanings*, 'That the best section for all purposes, whether with or without separators, is the $1\frac{3}{4}$ -in. wide;' and in answer to a query from the Editor of *Gleanings* in the January number as to 'Which is the best width of section to use when separators are dispensed with?' only two of the leading bee-keepers, in reply, actually oppose working

without them; a third says unless you know you will succeed, it is better to use separators, while the remaining twelve, with one exception, give the $1\frac{1}{4}$ in., or seven to the foot, as being the best width to use. This one exception, Mr. C. C. Miller, says, 'Perhaps $1\frac{1}{2}$ in.'

Our review, so far, places the dividerless $1\frac{3}{4}$ -in. section in the first rank as to both appearance and quantity, and shows it is increasing in the attention and favour of bee-keepers.

The writer has nothing new to say of it from his own experience. His hives these last two years have been in a very exposed place, and he has enough to do to keep his bees alive and eke out a little extracted, without troubling for sections. Such a situation is the worst possible for bees, but even there they can be made pay their way, time and trouble not considered. However, he has sold some hundreds of sections for cottagers and farmers worked without separators; of these the $1\frac{3}{4}$ inch wide were the best, the 2-inch good, when the hives had been kept level, rather overweight, but when not level, proportionately crooked. But a venerable clerical friend writes, 'I don't think bees like separators. This year (1887) I had 700 two and three-pound sections (till lately our rev. friend made his own sections) worked without separators, and among the lot there were not twenty but were as level as a moulded brick.' Besides this our friend had 5 cwt. extracted, and how much more I know not.

How is that our clergy make such good bee-keepers? Must it not be from a closer acquaintance with the Book to which so many references have lately appeared in the *B. B. J.*, and if the brother bee-keeper among us who has not been as successful as he wished, but desires to become more so, will only look up those references he will derive very valuable information from them. Statements there made, 3000 years back, concerning honey and food connected with it, and the reasons for such, proved true by science only, now science and modern discoveries but confirm Scripture. Learning on bee matters is good, but it is the self-reliance and the habit of looking up to a Higher Power for aid that makes the successful bee-man.

We find necessary a strong honey flow for best results with sections without separators; but, perhaps, Mr. Simmins' method of crowding the bees into sections, as practised by 'An Aged Bee-master' with such good results, and as evidenced in his new anti-swarming hive, might give the same good results other years that there might not be such a vigorous honey flow while it lasted as this.

Our 'Aged Bee-master' has been ahead of the best of us in large returns of produce for these last seven years, has completely eclipsed our American brethren in general average, and his testimony should be valuable.—W. B., *Patrickswell, Limerick.*

FLOOR-BOARDS.

[1483.] The sketch figured on page 66 is a reproduction of the drawing of my floor-board, published in the *English Mechanic*, October 14th last year. If 'W. Corkhill' is not satisfied with my arguments in that journal, I shall be pleased to show him (and for that matter any bee-keeper interested) the boards as they have been in use since first invented. (The Editor has my address.) The sketch I published shows the alighting-board extending to front edge, and this is as it should be. The board in 'W. C.'s sketch is too far back. I have stocks over these boards that have gone through the late frosts without loss of a bee, in hives 24 inches long inside. They have no dummies, and the air-space in front of the frames is about 12 inches deep. The clusters are at the back of the hive. I am also wintering stocks over the flight-holes without any loss in bees; these clusters are closed in with light dummies at the back.

I consider dummies an abomination, and hope to do without them altogether, as I understand Mr. Simmins is doing.

I make my hives three inches thick all round, packing the spaces with shavings. This leaves spaces beyond the frame-ends, which are fitted with strips same height as the frame-tops; the quilt then extending about an inch beyond the frames makes an air-tight top.—SILKE.

[We have compared Mr. Corkhill's sketch, and description thereof, with those in the *English Mechanic*, p. 160, and find the sketch almost identical, and the description nearly *verbatim*. The similarity is remarkably striking.—Ed.]

NOTICES TO CORRESPONDENTS & INQUIRERS

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

J. B., *Carrick-on-Suir*.—1. *Building brace combs*.—Bees frequently build brace combs when the space exceeds $\frac{1}{4}$ of an inch. We should place a slatted honey board between the two hives to reduce the space. This can be made of bars $\frac{7}{8}$ inch wide and $\frac{1}{4}$ inch thick, framed so that they will correspond with the tops of the frames. The hive above is placed with the frames across. 2.—*Queen ascending to third storey*.—If you have any objection to the queen going up into the third storey, place a piece of American cloth on the tops of the frames 1 inch smaller all round than the inside of the hive, so that the queen would not be able to pass up the centre, but the workers could enter the upper storey round the sides. We have found this to answer in most cases. 3.—*New edition of Guide-Book*.—We thank you for your kind remarks. The new edition which has been in a great measure rewritten to bring it up to the times, is in the printer's hands, and we hope it will be ready very shortly.

ROBIN W. WOODLEY, SUSSEX COTTAGE BEE-KEEPER.—It has been our earnest desire to bring the *Bee Journal* within the reach of cottagers by reducing the price to one penny, but after carefully considering the matter we have found it impossible to do so if we keep it the same size as at present and keep up its present standard. We hope the monthly *Journal* will meet the requirements for the present, and we shall always be ready to give replies by post to any of its regular subscribers, between the dates of publication on any matters requiring immediate advice, upon receipt of stamped-directed envelope.

G. WHALLEY.—Our thanks are due to you for your kind note of approbation of our conduct in the matter referred to.

JOHN BAINBRIDGE.—*Third-class Examinations*.—Place yourself in communication with the Secretary of your County Association; who will give all necessary information as to time and place where examinations are to be held. There is nothing formidable in the requirements of a third-class examination. You are not required to write or speak on bee-keeping, only to prove to the examiner that you have a fair knowledge of the management of bees.

M. H.—*Doubling*.—A frame of hatching brood in the centre of the upper hive, with frames of foundation around it, will induce the bees to commence work above, and if the colony is strong and the honey flow abundant a second storey will soon be required. Your failure probably arose from failure in the two points mentioned.

E. SEYMOUR.—*Bees in Peach-house.*—Bees never succeed when kept in conservatories. In the case you propound you would find great loss of bee-life from the inability of the bees to escape from the house. If you decide to move the bees, do it at once, but place your hive outside the house. The observatory hive might answer your purpose if well covered with woollen quilting.

NOVICE.—We shall be pleased to hear further from you on the subject of your letter.

W. J.—1. *Hive to Prevent Swarming.*—We do not like the sketch you enclose. You would certainly require an eke, even if you work for sections only. 2. *Large Sections for Extracting.*—We should certainly hesitate considerably before attempting to extract such large sections. Are you aware that the size you propose would, if the bees accede to your wishes as to filling them, contain about 4½ lbs. of honey? If you really wish for such large sections of heather honey, why not get the combs ready built out before going to the moors? We do not admire your taste as regards the fretwork flower over entrance.

W. L. BIRD.—*Carniolan Drones.*—The bees sent are Carniolan. It is impossible to say from your query what is the exact state of your stock. Most likely it is queenless. Some fine day, when the shade temperature is 50°, or over, examine the hive quickly but gently, and notice if there is any brood, and, if so, whether the cappings project considerably beyond the surrounding comb; if so, it is drone brood, and your queen is worthless, or you may have a fertile worker. Let us know the result of your examination, and we may possibly help you if you give full particulars.

C. WADE.—We have requested an expert to pay you a visit.

W. M.—A reply will be given in our next issue.

NOVICE.—*New Mode of Hanging Frames.*—Your description being unaccompanied by a sketch does not enable us to judge of the merits of your method. If you send sketch, we will be happy to give an opinion.

T. HEWGILL.—*Moor Honey Granulating.*—Heather honey is naturally much denser than, say, clover or lime honey. Last season's honey had a tendency to candy much more quickly than in ordinary seasons, owing to the prolonged drought. Did you keep your honey in a room at about 65° to 70°?

CHESHIRE.—*Economy in Foundation without Swarming.*—Under the circumstances, we would recommend you to try Simmins' non-swarming plan by putting a body-box containing frames with half-an-inch of foundation only in as starters, under the brood-nest. You would still tier up as you suggest, giving full sheets above. Ask any further information you may require.

'T. H.'s' reply to 'A. C.' p. 68.—'I do not fasten the pieces of wood for keeping the frames the proper distance apart at the bottom, but quite loose.'

Exchange Column.—Sales of Honey and Second-hand Goods.—Intended to aid Bee-keepers in the disposal of Bee-produce and Appliances for which they have no further use. Terms: Twelve words and under, Fourpence; for every additional Three words, One Penny extra.

Situations, Publications, Bee Plants, &c.—Twenty words and under, One Shilling; for every additional Three words, One Penny.

No reduction made for continuous insertion.

NOW READY.

SIMMINS' NEW BOOK.—'A MODERN BEE-FARM, AND ITS ECONOMIC MANAGEMENT.' Popular Edition, limp cloth cover, 3s. 9d. Special Edition, stiff covers, 7s. 6d., post free.

The Special Edition includes Photos of the Author's Domestic Hive; his Home Apiary, and another covered Apiary; also one of Queen and Workers on a Comb. Of the Author, Rottingdean, Brighton; NEIGHBOUR & SONS, 149 Regent Street, London; and J. HUCKLE, Kings Langley, Herts.

BEE-KEEPING, Plain and Practical: How to Make it Pay. By A. RUSBRIDGE, 1s. 6d., post free, 1s. 8d. Address J. HUCKLE, Kings Langley, Herts. A 1253

THE MANAGEMENT OF STRAW SKEPS. Designed to teach the Cottager how to obtain the best results at the least possible cost. By attention to its teachings, Cottagers will be enabled to make their Bees a more profitable source of income than hitherto. Price One Penny. Six copies and upwards, post free. J. HUCKLE, Kings Langley.

WANTED.—Copies of *British Bee Journal* for January 7th, 1886, and Nov. 1873. Full price given. Apply J. HUCKLE, Kings Langley, Herts.

OFFERS Wanted for 6 dozen 1-lb. Sections of Clover Honey. Address J. CRAGGS, Gilling, Richmond, Yorks. B 90

ADVERTISEMENTS for Derbyshire Bee-keepers' Association Report (1000) received at W. T. ATKINS, 6 North Street, Derby. 10s. per page.

HONEY, Extracted, very fine flavour, in 9-lb. tins, about 2 cwt. What offers? Address ADDINGTON, Chawson, St. Neots, Hunts. B 94

PRIZE HONEY for Sale. 28-lb. Tins, 15s. each. Screw-cap Jars, 9s. per dozen. Address J. R. TRUSS, Bainton Heath, Stamford. B 98

FOR SALE.—Vol. I. to X. *British Bee Journal*, bound in Publisher's covers, with Advertisements and extra blank pages. First rate condition. Vol. II. minus Index, otherwise complete. Price £1 17s. 6d. Cheap. Rare opportunity. Address T. LOWRIE, Brant Broughton, Newark. B 97

LANTERN SLIDES on Bee-keeping, all photographed from Nature, sent on trial before purchasing. Send Two Stamps for loan of Album of Subjects. Address ALFRED WATKINS, Hereford. A 3131

A MODERN BEE FARM AND ITS ECONOMIC MANAGEMENT. Limp Cloth Edition, 3s. 9d., post free. Special Edition, handsomely bound in cloth gilt, including four interesting Photos, 7s. 6d., post free of the Author, S. SIMMINS, ROTTINGDEAN, BRIGHTON. (180)

Publications of the British Bee-keepers' Association.

BEE HOUSES AND HIVES. By Rev. GEORGE RAYNOR. Second Edition (enlarged), Price 6d.

THE CHEMISTRY OF THE HIVE. By Mr. OTTO HEHNER, F.I.C., F.C.S. Price 3d.

A DULTERATION OF HONEY. By OTTO HEHNER, Esq., F.C.S., F.I.C. Price 6d.

J. HUCKLE, KINGS LANGLEY.

HAND-KNITTED SOCKS.—Six Pairs Warm Heather Socks sent Post free on receipt of 10s. 10d. by Miss FITZ GERALD, Valencia Island Knitting Industry, Ireland. Sample pair, 2s. A 3463

The best Journal of its kind, edited and published by the renowned C. F. H. GRAVENHORST, Brunswick.

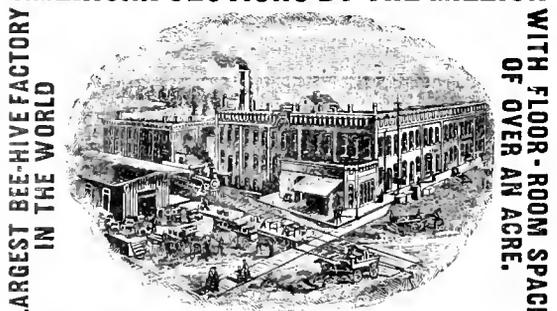

DEUTSCHE ILLUSTRIRTE BIENZEITUNG.

Sample copies sent on request.

Also, 'DER PRAKTISCHE IMKER.' Compendium of Rational Bee-culture, by C. F. H. Gravenhorst. Fourth enlarged and improved edition, with fifty-two new original Pictures, and a frontispiece. Price 4 marks (4s.), stitched; well bound, 5 marks.

C. A. SCHWETSCHKE & SON (M. BRUHN), Brunswick.

AMERICAN SECTIONS BY THE MILLION

The cut, taken from a photograph, represents our bee-hive factory where we annually turn out about 20,000 hives and 3,000,000 sections, besides enormous quantities of bee-supplies of every description. Dealers before ordering elsewhere should correspond directly with us. We are prepared to quote better prices on sections in quantities than we have ever quoted before. We are also publishers of *Gleanings in Bee Culture*, with a circulation of 7674 subscribers. A sample copy of our journal and our 40-page price list sent on application to **A. I. ROOT, Medina, Ohio, U. S. A.**

COTTAGER'S MONTHLY JOURNAL.

We should feel obliged to County, Provincial, and Local Secretaries, if they would kindly furnish our publisher, Mr. J. Huckle, Kings Langley, Herts, with the names and addresses of all cottagers and artisans who take an interest in bee-keeping, so that he may have the opportunity of forwarding each a copy of the new Journal.

COMB-FOUNDATION MANUFACTURE ON A LARGE SCALE.

During our travels in America, when we went to see Messrs. Dadant & Son, we were very much interested in their manufacture of comb-foundation, and we asked them to give us fuller particulars than those we could take away in our notes during our brief visit there. What we saw there, and the hospitable manner in which we were received, must be reserved for future record, but as they have been kind enough to accede to our request we are quite sure that our readers will be interested in a description of the largest comb-foundation manufactory in the world. We noticed the particular care and precautions taken in the manufacture, and the resulting uniformly good quality of the foundation. This care in the manufacture has met with its reward, seeing that they are at the present time the largest makers of foundation in America, and we believe Mr. Root, of Medina, comes next. We hope the description will prove not only interesting, but also instructive.—Ed.

The building into which the wax in bulk is brought, and where it is also melted, is furnished, on its highest or northern side, with a strong platform, against which the carriers push their carts, thereby facilitating the unloading. As the height of the platform corresponds with that of the cart, the casks, cases, or sacks containing the wax in bulk can easily be shifted on to the platform. This platform extends to the interior of the structure, with which it is connected by means of sliding double doors running on rails. Inside, the platform acts also as the base of a large weighing machine, the flat plate of which is even with the floor. As soon as a package is weighed its contents are sorted, the best coloured wax being put aside to be afterwards used for the manufacture of comb-foundation for sections.

The store-rooms consist of two compartments of unequal size, and are capable of holding from 10,000 to 12,000 lbs. of wax. Between these store-rooms and the

melting departments, there is a roomy corridor, allowing for the storing of many thousand pounds of purified wax in 40-lb. cakes.

The copper or boiler used for melting and purifying the wax is in the shape of an oblong, made out of thin sheet copper, and capable of holding 800 lbs. of wax.

This copper is moveable, and is simply made to rest upon the brick stove or furnace. Not being a fixture it is easily cleaned. In front this boiler is furnished with two taps, one of which is placed level with the bottom, and the other about four inches above it.

Before the fire is lighted the attendant puts some water in the boiler, say, four inches deep; then the wax is added.

As soon as the required heat is reached, the wax is carefully skimmed, and then drawn from the upper tap into tin moulds, into which about a couple of inches of hot water had already been put, drawn from the lower tap of the copper. These moulds are round, rather wider at the top than at their base, are furnished with two handles, and will hold about 40 lbs. of wax.

As soon as one of these moulds is filled it is taken to a kind of double-walled cupboard. There are several of these cupboards all round the melting department, each of which can hold as many as nine of such moulds placed one upon the top of the other, and arranged in three tiers of three each. As soon as one of these cupboards is full it is locked up, so that the wax may remain in a liquefied state at least twenty-four hours, and deposit in the water any impurity it may contain.

The melting operation is gone through three times a-day, making up from 2200 to 2400 lbs. of wax. When the wax is cold the moulds are carried to the back of the building, where they are turned over upon a tub, the bottom of which has been replaced by two small bars. In this position the water will run out: the mould is then lifted up, leaving the cake resting upon the bars. The attendant now scrapes off the cakes any impurities that may be found adhering and puts these into a tub where they are allowed to accumulate. Thus cleared, the cakes are piled up in the corridors or passages, pending their final removal either to the room where comb-foundation is made or to the purified wax-store. The latter is isolated from the other buildings and has been constructed of iron as an additional precaution against fire in the other buildings. As many as 1500 of these cakes can be stored in this building, representing an aggregate of about 60,000 lbs. of wax. The present stock stored in it is estimated at 30,000 lbs. The impurities, including such particles as may be found in the washings, are drained and put out to dry in sixteen large flat boxes, four inches deep and well exposed to the rays of the sun.

In summer, as soon as they are well dried, they are distributed among eight solar wax-extractors, three feet long by two wide. The wax dripping from them is taken to the coarse wax-store. What still remains about $\frac{2}{3}$ ths of the original bulk is once more melted down by steam

in water, containing a small quantity of sulphuric acid. It is then melted in a very large quantity of water in order to remove every trace of acid and to prevent the moulds from becoming oxidised.

Between the building which serves as store-room and the one in which the comb-foundation is made there is a large pump, by means of which water is pumped into two large cisterns. Rain-water is better suited for all these operations than spring and well water, and large quantities of it are required. The room in which the wax is worked into sheets of foundation is supplied with a small steam boiler placed in one corner. From this boiler a pipe conveys the steam into a cask, where it heats the wax, to be afterwards worked into sheets of comb-foundation. In the centre of the room is a copper vessel, vase-shaped, twenty inches long by eight wide and fifteen high. The liquefied wax is put into this. At one end a small tub, two feet six inches wide, is placed, full of water, this is always kept cool; at the other end there is another of these square tubs, the latter contains tepid water, into which the plates with which the wax-sheets are made are dipped. Besides these there are two other narrow vessels, covered with tin, and a sponge is placed on the top of each.

Two men are seated opposite each other, with the vessels containing the liquefied wax between them; they wear waterproof aprons to protect them from the water and the wax, which drips off the plates during the operation of dipping. One of them takes hold of one of the boards, passes the sponge over it, and dips it three or four times into the liquefied wax up to where he holds it; he then dips it into the cold-water tub, takes it by this cooled end and dips the other end three or four times more in the wax, finally he places it into the cold-water tub, whence it is taken up by the other man, who, after sponging it all over, repeats the dipping process and allows it to get cold.

A third man, he who heats the wax and serves it out to the other two, then takes the sheets more or less cooled out of the tub, passes a knife along their edges, strips them off the plates, and distributes them on eight or ten different piles, where they are allowed to get quite cool, thus preventing them from sticking to each other, which they would be sure to do if put up in one pile only. Twice a-day, that is, at noon and in the evening, these piles are weighed and taken down to the cellar, where they are allowed to get thoroughly cold and attain the necessary tenacity. Three men can dip as much as 1,300 lbs. of wax for thick foundation per day; four men, of whom two would be assistants, could do as much as 1,600 lbs. for thin foundation. The cellar is fitted with wooden cupboards to protect the sheets from dust, and in it as much as 10,000 lbs. of them can be stored.

The room where the rolling is done is next to the dipping-room, and the same boiler warms the water which is used for softening the sheets before they are passed through the rollers. As many as fourteen sets of these rolling machines are to be seen in this room, although only four of them are worked simultaneously. The others are kept there in readiness in case any of those in use should require repairing, which is not a rare thing, considering the softness of the metal of which these rollers are made. There are four tables, their longest side being inclined slightly forward, on part of which stands a machine, fixed to a tin plate. These tables have an extension sloping inwards, covered with tin and soldered to the plates above mentioned, which catches the water falling from the sheets and keeps the workmen from getting wet. This water, as well as any dropping from the machine, runs into a vessel placed under the table.

Two men attend to each machine. One of them stands by the handle, brushes the rollers with soapsuds, whilst the other sitting in front of the machine, takes a wax-sheet from the tepid water-tub standing on

his right-hand side, and places it in front of the rollers to be drawn in by them. The first man detaches the end with a comb, and pressing it against the upper cylinder, brings it within reach of the other, who takes hold of it with a pair of spring pliers with wooden jaws held in his left hand, whilst with his right hand he prepares another sheet. If the sheet comes out perfect it is piled up on the left-hand side of the table, but if it should show the slightest imperfection, it is thrown into a cask on the left-hand side of the workman, to be returned to the boiler and melted again. The sheets are afterwards cut to the proper sizes and then placed upon shelves. A ticket attached to each pile indicates their thickness.

Four times a-day, whilst this work is going on, a few of the sheets are cut and weighed to ascertain if they give the number of feet per pound which each of the five sorts is expected to. These five sorts consist of the following, viz., for brood-combs, thick, 5 feet; medium, 6 feet; and thin, 8 feet to the pound. For sections, thin, 10 feet; extra thin, 11 to 12 feet per pound. This checking of weights is necessary, because, when the sheets come from the machines their weight is not always uniform, but depends upon the heat of the rollers, which increases as the work proceeds.

Many bee-keepers are of opinion that soap should not be used for lubricating the rollers. Its use no doubt would be detrimental if the sheets were not of a sufficient thickness before they were passed through the rollers, for, in that case, the wax would not reach the bottom of the engraved lines on the rollers, and the sheets would be wet with soapy water. But with sheets thick enough to be doubled in length after passing through the rollers, every particle of soapy water is driven out, and the rolled sheets come out of even thickness through their length and perfectly dry.

The machines used are the Vanderwort. The rollers of those intended for thick foundation are from 12 to 13 in. long; those for section foundation are 6 in. long only.

To prevent the sheets from sticking to one another, tissue paper is placed between them. Those to be sent away are weighed and sent down to the packing-room by an inclined railway, where each lot is labelled with the customer's name, and on the back of the label the weight, quality, and size of foundation are given; thus all mistakes are prevented.

Comb-foundation-making requires a certain amount of experience and practice, which cannot possibly be attained without continuous practical work at the manufacture.

When the men resume their work after the winter is over it often takes them several days before they can get into the knack acquired the previous season.

Comb-foundation-making requires, moreover, keen observation and sound judgment, in order to profit by every incident, however small, that may improve results, both as regards saving of time, improving the quality, and avoiding everything that may be detrimental. Even the most experienced men sometimes find themselves confronted by difficulties, either in the wax-cleansing or the rolling process, which they are unable to solve satisfactorily, and these often lead to results which make it necessary for them to recommence the work afresh to try and do better. These facts bear out what Mr. James Heddon wrote lately in *Gleanings*. Comb-foundation-making is a specialty of itself, and it is no more possible for a man to make a perfect article by working only a few weeks a-year at it, than it would be to become a good workman at any other trade during the same length of time.

It is because we have made comb-foundation a specialty that we have succeeded in bringing up our sales for this year, notwithstanding the poor honey season, to nearly 58,000 lbs. (57,831 lbs.) These figures do not call for comments on our part.—CH. DADANT & SON, *Hamilton, November 12, 1887.*

USEFUL HINTS.

WEATHER.—Since our last the weather on the whole has been fine, but not sufficiently warm to entice forth the bees to frequent flights, and this is all in their favour. We have never known a good season to follow an unusually warm and bright February. In such case, increase by breeding and rapid consumption of stores are carried on in advance of the season, and too often a cold March and April follow, when spring dwindling, with other and even greater evils, speedily ensues. It is a pleasant thought, however, that days are gradually lengthening, that Nature is beginning to awake from her winter sleep, and one that should arouse the bee-keeper to make all possible preparation for the coming time of action. Although our colonies remain quietly at rest, to all outward appearance, yet within they are awaking to a life of activity. Cells are cleared out, and literally polished, for the reception of eggs: the brood-nest is day by day laterally and longitudinally extended; all *débris* is extruded from the hive; honey and pollen are conveyed from the outside combs to the immediate vicinity of the brood-nest; the young bees, on emerging from the cells, are carefully tended, brushed down, fed, and, on sunny days, enticed forth for their first flights by the older bees. In strong colonies, under these circumstances, stores rapidly disappear, and it behoves the careful, provident bee-keeper to see that none perish from starvation. For a month to come we allow no disturbances in our apiary by manipulation for interviewing queens, &c., but simply, by raising quilts, first on one side and then on the other, ascertain whether all is right within. If the sealed food has disappeared from the upper part of the combs, cakes of Good's food, mixed with a little pea-meal, are laid upon the frames and the quilts replaced, generally with an additional felt or woollen one, and the hives are closed for the next three or four weeks. Since no fear of attacks from robbers need at present be entertained, our entrances are left at full width. When such are anticipated, slides of perforated zinc are used for contracting, or a strip of glass of the full width of the entrance is placed on the alighting-board, resting back upon the front of the hive, so as to allow of exit for the bees at each end, and this almost invariably prevents robbing. Stimulation by syrup feeding should be eschewed for the present. The middle of March we consider early enough for this in our climate. It is well also to keep the bees confined to a certain number of frames, and as spring advances and colonies increase in numbers, to gradually increase the breeding spaces by adding a frame of sealed food from behind the division-board on either side, having first removed or abraded the cell capping in the centre of the comb on both sides and cut a passage through it. We are no advocates for stimulating to early breeding, since the early flights consequent thereon result in great loss to such colonies. We emphatically say, therefore, 'Still let your bees rest.' Give additional warmth by extra covering, but do not think of manipulation or disturbance of any kind except in cases of dire necessity.

Encourage cleansing flights whenever the weather is bright enough and warm enough, for nothing is more conducive to health and cleanliness. A sheltered position, a south aspect, and sufficiency of food, are conducive to cleansing flights, and consequent healthiness. We might have added to such requirements—young and vigorous queens. In any case these are a necessity to the highest attainments in honey production, but the very early stimulation of even such queens will end disastrously, and their laying powers will become temporarily suspended at the time when they are most required. Should there be any signs of dampness in the covering quilts, dry ones should take their place, and those removed should be disinfected and thoroughly dried, when they, in turn, may take the place of other damp ones requiring to be changed. It is better not to disturb the floor-

boards, unless they are foul with dead bees, excrement, &c., in which case let them be removed and replaced by clean dry ones, with as little shaking or disturbance as possible.

Bee-keepers who are fond of flowers—and what bee-keepers are not?—will do well to provide wallflowers, borage, and *Limnanthes Douglasii*,—the three best spring bee-flowers with which we are acquainted. The pretty little rock-plant, *Ambretia purpurea*, is also a great favourite, and in sheltered situations will bloom from May until August. Those are fortunate whose apiaries are within reach of fields of that beautiful crimson-flowered clover, *Trifolium incarnatum*, in which bees greatly rejoice, and which is the first to bloom of all the *trifolia*.

This, together with winter beans, form the mainstay of many apiaries, until the white clover blooms, with its abundant supplies of the finest honey producible, arrives. The tiny little yellow bloom on the common trefoil is also a great favourite with our bees.

The cotoneasters (*Macrophila et microphila*) and the mezeron, with its early pink bloom, are fully appreciated by the bees, as are all the willow tribes.

ARTIFICIAL POLLEN may be given towards the end of the month by sprinkling pea or lentil meal upon the blooms of crocuses during fine days when the bees are in full work; also in skeps or boxes filled with shavings, and placed in a sheltered sunny spot. Some prefer dredging the meal into empty combs, which are placed beside the brood-nest and confined by division-boards.

SURFACE MIXTURE.—Sawdust, sand, and ashes, or a mixture of all three, placed around the hives, save much bee-life at this season by forming a dry and warm material on which heavily laden bees, on returning wearied from the fields, may rest before entering the hives.

SNOW AND BIRDS may still demand attention, although of the former we hope to see no more for a long time to come. Should it again appear, however, it must not be allowed to remain on the hives an hour, but should be carefully swept off at once. Our old friends the tom-tits, as also sparrows, must be looked after, or our bees will suffer much from their depredations, especially where trees and evergreen bushes surround an apiary.

WATER.—We believe that much brood perishes during the early spring months from want of water, particularly where upward ventilation through pervious quilts is allowed. In small colonies, during cold weather, when the bees have difficulty in keeping up the temperature of the hive to brood-raising point, the larvae die from lack of moisture, and, putrefying, becomes a fertile source of foul brood, while the colony dwindles, and finally becomes extinct.

Circular earthen pans (milk-pans), which are often used as roofs for skeps, form good water-troughs. They should be supplied with a float of thin wood pierced with holes, upon which the bees may rest as they sip the water. They are best sunk in the ground, and the water should be changed occasionally, and a little salt mixed with it. Some prefer to fill these pans with stones, which prevent the bees from drowning. A warm sheltered nook should be selected, where the sun shines with full force upon the pans, and, when first established, a few pieces of comb honey, or a plate of syrup, placed near them will soon induce the bees to mark the locality.

STANDS AND ROOFS should be overhauled and rendered secure and weather-proof before the March winds and snowstorms—to which we are still liable—play havoc in the apiary. All chinks should be stopped, and a coat or two of paint where required would improve appearances, and render the hives impervious to moisture.

PRICE OF MONTHLY JOURNAL.—Mr. Watkins, secretary of the Herefordshire B. K. A., in his letter (1480) takes exception to the paragraph in our last 'Hints,' in

which we expressed the hope that county secretaries might find it practicable to supply the *Monthly Journal* gratis to all cottage subscribers of 2s. 6d. per annum, and charges us with raising undue expectation by the expression of such hope. But is such a hope really beyond the possibility of being realised? We hope, and think, not. Our county Associations, as well as their parent, are based upon a philanthropic foundation, and we think that the English counties, even in the midst of this unparalleled depression, will be able to find sufficient funds to supply so great a boon to the poor agricultural labourer, to whom, in these hard times, every penny is an object. To be able to call the *Journal* his own—to have it at hand for reference in his doubts and difficulties—and to be able to secure it by a rough binding at the end of the year, would, in our opinion, do more towards popularising bee-keeping amongst the very class we are so desirous of reaching, than almost any other measure which could be taken; and we cannot give up the hope of seeing it accomplished, sooner or later. Nothing could be further from our wish than to 'increase the difficulties of the management of county Associations,' knowing how great already these are. Nor did we 'assume that there was no other Association work to be considered,' nor 'that subscribers of 2s. 6d. were to be granted a boon denied to 5s. members.' But we did suppose that a subscriber of 5s. per annum and upwards neither required nor would accept—even if offered to him—the monthly *Journal* gratis. Depend upon it the expert's visits and the monthly *Journal* will be found to be the most effective weapons in the hands of the county secretary for reaching the cottager and 'bettering his condition.'

MESSRS. ABBOTT'S SECTION.—We are indebted to this old-established firm for a nice specimen of their patent section, as illustrated and described in our last issue, together with the wood separators and a triangular piece of foundation. The invention is simplicity itself, and so tight is the grip of the foundation, when inserted, that there is no possibility of its escape. The celerity with which the operation of insertion is performed leaves nothing to be desired on that score, and the extra cost of 6d. per 100 for sections, fitted with patent split bar, is a mere bagatelle.

BRITISH BEE-KEEPERS' ASSOCIATION.

The Annual General Meeting was held on Wednesday, February 8th, at 3.30 p.m., in the offices of the Royal Society for the Prevention of Cruelty to Animals, 105 Jernyn Street, St. James's, under the presidency of the Baroness Burdett-Coutts. The spacious Board-room was filled with a crowded audience of ladies and gentlemen, amongst whom were the Hon. and Rev. Henry and Mrs. Bligh, the Revs. Dr. Bartrum, J. L. Seager, F. T. Scott, G. Raynor, F. S. Selater, and W. E. Burkitt, Captain Bush, R.N., and Messrs. Graham, Bellairs, Martin, Blow, Buller, Garratt, Andrews, Sambels, Hooker, Baldwin, Zehetmayr, Leigh, Groves-Watson, Henderson, and the Misses Gayton and Brandard.

The Secretary (Mr. J. Huckle) read the minutes of the last Annual General Meeting, which were confirmed.

The President: I have now to put a resolution before you which as regards the wording of it might be considered merely a matter of form, but I am quite sure it will evoke heartfelt emotion and sympathy in the minds of all true friends of the Association. It relates to the great loss which we and all bee-keepers have sustained in the untimely decease of an esteemed friend, the Rev. F. G. Jenyns. Last year we had a similar motion to propose when it was our painful duty to express regret on the death of Mr. Fox Kenworthy, and condole with his aged mother. That gentleman was one of the most active workers in our cause, and it was natural that he should have excited our affectionate regard. Those who

only knew Mr. Jenyns as a supporter of this Association will feel we have lost a coadjutor competent to judge of all matters relating to bee-keeping, and one most anxious for the success and well-being of the institution. But his friends, among whom I may reckon myself, because I have seen a good deal of him, and had the pleasure of his company in relation with the Lytton family (Mr. Burdett-Coutts and I spend some time of the year in one of Colonel Bulwer's houses) can bear testimony to his many excellent qualities. I am able to say how greatly his loss has been regretted at Heydon, and how severe a blow his death was to those who knew him at home—Knebworth. We must all share this feeling, which our friends who remember his genial, kindly face and manly bearing, coupled with the highest intentions and upright-ness of purpose, will the best understand and appreciate. With regard to Mr. Jenyns' works on apiculture, I think I am right in saying that they have not only been of great service to the special cause they were written to promote, but also to those kindred subjects of agriculture and education about which Parliament will probably be called on to specially legislate this year. I beg to move:— 'That the members of the B. B. K. A., in Annual General Meeting assembled, desire to place on record their deep sense of the loss sustained by the Association in the death of the Rev. C. F. G. Jenyns, who for many years, until the time of his decease, was an active member of its General Committee, and in other ways rendered excellent service to the cause of British apiculture, especially by the publication of his well-known and highly appreciated educational work, entitled *A Book on Bees*. The meeting desires also to express its deep sympathy with Mrs. Jenyns and her bereaved family in the sudden and irreparable loss sustained by them.'

The Rev. J. L. Seager, in seconding the motion, said he felt in danger of forgetting how much the bee-keeping public owed to the late Mr. Jenyns, because he was too much occupied with the thought of his own personal loss in the decease of that estimable friend, whose home was within three miles of his own. He had grown to look on that gentleman as one of the wisest of all his acquaintance, a man to whom all of them might profitably turn to for advice in any difficulty, a man who possessed qualities comparatively rare in the world, for he (Mr. Seager) had never known him harbour an unkind thought against any one, or give expression to an angry or even a severe word. He was one of those who never sought popularity, and, as is nearly always a natural consequence, achieved popularity with all who came in contact with him. Every one who knew him was drawn towards him with a feeling of irresistible affection. He was ever ready to give advice, the best of advice, to all who desired it. In conclusion, he (the speaker) thought the meeting would heartily join with him and the President in expressing their sorrow at the loss of one of the most valuable members of the Association, because he was a good bee-keeper, and in every respect a sincerely good man.

The President moved, 'That the Report and balance-sheet issued for the year 1887 be received and adopted, with a vote of thanks to Mr. Kirehner, the auditor.'

The Report was taken as read, and after the resolution had been seconded, it was carried unanimously.

Mr. Garratt said he rose with feelings of great pleasure to propose the motion which stood No. 4 on the agenda. It was 'That this meeting tenders its hearty thanks to the retiring officers and Committee for their valuable services during the past year.' He felt sure that the audience would heartily concur in that expression of opinion, because they were all much indebted to the gentlemen referred to for the excellent assistance rendered by them to the bee-keeping world. The work of the past year has been carried on with its usual efficiency, and the interests of the Association had been carefully guarded and advanced.

Mr. Martin seconded the resolution, and expressed his opinion that the Committee deserved all the thanks bee-keepers could bestow on them for their disinterested labours.

The resolution was carried unanimously.

The Rev. G. Raynor proposed a vote of thanks to the Council of the Royal Society for the Prevention of Cruelty to Animals for the gratuitous use of their Board-room for Committee and other meetings. He said the obligations of the B.B.K.A. to the Royal Society had accumulated for some years past, and the Committee were especially thankful to their President (the Baroness) for having exerted her kind influence in this matter. What they would do if deprived of the use of the Society's room he could not say, but in any case serious expenses would be inevitable, therefore they were deeply indebted to the Society; and he trusted that, remembering one good turn deserves another, they would use their influence on behalf of the Society, which was doing excellent work.

The Rev. F. S. Selater, in seconding the motion, which was unanimously adopted, said that he could re-echo every word uttered by Mr. Raynor concerning the Association's indebtedness to the Royal Society for the Prevention of Cruelty to Animals.

The President returned thanks, and assured the meeting that the R. S. P. C. A., of which she was President of the Ladies' Committee, always felt great pleasure in lending their Council Room to an institution of a kindred character like the B.B.K.A., which was engaged in the promotion of objects similar to its own.

The Rev. Dr. Bartrum moved the election of the President, Vice-Presidents, treasurer, auditor, analyst, librarian, and secretary for the year 1888, in accordance with Rule 8. As regarded the President no words of his were needed to advocate her re-election. They all recognised her as the good queen-bee, who never grew old, and never needed to be replaced. He could not bear to think of the terrible loss the Association would suffer if any circumstances were to cause her ladyship's withdrawal from it. The speaker then paid a tribute of admiration to each of the before-mentioned officers, highly commending them for the valuable services rendered by each to the cause of bee-culture, and concluded by proposing their re-election.

Captain Bush, R.N., seconded the resolution, which was unanimously passed.

The Secretary reported the names of the members nominated for election on the Committee for the year 1888, which were as follows:—

The Rev. E. Bartrum, D.D.; the Hon. and Rev. H. Bligh, Captain Bush, R.N.; Captain Campbell, Mr. Thomas W. Cowan, the Rev. E. Clay, the Rev. R. Errington, Mr. J. M. Hooker, Mr. H. Jonas, the Rev. F. G. Jenyns,* the Rev. Geo. Oddie, the Rev. Geo. Raynor, the Rev. F. S. Selater, the Rev. J. L. Seager, the Rev. F. T. Scott.

The Hon. and Rev. Henry Bligh said that the motion which he had to submit was simply intended to make the Rules more intelligible, and carry out the proposal decided on last year. In the place of Rule 8 he proposed to substitute Rules 8 and 9 as follows:—Rule 8. 'The Managing Committee shall be elected annually. Every candidate for election on the committee must be nominated by two members of the Association, upon a printed nomination paper to be obtained by application to the Secretary; such nomination paper must bear the signatures of the members so nominating, together with the signature of the nominee. Those so nominated shall be the committee-men for the year unless the nominations exceed the number to be elected, in which event the election shall be completed by voting papers, which

shall be sent to each member of the Association. The names of the members nominated, together with the names of the nominators, shall be stated on the voting paper. Any vacancy that may occur during the year shall be filled up by the remaining members of the Committee.'

Rule 9. 'An Annual General Meeting of the members shall be held in each year as early as possible. The President, Vice-Presidents, trustees, treasurer, auditor, and secretary, shall be elected at this meeting, and questions of the government and management of the Association (of which at least fourteen days' notice has been given) shall be discussed and resolved upon.'

The Rev. F. T. Scott seconded the motion.

Mr. T. B. Blow moved the following amendment:—'That in case of any vacancy occurring in the committee, such vacancy be filled by election with voting papers in the ordinary way.'

Mr. Webster seconded the amendment, which was also supported by Mr. Baldwin.

The Rev. G. Raynor saw no cause for adopting Mr. Blow's suggestion, and deprecated the frequent alteration of rules, which in the present instance were working well. Mr. Bligh's proposal involved only verbal changes for the purpose of making the rules more perspicuous.

The Rev. Dr. Bartrum opposed the amendment, one of his objections being, that an election of the kind advocated by Mr. Blow would cost between 3*l.* and 4*l.*, which would be an unnecessary strain on the funds of the Association.

The discussion was continued by the President, Mr. Blow, the Rev. J. L. Seager, Mr. Garratt, Mr. Sambels, Mr. Webster, and Mr. Groves-Watson, after which the amendment was put to the meeting and lost by six votes, six being in favour and twelve against it.

The original motion was then put to the vote, and carried by a majority of twelve.

Mr. T. B. Blow moved: 'That the voting power of each member be limited to one vote, irrespective of amount of subscription?' He thought that proposal only just to the working classes, a large number of whom were only able to pay 5*s.* per annum. In their case that small subscription showed a genuine interest in the Association, and, in his opinion, represented far more than the guinea of the rich man, to whom money was no object. Besides, one man one vote was the general rule. The committee, who numbered fifteen, could command sixty votes, which almost enabled them to elect whomever they chose.

Mr. G. J. Buller, as a working man, and one who knew the feelings of the working classes on the question, seconded the motion.

The Rev. G. Raynor read an extract from a letter written to him by Mr. T. W. Cowan (Chairman), who, unfortunately, was not able to be present. Alluding to Mr. Blow's proposition, Mr. Cowan said: 'With regard to Resolution 9 I am quite sure this will be a wrong step to take, and would make it infinitely more difficult to get subscriptions than now. As long as I have anything to do with this Association, it must retain its philanthropic character. As soon as it becomes anything different I shall be obliged to leave it; it must be a society for promoting bee-keeping and nothing else.' He (Mr. Raynor) fully endorsed these opinions, which also represented the views of the late Mr. Peel, and should, therefore, strenuously oppose the motion.

Mr. Baldwin supported the resolution, and the Rev. Dr. Bartrum opposed it as being likely to chill charity, because many persons would be induced under the circumstances to lower their subscriptions, to the financial disadvantage of the Association.

The Rev. F. T. Scott and the Rev. J. L. Seager disputed the statement that the custom of one man one vote was now universal, the former quoting the case of orphan and other asylums, in which subscribers were

* Since died.

allowed votes in proportion to the amount of subscription paid by them; and the latter stating that under the Public Health Act the number of votes was regulated according to the amount of rates paid. It was only fair that those who subscribed most largely should have the largest share in deciding how the money should be spent.

After a few words from Messrs. Blow and Buller, the motion was put to the meeting and negatived by twenty votes to ten.

Mr. W. M. Graham moved: 'That the rules be so altered that any subscriber of five shillings per annum shall be eligible for election to serve on the Committee.' He had no ambition to serve on the Committee, and was acting entirely from disinterested motives; but he thought the members of Committee should consist of all classes.

Mr. Baldwin seconded the motion, which was supported by Mr. Blow, who considered, without desiring to be offensive, that the Committee consisted too much of one class.

The Rev. G. Raynor said that the qualification was lowered last year from 17. to 10s. on his proposition. He thought they had not yet given the present system a sufficiently fair trial to justify any alteration thereof. Any gentleman who could afford the time and expense of attending Committee meetings was able to pay 10s. yearly in support of the Association.

After a few words from Mr. Graham, Mr. Blow, Captain Bush, and the President, a vote was taken on the resolution, which was lost by a majority of five, the numbers being eight in favour and thirteen against.

Item No. 11 on the agenda, to be proposed by Mr. Graham as follows:—'That the Committee be enlarged from fifteen to twenty, and that the five new seats thus created be filled up by the votes of the County Representatives and the County Secretaries,' was withdrawn by permission.

Mr. T. B. Blow proposed: 'That any person who has sold or assigned the right of manufacture, or sale of any appliance designed or invented by the said person, shall not be qualified to act in the capacity of judge.' He brought no charges against anyone, but he thought it desirable that the Association should have a rule like the one he suggested, so that even an appearance of favouritism might be avoided.

Mr. Buller seconded the motion.

The Rev. G. Raynor said the rule, if passed, would disqualify Mr. Cowan and himself from acting as judges, as well as several of the best-known authorities in apiculture.

Mr. Garratt objected to the far-reaching character of the proposed rule, which would exclude some of the best judges, those who had been in the van of bee-keeping for many years.

The President considered that the interests involved in the motion were so great that a more careful and prolonged study of them was necessary before a decision should be arrived at, and she, therefore, suggested that the subject should be postponed for the present. She had never invented or assigned an appliance, and was, therefore, quite disinterested. (Laughter.)

A short conversation ensued, and eventually Mr. Blow consented to withdraw his motion.

Item No. 13, thus: 'That attention be called to a petition sent to the Committee (receipt of which was acknowledged on November 17th), and to the subsequent action of Mr. J. M. Hooker with regard to the said petition,' was withdrawn from the agenda on the application of Mr. Blow and Mr. Baldwin.

The Hon. and Rev. H. Bligh and the Rev. G. Raynor moved and seconded a hearty vote of thanks to the Baroness for her kindness in presiding.

The President expressed her best thanks to the members for their kindness in re-electing her, she also appreciated the complimentary title of queen-bee. It was an

immense pleasure for her to come to the meetings, and help, however slightly, in the development of a growing and important industry. She had lately spent a considerable time in the country, and was glad to note that the interest in bee-culture, far from abating, was growing rapidly. Perhaps that could be accounted for to some extent by the fact that everybody felt interested in that which gave them profit. No doubt people living in the country, particularly farmers, labourers, as well as persons of small means, had found they could add to their income by bee-keeping; such individuals were naturally anxious to dispose of their honey, and she thought the B. B. K. A. would do well to consider how they could best make known far and wide where a ready market could be found for such produce. But apart from monetary considerations, bee-keeping was looked upon to a great extent as a wholesome recreation—one of those innocent pleasures, of which the world was very full, if one only sought after them. It was a source of amusement and instruction, giving relief to mind and body after the day's work was over. No one could deny that the bees taught many lessons to those who watched their curious habits, order, system of government, all of which they inherited by nature and instinct. She could only hope that the efforts of their philanthropic Association would be rewarded with a higher measure of success, and that the exports and imports of honey would increase. She could heartily congratulate them on the excellent work already accomplished, for it could not be doubted that they had largely educated the working classes in regard to the science and utility of bee-keeping, one result of which was that the old custom of smothering the bees had been abolished. Her Ladyship then referred to some Bills which would be brought before Parliament during the present session, notably one by Mr. Jesse Collings, M.P., for the better adaptation of education in the country to agricultural purposes; and she hoped some effort would be made by means of that measure to advance the bee industry amongst a class who were suffering greatly from depression at the present time. Her Ladyship also alluded to the fact that a schoolmaster near Faversham, taking advantage of the Elementary Education Act, which permitted the teaching of extra subjects, had selected bee-keeping as one of these. The Inspector sanctioned this, but the Board had afterwards objected thereto. She had consequently undertaken to see Lord Cross on that matter, and endeavour to influence him in favour of introducing the subject into reading lessons. The Baroness concluded by wishing the members a prosperous new year (loud cheers).

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal," c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, Kings Langley, Herts (see 2nd page of Advertisements).

COUNTY BEE-KEEPERS' ASSOCIATIONS.

[1484.] On the subject of benefits conferred by the County Bee-keeping Associations on their members, I would like to add a testimony from my own experience as local Secretary. 'The Herefordshire Secretary' (1455) speaks of the 'waste of energy in attempts to help the cottager.' Scores of such instances may be brought forward, some most ludicrous in their results, while

others are so depressing as to deter any further attempts. But I hope to show that there is too often a fundamental mistake in the aim and object offered to the cottager. They have hardships enough to struggle against without deluding them into false hopes of immediate gain, &c.

Living in an agricultural district as I do, I find that this new teaching of the art of bee-keeping has been a God-send to the class, which has the most natural right to understand it and profit by it, though hitherto debarred from the means of studying it as a science until the B. B. Association was formed and spread its ramifications all over England. It is like a revelation to them. It has opened up a new trade and a new handicraft to them. It has developed their powers of observation and excited their ingenuity in the very tastes most congenial to their habits of life.

Organizations are the spirit of the age, and I know of none more calculated to strike deep into the hearts of the labouring class of all agricultural districts of England than the British Bee-keepers' Association, or more worthy of being powerfully supported for the good of all. As far as we local secretaries can help to improve the organization, let us take hold of this as a motive for willing co-operation, remembering that the cry of distress and depression of the farming trade is still painfully felt in our districts, and let us feel it an honour to be chosen as advocates of such a beneficial association.

The gratitude of most of our members to the British Bee-keepers' Association for having introduced them to such an interesting as well as a profitable occupation wins over new converts year by year. There may be small advance numerically in the yearly list of members, but I do not look on that as a mark of deterioration, because only those who entered the lists carelessly and with no real object have dropped out of the ranks, whereas the keenly interested stay on and become firm supporters of improvements and suggestions from headquarters, and draw in others who gradually see the advantage of these improved methods. To obtain the like advantages and to enjoy the social meetings, lectures, &c., these new ones willingly consent to join the Association. The spirit of emulation becomes stronger, the desire for competition in any form is easily excited, and when rewarded by an honourable mention (as has happened in our case) in your popular *Journal* as well as in our county's report, in the latter of which these italicised words are used referring to our Apiary Competition having 'indirectly strengthened the hold of the Association on its rural members. Besides this, the advantage was secured of bringing into prominence, in a concrete form, the benefits of applied science.' I think it may fairly be said that the *bono fide* cottager of the present day is not so ungetatable or uneducated as he is said to be.

The stimulus to good and interesting reading is a remarkable feature in the work of the Association, and is another proof of the zeal among the same class. A few of our members prefer subscribing among themselves for the *British Bee Journal*, finding its expense none too great in comparison with the amount of useful hints contained. Another copy, given as a present by a friend for members' use only, is circulated weekly, and eagerly read; and it was particularly noticed that the apiaries which were most praised last year for neatness and order belonged to cottagers who were regular readers of your excellent *Journal*. Surely the Herefordshire Secretary (in 1480) has misunderstood the '2s. 6d. subscriber!' The cottagers' annual subscription to the Association is only 1s., and if he only adds 1s. 6d. to that, he will then become entitled to the new monthly journal, sent post free. Any other subscriber by paying this additional sum will reap the same advantage. I have left much unsaid for fear of trespassing on your space, especially as regards the gratitude I owe to our County Secretary for his forbearance with my inexperience of the duties of a Secretary the first two years.—F. H., *Local Secretary*.

CONSANGUINITY.

[1485.] I have read with very much interest the articles that have appeared in the *Journal* referring to the breeding of bees. I have long since seen the advisability—I might say the necessity—for infusion of fresh blood; and to prevent, as far as possible, in-and-in breeding, fresh blood is annually introduced into my apiary by means of purchased swarms in summer or driven bees in the autumn. Consequently my apiary of thirty stocks consists of bees from at least a dozen different places, whereby the chances of consanguinity are considerably reduced although of course not entirely obviated. I have many times wished that some simple uncomplicated method could be devised which would enable us to cross our bees as readily as we can our poultry or other live stock, but I fear that happy day has not yet arrived.

If it is true, as we have good reasons to suppose, that the progeny of a given queen inherit the characteristics of the drone with which the queen was mated rather than those of the queen herself, it is evident that the selection of drones must, as is so ably pointed out at page 58, last week's *Journal*, receive special and very careful attention. The writer of the article referred to suggests that the bee-keeper should purchase a Ligurian, or some other foreign queen, from which drones should be raised for the purpose of mating with black queens. Drone-breeding from the rest of the stocks in the apiary is to be suppressed, and any drones that may chance to come into existence, in spite of the precautions taken by the bee-keeper, are to be trapped.

I am not going to say that such cannot be done; possibly it can by those who are able to devote the whole of their time to bee-culture. But we who have our daily duties to attend to, consisting of from twelve to fourteen hours per day, in addition to the garden, poultry-yard, and necessary work in the apiary, which at the time referred to is of a very primary nature, would be very reluctant to undertake the task of keeping twenty-nine out of thirty stocks entirely free from drones. But even if one could thus control drone-breeding in his own apiary, the chances of failure would be very great indeed unless the bee-keeper happened to live in a district where no other bees but his own are kept; an occurrence which, I should say, is very rare indeed. We ordinary bee-keepers will therefore have to await the invention of a more simple method before we improve the breed of our bees by the introduction of Ligurian or other expensive queens.

In his able and most interesting article (1454) Mr. Webster advocates the purchasing of virgin queens to be fertilised in the owner's apiary; but if we follow such a course and the queens purchased be of any of the foreign races, we shall, according to the article on 'The Coming Bee,' page 58, be propagating the very evils which we are most anxious should not exist. The only solution then of this important, interesting, but difficult problem, would appear to be the establishing of isolated apiaries containing only one kind of bee to which our virgin queens could be taken to be fertilised. But then the difficult question arises, Where are these isolated spots to be found? Query—Is it absolutely necessary that the drones and queens that we wish to mate should be kept at least two miles from any other bees?

I have an allotment which is at least three-quarters of a mile from my apiary, and my own bees are the nearest of any to the spot named. I should like to set there a stock of foreign bees and raise from the same as many drones as possible, and then raise queens from the best stock in my apiary and take them to the allotment to be fertilised. Will some one who has had experience in the matter be good enough to tell me if I should be likely to succeed? Up to the present I have had nothing to do with foreign bees on account of the unfavourable opinions expressed by those who have paid very dear for their ex-

perience. But of course judicious *versus* indiscriminate crossing may make all the difference between improving and deteriorating a race of bees.—A. SHARP.

CONSANGUINITY.

[1486.] The article of Mr. Webster on above subject seems to me to be rather strained taking it on the whole. He says our despised blacks could be renovated by the means he points out, and proceeds to call attention to the successful crossing with aliens as increasing the honey yield at once. I contend that our bees (English, I mean) do not require renovating, they are the result, and a good living specimen they are, of the doctrine of the 'survival of the fittest,' and no recent or living writer has been able to prove that they have deteriorated in any point of excellence which they may have inherited from their ancestors. Would Mr. Webster, or any other writer, assert that the introduction of foreign blood by the inter-marriage of his or their offspring with the natives of Italy or the swarthy nomads of Eastern lands would improve the species either socially or intellectually? Where and among what people do we find in the world's history greater acts of prowess, more heroic acts of endurance than in the annals of our own native land? Who would, I ask, except Englishmen, hold out in a besieged fortress until the uppers of their boots were consumed to satisfy craving hunger? And as the continual reiteration of the superior (?) qualities of foreign bees over the native race is made principally in the interest of dealers, I should like to ask if those queen-breeders in Palestine, Cyprus, Liguria, and other places, ever dream of sending for a supply of good, hardy English queens to improve their strain of bees?—I pause for an answer.

Mr. Webster takes birds first (page 62) to prove the baneful effects of in-and-in breeding, probably his deduction may be correct *re* the Barbary dove, but looking at the results achieved, was not the effect the result of design in the man to test the recreative powers in the dove? Where is Nature in the matter? simply perverted, I might say *non est*. I maintain if those doves had been in their natural state, and not forced by man to mate in confinement, probably without any billing and cooing, that they would not have died out in the fourth generation. And if friend Webster, or any one else, intends studying physiology, let him undertake it in the wide realms of nature, and not in the circumscribed area of a birdcage or the revolving wire drum of the imprisoned squirrel, neither in a confined space occupied by a pair of white mice or foreign rats.

May I ask Mr. Webster whence he gets his deductions that man begins to succumb to the baleful effects of consanguinity in the second generation? I think the present rather large population of the earth will refute him in his assertion, unless he can prove there was other inhabitants besides father Adam. If there was, or had been, even the possibility of mankind dying out by close consanguinity, would not the Allwise Creator have provided some other way or means of peopling the earth than the command to our first parents—'Go forth and multiply?' That was one of the first commands, and, judging by results, has evidently been the command most obeyed by the *genus homo*.

Then, in next paragraph, Mr. Webster speaks so confidently of the consequences to an apiary by the neglect of an owner in not introducing new blood, referring especially to the depreciation, then deterioration, and finally annihilation; though I give him credit for the admission that the *finale* will or may not occur till—shall I say—the crack of doom. Then he concludes his article by reference to location, compelling in-and-in breeding and the evil results arising therefrom, winding up with examples. So far so good, but when those examples can be refuted *in toto* by other examples in

direct contradiction, I think bee-keepers will not be so ready to be frightened by a bogey.

I give two cases that I have investigated this past week in the interests of bee-keepers, and I feel sure that, knowing both the parties personally and supplying the information first hand, that in-and-in breeding *does not deteriorate* the race of English bees as regards their size, working qualities or prolificness, though it should run on decade after decade and generation after generation of owners. In the first instance I walked several miles to see an old bee-keeper, who lives about seven miles from everywhere, or rather from any town or railway station. When I say old I do not mean that he is an octogenarian. Though probably he has seen sixty swarming seasons, I found him in full vigour of health plying his vocation as gardener and handyman on the farm. Our first greeting over our conversation naturally turned to bees, and after a few mutual inquiries I said to him, 'How long have you kept bees here?' 'All my lifetime, and my father before me, and my grandfather before him; they both lived in the same cottage and the bees always have stood in the same place, and I can tell you how my grandfather first had them. His master died at the farm, and when the sale took place his mistress (the farmer's widow) gave him a smart (a second swarm), and we have had them ever since.' 'Have you ever lost them by disease, or otherwise?' 'No, never. Those you now see are the same strain of bees my old grandfather started with.' 'How many do you generally leave to stand the winter?' 'Five.' 'Do you find them profitable?' 'Well,' he says, with a sly twinkle in his eye, 'I shouldn't tell every one, but I have made 6*l.* this year and twenty gallons of drink for the winter; but you see,' he added, 'I make all my hives, stools, and hackles, so that I have no expense with them.'

Now, here we have an instance of bees breeding in-and-in for three generations because of the isolation of the apiary. Yet here they are as prolific and as profitable as if the owner had spent every penny of his profits year after year in foreign or other queens, and where are the dire effects propounded by Mr. W.?—W. WOOLLEY.

(To be continued.)

NEW METHOD OF FIXING FOUNDATION IN SECTIONS.

[1487.] In the last issue of the *B. B. J.* I notice a claim by Messrs. Abbott Bros. as the inventors of a new method of fixing comb foundation in sections, by means of an angular cut through the top (?) of the section. I beg to state that I have for some considerable time used and sold sections cut in a very similar manner, the only difference being in the shape of the cut itself; that shown on page 72, No. 294, volume xvi., being larger at the top than at the bottom, whereas the cut used by me is the same all through.

I used to make a vertical cut, and that answered very well with sections in pieces, as a lateral pressure could be put on the unfixed half, so as to give a firm grip to the foundation before nailing; but when I endeavoured to fix foundation by means of a vertical cut in the one-piece sections, I experienced difficulties, because if the divided parts were pulled apart sufficient to admit the foundation, they often broke at the V joint, and if not so opened, when putting the unfolded half into position there was a constant tendency to displace the foundation by downward pressure.

To remedy these evils I made many experiments, and ultimately found that by cutting through the section at an angle of about 45° and the use of a wooden block similar to the block used when nailing sections, the sheets of foundations could be put in position and securely fixed, more expeditiously than by any other plan.

I may here mention that I have written Messrs. Abbott Bros. informing them of the similarity in the methods used by them now and that used by myself for a long time. I do not wish in any way to impute that my plan has been copied. It is, however, a lesson worth remembering.—S. J. BALDWIN.

'NOTHING NEW UNDER THE SUN.'—FIXING COMB-FOUNDATION.

[1488.] I see Messrs. Abbott are about to patent an invention I have worked out and improved long ago. The proof page of my 1888 Catalogue (yet in printer's hands) concerning angular cut rail, and foundation groove to sections, will show that I have a right to make and sell sections so treated.

I enclose you drawings nine months old (which please return) showing the said application to one-piece sections, and also to bar-frames. Is further testimony wanted? I will give names and addresses of those now far from Holme Apiary to whom I showed the invention.

The cut to top rail of section, at an angle of 45°, is all sufficient for holding the foundation, but side and bottom grooves are necessary to keep full sheets from buckling, and so treated the one-piece section is ahead in foundation-fixing of any section yet introduced. Yet this I have superseded, and have a method which will not only give fixing of foundation to sections and frames, but also securely against displacement of the honey and comb when filled, even should it so happen 'the Man in the Moon' (?) had an accident in his apiary and dropped a crate of well-filled and finished sections to Mother Earth. From what I know concerning inventions in useful bee appliances, I judge none would hold an argument supporting a patent, neither should there be if all the philanthropy given forth in the direction of bee-keeping is taken into consideration.—JOHN H. HOWARD, *The Model Apiary, Holme, Peterborough.*

[We have inspected the drawings Mr. Howard has kindly forwarded to us, and have been struck by the many ingenious contrivances he has discovered for the greater ease in apiculture. Among others there is the top rail of a section cut through at an angle of 45°. Messrs. Abbott's section has the angle rather wider at the top, affording a stronger grip.

We have received a communication from Mr. Bomber Chambers to the same effect as Mr. Howard's letter. He further says, 'From exceedingly careful experiments I have come to the conclusion that perfectly filled sections cannot be obtained without the aid of full sheets of foundation: this, I find, is a fact that has been recognised only for about the past two years, and is a point little known at present; hence the few arrangements that have been made, or even suggested, for fixing full sheets—the sort of foundation manufactured also not allowing full sheets being used until recently.

Mr. C. J. H. Fitch, of Sible Hedingham, and others, inform us that they have for the last two years had the identical plan of Messrs. Abbott in operation, and have sent out a vast number of sections filled with the guides so fixed.

Messrs. Abbott Bros. inform us that they have received numerous applications from all parts of the country from persons claiming to have previously invented their new mode of fixing comb foundation in sections; but after inquiry, every statement has proved incorrect, and the cut alluded to being in every instance the simple straight cut that was invented about the same time as one-piece sections. One would hardly expect a bee-keeper making such an important discovery would omit to let his fellow bee-keepers remain long uninformed.—E.R.]

THE PREVENTION OF INCREASE.

NUMBER THREE.

[1489.] In working for extracted honey, the prevention of increase is easily accomplished by a judicious management in tiering up and extracting. But when we come to the production of comb-honey, no system of management has as yet succeeded in absolutely preventing increase. There are, however, different methods of manipulation that tend to decrease swarming; but why try to entirely prevent swarming? Prevent it as far as is consistent with the largest amount of nice comb-honey, and then make use of the swarms *à la* Hutchinson, and double up in the fall.

Of the different methods tending to prevent swarming, I will offer the following as being with me the most successful.

I use Heddon's sectional hive, but my system of management can be varied to suit the workings of any hive. We will imagine white clover in full bloom and a good colony of bees occupying two sections of the Heddon hive, with honey-board and one section case on, the latter being about half full of honey; now lift off the section-case and one of the brood-cases, and from the case now remaining take four of the frames having the least amount of brood, crowding two to each side of the hive of the four remaining, and in the centre place four frames having a foundation starter half an inch wide, readjust your hive, and in about three days they will be ready for another case of sections, and as soon as the four frames below become filled with comb cut it out with the exception of half an inch for a starter, and replace them, making use of the comb removed to fill your sections. Thus by a judicious tiering of section-cases and the removal of the comb in the four above-mentioned frames when about three-fourths full, not more than twelve per cent will swarm.

The four frames of brood and honey first removed can be tiered up on a few colonies and will be filled with nice stores for winter.—C. SOLVESON, *Nashatah, Wis. (The American Apiculturist.)*

THE COMING BEE.

[1490.] I seldom read anything with greater pleasure than that which I felt on reading your article on 'The Coming Bee,' on page 58. I have long held the opinion that the present system of introducing foreign queens was radically wrong, and four years ago I destroyed my own and re-queened with blacks, and since that time have done my best to keep them pure, not because I believe them to be the best bee to be obtained eventually, but because I believe that the present system, or want of system, in importing all and every kind of queens that are advertised will eventually leave us with a race of mongrels, perhaps good, but according to my experience more probably bad. With cattle and poultry, &c., the crossing of the various breeds is easily controlled; with bees it is not so, and the ordinary bee-keeper with a few hives seldom exercises any control over the mating of his queens and drones. He purchases a queen because it is the fashion, introduces her to his best stock, makes swarms and gets a lot of hybrids. This is all very well so far, but the next year his hybrids go and hybridise his neighbours' bees, and very soon the neighbourhood is filled with vicious wretches, and bee-keeping loses part of its charm for want of a systematic method of trying to improve the race in place of the indiscriminate haphazard fashion now in vogue.

Our cousins at the Antipodes have set us a good example in keeping an island entirely for one race of bees, and I hope that some systematic plan will be adopted in England for raising the best possible race; and I think 'specialisation' in queen-rearing ought to be supported by bee-keepers. Surely it will be better to

purchase home-bred queens which are thoroughly acclimatised from 'specialists,' providing they can supply bees of a reliable standard of excellence, than sending money abroad, draining the pockets for the benefit of foreigners. Our Bee-keepers' Associations are formed for the purpose of teaching people how to keep money at home instead of sending it abroad for foreign honey: therefore, why send half the profit to the foreigner for his queens? I am not satisfied with my blacks altogether, but they are a better all-round bee than some of the mongrels I have come in contact with; and as I have not much time for attempting to improve by introducing foreign blood I shall keep them as pure as I can, and hope that the specialist will be able to offer us a better in the not very distant future.—W. COXON, *Ambaston, near Derby.*

HOW TO DESTROY WASPS.—(1432 and 1459.)

[1491.] Your correspondent F. Goodrich says that with his pickle-bottle he entrapped as many bees as wasps. I think I can teach him, and perhaps some others, 'a more excellent way.' Bees will scarcely ever go to the back of the hive to feed! If, therefore, the pickle-bottle be placed there, it will speedily be filled with wasps without a bee! If, however, the bee-hives are placed in rows, one before the others, of course the back one becomes the front of the other and the plan will not work so well, but even in this case by placing the bottle quite in the middle of the back of the hive the bees will very rarely interfere with the pleasure of the wasps.—C. C. P., *Volentia, Co. Kerry.*

HIS FIRST FRAME HIVE.

[1492.] About the middle of May, 1886, I was at a place about six miles from Ripon. While there, I called to see a bee-keeper, living in a neat cottage with a nice garden in front, in which he kept his bees; there were about six hives in all. He was pleased to see me, as he wanted some one to tell him how to put a swarm into a frame-hive he had managed to get. So he took me to see the hive, and explain to him how to put his first swarm into it. It was a pattern of the Cowan hive, rather clumsy, but still a serviceable hive. 'I've got it ready "baited,"' says he, as he pointed to the strip of foundation in each frame, 'now tell me what to do.' I explained to him how to hive the swarm in the usual way: put it on the stand the new hive had to occupy, then in the evening to shake them on a board in front of the hive and let them run in. He promised he would do just as I had told him. About the end of July I was there again, so I called to see how he had got on with his bees. He had had several swarms—the first he had put in his frame-hive. He asked me to look at it, and took off the top. Oh, what a sight!—the quilt not right on, frames on the top of each other, some with the metal ends off, the combs were built all ways. Now this is how it had been done. The swarm settled on a bush just the height of the garden wall, so he took the hive body and put it on the wall wrong side up to let the swarm run in; the frames in that way being all upset. I could do nothing with them as I had no veil. I can assure you I turned away from that garden, wishing it, at least, had never possessed a frame-hive. I was not surprised when I heard that this bee-keeper had said, later on, that he liked skeps better than the new hives.—JOHN WHARROX, *Honey Cott, Hawes, Yorkshire.*

DRONES.

[1493.] I am glad to see an article in your *Journal* setting forth some of the excellences of the drone bee, for, although a bee-keeper of only four or five years' standing, I have arrived at the conclusion, rightly or wrongly I know not, that in our anxiety to have good

queens at the head of our colonies, we have, or nearly so, overlooked the fact that good kings are equally to be had in reverence.

Would it not be interesting, perhaps profitable, if some of our more advanced brethren would discuss, through the *Journal*, not only *what drones are the best after careful crossing and recrossing*, but unravel for us, who are merely babes yet, the other duties of the drone bees, which, according to some people's ideas, are many, to others few, to others none? One can hardly be persuaded to believe that they are brought into existence as the swarming season approaches solely for the purpose of mating with the young princesses. If this were their only use, then, as some tell us, a smaller quantity of better quality would, perhaps, answer the purpose. *But is it so?* I suppose those colonies that are the most forward in the spring are the first to raise and send out drones. Is this the standard rule between strong and weak stocks, or is there some other reason? For bees, like most human beings, have a reason; ought I to say, on the part of the bee, *instinct?*

Are we doing exactly the right kind of thing in a hive of say ten frames when we use ten sheets, or nearly so, of worker foundation? Might it not be discovered some day that a little drone foundation given to each hive is helpful instead of baneful, even if it did help to fill the hive with the worthless, honey-eating, lazy drone! I have one hive—No. 4—which has been, and I am expecting will be again this year, the best of my nine. It was the largest swarm I ever saw, when it came into my possession on the 31st May, three or four years ago, and gave good account of itself; same year I sent out a swarm as well. This last season it gave me about 100lbs. of splendid honey (extracted) on the tiering-up system; and had there been any yield from the limes, I did hope to have got 30lbs. more, but they failed on account of the drought. I noticed in this hive, particularly, the large number of drones it sent out, or rather went in and out of it; no doubt that hive was their right home; and also, although they might be seen flying by hundreds on a fine day, there still seemed anxiety on the part of the bees to raise more, for, as the supers went on, drone-comb was built in nearly every bit of space where worker foundation did not intrude itself. Of course, I allow no breeding above-deck. As there is queen-and-drone prevention for all my hives, with bee-space above and below, I do not find the bees object to it, nor has there a queen ever got through to my knowledge. Other hives that only yielded, say about 50lbs. of honey, were nearly destitute of drones. I give this for what it is worth; perhaps some one else may have something to say on the subject more experienced than myself.—J. W. BLANKLEY, *Denton, Lincolnshire.*

BEE-KEEPING IN MALTA.

[1494.] You ask me in your number of 5th January for any particulars of bee-keeping in Malta. At present I believe I am the only frame-hive owner in the island, unless the Rev. Fathers at the Jesuit College have them. The natives keep bees largely in earthenware pots, about a foot in diameter and $1\frac{1}{2}$ long, shaped like a stumpy-necked bottle, the mouth being filled by a stone bung with four channels for the bees to pass through; but this they invariably refuse to do, and prefer to use the big end, which is simply covered loosely with a board, the pot being on its side, and generally on the ground, and under a tree. Consequently you can imagine the assortment of creatures to be found inside. They take the honey and wax once a-year, and leave little or no stores, and are astonished at the loss in numbers during the autumn.

My brother started three or four frame-hives late last year. One, the first, is in very good order; the

other very weak, but breeding fast, and they are getting in pollen in greater quantities already. I have made myself two hives, but on account of the great heat in summer and the temperate winter, I have not stuck to the English form quite.

My hive proper is single-walled, $\frac{3}{4}$ in. stuff, and this I place in a large box on legs, giving quite 3-in. room all round, with roof to lift or hinge, raintight but not airtight. To allow of a current of air in the summer, I intend boring holes in the outer case low down, and covering with perforated zinc, and leaving the tops slightly open during the day; and if I find the sun's rays too powerful, propose having a hood like a child's perambulator to draw over to shade the south side. The natives simply cover with grass mats, but these I do not fancy, as the ants and insects are in legions, and will harbour in them. Ants are a pest, but they are get-at-able. Hornets, however, are the enemies. Last year nearly 400 were killed round the hives. I am trying to devise a plan to lessen the evil, and offer a reward for each nest, or for each dozen of dead hornets. I do not like the Palestine dodge of smoke.

The bees themselves appear to be docile, but I am told that at certain seasons they get vicious. I fancy orange blossom and karob bloom affect them. They have, as far as my inexperience goes, all the appearance of Cyprian bees, yellow bands, &c., and fly in any weather almost. I sent some dead ones to Mr. Baldwin lately to look at, and if I visit England in the summer, shall try and bring a hive with me for examination by experts. The natives, as usual, are superstitious, and object, as a rule, to their hives being looked at, and I have difficulty in getting information. They laugh at my hives, and the trouble I take, and also the feeding, but I hope by the time the Agricultural Show takes place to have some frames and sections to show, and some extracted honey, and perhaps a hive; but wax as yet beats me, I cannot get it clean. Certainly I have only smelted down old black combs and scraps hitherto, and if any one could give me a few hints I should be grateful.

There is no question about it being a splendid place for a bee-farm. The winter is so mild that no wintering, other than feeding, and perhaps a stopping-up of draughts, is necessary, and already the honey is being gathered, white broom, mignonette, and other flowers being out. Later on the *sulla*, or crimson clover, will give a harvest, and orange and other plants until the end of August. From September I expect to have to feed a little, and during the heat water is the difficulty.

I am so afraid that the heat will cause heavy combs to drop that in fixing foundation I make the sides of top-bars moveable, then fix the sheet with glue on both sides, and screw the moveable piece back. Some I have tried without glue, and am waiting for results. I find screws are necessary, as the wood is so liable to warp that nails and tacks do not hold.

I have planted white clover and limnanthes, but I do not think they will do. In some parts of the island wild thyme grows freely, and some keepers move their bees to this, which comes much later.

Should I find out anything interesting or queer as I get along I will let you know.—MALTA.

A USEFUL SUGGESTION.

[1495.] Let me suggest to some one with leisure to draw up some striking handbills, which in the present time of cheap printing are produced at marvellously low prices. Most of the matter could be culled from the many useful hints which appear in the *Journal*: for instance, 'The Cure of Bronchitis,' from your correspondent last week. These could be distributed through the local secretaries, or the plan might be extended to print at foot the name of the retailer or the bee-keeper at a slight extra cost. In large quantities a bill 7 in.

by 5 in. could be produced at about 1s. per thousand; or if a better bill is necessary estimates could be asked for and the result published for the benefit of all interested in the sale of honey.

I am not writing without some knowledge of how honey can be sold, as my turn-out approached nearly two tons in the last nine months. If the suggestion is worth anything I shall be glad to send my idea of a bill, and perhaps others will follow suit.—H. J. B.

THE TIME TEST.

[1496.] Last autumn I made my first—and last—attempt to obtain the third-class expert's certificate. Much to my disgust, owing to the time test, I failed, being considerably longer than the stipulated time in finding her majesty. Now, whether or not my examiner could have found her earlier I know not. This I do know, that if he could honestly have passed me under the present rules he would have done so; but, though most flattering were his expressions as to my general fitness, he was bound by the watch. I cannot say I was less annoyed when I remembered that at the previous examination held here, a gentleman who was examined in my presence passed *who did not find the queen at all*—but it was under another examiner. On the day of my inglorious attempt, one of the best, if not the best, manipulators I know actually drove and found in *twice the time* I occupied; but he was not up for examination. Like all bee-keepers who have done much driving, I have had good and bad drives, but from the experience thus gained, anything so uncertain as a *time test* is most unfair when a *style test* would settle the matter at once.—H. J. B., *Southgate*.

QUEEN-BREEDING.

[1497.] I think the best plan to remedy the ill effects of in-and-in breeding is that given by Mr. Eley, page 49 of the present volume, in which he says, 'that frames of wired comb containing eggs have been invariably successful when subjected to proper treatment after arrival.' Bee-keepers could with advantage, and very little expense or labour, exchange eggs to raise queens from, and thus prevent in-and-in breeding by the following plan, which I think would be successful if proper care be taken.

Take your best stock which you wish to breed from, and insert in the middle of brood-nest a frame of $1\frac{1}{2}$ inches sections containing new comb, and as soon as filled with eggs remove with the adherent bees, taking care not to take the queen with them, and put in Woodley's tin section case, making a hole or two with a prickler for ventilation. Tie a cord round to secure the lid and forward by rail at once. The contents being visible they will be handled with great care and the attendant bees will prevent the eggs from being chilled. My opinion is that eggs sent without attendant bees will not raise such strong queens as those which have had sufficient bees to keep them on even temperature. As small a number of sections containing eggs may be obtained as desired by filling the frame up with sections having $\frac{1}{4}$ inch starters only where you do not want the queen to lay, which may be removed to other hives worked for comb honey when you remove the section of comb containing eggs. In one section there would be sufficient eggs to raise at least thirty queens on Mr. Alley's plan, as given in his book on *Queen-rearing* and as practised by Mr. Pometta in Italy (*A Bee-keeper's Experience in the East*).

In conclusion I would recommend those that exchange eggs to inform those to whom they are sending them when they are about to forward them, so that all may be in readiness to insert the eggs in the hive immediately after arrival, and be careful to accept no eggs from a district in which there is foul brood.—A. WOODHEAD, *Goole*.

Echoes from the Hives.

Twyndoln, Kirkcudbrightshire, Feb. 6th.—Seeing it is a long time since you had a 'bit' of jotting from me, I thought it would not be entirely out of place—at this, the beginning of another bee-season—to inform you how 'our pets' have survived the past winter in this corner of the kingdom. The 'deaths,' as far as I can learn, are at present very few; and I have only lost one out of eight hives, and that through utter starvation, it being a driven colony that refused to take the food supplied and therefore had to pay the penalty. Saturday, Feb. 4th, was very mild, and warm gleams of sunshine tempted the bees forth for a cleansing flight and in search of pollen, of which I saw some collected from the snowdrops, and which is a fortnight earlier than the first I noticed last year. Bar-frame hives are gaining ground here now, since I got an 'Abbott's Combination,' and old-fashioned notions are getting rooted out; thanks to the *B. B. J.* I am 'given down' by some people here to be 'daft about bees;' and one old woman had the 'cheek' to tell me, 'if my ghost was seen onywhaur it wad be among thae bee hooses' (that's always some consolation for the future at any rate); but when the honey-taking season comes on, and anti-bee-keepers get a 'taste' of the precious nectar, 'thae blessed bees' are transformed into 'wonderfu' wee craturs.' Hoping you will excuse me for spinning such a long yarn, yours, BONNIE SCOTLAND.

Honey Cott, Hawes, North Yorkshire, February 9th.—To-day with us has been a beautiful day. The bees have had a good cleansing flight. All my stocks so far have passed the winter safely. The snowdrops have commenced to bloom, and I noticed to-day that several bees were gathering loads of pollen from them. This is earlier than any other season I can remember for them to begin pollen-gathering in this cold and backward climate. Last year they took in the first grain on the 19th February, in 1886 on the 25th March, in 1885 on the 13th March. After such an early start may all bee-keepers have a prosperous year is the wish of—JOHN WHARTON.

NOTICES TO CORRESPONDENTS & INQUIRERS.

'ASPIRO.'—1. *Heather Honey.*—Heather blooming after nearly all other honey-producing flowers have ceased, renders it very easy to keep the former distinct from the latter, therefore you should 'run' your colonies for clover at the commencement of the season, and after prepare for the heather-flow. This is done by most advanced bee-keepers in the north. When sojourning in North England and South Scotland we paid particular attention to this subject, and found that the best results were obtained in the following manner: The hives were provided with section-racks at the commencement of the clover-flow, and just before the heather bloomed as many of the sections that had been filled with clover honey as were required for the heather harvest extracted. These empty combs were then placed in the racks; as a result heather honey only was stored by the bees in those sections. Before filling the racks with the empty combs, the hive should be contracted to eight frames. There is little fear so late in the season of the queen 'going up' in the sections. Do not super at the back of the hive, but 'tier up.' 2. *Queen Excluder.*—No doubt the excluder-zinc was the cause of the bees not 'going up.' 3. *Superseding Queens.*—With your present experience you ought to be able to find and catch the queen. It is a very simple operation. It is of little use miting with a cast, as perhaps the young queen would be killed. 4. *Scenting Bees.*—Sprinkle the bees with a small bunch of feathers, do not on any account 'drench' them. 5. *Candy Making.*—See *The*

British Bee-keepers' Guide-book for recipes for candy-making. 6. *Moving Bees.*—Move the bees after a spell of bad weather, and as soon as possible. The skeps can be transferred to bar-frame hives. 7. *Entrances.*—Entrances should be kept wide open even in your latitude.

C. WADE.—We have received the bee forwarded by you by post. But it arrived so smashed and flattened that being without shape or form it was impossible to say with any precision whether it was a queen or a worker bee. It was equally impossible to pass any opinion as to its race. We are, however, inclined to the opinion that the bee was not the queen, but a worker, and that it was a black bee.

ARTHUR S. HUGHES.—*Hoge's Horehound Honey.*—We are not unfamiliar with Mr. W. M. Hoge's pamphlet on the virtues of horehound and 'prepared' table honey. As a pamphlet it is interesting, and we should be pleased if a somewhat similar one were distributed by the Honey Company through the length and breadth of the kingdom showing the excellences of British honey. The first we heard of Mr. Hoge was at the Royal Agricultural Show held at Kilburn in 1879. As the agent of Messrs. Thurber, of America, he exhibited about two tons of honey in sections; and the clean, compact, and perfect appearance of the honey furnished very valuable lessons in marketing honey to the British bee-keeper. The 'prepared' honey of Mr. Hoge, of later years, would not, however, stand the test of the analyst. Several samples of Hoge's honey were forwarded to Mr. Otto Hehner for analysis, and he pronounced them, with great 'certainty,' to be adulterated. He said:—'They are products of the action of sulphuric acid upon starch, and consist in part of corn syrup, or of a mixture of the same with more or less of honey.' Mr. Hoge called himself 'purveyor to Her Majesty the Queen,' but on inquiry the title could not be sustained. Hoge's 'prepared' honey was not allowed to be exhibited in proximity to the department arranged by the Council of the International Health Exhibition to the B. B. K. A. at South Kensington in 1884. We believe that Mr. Hoge got up a Honey Company, but we have not heard much of it for some time.

R. L. RICHARDSON.—*Crate for Lee's Sections.*—1. Lee's sections as at present adapted do not fit ordinary crates, but we understand that Mr. Lee has an arrangement in prospect by which this desideratum will be managed. 2. *Water for bees.*—We do not consider the plan of giving the bees water inside the hive with a bottle desirable. Consult the 'Useful Hints' in this issue, under the heading 'Water,' p. 85, for a better manner of giving bees water.

A. L. C.—You state in your communication that a recent letter signed 'W. B. Webster' is 'nothing more or less than a series of fallacies and misapprehensions,' but that 'you have neither time nor inclination to go into the matter in detail.' It becomes us, therefore, not to give ear to an unproven or unsupported assertion, or to come to any hasty conclusion respecting the trustworthiness of so old and reliable a correspondent as Mr. Webster has always proved himself to be.

A. F. PARISH.—We are obliged to you for the copy of the *English Mechanic*; we dealt with the matter in our last number. 2. The foundation being of last year's manufacture will not be a drawback to its being worked by the bees. If found to be dry let it be exposed to a gentle heat, or it may be immersed in water slightly warm.

ERNEST WOOD.—*Bee Farming and Appliances: Manufacturing.*—This is a question which is now engaging the attention of apiculturists (see 'Simmins' Bee Company' in issue of February 9th, 1888). Like all

other businesses some have floated, others have sunk. To an 'outsider,' as holding no position in the 'bee world,' the manufacture of appliances would most likely prove a failure.

J. S.—North Devon.—We should not rely on such drones for fertilisation. We should not breed drones from the queen referred to. The drones sent appear to be hybrids.

COTSWOLD.—Moving Bees.—Yes, now at once; if done on a cold day when no bees are flying.

R. CHAPMAN.—Bees in Skeps Starving.—You must not attempt uniting till a warm day in April. If the skeps have feed-holes strew moist cane sugar over hole, say a pound, cover up nice and warm. If there is no hole put a quantity under skep on floor-board.

MARCUS J. ASTLE.—Preserving Frozen Queen.—The queen could be kept alive on one frame of comb with honey, and, say, a quarter to half-pint of bees if you had a single frame observatory hive and kept same at a comfortable temperature of 45°. Or fewer bees in a small box, ventilated, but kept warm. This is presuming you can get at your bees. As a last resource put her in a cage and insert same in feed-hole, sometimes bees will feed a queen so caged even when not queenless. Kindly let us know later on what plan you adopted and how you succeed. It has been noticed that queens exposed to great cold sometimes breed nothing but drones afterwards.

W. M.—Heavy Death Rate.—Without seeing any of the dead bees referred to we should say it is the old bees dying off and not being removed by their comrades, who have apparently quite enough to do to attend to their brood, judging from your report. Experience similar to yours is not unknown, though not very frequent. We would recommend you to introduce some new blood by means of a queen from a distance, and then raise queens from her eggs, and so re-queen your stocks. You might send us a few bees for examination.

FAR NORTH.—1. Obtaining Comb-honey from a Stock that swarms.—Place the swarm on the stand, till then occupied by the stock from which it proceeded, put the super from the stock—including any bees that may happen to be in it—on the swarm. Use queen-excluder over frames which should contain *only* *inch starters* of foundation. When the super is three parts finished, place another between it and the frames.
2. Raising Queens.—See 'Practical Work in the Apiary,' now running in this *Journal*, and the *many* references to this subject already given.

Received per post from Mr. G. Stothard, Welwyn, Herts, one dozen top bars $1\frac{1}{2}$ inches, these are handy for interchanging with metal end frames; a Gray's covered feeder, of an improved pattern, and a Klimitz queen-catcher and cage, easily made by a novice; a very clever contrivance for capturing a queen, which we hope to illustrate in a future issue.

Mr. Stothard writes: 'I tried a new foundation-holder last year which I found excellent, and, I think, is my idea. It consists of a metal clip to slip over a top bar and has two little screws to tighten on the foundation. Three are necessary to each bar; all three can be fixed on in two minutes. When the foundation is built out they can be easily removed, and used over and over again for years. The little screws do not press directly on foundation, but on two little strips of wood ($\frac{1}{8}$ thick, $\frac{1}{4}$ wide, and $1\frac{1}{2}$ long), which can easily be stuck on foundation by the fingers, one on each side of foundation. I have also schemed a strong steel spring for same purpose; the only fault these have, however, is that they tear away a small piece of comb when they are removed if left long.'

* * * On account of the extent of the Report of the annual meeting of the B. B. K. A. we have been obliged to postpone the appearance of the reports of several Associations.

*Exchange Column.—Sales of Honey and Second-hand Goods.—Intended to aid Bee-keepers in the disposal of Bee-produce and Appliances for which they have no further use. Terms: Twelve words and under, Fourpence; for every additional Three words, One Penny extra.
No reduction made for continuous insertion.*

Now Ready.

SIMMINS' NEW BOOK.—'A MODERN BEE-FARM, AND ITS ECONOMIC MANAGEMENT.' Popular Edition, limp cloth cover, 3s. 9d. Special Edition, stiff covers, 7s. 6d., post free.

The Special Edition includes Photos of the Author's Domestic Hive; his Home Apiary, and another covered Apiary; also one of Queen and Workers on a Comb. Of the Author, Rottingdean, Brighton; NEIGHBOUR & SONS, 149 Regent Street, London; and J. HUCKLE, Kings Langley, Herts.

BEE-KEEPING, Plain and Practical: How to Make it Pay. By A. RUSBRIDGE, 1s. 6d., post free, 1s. 8d. Address J. HUCKLE, Kings Langley, Herts. A 1253

THE MANAGEMENT OF STRAW SKEPS. Designed to teach the Cottager how to obtain the best results at the least possible cost. By attention to its teachings, Cottagers will be enabled to make their Bees a more profitable source of income than hitherto. Price One Penny. Six copies and upwards, post free. J. HUCKLE, Kings Langley.

WANTED.—Copies of *British Bee Journal* for January 7th, 1886, and Nov. 1873. Full price given. Apply J. HUCKLE, Kings Langley, Herts.

PRIZE HONEY for Sale. 28-lb. Tins, 15s. each. Screw-cap Jars, 9s. per dozen. Address J. R. TRUSS, Bainton Heath, Stamford. B 98

FOR SALE.—Four Stocks in Standard Frame Hives well stored, in good Hives. Owner leaving. Address E. TULLEY, Bolney, Sussex. B 99

HAVE got 100 numbers of Tit-Bits, will take 6 lbs. Honey in exchange. Address PARKS, Upper Villiers Street, Wolverhampton. B 100

FOR SALE or EXCHANGE.—*British Bee Journal* for 1884-85, unbound, perfect. Also for 1883, June to December. Address D. H. DURANT, 1 Gunnersbury Lane, Acton, London, W. C 1

WANTED.—Second hand Wax Extractor, large size. Address CHILDE, Semington, Trowbridge, Wilts. C 2

FOR SALE.—A few dozen Glazed Sections, good quality and condition, 7s. to clear. Address W. WOOLEY, Beedon, Newbury. C 3

FOR SALE.—Treadle Saw Bench, great power and speed. Cheap. Particulars of A. GREEN, Selston, Notts. C 4

FOR SALE.—Extractor (Meadows'), good as new, cost 25s., sell for 12s. 6d. Address JOHN BULL, Ringstead, Thrapston. C 5

AMERICAN SECTIONS BY THE MILLION

The ent. taken from a photograph, represents our bee-hive factory where we annually turn out about 20,000 hives and 3,000,000 sections, besides enormous quantities of bee-supplies of every description. Dealers before ordering elsewhere should correspond directly with us. We are prepared to quote better prices on sections in quantities than we have ever quoted before. We are also publishers of *Gleanings in Bee Culture*, with a circulation of 7674 subscribers. A sample copy of our journal and our 46-page price list sent on application to A. I. ROOT, Medina, Ohio, U. S. A.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

COTTAGER'S MONTHLY JOURNAL.

We should feel obliged to County, Provincial, and Local Secretaries, if they would kindly furnish our publisher, Mr. J. Huckle, Kings Langley, Herts, with the names and addresses of all cottagers and artisans who take an interest in bee-keeping, so that he may have the opportunity of forwarding each a copy of the new Journal. Numerous names have been forwarded, and we beg to thank those who have taken this trouble.

PRACTICAL WORK IN THE APIARY.

The bee-keeper most likely to succeed will be the one who is always ready to take advantage of every favourable circumstance. During the summer months he finds plenty of employment, and many think there is nothing to do in the winter. This is certainly a more leisure season, but it can be very profitably employed by the bee-keeper in making preparations for the coming season. Bees require little or no attention, but he must not neglect to attend to hives, crates, and any other appliances he may require. If he is of a mechanical turn of mind he will make a great many things himself, and only purchase such articles as frames and sections, which are required in large quantities, and require special machinery to turn them out accurately at cheap rates. Those who depend on purchased articles must bear in mind that hives and appliances are too bulky to be made in quantity by the manufacturers and stored, therefore what he is likely to require he should order without delay, so as to give the dealer sufficient time to complete them. Orders are frequently left until the swarming season, and then there is such a rush that many have to wait some time before their orders can be completed, and often do not get their things until too late in the season when they are no longer wanted.

We do not recommend one manufacturer in preference to another, and our readers are invited to choose from our advertisement columns, where they will find what they require. There are now a large number of manufacturers in England, and our columns are, and always have been, open freely to all to describe and illustrate any new and interesting inventions, and to advertise them, if they think fit to do so; and if they do not take advantage

of this they have only themselves to blame if they are not remembered when orders have to be given. We urge upon our readers the advisability of giving their orders at once.

All old hives and appliances which were used last season should be thoroughly examined and put into good working order. The hives should be well scalded, and put out to dry, after which they should be painted over with a solution of salicylic or carbolic acid.

In view of the prevalence of foul brood in many districts this precaution is doubly necessary. We would strongly advise no bee-keeper to purchase any second-hand hives or appliances without having them first properly scalded and disinfected, even if he is certain they come from a district where foul brood is not known.

Our own hives are in several pieces and are easily cleaned, and we prefer them to those on fixed legs, which also have their inner and outer casings fixed for this very reason. In fact it was a very costly experience with foul brood that determined us to have our hive so constructed that it could be easily taken to pieces and scalded. We have a copper holding about fifty gallons, and as the water boils the hive is dipped into it and scrubbed over with a whitewasher's brush. The bristles of this must be bound with copper, or they are likely to come out when the glue holding them becomes melted. Every part of the hive in this way becomes thoroughly cleaned, the wax and propolis coating the wood and forming a kind of varnish, which assists in protecting the wood and answers the purpose of a coating of paint.

We only paint our outer cases and those parts exposed to the weather. The bee-keeper should do all the repairing necessary, and then give all painted work a couple of good coats of oil-paint. The painting ought not to cost much, as good paint already mixed and of any tint required can be purchased in tins at sixpence a pound, and a very little practice will enable any one to turn out a creditable job. Look over frames of combs stored away, and if they show signs of damp, such as becoming mouldy, put them into a warm place and spray them with carbolic acid solution.

Now is also the best time to order what foundation is likely to be wanted as well as sections. We are frequently asked what sort of foundation should be used. For brood-frames we recommend that from four to six square feet, and if the frames are wired it can be even lighter, some using it eight feet to the pound. Those who are going in for extracted honey should wire their frames and they would not run any chance of combs

breaking. For sections the thinnest foundation should be used, twelve feet to the pound. As to ordering sections, the bee-keeper must decide upon the size of these according to his market, but those $4\frac{1}{2} \times 4\frac{1}{2}$ are just now mostly in favour. For every hive it is intended to use for comb honey we should lay in a stock of 80 to 100 sections and three section-racks. The racks should be made to hold from twenty-one to twenty-seven sections and should be provided with dividers. The dividers used last season should be scalded and then hammered flat, so as to fit properly in their places. If he is going to work for extracted honey he must see that he has plenty of spare body-boxes so as to be able to raise his hives to three or even four storeys. A proportionate number of frames will also be required. Make-shift hives are always useful in an apiary for hiving unexpected swarms and many other purposes, and can be made by almost any bee-keeper or purchased for a few shillings.

We cannot insist too strongly on making all these preparations now, so as to be ready when the honey season comes round again. The planting of trees and shrubs should also engage the attention of the bee-keeper now. The willow is one of our earliest pollen-bearing plants, grows freely anywhere, and is easily propagated by cuttings. Larger trees transplanted would yield a supply of pollen this season even. Plant also raspberry-suckers, as well as currant and gooseberry-bushes. Some of the finest flavoured honey we have tasted was obtained from raspberries, and these continue in bloom for a considerable time. Almost all trees and shrubs useful for bee pasturage may be transplanted now, but the transplanting should only be done on days when the weather is fine and the ground in a fit condition.

THE 'WILEY LIE' IN ENGLAND.

Under the above heading in the *American Bee Journal* for January 25, the Editor gives a *portion* of an article which appeared on page 568 of *British Bee Journal* for December 28. We are sorry the whole was not reproduced, but pending an inquiry into the truth of the information supplied, we reprint Mr. Newman's reproof as it appears in the *American Bee Journal*. He says:—

'As usual in such cases, a clergyman is brought into it, so as to give some appearance of truth to the story—for he "visited many of the adulterating bee-farms," says the article. It is a base slander—a *nefarious lie*: neither the clergyman in question, nor "any other man," ever visited any such "adulterating bee-farms!" They do not exist!! It is nothing more nor less than a *scandalous falsehood*—the production of a sensational reporter's brain, written for *spice*, but lacking even the flimsiest "thread" of truth! Its only possible excuse is the infamous "scientific pleasantry" written "for the fun of the thing," by Professor Wiley—who is so unprincipled as to let it "fly" on electric wires to "the uttermost parts of the earth," without a word of regret, or denial! When cornered by the *American Bee Journal* he admitted that he wrote it as a scientific pleasantry, never dreaming that any one would imagine it to be a sober fact. Now the *British Bee Journal* republishes it under the heading of "Facts." It is astonishing, to say the least! We have repeatedly offered large sums of money to persons (one of them a clergyman, too) who had repeated this story as a *fact*, to take us to the place where these "artificial combs" are made, or where the "adulterating bee-farms" may be found, but no one can take us to them! No such places can be found! Mr. A. I. Root, editor of *Gleanings in Bee-Culture*, has for two years had a standing offer of \$1500 to any one who will point out such places to him—yet there are none who can do it. They do

not exist! Now when honey is scarce and prices high, it is just the time for putting this "artificial comb honey" on the market at good prices, for our British contemporary says that it is "so much like the genuine article that only experts can detect the difference." But what are the *facts*? Not even a single pound of the "artificial honey" can be produced! Not even a single "adulterating bee-farm" can be shown!! Send your "clergyman" over here, Mr. Scribbler, to point out such farms. It will pay him to do so!'

ASSOCIATIONS.

SOMERSET BEE-KEEPERS' ASSOCIATION.

The annual meeting was held on the 26th January at the committee-room of the S.P.C.K., Union Street, Bath, only one member, besides the Hon. Secretary (Rev. C. G. Anderson), putting in an appearance. No business was transacted. The position of the Association is as follows:—Members of the Association, 39; Taunton Branch, 28; Bedminster Branch, 10; total, 77. Receipts of the Association, 24*l.* 18*s.* 6*d.*; expenditure, 36*l.* 2*s.* 11*d.*; balance against the Association, 11*l.* 4*s.* 5*d.* Taunton Branch receipts, 9*l.* 10*s.* 6*d.*; expenditure, 9*l.* 9*s.* 6*d.*; Bedminster Branch receipts, 1*l.* 12*s.* 6*d.*; expenditure, 1*l.* 6*s.* 3*d.* The work of the Association has been crippled both from want of funds and energy among the members. Shows were held at Bath, Bedminster, Taunton, Dunster, North Bethberton, Stoke Courcy, Nunney, &c. The Rev. Charles G. Anderson, having resigned the Hon. Secretary and Treasurerships, will no longer be responsible for the Association in any way. No business being transacted at the meeting, both offices are vacant; and no plan for carrying on the Association was proposed, though a letter was read from Mr. Hamilton Palairet, offering to assist in paying off the debt due to the treasurer.

LANCASHIRE AND CHESHIRE BEE-KEEPERS' ASSOCIATION.

The Lancashire and Cheshire Bee-keepers' Association held their annual meeting at the Bear's Paw, Lord Street, Liverpool, at 4 p.m., on Wednesday, the 8th February, 1888. Amongst those present were Revs. J. F. Buckler, Shellfield, Hardinge, and Thos. Slevan; Colonel Herne, Mrs. Milner, and Miss Rowe; Messrs. W. B. Carr, Geo. Roberts, Litherley, Williams, Scotson, Sadler, Procter, Bally, Bather, Caldwell, Wade, Lyon, Deane, Milner, &c. The Report and accounts were taken as read.

The Chairman (the Rev. F. Buckler) informed the meeting of a letter he had received from Lord Lathom, the President, regretting his inability to be present, as he was called to London for the opening of Parliament.

A vote of thanks to the officers of the Association for the year 1887 having been proposed, seconded, and carried unanimously, the re-election of officers for 1888 was proceeded with. To the list of patrons the Duke of Westminster had kindly consented to his name being added. The President, Lord Lathom, was unanimously re-elected amidst expressions of general thanks for his kind letter. The other officers of the Association were mostly re-elected, additions being made to fill vacancies, subject to the parties appointed consenting to act.

Rule 6 of the Association was altered so as to make subscriptions become due the day of the annual meeting and after the balance-sheet of the previous year had been published, and the Secretary was asked to write to those members who had not paid prior to the expert making his visit that the expert would be prepared to receive their subscriptions.

Tea was provided for the lady members, and there was a short discussion on the relative qualities of three samples of honey brought before the meeting by the

Hon. Secretary, when the meeting was brought to a close. Several of the members dined together and discussed the work of the Association for the year, all agreeing that every effort should be put to make the bee and honey department of the Royal Manchester, Liverpool, and North Lancashire Agricultural Society, to be held at Lancaster this year, a great success by offering a very full and valuable list of prizes.

It augurs well for the Association that already several new members have joined since the commencement of 1888.

HEREFORDSHIRE BEE-KEEPERS' ASSOCIATION.

The annual general meeting of this Association was held on Thursday, February 2, in the Woolhope Club-room at the Free Library, under the presidency of Mr. James Rankin, M.P., there being also present—the Rev. James Oakley, Dr. T. A. Chapman, the Misses Marillier, Mr. W. Tomkins (Burghill), Mr. George (Abbeystone), Mr. H. Lovesay (Holmer), Mr. W. Smith (Thinghill), Mr. M. Meadham (Burghill), Mr. J. R. Hole (Tarrington), Rev. F. S. Stooke-Vaughan (hon. treasurer), Mr. Alfred Watkins (hon. secretary), &c.

From the annual balance-sheet, which was read by the Secretary, it appeared that during the past year the expenditure (including 15*l.* 7*s.* 6*d.* offered in prizes) had been 45*l.* 19*s.* 9*d.*, and there was a balance in hand amounting to 1*l.* 19*s.* 7*d.* Mr. Watkins added that although the amount of subscriptions had fallen off 8*l.* during the year, their expenditure had been less, and the Association was in a no worse position than last year.

The Secretary remarked that at a committee meeting, held on January 8th, it was proposed that the county be divided into districts corresponding with the petty sessional districts, each district to be in charge of a local secretary. On the motion of Mr. Watkins, the recommendations of the committee were confirmed and embodied in the following minutes:—

1. The county is divided into districts corresponding with the petty sessional divisions, each district to be in charge of a local secretary, who shall, after the first holder of the office, be elected by the members of the district.

2. Each local secretary to have charge of the work of the Association in his district, and to be empowered to receive and give receipts for subscriptions: such subscriptions to be remitted to the Treasurer at the end of each quarter, any expenses incurred for postage, &c., being deducted from the amount remitted.

3. Each local secretary to call an annual meeting of all members in his district during the month of January (before the 20th) for the purpose of electing the local secretary for the ensuing year, discussing the work of the year, and any other matter of interest. He may also call such additional meeting as he may think fit.

The election of officers was then proceeded with. In reference to the hon. secretaryship, Mr. Watkins said he had come to the conclusion to resign, but would be prepared to act as local secretary for the Hereford district.

The Chairman, in appreciative terms, proposed that the best thanks of the Association be given to Mr. Watkins for his most useful services as general hon. secretary in the past, and for his offer of continued service as secretary of the Hereford district for the future.

The Rev. F. S. Stooke-Vaughan seconded, and it was unanimously passed.

Mr. Watkins replied, stating that it had been to him a labour of love, and he hoped still to be able to do some good work for the same good cause.

The Chairman then proposed that the Rev. James Oakley, Hereford, be elected general hon. secretary, remarking that that gentleman was fond of the work, and had consented to take up the post. Dr. Chapman seconded the proposal, and it was carried unanimously.

Sir Joseph Bailey, the member for the city, was elected president for the ensuing year. Local secretaries for the various districts were appointed as follows:—Abbeystone, Captain Freke Lewis; Bredwardine, Miss Kearsley Thomas, Winforton; Bromyard, Mr. E. L. Cave; Harwood End, Rev. G. Herbert, Llangarren; Hereford, Mr. Alfred Watkins; Kington, Mr. J. W. Lloyd; Ledbury, Mr. T. Charles; Leominster, Mr. A. Bannister, Doeklow; Ross, Mr. A. P. Small; Wigmore, Mrs. Cartwright, Leintwardine; Weobley, Mr. John Griffiths. The committee was also elected. The Rev. F. S. Stooke-Vaughan was re-appointed treasurer. The following were appointed experts:—Mr. J. R. Hole (Tarrington), Mr. M. Meadham (Huntington), and Mr. Thomas Pritchard (Bucknell); and as representatives to the British Bee-keepers' Association, the Rev. James Oakley and Mr. A. Watkins were re-elected.

Mr. Watkins then read the annual Report, which recapitulated the work done by the Association during the year, including private demonstrations, arrangements, and lectures, the bee-tent, and the Hereford Honey Fair. Referring to the position of the Association, the Report stated:—'About fifty names have been taken off the list of members during the year, but a number of these had ceased paying their subscriptions for several seasons. On the other hand, seventeen new members have joined.' It will be noticed that the income by subscriptions is 8*l.* less than last season, but that liabilities remain at about the same amount. The report was adopted, and a vote of thanks was heartily accorded to Mr. Rankin for presiding.

NORTHAMPTONSHIRE BEE-KEEPERS' ASSOCIATION.

The annual meeting of members of this Association was held on Saturday afternoon, January 28th, at All Saints' Schools, Northampton. Mr. A. T. Adams (Crick) presided, and there were also present—the Rev. J. Phillips (Weston Favell), Mr. Francis (Northampton, treasurer), Mr. Collins (Berry Wood), Mr. Adams and Mr. Kimbell (Spratton), Mr. R. Hefford and Mr. O. C. Hollis (Boughton), Mr. W. L. Bird (Horton Hall), and Mr. F. D. Douglas (Wootton).

Mr. Francis said the first business of the meeting was to consider whether the Society should be continued or dissolved. It would, perhaps, be advisable before they took the matter into their consideration to have a statement of the receipts and expenditure for the past year, and of the financial position of the Association submitted to them.

From the statement it appeared that, excluding the bee-tent, which was the property of the Association, the Society was upwards of 6*l.* in debt.

In answer to a question, Mr. Francis said the members of the Association numbered about seventy. Four or five years ago, when he became treasurer, the Society was encumbered with a debt of between 40*l.* and 50*l.* After some conversation he added that the Society could not work the county properly with its present income. If the bee-tent, with an expert, were sent to the different agricultural shows, a large outlay would be entailed, and this the funds of the Society would not permit.

Eventually Mr. Collins proposed, Mr. Bird seconded and it was carried without one dissentient, that the Association be not dissolved.

It was decided to ask Lady Knightley to kindly become President of the Society for the ensuing year, in place of the Hon. C. R. Spencer, the retiring president. The following gentlemen were then elected as the Committee:—The Rev. J. Phillips, and Messrs. W. E. Stimpson, R. Hefford, W. Adams, J. Rooke, W. L. Bird, and E. Adams. Mr. Hefford, at the wish of the meeting, undertook the secretaryship, and Mr. Francis, the treasurer.

The thanks of the Society were given to the Hon. C. R. Spencer, to the Committee, and to the Treasurer, for their services during the past year, and with a similar compliment to Mr. Adams, for presiding, the meeting came to a close.

ESSEX BEE-KEEPERS' ASSOCIATION.

The annual meeting of the Association was held at Chelmsford, at 6.30 p.m. on Friday, January 26th. Mr. Reg. W. Christy presided; and there were also present Messrs. Ed. Durrant, W. E. Bovill, C. R. Finch, W. R. Gibbens, F. W. Brenes (Brentwood), F. H. Meggy, honorary secretary, and W. Dehnam, expert and assistant secretary.

The Report stated that county shows had been held successfully on June 7th, in connexion with the Essex Agricultural Society, and November 16th in connexion with the Chelmsford and Essex Horticultural Society. At the first-named there was the best exhibition of hives and appliances which has been seen in the county, and at the latter the largest and best display of honey. At one or other the B. B. K. A. silver and bronze medals and certificates were awarded, and for the first time in Essex candidates were examined for the B. B. K. A. third-class certificate for proficiency in bee-keeping. Mr. Dehnam received the silver medal for comb-honey and the bronze medal for run-honey, Mr. Runciman the certificate for run-honey, and Mr. Cheek the certificate for proficiency.

The offer of the Association to give lectures in winter, or send the bee-tent in summer, wherever the cost incurred is guaranteed, was taken advantage of at West Hanningfield for a lecture, and at Rayleigh, on the occasion of the rural fête, for the bee-tent demonstrations and lectures. The bee-tent is found to be a welcome addition wherever it is engaged; and the attractive lecture, illustrated by lantern and slides, prepared by Mr. Ed. Durrant, is appreciated wherever heard.

The Committee attach so much importance to lectures in the winter season as a means of spreading the knowledge of economic bee-keeping, that they have recently decided to pay half the cost of at least one lecture in each year, to be delivered at some centre where they are not well represented. If the funds allowed they would gladly apply 10*l.* a-year in a similar way, which would enable them to hold many more village lectures.

The division of the county into districts has not, in many cases, borne great results; but the thanks of the Association are, nevertheless, due to all who have acted as district secretaries and local advisers, some for help given during the past year, and others for assistance hoped for in the future. A very slight effort on the part of each District Secretary, planted as they are all over the county, should bring such an addition to the funds as would enable the Committee at least to carry out the scheme for lectures advocated above. Thanks are tendered to all others who have helped forward the work of the Association during the year, and among them to Mr. Dehnam, who has waived all claim for recompense for the many hours he has given to the work of assistant secretary.

In reply to a question put by Mr. Durrant, the Secretary pointed out that centres for the sale of honey had been formed in the ordinary course of trade. Honey was sold at a dozen places in Chelmsford only, and it was staged by nearly every grocer. If some sold inferior, foreign, or manufactured stuff, the public were quickly learning to demand what was good, well-flavoured English honey. Mr. Durrant admitted if people did not sell it was generally because they wanted the high prices of times now passed. The prices offered by the honey companies were so low that only those could make a profit who had learned the lessons of the last few years and could make their bees produce double the quantity of honey. Of course they should sell near home if they could. Personally, he could sell almost any quantity.

Mr. Brenes, who took second prize for the best cottagers' apiary last year, corroborated, and stated, after the meeting, that he had sold nearly a hundredweight of honey near home without taking much trouble.

The following are the elected Committee:—Messrs. W. E. Bovill, Reg. W. Christy, H. S. Coleman, Ed. Durrant, C. R. Finch, W. R. Gibbens.

Among the notices issued by the Secretary with the annual Report is an intimation that the Essex Agricultural Society will hold their show this year at Ilford, June 28th and 29th, when it is intended to offer prizes similar to those offered in the past year. There will be a class for the best collection of last season's honey.

The terms in which the Secretary announces the cottagers' apiary competition, for which Mr. Ed. Durrant offered a prize, are for the best kept cottager's apiary giving largest returns, in comparison with the number of hives. The expert to judge on his rounds. Competitors to be allowed the right of protesting by letter to the Committee.

NOTES BEE-KEEPERS' ASSOCIATION.

The annual general meeting of the Nottinghamshire Bee-keepers' Association was held on Saturday at the People's Hall, Heathcote Street, Nottingham. Mr. T. J. Gosling was elected to preside, and amongst those present were—Mrs. Wootton, Messrs. P. Scattergood, jun., R. Turner, S. Godfrey, D. Burnham, H. J. Raven, S. Marriott, and F. H. K. Fisher.

Mr. Fisher (hon. secretary) presented the annual report for the year 1887, which stated that they had every reason to be satisfied with the results of the year. The committee had met six times, and had done all they could towards promoting bee-keeping and assisting bee-keepers. Last year's expenses had been met, although the membership had fallen off. With an increase of members there was every prospect of the Association paying off its bad debts. The great difficulty with members seemed to be the sale of their honey, and to assist them the committee arranged to hold a honey fair on the 16th and 17th December last at Nottingham. Messrs. Morris and Place kindly placed their mart at their disposal, and the amount of honey staged was a little over a ton, besides a small quantity of wax. The sales were, however, slow, only six or seven hundredweight being sold. At this fair the medals of the British Bee-keepers' Association and their certificate were offered for competition. There were numerous competitors, including most of the leading bee-keepers in the county. The silver medal was won by Mr. W. Silver, of Retford; the bronze medal by the Rev. R. A. McKee, of Farnfield; and the certificate by Mr. G. E. Caporn, of Newton. The honey fair was a loss of 8*l.* to the Association. The committee would be glad to arrange for lectures in different parts of the county if desired. Mr. C. E. Walton, of North Muskham, had resigned the office of expert in consequence of press of business. The balance-sheet for the year 1887 showed that the income had been 23*l.* 1*s.* 2*d.*, and the expenditure 24*l.* 1*s.* 6*d.*

Votes of thanks were then accorded to the retiring office bearers.

The office-bearers for the ensuing year were then elected.

The annual drawing for bee-keeping appliances, which had been presented by various manufacturers, was next proceeded with, and a vote of thanks to the chairman brought the meeting to a close.

IRISH BEE-KEEPERS' ASSOCIATION.

The Committee met on the 7th inst. Present—Mr. Millner (in the chair), Rev. P. Kavanagh, Mr. Sproule, Mr. Gillies, Mr. Read, and the hon. secretary.

The Annual General Meeting of members was fixed

for Thursday, 5th April, one of the days of the Royal Dublin Society's Spring Show. Mr. Sproule brought up the report of the Hive Sub-Committee, which was adopted. This report recommended the addition of further details to the description of the Association's Standard hive, which appeared in the *Bee Journal* for October 20th, 1887. The full description, with the addition of these details, is as follows:—The length of top bar to be 16 in. out to out; width, $\frac{3}{4}$ in.; thickness, $\frac{3}{8}$ in.; sides, $\frac{1}{4} \times \frac{3}{4}$ in.; bottom, $\frac{1}{4} \times \frac{3}{4}$ in.; outside measurement of frame, $8\frac{1}{2} \times 14$ in. The top bar of the frame to be what is known as open-ended, with screw-distance-keepers 1 in. in length, and $\frac{1}{8}$ in. across the eye, outside measurements, the eye screws to be inserted immediately over side bars. The runners to be of hard wood, as narrow as possible, and in every way calculated to reduce propolisation to a minimum, for which purpose also the top bars should be bevelled almost to a chisel edge. The hive to be 22 in. long, $14\frac{1}{2}$ in. wide, and $9\frac{1}{2}$ in. deep from the top of frame to floor-board inside. The walls, if single, to be of $\frac{3}{4}$ in. wood, and $10\frac{1}{2}$ in. deep, with a strip of wood at the top to cover the ends of the frames; the strip to be $\frac{3}{4}$ in. full when finished. With double walls these details may be varied when necessary. The floor to be of 1 in. timber, planed on both sides, nailed to rabbit in the sides, and, if joined, to be tongued and grooved. A super cover to be provided of same dimensions inside as outside of hive, so as to cover the latter without plinths, a strip being tacked inside each end to keep it in position; the cover to be of sufficient depth to hold a doubling-box, with frames exactly similar to the brood-frames. The flight-hole to be nine inches wide.

The following fittings to be supplied with the hive:—Convenient entrance slides, an effective porch, one close-fitting division-board; quilts, consisting of one layer of canvas, two layers of jute carpeting, and two of flannel or their equivalent; each quilt to cover the frames fully with an excess of a quarter of an inch all round. Legs, butting on slip along top of slides, raising the hive bottom nine to twelve inches from the ground; the legs to be screwed on and numbered, to facilitate replacement on unpacking; the screws to be well spread, and not less than three in number for each leg.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal," c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, Kings Langley, Herts (see 2nd page of Advertisements).

* * * *In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.*

CONSANGUINITY.

[1498.] To the account of an isolated apiary I gave last week, without any of the dire effects one would expect to see developed if there is any deterioration by in-and-in breeding amongst the *insecta*, as promulgated by Mr. Webster (and which I doubt), I will add another striking instance of long continued and still continuing success in another isolated apiary, situated, like the old lady's mentioned by Mr. W., in a valley, and surrounded at an easy distance by woods, and interspersed with arable land adapted to the growth of sanfoin, of which a good breadth is generally grown. Now for sixty years this

isolated cottage, with only a small farmyard adjoining, was tenanted by a labourer and his wife. Here they spent their wedding, and here, fifty years later, they celebrated their jubilee or golden wedding, and during that number of years they kept bees, and a good-sized apiary, too. The old lady told me they started with three stocks, and increased up to ten, which number they kept for several years, and, finding them profitable, they decided on keeping twenty stocks spring count, except from any winter loss, and which, she said, amounted to barely one per year on an average. They never had any disease among them—in fact, the old lady was incredulous as to bees being subject to disease. A point in this case on which I lay stress, and can vouch for from my own personal knowledge and memory, was this, that the W—s bees always swarmed very early in the season; and years ago when I was a lad I well remember hearing year after year of the earliest swarms of the season, by two or three weeks, falling to the share of the people in question.

I would add I kept bees then and remember staying at home to watch my bees instead of going to Newbury to the celebration and rejoicings on the conclusion of the war and restoration of peace with Russia in 1856. Now if these bees swarmed the last week in April and early in May, or say a fortnight earlier than any other neighbours' bees, and the nearest neighbour was nearly two miles in a bee-line, it follows that if ever a case of in-and-in breeding year after year by bees in one apiary was known, or could be proved, surely it is this one; yet here, on the testimony of sixty years' experience, we find that their losses were barely five per cent. Here we have queens mating with drones, probably brother and sister (according to our affinity), or with first cousins, without the possibility of meeting with any new blood, even in a long flight—the earliness of the season being an insuperable barrier from the very fact that in other apiaries the drones had not made their appearance.

The old couple have passed away to the home beyond, and their name with them, as they left no offspring; but the bees still continue to thrive, eye, and swarm early, and other apiaries have sprung from them within a mile of the original! The man who lives at the cottage now, a carpenter, called on me this week for instructions how to make a bar-frame hive, and a pattern of a frame. He told me his bees are strong and that the withies (palm) would soon be out in sheltered situations.

In conclusion, I submit these two cases of continued apianian prosperity during a lengthened period are entirely at variance with the notions enunciated by Mr. W. in his recent article on consanguinity; and when the weather is warmer I shall be pleased to send Mr. W. or any other gentleman a sample of the bees (subject to the owner's approval) so that he or they may see for themselves the results of long-continued consanguinity. As regards 'The Old Lady of the Valley,' mentioned by Mr. W., he must seek some other reason or cause, I think; to solve the question of failure rather than consanguinity extending to only the sixth season in face of the two cases cited above, one continuing through as many decades and the other to nearly as many generations (of mankind, not bees). Probably the secluded apiary in the pine-woods languished and died out by spring dwindling for want of sufficient food to carry them through till the heather came into bloom, as we know the undergrowth in pine-woods—or fir-plantations, as we call them here—is practically *nil* as regards honey-producing plants, and I should be much more inclined to say they died from slow starvation from sheer inability to gather a living for an increasing population in the spring than from in-and-in breeding, and the debility mentioned would be the natural result of a bare subsistence. Instances of this are everywhere apparent in all and every form of life. Creatures not receiving proper nourishment must be debilitated—W. WOODLEY

COUNTY BEE-KEEPING ASSOCIATIONS.

[1499.] I regret that I was prevented from noticing at the proper time Mr. McClure's further observations, and replying to the inquiries contained in his letter published on the 9th inst. He therein asks, 'In what way do I want the Committee of the B.B.K.A. to move?' To this I would answer that they should institute an inquiry into the condition of each county Association with a view to ascertaining how far they have fulfilled, or are fulfilling the primary objects for which they were formed; and then further consider and advise upon the objects which they should set before them. In this county of Kent the missionary work of spreading the knowledge of improved bee-keeping has been proceeding for ten years, and it is not unreasonable to suppose that its task has been largely accomplished. This being so, the question arises, how can we retain that interest and support which hitherto has been liberally given? Is it to be supposed that county bee-keeping Associations will find it possible to maintain a permanent position, depending only upon their benevolent purposes? Or has the time come to any of them when, benevolence having done its part, they shall begin to transform themselves into societies or clubs with defined practical and commercial aims? In asking this I do not wish it to be assumed that I am assenting to it, but the consideration of it may, at least, be of some use in elucidating the main question of the *continued vitality of the affiliated Associations*. In the remarks, which may be taken as the starting-point of the discussion which has now been running on for several weeks, attention was drawn to the now neglected condition of some of the counties which had made a fair start. What has happened to these may happen to others. In passing, I would observe that it is to be regretted that the counties thus implicated have not found a voice wherewith to deplore their condition or to support the suggestion for an inquiry.

To Mr. McClure's observation that I did not bring the subject under the notice of the meeting of county representatives last month, I would say that had I been able to attend I should have endeavoured to have done so, but not knowing beforehand whether an attack of illness from which I was suffering would allow of my doing so, the opportunity was, for the time, lost. I was even prevented from conferring with my colleague on the matter.

For Mr. McClure's kind invitation to pay him a visit I am much obliged, and would assure him how much I should enjoy an inspection of the field over which his Association holds sway, but for the purpose which we have in view I hardly think it is necessary. Generally speaking, our work appears to proceed upon very similar lines, but the result, so far as attendance at committees is concerned, differs in a marked degree. With a large infusion of new blood this year into the working body of this Association, I trust the close of the year may show a great improvement on the past.—JESSE GARRATT, *Hon. Sec. Kent Bee-keepers' Association, February 18, 1888.*

PARALLEL OR RECTANGULAR FRAMES.—
YORKSHIRE ASSOCIATION.

[1500.] The 'parallel or rectangular frames' controversy still continues in the *B. B. Journal*, and I read it with interest. Having a preference for the *former*, I was confirmed in it by seeing your advocacy of the parallel in a late number of the *B. B. J.*, and glad to have the support of your more scientific experience. My first frame-hive was obtained in 1875, a Cheshire of that date with rectangular arrangement. When Mr. Abbott subsequently proposed parallel frames I thought I saw many advantages in them, and had hives made by the village carpenter, combining *them* with Cheshire's *hinged cover* and chain to support it when open, and legs eighteen inches high. It is hinged on the front and

opens from the back so that I am shut out from the sight of the bees as they return to the hive, when I operate. I have myself made several hives on that plan and see no reason to alter it, and shall be glad if you can still continue to be a 'parallelist.'

And now I am going to rather find fault with you. Severe strictures on the want of energy of the Yorkshire Bee-keepers' Association and its secretary appeared in the *B. B. J.* at the end of 1886 which eventually resulted in your being appointed co-secretary with Dr. Rickards. I was glad to see this announced and said, Now with two secretaries we shall have more movement and energy, and a vigorous promotion of the district associations at numerous centres in the very large county of York, which you yourself advocated. But excepting the one at Horsforth, where you reside, I have not seen that any other has been set on foot. So I am much disappointed. You may naturally enough say, Why do not you yourself get up a York Association? I might if I was younger, but being obliged to resign my vicarage from age in 1883, to say nothing of very serious illnesses in '85 and '86, and being now in my eighty-first year, I am quite unequal to the task. Even the writing of this letter is a perfect labour. If you reply to it, and can suggest anything, I shall be glad to hear from you, and should you at any time be in York, still more pleased if you would give me a call. Believe me, dear sir, yours truly, Jno. HONGKINSON.

N.B.—I still keep on three stocks.

COPY OF REPLY.

January 31st, 1888.

DEAR SIR,—I cannot express to you the delight I experienced in receiving a letter from so venerable a bee-keeper as yourself, and I thank you for the trouble you have taken in writing to me.

I consider your letter quite in the light of a slight (and perhaps salutary) personal *parental* castigation, qualified by sufficient honeyed drops of praise respecting 'parallelism' to make your correction rather agreeable than otherwise.

Parallel Frames.—I can see nothing but the greatest advantages connected with this system, and if you will permit me to publish your letter, I will publish a reply, showing how I explain my apparent inaction since (twelve months ago) being appointed co-Secretary with Mr. Rickards. It may be useful in two ways: as showing how an old bee-keeper prefers the parallel frames, and how a young one explains his mysterious and seemingly inconsistent conduct to others who may feel the same as yourself.

I was a bee-keeper living about six miles from the Hon. Secretary Y. B. K. A., and could hear nothing of the Y. B. K. A., although I wrote, you know how strongly, in the *Journal*. Yet I was not going to personally unearth them by a visit to Dr. Rickards. A friend, however, showed him a *B. B. J.* containing my latest exhortation for information. He thereupon wrote me a letter saying the annual meeting would be held in a few days, and he would propose me as co-Secretary. I did not want this, for my leisure (very little it is) is filled up with physiological inquiries into bee-life—that is my hobby. In spite of my protest I was elected, and I promised to assist in anything Dr. Rickards would let me do. Upon this, my first acquaintance with him, I found him a very courteous, aged gentleman, who would gladly have sung *Nunc dimittis* (so far as regards bee-keeping) with joy. He was tired of the Hon. Secretaryship, and tendered his resignation, which we begged him to withdraw. I believe he is about your own age, and had been personally acquainted with my grandfather, I found.

I think he did not treat me properly, for, being co-Secretary with him, I judged he would ask me to look at the Secretary's books, list of members, and so on, but not so. He did not ask me to his house, and I could not ask an old man to wait upon me with the books, so I was co-Secretary in nothing but name, and in finding

out for myself what I could do. I could no longer harass one I found so far advanced in years, and I also partly regretted my past vigorous action. I was to wait. I answered very many letters of inquiry for information, acceded to every invitation to lecture during this my first year of office, without the least remuneration (or payment of expenses) from any one.

We issued a circular to every bee-keeper of the Y.B.K.A. advocating the formation of branch Association, and so on: formed one at Horsforth, and a very flourishing one at Skipton (they had a nice show of their own last year, and the Skiptonites are forming two new branches in their district this year). I wrote a reply to Mr. C. Atkinson, Tockwith, near York, begging him to call the York bee-keepers together: to Mr. W. Goodall, Bighouse, and to the others in the same strain. So, if they won't help themselves, how can we expect to get on? We cannot with an 11/ annual income send a secretary round Yorkshire. Well, on Saturday last Dr. Rickards finally resigned, and I am left with 'the dog to hold.' I intend to try twelve months, and if I cannot do something I will resign. I should have told you that I was determined to resign on Saturday, owing to my peculiar position as 'Secretary yet no secretary,' but Dr. R. opened the meeting by resignation. I was therefore compelled to keep office (at a general annual meeting consisting of five members) or create a panic for a few seconds. You will see by our report how we stand, and I hope you will acquit me of seeming inertness or idleness.

We have been governed by people who did not keep bees, by committee-men who did not attend meetings, and supported by members who never attended any, and through it all my mouth was closed out of respect for estimable old age. I was pledged to action, yet couldn't act for fear of wounding, and I had not sufficient leisure myself to undertake the whole duties.

Will you then permit me to send to the *B. B. J.* your very just and kindly worded complaint, and my explanation? The two letters may stir up a few lethargic souls.

I sincerely trust you may be spared many years yet of calm delightful twilight, in which the hum of home-returning bees will linger in the mind as the sweetest music Dame Nature can supply after the sun of your more active life has set. Such an evening of life as yours (if free from suffering) is a happy dream to such as I—a dream rarely realised.—I am, yours respectfully,
R. A. H. GRIMSHAW, *Hon. Sec. Yorkshire B. K. A.*

THE FORMATION OF DISTRICTS.

[1501] The idea was recently suggested to me by Mr. A. W. Henderson (a prominent bee-keeper in this district) that an excellent way of enlisting the sympathy and efforts of bee-keepers in the forming of branch or district associations, would be to write for your columns an appeal to all bee-keepers (and others interested in bee-keeping) in the county, asking for their individual help in forming desirable offshoots of the county Association in their immediate neighbourhood. The *B.B.J.* for the particular week containing such an appeal should then be bought, and a copy sent to every subscriber to the county Association. The suggestion seems so excellent that I hasten to comply with it, and I will, at an early meeting, ask our committee to authorise this extra outlay, for; taking the worst possible view of the matter, we shall be disseminating modern ideas on bee-keeping affairs, and probably increasing the circulation of (shall I say?) our *B.B.J.* One objection to this plan may turn out an advantage, *e.g.*, it will happen that copies of the *Journal* will be sent to those who are already subscribers to it. In this case I will ask them to give the matter their own attention, and to be kind enough to forward the surplus copy to some other enthusiastic bee-keeper.

My remarks shall be confined to the position of my

own county, but, perhaps, they may apply to others; anyway it is only to Yorkshiremen I am now writing.

The Y. B. K. A. was founded in 1822 with 74 members subscribing 12l. 10s.; 1883 showed 95 members subscribing 17l. 13s. 6d.; 1884, 86 members subscribing 15l. 13s.; 1885, 74 members subscribing 15l. 5s.; 1886, 43 members subscribing 10l. 13s. 6d.; 1887, 47 members subscribing 10l. 14s. So that, from these figures, it seems there was a wave of enthusiasm when the Association was formed, which, had it continued at the initial rate, would have led to our being a body having somewhat magnificent proportions. Instead of this, however, we seem to have slowly but surely dwindled to half our numbers and nearly half our funds, until (if this descent into Avernus be continued) we shall soon be

'Giving to an airy nothing
A local habitation and a name.'

Thanks though to the firm, regular support given through these six years by many estimable ladies and gentlemen, amongst whom I am pleased to record the usual grand preponderance of our clergy (the mainstay of British bee-keeping), support, ungrudgingly given, with a sturdiness characteristic of the county; given, too, without any return being made other than the annual report, and such help and counsel as the worthy late Hon. Sec. could give, we still exist.

We want *you*, the reader, to take up the question of forming a district B. K. A. in your own neighbourhood. We wish *you* to give it 'a local habitation and a name,' and by meeting and working together with your brother bee-keepers to prevent your Association becoming 'an airy nothing.' A few postcards sent to the known bee-keepers in your district, or a short advertisement in the local newspaper asking those interested in bee-keeping to meet at a given date, hour, and place in order to discuss the matter, will surely rally round you sufficient to form a 'nucleus.' You will at once appoint a hon. secretary and treasurer, and if your number be few, form the remainder into a committee. Next, by informing the county hon. secretary and enclosing 5s. (the annual subscription) you become a branch of the B. B. K. A. You will ask what advantage you derive from subscribing to the county. I reply that you may have for your local show the use of the bee tent, lecture diagrams, driving irons, &c. Your hon. secretary and another member also become members of the County Committee; they are admitted to the annual show of the Association, to the bee tent there, and at all the village flower and cottage garden shows. Your members may also compete for the prizes.

It may be urged that in forming districts we are robbing ourselves of members. This may be so, and we may be practising the song of the dying swan. I trust, however, that the greater spirit and *verve* (a sort of developing energy like that of generating steam) imported into our County Association by your action will, in quite the opposite way, *enable us to grow*. Be this as it may, it is our duty to get you established locally; and if the knowledge of humane and scientific bee-keeping be by this action further spread abroad we may say to the young District Association '*Munituri te subdant!*'

I, for one, believe it is only necessary to bring such an important question as the benefits conferred on the farmer by the bee before our landed gentry and our county families, to enlist and ensure their interest, following which their support to the County Association would guarantee its position and usefulness. If I can obtain their ear I do not hesitate to say to the nobility and gentry of this, the vastest county in England, that it is a disgrace to them, and to every one who can support County Bee Associations, and do not, that a body of voluntary workers should lack help when the owners of farms and pasturage are those who benefit most by the labours of the bee they represent.

Many benefits are *indirectly* conferred, but they are none the less distinct; the farmer little thinks that but for the gentle breeze which undulates his sea-like corn-fields, his harvest would be mostly one of straw instead of grain. Let my lord's steward ride amongst his tenants' farms and reflect that a moderately strong hive of bees will present the farmer with something like 280,000,000 clover seeds and 40 lbs. of surplus honey in one season.

These seeds all *weigh* (and heavily too) in the forage, and convey the bulk of nitrogenous flesh-forming matter; to say nothing of providing seed for another year. It is surely late in the day to reiterate the fact that if bees (honey and humble) were exterminated, we should have to import all our clover seed every year at an immense national loss! Must we again say that a bee-keeper is practically making a present of a great part of the annual fruit harvest to his neighbours, for fruit trees, beans, peas, &c., are all carefully attended to by his bees? The village doctor and the chemist, however, cannot look upon our bee as an assistant (excepting as it enables him to prescribe and dispense *mel horacis*), for bronchitis, asthma, dyspepsia, and many other ills, are dissipated by the use of honey.

Our well-to-do people, I am sure, are not apathetic on this point; they simply do not see a *direct* benefit, and consequently do not take a *direct* interest in it.

'It is more from want of thought
Than from any want of feeling!'

Every village in Yorkshire should have a district Association, even if they only mustered the parson, the clerk, and the gravedigger. The kindly word and bit of mutual help would go a great way in rubbing off 'cutting edges'—the one by a bit of scientific advice, and the other by a bit of hive-making. These would not appeal in vain for support to 'the squire and the ladies at the Hall,' I know. Ah! if only the half-crowns rubbing pockets through, and the half-sovereigns trying to hide away in purse corners, were only sentient! Would they not cry with Sterne's starling, 'I can't get out,' or I would come over and help you?

Reader, we must go round with the hat *sometimes*, but then this is not so much a necessity as is the will required by bee-keepers to 'help themselves.' Hon. Secretaries would personally wait upon them, and stir up the dry bones, but who is to pay the piper? We want you to make a little music for yourselves. There are many bee-keepers who would dearly like a district Association, but who wouldn't like any work; besides, they want to see *how much they are going to get back*. Such at present are not in our view; we will leave them to put the question to the churchwarden when he goes round with the hat.—R. A. H. GRIMSHAW, Hon. Sec. Y.B.K.A., Horsforth, near Leeds.

BEE-TENTS.

[1502.] The time will soon be round when Associations will be making their arrangements for the bee-tent to be present at agricultural and horticultural shows, and I think it will be well before the season begins to carefully consider how we can make the best use of the prominent positions usually assigned to the tents at such exhibitions. In almost every county the bee-tent is now well known, and every time I have witnessed the manipulations they have been practically the same, consisting of simply driving a skep and trying the almost impossible task of explaining to the public how by this means they can avert killing their bees to get the honey. Provided a cottager learns to successfully drive his skeps the bees are valueless to him in the autumn, unless he adopts the bar-frame hive. The instructions on the management of modern frame-hives are usually very scantily touched upon, the utmost that I have seen done

in this respect being to have an untenanted frame-hive and extractor in the tent with which the lecturer endeavours to explain the best system of working.

To my mind much more useful lessons could be given by having a frame-hive in the tent with three frames of foundation and three combs partly filled with honey. I would then suggest that the lecturer should bring into the tent a skep containing no combs, but only a swarm of driven bees. These he would hive in the ordinary manner, and afterwards show how easily frames may be added or removed, and also how to super the hive, how to feed, and how to pack for winter, &c. It may be urged that after once having the bees the lecturer could not go through that part of the proceedings a second time without having a fresh lot of bees and new hive, but I think he could easily explain exactly how he had done it and thus convey more instruction than by merely driving a skep. With the exception of hiving the bees the lecturer could go through the other details named as often as required.

In the present day, with foundation so cheap, no one counsels a beginner to transfer his combs and bees from a skep, but rather to purchase a new hive and to place in it his first swarm. If my suggested plan were carried out such a beginner would have performed before him the operation which we advise him to carry out. Many cottagers have asked me how they are to hive their swarms in a modern frame-hive, 'because if we turn the hive upside down the frames will fall out.'

Instead of hiving the bees in the tent it might be better to obtain a full working bar-frame hive from some neighbouring bee-keeper so as to ensure having no difficulty in repeatedly opening a hive containing a swarm just inserted, and for the lecturer to fully explain how to tenant such a hive.

I do not wish to find fault with what has been done in the past, for I am aware of much good having been done by bee-tents, but I think we may well consider now that 'driving' is so well known whether we cannot make the bee-tent more useful and at the same time more attractive than it has proved of late.—EDWD. J. GIBBINS, *Neath, Feb. 11th.*

QUEEN-RAISING.

[1503.] I was very pleased to see Mr. Edey's letter (1443) in a recent *Journal*, and also the writer of 'Useful Hints' in *Journal* of February 2, where he says, 'We should limit it to eggs only.' Well, I guess Mr. Edey intended it to be only eggs, and not brood or queen cells. A frame of eggs is easy to be got in, say, the months of June or July, by placing a frame of comb in the centre of a strong working colony of either variety which is wanted, and taken out at the end of thirty-six hours. Such a comb would contain a large number of eggs. Placed between two thin boards and a sheet of paper, sent off to the purchaser by the evening's parcel post, there is no harm coming to such eggs up to forty-eight hours or longer in a June or July temperature. I have no doubt that many would avail themselves of this mode of getting new blood, but this is the question which will be asked (and I have already been asked), 'What will such a comb cost?' This is the point. What will Mr. Edey, or some other queen-breeder, supply such a comb for (in June or July) when eggs are plentiful? If such a comb will cost as much as a fertile queen in the early autumn, it would be wiser for the amateur of only a few hives to get a queen, or queens, ready to put into his hives, and so do away with all the trouble of raising them, and maybe losing them when out to meet the drones, because there is a great risk with young queens. I am well aware such a comb supplied to a practical queen-raiser would be a success; he would raise a good number of queens, and so pay cost of original comb and all his trouble bestowed upon them; but not so

with him who only wants two or three just for a trial, or to see what they are like.—A COTTAGE AMATEUR, Barton, St. Margy Church, Torquay.

PAINTING THE INSIDE OF HIVES.

[1504.] This being the time of year when the industrious bee-keeper is busy preparing new hives, &c., for the approaching spring, I wish to give a word of warning to any one who is intending to paint the *inside* of his hives.

I can only give the same advice as was given by *Punch* 'To those about to marry,' 'Don't!' The year before last I painted the floor-boards, inner wall, and dummies of several hives, and covered the bees which I placed in them with waterproof quilts, intending to give the plan a thorough trial (it appearing to follow the instinct of the bees). The frames were placed at the back of the hives, with a dummy back and front, and parallel with the front of hives.

All apparently went on well until one warm day in February after a long spell of cold, when I noticed the bees were not flying nearly so freely from the painted hives as from those which were only painted outside. On examining the former to discover the reason, on looking down into the space between the dummy and front of the hives, I found the floor-boards more or less covered with water, and a great number of dead bees floating in it.

One of these hives (with a sunk floor-board) contained more than a pint of water, so that the bees could not leave the combs without being drowned, the water nearly covering the exit in the front dummy. I was obliged to change the bees into a dry unpainted hive, and cover them with porous quilts.

As the season advanced, and breeding was going on, the bees in the hives painted inside did better, and no difference was perceptible during the summer from those unpainted. I find this season the same excessive dampness in the hives which have the inner walls painted, many bees being lost from getting cast on their backs and unable to right themselves owing to the wet floor-board. I shall therefore remove (as soon as possible) the paint from the inside of the hives, as, instead of the moisture soaking into the wood and gradually evaporating, when the walls are painted it runs down and forms a pool upon the floor-board, so that the bees dare not leave the frame.

I shall take good care not to winter any stocks in hives which have been painted inside in the future.

Wintering.—I find that my bees winter better (the porous quilts remaining dryer) if the lift or second storey is left on the hive, there being then a large air-space above the frames in which the air circulates. Moisture is not so likely to condense on the inside of the roof or cover, and run down and wet the quilts, as is the case if the roof is close down over the frames. The extra weight will compensate for the greater surface exposed to strong winds, which might blow over the hive if in an exposed position.—HAROLD ADCOCK, Middleton, Northampton.

Reviews.

THE BEE-KEEPERS' REVIEW.—This is the title of a new bee paper edited by Mr. W. Z. Hutchinson, and is published at Flint, Michigan, U.S.A. The first number is on our table, and is, as its name indicates, a Review of the current literature on bee-keeping. In it the Editor says, 'Errors and fallacious ideas will be faithfully but courteously pointed out, while nothing valuable will be allowed to pass unnoticed.' Instead of copying articles in full, they will be condensed giving the ideas, and these will be gathered from every available source.

The task the editor imposes upon himself is great, for few people have an idea of the amount of labour there is in condensing long articles so as to make them readable, while they contain only just the pith of the matter. To give a column of 'Cleanings' in our own *Bee Journal* costs us considerably more time and labour than writing half-a-dozen columns of other matter, so we can sympathise with Mr. Hutchinson in the work he has imposed upon himself. He has long been known as a contributor to the leading American periodicals, being also author of *The Production of Comb Honey*, which we have had occasion to allude to in the *Bee Journal*. It is intended to make each number as much as possible a 'special' one. The one before us treats more especially on the 'Disturbance of Bees in Winter,' and extracts from the writings of different bee-keepers giving their views on this subject. As a practical bee-keeper of many years' standing, the experience of the editor will add to the usefulness of the journal, and we wish the enterprise every success.

THE BEE-KEEPERS' MAGAZINE, which has been published for some time past by Messrs. Aspinwall & Treadwell, is now entirely in the hands of Mr. John Aspinwall. The partnership between the above gentlemen has been dissolved, and Mr. Aspinwall has given up the manufacturing business, and intends to devote the whole of his energies to the editing of the Magazine and make it an independent expositor of bee-keeping progress. The January number is already an improvement on its predecessors. Having spent a most enjoyable time with Mr. Aspinwall last summer, we know his earnest desire is to advance bee-keeping and raise it to a higher level than making it merely a means for obtaining money. Being free from the trammels of a manufacturing business, we have no doubt the improvement in the last number will be maintained.

THE CANADIAN HONEY-PRODUCER.—We have received the first eleven numbers of the above, which is published, as stated, for the advancement of honey-producers exclusively. This journal gives the news of all that goes on in the bee-keeping world in Canada, as well as extracts from the leading British, German, and French papers. Also the American papers are extracted of anything of interest to Canadian bee-keepers. It is edited by our special correspondent, Mr. T. R. Holtermann, whose pleasing articles in the *British Bee Journal* are well known to our readers. *The Canadian Honey-Producer* is published by Messrs. Gould & Co., Brantford, who are manufacturers and dealers in appliances.

Conduite du Rucher, ou Calendrier de l'Apiculteur mobilist, avec la description de trois types de Ruches et la recette pour l'Hydromel, par Ed. Bertrand, Nyon, Suisse. This book, as its name implies, is a guide to the management of an apiary and a calendar of operations for the moveable frame hive. It is entirely devoted to practical bee-keeping in moveable comb hives, and is not filled, as is too often the case, with descriptions of obsolete appliances or exploded theories, which take up too much space in many books, increasing the size and cost without adding to their value, and which more often tend to distract than to instruct. Contrary to the usual style, the plan adopted by the author enables the bee-keeper to see at a glance what he has to do at any particular season. For instance, if the bee-keeper wishes to know what to do, say, in June, he has only to turn to that month on page 79, where he will find instructions under different headings, such as 'When to remove Honey,' 'Honey House,' 'Extracting Honey,' 'Comb Honey,' 'Wax Purification,' 'Precautions to be taken after the Harvest,' 'Transporting Hives,' &c. Descriptions of all these operations are very minute, and appliances brought into requisition are also fully described. To know something about the inhabitants of the hive, he must refer to March, and here he will find a long and

interesting chapter. Not only is the natural history of the bee entered into, not too exhaustively so as to weary, but also the method of handling bees at this season is described. M. Bertrand, who stands in the foremost rank amongst Continental bee-keepers, is the President of the *Société Romande d'Apiculture* and editor of the leading bee-paper in the French language devoted to modern bee-keeping, the *Revue Internationale d'Apiculture*. He is not only a practical master of bee-keeping, but he has also the gift of imparting knowledge in a pleasant and attractive style, explicit without being verbose. Having had many years' practice in the management of four apiaries and having tried many styles of hives and different systems, he has been able without bias to compare them and to advocate the best from practical experience. The first part of the book is devoted to practical operations and the second part to illustrations and descriptions of hives and appliances. Engravings of several large apiaries are also given and at the end two folding plates contain working drawings with dimensions of three typical hives, the 'Dadant,' the 'Layens,' and the 'Burki-Jeker,' the hives mostly in use in Switzerland. We are glad to find our friend at one with us on so many important points connected with the management of bees and that the methods differ so slightly. The hives in use differ little from ours, but are somewhat larger, for extracted honey is the object of Continental bee-keepers rather than comb, although some advance has been made in this respect of late, which we are convinced is entirely owing to the teaching of the *Revue Internationale*, and we hope the author may be long spared to see the good results of his teaching. On every page will be found good sound instruction, and a copious index makes reference easy. We have much pleasure in recommending this book to those of our readers who understand the French language, and we are sure that it will be welcomed as a useful addition to the literature of progressive bee-keeping.

Foreign.

FRANCE.

French bee-keepers are informed that among others the following local shows will take place in the course of the present year, viz., Auch and Nîmes—this will open on 21st of April and close on the 29th; Laon—this will open on 19th of May and close on the 27th; Châteauroux—this will open on 23rd of May and close on the 3rd June; Antun—this will open on 3rd of June and close on the 10th; Epinal—this will open on 9th of June and close on the 16th; Alençon—this will open on 16th of June and close on the 24th. Applications for exhibiting in these shows must be sent in at least one month before their opening date.

Among the subjects set down for discussion during the sittings of the Society of French agriculturists, which will take place in the course of this month, there will be two affecting apiculture, viz., the utility of floating apiaries and the teaching of bee-keeping in rural and normal schools. Both these subjects will be discussed in the eighth or entomology section. In commenting upon these two subjects the *Apiculteur* of Paris gives it as its opinion that the want or utility of floating apiaries is not felt in France as in some other countries. Our canals, adds our contemporary, are comparatively small, and run, generally speaking, along narrow and swampy valleys. It is very different in such countries as are crossed by large rivers like the Nile and the Danube, running across immense tracts of clayey and sandy soils, producing plenty of honey-yielding plants. They might probably be introduced also with advantage in some parts of Holland and China, some of whose plains are a net of canals.

ITALY.

The *Apicoltore* reports that Signor Francesco Paolo Nervegna, of Ortona-a-Mare, has decided upon introducing bee-keeping into his scholastic establishment, and, according to his present arrangements, whilst this tuition will be limited to theory in winter, it is to take the form of practical instruction at his apiary in the spring and summer. The *Apicoltore* praises Signor Nervegna for taking this important step in the interest of apiculture, and expresses the hope that others will follow his example.

Through the energy and influence of Signori Gabriele Passeri and Vincenzo Dei Michetti, a new Bee-keepers' Association has been started at Osimo. One of its objects that it has in view is the establishing of a model apiary where lectures and practical instruction will be given.

Signor Luigi Sartori, of Milan, has undertaken the sale in Italy of Prof. J. C. Bessler's collection of the photographs of 230 bee-masters of all countries. This work takes the form of a large sheet, forty-two centimetres by thirty-four, and will be sent to any address for frs. 5.50, or, say, 4s. 6d.

Generally speaking, the cold has hitherto been rather severe throughout the country, and bees have, so far, been prevented from making occasional flights.

CANADA.

ANNUAL MEETING OF THE ONTARIO BEE-KEEPERS' ASSOCIATION.

The annual meeting of the above Association was held at Woodstock, Ontario, January 10th and 11th. There were present at the opening session about forty-five, the number increasing considerably the second day.

The President, S. T. Pettit, Belmont, Ont., occupied the chair throughout the meeting. The production of extracted honey was the first topic for consideration, and was opened by a paper by F. Malcolm, Inverkip, Ontario. Almost all were in favour of extracting only from the upper storey, and not from the brood-chamber, as many had done in the past. Also that honey should be well ripened, and the honey capped over by the bees before extracting. All were in favour of this, and objected to advancing the idea that honey extracted when unripe and evaporated by artificial means would be as good as that finished by the bees.

The storifying system was apparently the one in use by all but one, and in a good flow two storeys should be used besides the brood-chamber.

J. B. Hall, Woodstock, Ont., gave a paper, 'The Best Method to Produce Comb Honey,' as follows:—

- 1st, Bee pasturage in abundance, of not more than two miles radius from apiary.
- 2nd, That said pasturage should not be over-stocked, but rather that it should not have enough bees on it to gather all the honey-flow.
- 3rd, That there be in charge of said bees an apiculturist adapted by NATURE, assisted by study and practice, to manage the same (but the Nature part I consider the most important).
- 4th, It is essential that a hive with moveable combs having a large top surface be used.
- 5th, That the bee-keeper be a specialist, or, as the phrase is, have all the eggs in one basket. In that case they can be jealously watched and guarded, and used to the best advantage; not so if said eggs are mixed in many baskets with other things.

If the bees have passed the winter and spring well, and are strong in bees and brood at the commencement of the surplus honey-flow, a good crop of comb-honey can be secured by putting on the hive a shallow super of sections primed with comb or foundation (I say sections, because if not in nice sections it cannot be sold to advantage). Open the entrance of hive to its full size, and when work is well commenced in the super, raise it up, and put an empty super between it and the hive. Continue thus until your judgment or experience tells you they have enough space to contain the surplus honey that will be secured. Other things being right, you will rejoice in a good crop of comb honey.

A long discussion followed as to the use of dummies for contracting the brood-chamber, and if swarms should be hived on starter-foundation, full sheets of foundation, or old combs.

The general verdict appeared to be that swarms should not be hived on dummies and a few combs, unless the bee-keeper was prepared to destroy the colony after the honey season was over. That starters would give nicer comb in the sections, but the combs built in the brood chambers were useless on account of so much drone-comb. With a young and vigorous queen such objectionable comb would be much less.

The President, in his address which followed, pointed out during his term of office (two years) the Association had secured incorporation, an annual grant of 500 dol. The exhibit had been made at the Colonial and Indian Exhibition. The prize lists of our leading exhibitions are under our control, and the laying of the foundation of an Association library. The first work having been contributed by Mr. T. W. Cowan of England. The President spoke of the necessity of measures being taken to keep down and stamp out foul-brood in the provinces, and the advisability of an affiliation scheme with county Associations. In closing, the President desired to have it placed on record that he considered the British honey markets had been practically lost to us at paying prices. The temperature favoured for cellar wintering was from 48° to 55°.

Mr. Allen Pringle, Selby, Ont., gave a paper upon 'Ought everybody to Keep Bees?' Mr. Pringle thought, after leaving out those who kept them for health, pastime, or entomological knowledge, no one would want to keep them unless it paid. Mr. Pringle appeared to take a moderate view of the question, and thought many could keep bees to advantage, yet, at the same time, there were many who had lost and would lose money on them. He thought if the Ontario Bee-keepers' Association could take a lesson from the British Bee-keepers' Association, they at least would not discourage others from keeping bees.

Mr. Jas. Heddon, Dowagiac, Mich., gave a very able paper on overstocking; and Doctor C. C. Miller, Meringo, Ills., on the question of the capability of specialists producing more and better honey than others. The doctor favoured the specialist, and the majority of speakers following took his side. Some, however, strongly dissented.

The committee of statistics reported that the Bureau of Industries was about to issue a schedule, which would enable the province to ascertain the extent of the industry in the province.

R. McKnight gave a paper on 'Our Honey Markets, and how to Cultivate them.' Mr. McKnight stated our best market was our home market, and he knew of no better paying market, and we must seek to cultivate it. The paper was very favourably received by the Association.

Messrs. Thomas Wm. Cowan, England, and Ivar S. Young, Norway, were elected honorary members of the Association.

A constitution and bye-laws were adopted, by means of which county associations can affiliate with the Ontario to advantage. Each member for 1887 will receive the revised copy of the Rev. L. L. Langstroth's work on *The Honey Bee*.

The officers for the ensuing year were duly elected. Owen Sound will be the next place of meeting.—R. F. HOLTERMANN, *Brantford, Canada*.

Selected Query.

[1.]—*In establishing an apiary, which would be the better situation, a low position sheltered from wind-storms, but rather damp, or one on high ground free from damp, with no shelter from winds?*

Neither position being desirable, I see little use in

discussing the question, but, if compelled to accept either forthwith, I should prefer the dry situation, if not too 'high,' and should at once set about creating shelter. On the other hand, what is meant by 'rather damp?' If an undrainable pit or bog, ankle-deep in mud and sludge, I would give it a wide berth; otherwise, the natural shelter supposed, is not to be despised, and thorough drainage might make the position tenable and advantageous. 'High' and 'low' might mean the top of a mountain and the bottom of a valley, the former without water and the latter with too much of it. Aspect, too, would weigh with me considerably.—C. N. ABBOTT, *Southall*.

Dampness is one of the worst enemies with which bees have to contend, but I should prefer the low situation until the higher one had been provided with shelter for the hives by planting hardy evergreen shrubs of quick growth, such as the Portugal laurel, &c.—GEORGE RAYNON.

With covers painted annually, and sound hives painted every second season, I would prefer the sheltered and rather damp position.—JOHN H. HOWARD, *Holme, Peterborough*.

I should prefer the low situation.—JOHN WALTON.

Of the two I should recommend that the low, sheltered position be chosen in spite of its being damp.—J. GARRATT.

There are objections to both the positions mentioned which should, if possible, be avoided in establishing a new apiary, and thus avoid, rather than contend with the evils of both dampness and exposure. A sheltered position has many and very important advantages over an exposed one, and as by judicious arrangements the bees may be made perfectly secure from dampness, I should give the preference to the low, sheltered position.—S. J. BALDWIN.

If I could plant or arrange some shelter, I should prefer a high and dry situation for an apiary, as I think bees do better in such a position, but I consider some shelter from the storms in spring and some shade in summer most important for the welfare of bees.—M. L. GAYTON, *Much Hadham*.

Neither position is desirable. A low, sheltered situation on dry soil is the right place.—SAM. SIMMINS.

I should choose the sheltered position, other things being equal, as it is so much easier to build up stocks in spring ready for the honey-flow in a sheltered situation than in an exposed one, owing to the great loss of bee-life (both young and old), so many perishing with the cold winds after being allured out by the fitful sunshine.—W. WOODLEY.

I should prefer a sheltered position with S.E. aspect, even though low, to one on high ground without shelter from winds.—JOHN M. HOOKER.

HOW TO COMMENCE BEE-KEEPING.

If a start in bee-keeping you're anxious to make,
The following hints may be useful to take,
That from the pursuit may arise satisfaction
Instead of disgust with your stocks, and distraction;
For bees when mismanaged are sources of danger,
And spare with their sting neither owner nor stranger.

Get a good strong frame-hive in the spring, for this reason,

The paint can get dry, and the wood can well season;
And in view of your harvest you'll have less vexation
If you have standard frames filled with good comb foundation.

The first hive you buy should be from a good maker,
Abbott, Neighbour, Blow, Baldwin, Edey, Howard, or Baker,

Or any good firm whom you see advertise
Will be glad to supply a good hive and advise.
Then with veil, gloves, and smoker, you need have no
fear of

The first four pound swarm you have fortune to hear of;
To get this in May will repay extra trouble,
Compared with July it is fully worth double.
And if possible try by all means to contrive it
To have it brought home the same day that they hive
it,

Say an hour before dusk; place your hive on the ground.
Prop it open an inch, then a sheet must be found;
Draw this well up the floor-board, place quilts on and
feeder,

Throw the bees on the sheet and they follow their
leader.

To see them march in is most truly delightful:
If vicious, your smoker will make them less spiteful.
They soon hasten in: close the hive about dark,
Lift the bees to their stand and they're ready for work.
They draw the foundation, and very slight feeding
Will stimulate better for working and breeding.
And now if the weather be clear, warm, and sunny,
Your hive will soon fill with the purest of honey.

If further advice of the best you would seek,
Consult the *Bee Journal* that comes once a-week:
And there you will certainly find the true key
To pleasure and profit from our honey bee.

—SAMUEL KIRKBY, *Beeston, Notts, 16 Feb.*

A REMINISCENCE OF THE REV. F. G. JENYNS.—I
remember the first time I ever saw Mr. Jenyns acting as
judge. The labour was heavy, the day hot. The class
was one of 'Amateur Hives made by cottagers,' the time
was up for to admit the public. I was shut in with the
judges, but there were many eyes peering through the
loops in the canvas. Presently a lad in knickerbockers
broke through and rushed up to our friend, and, clutching
hold of his coat-sleeve, said: 'If you please, sir, you did not
half look at my hive, you did not notice my new idea in
it: this is the one;' and leading him back pointed out a
neatly painted hive that looked nothing out of the
ordinary from the others. I see him now being led by
that lad of thirteen, who had worked his heart into his
hive. Officialism, in the person of the secretary of the
show, was for putting him out of the tent, remarking 'the
judges could not be interfered with in the execution of
their duty.' But no, the lad had got hold of one who
had something of the spirit of his Divine Master. He
looked well at the hive, allowed the boy to explain his
idea, asked him to retire from the tent, fetched back his
four colleagues, and persuaded them to award an 'extra.'
That lad is now a young man, and is still a bee-keeper,
and that judge is in the presence of Him who shall judge
righteously.—AMATEUR EXPERT.

Echoes from the Hives.

Honey Cott, Weston, Leamington, Feb. 13th, 1888.—
Here we are right into the middle of February, and what
changeable weather it has been: severe frosts for two or
three days, then very mild, which the bees have taken
advantage of. Last week they were out trying the snow-
draps and fetching water, while the air seemed all alive
with them; a few seemed to be on the look-out to
plunder one another if there was a possible chance. On
the whole, I think they have wintered exceedingly well
so far; and as the days are getting longer there will not
be much fear to the contrary. Hoping we may all have
another good season.—JOHN WALTON.

NOTICES TO CORRESPONDENTS & INQUIRERS.

T. NIXON.—1. *Simmins' Non-swarming System.*—Mr.
Simmins has given his 'Non-swarming System' in his
new book, *A Modern Bee-farm*, fully illustrated. 2.
Sections.—The $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{3}{4}$ sections without dividers
hold one pound. Mr. Simmins uses full sheets of
foundation, firmly fixed in centre, and he says that no
separators are required.

A NOVICE IN MODERN BEE-KEEPING.—*Removing
Vagrant Colony from Chimney.*—This is usually a
most unsatisfactory job, especially for a novice, but
from your description the combs are easily reached.
In the first place, make up your mind to receive a fair
allowance of stings; then remove the chimney-pot,
and while so doing keep the bees in subjection by
smoke. This can be done by burning some brown
paper in the drawing-room or bedroom grates, as there
must be a communication if the bees come down into
these rooms. When the bees have become intimidated
remove each comb and brush the bees off into a straw
skew. Serve each comb in a like manner, and if they
are got out in good condition tie those containing
brood into the frames of a bar-frame hive. After
take this hive to the ground and turn most of the bees
from the straw skew into it with the brood combs.
When all the combs have been removed from the
chimney, dust some carbolic acid powder around the
flue where they were attached and place an empty
skew over the flue, propping it up on one side. Early
next morning remove the skew, when most of the bees
will be found clustered in the inside. They can then
be placed with the others in the bar-frame hive. If
you cannot smoke the bees from the fireplace a smoker
or fumigator must be used from the top, but you
would have to remove the chimney-pot first, in doing
which the bees will be disturbed, unless it could be
done the night before. These directions might be
modified if we were in a position to view their posi-
tion. Advice in all such cases is very speculative.

W. J. SHEPPARD.—We should prefer to give good, clean
foundation.

THOS.—*Cowan's Extractor.*—This extractor can be
turned at any rate desirable, so that you were wrongly
informed. All honey extractors will throw out or
damage the combs if turned too quickly. Wired
foundation is much better for extracting purposes, as
then combs of the current season can be extracted
from, whereas without wiring they are most likely to
be damaged.

HORACE.—*Old Combs.*—With our present opportunities
of procuring foundation, we do not consider it advis-
able to use combs longer than four or five years. The
successive batches of brood, through the bees not re-
moving the exuvie, reduce the size of the brood-cells,
and consequently the bees reared therefrom will be
smaller in size.

EDWD. J. GIBBINS.—1. *Cottager's Bee Journal.*—The
greater portion of the matter that will appear in the
new Journal will be taken from the pages of the
British Bee Journal; but we do not bind ourselves
that it shall be so absolutely. 2. *Mouldy Combs.*—We
advise you to melt the combs. Damp, mouldy combs if
given to the bees would be hurtful, and if kept until the
summer, would be of less advantage than whole sheets
of foundation, since the mouldy, dried-up pollen would
be useless as food, and would be cast out of the hive,
and the combs having become tender, brittle, and dis-
coloured, would cause to the bees far more trouble and
loss of time than to build new ones from foundation.

J. S. WOOD.—*Moving Swarm.*—Very few of the bees
from the swarm will return to their original stand if
they are removed the same evening. You may thus
place them at a distance of 300 yards with safety.

E. S. R.—1. *Making Good Candy.*—Castor sugar will do nicely if *pure cane sugar*. The proportion of sugar depends on the consistency of the honey. Try a small quantity first, adding honey or sugar as may be necessary. 2. *Placing Good Candy in Frames.*—Your plan will do excellently well. 3. *Nadiring a Stock.*—The proposed sheet of quene excluder between the two hives would greatly impede the bees, besides they have a decided opinion *against* storing honey *below* the brood nest. No honey pressed out is equal to extracted, in our opinion. 4. *Placing Sleps on Frame Hives.*—The obtuse cottager could lift his sleps, but he *could not* extract much, if any, honey from the frames, because his bees are sufficiently obtuse to generally refuse to store *below* their brood. We should strongly recommend you to try to get supers. We recently saw a skep that had been treated as you suggest. The brood nest had been carried down into the frame-hive, as evidenced by the colour of the comb, but *no* honey.

THOMAS COLTON.—*Bee-house.*—1. A circular hole, three or four inches in diameter, in the upper part of each gable is desirable for ventilation. 2. The bees are prevented from gaining access to the interior of the house by inside packing of strips of wool around the entrances, which should correspond exactly with those of the hives, and should not be less than eight inches in width—better the whole width of the hive—with perforated zinc slides, fixed on the outer entrances for enlarging or contracting them. 3. There is no necessity for a pivot window if the ventilating holes are covered by slides of perforated zinc, which can be drawn aside to allow of the exit of bees. There is little difficulty about the escape of bees, since manipulations are carried on while the doors are open. 4. *Salicylic Acid in Candy.*—After the candy has been removed from the fire thoroughly stir in one scruple of the solution. 5. *Colony with Dysentery.*—Do not use artificial heat unless the colony is removed from the hive before so doing. Cannot you place them temporarily in a box while the hive is being dried? If so, take the frames out *en bloc* in a warm room. If you cannot remove the bees from the hive provide them with clean, dry warm quilts.

HONEY FLOW.—*Obtaining Honey.*—You have undoubtedly two advantages like others, and if orchards are so abundant in your district, you ought in favourable weather to get some honey. In this case you should commence stimulative feeding about the middle of March, by uncapping some of the honey-cells from time to time, and afterwards giving liquid food in small quantities very regularly, until the bees can collect more than they require for their own sustenance. Of course the clover will be the main crop on which you will have to depend, although in some districts a considerable quantity of honey is obtained from fruit blossom.

D. M.—We are not of the opinion that candied or granulated honey is injurious to bees.

C. T.—Mr. J. Camaschella, 10 Derby Villas, Forest Hill, will assist you.

C. W.—Inquiries will be made.

We have received from Mr. H. Dobbie, Hethersett, Norwich, one of our first-class experts, a packet of seeds containing twelve popular annuals, twelve choice vegetables, and six of the best bee-flowers, namely, mignonette, cyanus minor, motherwort, limnanthes douglasii, borage, mixed wallflowers, with directions when and how they are to be sown.

* * A number of Reports of Annual Meetings of County Associations are still waiting insertion.

Special Prepaid Advertisements.

Exchange Column.—Sales of Honey and Second-hand Goods.—Intended to aid Bee-keepers in the disposal of Bee-produce and Appliances for which they have no further use. Terms: Twelve words and under, Fourpence; for every additional Three words, One Penny extra.

Situations, Publications, Bee Plants, &c.—Twenty words and under, One Shilling; for every additional Three words, One Penny.

No reduction made for continuous insertion.

NOW READY.

SIMMINS' NEW BOOK.—'A MODERN BEE-FARM, AND ITS ECONOMIC MANAGEMENT.' Popular Edition, limp cloth cover, 3s. 9d. Special Edition, stiff covers, 7s. 6d., post free.

The Special Edition includes Photos of the Author's Domestic Hive; his Home Apiary, and another covered Apiary; also one of Queen and Workers on a Comb. Of the Author, Rottingdean, Brighton; NEIGHBOUR & SONS, 149 Regent Street, London; and J. HUCKLE, Kings Langley, Herts.

BEE-KEEPING, Plain and Practical: How to Make it Pay. By A. RUSBRIDGE, 1s. 6d., post free, 1s. 8d. Address J. HUCKLE, Kings Langley, Herts. A 1253

THE MANAGEMENT OF STRAW SKEPS. Designed to teach the Cottager how to obtain the best results at the least possible cost. By attention to its teachings, Cottagers will be enabled to make their Bees a more profitable source of income than hitherto. Price One Penny. Six copies and upwards, post free. J. HUCKLE, Kings Langley.

WANTED.—Copies of *British Bee Journal* for January 7th, 1886, and Nov. 1873. Full price given. Apply J. HUCKLE, Kings Langley, Herts.

FOR SALE.—A One-Frame Observatory Hive, for exhibition purposes. Also Six Years' *British Bee Journal*, bound complete. Apply C. CRST, Marquise Villa, Dorchester. c 6

STRONG STOCKS OF BEES, in well-stored Straw Hives, 15s. each; in Bar-frame Hives, 20s. each. Doubling Hive, new, 20 frames, 10s. 6d. Limnanthes Plants, 1s. 3d. per 100, free. S. S. GOLDSMITH, Boxworth, St. Ives, Hunts. A 3190

LANTERN SLIDES on Bee-keeping, all photographed from Nature, sent on trial before purchasing. Send Two Stamps for loan of Album of Subjects. Address ALFRED WATKINS, Hereford. A 3431

A MODERN BEE FARM AND ITS ECONOMIC MANAGEMENT. Limp Cloth Edition, 3s. 9d., post free. Special Edition, handsomely bound in cloth gilt, including four interesting Photos, 7s. 6d., post free of the Author, S. SIMMINS, ROTTINGDEAN, BRIGHTON. (186)

VOL. XV. OF

REARING & MANAGEMENT of BEE-HIVES

BY

M. AMBROZIC,

At **MONSTRANA, POST LENGENFELD,**
In Oberkrain, Austria.

53 MEDALS AND DISTINCTIONS.

TARIFF LIST, 1888.

Letters.	Genuine Bees of Carniola.	Mar.	May.	June.	July	Sept.
		and April.			and Aug.	and Oct.
		s. d.	s. d.	s. d.	s. d.	s. d.
A	A well fecundated Queen, with the accompanying Bees	9 0	8 0	7 0	6 0	5 0
B	A New Swarm, with the fecundated Queen. Weight of Bees, net, 800 gr.	...	14 0	13 0	12 0	11 0
C	A Natural Swarm, with the fecundated Queen. Weight of Bees, net, 1 kilo.	...	15 0	14 0	13 0	12 0
D	A whole Original Hive, with Brooding Eggs and Honey. Is provided with a layer of gum on account of the risk during transport	16 6	16 6	15 6

1. The commands are definitively accepted as soon as the required sum is sent in free of post with the command that has been made.
 2. The packing is in such a way performed that the bees will not meet with any accident on their journey.
 3. The packing up of the objects A, B, C, and D, is already included in the prices mentioned above.
 4. In orders of ten pieces, letters A, B, C, and D, the eleventh piece is given gratis.
 5. The commands are kindly requested to be made by some lines only in joining the desired letter.
 6. As I neither know the English nor the French language, I am obliged to get the letters translated, which costs money and time, and on which account the bees are often sent away too late.
- My stand of bees is in a cold mountainous country, only 1½ mile distant from the Triglav (9,000 feet, or 2,850 metres high). For this I take the liberty of recommending you my bees for every country.
- Experience teaches that each plant or culture seed brought from colder climates to warmer ones thrives very well, and thus it is to be believed that the same will be the case with the animals.
- M. AMBROZIC.

The oldest Weekly Bee Paper in the World.

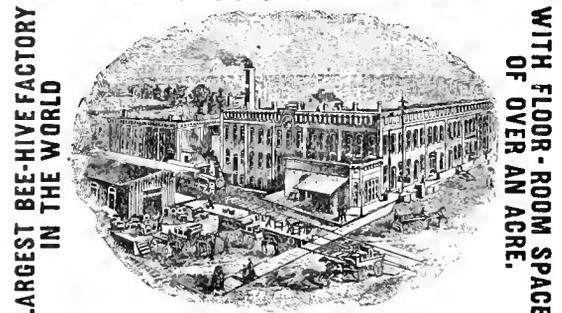

THE AMERICAN BEE JOURNAL

Established in 1861.

AMERICAN SECTIONS BY THE MILLION

The cut, taken from a photograph, represents our bee-hive factory where we annually turn out about 20,000 hives and 8,000,000 sections, besides enormous quantities of bee-supplies of every description. Dealers before ordering elsewhere should correspond directly with us. We are prepared to quote better prices on sections in quantities than we have ever quoted before. We are also publishers of *Gleanings in Bee Culture*, with a circulation of 7574 subscribers. A sample copy of our Journal and our 40-page price list sent on application to **A. I. ROOT, Medina, Ohio, U. S. A.**

THE BRITISH BEE JOURNAL

Communications to the Editor to be addressed 'STRANGEWAYS' PRINTING OFFICE, Tower Street, Cambridge Circus, W.C.

[No. 297. VOL. XVI.]

MARCH 1, 1888.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

COTTAGER'S MONTHLY JOURNAL.

We should feel obliged to County, Provincial, and Local Secretaries, if they would kindly furnish our publisher, Mr. J. Huckle, Kings Langley, Herts, with the names and addresses of all cottagers and artisans who take an interest in bee-keeping, so that he may have the opportunity of forwarding each a copy of the new Journal. The first number is now published.

BRITISH BEE-KEEPERS' ASSOCIATION.

The prize schedule for bee-hives, honey, &c., at the Royal Agricultural Show, to be held at Nottingham in July next, is now ready, and may be obtained upon application to the Secretary, Mr. John Huckle, Kings Langley, Herts.

The Annual Meeting of the Gloucestershire Beekeepers' Association will be held at the Raikes Memorial Hall, Brunswick Road, Gloucester, on Thursday, March 8th, at 3 p.m. Also a Committee Meeting from 2.15 to 3 previously.

PRACTICAL WORK IN THE APIARY.

Makeshift Hives.—There is hardly anything that is not absolutely necessary, more useful in an apiary, or that conduces to the comfort of the bee-keeper, than the possession of a few makeshift hives. These, as their name implies, are not intended as permanent dwellings for bees, but come into use occasionally. In them frames can be arranged temporarily for the reception of swarms which might come unexpectedly and undesired. Colonies may be placed in them frames and all, while their hives are being cleaned or repaired. They can be used for supporting frames while queen-cells are being cut out, and for a number of other purposes. The possession of a few makeshift hives makes the bee-keeper independent of hive-manufacturers during the height of the swarming season, when there is a difficulty sometimes of getting hives, and frequently avoids the necessity of purchasing more complete ones. Sometimes the bees can be kept in them until the end of the season, and then united to another colony, and they are as good for this

purpose during the summer as the more expensive hives.

Anything the right size in the shape of a box that will hold a few standard frames will do for a makeshift hive, and any amateur carpenter can, without the slightest difficulty, make from the simplest available material, such hives during leisure time in winter. Packing-cases, such as are used for tinned meats, can be purchased for a few pence, almost from any grocer, and contain sufficient material to make the hive. It should be made 9 inches deep at least (half an inch deeper would make it none the worse), $14\frac{1}{2}$ inches between the sides on which the frames are to hang, and any length the bee-keeper chooses, allowing $1\frac{1}{2}$ inches for each frame. These are inside measurements. Supposing one to hold ten frames be required, 15 inches must be allowed between the sides. The sides on which the frames rest must be $\frac{3}{4}$ of an inch lower than the others to allow the tops of the frames to come level with the sides, and strips of wood nailed on the outside level with the top will form the rabbit, and close in the ends of frames. Should the bee-keeper use frames with a long top-bar, provision must be made for this; but we would recommend him to cut off the ends to within $\frac{1}{4}$ of an inch of the rectangle. Any sort of opening may be cut to make an entrance passage for the bees, and it is immaterial on which side it is. By having one at each end and placing the frames parallel to the entrance at a pinch two small lots of bees can be accommodated if a division-board is placed between them. The floor-board can be nailed on, and with the addition of a quilt the hive is ready for any emergency. There is no necessity to plane the wood, as for this purpose it is none the worse for being rough. Those who cannot make, or who have not the time to do so, can purchase such hives for a few shillings ready-made.

Convertible Makeshift.—So far we have described the simplest form of makeshift hive, but in 1879 we adopted a pattern which has much to recommend it, and one that can be made into a permanent hive which will be as good as any.

In 1878 the new Langstroth hive was introduced in America. This was a combination of the ordinary Langstroth and the North Star hives, for which Messrs. Sperry & Chandler obtained a patent in 1877. It is shown in illustration fig. 1, and as will be seen it has a loose manipulating side *m*. We were amongst the first to get and use these hives, but we did not find in them all the advantages claimed, because the manipulating side was only moveable to a certain extent. This defect we remedied by making the side slide on the rabbits and made it moveable to any extent, so that we could contract and expand the hive as we liked without using division-boards. As makeshift hives we have found them most useful, and we have ever since used them for this purpose. Our ideas have been since copied, and, as is usually the case, without any acknowledgment on the part of the imitators. The illustration,

fig. 2, explains the construction of our makeshift hive, and which we called 'Convertible makeshift,' because it could also be used as a permanent hive, with very little alteration.

There are three sides, A, B, C, two of which, A and B, are nailed to the floor-board F. The side C is loose, and is kept in position by a screw, which goes through

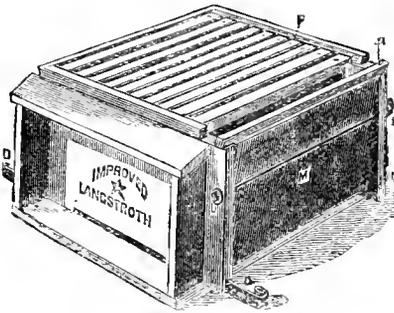

Fig. 1.

the floor-board into the end of side c. A slot in the floor-board at E, and through which the screw passes, permits the side E to be moved. The fourth side D is moveable, slides on the rabbets, and is in the shape of a close-fitting division-board. A 1/4-inch iron rod G passes through the sides A and c, and by turning the fly-nut H they can be brought tight against the board D and will hold it in its place. By turning the fly-nut in the opposite direction the sides are loosened and the loose side D can easily be pushed backwards or forwards. There is an entrance in the side B, and if it is desired to put in two lots of bees the board D can also have an entrance made in it, as shown in the figure. A quilt on the top with a board or roof over it completes the arrangement.

We used some of these hives without any entrances being cut out of the sides, but in this case they were

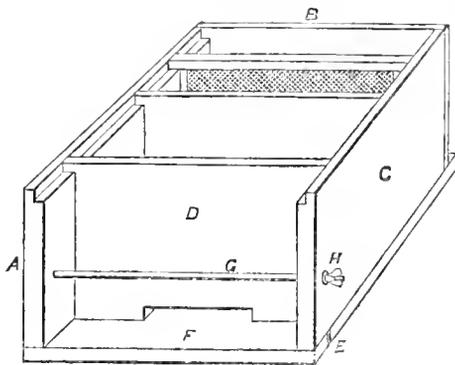

Fig. 2.

sunk in the floor-boards. By using such boards we could place the hives so as to have our frames at right angles to the entrance, a position we much prefer to any other.

It will be seen that as a summer residence this hive is complete in itself, is capable of expansion and contraction to suit all requirements, and can be used as a single or double hive. One of these hives is to be found in the collection we presented to the B.B.K.A. in 1885, and since 1879 we had four of them in our bee-house, where for wintering they were packed with chaff. Although we do not consider makeshift hives indispensable in an apiary, we think they are useful, more especially if they are made according to our pattern, for by having loose floor-boards they can be worked for stonifying, or in any other manner the bee-keeper may like, and during the summer months they may be substi-

tuted for any other hive. In the autumn the colony can be transferred to another hive for wintering, or it can be united to another colony.

With a very trifling addition at small cost this hive can be converted into a wintering hive. For this purpose we have to prepare a board with three strips of wood one inch thick, arranged as shown in Fig. 3. This board is fastened on to the side A by means of four screw eyes, and a similar one is fixed on side B. We now have on two sides double walls with a cavity between, into which chaff can be poured. Chaff division-boards are put on each side of the brood-nest, and with a chaff-box on the top and roof to cover all, the hive is complete for wintering. Such a hive need not be an expensive one, and can be easily made by an amateur carpenter. As the side D has to fit with some accuracy, and slide freely, the sides A and C should be planed, at any rate inside.

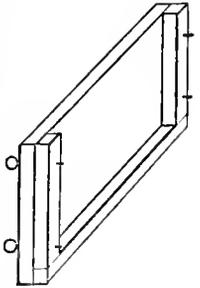

Fig. 3.

USEFUL HINTS.

WEATHER.—While in the great north-west of North America we are told that those awful visitations called 'blizzards' (*i.e.*, tornadoes of icy particles) have swept over large districts, destroying man and beast, that the whole country was freezing with the thermometer ranging from 50° to 60° below zero for several weeks, and then suddenly rose to 50° and 60° above zero, 'causing the bees to sport in the balmy air,' here, in old England, a week of unusually mild weather over the whole country was followed by a change to the opposite extreme, and for the last fortnight the earth has been frost-bound and covered in all parts by deep snow, the storms having begun in the north of Scotland and spread southward, until the whole face of the land is covered with an icy garment of snow. From Scotland, Ireland, Wales, Somerset, Cornwall, Jersey, France, Spain, Switzerland, &c., the same accounts reach us, of snow and frost in abundance with cutting, searching north and east winds, such as the oldest inhabitants never remember to have occurred at this season of the year, when we were all looking for balmy aits and gentle zephyrs to usher in the spring. In our southern counties the hazel catkins were beginning to appear, the dead nettle and speedwells were in bloom, and on sheltered banks beneath the hedgerows the spring flowers were bursting into bloom, when horrid Winter, with icy hand, again seizes upon every scrap of vegetation and nips it in the bud. And still, as we write, snow on the hills, snow in the valleys, snow everywhere, and snow still falling! But we shall be told that vegetation was getting too forward, that a check was required, that better now than later (yes, if we don't get it later as well) that—

'February should fill the dyke,
And if with the white
It's the better to like.'

Well, let those like it who can, but we don't think our bees will be among the number. By the cutting, withering blasts, and driving, piercing snow, their numbers will certainly be thinned, and many a colony will fail to greet the sunshine—when it comes—with murmuring joyful hum and gaily quivering wing. For ourselves we shall in future certainly pray, in dear old Virgil's words,—'*Di, talem terris avertite pestem.*—O ye Gods, avert such a scourge from the earth.' Ere long let us hope that the Golden Age will return to all bee-keepers; the Age when—

'Ver erat aeternum; placidique tepentibus auris
Mullebant Zephyri uatos sine semine flores.'

FORAGE.—When the present unseasonable weather departs, and the sun entices forth the bloom on the elms, poplars, willows, peaches, nectarines, early pears, plums, and cherry-trees—all of which we may look for during the present month—then will our bees greatly rejoice in the precious nectar, after their long and cruel imprisonment. But these gifts of nature will merely serve to whet the appetite, and to create a craving for more.

SYRUP FEEDING.—The demands on stores will increase as spring advances, and syrup will soon be required. Those colonies which are breeding fastest will require it most. Let the first potions be given thick and warm—the consistency that of well-ripened honey—from a bottle-feeder, on the crown of the hive, well covered with woollen material. A feeder which holds about three pints will be found a convenient size, and with three holes turned on should last about a week. Seven pounds of Duncan's pearl sugar to three and a half pints of water, boiled for a few minutes, with a subsequent addition of salicylic acid, vinegar, and salt, according to Mr. Cowan's recipe—see his *Bee-keeper's Guide-Book*, p. 151—is the best food we know, far better, indeed, than the solid, granulated honey, of which—after such a winter as we have passed through—plenty will be found in most hives. In a hive abundantly stored with such honey, bees will starve.

EXAMINING HIVES.—We still urge ardent apiarists to abstain from manipulation until the end of the month, or the beginning of April, unless in exceptionally fine weather. Since it is extremely probable that a late spring will follow the long and piercing cold still prevailing, a thorough examination of colonies may well be postponed for a week or two; and with careful attention breeding may be encouraged by judicious feeding, by changing filthy floor-boards, and damp and mouldy quilts, for warm, dry clean ones; above all, by providing that there shall be no stint of food.

QUEENLESS AND WEAK COLONIES.—When bees are in full flight the experienced apiarist will keep a sharp outlook on all colonies, and will decide, with few mistakes, as to the condition of each by the motions and actions of the bees. There are certain unmistakable signs of queenlessness, dysentery, sparseness of population, &c., which it is unnecessary to recapitulate here, since every one who keeps bees ought to know them. A queenless hive may be detected at this season, by the agitation of the bees around the entrance, which is kept up after other colonies have quietly settled down, and gone to rest; and, very often, a dead queen will be carried out, and may be found beneath the alighting-board. Such colonies carry home no pollen, while others are rushing into their hives with heavily laden legs. These queenless bees, as well as other weak stocks, should be nursed for the present, by a little judicious feeding, and extra warm wrapping, until later in the season, before uniting, for which next month will be quite early enough. But there is one exception:—

HUNGER SWARMS, as they are called, are those colonies which desert their hives—often in this and next month—*en masse*, even when possessed of food in plenty. Although such vagaries generally arise from starvation, sometimes dislike to their surroundings is the motive cause. The deserters will usually settle near their hive, exactly as a swarm, and as such they should be treated, and placed in a new hive upon clean combs and on the same stand previously occupied; and to these weak or queenless colonies may be at once united, and the queen changed, if that is thought desirable, since the desertion is sometimes caused by worn-out or unfertile queens.

QUEEN INTRODUCTION.—As queen-importation will soon begin, a few remarks on this well-worn subject may not be amiss. We have much yet to learn in safely introducing alien queens. How often do we hear complaints of queens being introduced successfully (?) both directly and otherwise, when lo! on examination a week

or two afterwards the successfully introduced one, *non est inventa!* One of the rules most imperatively prescribed by the advocates of direct introduction is—'Do not examine the colony for four days after introducing the queen.' Why? You will be told that nothing is more likely to cause an attack on the queen than examination and disturbance of the bees at so early a period. But the probability is that during the first three or four days after dropping an unprotected queen into a colony of strangers an examination would disclose the queen under encasement. Now encasement in nine cases out of ten means injury to the queen. We have had a queen under encasement for seven whole days, and she escaped with her life at last, but proved utterly worthless from injury received during her imprisonment. Mr. Alley, the most extensive and successful queen-breeder and introducer in the States of America, in his *Twenty-two Years' Experience in Queen-rearing*, gives us these very suggestive remarks:—'Unless properly introduced queens will be rendered worthless before they have been in the hive an hour. Sometimes they will be slightly stung, but not sufficiently injured to cause immediate death, although rendered incapable of laying. When the hive is opened, apparently, the queen is kindly received by the bees and successfully introduced, as the marks made by the sting are not always easily recognised. Occasionally they receive a sting in the leg, rendering it useless, and such injury is easily recognised. Nevertheless the queen will continue to lay, but not to the extent that she would had she received kind treatment from the bees when introduced. Sometimes several weeks elapse before they show any indications of failing or having been stung, and then are superseded, or, as the term is, "missing." If our memory serves us, it has been dogmatically asserted by more than one correspondent in these columns who professed to lay down a rule for queen introduction, which 'never failed,' that 'bees, under any circumstances, will never sting a queen.' Mr. Alley, at least, is of a different opinion; and his remarks, quoted above, afford a warning against the danger of plunging an unprotected alien queen into the midst of a strange colony. Hence we ourselves always advise the use of a cage in the hands of the inexperienced.

Selected Query.

[2.]—*Will honey stored in combs from which the honey was removed in the autumn, and the sections with comb kept through the winter, be as good-looking and as saleable when completed as those finished the same season that they are begun?*

Not as a rule.—S. SIMMINS.

Yes, if the comb remains unsoiled.—C. N. ABBOTT.

Extracted honey taken from stored combs of not more than a year old and free from pollen will be equal in quality to that extracted from any other comb, *ceteris paribus*; but sections of comb, even if carefully stored, when refilled and capped in the second season, are neither equal in appearance nor quality to those which are quickly worked and completed in one season. Sections of the first quality are always those which have been quickly worked during an unbroken honey-flow.—GEORGE RAYNOR.

No. As all new goods bear their own impress, even so is newly-built, stored and sealed comb honey its own witness. In all our comb-honey productions, none but the entirely new were ever selected for competition, and the awards given us have justified the selection made. Old comb-work, freshly stored and sealed, is more opaque than the newly-wrought; hence, when held to view under a strong light, no judge would select the former for a premier place. Good saleable honey

we have had in many a last year's comb, but from experience I am convinced it is unwise to gather sectional honey in old comb-work. Also the cells of combs for storing and extracting should be well cut down ere used. When so treated we have found the work of storing and sealing more progressive throughout.—JOHN H. HOWARD, *Holme, near Peterborough.*

I frequently have many sections left over at the end of the season, which I extract and place in crates on top of hives for bees to clean up; then I get the propolis cleaned off, and store them away in the crates, and use a few of them in each crate when first putting them on the hives, and can see no appreciable difference in the colour of the honey; the wood does not look quite so nice, but the presence of worked-out combs makes the bees take to them sooner.—JOHN WALTON.

Yes.*—J. GARRATT.

It frequently happens that the combs built in sections after the latter end of the honey-harvest are, as well as the honey in them, darker than those built in the early season, and such combs may retain their colour, and consequently will somewhat depreciate their value when filled the following year. If, however, the section combs are of a light colour, properly treated in the autumn and carefully preserved through the winter, their value to the bee-keeper is almost inestimable, as the bees may be tempted to commence active operations in supers furnished, or partly furnished, with such more readily than if foundation only be in the first place given, and they will be as good-looking and as saleable when completed as those commenced and finished the same season.—S. J. BALDWIN.

If the combs, whether in frames or in sections, are not discoloured, and are put away *perfectly dry and clean*, and kept during the winter in a warm, dry room, carefully protected from dust and insects, I have never found any difference in appearance between them and others *newly-worked* from foundation when both are filled and sealed.—M. L. GAYTON, *Much Hadham.*

Certainly not.—JOHN M. HOOKER.

ASSOCIATIONS.

MIDDLESEX BEE-KEEPERS' ASSOCIATION.

The annual meeting of this Association took place on Friday the 10th ult., at 5.30 p.m., in the Council-room at the offices of the Royal Society for the Prevention of Cruelty to Animals. The Baroness Burdett-Coutts (President) occupied the Chair, and was supported by the Hon. and Rev. Henry Bligh, Mr. Jonas, Mr. Harveyson, Mr. Rose, Dr. Rayner, Mr. Henderson, Mr. Pye English, Mr. Willan, Mr. Mason, Mr. Wm. Gardiner, Mr. W. M. Graham, and other ladies and gentlemen.

The Hon. and Rev. Henry Bligh read the minutes of the last annual meeting, which were confirmed.

The President moved that the report and balance-sheet for the year 1887 be adopted, with a vote of thanks to Mr. Arthur Kenworthy the auditor.

Mr. Rose read the balance-sheet, after which the resolution was carried unanimously.

A vote of thanks to the retiring officers and committee for their services during the past year was moved and seconded, and carried *nem. con.*

Mr. Jonas proposed a vote of thanks to the Royal Society for the Prevention of Cruelty to Animals for kindly granting the Association the use of their Board-room; Mr. Pye English seconded the resolution, which was carried.

The President, who is also President of the Ladies'

Committee of the Royal Society for the Prevention of Cruelty to Animals, expressed her thanks on behalf of that Society.

Mr. Harris moved the re-election of the President and Vice-Presidents of the Association. He thought it would be superfluous for him to say anything in advocacy of the resolution. The Baroness's name was a household word, and the other noblemen and gentlemen were men of the highest reputation and influence. Dr. Rayner seconded the motion, which was carried unanimously.

The President returned thanks for her re-election to a position she would be very sorry to lose.

Mr. Jonas moved the re-election of the Treasurer, the Auditor, the Secretary, and the Provincial Secretaries, which, after some discussion, was carried unanimously.

The Hon. and Rev. Henry Bligh proposed the re-election of the Committee, which was seconded, and debated at some length by Messrs. Harris, English, Graham, Jonas, and the President, and ultimately passed unanimously.

The Hon. and Rev. Henry Bligh proposed the election of Mr. Fewtrell as expert, which resolution was seconded by Mr. Mason. Mr. English moved that Mr. Baldwin's name be substituted for Mr. Fewtrell's. This amendment was carried without a division.

The Hon. and Rev. Henry Bligh proposed that Mr. Graham and Dr. Rayner be the County Representatives at the quarterly conferences of the B. B. K. A. during the current year, which motion was seconded and carried unanimously.

The Hon. and Rev. Henry Bligh proposed a cordial vote of thanks to the Baroness for her kindness in presiding, which was seconded and carried by acclamation.

The President expressed her sincere thanks for the kindly way in which she had been received. It had afforded her extreme gratification to be present that day as well as at the meeting of the B. B. K. A., which took place on the previous Wednesday. It might be said that she was a queen with a double sting, or better, perhaps, the queen of two hives (laughter). Her ladyship then referred to a Bill for the better adaptation of education to agricultural pursuits, about to be brought into Parliament by Mr. Jesse Collings, M.P., and recommended those present to do their best to aid the passing of that measure. A great deal might be done in the country to further the adoption of bee-keeping as a means of profit to labourers and others if the subject were taken up in schools. While admitting that education of any kind was good, she could not help thinking that some theoretical subjects were taught in country schools which were likely to be of little, if any, use to the scholars, and that it would be highly desirable to replace those lessons by technical education in agricultural and its kindred studies. The President then alluded to the circumstance of a schoolmaster at Faversham having chosen bee-keeping as an extra subject upon which to instruct his pupils; also that the Education Board had made objection thereto, and that she intended to bring the matter under the consideration of Lord Cross. Possibly he might be willing to receive a deputation on the subject, in which case she hoped to receive the co-operation of all present. Her ladyship concluded by heartily wishing prosperity to the Association.

Mr. Graham read a list of prize-winners who had been successful in the annual drawing.

DERBYSHIRE BEE-KEEPERS' ASSOCIATION.

The annual general meeting of this Association was held in the Guild Hall, Derby on Friday, February 10th. Mr. J. L. P. Barber, of Stanton House, Burton, presided, and amongst those present were Messrs. Cooper, Coxen, Turton, Hugh, Pearson, Morley, Smith, Rowland, Wilks, Shipman Handley, Rawson, Bryan, Atkins (secretary), &c. The Chairman moved the adoption of the Report

* I understand the question thus: The honey was extracted from combs and sections in the autumn, and in the spring given to the bees in an empty state to fill.

and statement of accounts. The following is an extract from the report:—During the year a much greater amount of work has been done than in any previous one, and the Society may be congratulated on the position it has gained as one of the institutions of the county. Notwithstanding this, it will be seen by the balance-sheet that there is a need for further and increased subscriptions and donations to the society, especially to meet the large increase in the experts' charges. The appointment of Mr. W. Coxen as expert for the southern division seems to have given satisfaction, and in conjunction with Mr. Handley, for the northern division, he has made spring and autumn visits which have been attended with good results. The number of subscribing members is now 411, and 19 donors, making 430, against 350 and 23—373 last year. Increase, 57. After paying all expenses, we are able to carry forward a balance of 29*l.* 16*s.* 6*d.*, against 25*l.* 16*s.* 2*d.* last year, and 7*l.* 8*s.* 4*d.* in 1885. The annual show and fair for 1887 was held as usual by the kind permission of the Committee of the Derbyshire Agricultural Society, on their grounds, on September 14th and 15th, and was again a success, the number of exhibits being fully fifty per cent more than on any previous year. The report was unanimously passed. The officers were then re-elected, and several alterations were made in the rules. The name of Mr. Barber was added to the list of vice-presidents, and those of Messrs. Barber, Rowley, and Turton, to the Committee. Messrs. W. G. Copestake, F. Holbrook, and W. T. Atkins, were re-appointed treasurer, steward, and secretary respectively; and votes of thanks for past services were accorded. Second-class certificates given by the British Bee-keepers' Association were presented to the following: Messrs. Coxen, Shipman, Rawson, and Austin. The annual draw for hives was made, the following being the winners: Mr. G. T. Banks, Church Gresley, Burton-on-Trent, and Mr. W. T. Atkins, Derby. Mr. Benjamin Skirmer was instructed to provide the hives at 10*s.* each. A vote of thanks to the Mayor and Mr. Gadsby for the use of the room was carried, as was one to the Rev. G. Shipton, Brampton, for lecturing on behalf of the Association. A similar vote was passed to the Chairman. This concluded the business.

THE SOMERSET BEE-KEEPERS' ASSOCIATION. ANNUAL MEETING AND CONVERSAZIONE OF THE TAUNTON BRANCH.

The annual general meeting of the Taunton Branch of the Somerset Bee-keepers' Association was held at the Coffee Hotel, Taunton, on Thursday afternoon, Feb. 16. There was a good attendance. The chair was taken by Mr. C. E. Lance, the president of the branch; and there were also present Mr. F. W. Newton (Barton Grange), the Rev. H. S. Hume (vicar of Wilton), Mr. C. Tite (Wellington), Mr. T. S. Penny, Mr. A. J. Smith (honorary secretary), Mr. C. Lewis, the Rev. W. B. Capam, Mr. H. Maynard, Mr. W. B. Maynard, Mr. Barter, Mr. Hosegood (Williton), Mr. James Buckland (Pitminster), Mr. W. Tout and Mr. C. Tout (Thorinfacon), Mrs. Newton, Miss E. Maynard, Miss K. Maynard, Miss Rawlins, Mrs. Tite, and Miss Scarlett.

The Chairman said the accounts of the branch were exactly balanced. The Hon. Secretary read the annual report, which was duly adopted, from which it appeared that the committee of the Taunton branch of the Somerset Bee-keepers' Association were able to give an account of increased success and progress during the past year. In February, 1887, Mr. W. B. Maynard was elected hon. secretary in the place of Mr. E. S. Hammond (resigned), and a representative and influential committee having been formed, with C. E. Lance, Esq., as president, arrangements were made with the Parent Society for the management by the branch of its own affairs, subject to

the approval of the county hon. secretary, and the payment of an affiliation fee fixed at twenty-five per cent of the 5*s.* subscriptions. A circular was published setting forth the objects of the association, which was sent to all the principal known bee-keepers of the neighbourhood, and a guarantee fund was started, which enabled the committee to offer prizes at the Taunton flower show to the amount of nearly five guineas. In consequence of the efforts thus put forth, the number of members was raised from about twelve to twenty-eight. The exhibition held in connexion with the above-mentioned flower show was a great success. The funds at the disposal of the Committee had not permitted the employment of a visiting expert: they therefore pleaded for augmented support in order that the Association might be made a greater source of benefit to its members than in the past. The committee regretted that Mr. W. B. Maynard had found it necessary to resign the post of hon. secretary, Mr. A. J. Smith kindly consenting to fill the office *pro tem.*

The annual report of the county association was also read, and considerable discussion thereon followed, general regret and surprise being expressed that Somersetshire bee-keepers had allowed the association to reach such a low ebb, notwithstanding the strenuous efforts of their zealous hon. secretary, the Rev. C. G. Anderson. It was felt that an effort should be made to carry on the county organization, and the following resolutions were passed:—

'That the president, committee, and members of the Taunton branch of the Somerset Bee-keepers' Association, express their sincere regret that Mr. Anderson should have to issue such an unfavourable report after so many years of arduous and painstaking work in the interests of bee-keeping, as well as their thanks for his unwearied services;' also, 'That Mr. Anderson be invited to hold a general meeting of the County Association at Taunton on an early date.' The meeting then proceeded to the election of officers. The hon. sec. said he had accepted that post very reluctantly, as he was a business man and he had very little time to spare. Provided, however, they could not find a better man he was willing to serve for another year. The Chairman was sure they could not find a better man. Mr. Smith was then re-elected.

The Rev. H. F. S. Gurney had resigned his place on the committee, and on the motion of Mr. H. Maynard, seconded by the Chairman, the Rev. H. S. Hume was elected to succeed him. The committee now stands as follows:—President, Mr. C. E. Lance; Rev. W. B. Capam, Rev. H. S. Hume, Colonel Lewis, Mr. J. Buckland, Mr. E. S. Hammond, Mr. C. Lewis, Mr. H. Maynard, Mr. J. Scarlett, jun., Mr. A. J. Smith, Mr. C. Tite, Mr. J. G. Vile; hon. sec., Mr. A. J. Smith. Mr. Penny proposed and Mr. Tite seconded a vote of thanks to Mr. W. B. Maynard for his services as hon. sec. in the past. This was carried unanimously; and Mr. Maynard replied.

A conversazione followed, and Mr. C. Tite delivered an address on 'Bee-keeping, for pleasure and profit.' In his opening remarks, he observed that he intended to pass over many matters which would interest those who did not keep bees, as he was aware that the members of the association were already well acquainted with the principal facts connected with bees and their management. His aim would be first to remind those who had begun bee-keeping as a source of amusement that it really was capable of affording interest and pleasure of a high order, and then venture to offer a few hints for the extension of their research. Secondly, to point out to those who wanted to make a profit by the pursuit that an apiary could be made to yield a very fair return for capital invested provided it was conducted on business lines. Those of his hearers who belonged to the class first referred to he strongly urged to start an observatory hive or two, so that they might test for themselves the theories

of scientists, and note carefully the life history of the bee in all its interesting stages, which he then referred to in detail. If they did this he thought they would all agree with Mr. Cheshire, who said that this was a 'field which must repay every investigator, while it must bring to our mind strange thoughts of the oneness of all things, whose interworking is the outworking of beauty, order, and development, the limit of which the dispensation of the fulness of time alone can reveal.' After referring to the writings of Cowan, Dzierzon, Langstroth, Lubbock, and others, the lecturer pointed out a number of matters still open for investigation which offered a fertile field for interest and study. He then turned to the more practical part of the subject, remarking that bee-keeping was one of those minor industries that might well be taken up by cottagers, market-gardeners, and others of similar occupations. There was no royal road to success, but if beginners would be content to commence on a small scale, and to gain their experience gradually, there were few men in the rural districts who could not make bee-keeping pay. The great outcry was that there was no market for surplus honey, but this he considered ridiculous when many thousands of pounds were being paid annually for imported honey. Moreover, he had met with many instances in the county where, in the same town or village, one man could sell all he had to spare and was compelled to buy in order to meet the demand, while another could not find purchasers for half his stock, and what he did sell was disposed of at a lower price than his neighbour obtained. The explanation of this was simple—one man was a better salesman than another, and probably put his honey upon the market in a more acceptable form. Another objection to bee-keeping, from a business point of view, was that the price of honey had fallen considerably of late years. This was perfectly true, but the yield of surplus under the improved system of management was so much greater than in days gone by that the decreased value was more than compensated for. Mr. Tite then gave a number of figures to prove this, mentioning among other matters that a series of returns obtained by the Rev. C. G. Anderson, hon. secretary of the Somerset Bee-keepers' Association, in 1884, from various parts of the county, showed an average yield of 57 lbs. from 230 stocks. Mr. Tite then referred to the work of the Somerset Association, and to the self-denying labours of Mr. Anderson. He also spoke of the great improvement in the literature relating to bee-keeping; and, in conclusion, urged his hearers to do their utmost to spread a knowledge of humane bee-keeping amongst their friends and neighbours, so that the use of super-less straw skeps and the cruel custom of suffocating bees may soon become things of the past.

A cordial vote of thanks was passed to Mr. Tite for his paper, on the proposition of the Chairman. A number of bee appliances and books on the subject, lent by Messrs. Neighbour, of London, Mr. James Lee, and others, were exhibited by Mr. Tite; also a set of photographic and microscopic slides illustrating the anatomy of the bee and work in connexion with the apiary, which were kindly lent for the occasion by Mr. Alfred Watkins, of Hereford. Mr. W. N. Griffin, of Reading, sent samples of his 'honey dubbin,' and Mr. C. Lewis, of Fore Street, Taunton, also had some model bee-keeping appliances on view, as well as a supply of confections, liqueurs, &c., in the manufacture of which honey is largely used. Refreshments were provided, and the proceedings concluded with a vote of thanks to the Chairman.

WIGTOWNSHIRE APIARIAN ASSOCIATION.

The annual meeting of the members of this Association was held on Friday, February 17th, at the George Hotel, Stranraer. Mr. McNally, Glenluce, occupied the chair, and amongst those present were Messrs. Ross (Governor

of the Reformatory), Fleming, Wither (members of the Committee of Management), and others.

Before proceeding with the ordinary business, the Chairman called upon Mr. Ross to make a presentation to their esteemed Secretary, the Rev. J. B. Robertson, for his valuable services to the Association.

The presentation consisted of two drawings in oil, executed by Mr. Nairn, artist, West Regent Street, Glasgow. The committee had entrusted Mr. J. D. McNally, Glasgow, to make the purchase. They each bore the following inscription:—'Presented to the Rev. J. Balfour Robertson, of Leswalt, by the Wigtownshire Apiarian Association, in recognition of his services.—17th February, 1888.'

Mr. Robertson, in reply, said that he did not know how he could really thank them for the very handsome present they had given to him. He looked back to the past, and to his connexion with the Association, and he felt he did not merit half of the kind words the Chairman had used regarding him. Some six years ago the Wigtownshire Horticultural Society did not grant prizes, but allowed an exhibition of honey. He then met Mr. McNally, of Glenluce, for the first time, and he ventured to think that the super of honey he showed was a good one. After that some correspondence appeared in the local papers, and a suggestion was made that an Association should be formed. He happened to reply to that letter, and afterwards the Apiarian Association was formed. In 1882 he had stated, and he did not think he was wrong, that all the honey gathered in Wigtownshire did not realise 50*l.* per annum. After six years he did not think he was wrong in saying that the honey gathered in the county and sold in the market did not realise less than 50*l.* That was, no doubt, particularly realised through the benefits of their Association. He referred to the difficulties they had to encounter at the outset of their Association, and the statement of a landed gentleman of the county that the Association would only exist for the benefit of a few, and not for the working man. This same gentleman had since stated that the Association had conferred great benefit on the working people, whose gardens were graced with hives. With reference to the making of money by bee-keeping, Mr. Robertson gave his own experience, showing that a good profit could be realised, and that even in the hands of a raw amateur not less than 30*s.* per hive could be realised. Mr. Robertson concluded by thanking the members heartily for the present of the pictures, which, he hoped, would long grace his manse, and be handed down by him to posterity.

The Chairman said that their Association, though small in numbers—at the commencement they were only seven, but now numbered more than thirty—had all heartily contributed to the proposal to make this presentation of these handsome oil paintings to the respected and honoured Secretary.

A vote of thanks was given to the Chairman.

INVERTED HIVES.—What was said in 1842 about them by John Wighton in his *History and Management of Bees*, p. 75:—'The inverted hive is better adapted to adorn the lawn and garden, and to amuse the curious, than to supply the purpose of the practical bee-keeper; while its expense is an obstacle to its general use. The name explains its principle, which wars against the natural habits of the bees in the construction of their cells, whence its position must either cause the honey to drop, or compel the little architects to alter their rule of building. All dirt also, and many of the dead, must fall to the bottom of the inverted cone, whence it cannot be removed—a manifest evil. In other respects the hive differs little from those on the storifying plan, and though I have tried it for years I have obtained from it scarcely so much as from one of these last.'

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal," c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, Kings Langley, Herts (see 2nd page of Advertisements).

* * * In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

BEE DISEASE (SO CALLED).

[1505.] I consider this, when the symptoms are clearly given, only another name for pollen-cold, or what is more commonly known as hay-fever. A bee-keeper (1366) consulted his doctor during an attack, and was told it was analogous to hay-fever, but evidently arose from some other cause, as he suffered from it throughout the year. Let us place side by side the symptoms of bee disease as shown by Mr. Heddon (Ed. foot-note, page 517, Vol. xv.), and the catarrhal symptoms of hay-fever as given by (now) Sir Morel Mackenzie in his work on that disease.

Symptoms, &c., of Bee-disease.—HEDDON.

First felt ten years ago itching sensation in ears, gradually extended to mouth and near root of tongue. Later on severe sensation in roof of mouth.

Eyelids itch and burn followed by swelling. After three years found out to open a hive, and breathe odour of bees, brought on the irritation.

Irritating and tingling sensation crept down bronchia until woke up with asthma.

Symptoms reappeared on coming back to his bees after a fortnight. Since ceasing working in apiary has been free. Disease reappearing on bee flying past his face, severe paroxysm; speechless eight hours.

Bee disease symptoms of 'A Bee-keeper' (1366). For last three years suffers from what appears like violent cold in head, comes without warning, with frequent sneezing and continued running at eyes and nose, lasts a few hours, sometimes one or two days.

We are told by various authors that hay-fever is produced by the pollen of grasses and flowers, and it is proved that pollen is an essential factor. I must, however, say that it has been attributed to an excess of ozone in the air. Dr. Blackley studied the effects of benzoic acid (*pace* 'W. B. W.') found as it is in sweet vernal grass, coumarin, essential perfumes of peppermint, juniper, rosemary, and lavender, *in vain* for symptoms; and it remains beyond doubt that hay-fever is caused by the irritating action of pollen-grains on the mucous membrane of the nostrils in the first place, probably next by long

Catarrhal Symptoms, Hay-fever, p. 31.

Itching, smarting sensation in nose and eyes, and sometimes in cavity and roof of mouth.

Not infrequently the attack commences with a feeling of extreme irritation of the inner angles of the eyelids; occasionally the eyelids became pulled so as to almost close the eyes.

The asthmatic form of the complaint may be superadded to the disorder just described.

Difficult breathing may continue, with only slight remissions, as long as the sufferer is exposed to the influence of pollen. The paroxysm may pass off in a few hours.

Dr. Roe thinks everybody who is subject to hay-fever has a cold in the head sometime during year.

Dr. M. M. says the irritation of the lining membrane of the nose causes running of the nose and eyes, and paroxysms of sneezing quickly ensue, followed by an abundant thin discharge from nose.

fingerlike growing of the intine of the grain absorbing moisture by a process termed osmose, and penetrating deeper into the tissue, thus increasing the irritation. Finally the chemical action on various parts of the throat and bronchial tubes of the contents of the burst grains will complete the list of causes for the symptoms above given. Such pollen-poisoning must be a very distressing affair to the small percentage of people subjected to it, for it has been calculated (Herapath) that in 'the granular matter of pollen-grains of several orders of plants there is forty-six per cent of a peculiar inflammable azotised principle insoluble in nearly every liquid. Mackenzie also says that as pollen granules are only one-tenth the size of blood-corpuscles, they may enter the blood-vessels by actual penetrations of the walls,' circulating, and thus causing the fever. All pollen-grains, it must be understood, will not cause annoyance, but only peculiar kinds, and these only upon peculiar idiosyncrasies of constitution.

For example, Dr. Marsh has stated that in America only the pollen of the Roman wormwood (*Ambrosia Artemisiaefolia*), is the cause of hay-fever, but this opinion is not generally received. Grasses, too (Indian corn excepted), have slight effect in America. The English and Americans are almost the only people subject to hay-fever, and it would be interesting to learn if any of our Continental brethren are subject to this alleged bee disease.

Again, those affected consist almost entirely of persons of some education and of fair position, they also nearly all belong to the highly energetic class, and are of generally nervous temperament. Let us now give a glance at the cause of pollen-poisoning, *alias* hay-fever as it affects the bee-keeper. It is agreed on all hands that the bee-keeper is only punished when he opens his hives.

If we read what Pastor Schönfeld tells us (p. 12, *B. B. J.*) on 'What do bees use in winter when the pollen collected by them is exhausted?' we shall find plenty of evidence that there is plenty of pollen at hand in the hive in winter, in old combs, cell-walls, and margins, membranes left by the nymphs, and in the excreta of larvae at the bottom of cells. He shows that even the stomach of the bee, let alone that of the larva, is unable to make all the pollen-grains yield up their contents, by reason of the hardness of the extine resisting their digestive or assimilative juices. Now when bees go out of their hives silver and golden in hue, the body hairs covered with pollen, bent, as the insects are, in making the most of a honey glut, and leaving the pollen-cleaning until dark, the whole hive will be not unlike a flour-mill, the air charged with floating grains. If one, at this time, only take a peep under the edge of quilt (even has a smell at the bees, as Mr. Heddon puts it) a current of hot air rushes out of the opening, carrying on it myriads of pollen-grains to the nostrils. By the showing of various bee-keepers, the disease instantly begins its course. What theory so reasonable as that he gets it from pollen-grains fanned about by multitudes of agitated wings, especially when the apparent causes and symptoms are so identical with those of hay-fever known under other names, *e.g.*, pollen catarrh, summer catarrh, idiosyncratic catarrh, rose-cold, peach-cold, and pollen poisoning?

I do not doubt that the bee which flew close past Mr. Heddon's face, and gave him an attack, instead of discharging poison, watted pollen-grains, which he inhaled. In short, with the infinitesimal percentage of people who are subject to pollen-poisoning, to keep off certain flora gives immunity, and equally keep away from the pollen collected by the bee, and there is no bee-disease. The two must be identical.

My remarks, however imperfect, would be still more so if I did not say something with regard to prevention, &c. Dr. Morel Mackenzie says, 'If the poison be continually introduced into the system, the antidote, if

one exists, can have but little chance of effecting a cure. Change of residence, from the country to the seaside or town, is recommended, (keep off the bees). And (strange to say, but welcome to bee-keepers), he recommends also a veil to be worn over the face. 'I have found a "double gossamer" veil, which can be had in several colours, answer the purpose in some cases. Protected in this way many people predisposed to hay-fever escape altogether.' *Verb. sap.* Tobacco-smoke sometimes affords relief. One part salicylic acid to 1000 of water, snuffed up the nostrils cuts short the disease. (Binz.)

Prevention being better than cure let those who are susceptible wear a fine silk veil.—R. A. II. GRIMSHAW, *Horsforth, near Leeds.*

COUNTY BEE-KEEPERS' ASSOCIATIONS.

[1506.] There is one thing that might be encouraged through the *Journal* and county Associations' reports which I do not remember seeing anything about, viz., each county committee to get one practical bee-keeper in each district who will fix five or six days, or rather evenings, during the months of May, June, and July to welcome members of County B.K.A., and to show and explain any different hives or supers which he may be working in his apiary or anything else.—JOHN R. CRITCHLOW, *Maer Farm, Newcastle, Staffordshire.*

SENDING QUEEN-CELLS.

[1507.] Mr. Sharp in his article (1485) inquires, should he take his young queens to his allotment to be fertilised with foreign drones he intends raising? I would say no. Let the following incident suffice:—A bee-keeper, distant exactly two miles from this village, about six years ago introduced Italian queens into his apiary, the following summer young queens from three different hives in the village had mated with the Italian drones, their offspring being finely marked in the two upper rings of the abdomen; I found them quite as harmless as my own old-fashioned blacks.

To encourage Mr. Sharp, at his request I will have pleasure in forwarding him as early as possible this summer a few ripe queen-cells, which he could make use of either in his old or nucleus hives. His foreign drones and pure Scotch black queens would impart fresh blood into his apiary. Foul-brood unknown in this locality.—JAS. PRINGLE, *Cockburnspath, N.B.*

THE TIME TEST.

[1508.] I quite understand 'H. J. B.' (1496) feeling disgusted, and saying that it was his first—and last—attempt to obtain the third-class certificate. I don't wish the rules to be altered to admit any bee-keeper to be a third-class expert, but I do think failing to find her majesty in a given time ought not to throw a candidate overboard, which appears from 'H. J. B.' to be the case. The men we want for experts are those who are thoroughly practical, and can work a good return from their own stocks. One of your correspondents, some months back, said all District Secretaries and local advisers (if I remember right) ought to hold a third-class certificate, and I say so too; but how many of these gentlemen, who are well-known bee-keepers, will come forward to be plucked and sent back empty? I know one District Secretary who would have been a candidate last year only for the above cause. The only reason he had for wanting a certificate was in case the County B.K.A. got short of funds he could take the expert's tour sometimes in his own district. This gentleman, to my knowledge, has spent weeks in the last five years for the good of our County Association by starting new

members, attending committees, shows, &c.; at least he is always ready to give a helping hand when his own duties will allow him,—*all gratis.*

It would not be a bad plan, after candidates have applied to be examined, for County B.K.A. Committees to say whether they have made a good stand as practical bee-keepers and also successful exhibitors, as I am sure if men are qualified to hold a certificate they will be well known by part of the County Committee.—SNOWDROP.

A USEFUL SUGGESTION.

[1509.] Your correspondent 'H. J. B.' (1495) has hit on the thing wanted to promote the sale of honey in my opinion, that is, better advertising, as there are thousands who only know honey by name, if they have heard of it at all; and if they do know more about it, where are they to get the pure British honey from which can be depended on at a market's price? What we want is a more uniform price, quality, and get-up for sale, and thoroughly bringing before the public. One of the objects set forth by County B.K.A. is to encourage the sale of honey, which I am afraid is little heard of, but still hon. secs. have plenty to do without selling for members their honey. A thought struck me several weeks ago that a honey club might be worked in connexion with the County B.K.A. something on the following lines: To appoint one hon. sec. for each thickly-populated district, with a small committee to arrange prices, rules, &c. Each member who joins this club must take one or more shares in the year's turnover, according to the amount of honey he wishes to sell, each share to represent 25 lbs. of honey at from 1s. to 2s. each. By this plan all members would be on the same footing, for if one has 200 lbs. to sell, he would have to pay eight times as much as one with only 25 lbs. The small subscriptions would go towards printing, postage, carriage of samples, &c. I think if the above could be put in working order, it might be tried for one year to see how it answers. I should like to hear the opinion of other bee-keepers through your valuable *Journal*.—SNOWDROP.

SUGGESTIONS.

[1510.] The *B. B. J.* so ably and wisely conducted by you, is a weekly source of pleasure to me in studying the marvellous works of God. The *Journal* supplies me with comb upon comb of beautiful honey in the shape of help and advice. I should therefore be pleased if I could contribute one single cell, or even a bee-load of honey, to the hive of knowledge, in gratitude for the knowledge I have extracted. I will jot down a few remarks for you to glance over, and should you deem any of them of interest to amateur bee-keepers, please make use of them as food for the *Journal*.

My apiary consists of twenty-four stocks; fifteen are the produce of last autumn's condemned bees. I endeavour to make everything required about the apiary, for to my mind half the charm of bee-keeping is the construction of the appliances. By rising in summer three or four mornings a-week before the bees, say from 3 to 5 a.m. a good amount of work may be accomplished, and personal health greatly benefited. A Britannia Company's patent circular saw, which is perfection, adds eighty per cent to the pleasure of a bee-keeper's life. This is only my second season of bee-keeping on the most approved lines. But when a lad of thirteen I had fourteen hives and made all the houses, &c., for them. Most of my present hives consist of an inner hive, $1\frac{1}{2} \times 16$, and an outer case 20×20 inside measure. I think double-walled hives are by far the best.

Suggestion I.—I find the most satisfactory way of keeping the water from getting in at the junction of outer

cases is by nailing strips of tin the length of the side by one inch width on each side. The tin should project $\frac{5}{8}$ inch beyond the side of the case, and as it is free at each corner, it fits nicely over any slight variation in the thickness of the case below. The strips of tin can be cut and nailed on very quickly if the proper mode be adopted. The bottom case of all needs no tin strip, since it projects one inch over floor-board, and strips of wood nailed round inside keep it resting on the floor-board.

Suggestion 2.—The best entrance slides I find to be made thus:—Nail a strip of tin the length of entrance, say fourteen inches, and one inch wide, just above the $\frac{5}{8}$ inch entrance. Then cut two strips of tin $7\frac{1}{2} \times \frac{5}{8}$ to slide between the tin and the case side. Turn up one end half inch of each tin slide at right angles to work the slide by. Then screw a piece of wood the length of the outside case (mine is twenty-one inches), $\frac{5}{8} \times \frac{5}{8}$, just under the $\frac{5}{8}$ inch entrance and flush with it, and then the slides run nicely on the wood. The flight-board, bevelled at the edge, rests up against the $\frac{5}{8}$ inch strip of wood and is hooked on to the case side. Perforated zinc slides can be worked without the tin ones being entirely removed. Wooden slides for narrowing the entrance are too much acted upon by the weather to be perfect. The tin slides are practically unaffected by weather, and are more quickly made. Porches I have discarded as not necessary.

Suggestion 3.—I have found the following frame-lifter of great service. Bend a piece of $\frac{3}{16}$ inch wire into a semicircle of fourteen to sixteen inches diameter, to suit hive and frame and bend the ends up $\frac{3}{4}$ inch at right angles. Then you can slip the right angles under the top of the frame and lift it with one hand and turn the frame about as desired. The cost of this lifter is about a penny, or less. I have not seen so simple and cheap a frame-lifter mentioned in *Journal*, so I draw attention to it as it might be of use to amateurs. It was of great service to me last summer, enabling me to manipulate without smoke, &c.

I should like to hear some suggestion on a quick, cheap, and effectual mode of shading hives from the glare of the snow. I unhook my flight-boards, which are 21×18 , and slant them against the hives. This is effectual, but it takes some time to do this for even twenty-four hives. I should also like to know if roofs without any inclination for the rain to run off have been much tried in this country, and with what results. I am thinking of making all future houses with level roofs. I have about six now and they have been tried for over six months and not a particle of moisture gets through them. I cover the joints with strips of tin. It is quickly done, and if well nailed and painted no wet can possibly get through. The slight drip there may be in front does not trouble the bees, and half-inch inclination to the back avoids even this. The advantages I find are, (1) the roof dries quicker, as the sun strikes it more directly than when inclined away from the sun. (2) More quickly made and easier for an amateur to make. An eleven-inch plank, ripped up the centre, just gives the sides of the roof a nice depth of five and a half inches. (3) They make good tables for placing things on. They are light to lift if bare half be used for the top, five-eighths for front and back, and half inch for the sides. I make my roof come down over the case one half inch; strips of wood being nailed round the inside to allow of that amount. I use nothing but good pine in making hives and cases, &c.

In the above remarks there may be nothing of profit, even to amateurs. But as I have profited for two years by hints on various subjects given in the *Journal*, I am wishful to contribute, if possible, honey to the hive, and so far I have been an unprofitable bee for two years. Wishing you, Mr. Editor, continued success in your arduous duties,—I am, yours faithfully, R. T. SHEA, *Little Waking Vicarage, Rochford, Essex, February 22nd, 1888.*

NOTES ON BEE-HIVES.—SECTIONS.

[1511.] In reading *Gleanings* of the issue of the 15th January, 1888, to-day, I notice some questions and answers that bear directly upon the important subject now being considered or mentioned in the *British Bee Journal*, and of which I make a few extracts for the benefit of some of your readers, hoping you can kindly allow the space. *Question.* 'Is it best to fill section-boxes full of foundation, or use starters only one inch in width?'

Favourable opinions.

Full.—C. C. MILLER.
 Fill full.—DR. A. B. MASON.
 Fill full.—GEO. GRIMM.
 Fill them full.—W. Z. HUTCHINSON.
 I prefer a full sheet.—PAUL L. VIALLO.
 I prefer to fill the section.—G. M. DOOLITTLE.
 So far as my experience has gone I prefer to use full sheets of foundation in my surplus boxes.—JAMES HEDDON.
I have found it best to use full sheets, though I often use triangular starters.—A. J. COOK.

Full-sized sheets have a chance to pay for themselves whenever the bees cannot keep up with their income.—E. E. HASTY.
 It is much more profitable to fill them full. If quality only is considered, starters are better. If foundation is made then, and used fresh, there is practically no objection to its use in full sheets.—JAMES A. GREEN.

The office of starter one inch wide is only to serve as guide-combs. They would not increase the crop of honey much. But to fill the section with foundation increases the crop materially. It does almost as much good as to fill them with newly-built comb.—CHAS. F. MUTH.

Friend Root states that Mr. Muth seems to have overlooked the fact that recent decisions place full sheets of foundation even *ahead* of newly-built comb; that is, where the cells are drawn up to anything like full length.

Question. 'Is a triangular starter, with the point reaching nearly to the bottom of the section, as good as a full sheet of thin foundation?'

No.—GEO. GRIMM.
 No.—DR. A. B. MASON.
 No.—W. Z. HUTCHINSON.
 I think not.—C. C. MILLER.
 I use full sheets.—G. M. DOOLITTLE.
 Not in our opinion.—DABANT AND SONS.
 No, not in my experience.—JAMES HEDDON.
 I prefer a full sheet.—PAUL L. VIALLO.
 It answers very well, but I prefer full sheets.—A. J. COOK.

A triangular starter is not as good as a full sheet of foundation. The section will not be filled in the same time as when full sheet are given.—CHAS. F. MUTH.

If it pays to use foundation, use it. Why stop half way? *Partly filled sections give the bees a chance to build two sizes of comb in the same section, and make a both of things.*—E. E. HASTY.

No. Firstly, because it will not be finished quite as soon. Second, because it will not be as well finished. The foundation should be cut as large as possible, without having it kick from the lower corners touching the sides, when put in with ordinary care. This gives a square, solid comb of honey, firmly attached all around that is easier to shake bees from, looks much better, and is much less liable to break out in shipment.—JAMES A. GREEN.

T. BONNER CHAMBERS, F.L.S., *Tref Eglwys, Caerws, Montgomeryshire, Feb. 16, 1888.*

(To be continued.)

THIRD-CLASS EXAMINATION.

[1512.] A candidate that enters for the third-class examination ought to know the time that is allowed him to drive his bees and find the queen. Under these circumstances he should repeatedly practise driving and picking out the queen, previous to the date of his examination, timing himself on each occasion.

If a little more pains were taken by candidates to make themselves proficient, we should hear of less complaints after the examinations were over. It is not a matter whether the judge can find the queen in so many minutes; he is not present to do the work, but to see that it is done. So if the candidate fails to find the queen in the time that is allowed him it would be much better taste on his part to hold his peace than to try and bring discredit upon the judge when the whole fault lies at his own door.—QUEEN.

[We have perused the instructions given for third-class examinations, and we find that no specified time is laid down for driving the bees from skeps. The candidate is no doubt credited in accordance with his expedition, care, and general efficiency in his work. We think the advice of our correspondent is very much to the point.—Ed.]

WEATHER IN AMERICA.

[1513.] You have no idea what storms of snow we have had. You, perhaps, remember the little town of Red Hook, about two miles east of here. About two weeks ago I sent my boy Joe with horse and cutter (single-seated sleigh) over to Red Hook. Our waitress Addie accompanied him, and they left here at 12.30 p.m. It snowed some fourteen inches the night before, and at 12.45 p.m., fifteen minutes after they left, the wind started up from the north with considerable vigour, and in twenty minutes was blowing half a gale. Shut up in our house and placed, as we are, on a hill or ridge-top, we did not appreciate the drifting of the snow. Hour after hour went by and no tidings of the two. About four o'clock one of the men working on my mother's place came to the house and reported that about one hour before, with infinite labour, my sister's coachman had reached home in a sleigh and that he declared it impossible for Joe to reach home that night; but to our astonishment, not many minutes later, in walks Joe, looking quite exhausted. He reported having left the horse at a livery stable, and that Addie had stepped into a store to make some purchases, and when her errand was over was astonished to find that to get anywhere she had to wade in soft snow up to her waist! Joe had beat his way through snow up to his neck, as he expressed it, and when I saw the roads and paths subsequently I did not doubt his word.

We have never seen anything to compare with this storm since 1857.

Of course it was useless to send out men that afternoon (January 26th) or evening, as the gale was still blowing. About 10 a.m. next day the wind subsided, and I at once ordered all the men on the place out with shovels and our snow-plough with heaviest team. Of course all our neighbours turned in and helped, and by night the roads were opened part way to Red Hook. From a point about half-way over the teams were compelled to leave the road and strike into the fields. A detour of about a mile was made before they could get into the town. Gangs of men were out working our way, so that the road, or I had better say 'trail,' was passable by 5 p.m., and Joe managed to bring home Addie and the horse. Some of the drifts were ten feet high.

The temperature has been toying with zero altogether too freely: several mornings at ten o'clock the thermometer has stood at 15° Fahr. They are harvesting ice seventeen to eighteen inches thick, as clear as crystal. I filled my ice-house in four days. We had a thaw yesterday for the first time in six weeks. We are all tired enough of this wintry weather, and shall greet with joy the first signs of spring.—J. A., February 5th, 1888.

[The above is an extract from a private letter received 20th February, and will give some idea of the weather our friends in America are having.—Ed.]

PAINTING THE INSIDE OF HIVES.

[1514.] Having had hives with all the woodwork (except the frames) of the interior painted, and wintering most satisfactorily for ten years, I differ with your correspondent Mr. Adcock (p. 105) in the advice he gives. In the volume of the *B.B.J.* for 1887, p. 119, I gave my reasons for adopting the practice, which had been previously recommended in 'Useful Hints,' and which was subsequently advocated by another writer at p. 143.

Since I wrote that letter, now just a year ago, I have had very fair success with my bees. My honey yield has been good, and there is nothing to be dissatisfied with the way the bees have passed through the varying changes of this past winter.

My hives, all of which have the insides well painted, are tenanted by strong stocks, and I find no pools of water in them such as Mr. Adcock found in his. Might I suggest that Mr. A.'s hives have not sufficient width of flight-hole for the winter? Mine always have the full width of nine inches, which I consider has a great deal to do with keeping the interiors dry. As to his hives with floor-boards so made or so placed that one 'contained more than a pint of water,' and the others were 'more or less covered with water, and a great number of dead bees floating in it,' I cannot understand it. There must be something astray, or the hives are not set level, or with the least possible inclination from back to front—I give mine a bare quarter of an inch fall—or is there not another possible cause for the extraordinary watery condition of Mr. A.'s hives? Could there be any cracks or chinks in the roof through which the rain penetrated?

I hope some other bee-keepers who have given the subject a fair trial, such as I have done, will write to you. Many mistakes are often made by beginners, who attribute results to wrong causes from want of thought and careful observation of all the circumstance of the case.

If I possessed five hundred hives I should paint the insides of every one in order to have no damp, water-soaked wooden walls about my bees.—H. W. LEFT, M.A., *Aghadery Glebe, Loughbrickland, Co. Down.*

INSERTING FOUNDATION IN SECTIONS.

[1515.] Under the above heading (*British Bee Journal*, page 5, January 5th, 1888) an article is quoted from the *American Bee Journal*, written by E. S. Eden, of Canada, and the article commented upon in the *B.B.J.*, and a statement made that a Mr. James Lee has invented a superior method of putting in foundation, and we in Canada and the United States are to take a note of the fact that he (Mr. Lee) is about to patent this and a brood-frame similarly constructed in America.

It might be interesting to know that Mr. Eden was simply working in an advertisement for his own ingenuity, and to draw attention to the subject, so that it would pave the way for the fruit of his thoughts. Mr. Eden has invented a machine which also does away with all the difficulties he mentions, and can be worked very rapidly. I am not in favour of a writer 'blowing his own horn' for selfish ends under the guise of giving the public information. Nevertheless, I doubt very much if Mr. Eden's machine, or that of Jacob Alpaugh, St. Thomas, who has also invented a machine for putting foundation in sections, will be very much improved upon for some time. Mr. Eden has his machine patented. I know of no man who has made any money out of a patent upon bee-keeping appliances in Canada. However, should Mr. Lee see fit to patent his invention in Canada, I trust he will not regret his decision. Of course, I am not in a position to say anything about the invention, but unless very inexpensive the demand for such will be very limited; bee-keepers prefer a little

extra trouble to extra expense. An important feature in the machines here is an iron plate heated by a lamp; upon this plate the edge of the wax is melted. It works well and rapidly.—R. F. HOLTERRMANN, *Brautford, Canada.*

YELLOW RACES.

[1516.] Will you kindly inform me in an early issue as to why all authors on works on bee-keeping, English and American, as well as bee-keepers when referring to the colour of certain varieties of bees, make use of the terms *yellow-banded*, *yellow-striped*, &c., when the colour alluded to is not at all yellow, but a dusky orange?

I may mention that I possess stocks of Cyprian, Italian, Carniolan home-raised from Mr. Simmins, and also pure bred from Mr. Benton, Syrian, and Palestine varieties, together with the common English kind, and no yellow whatever occurs on any of these bees, but only bands of a warm grey tint and a dusky orange shade in connexion with the dark brown colour commonly found on most races.

It would be very interesting and valuable if you could prepare, in connexion with the *B. B. Journal*, a sheet in chromolithography for framing, giving the various races of bees with their respective forms and colours. Queens, workers, and drones, of each race might be represented, and perhaps some of the hybrid kinds. I feel certain that the cost of such a sheet of illustrations would be gladly met by your subscribers, and I should have much pleasure in preparing gratis the necessary drawings for the stones.—W. G. MUCKLE, *Loveswater, Cumberland.*

[Although not generally of a bright yellow these races have been called the yellow races because of the yellowish tinge of their bodies. The Italians are described by some German writers as having orange-yellow belts, others say yellowish; and we believe they have been generally called yellow races because of this yellowish hue, and in contradiction to the brown or what are also called black bees. We are not inclined to quarrel with the term, for, after all, orange is only a reddish shade of yellow resembling gold, and the word itself is derived from the Latin *aurum*, signifying gold. Yellow is also defined by Dr. Ogilvie as the colour of gold, a golden hue, and is also derived from gold, in Danish *guld*. These bees have also been called golden bees; Virgil says:—

‘Two different kinds of regal bees behold,
The better bears a coat that glows with gold.’

And again,—

‘The better race refulgent hues unfold
Bedroit with equal spots of glistening gold.’

Dr. Pollmann, a leading German authority, in his book on the value of the different races of bee, describes Italians very minutely and says the workers have orange bands instead of brown. Some queens, he says, have the forepart of the abdomen golden yellow, or orange-coloured, and others have the whole of the abdomen golden-yellow as though cut out of ducat gold. Some bees are much brighter than others, and this brightness is still more apparent when we look through them, especially if the sun be shining, then we think golden-yellow would not be a very inappropriate name. The name of ‘yellow races’ is so established that we do not think it would be easy to change it. We are much obliged to our correspondent for his kind offer, and we should be happy to carry out his suggestion and publish a lithographic sheet of various races of bees if we could get them lithographed to our satisfaction. We have seen a great many attempts made in this direction, but none hitherto that have proved entirely satisfactory. —Ed.]

BEES NATIVES OF ENGLAND.

Bees are mentioned in some of our earliest national records, and the mention of them is such as demonstrates how highly they were valued. Nor is this a cause for surprise, inasmuch as that mead or metheglin was the choicest drink of the Britons’ feasts; and although the household of the Prince of Wales one thousand years ago comprised but twenty-four officials, the eleventh of them was the mead-maker, and he ranked next before the royal physician.

So highly was superior mead prized in those days that one of the royal privileges was to have the first offer of every cask that was intended to be sold.

We are accustomed to consider our forefathers of those days as rude and barbarous, and they were so if measured by our present standards of habits and education, but compared with contemporary nations they appear to advantage, for their laws and customs were fully equal in good sense to those of their neighbours on the Continent. As an illustration we will quote from the laws relative to bees enforced by Howel Dha, who was chief ruler of Wales about A.D. 940.

‘OF THE PRICE OF BEES.

- ‘An old hive is valued at 24 pence.
- ‘A spring swarm at 16 pence.
- ‘A second swarm at 12 pence.
- ‘A swarm from a first swarm at 12 pence.
- ‘A swarm from a second swarm at 8 pence.
- ‘A swarm after the Calends of August at 4 pence, and that shall be the price until the Calends of November.
- ‘After the Calends of November an old hive is valued at 24 pence, and the swarm which came off after the Calends of August shall not be considered as an old swarm before the Calends of May, and then it shall be valued at 24 pence.

‘Three huntings are free (that is, you may follow them upon another man’s ground), of a swarm of bees settled upon a branch, and of a Fox, and of an Otter, because they have no certain abode.

‘Bees were first born in Paradise, and were driven thence on account of man’s sin, but God blessed them: therefore mass ought not to be sung without their wax being present.

‘He who finds a swarm resting on a branch in another man’s land shall receive 4 pence from the possessor of the land, if the latter wishes to retain the swarm.

‘No swarm shall be valued at more than 4 pence until it has remained quietly for three days and three nights in the same place, and that in fine weather. Of those days the first is required to ascertain whether it will settle; another in examining whether it will cluster, and the third whether it will continue here.’—*Wotton’s Leges Wallicæ*, page 254.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

JOHN MAIN.—1. *Sections*.—The sections mentioned are not, generally speaking, taken to by the bees. We do not advise sections narrower than $1\frac{1}{4}$ inch. 2. *Haddon Hives*.—These may be obtained from several of the dealers in appliances.

NORTH DEVON RUSTIC.—1. *Hoya carnososa* is a tender exotic and requires the protection of a warm greenhouse in this country. It is a pity it is not hardy, for we know of no plant, native or foreign, that secretes more honey than does this species of *hoya*. The

honey, however, does not hang on every petal as our correspondent remarks, but collects in pearly drops in the centre of each flower, which are deliciously sweet-scented and pretty. Each generation of these wax-like flowers proceed from the same flower-stalk, hence it is advisable to cut them as little as possible.

2. *Closing Entrances to Hives.*—We never close the entrances to our hives; they are now at summer width, but have a board resting against the porch of each to prevent the snow reflecting the light into the hive.

C. MARKS.—*Bees in Roof.*—The bees, as you say, are no doubt between the roof and the ceiling; this could easily be ascertained by listening on a warm day, and their exact location found out. If the farmer thinks of removing a portion of the roof they could be easily removed, but if not the 'game is not worth the candle.' At the end of the honey-harvest would be the best time if they are to be taken for their stores, but if for the bees early spring. Use plenty of smoke, as the slates or tiles are being removed, and when the bees are thoroughly intimidated cut the combs out one by one, brushing the bees off into an empty skep. (See answer to 'A Novice in Modern Bee-keeping,' in issue of 23rd ult.).

HORACE.—*Replacing old Combs.*—Towards the end of March, on a warm day, remove any surplus combs; insert new sheet-foundation about the centre of the brood-nest. Should the weather continue favourable give a fresh sheet of foundation about once a-week in the same manner, removing the outside comb. Feed gently but regularly, and take care you do not spread the brood-nest faster than the bees can with their increasing number cover all brood. There is nothing whatever to prevent you getting a full return from this hive during the coming season. Wired foundation is suitable.

NOVICE.—*New Hive.*—We are sorry to do so, but must condemn your plan. Just fancy trying it with Cyprians or pugnacious hybrids! Who could live to tell the tale?

R. M'WHIRTER.—*Queen Excluder.*—We always deprecate the use of excluder between rack and body of hive. It is rarely that the queen ascends; even if she does the portion of section in which she lays her eggs can be cut out. When upon being given back to the bees they will repair and make good any damage.

K. SANDALL.—1. *Transferring.*—The advice we give is intended for the benefit of novices, and is the best plan for such; an adept can transfer at any time. 2. *Using Queen-cells for Re-queening.*—Yes, if they are inserted twenty-four hours after removal of queen, or they could be placed, if in queen-cell cages, in the hive immediately upon such removal. A queen-cell cage is a cone of wire cloth into which the cell is put; the apex is open. Through this opening the queen emerges, the sides of the cell being protected from the attacks of workers by the wire cloth.

R. E. T.—1. *Neglected Honey.*—Remove all the combs having uncapped honey in them and place them in a basin in the oven. When the wax is all melted allow it to cool. The wax can then be removed in a sheet; feed the honey back to the bees in the spring. The few frames can be given the bees to clear out, but not until they commence working before the honey-flow sets in. 2. *Hives.*—You will find a bee-house just as expensive and not half as handy. To hold eleven or twelve frames is the best, as such a size is easily 'tiered up.' 3. *Foundation in Frames.*—Whole sheets. We prefer 'Pelham.' It is very much a matter of individual opinion, though we strongly object to flat-bottom in the brood-nest.

C. WHITING.—The bees forwarded are hybrids.

A GRATEFUL READER.—*Glossary of Apicultural Terms.*—Your suggestion meets our views, and it will in an early number be carried out.

W. P. MEADOWS.—1. *Bee Flora.*—We have in previous volumes given this subject our best attention; but as we are continually receiving fresh subscribers we shall not lose sight of your suggestion. 2. *Railway Companies and Rates to Bee Appliance Manufacturers.*—In the year 1883 the British Bee-keepers' Association took a considerable amount of trouble, and incurred some expense, in placing the claims of the bee-keeping industry before the several Railway Companies. Printed memorials were prepared and signed by the executive of each County Association, and these were subsequently considered at a Conference of railway managers. A reply was in due course given by the Secretary of the Conference to the Secretary of the B. B. K. A. to the following effect:—'I beg to inform you that this subject has been fully laid before the different Railway Companies, and I regret to say that they do not see their way to make any reduction in the rates.' It will be found from the report of the Committee of the B. B. K. A. for the past year that this subject has not been lost sight of. We would suggest that our correspondent and others should communicate their views on the subject to the Secretary of the B. B. K. A.

D. R. DALY.—*Feeding.*—If you desire to get the full advantage of stimulating brood-rearing early in the season, as soon as the bees fly freely it will be well to supply them with liquid food (the receipt for which you will find in Cowan's *Guide Book*) and regulate the feeder so that only a small amount can be taken at a time. If the bees are not, through the weather being cold or other reasons, inclined to take the liquid food, flour candy can be placed under the quilt above the frames. 2. *Transferring from Sleps.*—Let the bees swarm, and twenty-one days after transfer to frame-hives. Whether it be better to transfer or unite should be determined by the strength of the stocks.

E. H. TURNER.—The most exhaustive work is *Apidae Europæe*, by Dr. H. L. O. Schmiedeknecht. As a book of reference it is invaluable, and the numerous excellent illustrations are a great help in determining species. Professor Siebold on *Parthenogenesis* would be of great service in your special study. We shall be pleased to receive results of your investigations.

C. WADE.—You will get the information you desire by looking at advertisement of Messrs. Abbott in this week's issue.

NORMACOT.—*Mouldy Comb.*—There is no necessity for your destroying the combs. The pollen-filled cells are mildewed through being kept in a damp place. When dried rub them with a soft brush, and spray with salicylic acid; when required they may then be returned to the bees.

J. M'GOWAN.—We are informed that Lee's sections will be in the market in the course of a fortnight. Some difficulty has been experienced in providing the requisite machinery.

PIKE.—*Enamelled Cloth.*—The sample of cloth will be found serviceable. The shiny side is placed on the tops of the frames.

Received from Mr. T. B. Blow, of Welwyn, Herts, his Illustrated Catalogue of Bee-keepers' Appliances, 64 pages. We note that it has a small piece of scarlet cord, which makes it convenient for hanging up in the bee-keeper's room. It contains a number of new illustrations.

Received from Messrs. W. P. Meadows, of Syston, near Leicester, and J. H. Howard, of Holme, near Peterborough, their joint catalogue of Bee-hives and other Appliances, 48 pages. This catalogue embraces every article both of wood and of metal that is of service in the apiary.

BEE-KEEPERS' GUIDE BOOK. Containing Management of Bees in Modern Moveable Comb Hives, and the Use of the Extractor. By THOS. WM. COWAN, F.G.S., F.R.M.S., &c. With numerous Illustrations. Fcap. 3vo., price 1s. 6d.; or in cloth gilt, 2s. 6d. Postage 2d. To be had of HOULSTON & SONS, Paternoster Square, all Hive dealers, Secretaries to Bee-keepers' Associations, and of J. HUCKLE, *British Bee Journal* Office, Kings Langley, Herts.

AMERICAN SECTIONS BY THE MILLION

LARGEST BEE-HIVE FACTORY IN THE WORLD

WITH FLOOR-ROOM SPACE OF OVER AN ACRE.

The cent, taken from a photograph, represents our bee-hive factory where we annually turn out about 20,000 hives and 3,000,000 sections, besides enormous quantities of bee-supplies of every description. Dealers before ordering elsewhere should correspond directly with us. We are prepared to quote better prices on sections in quantities than we have ever quoted before. We are also publishers of *Gleanings in Bee Culture*, with a circulation of 7674 subscribers. A sample copy of our journal and our 40-page price list sent on application to
A. I. ROOT, Medina, Ohio, U. S. A.

PRACTICAL WORK IN THE APIARY.

FEEDING.

There is, perhaps, no branch of work in an apiary less understood than feeding. Many think bees ought to find sufficient food for their own requirements; but they forget that we take away their honey, the very stores they have laid up for their sustenance. Besides, do we not feed our cows and other domesticated animals? Should we not be considered bad farmers if we expected our cows to give us a good supply of butter and milk without providing them with good food? It is not different with our bees. And both cows and bees, when pasturage is abundant, good, and rich, do well without our attention; but at other times we must furnish them with food, otherwise they suffer much, and the loss is to our own detriment. Langstroth says: 'Few things in practical bee-keeping are more important than the feeding of bees; yet none have been more grossly mismanaged or neglected.' This author treats the subject of feeding very fully, and, although his book was written nearly thirty years ago, the above remarks would apply with equal force at the present time.

How to feed and when to feed will depend upon the different purposes for which we have to feed. We will briefly consider the different reasons for which bees have to be fed. These are—for stimulation, for preservation, and for comb-building. The time and method of feeding, as also the description of food to be used, will vary according to the object the bee-keeper may have in view. For instance, in the spring and summer, when there is a great scarcity of pasturage and brood-raising is proceeding rapidly, bees must be fed, both for the purpose of stimulation and preservation. Stocks, which in early spring are so light as to seem to be of no value whatever, may be so stimulated into activity by regular and gentle feeding as to very shortly surpass in strength those left to themselves, and which appeared strong enough. Early feeding promotes early breeding, and strong colonies are the result. The bees may have sufficient stores in their hives, and some bee-keepers think it unnecessary to feed them at such a time; and we often hear nature appealed to, and the statement made that bees would help themselves to their stores as nature prompts them to do. This is true enough; but nature only prompts bees to take what food they actu-

ally require at such times for self-preservation only, and will not induce breeding until honey is coming in regularly. When the honey-flow is abundant, brood-rearing proceeds rapidly. Bees left to their own devices will develop themselves fast enough for their own preservation, and will be strong enough to lay up sufficient store for their own use. Is the bee-keeper, however, satisfied with this, or does he not aim at having a large surplus, which he can appropriate to his own profit? To insure this he takes advantage of the natural instinct of the bee; and without waiting until honey is coming in plentifully, in order to procure the increase of workers he will feed his bees gently and regularly, in order to have them ready to go out in large numbers when the honey-flow arrives.

In order to understand the advantages we may derive from feeding, we must bear in mind that the *queens lay eggs rapidly only when the workers are bringing in stores* regularly, and by stores we mean, not only honey, but also pollen, which they require for themselves as well as for preparing the food for the brood. We must also not forget another fact, and that is, when a colony is rapidly rearing brood, and it finds honey is scarce, the bees stop feeding and destroy the larvæ and eggs. In such a case they are thrown back in their development in a few days much more than they can regain in several weeks.

In the spring, when breeding goes on rapidly, as the brood increases so also increases the consumption of stores. Strong colonies are sometimes induced, by genial weather and abundance of blossoms which furnish honey, to consume the whole of their supplies in their endeavours to increase their numbers; and if at such times we have a few days of wet or cold weather they may be reduced to starvation. The early flowers also furnish honey to encourage development, but when this fails there is probably little honey and much maturing brood. A little judicious feeding would keep such colonies progressing, and make us independent of natural circumstances. The great secret of successful bee-keeping is in having strong colonies ready to gather surplus whenever a good honey-flow sets in. Now, it generally happens that before such a flow circumstances are not the best suited for the development of the colony to its full strength, so that the full advantage of the honey-flow is lost. Of course, the colony will develop during the flow, and be ready for the next, but the bee-keeper has irretrievably lost one source of surplus. Then, again, it often happens after the first flow there is a long spell, when the bees gather very little, and hardly enough to

sustain them; this will cause a relaxation of the breeding, and sometimes even put a stop to it altogether, so that the colony must build up again before it can lay in supplies. Gentle feeding at such times is beneficial, as it keeps the colonies up to their proper strength.

After the honey-flows are over and the honey taken away, late feeding becomes a necessity in order to preserve the bees through the winter. Then there are times when bees can be induced by feeding to employ their time profitably in building combs, which will come in useful for extracting purposes. In giving directions how to feed at different times and under different circumstances, we must bear in mind that bees require, in addition to honey, pollen and water. Another thing we must not forget, and that is, that the taste and smell of honey are likely to induce robbing; therefore, we must guard against this by giving food in such a way and at such times as to have little tendency to attract other bees. We would here strongly deprecate the plan of outdoor feeding as being both dangerous and wasteful. It induces robbing, and the bee-keeper not only feeds his own bees, but also those of his neighbours. The best method of feeding is undoubtedly inside the hive, on the top, or at the hive entrance; but this last plan should only be resorted to at night. Of course, these remarks only apply to syrup or honey feeding; it is different for pollen, which can be given outside the hive without danger.

There are two methods of feeding—gentle and continuous feeding and rapid feeding. Gentle and continuous feeding is so called from the fact that only as much food is supplied the bees as they need for daily consumption, and is stimulative in its effect, inducing a production of brood. Rapid feeding, on the other hand, is giving food in such large quantities as to enable the bees to store it in their combs for future use, and has the effect of checking the production of brood, owing to the cells in the brood-chamber being occupied with stores.

‘THE WILEY LIE.’

Under this heading our contemporary, the *American Bee Journal*, in the issue of January 25th, page 52, takes our article ‘Facts’ in the *British Bee Journal* of December 25th, page 508, to task. The greater part of the article has been quoted by the *American Bee Journal*, but we wish the remainder had also been reprinted, as from that it reads: ‘We know too well the practice of mixing glucose with honey, and the methods of detecting it, and how a London firm has been manufacturing another substance, palming it off as honey; but we feel confident that the bee fraternity, located in whatever part of the world, will, as the Cornish motto has it, “one and all” endeavour to stop such practices, prejudicial not only to the bee-industry, but injurious to the health of the community at large.’

From this it will be seen that in our midst other substances are tried to be floated on to the market as honey, and we call on bee-keepers all over the world to try and stop such practices.

Bee-masters, whether in the British Isles, Australia, Canada, or the United States, cannot by any means take offence at our article, as persons carrying out the practices referred to cannot be called bee-keepers. Glucose has, without doubt, been palmed off on the public as honey. Bee-keepers all over the world have a common cause to see to,—the production of pure honey; and whenever we hear of anything injurious to the industry, it devolves on all periodicals devoted to the subject to bring such things to the notice of their readers.

On page 98 we reprinted the reproof of the editor as

it appeared in the *American Bee Journal*, without comment on our part, and have made inquiries, and find that, so far as we can gather, all said in the article headed ‘Facts’ is true. The clergyman who supplied the information, and whose name for obvious reasons we withhold, is a well-known dignitary of the Church, whose word we cannot for a moment doubt. Whether he was a victim to a fraud we cannot say, but he further informs us:—‘The farm I was on was fifteen miles from Kansas City. I do not remember the name, but there are plenty of them in the Western States.’ Perhaps, this will give American bee-keepers a clue to the detection of those unprincipled adulterators who are doing so much harm to bee-keeping. Our article was based on the above information, and we also gave an extract from a magazine, *The Monthly Magazine of Pharmacy, Chemistry, and Medicine* for December last, part of which—‘So much like the genuine article that only experts can detect the difference’—the *American Bee Journal* considers the *British Bee Journal* to have said, but which was only a portion of the quotation from the *Monthly Magazine*.

The *American Bee Journal* says, ‘Its [the article’s] only possible excuse is the infamous “scientific pleasantry,” written, “for the fun of the thing,” by Professor Wiley, who is so unprincipled as to let it “fly” on electric wires “to the uttermost parts of the earth” without a word of regret or denial.’

Naturally, subjects coming from a *Professor* would be considered facts, and we hope that our informant was deceived, although we must point out that there is a difference between ‘artificial combs’ as described by Professor Wiley, and which no bee-keeper for one moment would believe it possible to produce, and the productions of combs by feeding, which is not at all impossible, as every bee-keeper will know. As it has called forth attention in America, our object in stating what we did has been gained, and we hope that apiarians will not have such dangers to contend with.

Selected Query.

[3].—*Will drones reared in one colony be admitted into another in the same apiary?*

Nearly always, until the general slaughter commences. While the massacre is going on drones shift their quarters constantly.—SAM. SIMMINS.

Yes; without a shadow of a doubt in queenless hives.—C. N. ABBOTT.

Yes, if the colony be queenless; otherwise, no, in my experience.—GEORGE RAYNOR.

Drones, from their perfect vision, are well certain of their own home. We have seen them alight at other hives on the return of a virgin queen, but they are not always accepted. When no stores are coming in, and the drones are driven forth by their own bees, the case is different; any queenless colony will then accept the wanderers if they seek admission.—JOHN H. HOWARD, *Holme, Peterborough.*

I think they will, especially in hives that are queenless.—JOHN WALTON.

I should presume not.—J. GARRATT.

When the honey-flow is abundant, drones appear to be unnoticed by the bees of another colony when they by accident or design (?) enter the wrong hive. I have noticed when making swarms, &c., that some of the drones have entered adjoining hives, and have not been unkindly treated. I have also put strange drones into hives, giving them admission under the back dummy, and these have been unmolested, but this amicable-ness on the part of the workers towards strange drones is variable.—S. J. BALDWIN.

Queenless colonies will occasionally allow drones from other hives to enter, especially late in the season when drones are turned out of hives that have fertile queens.—M. L. GAYTON, *Much Hadham*

At times, not always.—JOHN M. HOOKER.

Yes; and at the time when they are being destroyed a queenless stock will form a refuge for all the drones in the neighbourhood.—J. A. ABBOTT.

[4.]—*Is it advisable to allow a queen to become more than two years old before replacing her with a young queen?*

Not as a rule.—SAM. SIMMINS.

Yes, if sufficiently productive, otherwise kill her at any age.—C. N. ABBOTT.

Yes, if she continue prolific, but, as a rule, queens decline in fecundity on reaching their third year, although there are numerous exceptions. Queens of good and prolific strain, bred in full colonies under the natural swarming impulse, enjoy greater longevity and retain fecundity, in my experience, longer than those raised on any other system. This remark applies to all races, but more especially is it true of the old English black bee.—GEORGE RAYNOR.

No; for no bees with us have given such results as colonies headed with a queen in her second year. We have, so far as time would permit, reared queens directly after the honey-flow each year, which here is all over by the second week in July. Our young queens are laying during August in time, with judicious rapid feeding, to enable us to get quickly into quarters well prepared for winter and the following season's work. Therefore we recommend, when working by storifying for comb or extracted honey, to have none but queens in their second year heading a colony.—JOHN H. HOWARD, *Holme, Peterborough*.

I do not think it is advisable, though I sometimes keep some of my queens three or four years, except the bees replace them themselves.—JOHN WALTON.

Yes; for the same reason that I would permit a good laying hen to live longer than ordinary.—J. GARRATT.

Although it is very generally agreed that a queen should not be depended upon after the second or third year, I have known queens to do remarkably well, even in the fourth year of their age. This is, however, I think, exceptional, as many queens in a well-conducted apiary, are thoroughly and completely exhausted by the end of their second year, so that the age of a queen should not alone be considered. It certainly will not pay to allow a queen to go on to the natural period of decay, or she may die at a time when she cannot be replaced, and the loss of the colony would follow. A queen is, of course, able to lay a certain number of eggs during her lifetime, but the bee-keeper may, by his management, determine how long it shall take to exhaust her powers, and therefore the amount of work accomplished by her, together with the possession of certain desirable qualities, both in the queen and her progeny, must guide one as to the advisability or otherwise of allowing a queen to become more than two years old before replacing her with a young one.—S. J. BALDWIN.

Not as a rule. A queen is considered of most value in her second year, and, generally speaking, her powers begin to decline after that time, but I have had some most valuable queens three years old.—M. L. GAYTON, *Much Hadham*.

Yes, if she shows no signs of failing powers. I would never supersede a queen, no matter how old, all the time she keeps the colony strong in bees and fills the frames with brood. Dealers in queens and queen-breeders will no doubt differ from me. 'Prolificess, not age, should be the test.' The bees will make fewer mistakes

in this delicate matter of 'replacing' than we are likely to do. On referring to my letter in the *B.B.J.*, [300], June 24th, 1886, you will see that Professor Cook, Dadant, Demaree, Doolittle, Heddon, Hutchinson, Pond, and Boardman, hold these views in the *American Bee Journal* in answer to a precisely similar question.—JOHN M. HOOKER.

I would not destroy her till three years old, unless she showed signs of weakness.—J. A. ABBOTT.

A CHAT ABOUT NAILS.

The 'X-tractor' has told you about his attempt to 'smoke me out.' On the occasion of his visit we talked of 'nature,' as you have heard; we also talked of 'nail-makers' and *nails*. Poor Elihu Burritt and his fond dream of a universal brotherhood! who reads his book or heeds his pleadings for poor downtrodden humanity? But I remember how it fascinated me when it was first published.

I am of all men most unfortunate in the way of ink-slinging. In a moment of wild impulse I once wrote:—'Birmingham is the place to sell hardware.' A humorous old friend replied:—'Dear "A. E.,"—You hit the right nail on the head when you wrote that.' Being a dull hand at punning the incident had passed from my memory until recalled after the visit of the 'X' in a way that I now wish to explain.

I have often told you I delight in making my own appliances, consequently I use nails. When first I took to making section crates I used what are known as French wire nails (shown at Fig. 1). These are excel-

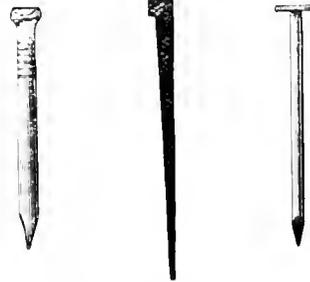

Fig. 1.

Fig. 2.

Fig. 3.

lent for driving, as they do not split the wood, and require no bradawl to prepare the way for them; but I found they have the serious fault of not holding the wood together firmly. My next resource was to return back to the old 'cut-brads,' shown at Fig. 2, but how slow was the process, and what a trial of patience! First to make a hole with an awl, then drive the nail, and finish off by driving it well down into the wood by the aid of a 'brad-punch.' But the work holds together firmly, as a reward for one's pains and patience; so I plodded on, patiently considering strength of work a sufficient reward for the tediousness of the operation. Presently I knocked a packing-case to pieces, and found it was held together by nails that were most provokingly obstinate (Fig. 3). They were oval in form, with a peculiar head, and remarkably tough, and, moreover, can be driven home without the aid of a bradawl, and will not split the wood. How I hunted the four corners of the enterprising town that comprises 'civilisation' to me! But 'oval wire brads' were unknown within its borders. In London, of course, I soon found them; I also found an enterprising appliance-manufacturer used them, but he did not name them as 'oval' as distinct from 'round' in his catalogue.

At last, as I have told you, came the 'X-tractor' and the talk about 'nature and nailmakers,' and in answer to my inquiry he told me oval wire nails were made in England, and were not imported from 'over the pond.' Here the matter, as far as we were concerned, seemed to

come to an end, but not so: a fortnight later I received a parcel by post that looked rather mysterious. I removed the twine and brown paper. Inside I discovered a stout bag labelled most ostentatiously thus:—
SILVER £10.

FROM
THE CHECKEM & CASHEM
BANKING COMPANY, LD.

Zounds! here is a joke!

'I see their knavery, this is to make an ass of me;
To catch me if they can.'

But no, it was a bag of 'oval wire brads' with 'X-tractor's' compliments. But I did not miss the chance. Not ten minutes previous Mrs. 'A. E.' had asked for the 'needful' to go shopping. So I neatly closed the bag, and turned it over to her. 'Ugh, I might have known you would not become so suddenly generous.'

Well, gentle readers, if you ever wish to use nails with comfort and expedition, I can recommend you these oval wire brads. Being slender there are a large number to a pound, and were they double the price, on the score of strength of work combined with pleasure in their use, they would be cheap.—AMATEUR EXPERT.*

LEICESTERSHIRE BEE-KEEPERS' ASSOCIATION.

The Committee met on the 25th ult., and made arrangements for some lectures and a conversation. At the latter the Mayor of Leicester will preside.

Foreign.

SOUTH AMERICA.

A BEE HUNTER IN TROUBLE.

Being naturally very fond of bees, and having had my curiosity excited by what the natives told me regarding their indigenous races I made up my mind to bring together a collection of those to be found in Brazil. With this object in view, I let several of the people living near the forests know that I would repay them for their trouble if they would send me word whenever they came across a swarm in their neighbourhood.

I was not long in reaping the fruit of the offer I made them, for I was soon put in the way of making the acquaintance of these famous insects and of their abodes which in the generality of instances are the hollows of forest trees.

Early one morning while following my guide across woods through paths only partially trodden, I was so busy thinking of the approaching pleasure of adding other specimens of races to my collection, that I hardly paid any attention to what my guide was trying to explain of the sundry dodges they had to adopt in order to find their way through those parts of the country. I noticed, however, that from time to time he cut down branches of trees so that when returning he might recognise the ground we had gone over.

Having at last arrived before the hollow tree, and not wishing to let anyone interfere with my operation, I set to work, sawing and cutting the tree, while my companion left me in order to go about foraging for something to eat in the shape of game and so forth.

Having got my bees and comb safely secured in large jars with which I was provided, and seeing nothing of my guide I took up my load and made, as I thought, my

way back. I was not long, however, in discovering that I had undertaken a more difficult task than I had anticipated, for in about ten minutes all traces of the path I was following had vanished, nor could I see any of the many branches which my guide had cut. My best course would no doubt have been that of returning the same way I had come, but somehow I thought I should do it quicker by taking a short cut. Unfortunately, whenever I thought I had a good path to guide me it always disappeared, and I could see nothing but cacti and other plants pointing thousands of their prickles towards me. There were nothing but obstacles in the way; sometimes it would be a cluster of shrubs into which it would have been dangerous to enter or else an impassable thickness of trees. One thing was, however, evident, viz., that the more I travelled the farther I was getting from my starting-point.

At the end of an hour or so of running about loaded with my bees, saw, axe, and other *impedimenta*, I began to feel not only fatigued, but also experienced great inconvenience through the strong smells which certain trees threw off during the hot part of the day. In fact I began to feel very anxious about the result of my excursion, and began to think seriously of the consequences which might follow from such a position as I was in. I tried not to think of these dangers, but rather how best I could overcome the difficulties with which I considered myself surrounded, when all at once I found myself in front of—what would you imagine? The very tree I had cut down an hour or so before in order to extract from it my bees. Never was I more surprised, and it was with difficulty that I could believe my eyes. How is this? said I to myself. I have been travelling fast for the last hour, and now I find myself where I started from. Again I began to reflect on the situation I was in. The prospect of having to wait, perhaps indefinitely, for my guide in the midst of such surroundings was certainly anything but encouraging. However, when I was on the point of making a fresh start this time in another direction, I had the agreeable surprise at hearing at a distance my guide's voice. You can easily imagine how pleased I was to see once more my companion, particularly in view of the fact that a few minutes longer and I would have set out in some other wrong direction. Be this as it may, we were not long in finding ourselves out of the wood, and where we found that the breakfast the guide had prepared was ready for us.

As for the bees, every possible care was taken of them, and before the day was over I had them safely placed in a glass case in which they appeared to feel quite at home, and I trust that they will repay me for all the trouble I have taken of them by imparting to me some of their secrets.—E. BLONDET, Barra (Brazil), December 28 1887. (*Apiculteur of Paris.*)

ANCIENT BEE-KEEPERS.—The following reference to Westbury, Wiltshire, is translated from *Domesday Book* (1083):—'The king holds Westberie; Queen Editha held it, and it paid geld for forty hides. The land is forty-seven carucates. In demesne are seventeen hides, and there are seven carucates, twenty-eight serfs, and sixteen coliberts. There are thirty-eight villaus, twenty-three borderers, and nine bee-keepers.'

HOGG'S HONEY COMPANY.—I note in answer to correspondence in *Bee Journal* of the 16th inst., that allusion is made to the above Company, the question arising as to what has become of them. A short time since (three weeks) I saw the following paragraph in a trade journal, 'A curiosity in bankruptcy is a *first* and *final* dividend of '65 of a penny, which has just been announced by circular to the creditors of Hogg's Honey Company. Final dividends of a fractional amount have been frequently known, but a first and final amount equal to only 2*l.* 14*s.* 2*d.* in 1000*l.* is decidedly wonderful.' The above speaks for itself.—W. B. WEBSTER.

* Since the above was written Messrs. Abbott have advertised the nails alluded to in the *Journal*. You will kindly understand this is not 'grinding an axe' for our versatile friend; he does not sell nails, so kindly do not apply, but it was refreshing to me to learn that such a good thing did not come from 'over the pond.'—A. E.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal," c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, Kings Langley, Herts (see 2nd page of Advertisements).

* In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

ADULTERATED HONEY.

[1517.] In the Report of the New York Bee-keepers' Convention, held at Utica, 'An extract from the *American Grocer* was read, in which it was stated that in New Jersey forty-two samples of bottled honey were analysed, and it was ascertained that out of thirty-one samples put up by packing houses, only six were pure. The samples purchased of farmers, however, were all pure.

'Mr. Root said, "I fear there is a mistake about some of those samples examined. The State Chemist of Ohio says that it is a difficult matter to tell where honey is adulterated. Bees gather every variety of honey."

'Mr. Aspinwall said, "With the polariscope you can detect the presence of five per cent of glucose. A point in the article just read is, that the honey procured of dealers was nearly all found to be adulterated, while that purchased of bee-keepers was all pure. There is a law against adulterating honey, and can we not induce the State chemist to analyse honey sold on the market?"

It is only right that it should be well known by all in England that American dealers continue to put up adulterated honey for market, and that the only way to obtain pure honey is by importing direct from the producer, and save the profits of the dealers and middle-men, or to purchase such only, whether English or not, that bears a warranty of purity on the label. I am afraid Mr. Hoge's experiences have not deterred others.—JOHN M. HOOKER, 76 Tyrwhitt Road, St. John's, S.E., March 5th.

THE NEW MONTHLY JOURNAL.

[1518.] The first number of the *British Bee-keepers' Adviser* has come to hand, and although it contains nothing that is not to be found in the weekly *B. B. J.* yet I hail it with feelings of pleasure and satisfaction. I have been wanting to see a journal that the cottager could afford to buy and keep in his own possession, so that he could con over its contents evening by evening by his own fireside, and read and re-read its pages over and over again, until he had mastered the facts that so many pages of printed matter have to speak about.

The circulation of the *B. B. J.* amongst members of County Associations was a good thing in its way, but it was, and is often, very aggravating to people of limited acquaintance with literary learning. The hackneyed expression of 'limited education' I purposely avoid, because it is erroneous. Put clerks to care for sheep, and how about their education? or take book-worms, and set them to plough land, and 'Hodge' would soon get the laugh of them; and so on all round society. That assembly of 'the first gentlemen in Europe' would fare rather badly if transported to a desert island and left to their own resources. We have all some kind of 'education,' even if we cannot distinguish a great A from a duck's track. This is digression. Two evenings after supper is not sufficient time for a cottager to master the contents of the *Journal*, especially if he has to be in bed in time to give his body sufficient rest to enable him to

be out again at 5 A.M., consequently I have always advocated a cheap journal that all could buy and keep by them. I have a letter I value greatly, written only a few days before the lamented death of Mr. Peel, wherein he expressed a hope 'to be able to arrange it very soon.' The good time has come at last, but it has been the work of others to bring it about.

Many would have wished to see the *B. B. J.* reduced to a penny per week, but that would entail a serious loss, and after due reflection I feel certain of the wisdom of the present arrangement. We sometimes complain about our *Journal* when full of reports of Associations, &c., but remembering its position as the organ of the B. B. K. A., as well as an exponent of practical and scientific bee-keeping, I fail to see where an alteration could be made that would be an improvement.

Unlike bee-keeping in other countries, in this kingdom it stands on a philanthropic and scientific, as well as a commercial basis. Hundreds of subscribers to our Association and its affiliated branches only do so on the two first of the three considerations enumerated above. While that is so the *B. B. J.* must cater for these two aspects of apiculture equally as much as for honey-getters. Having no knowledge of foreign languages, I can only speak personally of those published in the English language; and after seeing most, if not all, of the trans-Atlantic bee-papers, I am sure we may all be proud of our *Journal* as standing second to none. Across the Atlantic the complaint is that the 'honey-growers' get too much attention; with us it frequently is the reverse, but our new *Journal* will obviate this. The cottager has now an '*Adviser*' that is all 'advice.' My only fear is that he does not find it too dry reading. Cannot arrangements be made that county Secretaries may get local matter printed on one of the fly-sheets at a little cost on the model of the various parish magazines?

In a private communication to myself, Mr. Cowan, the esteemed editor and proprietor, told me of his decision to publish the *Adviser* on March 1st, adding it was his wish that the cottager should make it purely his own journal, writing his thoughts in his own language, and never fearing if the ideas were put in language not grammatical or badly spelt—the sub-editor would correct all that. But if the working bee-keepers of England, Scotland, and Ireland, did not get well served, it should be no fault of his, as he (Mr. Cowan) was prepared to make it whatever they chose (except a bear-garden of course, although he did not say so).

I have been induced to make these remarks that all may feel perfect freedom in getting as much benefit as possible from the new *Journal*; as well as in fairness to Mr. Cowan, whose only desire in this new venture is to advance bee-keeping as a healthy and profitable pursuit, which he, equally with myself, feels is calculated, especially amongst the rural population, to be a counter influence to the beer-shop. May he not be disappointed is the earnest desire of—AMATEUR EXPERT.

IN THE HUT.

'About his shelves,
A beggarly account of empty boxes.'

Romeo and Juliet.

[1519.] Empty feeders, sections, and hives on all sides, waiting for spring. This is just the time to prepare for the season which will soon be on us at a bound. Nailing frames together, painting spare hives, and fitting foundation into sections, should be no longer delayed now the evenings are long, for, in another fortnight or so, all our leisure time will be filled up by spring examinations should the thermometer give us 50° to 60° in the shade at noon.

An opportunity like this, a fortnight ago, enabled a Huttite to examine a dozen hives. In all but one there was plenty of sealed brood, and young bees were seen

emerging from their cells. (These young bees, I fear, will come badly off in the present 'blizzard.' To parody Mark Twain, I don't know exactly what a 'blizzard' is, but *that's what this storm is.*) Where the bees seemed to need it, a frame of food was removed from the back, quite to the side of the brood-nest. This was done with little or no disturbance, and, of course, without smoke. Had the warm weather continued, empty combs would have been removed, and the hives contracted by the dummy. Here, in the garden of the Hut, I am on principle leaving hives *severely alone*, until, say, the middle of March. At times I am sorely tempted to examine the contents of a thin-walled hive, which loses a hundred or so bees, dropped off the combs every time we have a cold snap. They are wintered under American cloth, shiny side down, plenty of quilts, doorway left full width and shaded from sun when snow is on the ground. Live or die, I shall not disturb them yet, for bitter experience has taught me that more harm results from early meddling than from a policy of '*laissez aller*,' in spite of the forenamed successful examination.

'Malta' (1494) fancies orange-blossom and karob-bloom make his less vicious. This is fact. If he will experiment with a piece of orange or lemon peel, or go (or, worse still, allow the children to play) near hives after eating oranges, he will be confirmed in his opinion. The stigma of orange-blossom (part of the future fruit) smells exactly like the essential flavour secreted in the cells of the ripe fruit rind. With us, the smell and taste of heather nectar make docile bees veritable demons; they positively hiss at us; and a fox-terrier puppy, brought one Sabbath morn to look at our hives on the moors, knows this now. His owner put a veil on himself, but in a few minutes a disconsolate man, with a much bee-stung dog under his arm, was seen wending his way homewards, for the dog was well-bred, and much prized withal.

The karob (carob, karoub) is only known in this country by its fruit, the locust-bean, or St. John's bread, erroneously supposed to have been, along with wild honey, the food of St. John Baptist in the wilderness. The seed of the carob (*Ceratonia Siliqua*) is said to have originated the jeweller's carat weight. I can well imagine the peculiar smell of carob, a sickly sweet, being irritating to bees.

The Coming Bee. When the specialist requires to impart the qualities of any particular variety to what we may call his stock strain, a short way to do this would be by working a virgin queen for his drones.

The following is a good linctus for cough, sore throat, &c.:—Add to the juice of a lemon the same quantity of honey. A sip occasionally. Some would prefer equal quantities of whisky, or rum, and honey; whilst others, oh, shade of Sir Wilfrid! might prefer a wine-glassful of Athol brose, the recipe for which I got near Blair Athol:—Equal parts of Scotch whisky, honey, and cream. The scarcity of cream may act as a check upon the consumption of this 'awful' guid' mixture. Speaking of consumption, I can fancy nothing better for the early (aye, and later) stages of this disease than a table-spoonful of Athol brose first thing in the morning. Ask your doctor about it, for the profession are recommending again the old-fashioned dose of rum and honey.—
X-TRACTOR.

VIRGIN QUEENS.—CONSANGUINITY.

[1520.] It has given me a considerable amount of gratification to find that the above subject, which was introduced into these columns simultaneously by the writer of 'Useful Hints' and myself, has elicited some amount of discussion from one or two readers of this *Journal*, who, as a rule, I think, hide their knowledge just a little too much under a bushel. I must also thank those bee-keepers who have written me privately, in each case falling into my views.

In my last communication, I observed that the above subject was well worthy the consideration of every apiarist, and I think there are but few advanced bee-keepers who would gainsay this assertion; but those who differ from any of the arguments or theories would do well to exercise just a little charity. No new theory can be advanced but that there are some who impute motives to the advancers. Perhaps, it would be as well if such writers would hang in a conspicuous position over their desks that salutary proverb, 'Those who in amicable controversy impute ulterior motives to their adversaries neglect the first laws of friendly discussion.' I find that a knowledge of this often tones down what otherwise might be a slight slip over the boundary which separates the kindly spirit from that of uncharitableness.

I have to thank Mr. Sharpe for his kindly remarks upon these articles, and with him agree that the introduction of virgin queens promiscuously into an apiary is not the right way of producing the 'coming bee.' But where is it? Has it come? When is it coming? The production of this *rara avis* (*apis*) is yet to be accomplished. It has puzzled for some years the queen-rearers of America, where queen-rearing has become a business of a magnitude hardly credible to the uninitiated. What are we to do in the interim before the advent of this phenomenon? The production of this will have to be left to the specialist, and while he is busily engaged in producing this prodigy, let us obtain the best results from the materials now laid before us. Let us study how to obtain the best results at a minimum of cost. Even if we increase the yield of one colony by half a pound of honey we have attained a success; we have succeeded in producing that which otherwise would have been lost to us.

In reply to Mr. Sharpe's query. It is absolutely imperative in order to be quite certain of the true fertilisation of every queen, no drones of another variety must be allowed to fly from a hive even more than two miles away; at this distance cross-fertilisation will frequently take place. The Kohler method is the only one where, in an apiary surrounded by other hives, true fertilisation can be accomplished with anything like a certainty. Of course if you have queens and drones before any one else in the neighbourhood has reared drones you will obtain the desired result.

I will now proceed to answer the letter of Mr. W. Woodley. In the first paragraph he calls attention to the qualities of the English nation as eaters of boot-uppers when pressed with hunger, of their prowess, of their endurance, and, I may add, of their indomitable perseverance and pluck! Yes, all this I own, but did it never strike Mr. Woodley that the Englishman of the present day is *not* a true descendant of the Ancient Britons but a mongrel? (Patriots, spare the simile.) To form the Englishman, Saxons, Norsemen, Normans, Romans, &c., have been called into requisition, and so have produced the Englishman with his superlative gifts. (Excuse this patriotism.) I say most emphatically that bees when crossed with some selected foreign variety (Italian) are considerably improved in their honey-gathering qualities, and I challenge any reader after examining the numbers of tabulated records of honey yields in this *Journal* to prove the contrary. I exclude all apiaries above 54° north latitude. Is Mr. Woodley's experience of crossing his bees with Ligurians so extensive that makes him so positive? Methinks I have heard him say that his bees should never be crossed with other varieties if he could help it; this occurred some few years ago, and I know he very recently expressed the same opinion.

By Mr. W.'s arguments he would wish one to assume that there is no such condition of things as consanguinity, and that if so it has no perceptible effect upon the offspring. I am glad that its effects have never been presented to

his eyesight. I can look around and see its effects in all directions where living things have been brought within its influence.

We do not live in a state of nature. Our cultivated beasts and birds do not live in a state of nature. Our plants are the same, and so are our bees. Man has moulded them to his wishes, or gathered them together in abnormal quantities, thus bringing them to a condition that they may be of greater use and service to him. I ask the questions, Would they have been of such utility to him if he had allowed them to take their own course and live in a state of nature? Would our cows, our sheep, our fowls, our bees, our trees, bushes, and plants produce what they do if they had been allowed to revel in a state of nature? How have they been improved? Has no foreign variety been imported to improve their condition? Has no foreign variety of tree or plant been imported to improve and has improved our own? How have our fine-wooled sheep been produced? How our fleet horses? How our large egg-producing fowls? How our luscious fruit? Should we be satisfied now with the crab-apple, the wild pear, the wild cherry, or will strawberry and raspberry? In improvements pleasing to the eye, How have our fancy pigeons been produced? How our useful or pretty dogs, cats, rabbits? Why, each and all of these have been produced by a judicious crossing of varieties—in every case of foreign varieties. Why, then, should not we do the same with our bees? Are we to remain *in statu quo*, and thus rest satisfied with what they *have* produced, or are we to advance as other stock-keepers have advanced before us, and endeavour to improve the present stocks? Nature is sufficiently plastic that it can be moulded into almost any form. An all-wise Providence has planted reasoning power in man's brain giving him the faculty to mould His gifts to any shape better suited to man's purposes.

In the third paragraph of Mr. Woodley's letter, he writes, 'May I ask whence Mr. Webster gets his deductions that man begins to succumb to the baleful effects of consanguinity in the second generation?' I have so asserted it, and will go further by telling him that such commences to take place directly the influence is brought to bear upon the subject, though perhaps not apparent to a superficial observer. I cannot find time to hunt up all authorities, but from Aristotle to the last work on physiology may be cited as authorities in support of this fact—*quod semper, quod ubique, quod ab omnibus, ipse dixit*.

I observed in my article that total annihilation of a colony of bees by consanguinity could not possibly take place in England; quoting my first article, 'In what county in England can we go at the present time where it can be guaranteed that there are not colonies of bees within two or three miles of any position we like to take in that county? I venture to say there is not one.' Did Mr. Woodley examine the roofs, chimneys, and walls, of all houses, cottages, barns, and other outhouses, or all hollow trees within six miles each way of the cottagers' houses where the bees were kept, in order to satisfy himself of a definite case of consanguinity? Because if he did not the example is of no use, it collapses and falls to the ground. At this time of the year such an examination for vagrant stocks would be impossible, so that it must collapse. Will he assert that no absconding swarm has come nearer than six miles of these cottages during the last three generations, which, computing at thirty years for each, would make ninety years?

By what means does a cottager not conversant with the physiology of the bee deduce his theory (it must be very much of a theory) that it is the same strain quite untainted with any other that he has possession of now? Can he follow the mating of all his queens for ninety years? Impossible. In point of fact, the average cottager knows nothing at all about it, and even the majority of enlightened bee-keepers have only become

somewhat educated upon this subject during the last decade. In my example the stocks had gradually lost their prolificness; there was no disease; no other cause discoverable; therefore, as most of us know what consanguinity will produce, I, as any reasonable person would do under a similar circumstance, laid the damage at the door of it, especially as the surrounding country favoured such an idea. If the stocks had been in a flourishing condition I should have known that successive cases of consanguinity had not taken place.

Deterioration of colonies will be the result of in-and-in breeding; therefore let us remove all chances of such taking place, bearing in mind the fact that cross-bred stock, be it animal or vegetable, is in all cases constitutionally stronger than pedigree stock where the latter, as is usually the case, has been in-bred.

'A Cottage Amateur' has never tried keeping a frame of eggs away from a stock for forty-eight hours, even in a July temperature, or he would know that it would be equivalent to keeping a hen off her eggs for forty-eight hours and then expect them to hatch.—W. B. WEBSTER.

MALAGASY HONEY-BEE.

[1521.] I do not know if it will interest any of your readers to have a few notes taken by me on the Malagasy honey-bee (*Apis unicolor*). I have now kept this bee for a short time. My first two swarms proved queenless, and as I had no means of supplying them with a new queen, or young brood, it is needless to say I lost them. They, however, taught me that fertile workers are not uncommon in this bee, and that they behave in the same way as queenless hives of *Apis communis*, building drone-comb, keeping their drones, &c. They at last were found out by the wild bees in a wood at least three miles distant, and robbed mercilessly. This shows that they wander a long way in search of food; in fact, when one looks at the country round about, so bleak and bare, only one or two small woods and absolute desert in between, one cannot help wondering from where the honey comes. Even in the forest, their natural abode, flowers are very scarce indeed; but I suppose the tropical flowers yield more honey. Some people have an idea that a tropical forest is a mass of strong-scented flowers, but one may go miles and miles without seeing even one flower; what there are, however, are most beautiful.

The bees when robbed fought well, and although daily growing weaker defended themselves to the end, fighting manfully, but of course to no purpose; the wax-moth finished off what the robbers left, and that was the end of my first two attempts. The next swarm I managed to obtain was in an earthen pot, it had to be brought a long day's journey slung on a pole between two men, but I would not have it moved till there was young brood, and so being sure of a queen, and, if she were killed in the moving, of means of replacing her. They arrived in a wretched condition, very many killed and some of the combs fallen in, but they set to work at once and soon put all right, and in a day or two I had proof of the queen's survival. This encouraged me to move a second and stronger lot, also in an earthen pot. I was not so successful, however, for the men sent to fetch it carried it upside down, and when it arrived the pot, too, was broken, the dead bees lying in masses, and the combs all fallen but two. I placed the hive and mended the holes with clay.

For the first week they did nothing, or little, but put it straight, carrying out the dead, and building new combs from the spilt honey. A week afterwards I removed the remnants of broken comb; and in another week they had built five new combs, varying from a foot to six inches in length. How the queen survived I cannot imagine. The queen must be a very prolific one, as I moved three of the largest brood-combs that were not

much injured into another weak hive, but notwithstanding they picked up their numbers very quickly. I have not yet moved them into bar-frame hives, but left them in the pots until next spring, when I shall move them. These pots are of rough earthenware of about one foot and a half in diameter, and nearly spherical, with wide lips turned back. Over the mouth they place a clay cooking-pot with holes bored in the bottom and the edges plastered with cow-dung. This is not the most common hive, which is a hollow tree trunk with a block at each end. These latter are more easily manipulated, as by blowing smoke in at one end you can drive the bees to the other and cut the combs. The natives near the forest have a fair knowledge of bees, but how much they understand of the habits of the queen I do not yet know, but as I shall soon be visiting the forest I mean to find out their way of bee-keeping. I should have done this sooner only I am some way from any bee-keeping village, and on my last visit I could not speak the language sufficiently well for the purpose. They smoke their bees when they take the combs, but only slightly, and never kill any if they can help it; and as they always take the nearest combs to each end of the trunk they seldom destroy much brood. Their time for taking the honey is in early spring, so that the bees may have sufficient in winter, and they know how to make an artificial swarm, and being great cheats they usually sell such queenless, so as not to spoil trade. Natives away from the forest know nothing about them, and are consequently taken in.

I think I mentioned in my last letter that the wild bee often builds its combs exposed. I have seen one like that, but I believe if they can find a cover they invariably prefer it. Rocks are a favourite resort. On the coast, where the natives bury their dead in wooden coffins exposed to the air, the bees often take possession. On one occasion a part of the coffin had fallen in, and the combs might easily be seen filling the ribs; and, by the way, the bees were entering the skull; I expect it was used as a 'super.' Nothing could be better than ribs for a ready-made foundation. These, of course, were the wild bees, and the natives, I have been told, do not like the honey, but sell it at a distance.

It is a curious fact that my bees refuse all the flowers in my garden. Most are European flowers, and almost all unindigenous, but one would suppose such flowers as beans, verbena, manandia, different kinds of jasmine, when growing close to the hive, would be at least once visited, but they go straight away a long way off; where I do not know, unless it is to the wood mentioned above. However, wherever it is, there is a great deal of honey, as the flow never seems to lessen. I have often counted the bees leaving the hive, and the average in the middle of the day is eighty per minute leaving, and, of course, as many entering; and, as far as I at present know, they are away from quarter of an hour to five-and-twenty minutes, but I cannot state this for certain until I have made further observations.

How the Malagasy bee would succeed in England I cannot say, but as far as I at present know it is prolific, hardy, bold, and very quiet, allowing itself to be freely handled even by strangers, and seldom stings.—C. P. Cory, *St. Paul's College, Ambaloharanana, Malagascar, January 23rd.*

GRANULATED HONEY: IS IT SUITABLE FOOD FOR BEES?

[1522.] I beg to say I keep a few stocks of bees, and am fond of them, and try to study their welfare. I am a reader about bees, and get your *Journal* for my guide to their management, and generally I find what I want in the way of advice. Now I have some comb honey which has become candied, and I had thought of feeding my bees with it, to save trouble and expense of making

food specially; but I was a bit bothered and felt sorry when I read in 'Useful Hints' on page 60 in February 2 *Journal*: 'Then comes the question, Is granulated honey suitable food for bees? The answer must be, No.' Now in *Journal* for February 23, page 109, in answer to 'D.M.' I read, 'You are not of opinion that candied or granulated honey is injurious to bees;' with these two such opposite statements before me I am more bothered than before, not knowing which to take as the safest and best. I should be glad if you will give space for this in your next issue, it might be the means of bringing out the opinions of other leading bee-keepers who may have had experience in the use of candied or granulated honey for feeding bees, and so assist those in doubt, as also yours,—
INQUIRER.

[The paragraph to which you refer in 'Useful Hints' has reference to 'cold slabs' of hard granulated honey in the outside combs of a hive, of which the bees can make no use and which we advised should be removed. On such combs, as we stated, we have often known bees to perish, from inability to assimilate such food. Moreover, we have often known bees to take dysentery from feeding on partially granulated comb honey, the liquid portion having become acid, as often is the case. When honey is extracted, and granulates a few days afterwards in the jars, from the air introduced in the process of extraction, there can be no doubt that such honey, when reduced to fluidity, is the best of food for bees. But it is very different from the granulated honey of which we spoke in the passage to which you refer. We shall be glad if our readers will give their views on this point.—
EDITOR OF 'USEFUL HINTS.']

PAINTING THE INSIDE OF HIVES.

[1523.] Last year I painted the inside of one of my hives, after reading Mr. Lett's letter. The first difference I noticed was in scraping the floor-board in the autumn; it was so dry and clean, and was so easy to scrape. I wintered the hive with an unsmelled quilt, leaving no ante-room between the front dummy and front of hive, but putting between them a frame filled with cork-dust. I did this because I feared the very thing that happened to Mr. Adcock's hives, viz., that the ante-room would become cold, as the bees could not keep it warm, and consequently, on a sudden rise of temperature the moisture would condense in it.

My hive kept perfectly dry through the winter until about the 12th ultimo, when I noticed a pool of water under the front dummies, at the east side of the entrance—i.e., at the side at which the warm air escapes from the hive. The weather was then frosty, with N.E. wind. I think it was owing to breeding going on in the hive, and the entrance having been left the full width of about eight inches, instead of being reduced in February, as advised by Mr. Simmins.

I took out the water with blotting-paper, raised the hive a little more at the back, and closed the entrance to two and a half inches. The reduced entrance has since been only slightly damp though, but there is still a little wet behind the door slides. When I reduced the entrance I put in a stick to rake out dead bees, but only found one. I also did this several times during the winter, but altogether I have not found more than six dead bees, which I attribute principally to having packed the floor-board with cork-dust. Surely bees must get chilled on a thin floor-board mounted on legs from the cold striking through it. If the hive is without legs, the ground, of course, keeps the floor-board warm.

I was very much interested in Mr. Adcock's letter, as it is strictly in accordance with what I said in writing on 'Upward Ventilation' in the *Journal* of 1856, p. 179.

I gave the bees a sugar-cake to-day over the feed-hole, and I saw no signs of damp.—T. F. L., *March 4th.*

RAILWAY RATES.

[1524.] Who amongst bee-keepers but is aware how heavily the railway rates for honey have told somewhat to the detriment of the industry? Under most circumstances honey, whether extracted or in comb, has been charged by the various railways under Class IV., as the wording of their classification was somewhat as follows: Honey in tins packed in wooden cases to be charged under Class III. Honey in jars or otherwise packed, Class IV.

I have for some time past been trying to get the rates lowered, and have explained to the different officials that extracted honey packed in strong cans should invariably come under Class III. Bee-keepers will, I doubt not, be glad to hear the result of my endeavours.

The G. W. R. last month issued a memorandum to all their stations, that, in future, honey in bottles packed in boxes and sections sent in spring crates to be charged by goods train under Class III. And further, they have under consideration the idea of allowing extracted honey in cans to come under Class II. (the rate charged for milk in cans); and I have every hope of this being acceded to ere the honey season commences. They propose to bring the subject under the notice of the goods managers of other lines in connexion with the G. W. R. But in order to be successful, I must have the assistance of others applying to their respective lines; and I feel confident, with a little perseverance, we shall obtain our wish.

Bee-keepers, who have been sending away large quantities of honey, I ask to keep the ball rolling in their various districts, and in a short time apiarians throughout the British Isles will be able to reap the same benefits.—Wm. N. GIFFIN.

REMINISCENCES OF AN UNCERTIFICATED BEE-KEEPER.

[1525.] In the year 1870 I first had my attention called to bee-keeping, and I have not forgotten that time and the many muddles I got into. My employer had a few bar-frame hives, also a few skeps, given him by his brother with other bee-furniture. Now neither he nor I understood bees, but after reading a little and asking a few questions we commenced to do our best. We thought it would be desirable to get a straw skoppist to give us a lesson on hiving. We had not to wait long before out came a swarm, which settled on the end of a high tree. Of course, as in duty bound, I rang them with door-key and shovel. When the bees settled I went for my friend to hive them for us, but he being from home I had to return without him. I just arrived in time to see the swarm take wing across a red-clover field. We followed them all the time sounding the timbrel, but I found, charm I never so wisely, that they would not settle, and they were soon lost to my sight. After this I determined to try to hive the next swarm myself. I had not long to wait before out came another lot, which settled up in a yew-tree. I donned the beedress, a thing like a sack with sleeves in a piece of gauze that covered the eyes. I now, armed in my coat of mail, hailed a man in a field close by, of whom I was told that either his mother or grandmother did keep or had kept bees. So, of course, I expected him to know something about the process. Well, he pronounced me all right. So I mounted the ladder, skep in hand. I commenced to shake the tree and the bees all over myself and the skep; and didn't I shake too, expecting every minute to be stung! But by some means I undoubtedly got the queen, for in a very short time all were safe. This lot I did not ring, as I could not see the reason of it, but a friend of mine took me to task over this. He maintained the bees had a certain music of their own, and the ringing caused certain vibrations in the air and confused

the bees and made them settle. He said he had a gong made for the purpose of ringing down his bees.

Well, the time came to take the honey, so my employer and I held a council of war as to how we were to proceed. We had read about smoke, but how it was to be applied we knew not. However, we rolled up some brown paper like a huge cigar, lighted it, and attempted to blow in the smoke between the hive and the super, after raising the super with a screw-driver; but I don't think we got a whiff into the hive. Then and there they commenced a fierce battle. One bee landed a sting on the bridge of my nose. I retired, and on looking up saw my employer in full retreat with the enemy furiously pursuing with fixed bayonets. He pulled off his coat and cut some curious capers; he was soon lost to my sight. I made my way round to the kitchen. I was told that salad-oil, vinegar and soda, also the blue-bag, were all good things. I tried the lot, but my poor face enlarged so that I looked as though I had neuralgia; and what with blue and oil I had a very conical appearance, but in the morning my appearance was that of a fat pig.

Oh, if that cook had let things alone we might have been saved a deal of trouble, as it appears that amongst the gifts of my employer's brother was a smoker, one of those you blow with your mouth, until your lips are very much swollen, and eyes the appearance of your having ophthalmia. This article the cook claimed as having some connexion with a sausage-machine. Five or six years after when lighting my new smoker she told me she had a thing like that in the kitchen, but she could never make it do its work properly, so she had to put it aside. This I examined, and found the name of 'George Neighbour & Sons' on it.

After this I read everything I could about bees, Langstroth amongst the rest. Thinking I knew something about bees more than I did previously, I volunteered to drive some for a friend. He thought very highly of my abilities. I, armed with my smoker and veil, went to work. After I had given a few whiffs to the bees I turned them up, carried them on to a gravel path (my friend the meantime standing behind a bush). After pinning on my top hive (for open driving) I commenced to drum and the bees to sting. Now I had on a very thin pair of trousers, and, stooping down, gave the bees a fine chance to sting my legs, and sting they did, but I didn't tell my friend, or he might have thought less of my abilities. After this I thought over the matter to see where I was wrong, and soon succeeded beyond my expectation.

About this time a certain County Association held its show. This nearly sent some of my neighbours off their heads. What with 2s. 6d. a lb. for honey, and one hive yielding 90 to 100 lbs., as the man in the bee tent told them, set everyone on fire, and I, too, caught the fever. Every night after a hard day's work I went to some meeting, to the loss and neglect of my own bees. One of my new pupils, seeing how much my time was occupied, thought he would try and manipulate himself. He had seen me use my pipe to smoke his bees, and he thought he could do the same. He had been a non-smoker, and his system not being charged with the narcotic, told on his brain. He had to leave the hive as it was, but before he could get far he reeled, and the ground met him before he thought of it. He again tried to walk, and managed to get into the greenhouse and lay on the stage. A friend just dropped in, and with a great deal of telling believed his story at last. (This was rather a curious predicament, for being a total abstainer his friend seemed to doubt his word.)

I now gave lessons to a clergyman. He, of course, took to it quickly, and thought he knew all about it, so he found amongst his flock an old straw-skoppist, a regular brimstoner, whom he persuaded to let him drive his bees. The night being fixed, we went. He was boiling

over with enthusiasm. The old man said he knew he could not do it. It was no use me trying to tell his reverence anything, so to work he went, and before he was ready first his veil was badly fitted, then honey all sealed over bees had not time to gorge before he turned up the hive, and the bees went at him left and right. Now see his reverence cut some capers, first under this bush, now under that; at last he made across the old man's potatoes, over the carrot-bed, through the pear-row, over the gooseberry-bushes, round the house, the old man chuckling, 'They've got ye, they've got ye! I told you he could not do it.' And I still remain—**UNCERTIFICATED.**

NOTES ON BEE-HIVES.—SECTIONS.

[1526.] I was very much surprised to read the letter to Mr. Chambers (1468), for I, too, have been experimenting with a grooved section, but not with the same object; my object being to gain time. I found it rather awkward at first to slide the foundation in while folding the section, but having made a wooden block for this purpose I found it the most expeditious way of preparing sections for the crate. The sections are always true, the foundation always firm, and the process is simplicity itself.

I have enclosed a sketch showing how the section is pushed into the grooves, and how (both hands being free) the foundation is placed in the grooves of the section.

The plan of the block (which is screwed to the bench or table) is thus—

Half full size plan.

I use $4\frac{1}{4}'' \times 4\frac{1}{4}'' \times 2''$ sections, and cut the foundation exactly $\frac{1}{8}''$ larger than the inside measurement, having a zinc template for this purpose.

I hope there are no patent rights here involved. I have no recollection of seeing anything of the kind before, but as I get many ideas from the *Journal* I venture to give this in the hope that it may lead to improvements in the system.—THOS. F. WAID.

CROSS BEARINGS FOR SKEP HIVES.

[1527.] As supports for the comb in skep hives I would suggest that smooth round rods of some strong durable timber, such as oak, teak, or ebony, might be used; one end being allowed to project a little outside the hive, the interior portion to pass through as many short uniform lengths of hollow cane or elder as will cover the entire length from one side of the hive to the other.

The object of the loose covering being to prevent any attachment by the bees, so that when any one wishes to remove the combs they would be able to withdraw the rods from the outside and take out the combs one at a time unbroken; and a skilful operator would probably be able to leave the brood-combs in the hive uninjured, and replace the rods and ferrules and return the bees to the hive.

And if no objection could be found against steel skewers on account of loose specks of rust soiling the combs during the process of removal, or on account of their injuriously affecting the temperature of the hive, they would be more convenient for the purpose than wood, the interior portion being, of course, covered with loose ferrules as stated.

This is a recent idea that I have not yet myself tried,

and simply offer it for the consideration of bee-keepers, with the hope that they will be able to work it out to their mutual advantage.—S. C. K.

ON THE FIRST FLIGHT OF BEES IN SPRING.

[From the German of ADALBERT BRAUN.]

Hark! what is so gaily humming
In the little garden there?

Hark! what is so briskly whizzing
Through the still and silent air?

Friend, it is our bees—the darlings—
Now enliven'd by the spring:

Yes, the winter is departed,
And once more they're on the wing.

Happy he, who winter's perils
All his stocks brings safely through;

Thank Him, of all good the Giver—
Faithful Watchman He, and true.

Of my own are none departed,
All as yet unhurt remain;

Though no longer rich in honey,
Yet is spring returned again!

Come, and let us view them nearer—
Enter by the garden gate;—

So—stand still and watch their doings
Light your pipe, and patient wait.

See how busily they traverse

To their pasturage and back,

That they may by toil unweari'd

Save the commonwealth from wreck.

Look, oh look, what loads of pollen,

Bring they in with heedful care.

Nurslings, fear not; for your cravings

Here's sufficient and to spare.

How they dart and how they hurtle

Through the genial balmy air!

To the mountains—to the meadows—

'Tis the scent attracts them there!

There they dexterously rille

Nectar from each flower in bloom.

Toil they for our honey harvest,

For us fill the honey-room.

Yes, our bees, our darling darlings,

We salute you all to-day;

For your life is our enjoyment—

Winter's sleep has passed away.

Grant prosperity, O Heaven!

To the new-born honey-year—

Give Thy favour—give Thy blessing—

To these objects of our care.

Now let each attentive guardian

In devoted service strive

For the proud, the matron-monarch—

Sovereign of the honey-bee.

So that we may learn by watching

Who that in the noon-tide glance;

Or in midnight's darkest moments,

Summon her to Hymen's dance.*

Ev'ry bee-hive calls for patience,

Whilst great HALLER'S lessons teach

Without patience Nature's secrets

None successfully can reach.

—T. W. WOODBURY, *Mount Radford, Exeter.* (1862.)

Echoes from the Hives.

Honey Cott, Weston, Leamington, February 27th.—Well we have had winter this last fortnight and no mistake. Drifting, blinding snow nearly every day, and very severe frosts at night; hives all had to be shaded,

* This point cannot now be considered doubtful, but it must be remembered that Herr Braun's verses were written many years ago

so as to keep the bees in as far as possible, as when there was a bit of sunshine the glare was so great as to fetch many out to their destruction. I am glad I qualified my last Echo with passing the winter 'so far.' Some of our roads had to be cut through six feet of snow for passage-ways; it is not yet over.—JOHN WALTON.

Stoke, Devonport, February 28th.—A beautiful, summer-like day, after a fortnight's frosts. Bees thoroughly enjoying it. My three stocks have each been carrying in pollen—viz., two with right-angled frames were fanning from noon until 3 p.m.; one with parallel frames (last year's artificial swarm) very active, but not fanning. Each was fed up to October 25th, and has now a first candy cake over the feed-hole. My small garden is only seven yards square, surrounded by a seven-foot wall; hives on south side of north wall.—J. F. R. A.

North Leicestershire, March 3rd.—Snow, snow, snow, and nothing else but snow; wreaths three to four feet deep in front of hives. Bees flying out during gleams of sunshine, to fall and perish in the snow. All stocks alive, and 'choke full' of bees from corner to corner. Oh, for a mild day, to give them a 'slush' of syrup.—E. B.

Limerick, February 29th.—Perhaps, your English bee-keepers might like to hear a little more of their afflicted brothers over here, though I cannot complain, as I averaged 74 lbs. per hive last season, about 10 lbs. of that being extracted, and increased my stocks to twenty-six. Early in August I divided my twelve hives, and gave a young queen to each half hive, fed up, and got them to work out frames. In the end of same month I gave each a driven swarm, and made up two hives out of five swarms, put them on stored comb, and fed up well with about 4 cwt. of sugar, which gave me late brood. All the hives were closed up at the end of September. On looking at them last week, I found all in good condition and plenty of food. Some of the straw hives I bought weighed up to 66 lbs. of maiden honey, the combs being up to three inches thick. I worked on non-swarming system, and used 1½-in. sections, unless about fifty 2-in. I could dispose freely of the former at a good price, whereas the latter did not find a ready market. The 1½-in. have such a complete appearance, especially the open-sided, when well worked out. I find they travel just as well, but require careful handling in removal from erate. I send mine about one hundred miles to market, and have no breakdown. I use spring crates, home-made. The position of the bar-frame is a subject bee-keepers seem not to agree on. Why not use a hive such as 'The Cowan,' with moveable lift for frames? Have the outside case 19 in. square inside; it leaves plenty of room for packing, and you have a cool hive in summer. The frames can be put either parallel or at right angles to the entrance, which is a great advantage over any other make. Some of my neighbours feed their bees on roast sparrows. They certainly pick the bones clean, and owners say they get a gloss. I trust I have not trespassed too much on your valuable space.—ALBA.

Belmont, Ontario, Canada, February 14th.—The weather is very steady, too much so for outdoor wintering. In most places bees have not had a fly since November, but so far they appear to be in good condition. If stores are good, and bees have one good fly in midwinter, and other conditions are properly attended to, their safety is assured, though they should not have another until April.—S. T. PETTIT.

NOTICES TO CORRESPONDENTS & INQUIRERS.

S. J. G.—1. *Moving Bees into Clean Hives* should not be done except on a mild, genial day when bees are freely on the wing; say, quite the end of March or during April. In this matter *hurry slowly*. 2. *Use of*

Excluder on top of Brood-nest.—There is a divergence of practice in this matter. The advice referred to relates to two entirely different sets of circumstances. If the queen has plenty of room below, there is little fear of her ascending, but to prevent mishap most of the Americans who produce sections largely use some kind of honey-board as a deterrent.

F. G.—1. See reply to 'S. J. G.' We would spray slightly. 2. *Combs too Wide.*—Pare them down with a sharp knife dipped in warm water. 3. *Sketch of Drone Trap.*—We have no block just at present. 4. *Working for Extracted Honey.*—Wired foundation is not essential. We have done well with ordinary foundation.

SCOTSMAN.—1. *Spring Dwindling: to prevent.*—Have no weak colonies. In the autumn weed out all weak colonies, supersede all poor queens, give each colony a good supply of wholesome food. In the spring, unite all weak colonies, contract brood-nest according to the size of the cluster, keep them packed up cosy and warm. Do not retain any old queens. Shade entrances when there is snow laying. 2. *Correct Quantity of Syrup for Stimulating.*—This varies according to the quantity of brood being raised by each colony. It is easy to commence gently and increase slowly as the brood increases, always watching that the bees do not store it. Thoughtful observation must be your guide. 3. *Getting Foundation drawn out in Spring.*—Feed gently and very regularly. After, say, 10th April, you can, if the weather is genial, insert a sheet of foundation in centre of brood-nest, which should be drawn out in twenty-four hours. Remove it, inserting another; remove that, but leave the third for bees to rear brood in. You can repeat this operation once a-week, at the same time removing any combs at the outsides of the brood-nest which may become empty. Do not let them be short of food. 4. *To get Straight Combs.*—In spring pare down any inequalities. Notice that the most even side of an old comb is next to any fresh sheet of foundation you may insert. Have your hive level. Some bee-keepers give less space to a sheet of foundation than 1½ in. until partly drawn out. We sympathise with you as to your climate, but envy you your delicious heather honey.

H. J. A.—*Wire for Cage of Extractor.*—Tinned wire is the best when it is to be got. You need not fear to use galvanised netting. Carefully wash when done with.

DUROTRIX.—*Wire for Foundation.*—Nothing will do except tinned wire: No. 30 size. Vertically, about four or five wires to a frame.

R. E. THOMAS.—1. *Foundation.*—Give full sheets of natural-based. 2. *Unsealed Honey.*—We should like to see an ounce sample. 3. *Bee House.*—If properly built, it will cost you more than a separate weather-tight roof for each hive. Have you tried very thin zinc painted with two coats of white paint on both sides over ½-in. boarding? 4. *Capacity of Hive.*—Twelve frames are very useful.

IGNORAMUS.—*Suspected Comb.*—The comb sent is free from foul brood, and may be safely used as required. 2. *Secretary of Lancashire and Cheshire B.K.A.*—Mr. W. L. McClure, The Lathams, Prescott, Lancashire.

W. M.—*Dead Bees.*—Without a critical microscopical examination we should say the bees sent died from natural causes. Perhaps they have not been able to reach sufficient food.

MALTA.—1. *Do Bees Sleep?*—We are inclined to reply to this in the affirmative. When the quilt is gently removed, they are often seen in their cells perfectly motionless, lying with their heads against the bottom of their cells and their abdomens slightly protruding. 2. *Sugar for Syrup-making.*—In feeding bees that sugar is best which is as far as possible free from any chemicals or other results, as well as from those dyes

which are freely used to make sugar bright-yellow or snow-white. The primitive uncrystallised sugars are therefore the best—Porto Rico, Barbadoes, &c.—then refined, Pearl sugar (Duncan's), small white crystals, &c. Unless, however, the Porto Rico or other soft raw sugars offered in the shops can be relied on as true to their names, and also as such sugars leave a sedimentary matter clogging up the holes of the feeder, we advise the use of the Pearl (similar to the granulated sugar so much in use in America) or refiners' small white crystals. 3. *Pollen*.—This, the fertilising dust of flowers, is moulded to the shape of a small ball, and is carried by the bees on their hind-legs to the hive. The pollen seen by you on the heads of bees has not been placed there by their voluntary action, but has adhered to them: this is frequently seen when the pollen-masses of orchids are visited by the bees. 4. *Wasps and Hornets*.—Wasps belong to communities similar to those of bees. These communities consist of a queen, males, and neuters or workers. The hornet (*Vespa crabro*) is a large kind of wasp. The community (which is supposed to contain about 200 individuals) is governed by the same laws as wasps. On the approach of winter, the males and neuters perish, some of the females alone surviving.

H. SHARP.—*Gorse*.—Bees visit this plant in numbers, but they are not very partial to it. They gather from it pollen of a light-brown or dirty-yellow colour.

ENQUIRER.—*Standard Frame*.—The standard frame of the B. B. K. A. is 14 inches long by $8\frac{1}{2}$ deep, the top bar being 17 inches long, $\frac{3}{8}$ ths of an inch thick, the bottom bar $\frac{1}{4}$ th, the side bar $\frac{1}{4}$ th, the width being $\frac{3}{8}$ ths of an inch. There is much diversity of opinion among bee-keepers respecting distance-keepers, broad-shouldered frames, &c., each different kind having its supporters. But we are of opinion that frames can be manipulated with greater ease and rapidity by not having any distance-guides at all.

R. W.—*Bacillus Minor*. *Hives, &c.*—1. Examine the hive on the first warm day, when bees are flying, and if you find a fair number of bees—say sufficient to cover three or four frames—confine them to these frames by division-boards, and feed with phenolated syrup according to Cheshire's recipe (about $\frac{1}{15}$ part phenol) from a bottle-feeder. 2. Remove from the hive all spare frames of comb, and clear them of dead larvæ. Then spray these combs with carbolic solution (two ounces of carbolic No. 5 to a pint of water). Expose them to the sun and air for a few days until dry, and keep them for enlarging the hive space as required. 3. Directions as to quantity are given on the bottles of phenol, sold as Cheshire's by all dealers. 4. Tiering-up hives having ten standard frames are large enough.

* * *Several Replies to Queries are postponed till our next.*

We should be obliged by any trouble taken by Bee-keepers in forwarding to us the names of Cottagers to whom the 'Bee-keepers' Adviser' may be sent.

Mr. J. Huckle, Secretary to the British Bee-keepers' Association, desires us to state that he has received an order for various pamphlets, with an inquiry respecting loan of diagrams. No enclosure was made with the order, nor the name of the writer given.

MARCH 15, 1888.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

'THE BEE-KEEPERS' ADVISER.'

We desire to express our thanks to all who have kindly assisted us in the distribution of the *Bee-keepers' Adviser*, and in forwarding us the names of surrounding bee-keepers. We are sure it will give all pleasure to hear that we have every reason to be satisfied with the manner in which it has been received and the measure of support which has been accorded to it.

We shall still be pleased to send copies for distribution on receipt of names and addresses from any who may be interested in the development of bee-keeping; and we shall feel grateful to all who will kindly second our endeavours to circulate our publication amongst that class which we have so earnest a desire to reach.

A CO-OPERATIVE FESTIVAL.

The National Co-operative Flower Show, which created so much interest at South Kensington last year, will assume much larger proportions this year, and will be held at the Crystal Palace on Saturday, August 18th. The prize schedule shows that upwards of 320l. have been subscribed in prizes, as against 60l. last year, and every kind of vegetable, fruit, flower, and honey in season, is included in the 200 different classes. If the entries are at all in proportion to what they were at the last Show, it will be one of the largest collections of *bona fide* cottagers' productions ever held. There is also to be an exhibition of home industries, which should be very instructive, and an exhibition of produce from co-operative workshops, both English and foreign. Cheap excursions will be arranged in connexion with almost every Co-operative Society in the kingdom, so that their members—there are now upwards of a million—will be able to attend the first holiday festival for Co-operators which has been held. The Secretary of the Show, Mr. W. Broomhall, of 1 Norfolk Street, Strand, will send particulars to all interested inquirers.

PRACTICAL WORK IN THE APIARY.

SPRING FEEDING.

In our last article we alluded to feeding generally, but we will now treat more especially of feeding in spring, what sort of food should be given, and how it is to be given.

If the bee-keeper wishes to derive full advantage in stimulating brood—rearing early in the season—he must commence to feed his bees as soon as they begin to fly freely in the spring. Before the bees are examined and the hives are overhauled we make it a rule never to give liquid food, but supply them with candy pushed in under the quilts on to the tops of the frames. The way to make candy has been described on page 57 of this year's *Journal*. But after an examination has been made, and the hives have all been overhauled, we can safely give liquid food. We, however, make the bees first use up what stores they may have in their combs, and this is done by either uncapping some of the sealed cells with a knife, or scratching them with some sort of pointed instrument, such as a fork, nail, or anything that will break the sealing and allow the honey to flow. This will stimulate the bees to activity, and in a few days some more may be uncapped, and when the bee-keeper sees the store nearly exhausted he may resort to syrup. This must not, however, be given in large quantities, about one quarter of a pint is usually sufficient, although a little more can be given if the colony is very strong and there is much brood. The chief thing is to give bees just about as much as they can consume, and not to exceed this amount, or they will store it in their cells, and this is not our object. As the colony grows and brood increases the quantity of food will likewise have to be increased. Above all things the bee-keeper must bear in mind that when feeding is once commenced it must be continued regularly without intermission, for if stopped, and the bees are not able to collect any out-of-doors, the consequences may be fatal. The bees have learned to depend upon the food, and consequently have reared large numbers of young; and the most critical time, just before the honey flow, is at hand, during which it is more important than ever that they should not run short of food.

Spring flowers will yield some pasturage, but frequently not enough to keep the bees going, so that the deficiency must be made up by the bee-keeper, although unfortunately some stop feeding just when the bees most want it. Far better not feed at all than having once commenced stop too soon. When bees commence to collect abundantly out-of-doors, they will disregard the food given to them. There is no necessity to give bees food every day, for feeders may be so arranged that they can take the food as they need it in small quantities, so that when once filled there will be enough syrup in the feeder to last several days. We prefer feeding on the top of the hive,

and if the bee-keeper does not wish to go to the expense of a special feeder he can make one himself at a trifling cost. He will require a piece of board with a hole in it, 1½ inches in diameter, and on this he can place a piece of tin pierced with a few small holes in such a way that the bees can have access to one, two, or more at the will of the bee-keeper.

A better material than tin would be vulcanite, and holes are easily made in this with a small knitting-needle made red-hot at the point. To hold the syrup an ordinary low wide mouth pickle-bottle will do, if there is nothing better available. The quilt must have a hole cut in it, and the board, as in Fig. 1, placed over it, taking care that this is level,

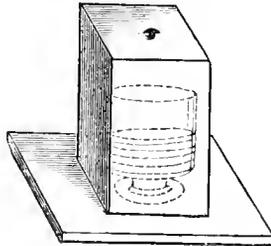

Fig. 1.

otherwise when the bottle is inverted the syrup is likely to leak out. The bottle is then filled with syrup, and on the mouth we place a piece of tin or a tin shovel, invert it, as shown in Fig. 2, place the shovel on the vulcanite stage, and with one hand draw it away, holding the bottle steady with the other hand. If carefully done, not a drop of syrup will escape. Adjust the vulcanite so that the bees have access through only one or two holes at a time, and cover the bottle. Any rough box may be made to go over the bottle, as this

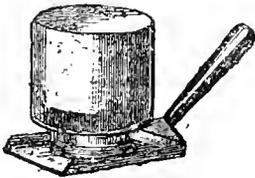

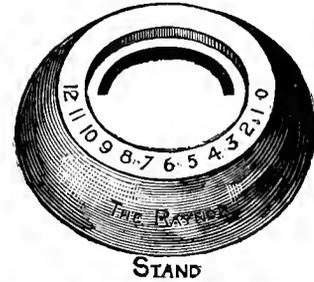

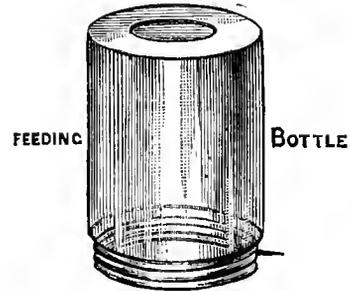

Fig. 2.

will prevent it being knocked over, and is better than flannel or other bags, which only soak up any spilled syrup, and are always messy and sticky. Bottle-feeders with regulating stages may be purchased of manufacturers at from 1s. 6d. upwards, their number is legion, but they all work upon the same principle. The illustration, Fig. 3, of one of the most convenient, the 'Raynor,' will show the principle upon which they are constructed. The bottle, which holds about a pint and a half, is fitted inside with a screw metal cap, coated inside with cork, so that when screwed on tight no leakage can by any possibility take place. The cap has a semicircular piercing of twelve small punctures, corresponding with a slit in the stand or stage, one eighth of an inch wide, and an index finger for regulating the supply, rendering the feeder available for gentle stimulation or copious feeding, when all the holes are turned on.

The principal difference from other feeders of the same type is that the feeding-stage, instead of being of the ordinary form, is dome-shaped, and the under side is lined with cloth, which renders it impervious to moisture and non-conductive of heat. The section of stand in the figure represents the interior of the dome, with a projection in the centre, to which the bees extend the cluster from the combs beneath. The stand is entirely of wood, and the bees do not come in contact with any metal. The liquid food should consist of sugar syrup. Some years ago we carried out a number of experiments, and found that the best food, and one that suited bees better than any other, was made by boiling 10 lbs. of white lump sugar in 7 pints of water for a few minutes after all the sugar has dissolved. When taken off the fire, we put in 1 oz. of vinegar, 1 oz. of salt, and 1 oz. of salicylic acid solution, as a precaution against foul brood. This solution is made by dissolving ½ oz. of salicylic acid and

½ oz. of soda borax in 1 quart of warm water. The syrup is then put into a can with a spout and is ready for use. A caution is here necessary, and that is, on no account use zinc cans or shovels for the syrup, for the acid in the syrup acts upon the zinc just as we have repeatedly pointed out does that of the acid in the honey. By far the best form is the 'toilet can' shape, like that introduced by Mr. Abbott many years ago. It has an

SECTION OF STAND.

Fig. 3.

ordinary spout and a brass nozzle with three tubes in it, which can be screwed on or taken off, and the tubes enable the bee-keeper to pour out a fine stream of syrup if he wishes to fill combs. The spout should not be covered with perforated metal, as this is constantly being stopped up by the solid impurities in the syrup, and is a constant nuisance, as we have found to our cost. A general caution is necessary in feeding: Never spill or leave any liquid sweets about, and cover the food bottle to prevent the bees getting a scent or taste of the syrup, which would invariably induce robbing. Filling the bottles is better done at night.

ONE SIDE CELL COMB FOUNDATION.

Under the heading 'A New Artificial Comb,' we gave, on page 7 of the *B. B. J.* for this year, a letter from M. Koerbs, respecting a new comb which he had discovered, and which he stated could not be used for brood-rearing, and also the remarks of M. Gravenhorst respecting it taken from the *Deutsche Illustrierte Bienenzeitung*. This announcement has, naturally enough, caused a great deal of talk, and many speculations and 'guesses' as to what this artificial comb could be have been the result. The article was inserted after some correspondence with M. Gravenhorst about it, and a promise from M. Koerbs to send us a sample comb for inspection if we would keep the secret. This we consented to do: but, at the same time, pointed out that we did not consider the means adopted for making the invention public would be one that would commend itself to British bee-keepers, and that they would regard with suspicion a promise to send out a pamphlet only when a few thousand subscribers at

1s. 6d. each were obtained. How many thousands it was not stated. We also suggested that M. Koerbs would do better by selling the invention to some foundation-maker, or take out a patent. Our suggestion has been acted upon, and now the invention is in the hands of M. Otto Schulz, of Buekow, one of the largest manufacturers of foundation on the Continent of Europe. In the meantime, the ball being set going, ingenious minds went to work, and not having any secret to keep, we, as well as others, had our own ideas of how a comb should be constructed to fulfil all the requirements set forth.

We were led to the ideas from our recollection of the behaviour of our bees with the flat-bottom wooden base foundation, introduced many years ago by Mr. Abbott, and his proposal at the meeting on the 7th of April, 1881, to use these combs with wooden bases as dummies. In that year we had several such combs, and on some of them, strangely enough, the bees built regular cells only on one side, nibbling the wax on the other side and using it for making struts or braces at right angles to the board. This we found was because the board was not sufficiently covered with wax, there being more on one side than on the other. Bearing this experiment in mind, the thought occurred to us that if bees were induced to build combs only on one side and to lengthen the cells so that the queen could not lay in them, the desired result might be attained. We therefore prepared a drawing, and asked a manufacturer to make us some foundation on calico with cells on one side only. The illustration is a reduced copy of drawing sent, and shows our plan of fixing the foundation to the side of the frame. Since then there have appeared the ideas of some of our own bee-keepers on pages 22 and 34 of *B. B. J.* However, it now appears that the same idea of having cells built on one side of foundation only and fixing this to the side of the frame instead of the centre occurred to others besides ourselves, for about a week after this our friend M. Bertrand sent us a circular describing the identical thing. A few days later, in the second number of the *Nordlingen Bienenzeitung* for this year, appeared from the pen of W. Vogel, the editor, a description of the very same thing, and it has since transpired that the invention of M. Koerbs is the same.

With the *Centralblatt* for 1st March we receive a circular from Otto Schulz, in which he states that the same idea occurred to him, and he corresponded with Koerbs about it, but as the latter asked so high a price for his invention, he could not come to terms. He, however, made application for a patent, and subsequently visited Koerbs and submitted his own ideas to him, with the result that they have come to terms, and by amalgamating their ideas the article will be manufactured and sold by the name of 'Schulz-Koerbs' foundation. The new foundation is made on glass, wood, tin, card-board, or other material, with the impression of the cells in wax on one side, the other being left smooth. Of those who wrote to us, it will be seen that only one is anywhere near the mark, namely, Mr. J. Hall, who 'guessed' that Koerbs did away with the midrib, although he did not 'guess' that the rib was placed on one side. Although we do not for one moment wish to claim any priority in the invention, and should have thought nothing about it had not our attention been directed to the matter; still, while giving M. Koerbs the credit of the invention, it shows that when a number of minds are directed upon one subject, the same idea may occur to several at the same time, as it has to Vogel, Schulz, and ourselves;

and we might even include Mr. Hall, as his idea is very near the mark.

The idea of having one-sided foundation is certainly novel, but it remains to be proved by experiment whether it will be of so great a value to us as it would be to German bee-keepers, whose hives have a brood-space so much smaller than ours.

Embedding various materials in wax for foundation is not new, and has been tried from time to time during the last twenty years or more; we ourselves used foundation on paper fifteen or sixteen years ago, and it has been repeatedly described, as well as embedding thread, silk, and other substances, both in the English and American journals, so that there is no novelty in this. We take the present opportunity of mentioning this because a correspondent on page 38 has evidently fallen into error by supposing that 'the idea of embedding other material than wire' originated with him. A search in the back volumes of the *B. B. J.* would have shown him he was mistaken.

USEFUL HINTS.

With a change of wind from north to south we have a higher temperature, and a few hours' sunshine has afforded the bees the opportunity of flight so long desired. High winds and threatening showers have forbidden manipulation even where desired; but the departure of frost and snow, with the advent of milder weather, is a decided gain.

ARTIFICIAL POLLEN is now more necessary since the late severe cold has effectually prevented a natural supply for some time to come, save, perhaps, in the Southern counties and the 'Emerald Isle.' Of this island the Venerable Bede, in his *Ecclesiastical History*—written circa 800 A.D.—tells us that: 'For wholesomeness and serenity of climate, Ireland far surpasses Britain; for the snow scarcely ever lies there above three days; no man makes hay in the summer for winter's provision, nor builds stables for his beasts of burden. The island abounds in milk and honey.' An El-dorado, truly, for members of our craft! No wonder that our Irish brethren should so far surpass their English compeers in obtaining large yields of honey.

By those who prefer the plan, pea or lentil meal—which can be procured in small packets at almost any grocers—may be presented to the bees thus: take clean dry empty frames of comb, and dredge the meal from an ordinary flour dredger into the cells, while the combs are held or placed at an angle of 45°. When the cells on both sides of the combs are nearly full, place the combs in an ordinary frame-hive and set it in a sheltered, sunny position near the hives and beside the water-trough. If a comb containing a little unsaled honey or syrup be placed amongst the pollen-combs, the bees will speedily find the spot and proceed forthwith to utilise the pollen; if placed on a stand, and sheltered by a roof raised a few inches above the hive, the latter may be considered a fixture for the spring months, the combs being replenished with meal as often as requisite. At a time like the present, when little or no natural pollen is to be obtained, an artificial supply is of great value in encouraging breeding, and in eventually raising the population of the hives to the highest point by the time of plenty arrives.

MANIPULATION, or examination of colonies, may be made in fine weather towards the end of the month if done judiciously. Bees even now are much inclined to rob their neighbours, therefore the greatest care must be exercised when opening hives. The best time is from four to six p.m. on a calm, mild evening, when there will be little danger of incitement to robbing. The carbolised cloth is preferable to smoke, causing less excitement and subduing the bees more effectually.

The quilts should be quickly stripped off, and the car-

bolised cloth as quickly spread over the frames. Manipulation should proceed from each side to centre alternately. But if the bees show themselves in force, and display a vindictive temper, do not insist on gaining a sight of the queen; but when the frames have been examined from the sides to the brood-nest, *i.e.*, as far as the cluster of bees, forbear to disturb the nest further, especially as soon as evidence of breeding is afforded. There is no surer guide to the prosperity of a colony than the dash of its individual members, severally, or simultaneously. 'Aye, buy the wicked skep,' is sound advice, but in these days of 'Bee-keeping made easy,' by the application of 'Apifuges' to the exposed portions of the human frame, and of 'Carniolanising' our colonies, such advice will be of no further use; and the exclamation of our highly esteemed Scottish brethren—'Eh, mon, bit they stang deevilitch!' will never again be heard in a Northern apiary when an attack by hybrids is delivered upon the person of an unsuspecting inquirer into the mysteries of apiculture. But we cannot forget the 'good old times,' and so, despising 'Apifuges' (save the mark!), and 'Carniolanising,' we continue to prefer 'the wicked skep' and the 'fiendish' hybrid colony domiciled in the frame-hive.

QUILTS.—Enamel cloth, glazed side downwards, may now be placed upon the frames, and covered with felt, carpet, or chaff cushions. The more warmth the better for our bees. Over all, a crown-board of wood, or preferably of straw, slightly weighted to keep all quilts firmly in place, will be an advantage.

COMBS left by defunct colonies should be thoroughly cleared of dead bees, and sprayed with carbolic acid, or salicylic acid, solution, then dried in the open air, and afterwards stored in a dry place, secure from moths, until required for further use. We keep an old extractor with powerful gearing solely for suspicious combs, and through which we pass all old combs, after well soaking them in warm water. Greater part of the dead bees and useless pollen is thus extracted with little loss of time and less trouble. But this machine is never used for normal extraction.

OLLA-PODRIDA.—*Eggs by Post.*—We have no doubt that a frame of eggs, if despatched immediately after deposition, by mail, on a warm summer's day, will answer perfectly for queen-raising, and we do not speak without experience. *Fresh Blood.*—Some thirty years ago, before the introduction of the Italian Alp bee into this country, and before the extraordinary strides in the improved methods of bee-keeping commenced and carried on chiefly through the instrumentality of the B. B. K. A., and spread to every corner of the land, we may well suppose that remote districts existed in which in-and-in breeding of bees prevailed to a great extent. But that the case cited by Mr. Woodley in his letter (1486) as a case of perfect isolation—'seven miles from everywhere'—where bees had existed for a century without any infusion of fresh blood, is 'proven,' we cannot for a moment grant. And from his second case, cited in his letter (1498) of sixty years' isolation, we must withhold our *imprimatur*. In Mr. Woodley's argument, the instinctive preference of queens to mate with drones of fresh blood, or with those of new varieties, is kept entirely out of sight, as also is the chance of the existence of colonies *fero naturâ*, domiciled in hollow trees, roofs, or walls of buildings, &c. This propensity of queens to mate with drones of fresh blood has been repeatedly referred to for years past in this and other many Journals. In the *B. B. J.* (vol. v. p. 11), 'Renfrewshire Bee-keeper' writes on this point and on in-and-in breeding thus:—'In the first volume of the *Journal of Horticulture* I referred to cases of parties keeping bees in good localities, far isolated from others, doing well at first, and gradually and unaccountably dwindling away until they became extinct. A fresh stock procured again flourish remarkably, and in the course of a few years again dwindle away; and always point out to stock-owning and

poultry-keeping friends how nature guards against the evils attendant on breeding from near affinities in the honey-bee. Did the young queen mate *within* the hive, she must inevitably pair with full brothers; did she indulge in but a short flight over her own apiary, probably with cousins nearer or more distantly removed. But, to avoid all this, she is impelled to a far flight through ether for that indispensable change of blood. Confirmatory of all this—with a well-stocked apiary of strong colonies, with pure-bred Italian queens by the mother's side, and, consequently, clouds of equally pure drones—through all these years I only *once* managed to secure pure impregnation, and that was in the case of a queen hatched early in spring—presumably, fertilised by Italian drones, the progeny of a drone-breeding queen—long before any black drones appeared in our district. Although the agile Italian princesses seem to outstrip in flight their lazier drones, and seek alliance with the dark sons of the land, the Italian is equally the favoured swain with the native brunettes. In a radius of from one to close on five miles from my apiary, crosses from the reversed parentage abound, and the humble cottager points with honest pride to his "striped bees," and the value of such crosses on that side are so much appreciated for prolificness and industry that in their disposal the extent and distinctness of the banding are carefully appraised. I am decidedly of opinion that even the poorest cottager would be handsomely repaid for purchasing an Italian queen, and placing her daughters at the head of every stock in his apiary.' So superior to the old black race had this experienced Scotch apiarist proved the Italian black cross to be both in fecundity and honey-collecting powers. And his experience is *exactly* our own. Every word he has uttered we can fully endorse. Nearly twenty years ago we were the first to introduce the Italian bee into our own neighbourhood, and in a few years afterwards there were few colonies within several miles of our apiary in which the 'yellow stripe' was not present; while in our own apiary, except by practising the Kohler method, it was impossible to obtain pure fertilisation. Surely, then, if nature has implanted this instinct in the queen and drone bees, we are going contrary to nature in arguing, as Mr. Woodley does, that the same rule which applies in the cases of cattle, sheep, horses, birds, and all other creatures, does not apply in that of insects, notably in that of our bees. All experienced apiarists—so far as we know—hold the same views on this subject. Mr. C. N. Abbott, if we rightly remember, has stated somewhere in the earlier volumes of the *Journal*, that nine out of ten of his young Italian queens persisted in mating with black drones. Why this longing for change if in-and-in breeding succeeds so admirably as Mr. Woodley supposes?

INSIDE PAINT AND ENAMEL CLOTH gave precisely the results we should have expected when applied under the circumstances described by Mr. Adcock in his letter (1504). Had his hives been on the right-angled system, and full ventilation below allowed, with a forward pitch, he would have found neither internal dampness nor dead bees to any extent; at least, this is our experience. It is very important that hives should have a southern aspect, and that the bees should be able to cluster on the front side.

ASSOCIATIONS.

BERKSHIRE BEE-KEEPERS' ASSOCIATION.

In your issue of February 9th a letter appears (1472) from Mr. W. B. Webster, respecting the publication of a monthly paper by our Association as its own organ. The letter contains an account of the action of the Association, which we cannot (in the interests of the Association) allow to pass uncorrected. The facts of the case are, briefly, as follows:—

After consultation with various members of the Com-

mittee, a definite proposal to originate such a paper was submitted to the quarterly meeting, in the draft annual report. On the suggestion of Mr. Webster this proposal was modified to the following terms:—'Your Committee consider that the time has now arrived when they should adopt some more convenient and effective means of inter-communication among the members, and have decided at an early date to consider the advisability of publishing a monthly paper for free distribution to all members of the Association.'

At the annual meeting of the members, which was fairly attended from most parts of the county, this proposal was supported by all who spoke on the subject, except Mr. Webster, whose speech failed to elicit any response, while those in favour of the scheme were heartily endorsed. The general meeting of members having so emphatically approved of the proposal, the only matter really to be decided by the Committee was its practicability. A special meeting was called for the purpose, at which there was more than an average attendance: and it was then announced that one of the members had offered to take all financial and editorial responsibility in the matter, so that the Association would incur only a small expense beyond that incurred by the circulation of the *Bee Journal*. The question was therefore decided in the affirmative, Mr. Webster being the one dissentient voter.

With reference to the prospective character of the 'Berks Bee-keeper,' of which Mr. Webster writes at some length, we will only say that had he waited until the publication of its first (or February) number, we think he would not have written as he did, and we are confirmed in this belief by the fact that the March number contains a voluntary contribution from his pen.

It will, we think, be now seen that the action of the Committee was perfectly *bona fide*, and that by their action they were carrying out the wishes of the members as expressed at the annual meeting.

ARTHUR L. COOPER, *Honorary Secretary*,
A. D. WOODLEY, *Assistant Secretary*,
Berkshire Bee-keepers' Association.

[We are very pleased to present the 'account of the action of the Association' from the point of view of the secretaries. We think, however, the proposal of a local paper was inopportune, and scarcely necessary, as with the *Bee-keepers' Adviser* the Association could have done all they contemplated without it.—ED.]

WORCESTERSHIRE BEE-KEEPERS' ASSOCIATION.

The Annual General Meeting of the Members of this Association was held at the Guildhall, Worcester, on Saturday last, March 3.

The Rev. W. M. Kingsmill, of Tibberton Rectory, Droitwich, presided, and there were also present:—Mr. A. C. Dowdeswell (Ripple Hall), Rev. R. T. W. Brayne (Broomhall), Mrs. Swinden (Defford), Mr. C. H. Haynes (Hanley Castle), Mr. A. W. Martin, Hon. Sec. (Evesham), Mr. H. H. Griffin (Cleobury, Mortimer), Messrs. Herbert Goldingham, G. H. Latty, W. E. Williams, J. Neale (Worcester), Mr. H. H. Beakbane, Messrs. J. H. Landon and P. Glover (Stourport), Mr. A. Thorpe (Hallow), Mr. John Clearby (Offenham), Mr. and Mrs. E. T. Footman (Martley), Mr. J. W. W. Boughton (Lower Wick), Mr. J. Powell (Lulsley), and Mr. E. Davenport, Expert (Stourport).

The Hon. Sec. read the Treasurer's statement and the Report of the Committee for the past year, which were ordered to be printed and circulated amongst the members. The Report stated that the committee had not felt themselves justified in holding any annual show during the past year, owing to insufficiency of funds to defray the expenses of the same, and the bee-tent had not been

sent to any horticultural show, as the festivities connected with the Jubilee had thrown other arrangements on one side. The number of members at the close of the year is 161, many withdrawals having taken place through non-payment of subscriptions. The total receipts from members amounted to 39*l.* 19*s.*, and it is satisfactory to report that there is a balance of 14*l.* 13*s.* 7*d.* in the hands of the Treasurer. The past honey season had, on the whole, been a good one, and though short owing to the hot and dry weather the quality and quantity gathered was above the average. The circulation of the *Bee Journal* had been carried out fortnightly during the year, but it had been sent on so irregularly that the committee do not recommend its continuance, unless some plan can be devised under which members will forward it at stated times. In conclusion, the hope was expressed that members would display more energy and enthusiasm during the coming year, and use their best endeavours to promote the good objects the Association has in view.

The election of officers then took place. Earl Beauchamp was re-elected President, and the following as Vice-presidents:—The Bishop of Worcester, The Dowager Lady Hindlip, Lady Georgina Vernon, Lord Edward S. Churchill, the Hon. G. H. Allsopp, M.P., Sir Richard Temple, Bart., M.P., Sir E. A. H. Lechmere, Bart., M.P., Mr. John Corbett, M.P., and the Mayor of Worcester. The committee were re-elected, Messrs. J. H. Gunn and W. E. Williams taking the place of two retiring members. Mr. T. J. Slater was re-elected Hon. Treasurer, and Mr. A. W. Martin Hon. Sec. Messrs. A. W. Martin and C. H. Haynes were appointed representatives to the Quarterly Conferences of the B. B. K. A.

The annual ballot for hives resulted in Mr. Thomas Moseley, Bishampton, Pershore, and Mrs. E. E. Davis of Welland, Malvern Wells, being the winners.

Mr. E. Davenport (expert) read his report, of which the following is an extract:—Although in many respects he wished he could give a brighter report, yet compared with some other associations the members are more numerous, the funds in a better state, and the vitality of both members and the executive strikingly greater. The income is in excess of the expenditure, and the zeal and energy of the hon. sec. cannot be surpassed. He started on his tour of inspection on April 13, which was continued at intervals till the end of July. Inclemency of weather at times compelled him to desist. Many strong stocks perished during the cold spring weather from lack of judicious feeding. In three instances the bees had actually died in the act of clustering in the central brood-nest, the combs surrounding being empty and dry, while in the outside combs there were stores in abundance. During the season 160 members were visited, and 544 stocks inspected, viz., 384 bar-frames, 241 skeps, and nineteen nondescripts. On comparing these numbers with those given by his predecessor, Mr. C. Brown, he found that the Association was on the 'downward grade.' In 1885 there were 523 skeps examined, and 520 bar-frame hives, making a total of 1043. This difference is accounted for by the diminution in the number of members, many of whom have become apathetic and withdrawn their membership. The stocks as a rule were very healthy, there was plenty of evidences of the vigorous condition of many of the apiaries, which was shown by the large quantities of honey gathered when the weather became warmer. No case of foul brood was met with during the tour; its existence was suspected at one place, but on minute examination it proved to be a bad case of chilled brood. Several incidents of varied character were met with: in one case crates of full sections which had been left on all the winter, as the owner in attempting to remove them was stung, and, beating a hasty retreat, had not courage to renew the attempt. In another instance two stocks were actually suffocated, and several others just on the verge, for in

another day or two they would have been dead; these were in straw skeps, with barely half an inch entrance, so when they became heavy with brood, the straw was pressed down, and egress and ventilation became impossible. There are many large apiaries in the county. At Welland, near Upton-on-Severn, there is one containing fifty stocks, belonging to Mr. J. H. Gunn, another at Evesham, owned by Messrs. Bailey and Gardiner, and another at Scaford Grange, Pershore, belonging to Mr. W. F. Gibbon, with this peculiarity that the owner is not anxious about the production of honey, but keeps his bees for the fertilisation of the fruit-blossoms, and sells his swarms at the low price of 1s. each to his work-people, on condition that they are kept in the neighbourhood. Other smaller but well-conducted apiaries exist at Hanley Castle, Martley, and Defford. In conclusion, Mr. Davenport wished to acknowledge the assistance he had received from so many of the members, and especially that of the hon. sec.

On the motion of the Chairman, seconded by Mr. Haynes, it was resolved that in order to free Mr. Martin from the considerable labour entailed in the discharge of the clerical duties connected with the Association, he be authorised to pay out of its fund at his own discretion, for the performance of such labour by a competent person, and he wished it to be understood that if Mr. Martin withdrew from the hon.-secretaryship it would probably mean the collapse of the Association, for it was by his energy and enthusiasm that it had grown, and he felt sure that there was no one else who could be found to do the work that he had done in its behalf.

Mr. Martin, in returning thanks for the vote, said that his professional duties were constantly increasing, but at the same time he should not like it to be said that the Association would fall to the ground in consequence of his being compelled to resign his office, which on his part had been a labour of love. He would be glad to see a little more energy displayed by the members generally and wished that his voice could reach to the extreme limits of the county and persuade some of those bee-keepers who were foremost in their ranks when the Association was started, but who, from apathy or selfishness, had since deserted them, to come back and give him and them all practical help. He would ask them to bear in mind that one of the fundamental objects of the Association was not so much to benefit themselves as others by promoting an industry, which, in spite of even adverse conditions, or some disappointment, was, he felt, surely spreading through the county and the country at large.

A vote of thanks to the Chairman, which Mr. Kingsmill acknowledged, concluded a very successful meeting.

Foreign.

UNITED STATES.

In Memoriam.

A. G. N. TODD, F.G.S.

Mr. Arthur George Nicholson Todd, Fellow of the Royal Geographical Society, and Associate of King's College, London, England, was born at Sandymount, Dublin, Ireland, on the 25th of February, 1843. He died on February 11th, 1888, at his home, 2122 North Front Street, Philadelphia, after a short illness from typhoid pneumonia. He was buried, with masonic rites, at Mount Moriah Cemetery, Philadelphia, February 16th.

In early life Mr. Todd was engaged in the dry-goods business, afterwards representing the large firm of Pim Brothers, & Co. as the manager of their branch house in London; in 1873 he made a flying visit to the United States in their interest. He first became interested in apiculture in 1870, and from that time he pursued the study of the bee and its products with ardour, upon both

scientific and practical lines. During his travels in France, Italy, Switzerland, Germany, and Algeria, he became acquainted with most of the prominent bee-masters of those countries, especially with M. George de Layens, the famous French apiculturist and author, between whom and himself a warm friendship existed, and they were correspondents till quite lately. He commenced bee-keeping for a livelihood at Blidah, in Algeria, in 1877, and about that time he first imported comb-foundation and foundation-machines from Mr. A. I. Root, into France and Algeria. At the Paris Exhibition in 1878 he took the large diploma for bees, hives, and honey. He kept bees in Rambouillet, a small village near Paris, in 1878-9. At the Ville de Beauvais Exhibition, in 1879, he gained a gold medal, and at the Amiens Exhibition, same year, two silver medals.

Mr. Todd returned to America in 1880, and joined the Philadelphia Bee-keepers' Association in 1882, of which he was elected Vice-President in 1884, and re-elected in 1885, many of the meetings were made intensely interesting by his original papers and the active part he took in discussions. He was also a member of the New York State Bee-keepers' Association and Vice-President for Pennsylvania of the North Eastern Bee-keepers' Association. He made extensive displays of bees, hives, and honey, at the Pennsylvania State Agricultural Society's fairs in Philadelphia in 1884-5-6-7, taking eleven silver and bronze medals, and numerous cash prizes and diplomas. At the Burlington County Agricultural Fair, at Mount Holy, New Jersey, 1886, he was awarded a medal for honey manufactures. In 1886 Mr. Todd established an exhibition apiary in the Zoological Garden, Philadelphia, which has proved highly successful, thousands of visitors observing the bees at work in glass hives and the general manipulations in practical bee-keeping. This is the only exhibition apiary in a public garden in the United States. At bee-keepers' conventions and all assemblages of beemen, when the subject of honey has been discussed from a financial point of view, the cry has been, 'Create new markets and cultivate the public taste to a greater consumption of honey for domestic purposes.' It is safe to say that no one man has done more to popularise its use than Mr. Todd, and for this he should be gratefully remembered by bee people generally. If we had a few more workers of his stamp and energy we should soon see honey in daily use in most households.

LECTURE ON WASPS.—On Saturday, March 10th, a paper on 'Queen-wasps and Worker-wasps in the years 1886 and 1887' was read before the Microscopical and Natural History Society of Ealing, by Mr. George Henderson, of Ealing. The interest of the paper was much enhanced by the exhibition of wasps and hornets' nests, &c., kindly lent by Mr. J. Hiam, of Astwood Bank, Redditch. After the reading of the paper, the lantern slides of Mr. Watkins, Hereford, were exhibited. The paper and its accompaniments were much appreciated.

EXPLANATION REQUIRED.—In the close of January last the wife of a neighbouring bee-keeper was removed by death. Two days before the funeral, on a warm afternoon, the husband and a son walking in the garden were surprised to see all their four stocks of bees out *en masse*, so that the air was filled with them as if with swarming. That same afternoon only a few of one of my seven stocks came out at all, about half a mile distant. Recalling to mind an old superstition, the father bade the lad tap the hives. And as he tapped them, at once the stocks respectively returned, not one stayed out. My friend was more astonished at their disappearance than at finding them flying out. I write to ask if there is any known clue to such conduct from a natural cause. I can vouch for the veracity of my friend, who sent me word the same evening, asking an explanation.—E. C. P., *Harrow*.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal,"' c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, Kings Langley, Herts (see 2nd page of Advertisements).

**. In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.*

'OUR HONEY IMPORTS.'

The value of honey imported into the United Kingdom during the month of February, 1888, amounted to 528*l*. [From a Return furnished by the Statistical Department to Mr. Bellairs.]

A NEW HUT.

'No plot so narrow—be but Nature there—
No waste so vacant, but may well employ
Each faculty of sense.' —COLERIDGE.

[1528.] On the approach of winter we left the old hut to the earwigs, centipedes, and other creeping things. It was all right, the old spot, in the height of summer, but woodlice and all sorts of strange crawling forms abhorrent to most people are not agreeable co-inmates of such a conversational, cosy den as we desired. Therefore I set to work, with the help of a flutite, to build a new one. A few particulars may be useful should any of your readers feel inclined to go and do likewise.

A sketch was drawn to scale giving seven feet by six feet inside measure. An estimated quantity of $4\frac{1}{2} \times 1$ boards (tongued and grooved) were brought together with 3×2 wood for the framework. These latter were rabbeted together and fastened each with three strong screws. The framework was levelled by spirit-level and rested on four large stones, one at each corner. The boards were then nailed to the framework, roofed with the same kind of boards and covered with roofing felt, the projecting ends of this roof being ornamented with a stamped zinc border. A lightning-conductor-looking finial was next fixed at each end of the peak of the roof, wooden flooring laid down, and so on. The whole labour was performed on three Saturday afternoons and evenings, and a jolly time it was. Cost of timber and nails, 1*l*. 6*s*. As it stands at present the hut is painted inside and out, and is bee-proof. Shelves are fixed round the inside, and under a revolving window is a table hinged to the side of the hut in front of two long settees (moveable). At one end (outside) a bee porch and alighting-board are fixed, whilst inside is a shelf on which is placed one of Abbott's 'Special' Observation hives, so that one can sit with the hive between and the light and watch the bees at work. An Aurora paraffin lamp on a bracket near the table gives both light and heat. The floor is covered with thick kamptulicon, the table with a tapestry cover, the seats with bright-coloured rugs; a fibre mat completes the hut. In two hours we have got the temperature up from 26° to 55°, so we have at last a very comfortable meeting, smoking, and chatting-box. In summer time thirty seconds will give time enough to drop the table and carry out the seats, when extracting may be proceeded with. To make all bee-tight, an escutcheon covers the keyhole, perforated zinc the ventilators, whilst such bees as are carried inside can be set at liberty by giving the window a half turn.—X-TRACTOR.

PAINTING THE INSIDE OF HIVES.

[1529.] I can thoroughly endorse the Rev. H. W. Lett's (1514) advice to paint the inside of all hives with good oil paint. I have painted all my hives inside for thirty-five years, with the best results, as I found the wood in unpainted hives so wet in spring, that it is summer before the bees could get them perfectly dry; and in spring it is most important to have the hives thoroughly dry, to encourage breeding and health.

I have my hive-stands to slant to the front one inch in ten; the entrance is cut out of the floor-board and grooved to the back, so that all moisture immediately runs out of the hive; and I have had icicles two to three inches long from the water run out of the hive in twenty-four hours. No water ever lies on my floor-boards, which is most important in successful bee-keeping.—WILLIAM CARR, *Newton Heath Apiary, near Manchester, March 5th.*

PAINTING HIVES.

[1530.] May I say that I have made most of my hives, and have always painted the boards before putting together, those for the inside box with two coats on the air-space side; those for the outside box with two coats on both sides. Dovetails and ends were also painted. Floor-boards I generally paint on the ground side, and on the other side where the hive rests with a broad ribbon. The only hive that has been damp this winter was one which had the floor-board painted all over. I found combs of sealed honey to keep better in all the hives except the last mentioned, than in the very damp house I live in.

As to painting, it should be understood that painting as usually practised is more likely to make wood rot than not. Suppose you get a new gate. The carpenter brings it, beautifully made and fitted, and hangs it. Then he proceeds to paint. If the wood is not perfectly dry, as soon as the sun shines on the paint it will raise blisters. Then the sun and rain will loosen the joints and wet will get in, and the tenons and mortises will rot. Then the ground damp acting on the unprotected ends will rot them. If all the joints and the ends where the grain is cut across were well saturated with creosote before fitting together, the parts usually painted might be left in their natural state.

I am doubtful as to the good of painting both sides of boards, but if one side is to be left bare I certainly think it should be the inside, except the flat boards of the roof. I think that wax-cloth causes, perhaps, an excess of moisture.—W. M.

PAINTING THE INSIDE OF HIVES.

[1531.] The Rev. H. W. Lett appears to object to my advising bee-keepers not to paint the inside of their hives, and criticises in a doubting manner the description I gave (in the *B.B.J.*, No. 1504) of the condition of the hives I had so painted.

My winter dummies are about an inch and a half thick, filled with cork-dust, and have india-rubber tubing, such as is used to prevent draughts in ill-fitting doors, tacked to the sides and bottom, so there is no possibility of either heat or moisture escaping, except from the flight-hole, which varies in size from two to four inches by three-eighths of an inch. Perhaps Mr. L.'s dummies do not fit closely, so the heat escaping above draws a current of air in at the large flight-hole, and by that means gets rid of the moisture.

Concerning the hive which contained more than a pint of water, the floor-board is made so as to form a rapid feeder for condemned bees, the sides are raised all round flush with the inner walls of hive, forming a space sixteen inches by fourteen and a half by three quarters of an inch deep. Into this space a board or float half an

inch thick, and perforated with a number of holes, is fitted, upon which the bees rest while taking the syrup which is poured through a tube in the side of the hive. This board or float was removed when putting up the bees for the winter, leaving an enlarged space beneath the frames, and which I trust Mr. L. will now understand would easily hold more than a pint of water. Mr. L. has erroneously used the reasoning power of which he seems to think I am lacking. The wet standing in pools upon the floor was not due to the hives being not set level, but to the fact that they were *exactly* level, as Mr. L. can prove for himself by placing a hive with its painted floor-board perfectly level, and then gently pouring water upon it, he will find that it will hold considerably more than he at present appears to think possible, and quite sufficient for bees to float upon. His hives being tilted forward, the wet perhaps ran off unobserved by him. The wet certainly never came through the roof of the hive; had it done so, the quilts would have been wet, which was not the case. I make my own hives, and am most careful that all the parts are water-tight.

The imputation that, as a beginner, my statement as to the condition of my hives is not worthy of credence, I consider of but slight importance, for Mr. L. cannot possibly have any knowledge of the length of time I have been a bee-keeper, or of my experience in matters concerning their culture.

I confess I am puzzled by the concluding paragraph in Mr. L.'s letter (1514). If the walls are soaking with moisture (as he admits) when unpainted, what becomes of the wet when the walls are impervious to it by reason of the paint? In the winter the bees are at rest, and cannot fan it out (as I have seen them doing in the spring). It cannot surely all disappear in vapour at the flight-hole.

I still more strongly say, 'Do not paint the inside of your hives, for yesterday I found dead what was one of my strongest stocks and with young queen (on nine frames) that was in such a painted hive; plenty of honey in combs, which were in a dreadfully mouldy condition, as are all the combs that are in the other painted hives, the other thirteen stocks appearing very dry and strong. Other combs quite clean as far as perceptible from the slight examination made.

I also should be glad if others would give their experience, two winters' trial of the system being quite sufficient to satisfy me that it is better to leave the *inside* of hives unpainted.—HAROLD ADCOCK, *Middleton, Northampton.*

BEEES IN NEW ZEALAND.

[1532.] I have just received the following account from my brother, an old member of the Worcester B. K. A., who is settled in Waimata Valley, Gisborne, N.Z., and think it may prove interesting to some of the readers of the *B. B. J.* :—

'I have not brought my bees up to where I am now living, but left them down in the flat country, but when I am quite settled I shall do so. There are plenty of wild hives about. I took 12 lbs. of honey out of a tree the other day from a swarm that had only been there about ten days, and did not hurt the bees at all, and did not get stung. They were in the hollow at the bottom of a large tree, about seven feet in diameter, and I managed to creep into the hole with a piece of lighted corduroy and smoke them a little, then cut out the honey and put it in a bucket. I intend to fell the tree, as there are two more colonies of bees in it, and I shall transfer the bees into two hives. The bush is full of bees, which seem just like ordinary "Britishers." I have not seen any "natives" except mason bees, who plaster up everything, from sun-barrels to mackintoshes; they catch spiders and stupefy them, and then seal them up

for the grubs to eat. There was a row of cells in an old coat-sleeve in the wharre here, and I counted seventy odd spiders in it and none of them dead. The spiders here are most wonderful; there are some flat silvery ones that never spin webs, but pounce on the flies, and it is great fun to watch them as they walk backwards and forwards and sideways; you can almost hear them swear when they miss a fly. I am glad your bees have done well; you seem to have had a very good season.'—A. H. MARTIN, *Hon. Secretary, Worcester B. K. A. Eversham.*

CONSANGUINITY. (1454.)

[1533.] I cannot let the opportunity go by of saying a word or two on this subject, more especially as it seems to me the object of Mr. Webster's article is likely to delude bee-keepers into the belief that our native bees are degenerating. This theory, which has not a shadow of foundation in fact, is so often put forth by writers in the *Journal* that one suspects there must be some other object than that ostensibly stated to warrant its so oft repetition; nor is the reason far to seek—but I will not go into that now, but will endeavour to show that in-and-in breeding is not accompanied by such disastrous results as stated, and that bee-keepers need not be alarmed at any such bogey as that; because it is impossible, by reason of their almost universal distribution, for our native bees to be affected thereby, except in a very few instances in the most isolated and remote situations.

Now what are the facts regarding consanguinity, and where indeed would have been our breeds of horses, of cattle, of sheep, of dogs, of fowls, of pigeons, &c., had there been no in-and-in breeding for generations? They would never have had an existence. Did not Mr. Bates produce his famous shorthorns by breeding them in and in for generations? and were not the Bakewell longhorns produced in the same way? and so on throughout the whole chapter with our breeds of dogs, fowls, ducks, &c. But it is amongst pigeons where the results have been so marvellous, since it is generally conceded by naturalists that all our domestic varieties, or breeds, be they Pouters, Fantails, Tumblers, or what, are all descended from the wild Rockdove of our coasts (*Columba livia*). What in-and-in breeding all this represents! And what grand results have been achieved by man's selection amongst all our domesticated animals—all such, at least, whose reproduction is under his direct influence, for where this is not the case no modification of structure has taken place. Cats, for instance, though they are said to be domesticated, being nocturnal animals, their amatory gatherings are outside man's influence; indeed, so far as their mating is concerned, they may be said to be still *fero natura*, and this circumstance is so exactly analogous to the case of our hived bees that any fact or argument in the one case may be taken as illustrative of the other; what lesson then have cats to teach us? This, that while all other domesticated animals have yielded (more or less in accordance with their plasticity) to man's influence, and have given us almost endless varieties, cats have retained their original character, and have not produced a single variety or breed—which they most assuredly would have done had their mating been directly under man's control. In like manner our hive bees, whose mating is also not controlled by man, retain their normal character throughout the whole of our island; and notwithstanding all the care, and skill, and energy, bestowed upon them for centuries, not a single well-marked variety is to be found.

I need scarcely point out how significant these facts are as bearing upon the subject under discussion, nor how unlikely it is, under the circumstances, that our native bees are degenerating through consanguinity. Where, within the whole realm of zoology, is there to

be found a single species in a naturally wild state, be it vertebrate or invertebrate, suffering from too close interbreeding? I can answer the question myself—there is not one. It may therefore be taken for granted that whenever an animal has sufficient freedom to mate naturally, there is no fear of its degenerating from too close interbreeding; least likely is it that bees, which are known to travel long distances at mating time, and it is stated on good authority that drones have been found in hives eight miles from where they were bred, will ever be likely to need the introduction of any foreign blood. Where is there a district so isolated that the bees are not within the reach of fresh blood either from vagrant colonies or from other hives? The answer to this question has been eagerly looked for by queen-raisers, for I believe that none of them have yet found such a place where they could keep their foreign bees pure.

If, then, what I have stated are facts, and I challenge contradiction, it follows that our native bees, being the survival of the fittest, *i.e.* naturally selected, through long centuries of climatic influence, are not likely to be benefited by any cross of foreign blood, more especially if such blood be from a country whose climate differs much from our own. Mind, I am not against a cross if such can be got from a bee in all points *better* than ours, but those who would deteriorate our native bees by crossing them with any degenerate race the foreigners choose to send us I regard as enemies to bee-keepers and bee-keeping. Some, whose ignorance of climatology is truly appalling, have advocated the introduction of bees even from tropical countries. To all such I say, Go to our greenhouses and our hothouses, and see if you cannot learn a lesson there.—F. BOYES, *Beverley*.

CONSANGUINITY.

[1534.] First allow me to thank those who have privately commended my views on above subject in a previous letter, including, I am proud to say, some of the first bee-keepers in England to-day. Secondly, that I have no wish to engage in a wordy warfare with such a knight-errant of the quill as Mr. Webster, feeling sure the pages of our *Journal* should not be crowded with verbiage, interesting only to the parties immediately concerned in the quibble, therefore I shall not follow his letter (1520) *seriatim*. Regarding proverbs, I would also commend to his memory that sensible old proverb which says, 'An ounce of practice is worth a pound of theory,' as also an excerpt from Montaigne's *Essays*, 'I would have every one write what he knows, and as much as knows, and no more.'

Notwithstanding the assurance in which Mr. Webster wrote his previous article, he is now doubtful of success in unearthing or discovering that *rara avis*, the accomplishment of the task he will leave to future generations of bee-keepers, though he went so far as to say that the honey-producing qualities were enhanced in a first cross; one would be led by that to think that the 'coming bee' was at least within measurable distance, that some, with the faculty of hearing inordinately developed, may possibly catch the hum of its wings; but no, the longing hopes are doomed to be blighted, or, at any rate, deferred indefinitely, and we are told to make the best of the bee we now have. Good advice, friend! and we will endeavour to do in the future as we have in the past, tot up a decent little hump of their produce for our next annual show, hoping to have the pleasure (?) of dividing honours with the produce of the Binfield apiary.

It is refreshing among so much theorising to come across a fact. Mr. Webster says emphatically, that a cross between English and Italian bees considerably improves their honey-gathering qualities. Is that where the extra half pound of honey per colony comes in? In lieu, I suppose, for the *7s. 6d.* queen. And in support of his emphatic assertion, he appeals, not to practical ex-

perience, but to the tabulated accounts in *B. B. J.* Has it never occurred to Mr. W. that a new strain of bees in an apiary would of necessity receive far greater attention than the colonies there before? And this would account in a great measure for any extra ingathering of honey by that carefully attended colony.

I have never hinted in the *B. B. J.* that I know, by experience, anything about foreign races of bees, except the painful one (to some) of feeling their stings; and if my memory serves me right, Mr. W. has not had a very long experience in the matter, neither on an extensive scale. Mr. Webster mentions among a host of things, 'large eggs.' We in West Berks fail to get them larger than they were a quarter of a century ago, and, unfortunately, only two-thirds of the number for the same sum; but perhaps it takes *oons* to increase the size of eggs, and our friend is prospecting. Now, does Mr. Webster seriously contend that the Blenheim orange-apple was produced from a crab by the ingenuity of man? That is somewhat on a par with the evolution theory and the jelly-fish—it requires a large faith. Then, as to fancy pigeons, no doubt, each breed has some distinct characteristics of its own, and by crossing the breed may produce a prodigy in shape and colour. But, after all the admixture, the wild pigeon of the forest, left to the instincts of nature, will outweigh it in the scale. And I question if our horses are fleetier now than they were over a century ago, when Matchem and Trajan ran at Newmarket.

Mr. Webster, by his reasoning in pars. 4 and 9, shows the preposterousness of his theory of dire effects, in fact, cuts the ground from under his own feet in asking if I examined every hollow tree, hovel, barn, and cottage, during the three generations quoted in my first example, to be sure that no colony of bees existed within six miles of the apiary. Six miles, friend W.? Where was the old lady's declining apiary in the valley? Was that so isolated that no stray colony was located within a radius of six miles? Where was the pinewood's apiary? Was that in the centre of a forest of fir-trees six miles from an outside? Really, friend, you are arguing against yourself in trying to demolish my simple facts.

As I stated in my previous letter it was solely in the interests of bee-keepers I investigated the above, trusting to allay their fears, raised, no doubt, by Mr. W.'s bogey of in-and-in breeding as likely to produce the almost instant extinction of their strain of bees if their apiary should happen to be at a distance from other bee-keepers; and apparently my arguments and examples have had some effect, for we have got the long distance of six miles now as a bar to close consanguinity. I hope those foul-broody drones or queens (which sex is it that flies six miles *pour amour*?) will not have the staying powers requisite to cover the distance hitherwards. I don't think there is anything in my letter even hinting that I was adverse to the introduction of fresh blood into my apiary; in fact, for several years I have introduced the same by driven bees in the autumn, and often by purchase of stocks in the spring. What I stated, and by examples proved, was the folly of Mr. Webster's examples at the end of his letter (1514), *re* the valley and pinewood apiaries becoming extinct solely from in-and-in breeding. I am afraid the old lady was not a very apt scholar, as Mr. W. says he coached her up *re* ages of queens. Neither did I positively state there was no chance introduction of fresh blood. Still there was none by purchase or design in my first case; but why is my second example (perhaps it is conveniently) ignored? Probably because it is incontrovertible (*vide* par. 4, 1520), from the fact of the early swarming of the bees year after year preventing the chance mating with amorous drones from other distant apiaries, from the simple reason they were not on the wing.

As the plasticity of nature or its products, either animal or vegetable, is entirely beside the question, and

is no more relevant to it than the recent revelations of minute forms of life brought within range of our vision by improvements in the microscope, those forms of life, and probably other and smaller forms, have been existent for ages, though unknown to us; and so in centuries to come bees will exist in same form, shape, and colour, and with same instincts fulfilling their mission in the economy of nature; and I think Friend Webster will bear me out when I assert that neither the wild cherry nor the crab-apple would ever by ages of cultivation produce a 'pippin' in one case, or the 'amber-heart' in the other, except by grafting or budding.—W. WOODLEY.

BIRDS AND FRUIT BUDS.

[1535.] Last autumn I sent a warning note to many publications for fruit-growers to be on the alert for bullfinches, as they were here in unusual numbers. I advised catching them for many reasons in preference to shooting them, and thereby damaging fruit trees, as I know from experience that plum-trees 'bleed' or lose their sap from the shot wounds all the following summer: I have seen the ground quite wet under trees from this cause.

These birds are very easy to catch with properly constructed trap-cages during September, October, November, and December, but after Christmas their nature seems to change, and they will not heed a call-bird during the time they devastate fruit trees. Although I caught no less than sixty of these birds in my garden and orchard, some escaped, and my plum-trees never suffered more, some being almost cleared of every bloom-bud, which, in addition to the more serious prospect of a good crop of fruit being lost, is a great loss to my bees. These birds nip off the buds at the rate of twenty-five in a minute, and as they only eat, or rather swallow, just the tiny bloom, it takes an enormous quantity of buds to make a meal: thousands are lying under my trees; and as each bud would produce several blossoms the loss to bees is apparent.

Sparrows are almost as bad as bullfinches on plums, gooseberries, and currants, but these are easier to check with soot, and lime, and cotton, on trees. In catching bullfinches, tom-tits (*Parus major*) frequently shut themselves in prison, but I generally release them. I have taken three in ten minutes from one trap-cage this winter. My great objection to these birds is on account of their pea-destroying—not bee-killing—propensity.—J. HAM, *Astwood Bank, Redditch, March 8th.*

MORE ABOUT THE CO-OPERATORS.

[1536.] In the *B. B. J.* for Sept. 1st of last year I gave a sketch of my adventures 'Amongst the Co-operators', remarking, in closing, that what I saw was only an earnest of greater things to come. This year the show is to be at the Crystal Palace on August 18th, on a scale that promises to assume colossal proportions.

The title is, 'The National Co-operative Flower Show,' and the motto (the old Cornish one), 'One and All,' must be taken to mean one and all co-operators, so those of us who are not co-operators had better become so at once if we wish to compete, or by-and-by our only fate will be to 'look and weep.' The prize list in money and kind is some 320l. The portion offered in the 'honey' classes represents about 10l. 10s., besides the silver and bronze medals of the B. B. K. A.

Co-operators are exclusive and conservative, as well as 'fair traders.' You must sow only 'co-operative' seeds, grow only 'co-operative' flowers, fruit, vegetables, and HONEY—I had nearly forgotten the latter—and be a 'co-operator' yourself, or you may not compete for these prizes. Of course the bees were always 'co-operators,' and profit greatly by the arrangement.

Co-operators are 'cute,' 'cute enough to be a company of Celts. Here is a wrinkle for secretaries who are getting up a prize list. Of the general section I will say nothing, as that does not concern us so much as the honey classes. Amongst the 'special' prizes I find the following:—One silver and one bronze medal, presented by the B. B. K. A., and two vols. *B. B. J.*, presented by the Editor; the veteran firm at Southall gives a 'Gayton' hive; Mr. Howard, one of his new patent 'feeders'; Mr. Meadows, an extractor and a dozen section show-cases; Mr. Baker, of Muskham, two hives; Messrs. Brevet & Co. and the Aire & Calder Bottle Company give 12 doz. honey bottles each; Mr. Parker gives 3 doz. honey tins; Mr. Pearson, 1 doz. 1-lb. sections of honey; Mr. Simmins, six copies of his new book, *Modern Bee-farm*; Mr. Jenkins, one of his section crates; Mr. Hutchings, a feeder, a fumigator, and a section-rack; the B. B. K. Stores, 1 doz. 'Woodley' section-cases; and 'Expert-in-Chief' Baldwin, a smoker, feeder, and 2 lbs. foundation.

Now this list means either that these various manufacturers of bee-gear who have contributed so liberally are co-operators, or the energetic Secretary of the show is good at carrying 'round the hat.' Live and learn!

I wish them all a good show, a fine day, plenty of competition, crowds of visitors, no speech-making, and a *bee-tent*. I hope the latter will not be omitted as I shall like to be amongst the bees if I go, as I hope to. But I am running on too fast, there will of necessity be—

'Co-operative bees, in a co-operative hive,
With a co-operative expert to show 'em alive
To a co-operative crowd, at a co-operative fôte,
Where only co-operators are allowed to compete;'

and I am not a co-operator, and as a matter of fact only an—AMATEUR EXPERT.

RESCUING DROWNING BEES.

[1537.] In windy weather in spring many bees are blown down in crossing a pool in my garden, and as I feel sorry for them I rescue them from an untimely end by procuring some hot water in a bucket over which I place a cooking colander, into which I put the bees to drain and warm. I find a slate lath six or eight feet long best to place under them, as the hooked feet of the bees cling to the rough wood, and half-a-dozen may be lifted at one turn, a smart tap of the wood shakes them off. After draining they soon recover if placed on something warm in the sun, and fly off to their hives. I rescued at least fifty to-day at one time.—J. HAM, *Astwood Bank, Redditch, March 9th.*

FINDING THE QUEEN.

[1538.] I can fully endorse what 'Snowdrop' (1508, page 118) says in respect to time test. I have kept bees nine years, both in skeps and frame-hives, and have driven a large number at various times, both for myself and others, and have tried to find the queen in open driving, but have never found her yet, not that I don't know a queen when I see one; perhaps, my eyesight is not so quick as some people's, and having to wear a veil will impede my sight as well. So if finding the queen is one of the conditions to gain a third-class certificate, I have faint hopes of ever gaining one. I have taken the *B. B. J.* since 1885, and read them all through every week, and have learnt a great deal by the suggestions and practical experience of correspondents. No. 1512, page 119, advises candidates to repeatedly practise driving and picking out the queen previous to his examination, which suggestion is very good for those who have time to do it; but a working man that is away from home from morning until night all the week through has not the time to spare, morning and evening not being always fit for driving.—J. B., *Sheffield.*

NOTICES TO CORRESPONDENTS & INQUIRERS.

C. N. PARKIN.—*Simmins' Large Frames*.—I think of adopting Mr. Simmins' large frames, but would like to know, if Mr. Simmins would kindly inform me, 1. What equivalent is there for *tying up* so as to obtain the same results as are obtained with the forty-frame colonies? In other words, can one's stock of Standard frames be used in any way for extracting whilst using the large frames for brood-nest, single-walled tying hives being in use. 2. How are the large frames extracted from? The ordinary extractors would not be large enough. 3. Would empty body-box be required below frames in summer, or would the large size (perpendicularly) of brood nest suffice to prevent swarming?

Reply.—1. The shallow extracting chamber of eight frames is used for extracting, tying up as high as needed. The same with usual Standard frames, using an extra rim to bring the sides of your hive up to level of large frames; then pile up the standard hives of comb. 2. If the above is properly carried out there will be no honey in the large frames to extract. 3. Use several large frames in front or at one side (nearest entrance) with starters only.—SAMUEL SIMMINS.

C. A. J.—*Bees Dead*.—Your stock, since dead, having worked forwards, and a spell of cold weather intervening, were unable to shift the cluster to the back of the hive so as to get to the stores there. Had you cut winter-passages through the combs, it is quite probable your bees would have been saved. Six frames well stored would have been ample. An enamelled quilt would have been preferable to boiler felt for placing next the frames. Of course any necessary candy can be placed on the frames as desired. We believe stocks generally are very short of food this spring. Ours got their first pollen on the 10th: the crocuses were filled with them.

GEO. MURRALL.—*Dry Sugar Feeding*.—Castor sugar is quite useless for dry feeding. If Porto Rico cannot be got, we should certainly prefer syrup, though the former is better for stimulating in spring.

JACKDAW.—1. *Silke-Corkhill Hive*.—We see no reason why this hive should not be a success. We have knowledge of a very similar design having been tried successfully. Your alteration of entrance would possibly be an advantage. 2. *Malt-wort for Feeding*.—We consider this most improper food for bees. Sugar is cheap enough. Our advice is, never try doubtful substitutes, it may mean death to good colonies. 3. Kindly repeat your other question.

W. M.—1. *Colour for Hives*.—Try plinths white, red, green, brown, blue, alternating the various colours in different groups. These colours will give you sufficient diversity for a large number of hives. 2. *Honey Flow*.—There is said to be a honey flow when large quantities of bloom are freely distilling nectar and stocks are gathering considerably more than they consume. 3. *B. B. K. A. Library*.—The annual subscription to B. B. K. A. of 5s. includes free use of Library. Mr. John Huckle, Kings Langley, will receive subscription and forward you catalogue. Any of the books named therein can be borrowed by members. Borrowers to pay cost of postage both ways.

S. B. FOX.—*Floor-boards*.—For the purposes of cleaning floor-boards, it is better to have them moveable in the ordinary Woodbury hives; but for larger hives fixed boards are preferable: in this latter case, when required to clean the boards, the frames can be moved from one end to the other.

W. A. TRÜSSLER.—You should get pollen from elms, chestnuts, &c., and honey from hawthorn, and limes, also trifolium. But success lays quite as much in the management as the surroundings. Get your colonies as strong as possible by May 10th.

W. L. BIRD.—*Drone-brood*.—We should consider the queen useless, as you mention there being no *worker brood*. We should remove the queen and unite them to one of your weak stocks, then you could divide them again early in May, as soon as you can obtain a queen to introduce. They will die off if left alone.

JOHN STUART.—We are of opinion that there is no law by which your neighbour can compel you to remove your hives; but if your neighbour is disturbed and disquieted by the presence of your bees, we think it would be but courtesy to place them where the annoyance would cease. If 'A. E.'s' motto, *Mel sapit omnia*, be correct, perhaps a present of a section or so of honey might heal the strife. Try it.

JO ROBO.—1. *Hiving Swarm*.—Six frames are enough, and feed gently if honey is not coming in freely. If there is a good honey-flow, and the hive holds ten or twelve frames only, then put in all the frames with $\frac{3}{4}$ -inch starters *only*, and place the supers on at once, giving full sheets in the section boxes. The bees will store above, and gradually build out comb in the frames, which the queen will keep filled. It would be safer to put excluder-zinc on the frames. Set the swarm on the stand of the old stock. 2. *Box Hive*.—The time of the first honey-flow varies in different places. If you have plenty of hawthorn or clover in your neighbourhood, super as soon as either of these is opening freely. We should prefer to put a frame-hive underneath, with full sheets of foundation in the frames. Then, as soon as the queen is laying freely below, put excluder-zinc between the two hives, so making the old brood-box a super for extracting at the end of the season. For the future you will then then be able to examine as may be advisable.

F. GOODRICH.—*Transferring Bees*.—Under the circumstances, yes, on first suitable day. You might, however, replace coverings with clean, dry ones in a very few minutes. Do not use smoke if you can possibly avoid it when changing the quilts. As you turn up those now on, let the new *warm* ones gently take their place. You can slide them correctly into position at the last. We will inquire about the trap.

BLANCHE, *Vaulcuse*.—1. *Keeping Hive-sides Packed*.—We keep ours packed with cork-dust (that in which grapes are packed) all the year round, and find it answer admirably. Reduce the number of the quilts, give free ventilation and wide entrances. A penny placed under each corner of a hive having a loose floor-board gives good ventilation. Your hives should be shaded from the midday sun. 2. *Irregular Combs*.—Combs with brood must not be pared down. As soon as the double comb has the brood sealed, place it at the outside of those which contain brood, putting a good, straight built-out comb in its place: when the brood hatches, remove it altogether. Gradually work the other irregular ones out in the same manner. As soon as you get two good, straight combs in the centre of the brood-nest, you can about once a-week insert a frame with sheet of new foundation instead of a built-out comb. This is called spreading the brood-nest. 3. *Unsealed Food*.—Considering your bees are so strong, and are bringing in pollen freely, the frame you refer to is most likely food they have liquetied for feeding the brood. 4. *Propolis Frames*.—If your bees are not vicious, you had better scrape them at your first opportunity. 5. *Moving Bees into Clean Hives*.—Unless the hives are really dirty the spring shift is sufficient, but another shift in end of September would keep them nice. 6. *Weak, Queenless Stock*.—Unite them to your other stock, and divide, say, in about four weeks' time. The other subjects of your letter will be treated next week.

ROBIN HOOD.—*Disinfecting Hives and Combs*.—There is no utility in disinfecting the hives and combs unless

disease has appeared in them, or they have become a fertile source of the growth of disease by becoming dirty, damp, and mouldy. A hot disinfectant in the case of hives is more effective than if applied cold, as it enters more freely into the grain of the wood and crevices; carbolic acid is the best for this purpose. Dipping the combs into the disinfectant would have the desired effect, but they must be drained and allowed to dry before placing them in hive. Spraying would be equally as effective if done properly.

A. H.—*Trapping Drones*.—Where a hive is abnormally populated with drones we should trap them, but such a condition of things cannot take place in a frame-hive if same has been properly attended to. Drones do not act the part of nurse-bees; this is principally performed by the young bees before taking their place among the army of honey-gatherers. 2. *Queen's Cage*.—We did not make the offer, but one of our contributors. This offer, we believe, has been withdrawn. 3. *Removing colony from makeshift hive*.—This can be done on any fine, warm day by simply removing the frames and placing them in the fresh hive, which must occupy the position vacated by the makeshift. 4. *Removing stock from box*.—You must drive them, or at least a portion of them, with the queen. The vacated hive is then placed upon the tops of the frames of the fresh hive, a sheet of excluder zinc being placed between them. The queen with bees are then turned into the lower hive, which must be fitted with sheets of foundation in about four or five frames, the dummy board being shifted right close up to them. All means of communication between the upper hive and the outside excepting through the excluder zinc, must be stopped up. The bees with queen will draw out the foundation in the lower while those in the upper hive will hatch out the brood contained therein. In three weeks the upper hive must be removed and driven, the bees being turned into the lower one. 5. *Ventilation of hive*.—This is only necessary where a colony is very populous if you have an entrance all along the front. You must raise outer case as well and stop up space between the inner and outer case, or the bees will most likely build comb between them.

J. C. WALTHAM.—*Dividing Colony*.—On no account must you raise a queen in a nucleus colony as proposed by you. By dividing a colony you materially reduce the chance of a good honey crop. You cannot expect a large increase of stocks and a heavy return of honey at the same time, but if you require two colonies act according to the directions of the book you have or purchase another.

RECEIVED from Mr. F. C. Andreu, of Port Mahon, Minorca, the Catalogue of Hives and Bee-appliances.

RECEIVED from Abbott Bros. their Catalogue of Hives and Bee-furniture, 72 pages, illustrated with numerous wood engravings. In this catalogue the bee-keeper will find every appurtenance he can possibly require, and at very moderate prices.

SENDING QUEEN-CELLS.—I beg to thank Mr. Pringle for his generous offer (1507), which I shall be very pleased to accept.—A. SHARP, *The Apiary, Huntington*.

ERRATUM.—In 'Echoes,' from 'J. F. R. A.' line 8, it should read, 'Each was fed up to 25 lbs. in October, and has now a one-pound candy cake over the feed-hole.'

THE BRITISH BEE JOURNAL

Communications to the Editor to be addressed 'STRANGEWAYS' PRINTING OFFICE, TOWER STREET, CAMBRIDGE CIRCUS, W.C.

[No. 300. VOL. XVI.]

MARCH 22, 1888.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

THE PROSPECTS OF BEE-KEEPING.

Many of our readers who can recollect the pleasure derived from selling honey in the comb at 2s. per pound doubtless feel very despondent at the continued diminution in the price of honey, and probably some are sufficiently pessimistic to not only think but say that the production of honey in the future may, perhaps, be an elegant hobby, but certainly never a paying business. Looking at the subject in all its bearings we beg to take exception to this view, and at the same time to impress upon our fellow bee-keepers that at no previous time have the bee-keepers' prospects been of such a roseate hue as at the present. Till within the last few years honey of good quality was a very scarce article to be found only in the houses of the well-to-do, and but as a medicine even there. Now it is fast becoming a necessary requisite of the breakfast and tea-table; consequently the demand is rapidly increasing, and if honey-producers will only use their utmost endeavours to keep their honey clean, and at the same time put it on the market in an attractive form, we are of opinion that within the next decade there will be a ton used for every hundredweight now consumed. We would point to the jam trade as a collateral case. Within the memory of many who would resent being designated as old people, fair jam was 10d. to 1s. per pound; now the same quality can be readily purchased at 5d. retail. Then only one, or at the most, two grocers in a town kept it, and those only to a small extent; now every grocer's shop, though of the most modest pretensions, even in out-of-the-way villages, has an exhibit of jam as one of its leading articles. The firms who years ago made large prices of a small quantity now thrive far better on a larger sale at half the price. It is admitted they have many facilities for procuring several of the articles they require at a much lower figure, but labour is dearer. The bee-keeper occupies a very similar position as regards the cheaper prices at which he can obtain the necessary outfit, and it only requires the actual facts of the case to be clearly understood and fairly grasped to enable us to achieve as great a success as our most ardent wishes could desire.

It is an indisputable fact that taking, say ten average seasons together, there is no other pursuit in which small capital can be invested with the prospect of such large returns, if the bee-keeper will only remember that it is quite as necessary to thoroughly master this business in all its details as it is for the professional man or tradesman to master theirs when they aim at success.

At no previous time has it been possible to purchase the hard-earned knowledge of others in the form of books at so cheap a rate as now. Improved methods of management, &c., are freely communicated and most valuable hints scattered broad-cast on every hand. This should give encouragement to the faltering and brighter hopes to those who have attained to some measure of success.

We fail to see why, if the price of extracted honey should not in the future exceed sixpence per pound, it would not be possible to make bee-keeping pay even with a few hives. At that price every hive ought with care to give the owner a profit of at least a sovereign either by the quantity of honey alone or by the honey and a swarm combined. This is putting it at a most moderate figure. Our most successful bee-keepers are persons who are always on the alert for anything which shall conduce to the well-being of their bees with a view of fitting them to be better producers of honey. It is needless to recapitulate here the several things that go to make success, because the owner himself is the most important factor in the calculation. It is of no use his knowing what should be done if he does it just too late. Let him work never so hard to attain success his efforts will be fruitless.

In conclusion, we would say be every ready and watchful, diligently accumulating knowledge at every opportunity, manfully meeting every difficulty and fully determined that no obstacle or disappointment shall divert you from your purpose. Then shall success be your reward if your work is intelligently carried out.

PRACTICAL HINTS FROM COUSIN JONATHAN.

Amongst American bee papers, for practical information the *American Apiculturist* bears the palm. At intervals of a few months an extra-good number comes from the desk of Mr. Henry Alley. The number for March is so exceptionally good that I have condensed

the following hints from it—which is always a difficult matter—and do justice to the writers at the same time. Several other subjects were treated on, but I have selected what I thought would be of most interest to readers of the *B. B. J.*

Mr. R. L. Taylor aptly remarks that 'many men have many minds,' and this is as true of bee-keepers as of any class; and while we have many likes and dislikes as to hives, appliances, and systems of management, yet we may all learn something from the 'hints' given by others, although we may not be prepared to slavishly follow their systems.

BEGINNERS

should start with two or three hives, and learn by experience and amid comparative leisure. To produce large crops of honey they must learn to get their

COLONIES STRONG

as early as possible. The one great pre-requisite for this is superabundance of stores. Spreading brood he considers of doubtful utility. If the bees are supplied generously with stores, the

NON-MEDDLING POLICY

will result in a healthy and rapid increase.

Mr. J. E. Pond prepares for the harvest during the winter by getting hives and appliances ready for summer's use. In the spring he examines and cleans out the hives and

EQUALISES HIS COLONIES

as far as possible. He gives the weak colonies brood from the strong, unites the queenless to others, but prefers building up weak colonies with good queens at their head, to uniting together those that are

NOT QUEENLESS.

Colonies must be well supplied with food, and the inexperienced is warned that the consumption of food is very great during early spring breeding, and colonies are 'liable to play out rapidly for the want thereof.' The

REARING OF YOUNG BEES

must be timed to take advantage of the crop. From thirteen to fifteen days are given as the age of the young bees before they become foragers. The golden rule of Otto—'Keep all stocks strong'—is as true as ever, remarks Mr. Pond, which many are apt to forget in these days of

PATENT RATTLE-TRAPS,

and put their dependence in 'wonderful back-action, incontrovertible, interconvertible, interchangeable hives; but it won't do. The only honey-gatherer is

THE HONEY BEE.'

Mr. G. M. Doolittle says all work with the bees to be successfully done should be done with an eye open to the probable time of the blossoming of the

MAIN HONEY PLANTS

in one's locality. It takes six weeks to build up a colony to a state capable of doing its best work on a given field of blossom, consequently you should time your operations according to your crops. To commence too soon is to have large numbers of bees loafing around waiting for the harvest, while being too late gives you consumers instead of producers. The bee-keeper must use

COMMON SENSE

in regard to bees as in other things, not only by rightly timing his breeding operations, but by using the best races of bees, and the best of queens from that race, as all

DEPENDS ON A GOOD QUEEN,

as far as the bees are concerned, and on the amount of brains possessed by the owner, to realise that no stone

must be left unturned that tends towards success if he wishes to make his bees a

SOURCE OF PROFIT.

Mr. Joshua Bull says, although we cannot compel, we can stimulate bees to rapid breeding by amply providing for their needs during spring, and keeping them warm, comfortable, and happy. He keeps

A RECORD

of all his colonies, numbering the queens, and painting the number on a piece of tin, which he fastens to the hive that contains her, shifting it to other hives if she swarms or is shifted by any other means. His

SPRING MANAGEMENT

consists in overhauling each hive when weather permits, taking away the unoccupied combs, seeing that they have plenty of food, cleaning out the hive, closing up the dummies, and filling in the outside space with dry chaff or sawdust, giving dry quilts, and over the quilt laying an *old newspaper*, to retain the heat, contracting the entrance and recording the

CONDITION OF THE STOCK

in his note-book and the date of examination. Mr. Bull, unlike Mr. Taylor, does believe *that the spreading of brood, with judicious management, may be productive of highly beneficial results.** The greatest danger lies in the liability of extending the brood beyond the capacity of the bees to keep warm during any period of cold weather which might occur.

WHEN TO SPREAD BROOD

can only be learnt by discretion. It is an easy matter to handle bees to death in the spring of the year by continually fussing with them, by overhauling them to see how they are getting along just to satisfy curiosity. Always choose

A WARM DAY

for examination, so that the bees can fly during operations; and the best judgment of the apiarist must be constantly exercised as to how much room, and when it should be given, and every change in the condition of the colony should be

NOTED DOWN IN THE BOOK

spoken of above.

It is difficult to specialise where all is so good, but Mr. Bull's article on spring management is excellent reading throughout.—AMATEUR EXPERT.

(To be continued.)

Selected Query.

[5.]—Which is the best way of preserving combs from wax-moth and keeping them over the winter? What should be done with the pollen in them?

1. Leave them in the hive. 2. Pile up body boxes, filling them with frames of comb so they stand about $\frac{3}{4}$ in. apart. 3. Provide a large comb cupboard and space as in No. 2. With the latter, provision is made for burning sulphur or live coals in a pan at the bottom, if found necessary, but this is seldom required if the combs are used the following spring. Leave the pollen alone.—SAM. SIMMONS.

Suspend them separately in a dry, airy room, and leave the pollen alone; it will become dry and will keep. In the spring, copious moisture with thin, warm syrup will make it again available for the bees.—C. N. ABBOTT.

Combs of one or two years old, from which honey has been extracted, if not containing over-much pollen, may be immersed in water for an hour or two, and again

* Italics mine.—A. E.

passed through the extractor, when, after being sprayed with thin syrup, and cleaned by the bees, they may be fumigated with sulphur and stored in boxes in a dry room. Many prefer to encase such combs in sheets of paper in order to preserve them from the moth.—GEORGE RAYNOR.

All combs should first be thoroughly cleaned out by the bees of any remaining honey after extracting, and in the bodies used for storifying be fumigated with sulphur fume or carbolic acid spray. All joints and openings being made secure from insect life, these bodies may be stored in a dry room, or manipulating-house, tiered any convenient height. In *small* apiaries, after cleaning and fumigating, spare combs may be nicely stored in a box, with close-fitting lid, sufficiently large to take two or three frames deep by any length needed. The frames therein hang on moveable strips, so that the box may be filled from the bottom upwards. Brown paper lining to box, with sheet of same on top, each tier will repay the extra trouble. This winter we have kept combs in very good condition storified over colonies, the necessary quilting, &c., over latter, shutting off all communication above. Small quantities of pollen may be left and given back to the bees with no bad result, but if combs are largely pollen-stored, it is well to scrape all such pollen-cells away, leaving the midrib only. Many of our attempts to otherwise rid combs of pollen have proved futile. All spare combs which are excessively pollen-stored it is best to break up and replace with a full sheet of worker foundation.—JOHN H. HOWARD, *Holme, Peterborough.*

I tier my spare combs up in spare hives, and occasionally blow some smoke in at the bottom. If there is a moderate quantity of pollen in them, I let them remain; if they are rather full of it, and I do not wish to destroy them, I just scrape them down a bit before giving them to the bees.—JOHN WALTON.

I cannot recommend the keeping of surplus combs containing pollen over the winter. What could be better than a close-fitting box, either of tin or wood, to keep the combs free from wax-moth? A piece of camphor should be put in the box.—J. GARRATT.

All combs to be kept through the winter should, after extracting the honey, be given to the bees to clean, and for this purpose they may advantageously be placed behind the back dummy of a needy colony, raising the dummy $\frac{1}{4}$ in. for passage. Combs containing much pollen should be given to stocks which are being fed up with syrup, or broken up for wax. When thoroughly cleaned and dry they should be carefully tied up in paper, putting a small piece of camphor in each parcel, which will keep away the moth, and hang them at the top of a dry, airy room. Any little pollen in the combs thus treated may be left, and when given to the bees they will soon decide as to whether it is required or not.—S. J. BALDWIN.

Let the combs be perfectly dry and clean when ready to put away. Hang them in a warm, dry store-room, so that the air can circulate round them, but protect them from dust and insects. Any pollen soon becomes dry, and the bees clean it all out when the combs are given to them in the spring. I have never found any difficulty in keeping combs in this way, and I always spray them with sal. acid solution, as advised in the *British Bee-keepers' Guide-book*, before giving them to the bees.—M. L. GAYTON, *Much Hadham.*

Combs should be cleaned by the bees after the honey is extracted, the frames should be scraped clean and hung in racks about two inches from centre to centre, and several rows in height, in a dry room or cupboard that can occasionally be fumigated with sulphur. If there is a quantity of dry, hard pollen in the combs I should melt them down.—JOHN M. HOOKER.

Keep them freely exposed to the air, or wrap them closely in brown paper parcels, putting a little camphor in each. Do not interfere with the pollen.—J. A. ABBOTT.

Presuming the query refers to combs that have been through the extractor, and cleaned out afterwards by the bees at the end of honey season, I should store them in a dry room or chamber where facilities for hanging them in same position as when in hive, or they may be stored in the storifying compartment of the hive in a dry room; when the pollen in them gets perfectly dry a great part will shake out, and the remnant may be left to the bees for clearance.—W. WOODLEY.

A REVIEW OF THE BEE LITERATURE OF GERMANY AND AUSTRIA.

(a.) *Nordlinger Bienenzeitung*, Editor, H. Vogel, forty-fourth year. No. 4.

The most active contributor to this, the oldest of all bee journals since its commencement is Dr. Dzierzon, the grandmaster of bee-keepers. As usual the number referred to commences with an article by Dr. Dzierzon, entitled 'The Hive Question,' in which the author discusses the bees' power of acclimatisation, which enables them to thrive in very cold countries and exist even in high northern latitudes where the winter is long and severe; it is even said that colonies of bees have been discovered in the rock-caverns of Iceland. Although this seems incredible, we have authentic accounts of the possibilities of bees existing in an arctic climate. In south Iceland there are some sheltered fertile valleys, where during the short summer months the heat becomes very great, and where the bilberry and other arctic plants grow in profusion. The shortness of summer is compensated and equalised by the length of the arctic day, thus giving time for bees to collect and store sufficient honey to last them through the long winter.

As a protection for the roots of plants against the extreme cold in winter kind Nature covers the ground there with a soft covering of moss, which, at the commencement of winter is overlaid by a thick layer of snow, below which the temperature generally remains stationary at about freezing point, whatever temperature the thermometer may indicate above the snow.

The maximum of the climate of Iceland in summer is 26° R = $80\frac{1}{2}^{\circ}$ Fahrenheit; the minimum in winter -20° R = 15° Fahrenheit below zero. The duration of the longest days there is twenty to twenty-one hours, and of the shortest four hours. Enormous tracts of country are covered with heath and bilberries, which ripen in September.

The same number of this *Journal* contains an interesting account of 'The Importance of Honey to the Ancients,' from the able pen of Mr. Bessler of Ludwigsburg, the well-known author of *Geschichte der Bienenzucht* (History of Bee-keeping), a work recently published. A further article refers to Mr. Ludwig Huber, who died at Niederschopflheim in the duchy of Baden at the age of seventy-four. Shortly before his death Huber's popular and extensively read work *Der Dzierzonstock* (The Dzierzon Hive) appeared in its tenth edition. The latter article is illustrated by a portrait of Huber.

(b.) *Deutsche illustrierte Bienenzeitung*. By C. F. H. Gravenhorst, fifth year.

The February number of this *Journal* contains a charming article on Flowers and Bees, by Miss Sophie Warnken, entitled 'The highest intellectual Enjoyment,' the authoress concluding with the remark that he who wishes to experience an intellectual enjoyment should 'at once commence bee-keeping, a hive of bees affording a never-failing source of pleasure; as one watches their labours in the flower-garden, or in the woods and meadows.' Then follow articles on the 'Bogenstülp

at the Upper Rhenish Industrial Exhibition at Freiburg in Baden, by Mr. Roth, and 'The Dathe Hive' by Mr. Dathe of Eystrup. It will be in the recollection of bee-keepers that the latter hive, containing three storeys in which the frames have a width of 23.5 cm. = 9¼ inches, was adopted as a standard for fixing the measurements of bee-hives in Germany.

(c.) *Deutscher Bienenfreund*, by L. Krancher, twenty-fourth year. No. 3.

Mr. L. Stachelhausen of Selma, Texas, gives a description of 'The Construction of the Langstroth Hive,' as suitable for use in summer. He is decidedly in favour of hives that can be manipulated from above. Mr. H. Rabes, Secretary of the Niederhasslau Bee-keepers' Association, gives a short 'Explanation in reply to Mr. Koerbs,' with regard to this gentleman's new invention of artificial combs—a general subject of conversation among bee-keepers at present. Is this artificial comb likely to prove useful and of real advantage in practice? The future will show.

(d.) *Die (württembergische) Bienenpflege*. Editor, Mr. Baetz, tenth year.

No. 1 contains an article on 'Honey' from the *Letters on Diet*, by Dr. Joh. Aug. Schilling, in which the author gives an account of what has been written about it, and its use as a food and medicine.

(e.) *Bienenwatter (wien)*. Editor, Mr. Ferruges, twentieth year.

No. 2 of this *Journal* contains a very interesting and instructive article by Mr. E. Drory, entitled 'From my Diary,' being notes on bees during a trip round the world. The most entertaining of these are dated from the island of Ceylon, where the learned naturalist made observations not only on the various kinds of bees, but also on *Meliponas* and *Trigonas*, in the propagation of which he displayed so much skill and perseverance during the time he was editor of the *Rucher* at Bordeaux.

(f.) *Bienenwirtschaftliches Centrablatt, Hannover*. Editor, Mr. Lehzen, twenty-fourth year. No. 3.

This number reproduces the speech made by Mr. C. Lützow at the second bee-keepers' meeting on 'The Eyes of the Bee,' illustrated by numerous drawings. In another article entitled 'A Lawyer's opinion on the Act of Parliament of May 14, 1879,' respecting the traffic in articles of Food and Drink,' Mr. Letocha expresses himself satisfied that the provisions of this Act afford sufficient protection to bee-keepers and the consuming public, as by its enactments the former are very well able to defend themselves against dealings in spurious honey, and the latter against dishonest tricks on the part of producers and sellers of honey.

(g.) *Oesterreich-ungarische Bienenzeitung*. Editor, Father Schächinger, eleventh year. No. 2.

The Rev. gentleman whose honey aërometer has been declared to be a failure in his leading article in this number defends his invention, saying that no reliable experiments have been made to justify this assertion. Mr. Franz Zavadil recommends the manufacture of artificial combs with square cells.

(h.) *Leipziger Bienenzeitung*, published by Liedlof & Co., third year.

No. 2 of this *Journal* contains a description of the 'Twinstock Hive, the most suitable bee-bive of all,' by Dr. Dzierzon, followed by a continuation of the 'History of Bee-keeping.' The same number also reproduces some forest regulations which were in force in parts of Germany during the sixteenth and seventeenth centuries. There is also an article, headed 'Formic Acid in Honey,' in which the writer endeavours to prove that this acid is a product of oxidation of the carbohydrates of plants.

(i.) *Allgemeines deutsches illustriertes Bienen-Organ*, by Mr. Felgentreu, third year.

No. 2 contains a description and illustration of the Alberti hive, by A. Alberti. This hive is an oblong box, one of the broadsides of which is accessible by doors, while all the other sides are fixtures. The frames are resting on a grating, and are kept at the proper distance from each other, and from the walls and doors, so that when the doors are removed, the frames are perfectly free and may be turned to and fro. It is also possible to take out of the hive any frame which it may be desirable to remove.

(k.) *Die Honigbiene von Brünn*, twenty-second year. Editor, Mr. H. Rull.

In No. 2 the editor publishes extracts from Mr. Denner's work *Das Bienenwachs* (Beeswax), on the subject of adulterating and testing wax, and the employment of wax for industrial purposes.

(l.) *Münchener Bienenzeitung*, tenth year. No. 3. Editor, Dr. Hauler.

In this number dronetrap are described as dangerous appliances which should not be used in the apiary on any account, as they frequently cause the loss of the queen.—DENNER, *Enzheim, in Alsace*.

ASSOCIATIONS.

IRISH BEE-KEEPERS' ASSOCIATION.

ANNUAL REPORT.

The Committee have much pleasure in reporting satisfactory progress during the past year in spreading a knowledge of advanced methods of bee-keeping, and in the work of the Association generally. The number of members has also very largely increased, the total being now 141, as against 85 in 1886. In spite of the injurious effects of extreme drought, the year 1887 has been marked by an exceptionally bountiful honey crop. This, however, has had its usual drawbacks, in the shape of dull demand and low prices. Under these circumstances the Association may be congratulated on the results of the market established for the sale of members' honey; and great credit is due to Messrs. Carton Brothers, the agents, to whose unremitting exertions the large measure of success attained is mainly due.* The bulk of the honey sold was in the form of one-pound sections. Two-pound sections are most unpopular, but the few sent were all disposed of.

Extracted honey, being apt to candy rapidly this season, found so little favour with the public, that the supply had to be stopped, but consignments already received were sold at an average price of a little over 8½d. for 1-lb. bottles, and about 4½d. a lb. for honey in cans. Better results may be hoped for hereafter, if individual members will join with the Committee in combating the prejudice against candied honey, which even now is not universal.

The average price of 1-lb. sections, taking good and bad together, was a little over 7d. For good sections the following prices were obtained:—From January to June, 9d. to 1s.; July, at first, 8d. to 8½d., decreasing, as the month advanced, to 6d.; August, 7d. to 8d.; September to December, 8d. to 8½d.

The sale of honey during the year 1887 was,—1-lb. sections, 3814 lbs., 141l. 17s. 11d.; 2-lb. sections, 70 lbs., 1l. 11s. 4d.; 1-lb. bottles, 403 lbs., 13l. 17s. 6d.; honey in cans, 76 lbs., 1l. 9s.—Total, 4363 lbs. 128l. 15s. 9d.

An important exhibition of hives, appliances, and honey, was held early in August in the Salthill Gardens, near Dublin. The hives and appliances exhibited—which were, with one exception, from Irish makers—

* Messrs. Carton Brothers have now resigned the Agency, which has been taken up by Messrs. Abbott Brothers.

were calculated to give encouragement to those who have the interests of home industry at heart; but the almost entire absence of British competitors materially diminished the receipts from entrance-fees, and was disappointing, as ample notice of the show had been given to all the leading firms.

The display of honey was large and attractive. A considerable amount was sold at the show, and, whenever exhibitors desired it, the unsold portions of their exhibits were forwarded to the Market and disposed of there.

There was a very satisfactory attendance at the beehive, where Mr. Roland Green, the well-known expert of the British Association, excited much interest by a highly instructive course of lectures and skilful manipulations.

On this occasion every effort was made by the employment of military bands and other attractions to draw public attention to the show. The result was a fair attendance, though by no means such as had been expected, and also long and highly appreciative notices in the Dublin papers. By these means it is believed that the position of the Association has been greatly improved, as evidenced by the largely increased number of its members. The expenses, however, were heavy, but, owing to the kindness and liberality of some of the members in subscribing to a guarantee fund, they have not, to any important extent, exceeded the resources of the Association. On the evening of the first day of the show, a *Conversazione* was held, by kind permission of Dr. Traill, at his rooms in Trinity College. There was a good attendance of members, and Mr. Roland Green was also present. An important paper was read by Mr. M. H. Read, and an interesting discussion followed.

The bee-tent appeared also at a flower-show at Waterford, and at the Meath Poultry, Pigeon, Cage-bird, and Bee Show, held at Trim, having been hired on each occasion from the Association.

A noteworthy feature of the year was the adoption of a standard hive, capable of being manufactured cheaply. Of this a full description has already appeared in the *British Bee Journal*.

The Committee met on the 6th inst. President, Rev. P. Kavanagh in the chair, Dr. O'Farrell, Messrs. Millner, Vanston, Read, Sproule, Gillies, and the Hon. Secretary. Steps were taken for the due application of the Cottiers' Fund. It was resolved to request certain members to act as district secretaries for the counties in which they reside. Important changes in the system by which honey is sold for members were reported by the Secretary.

GLOUCESTERSHIRE BEE-KEEPERS' ASSOCIATION.

The annual general meeting of this Association was held at the Raikes Memorial Hall, Gloucester, on Thursday, March 8th, 1888. Present:—J. Hutchinson, Esq. (Chair), Miss Hayward, Messrs. H. M. Appleton, E. A. Brown, J. B. Butler, T. Butler, C. Marshall, Jun., W. H. Fox, C. M. Penley, W. D. Slade, Hon. Sec., with others.

The Annual Report was read as follows:—

The Committee have much pleasure in submitting their report for the year 1887, and to congratulate the members on the progress the Association has made in the increase of subscribers, and, too, in the amount of receipts, of the interest taken, of the marked improvement in the method and practice of bee-keeping in the county. There are now 266 members, divided into 13 districts, with two more districts about being formed, viz., Wickmar, Hatherley, and Churchdown. The gross receipts amount to the sum of 118*l.*, and the Committee are glad to state that they carry forward a

favourable balance in the Treasurer's hands after providing various appliances, such as hives, extractors, &c., which have been greatly appreciated.

The number of stocks in the autumn was 1369; 1029 in bar-frames, and 340 in skeps and boxes. Seven exhibitions have been held during the year. In connexion with the Gloucestershire Agricultural Society's Show, held in Pittville Gardens, Cheltenham, July 26th, 27th, and 28th, 1887. This, our annual show, was one of the largest and best attended, and in every way the most successful ever held in the county, upwards of three quarters of a ton of honey being staged, and nearly half a ton finding ready purchasers; thus assisting the members to find a market for their honey. There were sixty-eight entries, twenty-three being free to cottager members. The Committee's thanks are due to J. M. Hooker, Esq., for acting so ably as judge, in many cases the entries being numerous and the competition keen; the Committee thank, too, J. Hutchinson, Esq., for his kindness in so hospitably entertaining Mr. Hooker. The second exhibition was held at Yate, in our Bristol district. We desire to note his generosity in returning the prizes obtained; 3rd, Dawn Hatherley, August 1st; 4th, Tuttleigh Flower Show, July 21st; 5th, Stonehouse Flower Show, August 4th; 6th, Winchcomb, August 17th; 7th, Minchinhampton, August 11th.

The Committee would press on the members the desirability of qualifying themselves to obtain experts' certificates, and hope that this year there will be one at least in each district, and congratulate the following, who have been successful:—A. J. Brown, Bradley, Wotton-under-Edge; J. White, Toddington, Winchcomb; R. Woodward, Charlton Kings, which with E. J. Burt, and Hon. Secretary, each holds 2nd and 3rd class certificate; P. Newman, Gloucester, 3rd class. J. M. Hooker, Esq., and Dr. Bartrum were the examiners. The Committee look forward with confidence for the new year, and ask that each member will use his and her utmost endeavours to gain the support of their friends and neighbours and make the advancement of this Association known and appreciated.

After the report had been received, the officers for the ensuing year were elected, and the division of the county into districts with their advisers was arranged.

LEICESTERSHIRE BEE-KEEPERS' ASSOCIATION.

A General Meeting and *Conversazione* was held in the Mayor's Parlour, Old Town Hall, Leicester, at 2:30 p.m., on Saturday, 17th inst. The Mayor of Leicester had kindly undertaken the office of President, but was unfortunately by unforeseen circumstances detained in London. Another of the Vice-Presidents of the Association therefore took the chair, and under the presidency of K. B. De-la-Bere, Esq., of Burbage Hall, the meeting proved a great success. The attendance, taking into consideration the vile state of the weather, was good, and larger than an ordinary general meeting. Prior to the General Meeting, a Committee Meeting was held, at which the prize schedule for the annual show was drawn up, and other routine business transacted. During the course of the afternoon, Mr. J. H. Howard, of Holme, Peterborough, and Mr. W. P. Meadows, of Syston, held forth eloquently on storifying, queen-rearing, wax, honey, and other kindred subjects. A lively discussion sprang up now and then, and a very pleasant afternoon was spent by all present. Votes of thanks were recorded for Messrs. Howard, Meadows, and the chairman, and the proceedings terminated.

Mr. J. H. Howard was engaged to lecture on the 16th at Sheepshed, and on the 17th at Market Harborough. Reports not yet forthcoming.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal," c/o Messrs. Strangerays and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, Kings Langley, Herts (see 2nd page of Advertisements).

* In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

GLASGOW INTERNATIONAL EXHIBITION.

[1539.] The final allocation of space has taken place in connexion with this Exhibition, and we have only succeeded in obtaining twenty-five square feet. This of itself might have been a trivial matter had other exhibitors come forward, but the space is small indeed in comparison to the vastness of the industry we are trying to do justice to, and in accord with the apiarian talent which exists in this country. A very large number of American visitors are sure to be here, and I am fully convinced that our leading bee-keepers have on the present occasion lost a splendid opportunity of showing the advancement they have made in recent times.

Since the appearance of my first article on this subject in the *Journal*, I have had a great deal of correspondence from all parts of the country, offering honey of every description; but from these foregoing remarks it will be seen that only a very small space is at our disposal. Our samples to be varied must be small, and we hope to show some of the uses to which pure honey is now applied. The case we are getting fitted up will have six feet frontage, by three feet high, and four feet in depth—a total height from ground of about eight feet, and will be situated in Court 21.

In order to carry out the desire of some of those who have forwarded samples of honey, &c., we purpose acting as agents, and will issue a small catalogue of the different exhibits; and we are hopeful that this, in the hands of a regular attendant, will prove of mutual advantage.

We have thought of circulating pamphlets on the value of honey, &c., of exhibiting wax, and some of its useful purposes; indeed, the field is such a large one that perhaps in our anxiety too much may be attempted. At the same time, it is my brother's desire and my own to make our exhibit as interesting as possible, and we will be highly pleased to receive any further suggestions from bee-keeping friends, and any samples which may be forwarded.

As goods must all be inside the exhibition by April 15th, we hope all who have any desire to assist in adding to the interest of the exhibit will communicate with me at the earliest opportunity.—EBENZER McNALLY, *Main Street, Rutherglen.*

SHOWS AND RULES.

[1540.] I am quite aware of the trouble and thought the various Associations have taken in framing the rules applicable to shows and exhibitions, but occasions arise from time to time when slight modifications should be made as to carrying them out strictly to the letter. Rules are binding, otherwise it might be argued, what is the use of them if they are to be enforced in one case and overlooked in another. In the latter we certainly have a very strong precedent in a notable South Kensington Exhibition, where particular rules were most rigidly observed in some classes, and certainly ignored in others.

My remarks in this letter are chiefly to point out certain errors which must creep up from the enforcing in all cases the following:—*No cards other than those provided by the Secretary, label, trade-mark, or name of the exhibitor, can be placed on any part of an exhibit*—a splendid rule under most circumstances, but very hard in others. When this rule was framed it was to do away with a great evil, names, or any mark of ownership, being a great bother to judges in the classes for hives, sections, feeders, extractors; also honey, extracted or comb, &c., &c., as all these come into competition with similar exhibits of their kind, and are judged not only on their merits, but in comparison with others of their sort. Here the rule is of the greatest service. But, now, in classes for new inventions, since the rule was drawn up, articles of all kinds in which the products of the apiary form a prominent part of their manufacture, are admitted in these classes, and it is here that modifications should be made, and all must see at a glance that it would not only be an assistance to the judges in arriving at their decision, but it would also be disposing of an injustice to exhibitors. My twofold reasons are these: First, such exhibits are judged exclusively on their own merits, regardless of other exhibits in the class, and it is certainly wise that here judges should know something about what they have before them. I could bring forward a long list, but two well-known articles will suffice for explanation—'Mella' and 'Api-fuge.' Fancy a bottle of the former shown without a label; the judges might imagine it was a new wash for the face, or an antidote against stings, &c., and would not venture to taste it. Then the latter might be thought a cure for foul brood, or a solution for other purposes. Here, for want of a label bearing description, &c. (*a name is a trade-mark*) exhibits would be passed over. Then, as to the hardship on exhibitors in this branch, not allowing description cards, &c., to appear during the show. Persons are placed at a great expense in exhibiting. Their things help to make up the show, and further illustrate to the public the great value of honey in applied forms. If the rule is enforced, exhibitors are prevented from making their inventions known, and the various exhibits to the mind of the public appear like a meaningless collection of bottles, tins, jars, &c. Anybody can see that a hive is a hive without a label, but a bottle of 'Mella' without a label might be anything.

The remedy is very simple, and is, I believe, practised by some societies. That exception is made to the rule when the exhibitor previously to the show explains to the Committee that his exhibit is of such a nature that it cannot be exhibited without the regular label and a descriptive card. Or, on the prize schedule a note might be inserted that the rule will not be strictly enforced in a certain class or classes. By the first of these suggestions the Committee could have the descriptive card submitted for their approval, and prevent the show being converted into a bill-posting station. But I am firmly of the opinion that if something is not done at once to avert this, many valuable exhibits will not appear, proving an injury to our shows and the industry at large.—EXHIBITOR.

GRANULATED HONEY: WILL BEES LIVE ON IT?

[1541.] In the spring of 1883, Mr. Garratt, Secretary Kent B.A., paid a visit to my apiary. In going over the stocks he pointed out to me that I had over-fed. I removed the combs, four in number; as they contained sealed sugar, syrup, and honey, they were not extracted from, but kept in a dry place till autumn, by which time they were complete solid blocks of granulated store; my stock, likewise, being well found I had no need of them. At length I decided to get some condemned bees

and put on them, which I did, adding one empty comb. There can be no doubt as to the honey being granulated, as the fact was proved when I cut winter passages, which I did before putting the bees on them. I fed them with 3 lbs. sugar syrup, slowly, until the queen commenced to lay, after which they were packed up well and never touched till Good Friday, 1884. When they were opened they were equal to any stock in the apiary. An artificial swarm from them gave 40 lbs. in Stewarton supers; about 15 lbs. granulated store, *i.e.*, honey and syrup, and the 3 lbs. liquid syrup carried them through.—PLATELAYER, *Ruckinge, Ashford.*

GRANULATED HONEY.

[1542.] A reader of your *Journal* was last week inquiring if granulated honey was good for bees. I have not had more than eight years' experience, therefore my opinion must be taken for what it is worth. I have found bees do very well on granulated honey, but not in cold weather. In April, when the weather is warm, I have known them do well on it; but they carry a great deal of water into their hives while consuming it.—CHARLES EYLES, *Boc, Wilt.*

IS GRANULATED HONEY GOOD AS FOOD FOR BEES?

[1543.] Your correspondent 'Inquirer' (1522), in *Journal* of the 8th inst., appears somewhat perplexed, and speaks of the rather confounding opinions given in previous *Journals* as to the good or evil which might result from feeding bees with honey that has become candied or granulated in the comb or otherwise. Presuming 'Inquirer' to be, like myself, an amateur, though I might hope a less aged one, anxious of learning as much as possible, and desirous of avoiding any mishaps, I am not much surprised at his putting his question, which, as I read it, simply means, which of the 'doctors' advice is best to follow?

It just occurs to me 'Inquirer's' question would have been a very suitable one for your 'Selected Queries,' when possibly we might have had the benefit of reading the able views of our specialists. I observe, however, in your editorial note to 'Inquirer' you solicit the views of your readers upon the question, which is certainly an important one, so that I hope to have the pleasure of seeing a good response in next issue.

On glancing over what has been written, I am inclined to think the very decided opinion expressed by our valued friend, 'Useful Hints,' opens up a broad question, not only of the natural food supply for bees, but also the internal working of the hive, whereby none other but liquid honey shall be available to the bees, which means all honey left in the hive at the close of the season must be so preserved as to keep it from becoming granulated. Now I judge that most bee-keepers follow the good and oft-repeated advice you give, and leave abundant supply of natural store when packing down at the close of the season; but then if any portion of such store should become granulated, and is to be condemned as unsuitable food for the bees, the question arises what is the best and most simple course to adopt. In most cases when I have found stocks dead with store in hive, the store has been of that hard sealed nature so often found in old combs, and which at a low temperature bees are unable to remove. Here is a point too often overlooked when packing down for winter, and it would be well not to gauge supply by store thus sealed, all such sealed store should, in my opinion, be uncapped at the close of the season when the bees could remove it and re-seal it so as to make it convertible.

In venturing to advance my own opinion as to granulated honey being suitable food for bees I may say that

I have long followed the practice of using any candied honey I may have had for the purpose of feeding (first uncapping it) and without ever having noticed anything which led me to conclude that such food was injurious, therefore I do not consider there is the least to be feared from bees feeding on honey that has become candied in the comb in the hive, nor of feeding bees with honey which has become granulated in the comb that has been removed from the hive at the close of the harvest, provided such combs have been kept dry; nor is there any risk of injurious results from feeding bees with extracted honey that has become candied, most will admit that sound liquid honey is the *best food*; doubtless there is some danger in feeding with extracted honey that has long remained liquid, as such is so often topped with partially fermented honey. *Caution* in this case must be the watchword.—R. R. GODFREY, *March 12.*

GRANULATED HONEY AS FOOD FOR BEES.

[1544.] In compliance with the request of the Editor of 'Useful Hints,' I wish to say that he is quite right in what he states regarding those 'cold slabs of granulated honey' being unsuitable food for bees, but it is not through granulation so much as through fermentation having set in and partly changed what before was excellent food into the poisonous substances alcohol and carbonic acid. I do not think any of us would find our health improved if we found our wine and beer changed into vinegar and were compelled to sup it. However, bees can put up with a good deal, and if the weather be sufficiently warm to enable them to get water to dissolve the hard granules, they will not perish for want of food with plenty of these 'cold slabs of granulated honey' in their hives; in cold weather they will starve on it.

'When honey is extracted and granulates'—may I suggest that the word 'solidifies' be used instead of 'granulates,' when honey assumes the 'set' condition?—F. BOXES, *Beverley, March 12th.*

'BEE-KEEPERS' ADVISER'—DISPOSING OF HONEY.—DIPLOMAS.

[1545.] Allow me to congratulate you on your 'new departure'—the *B. B. K. Adviser*—a copy of which reached me a few days ago. It should prove most serviceable to the class for which it is especially intended.

I have been intending to write to you on many points for the last six months, but have let the opportunity slip, and now it is needless to refer to subjects which have been fully discussed in your columns. Some time ago there were several letters complaining of the difficulty of disposing of honey, and generally of making sufficient profit from bees to pay for labour expended. To judge from my own case, I should advise beginners never to despair. For a long time I could not obtain a really satisfactory result, and fancied that your own exhibits and those from Scotland (I am speaking of twelve or thirteen years ago) were due to better pasturage for bees, &c., and, in fact, everything but *my* want of skill. Time went on, and I began to know my subject better, and then my honey 'tale' began to improve; and it may interest a correspondent of yours, who has been lately writing from a south country town, that in a neighbouring county to his, in the first year that I was really successful, I made more than 24*l.* from eight hives. Of course it will be said that at that time the price of honey was much higher than it is now: this is true, but, on the other hand, bee-keeping is a hobby of mine, and therefore the sale of honey, though a satisfaction, is not of vital importance to me. I have never had any trouble in disposing of honey (my experience is almost entirely with sections), and this I attribute to being very careful to

clean up sections nicely, to taking off the honey just at the right time, and to other things which experience shows conduce to a section being considered quite 'first-rate.' A second-rate section will never repay the producer. All this leads me to think that bee-keepers should not despair, though they fail at first.

Certainly, now-a-days, it seems that a person thinks himself a bee-master as soon as he gets a hive with bees and has obtained a few hints from experts, advisers, or bee-books, which were wanting twenty years ago; but knowledge of this sort must be supplemented by practical experience before an apiary can be expected to pay its own way.

An allusion, some time ago, by one of your leading contributors to honorary diplomas from the B. B. K. Association reminds me of a conversation I had once at a county show. I was watching an examination for third-class certificates, and was making some remarks to a bystander, when he posed me by asking if I had a certificate. I had to confess I was going to wait until one was given me, but my position as an 'authority' was at once gone. Honorary awards would, I think, raise the value of certificates in the eyes of the world; though I know it would be difficult to make fit selections, and it should be done very carefully.

One of Messrs. Abbott's new sections has been submitted to me. Though the improvement is *seemingly* slight, the section is essentially different from any I have seen, and I think it is as perfect as any one-piece section is likely to be.—EAST GRINSTEAD.

PAINTING INSIDE OF HIVES.

[1546.] I have painted inside of my hives for years and never experienced the slightest difficulty arising therefrom. One of mine was rather damp in January, I simply slipped a couple of thin stones (that being first thing to hand) between hive and floor-board, lifting it about one-eighth of an inch. I take it a hive is as likely to get damp unpainted as painted, the only difference being, in unpainted the moisture sinks into the wood, in painted runs down to floor-board, which, if raised soon dries. After using an unpainted hive a few years, how dark the wood gets and how difficult to thoroughly clean. Painted hives wash easily, and can have another coat of paint, which makes them as good as new. That is the opinion of a—NORTH DEVON RUSTIC.

PAINTING THE INSIDE OF HIVES.

[1547.] The description given by Mr. Adcock (pp. 143, 144) of his hives satisfies me that the internal wet from which his bees suffer and die is not caused by the inside having been painted. My bees have got on very well for eleven years, and so Mr. W. Carr writes have his for thirty-five years, in hives the insides of which are well painted. But Mr. Adcock makes a hive with the floor-board constructed as a veritable swimming-bath, which is certain in winter to get filled with a depth of three-quarters of an inch of water. No wonder his bees get drowned. I should as soon think of arranging a watertight floor for my fowl-house in which if six inches of water chanced to get it could not escape. If it is absolutely necessary in order to feed up condemned bees to have such an extraordinary feeder, the big float should have been left on when the feeding was over, and the poor bees could have had a chance with it as a lifeboat.

Mr. Cheshire says: 'The floor-board should gradually slope towards the "mouth,"' a principle on which I have always acted in making and arranging all my hives. Then the damp that condenses on the side walls at once runs off, and escapes by the flight-hole, where on such days as yesterday (March 16th) the remains of it were to be seen in the form of an icicle at either corner of the

alighting-board, just as Mr. Carr described his, whilst all within was snug and dry. As I mentioned in my letter on this subject in the *B.B.J.* for last year, bees varnish the insides of straw skeps, and render them impervious from the inside to damp, and I have examined a skep occupied by a strong colony during such a black frost as we are now experiencing, and the sides had a thin coating of ice where the moisture had condensed. The moment a change of temperature came this would dissolve, and instantly find egress at the flight-hole.

If Mr. Adcock will refer to Mr. Cheshire's work on Bee-keeping, which I quote from as being the latest and most complete work on the subject, he will find that two to four inches is much too narrow a flight-hole, especially when there is no possibility of the slightest upward ventilation in winter. I always afford mine the full width of nine inches by a quarter of an inch all the winter. At p. 530 of Vol. II., Mr. Cheshire writes:—'Bees stifled by contracted hive-mouths, and the careful closing of all apertures above, are in the condition of coke in an Arnott stove with the draught-hole closed. The process of heat-production cannot go on, and the bees, stupefied by carbonic acid, possibly drop from their cluster to die.' This, I believe, explains the lamentable mortality among Mr. Adcock's bees.

After reading what has been written on the subject, and comparing it with the results of my own experience, my advice to bee-keepers, in order to secure dry and sweet insides to their hives in winter, is:—1. Have your floor-boards gradually sloping towards the flight-hole; 2. Paint well the insides of your hives; 3. Give a flight-hole in winter of nine inches long by a quarter of an inch high.—H. W. LERT, M.A., *Aghaderg Glebe, Loughbrickland, Co. Down.*

HORNETS AND WAX-MOTH IN PALESTINE.

[1548.] All southern lands abound with hornets (*Vespa crabro*), especially such places as afford good nourishment. They thrive well in Palestine, living on carcasses and on fruit. Hornets live in communities like the bees. In spring the queen, the only surviving individual, comes forth from her winter quarters—in the stem of a tree, old house, &c.—and takes possession of either an old nest, or starts building a new one, in walls, fissures of rocks, or in the ground, which she digs herself by carrying out small stones and clods; she has to do all the work till the first young ones are out. Having prepared a fit place, she builds her first comb horizontally, the lower part only having cells; she lays as many eggs as she can easily care for, and flies out to carry home food for her brood. The first workers appear in June; as soon as they appear, the mother remains at home, having no more work left but that of laying eggs. As the workers increase, fresh combs are built one below the other, attached to the top comb by a stout central column and by a lesser side column. All is built of mud and some woody fibres; some combs are as big as fifteen inches in diameter, and five or six combs are often found in one nest. Sometimes in August they have grown to be very dangerous to the bees, and will destroy apiaries wherever they get a chance to enter the hives. In September they lay drone eggs in the same cells in which the workers were hatched. New combs for queen-rearing are now built; the cells are a deal larger, and very often these combs are superior in number to the worker-combs. In November all workers are gone; the drones too, having fecundated the queens for the following spring, disappear. This is a good time to destroy numbers of queens at a time. We destroy every hornets' nest we can get hold of by putting fire to the entrance; and if in the ground, open the nest by degrees to get out every one of them. Naturally enough this is done by night, as it would be impossible to attempt disturbing such a nest in the day-time, as the hornets which are out would attack you, and their long sting penetrates even through

the clothes. The badgers, too, help us by invariably digging up such nests as are accessible to them; they open the hives, too—it is the brood they are so fond of. Happily the hornets do not develop equally strong in every place, nor in every season. In 1885 and 1886 the Plain of Sharon was full of their nests; in 1884 and 1887 the mountains of Judea (around Bethlehem), whither we take our hives for the thyme-blossom in July, were full with them. Some parts near Jerusalem are quite rid of them: it is there we resorted with our apiaries. Mr. F. Benton and myself killed numbers of hornets daily at Beyrouth (Syria) in 1882. The method we then employed was by taking a board fit to handle and striking them as soon as they attempted to take the bees gathering at the entrance. Last spring we killed innumerable numbers of hornet-queens, still the development was very strong.

In 1886—a very favourable year for hornets here in Jaffa—I put down in my diary—'Hornets killed: Sept. 30th, 2582; Oct. 1st, 608; 2nd, 903; 4th, 104; 5th, 2604; 6th, 2637; 7th, 3352: total of seven days, 12,790.' Does not your correspondent (page 93) say:—'In a whole year nearly 400 hornets were killed round the hives?' Hardly worth the trouble to talk about hornets! I did not note the hornets killed either before or after these seven days marked, but during two long months have I been troubled with them sufficiently, and have taken to every possible remedy: firstly, by killing them by thousands almost daily; secondly, by the 'Palestine dodge of smoke' (a very good one, too); thirdly, by closing the entrance of hives—the bees themselves had no objection to being shut up from morning to just before sunset, when I used to give them a chance of having a flight; and fourthly, by putting hives with combs and honey (no bees) open to attract hornets; by this method I sulphured on one occasion over 500 hornets that had gone in to get the honey, repeating the same again and again the same day. Another good method to observe is to kill every hornet flying about from March to June—they are the queens; are much bigger than the workers, are very easily recognised, especially later on when some workers begin to fly. By striking a queen dead at that time a whole nest is broken up. After that time they no more appear till November. A few hornets killed here and there almost make no difference to bee-keepers, as I can well assert, for, after having killed 12,790 hornets in seven days, besides having killed just as many, or nearly so, weekly during five or six consecutive weeks, I hardly noted the difference. I suppose Malta is very much in the same conditions for bee-keeping as Palestine, as we read of orange, karob, and thyme blossoms, also the way the natives keep their bees. We have single-walled hives, one inch lumber, ventilating holes, two on each side of the hive, which are made especially for the moving to and from the mountains in June and November. We depend on orange-blossom in April, cactus in May, thyme in July, the karob is too scarce to afford any crop. Our hives are unprotected from the sun, and though the thermometer goes as far as 95° Fahrenheit in the shade, we never knew any full-built and heavy combs to drop from the heat; fixing the comb-foundation with fat or waste-wax, to keep as long as the bees have not fixed it, has no effect whatever on the built-out comb later on, as it is fastened enough by a strong colony of bees. The bees now begin building foundation combs, which we fix in the nailed frames. We have about fifteen thousand frames in use, they are made of Swedish pine-wood and never warp; they will hold as long as the comb is well preserved from the wax-moth, a very serious enemy, which has to be combated by putting in air-tight hives or boxes all surplus combs, and sulphuring them once a-week at least during the first month, and once a fortnight in the following two months, then once a-month till the beginning of January; they are, then, almost safe, still occasionally looking for them.

The wax-moth will eat up and utterly destroy any number of combs not sufficiently separated, *i.e.*, hang them two inches apart from centre to centre, and light a piece of sulphur, put in some old plate and hang or put it in a free space inside the store-hive or box, shutting it tightly to have the combs well impregnated with sulphur. Water is absolutely necessary (for bees) to be provided for in such places as where fountains or pools are absent; a few hives are easily supplied with water, and bees find their way to get water, any hour, in an inhabited place.

We now freely give stimulative food to prepare for the orange crop, which is coming on very soon, in fact, too soon to have the colonies sufficiently strong to get surplus by letting them develop naturally.

We are five brothers, and own 680 bar-frame hives all in one place; we move all on camel-back, each camel taking eight hives.—PH. J. BALLENSPERGER, *Jaffa, 7th March, 1888.*

CONSANGUINITY. (1520).—VIRGIN QUEENS.

[1549.] If 'A Cottage Amateur' has never tried keeping a frame of eggs away from a stock in a July temperature, a 'Platelayer' has, with the result that the eggs hatched, at least most of them, into dwarfs, cripples, stingless, wingless insects. Of course the experiment with me was accidental, and I am not likely to repeat it.—PLATE-LAYER, *Ruckinge, Asford.*

EGGS BY POST.—CONSANGUINITY.

[1550.] In my letter (1520) occurs the following passage:—'A Cottage Amateur' has never tried keeping a frame of eggs away from a stock for forty-eight hours, even in a July temperature, or he would know that it would be equivalent to keeping a hen off her eggs for forty-eight hours, and then expect them to hatch.' These observations we made upon the strength of two circumstances that came under my notice during the last season, and were as follows: Upon removing some frames containing brood and eggs from two hives, at different times, one was in each case inadvertently allowed to remain behind the dummy-board until the following day; having replaced them in the hive, I found that the fertility of the eggs was destroyed, they failed to hatch. I think that such a position during July or August would be found warmer and of a more equable temperature than that which would be experienced in sending them by post where, perhaps, the mail-bags may be placed in a direct draught from under the doors of a train, perhaps travelling at the rate of forty or fifty miles an hour, which would materially reduce the temperature; or being carried in early morning a few miles on the back of some rural postman; or, perchance, lying for hours in a cold post-office. Of course it is quite possible to send eggs if they are, by artificial or other means, kept warm during transit. When reading Mr. Edey's letter upon the above subject, I fully understood him to mean sending frames of eggs together with adhering bees, and which I now believe he means.

During the coming season, if any bee-keeper will remove a frame of eggs from a hive and allow them to remain exposed to the variation of temperature which must be experienced even in July for forty-eight hours, he may safely depend upon their failing to hatch.

If our friend, Mr. Boyes, will inquire, he will find that Mr. Bate's, and, in fact, all pedigree herds, were not *produced* by in-and-in breeding. Consanguinity is resorted to by pedigree stock-breeders—which I have before pointed out—not to *produce* a variety, but to perpetuate certain features in a herd at the very frequent expense of stamina. He will also find that all herds are recruited from time to time by the introduction of fresh blood of the same variety from other herds, in order to prevent the ill effects of in-and-in breeding. I have advocated a

cross to improve our bees, not to go 'jog-trot' on the same lines as of old. If we can improve our stock—and we most certainly can—why not do it?

Mr. Woodley's advice, in the first part of his letter (1534), to all, to write what they have a knowledge of, is truly rich, when in the last paragraph he writes the absurdity of a crab-apple producing a 'pippin' by grafting. Allow me to inform him that it is the scion that produces the 'pippin,' and this scion has been produced by cross-fertilisation before it was grafted to the crab stock, the crab stock would only produce a crab if allowed to produce anything. Grafting is a means of perpetuating a variety already produced that it may be of greater utility to the owner.—W. B. WEBSTER.

JOTTINGS BY WOODLEIGH.

[1551.] I think my letter (No. 1534, par. 6) will answer Mr. 'Useful Hints' in his paragraph 'Olla-podrida,' where he animadverts to my previous letters on consanguinity, he will see that I do not advocate in-and-in breeding. The object of my writing was to allay any fears that the theories of Mr. Webster may have raised in the minds of some bee-keepers, and to prove that his opinions in the declining prosperity of the two cases cited by him must proceed from some other cause than in-and-in breeding. Mr. 'U. II.' has kindly given an extract from a letter in Vol. V., p. 11, *B.B.J.*, by 'A Renfrewshire Bee-keeper.' Evidently our Scotch friend was not conversant with methods adopted to keep his stock pure, or he would not have had to bewail only one instance of pure impregnation during many years, and which he imputes to chance by having an unfertilised queen at the head of one of his colonies. How different from the results obtained by a great master in the bee world, the great Dr. Dzierzon, who exhibited the *finest* amongst many *fine specimens* of queens at the Congress of Austro-German bee-keepers that year, 1883, (*vide* Vol. X., p. 271, *B.B.J.*) and asserted by Dr. Dzierzon to be a *direct* descendant of the first Ligurian stock brought into northern Europe thirty years before. Here is an instance of one of the first masters in bee-culture in Europe keeping his race of bees pure.

As an instance of how easily bee-keepers are alarmed by recognised teachers, take the case of 'Inquirer' (1522). Here we have a bee-keeper with a stock of natural food on hand, probably crystallised sections, and afraid to give it to his bees because Mr. 'U. II.' says it would be injurious, yet a fortnight later our Editor says it is not injurious to bees, *i.e.*, granulated honey. No wonder a new hand was in a quandary over the matter, but if he thinks my advice worth following, I say give the granulated honey to your bees. If in sections place two together with glass on the outside, secured as in glazing your sections for market, place over the feed-holes of your hives, then wrap up in some soft, warm material; and if your colony is strong they will soon clear out the honey, leaving you the combs beautifully clean, and ready for refilling in June. I myself have been feeding as above with sections that were solid by crystallisation, and have not seen the slightest sign of dysentery, and my bees have utilised every scrap of honey in the sections.

It is only a reasonable deduction that if bees can reduce hard cakes of crystallised sugar that they will be able to liquefy crystallised honey; and if honey so soon granulated, that is gathered from the seed-farms of Cambridgeshire, the bees in that locality must live on hard slabs of crystallised honey the year through.

I trust bee-keepers will take the hint of Mr. Griffin (1524) *re* the *Railway Rates* for honey. It will be by concerted action in the matter that we shall be able to make our influence felt, and with the many patrons of bee-keeping who figure in the various reports of the County Associations, we ought to have any amount of

influence if the matter was brought before the different Railway Companies by some of our patrons and supporters.—WOODLEIGH.

FRESH BLOOD.—ITALIAN BEES.

[1552.] If 'Useful Hints' does not eventually turn all our bees into Italian hybrids it certainly will not be his fault, judging by the persistent manner in which he extols his favourite Ligurians in the *Journal* and denounces our native bees; indeed, he seems never more happy than when lauding the praises of the former and blackening (no pun, please) the latter.

Now, valuable as his instructions undoubtedly are on most other subjects, on this particular one it seems to me his enthusiasm gets the better of his judgment, and he allows his hobby to run completely away with him. Don't be alarmed, please, Mr. 'U. II.' I am not going to condemn your favourites, only to point out what to me seems like a little inconsistency in your last week's contribution on this subject, which is this, that you allow Mr. Webster to give two cases of supposed degeneracy through isolation and interbreeding without a word of comment; but no sooner does Mr. Woodley bring forth two other cases to show that no bad results had followed isolation and interbreeding, than you at once come down upon him 'like a barrow-load of bricks.' I always thought that 'what was sauce for the goose was sauce for the gander;' and there is no other reason for supposing it otherwise—except that the one case was favourable to your argument and the other was not.

What 'A Renfrewshire Bee-keeper' found out in regard to his Italians crossing with the surrounding native bees, and what you yourself advance on the same subject, is perfectly well known to be true, and to be in accordance with that general law which not only enjoins, but provides for, the crossing of both animals and plants, and to which I alluded on page 145 of last week's *Journal*; but it is not necessary that the cross should be of *foreign* blood, any more than that an Englishman should be compelled to go abroad for a wife to prevent consanguinity. All those bee-keepers have to do who keep our native bees, is to get some driven bees or queens from a distance (and I have gone and driven bees as far away as thirty miles on purpose to get a cross), and there will be no fear of too close interbreeding.

I have been most particular to make inquiries that no foreign bees were kept within ten miles of where I have got my cross. The very name of foreign bees is distasteful to me, because I cannot find out that the foreigners take any pains to cross their bees or in any way improve them, but concentrate all their energies on producing queens in large numbers so as to reap the rich harvest of English money which awaits them; not only so, but the disastrous results from foul brood, which followed the introduction of Italian bees into the apiaries of Mr. Woodbury and others, should make us pause before placing such a terrible curse amongst our bees.—F. BOXES, *Beverly, March 19th.*

Echoes from the Hives.

Vaison, Vaucluse, France, Mar. 10.—We have had a long and severe winter, but the last four days have been almost like summer, and my bees seem almost wild with joy! This afternoon I noticed pollen was brought in large quantities; the bees were so laden that they could scarcely crawl in through the surging mass of young bees at the entrance. I should say quite thirty bees came with pollen every minute. Our hills are covered with box-trees, or, rather, shrubs, which are just coming into bloom; and a little later on there will be hundreds of peach, apricot, cherry, plum-trees, &c., in blossom. We have also acacias and lime-trees, and wild thyme

abounds everywhere, as well as wild mint and sage. Near our house there are several fields of sainfoin and lucerne. Do you think these ought to yield the best honey? What I had last year was most fragrant, and had a delicious flavour; colour, pale amber. I am a novice, and having no one here to help me, bee-keeping being in its infancy (brimstone is the fashion), I have to learn by reading and practising to the best of my ability (a poor best at present). I much enjoy reading the *B. B. Journal*, especially those passages relating to the early experiences of bee-keepers. I have only one stock at present. It was a first swarm last May; consequently, the queen is in her third year. As I cannot replace her, I shall have to make an artificial swarm, and let the bees raise a new queen in one hive, but I am puzzled how to manage about the other, if I have to destroy the old queen. I have not been able to see her majesty yet. Yesterday I tried my very best, but the combs were so covered with bees I failed to discover her. One frame was so heavy I had to rest it on the edge of the hive, and while reaching for a knife which had fallen beside me, the frame slipped from my gloved fingers, and down went frame, brood, honey, and bees! I never looked, but fled to the house before the infuriated bees had time to recover from their surprise. Shortly afterwards I was thankful to see they did not seem much the worse for the shock they had sustained. I have bar-frame hives (Abbott's); in time I hope to have some like Mr. Cowan's, as illustrated and described in his book. All the hives here consist of four planks nailed together, which form a box about ten or eleven inches square and five feet high; two cross sticks are placed in the middle. The bees are not fed, but are suffocated when the honey is taken. All our neighbours laugh at me, and evidently think I am a harmless lunatic, but I do not intend giving up such a delightful pursuit, especially after having been stung so many times. This place is twenty-seven kilometres from Orange. It is very hot in summer, and very cold in winter; we have so much north wind, which, I suppose, is very bad for bees.—BLANCHE G.

[*Artificial Swarming and Raising New Queen in Old Stock.*—First divide your stock, ascertain which portion has the old queen, taking care the swarm has two frames of sealed brood almost ready to hatch, and one frame of eggs, which can easily be obtained in one of the frames with foundation, about twenty-four hours after it has been inserted in the old hive. Wait until the new queen has commenced laying in the new hive, say, thirty days, then destroy the old queen, removing all frames with larvæ to the new swarm, but leaving eggs in the old one; they will then raise a new queen under the best conditions. In both cases, insert a frame of brood, not sealed, into the hive where the young queen is about to hatch out. This should be done about two days before the queen appears, and at the same time destroy all queen-cells except one. You would be doing well to purchase a new queen for the swarm. *Honey Supply.*—We very much doubt if your prospects of obtaining good-flavoured honey could be much better than they are. We should be pleased at any time to receive notes from you on any local system of bee-keeping, and also to assist you in any way. We regret your accident, and hope the bees did not lose their queen.—ED.]

Tinahely, March 13th.—Herewith find postal order as my subscription to your *Cottage Bee-keeper*. It is quite a boon to the agricultural community, and will (in Mr. Cowan's hands) 'be up to the times.' Our Poor Law Unions here are asking Government to give each of them 100*l.* annually as prizes for well-kept farms, best bulls, minor industries, such as fruit-raising, bee-keeping, and poultry-farming. I think your people ought ask a like grant, as well as a Minister of Agriculture like our Colonials. Bee-keeping is spreading well here, but our

medical friends don't advocate well enough 'honey as food.'—J. TRAYNOR.

Alton, Hants, March 15th.—To-day the weather is warm. The bees seem very strong and very numerous. They are working on the crocuses. The weather has been very serious for bees this winter. Being so warm in January some of them started brood-raising. I find one of my stocks, a very weak one which started brood-raising, the whole lot are dead. It was a weak lot last season, the queen being lost or killed; they raised a new queen in place of the lost one, so I had been watching this stock to see its progress, when, to my dismay, I found the whole lot dead, with plenty of food.—F. G. AYLING.

Goole, March 17th.—During the past week we have had a return of severe winter weather, snow and rain having fallen rather heavily, accompanied by keen frosts during the nights. It has been blowing a gale most of the week, from the north and north-east. We are wishing for a fine, warm day, to enable us to examine two hives that we have some doubts concerning the queens.—A. WOODHEAD.

Forfar, March 19th.—We have had a severe snow-storm here, which has put a stopper on everything. Crocuses would have been in full bloom by this time if the weather had kept as warm as it was before this came on. Bees were flying as it was, but I saw no signs of pollen being got. My bees were out yesterday too, and I had to shade the front of the hives with boards. I saw many of the bees lying dead on the snow, and many of them alighting on it. Food is getting scarce in many hives, and I have had to feed several of them some time ago with Saddler's candy, the first allowance of which was soon eaten up. I may mention that the whin (gorse or furze) has been in bloom here the whole winter. I found it in bloom at the seaside in November, and since that time here. Wishing you all success.—D. KYDD, M.D.

Streetsville, Canada, February 27th.—Our bees in this locality seem to be wintering pretty well up to date, but the trying time is to come yet, as bees that are in the hives now were hatched last July and August principally. There have been a few days this month that bees could fly in this part of Ontario.—W. COURSE.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

M. D.—Moving Bees.—Move them back about three feet every evening of such days *only* that the bees have been on the wing. Set a piece of board to lean against the front of each hive so that the bees may mark their new surroundings. Had you moved them, say in November or December last, they could have been shifted to their new stands direct.

INQUIRER.—Salicylic Acid added to Bees' drinking water.—It is highly improbable the bees would avail themselves of your kindness.

D. M.—1. Disinfecting Suspected Combs.—We should prefer the spraying as much as possible for the simplest plan, but, considering the present price of foundation, it is positively unwise to use any combs about which you have any suspicion. **2. Wiring Frames.**—Certainly the bottom rail will bend if you put any strain on it by drawing the wire tight. We hardly understand how your wire slacks if you have your block the right thickness under the foundation. We also refer you to page 256 of *B. B. J.* for 1887.

KINGSTON.—*Phenol in Drinking Water.*—The bees will not take it while they can get pure water.

J. R.—1. *Granulated Sections.*—Cannot be restored to their original consistency. 2. *Storing Comb Honey.*—We presume you mean sections. They should be packed away from the light, and kept at an even temperature of about 65 to 70 degrees. See recent article by 'Amateur Expert' on this subject.

J. RODO.—*Management of a Bar-frame Hive.*—Hive a swarm on, say, five sheets of foundation. As soon as the outside ones are being drawn out, add a fresh frame with foundation in the centre of the brood-nest. Give full sheets of foundation unless you have a honey-flow at the time of hiving the swarm; if so, give $\frac{1}{2}$ -in. starters only, place queen-excluder on the frames, and a section rack with full sheets of foundation on top at once, cover up warm, and place on stand of parent stock. Watch that they do not run short of food if the honey-flow suddenly ceases. Seven frames of brood only will give the bees a better chance of storing a surplus than ten. Give the other three at the front with starters only; they will only build them then as they require them. We have found eggs laid within twenty-four hours of hiving a swarm, although the comb had to be entirely built by the bees without the aid of foundation. Unless you have exceptional advantages, you ought to get your sections finished and removed by the beginning of August. About six frames are sufficient for an ordinary stock to winter on. There should be about twenty to thirty pounds of either honey or syrup in these frames for winter store. We should advise you to study Cowan's *Guide*, also the back numbers of the *B.B.J.*, from which you will get much help. We will be pleased to help you at any time.

W. M. E. L.—*Will Strange Stock Fight?*—You need not fear to move your bees to the farm, neither need you fear they would kill any swarm you might buy. Bees are most peaceable folk. Ten shillings for a first swarm in May is very reasonable. Second swarms of course are not so valuable as first swarms, but local circumstances *must* determine local prices. No doubt if you take all swarms the farmer may have, you will find no difficulty in arranging the price.

T. N.—1. *Zinc over Feed-hole.*—Use tin by preference; you can easily punch some holes in it. 2. *Space below Frames.*—About half an inch is quite sufficient. 2. *Bees dead.*—Probably cold or starvation, but it is impossible to say for certain without either seeing the hive as you found it, or else having a detailed description of packing, relative position of dead bees, and their unconsumed stores, &c. 4. *Bees Killing one another.*—This looks like robbing. Try placing the hive mentioned in an entirely fresh position, and contract the entrance to about $\frac{1}{2}$ in. for a week or two until they get stronger.

C. M. P.—The sample of sugar may do for the bees, but you will not find it so suitable as Porto Rico.

NATIONAL CO-OPERATIVE FLOWER SHOW.—By an oversight, amongst the prizes to be given was omitted Turner's Cottagers' Hive, value 10s., presented by Messrs. Turner & Son, Radcliffe-on-Trent.

PRACTICAL WORK IN THE APIARY.

EXAMINATION OF HIVES.

The time has at length arrived when it is necessary to examine hives, so as to ascertain their exact condition. The weather hitherto has been so cold and changeable that wise bee-keepers have not disturbed their bees. Now, however, it is quite time to do so, that they may note the condition of their colonies, and be able to settle on the course to be pursued. Have everything that is likely to be wanted ready at hand, so as not to keep the hive open longer than is absolutely necessary. Although the sun may be shining on fine days, the warmth is deceptive; the air is chilly, and brood long exposed to its influence at this season is likely to suffer and become chilled.

Having everything ready, we remove the roof and quilts, or chaff-box, and subdue the bees either with smoke, or carbolic fumes, or carbolic-acid solution. If smoke be used, it can be administered by gently turning up the last quilt next to the tops of the frames, and by blowing in a few puffs at the ends of the frames. We prefer blowing in the smoke at the ends, because it will travel right along the passages between each of the combs, and will reach every part of the hive much sooner than if it strikes the face of the comb at the side of the hive. Pat down the quilt and allow the bees a few seconds to gorge themselves with sweets. Then turn over one side of the quilt, exposing one or two frames, and give the bees another puff or two of smoke before proceeding to examine them. We have also used successfully the carbolic sheet recommended by the Rev. G. Raynor instead of smoke, and bee-keepers will find its application very easy. The solution is prepared in the following manner:—

Calvert's No. 5 carbolic acid	1½ ounces.
Glycerine	1½ „
Warm water	1 quart.

The acid and glycerine should be well mixed before adding the water, and the bottle must be well shaken before using the solution. Bee-keepers should keep this solution always in stock, as it is useful not only for manipulations but also in cases of robbing. A piece of calico, or cheese-cloth, can be soaked in it, and after wringing it is ready for use. Before opening a hive moisten a goose-quill with the solution and pass it over

the alighting-board and around within the entrance. Then gently raise the quilt on one side of the hive and pass the feather moistened with the solution over the frames as far as the centre of the hive. Lay the quilt down gently, and do the other side in the same way. Then take off the quilt and lay the carbolic sheet over the frames. The carbolic sheet can also be applied without the use of the feather, by rapidly stripping off the quilt and laying the sheet in its place before the bees have time to recover from their surprise. Afterwards turn up the sheet and push the division-board on one side, so as to give plenty of room for the removal of the first frame. Take hold of the frame by the projecting ends, and carefully lift it out of the hive without crushing a bee. Then raise it to the level of your face and examine it. If the bee-keeper wishes to find the queen he must look very carefully for her, as at this season queens are very likely to escape notice, being much more active than they are later in the season. Both sides of the comb should be examined as rapidly as possible, and with a little practice dexterity will be acquired, and the bee-keeper will be able to turn his frames with the greatest ease if he carefully follow our instructions.

Having the frame on a level with your face, lower the right hand and raise the left until the top-bar of the frame stands perpendicular. In this position the same face of the comb will still be towards you, with the bottom-bar of the frame towards your left. Now give the frame a half-turn round towards the right. This will bring the other side of the comb to the front with the bottom-bar turned towards your right-hand side. Lower the left hand, which is at the top, and raise the right so as to bring the top-bar to a horizontal position. Now you have the top-bar at the bottom, the bottom-bar at the top, and the comb in the same place as it was hanging in your hands when first taken out of the hive. In this way the comb is reversed, and you are enabled to examine the other side. To bring it back to its original position, reverse the operation, always taking care to keep the comb perpendicular. This method of procedure applies specially to combs built in frames that are not wired, as of course combs that have been secured in wired frames are not liable to give way like ordinary combs. If an ordinary comb is only fixed to the top-bar and part of the way down the side-bars, as is generally the case, when this is turned up, unless kept in a perpendicular position, it is liable from its weight to break from its attachments, and fall out of the frame. After the first comb is examined, put it gently into the hive

and place it slowly into the rabbets so as to allow any bees upon feeling the slightest pressure a chance of getting out of the way. This frame is placed at the proper distance from the division-board, and the next can be taken out and examined in the same way. Examine the combs from outside to the centre, then cover them over and commence operations from the opposite side.

When all the combs have been inspected, remove those that are found to be superfluous, allowing the bees only as many as they can comfortably cover. Brood will be found in all strong hives. We examined some hives about a week ago, and found five frames of brood in one and six frames in another hive, there being enough bees to cover eight and nine frames respectively. These bees had been put into winter quarters in September, and not touched since. The centre combs had brood to within a couple of inches of the end bars, and there was a good deal already hatching out, and a great many young bees in the hive. Such hives are in good condition and do not require much attention, except a little stimulative feeding to keep them going. When all the frames have been replaced, push up the division-boards, put on the quilts and cover up comfortably. Go over all the hives in the same way, noting the quantity of brood, the number of frames in each; and if the queen has not been seen make a note of this also, so as to be reminded to look for her at a future examination.

Bees require now to be kept warm more than at any other time because the nights are very cold, therefore leave no more combs than they can cover. Be sure that the bees do not run short of food, or have too much, otherwise the queen will not find room to lay her eggs, and the development of the colony will be retarded.

The first examination should be done on a fine day; and if the bees are inclined to rob, late in the afternoon. Do not leave the hive open long, but keep it covered with the carbolie sheet, which will generally keep robbers at a respectful distance. Clean hives and floor-boards may be given to any colonies requiring them, although we prefer to defer this operation until warmer weather sets in, as it takes much longer to accomplish than a preliminary examination such as we have described.

PRACTICAL HINTS FROM COUSIN JONATHAN.

(Continued from page 150.)

Mr. G. W. Demaree says, those about to start bee-keeping on an extensive scale should select the most suitable location. Then he goes into the most difficult question of the

BEST HIVE,

which really means the one he is most used to; but he insists that hives must be light, substantial, and capable of being 'tiered,' adding the

'TIERING UP'

is essential to the largest yield of the best quality of honey. The best bees, he says, are the first crosses between the Italians and the blacks. To successfully winter and have stocks strong in spring, they must have

PLENTY OF STORES,

so that they require no interference till they begin to

gather honey and pollen in early spring. Then all upward ventilation should cease, as bees require plenty of water for breeding, and the moisture will do no harm, but, on the contrary, be an advantage.

SECTION CASES

should be put on before the bees have filled the brood-nest with honey, and partly built-out sections from the previous year should be pared down, till the cells are only half an inch deep, to give satisfactory results. He also advocates leaving the honey on the hive sufficiently long to be

WELL RIPENED,

and that all should take pains to build up a home honey-market, and not glut the great cities and towns and bring down the price.

Mr. Eugene Secor says, inferior honey is as great a bane to bee-keepers as adulterated. Most of the blame for the

INFERIOR HONEY

he lays at the door of the extractor in the hands of the novice and inexperienced, who instead of honey extract nectar. 'Instead of a rich, oily, aromatic delicacy, whose fragrant memories will linger long after the joy has passed, he has some sweetened water that will hasten to convert itself into vinegar, as if ashamed to attempt to counterfeit what it can never equal.'

HONEY TO SELL WELL

must be well ripened, and put up so attractively that the purchaser will delight to take it home when he or she has company to tea.

Dr. C. C. Miller has discovered that every producer should not only use

THE SIZE SECTION

that he can sell best, but stick to one size, and not change without a reason, nor try to work two or three different sizes. The doctor also writes about

OVERSTOCKING,

trying to settle the question as to how many stocks it is profitable to run in one apiary. He finds it hard to fix the number as there are so many factors to be taken into consideration, and at last sets it down as somewhere between 75 and 125 stocks—a pretty wide range, as he admits.

Mr. Henry Alley, *the manager*, as the editor of *Api* modestly styles himself, comes last. He also writes about overstocking, recommending bee-keepers to feel their way slowly into the capabilities of their district. He also gives a few hints about developing a

HOME MARKET,

which are very practical and well put. To find a veteran of thirty years' standing recommending experimenting need not surprise us, especially in the way of

IMPROVING THE STRAIN

of bees and building up colonies in spring. Foul brood, he says, 'stamp out' with merciless vigour—bees, combs, hives, and all, and start with a fresh lot of bees from a distance. The best

ARTIFICIAL POLLEN

for feeding bees in early spring, he says, is wheat-flour. He is unfortunate in being four miles from the nearest bee-keeper, as he recommends all bee-keepers

TO BE SOCIABLE,

and meet as often as possible, and talk over the best ways of wintering bees, marketing honey, the best hives, &c. &c., which certainly is the best advice that we can endorse in closing these lengthy extracts.—**AMATEUR EXPERT.**

USEFUL HINTS.

What more can we say of the weather? The chief topic of conversation—the one subject of which Englishmen never tire? and truly our climate affords just cause. But of late the extraordinary vagaries permitted by Æolus and other responsible deities have not been confined to our island home. Europe, even to its remotest corners, and America, the land of ‘blizzards,’ have been alike visited by ‘*Africusque, Eurusque, Notusque*!’ and blinding blizzards, with mountains of driven snow, have prevailed everywhere to the discomfort of all, and sounding, alas! the death-knell of many. And what about our bees in all this hubbub and turmoil of the storm-gods? Doubtless many a colony will fail to ‘put in an appearance’ when May with her floral inducements fain would entice them forth to sip her ambrosial dainties. For strong colonies, well provisioned, in strong, well-built hives, we have no fear; but the weak ones, located in the modern, cheap (?) ‘tuppenny-apenny-ives’ must assuredly ‘go to the wall.’ ‘Penny-wise and pound foolish’ is still too much the order of the day, which we fear many will find out to their cost. ‘Right here’ (Am.) let us ask a question: What is the derivation of the word ‘Blizzard?’ We have sought all our dictionaries—some half-dozen—through and through, and in only one (Nuttall’s) do we find the word given, and there its *meaning* only, *sic*: ‘A sudden, violent, cold snowstorm [U.S.]’ We ‘guess’ the derivation to be thus traced: Blind (blink, blinker), blinder, bludzer, blizard, blizzard—meaning literally a ‘blinder.’ Just as our word ‘blinkard’ means one who blinks, so ‘blizzard’ will mean a storm which blinds or causes to blink. Pardon the digression.

FEEDING, after the late severe weather, is of the utmost importance, and must not be postponed for an hour. Before the advent of this latter ‘cold spell’ bees had commenced breeding, and serious inroads had been made upon their store. Now, with many colonies, a supply or non-supply is a matter of life or death, and those which show in largest numbers on a bright, sunny day are probably as near starvation point, or nearer, than those which scarcely show at all. The more mouths the greater the consumption of food at this season. Often have we found our most populous colonies semicomatose—sleepy, sluggish, languid—and at death’s door in the months of April and May from the absence of food in hive and field. Let the food now be syrup, made from loaf sugar or granulated sugar of any kind, but it is not economical to buy the low-priced sugars. The following is a good recipe for syrup for spring feeding:—

White loaf sugar	5 pounds.
Water	3 pints.
Vinegar	1 tablespoonful.
Salt	1 "
Salicylic acid solution	1 "

The salicylic acid solution is prepared thus:—
 Salicylic acid..... 1 ounce.
 Soda borax..... 1 "
 Water..... 4 pints.

Mix with warm water, and shake well in a large stone bottle. Syrup should never be given without this solution, which is an effectual preventive of foul brood, generally speaking. Feed at the top of the hive, to prevent robbing. Any cottager may easily manufacture a bottle-feeder for himself. Take a block of wood, four inches square and one inch thick, with an auger-hole in its centre large enough to receive the mouth of an ordinary wide-mouthed pickle-bottle. Tack a piece of stout canvas over one side of the block, and place it (canvas side downwards) on the feed-hole. The pickle-bottle, filled with syrup, and having a piece of cheese-cloth tied over the mouth, is then inverted, and its neck

inserted in the hole in the block, and we have a perfect feeder which cannot leak, and from which the bees can take food as required. No shovel is required when inverting the bottle. An excellent food, used for queen-cages, and by many preferred to syrup for early spring feeding, is the following:—

Powdered sugar (confectioners’ ‘frosting’)	5 lbs.
Liquid honey (warm)	1 lb.

Well kneaded together for some time, until perfectly mixed. Two pounds, spread on cheese-cloth and covered with stiff paper, is laid on the frames, under the quilts, and will last an average colony about a week at this season.

Our advice is,—Feed all colonies, weak and strong. If there is a superabundance of honey in any hive, by uncapping a few cells now and then, turning aside the quilt, without further disturbance, the bees are as effectually stimulated as by syrup feeding. Pollen supply must be continued, as recommended in last ‘Hints,’ for which see ‘Manipulation’ also. Iteration of the same advice week after week is wearisome to all, and reference to late ‘Hints’ can always be made by those who file their *Journals*. For this reason, we are very anxious that every bee-keeping cottager should have brought to his door our monthly *Adviser* to keep for *his own*, and thus have it in his power to refer at any moment to any particular piece of advice or suggestion. We all know how much anything which we can really call *our own* is prized. What a touch of nature is there in the old nursery rhyme:—

‘Oh, pretty new doll, it looks fine,
 And its cheeks are all covered with red;
 Oh, pray, may it always be mine,
 And, pray, may I take it to bed?’

CHANGING HIVES.—When making the first spring examinations it is well, if the hives have been fouled by dysentery, to substitute clean, dry ones in place of the damp, dirty ones. This is easily accomplished, thus:—Remove the hive under examination from its stand—or stand and hive altogether, as the case may be—a few feet backwards, or sideways, and place the clean, dry, empty hive exactly where it stood. Smear the entrance of the occupied hive with carbolic solution and strip off the quilts, quickly replacing them by the carbolised cloth. Remove the frames which are unoccupied by bees, one by one, to the same position in the new hive as they occupied in the old one. Now you have the brood-nest alone left. Remove this bodily by placing beneath the ends of the frames pieces of lath, or strips of wood, and, carrying it to the new hive, insert it as it was before. We have often performed this operation on a fine evening in April without causing a dozen bees to take wing, and seemingly without the bees knowing that any operation at all had been performed upon them or their hive. Let the old hives be scraped, cleaned, and thoroughly disinfected by washing with carbolic-acid solution—1 oz. of acid to 1 pint of warm water—then dried, and placed ready for further use.

CONFINING BEES to as many combs only as they can fairly cover is certainly advantageous, especially in the case of weak colonies. Their domain can be enlarged at pleasure, as required, by moving back division-boards, on either side, and inserting combs, one by one, at intervals longer or shorter as demanded.

UNITING weak colonies has never availed much in our hands; but of course much depends upon the queen, as dwindling is often caused by an unprolific or aged queen. We prefer taking a frame of brood from our *strongest* colony, and placing it in the centre of a moderately weak one; but this must not be done too early, before there are sufficient bees to brood it well. Very weak colonies are not worth the trouble or expense of nursing. By this we mean those which cover a couple of frames only. If such possess a good queen it will be best to place her at

the head of another colony, whose queen requires to be superseded, or to keep her at the head of a nucleus in case of further need. Queenless colonies should be united to those having fertile queens and requiring bees.

Continue to keep all hives well protected from cold. Where the enamel quilts have not been given, they should be supplied at the first opportunity, and covered with several other quilts, of felt or carpet, chaff-cushions, &c. Warmth now, to breeding colonies, being of the greatest importance.

OLLA PODRIDA, &c.—In consequence of going to press somewhat earlier than usual—in anticipation of the Easter holidays—we are compelled to omit our notes under this head, but shall hope to return to the subjects of Messrs. Woodley, Boyes, and Godfrey's courteous letters, at no very distant date. Meanwhile, we beg to assure Mr. Boyes that we have not the slightest wish to apply a 'sauce' to Mr. Woodley and to withhold the same from Mr. Webster: albeit, so far from classing these gentlemen under the title *anserine* we consider them amongst the foremost of modern apiarists.

As regards Italians and hybrids *versus* blacks, our opinion has been formed on a twenty-five years' experience. And since we do not plead guilty to riding a hobby, we do not see how it can have run away with us.

According to Mr. Gradgrind's dictum, 'Facts are stubborn things,' and on these, so far as they have come within our own knowledge, our foundation is laid and our edifice raised.

Selected Query.

[6.]—*If only starters, two or three inches deep, are used instead of whole sheets of foundation, in the brood-nest, how is the production of drone-comb prevented?*

By preventing (if possible) the too-rapid incoming of honey, naturally the formation of drone-comb is, in a sense, accidental, depending on the honey-flow — if meagre, the bees will build worker-cells as a rule; but a glut lasting a few days will cause them to build store, or drone-cells to receive it.—C. N. ABBOTT.

By placing the frames at a distance of $1\frac{1}{4}$ in. from centre to centre, instead of the usual distance of $1\frac{1}{2}$ in., and by confining the bees to as many frames only as they can cover, giving more room by adding frames as required, in the case of newly-hived swarms.—GEORGE RAYNOR.

By placing the starters $1\frac{1}{4}$ in. distance, and having colonies or swarms in a normal state (with the queen in prime condition) to carry out the work. Once in our experience we set up a strong swarm, which (then unknown to us) was headed by a virgin queen. Next morning's examination showed us drone-cells worked, at the $1\frac{1}{4}$ distance, upon worker foundation. My astonishment revealed the probable cause, and I now espied the slim virgin rushing about 'all life and gay.' A frame of hatching brood was given, and the hive well marked for the queen's return from mating. Forty-eight hours after I again examined, and found the queen had mated, and the bees, with their instinctive knowledge of the fact, had returned to worker-cell production. My super crates were placed, and all went well. I mention this to prove 'No rule without exception.'—JOHN H. HOWARD, *Holme, Peterborough.*

I have never tried starters for many years, so cannot say.—JOHN WALTON.

I am unacquainted with any way, if the arrangements are of a normal kind. Possibly crowding the frames closer together might act as a preventative, but I am not prepared to say that it would.—J. GARRATT.

I do not think it can certainly be prevented; but if only a sufficient number of frames are given for the bees to cluster upon and entirely cover, in the first instance, provided food is coming in, either naturally or artificially, *regularly and not too fast*, while comb-building is going on, worker comb will probably fill the frames. A swarm usually builds sufficient worker comb for the bees to cover, and then they surround their brood-nest with drone-comb. Hence the advisability of having large swarms and crowding the hive as much as possible in the first instance. As soon as the frames are all built out the bees will gladly avail themselves of surplus room, where, perhaps, drone-comb will not be an objection. Swarms headed by young queens do not appear to be so anxious to build drone-comb as those headed by older ones.—M. L. GAYTON, *Much Hadham.*

If starters only be used in the frames it is absolutely necessary that they, the starters, should not be placed more than $1\frac{1}{4}$ in. apart to prevent drone-comb being built.—S. J. BALDWIN.

By keeping the frames $1\frac{1}{4}$ in. from centre to centre, using Mr. W. B. Carr's metal ends, or those made by Mr. Godman, which obtained a medal at Newcastle, either of which will keep the frames $1\frac{1}{2}$ or $1\frac{1}{4}$ in. from centre to centre as required.—JOHN M. HOOKER.

The bees are sure to commence with worker-comb, and so long as they continue to build without a check they will not build drone-cells, but when they stop building they will not generally recommence until they are short of storage room, when they are liable to build drone-comb. Therefore they should be fed in bad weather till the hive is filled with comb, but it is best to use old foundation.—J. A. ABBOTT.

By giving only a part of frames at first, then inserting the remainder as required in centre of hive, I have found that some swarms build more drone comb than others treated on same lines, though I cannot say yet if it is an hereditary propensity or the result of some occult influences.—W. WOODLEY.

ASSOCIATIONS.

STAFFORDSHIRE BEE-KEEPERS' ASSOCIATION.

The Annual Meeting of the Staffordshire County Bee-keepers' Association was held on Thursday, March 15th, in the Guildhall, Stafford. Major-General Buller presided, and about forty members were present, including Mr. A. H. Heath (the Hon. Sec.), the Revs. J. D. Glennie, A. R. Alsop, and G. R. Bailey, Messrs. W. B. Yarde, Lieut.-Col. Mort, H. H. Pratt, J. R. Critchlow, Elihu Clowes, H. Wood, A. W. Rollins (expert of the Association), &c.

Mr. Heath read the Annual Report, as follows:—'The work of the Association during the past year has been carried out on much the same lines as in the previous four years of the Association's career, commencing in April last with the spring tours of the experts, Messrs. Rollins and Clowes, in the south and north of the county respectively. 141 members were visited, 151 skeps and 482 bar-frame hives were examined; and the cost of the tours was 16*l.* 17*s.* 10*d.* In the autumn the experts visited 153 members, examining 172 skeps and 572 bar-frame hives, and the cost of the tours was 19*l.* 4*s.* 9*d.* Thus the average cost per member visited in the spring tour was 2*s.* 4*d.*, and in the autumn tour 2*s.* 6*d.*

From their reports we are led to believe that bee-keeping in Staffordshire is carried on the most approved and scientific principles. The one feature which is unsatisfactory is the prevalence of foul brood in certain districts. This is a serious matter, and should occupy the attention of all bee-keepers in districts where the disease exists; the cures for it are well known, and

should be applied without delay, so that the infection may not be carried into every quarter of the county.

'The bee-tent was engaged at eight shows or fêtes, and left a balance in hand of 12*l.* 4*s.* 1*d.*, being a decrease of upwards of 2*l.* on the previous year's profits.

'The annual show was held at Burslem on September 7th and 8th, in connexion with the Staffordshire Agricultural Society's show, and was by far the most successful held under our auspices. The entries were more numerous, and the exhibits were throughout of the highest class. There were ninety entries in ten classes, and over 13*l.* was offered in prizes. The exhibition of honey in classes for the best display of honey in any form, open to members of the Association, was quite up to the standard of open exhibitions, and the honey produced in classes confined to artisans and agricultural labourers was most encouraging. If agricultural labourers could be persuaded to take the same interest in bee-keeping as Edward Richards of Wrottesley Lodge, near Wolverhampton, they would find no difficulty in paying their rent, and their subscription to the Association would prove to be a very good investment. The arrangements for the show were carried out in the most satisfactory manner. Mr. J. M. Hooker officiated as judge, and Mr. T. B. Blow gave a series of lectures in the bee-tent, which was fairly well patronised on both days.

'The *Bee Journal* has been circulated among about one hundred applicants during the past year in the various districts by Messrs. G. Farrington, E. E. Crisp, J. R. Critchlow, E. Joberns, and Z. Cartwright—fifteen copies weekly. The Committee have decided that in future the monthly edition, which has been brought out since March 1st, shall be circulated, notice of which will be given to members on the earliest opportunity.

'Four committee meetings have been held during the past year, and all the members of the committee are eligible for re-election with the exception of Rev. R. Rigden and Messrs. Edward Clowes and C. Wilson, who have retired.

'Some members present may remember the spring invasion of the county by Mr. S. J. Baldwin, under the B. B. K. A.'s flag in 1883. His object was to make known to us the advantages we could derive from a scientific method of keeping bees, and at that time, when honey was worth 2*s.* per pound, how it could be carried out with reasonable prospect of remuneration or *considerable profit*. The result of his efforts was that, at the first meeting of the S. C. B. K. A., held in April of that year (that veteran bee-keeper, the Rev. J. D. Glennie, in the chair), I announced that we had made a start, and that 112 members' names were on the list. I need not remind you how quickly our numbers increased, and how honey—so called, a questionable article of food at that time—has improved in quality, and how much the competition we have around has brought down the price; perhaps nothing testifies to the efficacy of our work so forcibly as these facts. But having so spread a knowledge of bee-keeping in the county among those who have come under our care, it seems to me that our efforts in future should be carried rather into districts at present unsweetened by our labours, and that the work done should be well within our financial capacity.

'The number of members on the books at the commencement of 1887 was 485; a thorough weeding of the list leaves us with only 325 at the present time. I do not think that on account of this reduction we shall find our subscription any the less, but so far our income has not come up to our expenditure: and in future, the Committee will have to consider the means at their disposal, and must make the most satisfactory use of them in carrying out the objects of the Association.'

The Treasurer's statement was next read, showing a balance due to the treasurer of 15*l.* 8*s.* 5*d.*

The officers and committee were re-elected, with the

exception of those mentioned above, with the addition of Mr. E. W. Turner of Stafford, and Mr. W. B. Yarde (H. M. Inspector of Schools) of Gnosall.

An alteration in Rule VI., agreed on by the Committee, was proposed by the Rev. G. R. Bailey, and seconded by Mr. T. Bailey, and, after some discussion, was carried. The rule reads: 'All subscriptions shall be payable in advance on January 1st, and shall be considered in arrear if not paid on 1st of May following.' For the words, 'shall be considered in arrear,' &c., was substituted: 'All members whose subscriptions are unpaid on June 24th shall cease to receive the benefits of the Association until the subscription be paid.' Mr. Bailey stated that the great difficulty the Committee had to contend with was getting in the subscriptions, as many members who received the benefits of the Association took not the slightest notice of printed applications, and it was quite impossible for the district secretaries to apply personally to all the members.

Mr. T. Bailey, a working-man member, considered that six months' grace ought to be sufficient for anybody.

At the conclusion of the meeting two hives made by Mr. S. B. Fox, of Maer, provided by the Association, and a Benthall crate of sections, made by Mr. Rollins, and presented by the hon. sec., were drawn for, and were won by Mr. W. Stenlall, Rollibaston Hall, Penkridge, Mr. W. Blood, Lichfield, and the Rev. A. R. Alsop, Bednall.

The meeting concluded with votes of thanks to the Chairman, the Hon. Sec., officers, and committee, and to the Mayor of Stafford for the use of the Hall.

NORTHAMPTONSHIRE BEE-KEEPERS' ASSOCIATION.

At a special meeting of the Committee of the N. B. K. A., held in All Saints' Schools, Northampton, on Saturday, March 17th, called to consider the advisability of supplying the *Bee-keepers' Adviser* gratis to members or for a slight remuneration, it was decided to send the *Bee-keepers' Adviser* gratis to members who subscribe 2*s.* 6*d.* and upwards, and to cottagers paying a subscription of 1*s.* 8*d.* per annum in advance (to all members who desire to have the *Adviser*). And it is earnestly hoped that by making this concession the Association will gain many new members, especially among the artisan and cottager bee-keepers, who at present hold aloof from the Association, but who, indirectly, are reaping a benefit through the diffusion of the knowledge of advanced bee-keeping made known through the Associations, and those members who devote time and energy in furthering the aims of the Association.

All who desire to have the *Adviser* are requested to send their subscriptions to the Hon. Secretary, Mr. R. Hefford, Boughton, Northampton, or the several district secretaries at once.

It is also advisable to state that any member of the N. B. K. A. can have the *B. B. J.* through the Association at cost price, viz., 8*s.* 8*d.* per annum, paid in advance—half-yearly if preferred. By arrangement the *Journal* is sent direct to subscribers from the office weekly, causing no delay.—A. T. ADAMS, *District Secretary*.

LANCASHIRE AND CHESHIRE BEE-KEEPERS' ASSOCIATION.

The Committee of the Lancashire and Cheshire Bee-keepers' Association held their first meeting of the year at their room, 2 South John Street, Liverpool, on the 19th March, 1888, when twelve members put in an appearance and unanimously elected the Rev. J. F. Buckler, of Bedstou Rectory, the Chairman for the year.

After passing the accounts to date, and arranging several details of work for the year, there was a discus-

sion whether it was advisable to make a county competition a feature of the show to be held in conjunction with the Royal Manchester, Liverpool, and North Lancashire Agricultural Show to be held at Lancaster from the 5th to the 7th of September, 1888, when it was decided to set apart 15*l.* to be offered in prizes for the best exhibits of honey staged by Counties affiliated with the B. B. K. A. — W. LEES McCURE, *Hon. Secretary, The Lathams, Prescot, March 19th.*

WORCESTERSHIRE BEE-KEEPERS' ASSOCIATION.

We are glad to be able to announce that Mr. E. Davenport, the expert to the above Association, who, for private reasons, sent in his resignation to the hon. sec., has reconsidered his position, and will continue his duties for the current year. His address will be, as before, at Tontine Buildings, Stockport.

Foreign.

BELGIUM.

If we are to judge from the tenour of a communication which has reached the *Revue Internationale d'Apiculture* from M. Karel de Kesel of Amougies-les-Renaix, Belgium is at last not becoming alive to the importance of apiculture as a means of improving the condition of farmers and others engaged in agricultural pursuits, but is about to take such practical steps as will place it at no distant date in a line with other European countries. We cannot do better, therefore, than place before our readers a translation of M. Karel de Kesel's communication as published in the *Revue Internationale d'Apiculture*, and which is to the following effect:—

'I am in a position to inform you that our Minister of Agriculture has just approved a report upon *Practical means for spreading the knowledge of keeping bees in our country*, and decided to at once give effect to the following two recommendations, viz.:—

'First.—To hold an International Bee Exhibition in Brussels in the course of the present year, of which I will send you later on the prospectus.

'Second.—To order fifty lectures to be given in the most suitable Belgian districts for successful bee-keeping.

'In order to spread as much as possible the knowledge of bee-keeping it has been decided that for this year no more than one lecture is to be given in each district. This first lecture will deal merely upon the rudiments of bee-keeping and manipulating, so as to initiate into correct principles those who have already acquired a natural instinct in the management of bees.

'The lecturer will be furnished with horse and trap. In these he will carry about with him, among other things, a stock of bees to be used for practical demonstrations at his lectures. An adequate amount of publicity will be given, to the effect that a *bee expert is about to arrive with an ambulant apiary*, that he will bring with him bee-hives on the moveable bar-frame principle, that the combs will be removed from and replaced into the hive at pleasure, and that the bees will be seen working through glass. Mention will also be made that the lecturer will bring with him bees of several breeds, as well as bee-hives, from which as many as 75 kilos of honey can be obtained in favourable seasons; and that, in fact, he will show them sundry bee-furniture of the latest invention, &c. It will also be made known that editors will be supplied gratis with a summary of the lectures, together with a lithographic design of an improved bee-hive, together with explanations and a list of the most approved books on bee-keeping. The explanations and documents which you have sent me, showing how a Bee Association could

best be organized in Belgium, will be of great assistance to me. Again M. Vernieuwe, attached to our Ministry of Agriculture, himself an amateur bee-keeper, has received the particulars which you and Mr. Cowan have sent him.

'We shall soon send out to all the bee-keepers known in Belgium an invitation to a general meeting, in order to agree upon the main point of a proposed association.

'I have perused over and over again all the numbers of your *Revue Internationale d'Apiculture* for 1887. For me it has been a very useful and encouraging reading. For years I have had to do as best I could with my bees without the assistance of a reliable guide; hence it is only since I adopted, three years ago, large hives with strong colonies that I have been able to obtain satisfactory results. When I look upon the past I cannot help thinking of the many things that I have learned at my cost, and of the money that I could have saved if I had known of the existence of the *Revue Internationale d'Apiculture* from the first. (Signed) KAREL DE KESEL.'

ITALY.

The Board of Management of the Central Bee Association held recently a meeting at their head office at Milan for the purpose of electing and reappointing honorary representatives at home and abroad. Mr. John B. Camaschella, of Forest Hill, S.E., was re-elected representative for Great Britain and its dependencies. Mr. Camaschella has held this honorary appointment ever since 1877.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'THE EDITOR of the "British Bee Journal," c/o Messrs. THE ODOUR OF NECTAR.

[1553.] I dare say much of what I say on this subject will interest those who have made horticulture a hobby rather than bee-keepers, whom it affects only in a slight degree, and that little is purely of a scientific character.

We take it for granted that the odour of flowers is the odour of the nectar, and that it is given off by the plant at certain parts of the day or night, more at one time than another, according to the surrounding atmospheric conditions and in proportion as it requires the visits of such animals as are useful to it in securing cross-fertilisation, for whose services the plant is bidding, with its seductively attractive perfume and its deliciously flavoured food, the nectar.

It is only in keeping with a law of nature (affecting not alone individuals of the vegetable kingdom) that peculiar degrees of heat and moisture, together with certain unknown electrical currents or conditions, perhaps also accompanied by seismic fluctuations, produce activity in those parts of flowers which are destined to play an important part in securing for its kind a future on the earth. The ovaries, the pistil, the stigmatic surface, the anthers and pollen-grains, are all distinctly acted upon by the suitable surrounding conditions, and in the same measure is nectar secretion copious when an agitated, irritated state is produced by such sur-

roundings. The nectarlike, perfume-laden breeze has only become so by gently brushing about the pendent catkins and flowers against leaves and branches until the agitation stimulates an extraordinary nectar flow or transudation through the cells of the nectaries. In order to test the question as to irritation increasing nectar flow, it is only necessary to fillip with the finger the stem of a perfume-bearing plant in bloom, and the increased scent is distinctly perceptible; the nectar will continue to be secreted by the flower so long as the atmospheric conditions remain suitable, or until its seed has been fertilised. A very interesting study may be made of the mechanical contrivances found on various plants, which are used by them to assist or prevent insects visiting the parts of flowers where nectar is lodged. Amongst these protective appliances I may name prickles, hairs, and sticky exudations, and these are generally found at the nodes or parts where branches join the stem, where branchlets join branches, and where leaf-stalks join the branchlets.

Nature is far more sparing of original elements than one would at first suppose, but she is multitudinous in her combinations of those elements; products are given which in no manner resemble the parentage. In colour, every hue is made by the intermixing of red, blue, and yellow; every tint, from rosy dawn to golden sunset. In music we have a similar trinity of notes, the intermediate shades and combinations of which give us the grand harmonious notes of thunder rolling amongst the mountain-tops, the seemingly discordant screeching of the storm rushing through the forest or beating its waves of wind and sea against Nature's rugged breast; the sighing of the wind amongst the tree-tops, the weird noises through the night of the myriads of falling pinecones, the startling cracking of the tree trunks as the rising sap of spring bursts the bark and splits the stems; these, down to 'the utterances of the ins-et,' merely vary in combination or intensity, the few simple primaries of sound formation. In the sphere of chemistry the compounds of carbon, hydrogen, and oxygen, are innumerable, and have become a distinct branch of study.

We are shown how to obtain the most dazzling tints from coal-tar, the brilliant aniline dyes locked up in a piece of coal. We are obtaining from the same source most enticing flavours of raspberry, strawberry, pineapple, pear, apple, &c., sweetened with saccharine, itself a hundred times sweeter than sugar; perfumes follow on in the same line, and all from a bit of Nature's carbon compound; and here we come back to the nectar and its odour. Now, instead of being at the trouble—to say nothing of the difficulty—of mixing various nectars in order to obtain new combinations, let us experiment with sprigs of the flowers themselves; you may then, perhaps, agree with me in my assertion that Nature is just as chary and economical in her elementary perfumes of nectar as she is in those other objects which appeal to other senses besides smell and taste—I mean colour and sound. The perfumer uses very few bases, but he builds up new scents (to which he gives startling and attractive names) by scientific combinations alone. Let us do this for ourselves with a sprig each of mignonette, wallflower, and garden-pink; these three, or, indeed, any other three, will give a blend, in which—if tested fairly—it is most difficult to recognise the separate components; so it is with our honey, it is only recognisable when one component predominates over another.

In order to show how the same flower (nectar) scents repeat themselves throughout nature I will give you a list of notes I made on February 20th, 1883, comprising plants—principally orchids—from all round the belt of the earth, with the associations they gave me to other odours.

Lalia anceps (orchid), scent of honey.

Cattleya Mossiae (orchid), two petals, scent of honey (lip no scent).

Hyacinth (pale blue), like a vanilla pod or like *Stanhopca Tirgima* (orchid).

Zygopetalum Mackayi (orchid), lilac-coloured, scented like lilac.

Odontoglossum Halli (orchid), like a beanfield.

Orange flower, stamens and petals like jasmine.

Orange flower, stigma, of orange.

Odontoglossum pulchellum majus (orchid), of May blossom.

Mormodes pardinum (orchid), of sandal-wood.

Dendrobium heterocarpum (orchid), of Windsor soap.

Cælogyne cristata (orchid), of May blossom.

Cytisus fragrans (yellow), like *Cattleya citrina* (an orchid, also yellow).

Cattleya citrina (orchid), of lemon or citron.

Dendrobium crystallinum (orchid), of heather honey.

Epidendrum fragrans (orchid), of plum stone kernels or hydrocyanic acid.

Epidendrum virens (orchid), of chopped hay, slightly of bergamot (like a mangel).

Lalia albida (orchid), of sweet honey.

Pilumna fragrans (orchid), of weak vanilla.

Odontoglossum maculatum (orchid), like Daphne.

Odontoglossum blandum (orchid), disagreeably of jasmine.

Polyanthus narcissus, disagreeably of jasmine.

Orange blossom, disagreeably of jasmine.

Azaleas, of pinks.

Skimmia Japonica, of Daphne.

Lily of valley, weak Daphne.

Panacratium caribbeum, sweet Daphne indica.

Crinum Careyanum, vanilla.

Dendrobium fimbriatum (orchid), red inky or creasote.

Dendrobium primulinum (orchid), lilac and honey.

Dendrobium Wardianum (orchid), wild rose.

Phalaenopsis Schilleriana (orchid), of daphne indica and violets.

Cælogyne flaccida (orchid), urine of horses.

Gleandra Devoniana (orchid), heather.

So it is, almost throughout the floral world, the innumerable changes are rung on comparatively few bells. With us, our honey, mixed by the bees, changes its character with almost every section where one kind of flower does not strongly predominate in bloom; and in this case, who has not found a friend who simply could not bear the flavour of honey from one source alone, clover, lime, or heather, the intensified flavour of which *per se* is decidedly objectionable? A good mouthful of clover-honey reminds one of the smell of a mill-pond on a hot autumn evening, the lime, like resin or varnish, and a comb of heather highly suggestive of a farmer's boy drying his damp fustian or cord before the fire. Attenuated or blended, I don't care which, the same substance produces on the palate what, without blasphemy, may almost be called a divine sensation.—R. A. H. GRIMSHAW, *Horsforth, near Leeds.*

NEW ARTIFICIAL COMB-FOUNDATION.

[1554.] I have read your article on 'One-side Cell Comb-Foundation,' on page 138 of the *B. B. J.* for this year, with much interest, as I had myself, when in conversation with Mr. Alfred Neighbour some six weeks ago (about Mr. Marshall's invention), suggested that the fixing the foundation at the side of the frame or section would fulfil the objects Mr. Koerbs proposed to obtain.

I think the one-side cell comb-foundation can be readily made by any one having an ordinary comb-foundation mill, which will answer both purposes at a small additional expense. For the one-side foundation, the upper roller in the mill has simply to be taken out and replaced with a smooth one. The sheets of wax are prepared exactly as before. A piece of calico washed free from dressing and dried is placed on the wax on the table, and about half an inch is turned down under the sheet of wax. The handle of the machine is turned round once or twice, to lubricate the under roller, and the wax-

sheet, with the calico on the upper side, is then fed through the mill. Directly the pressure comes on the calico, the end turned under is embedded in the wax, prevented from slipping, and when passed through the machine, comes out with a backing of calico on one side, and the usual impression of foundation on the other.

It can, I think, also be fixed to thin board or card-board, or anything that will bear the pressure of the rollers. I have not tried to make foundation in this way, not having a mill, but I feel pretty certain it will answer. I hope some of the makers of comb-foundation will experiment a little and say what they think of this plan.

The reason the bees may be expected to build on one side only is that there is no wax on the other to induce them to start building, and as the space between the foundation is about $1\frac{1}{2}$ inches, they will not attempt to insert one.

Nothing but careful experiment will enable us to be certain how the bees will act, and at present no opinion can be formed as to whether or not there is any advantage to be gained.

If the bees will build out the comb and fill it with honey only, combs with a backing will be much stronger, and when extracting, less liable to break, as there will be no weight of honey on the other side of the midrib endeavouring to fly from the centre, tending to break the comb.—JOHN M. HOOKER.

BEEES FOR PLEASURE AND PROFIT.

[1555.] Seeing in your first number of *Adviser*, which I by chance got hold of, that you would gladly correct any mistakes, &c., and put in shipshape any commentary which you might receive from any cottager, I gladly take the opportunity of giving [my little experience in bee-keeping. I have received very valuable assistance through *Gardening Illustrated*.

I started some six or eight years ago, and of course with the old-fashioned skeps, but I did not succeed, for after a year or two all my bees died, and so I determined to try a bar-frame, so I bought an old one for five shillings as a pattern, as I wanted my bees more for pastime than anything else. I determined to make all my own hives and everything connected with them. And this is how I proceeded: I got an old tea-chest, which is inside measurement $16\frac{1}{2}$ inches square, then I made a false bottom and cut a slit in one side for an entrance for the bees, 6 inches long by half inch wide. Of course the tea-chest not being thick enough to keep out the winter, makes it require the extra bottom; then I take two pieces of wood (I do not mind about thickness), cut them $16\frac{1}{2}$ inches long, and $8\frac{1}{2}$ inches deep, and nail them fast inside and outside about one inch from front and back. Of course the front one must have a little taken out at the bottom for an entrance. Then I take two other pieces of wood, $8\frac{1}{2}$ inches deep, and cut them just to fit so that they can be moved backwards and forwards at pleasure. This makes my hive like two boxes, one inside the other, the inside one being about an inch smaller than the other; the advantage of this is I can stuff a piece of sacking, or hay, or sawdust, down the side for winter. Then I make my own frames, I make them of such size first to allow quarter of an inch betwixt the side of the hive and the frame ends so that the bees can pass at the ends of the frames; and I make them $8\frac{1}{2}$ inches deep: I find I can get seven frames in such a hive, which is sufficient to keep the stock through the winter. I had forgotten the landing stage. Well, I nail a piece of wood in front for landing, and a piece above slanting downwards to shade and cast off the wet, then I make ends for the roof and take three pieces of board like most wooden hives one sees, and my hive is complete except the painting. Of course it requires a certain amount of putty, and with

two coats of paint I can assure you it is not at all a bad hive, and it costs me next to nothing, and there is plenty of room to put sections on one above the other, and making these appliances is a far better occupation on a winter evening than going to a public-house.

Well, after I had made this, I bought a swarm the beginning of June 1886, for which I paid twelve shillings, and put it in. The first year I took nine pounds of honey from the bees, and showed it at our local show, got a prize of two shillings, and sold my honey for nine more shillings. I thought I was getting on famously.

When 1887 came I had my one stock strong and healthy, and on June 15 it threw out a swarm; and such a swarm it was, it weighed six pounds of bees good weight, and I hived them in another of my own manufacture, and let them stand about a fortnight and put on some sections, which were soon filled; and from my swarm I took twenty-four sections and a glass; the glass weighed a little over four pounds, and I sold from both my hives over two pounds worth of honey at tenpence a pound, and have both my stocks strong and healthy ready for 1888.—A COTTAGER.

ARTIFICIAL FECUNDATION.

[1556.] As a skilful bee-keeper here in Denmark Mr. P. O. Berg, Tørring) has in the last two seasons tried some very interesting experiments in this direction, I shall relate these to you, as they may, perhaps, lead to some very important discoveries on this head. Mr. Berg's experiments were made at the same time as Professor MacLain's in North America, but without his knowing the latter, and the former are in several respects better arranged.

Mr. Berg has not caught his drones among the multitude of drones in a strong stock (as did MacLain), but at the entrance of the hive, at the moment when the drone intended to take a wedding flight. This accounts for MacLain's complaint that most of his drones were not fit for the purpose, while with Berg every one of his was suitable for fecundation. He seizes the maiden queen by her wings with the thumb and forefinger of the left hand. In this situation the queen will bend her abdomen downwards towards the thorax. Then he seizes with the right hand thumb and forefinger the drone on both sides of the thorax, and cautiously pressing the abdomen, the desired effect is produced, and fecundation may be accomplished. Mr. Berg tells us that the queen when released will disengage herself in some fifteen minutes. He has in this manner artificially fecundated six queens in the season 1886, and four in the last season, and in all ten cases with an excellent result.

As these very remarkable experiments, if they are confirmed, undoubtedly will lead to very important progress in apiculture—that is, to an easier and more sure fecundation of the queens—I hope that you are willing to acquaint your readers with them through your valuable *Journal*.—HANS ERSLEY, *Editor of the Danish Bee Journal*.

QUEEN-RAISING. (1503.)

[1557.] 'A Cottage Amateur,' in writing on the the above subject, appears anxious to put the matter on a practical footing, so that all may be ready when the host of bee-keepers will be wanting cells and young queens for expected swarms. This is all right, and as it should be; but the next question, 'What will such a comb cost?' is a matter for consideration, the more so as 'A Cottage Amateur' so pointedly refers the question to me, as the writer of the previous article. Now, I am quite willing and ready to quote on learning his *bona fides*, but the mere thought of naming prices in these columns, sacred to correspondence, is enough to shock

any manufacturer, not to mention our courteous editor. If 'A Cottage Amateur' will write his name and place of abode on a post-card, I will then tell him in whose catalogue he can find the prices of 'Wired combs containing brood, eggs, &c.,' first published in 1884. As eggs only are wanted in this case, if he deducts, say, 33 $\frac{1}{3}$ per cent, or one-third from the value of a comb in its normal condition in the brood-nest, he will arrive at a fair price for what is asked. Again, if he wants a same comb to contain eggs from different queens—say, Syrian or Cyprian on one side, and Carniolan on the other (and, by the way, this cross will be hard to beat for business)—let him then add one-third to these figures, and he will then arrive at 'What such a comb will cost.'—JOHN EBBY, *St. Neots*.

[This letter should have appeared in our last issue.—Ed.]

HONEYED FOOD.

[1558.] The aim of your new venture would, mayhap, be furthered by the gathering together of receipts for eatables in which honey forms a part.

In the hope that you will find room for such, and that others of your readers will add to the stock, I send the following by way of beginning:—

In Miss Gordon-Cummings's *Wanderings in China*, wherein she describes a Chinese dinner, occur 'ham stewed in honey,' and 'pears sliced in honey,' 'crab-apples and chestnuts preserved in honey and dried.' We are not told what kind of pears are used, but our stewing pears seem suitable.

It does not appear whether the *ham* is cured, or stands for *leg*; but perhaps the latter, for we have it, in his own *Confession*, that St. Patrick found fresh pork seasoned with honey so luring that he ate more of it than was good for him. Being on board ship, where they were short of provisions, at last they fell in with a herd of swine, of whom, killing many, they ate their fill, seasoning the meat with an opportune find of wild honey. As might be expected, St. Patrick had night-mare. This was not due to the honey, but to the surfeit of pork to a starved stomach.

Your readers are advised (1) to try such of the Chinese dishes as they have a chance, and (2) to take warning by St. Patrick.—G. O. WRAY, LL.D., *Bedford, March 22*.

DRONES.

[1559.] Since writing my last article I have had the pleasure of seeing the first volume of Mr. Cheshire's admirable contribution to the *Physiology of the Honey-bee*. Without defining the time when the drone is disposed to mate, Cheshire demonstrates, microscopically, that it must be at least several days old: and my observations show that sexual desire comes much later.

Mahan, as stated in my work, first made the important observation that drones, leaving the hive to mate, have a large supply of honey, which is found on their return to have been almost entirely consumed. I failed to ascertain how many marital excursions drones would average in a single day; but as they are often flying about three hours in favourable weather it is probable that they make three such trips at least. To do this they must consume twice as much honey as a swarming worker that carries off in its honey-sac almost a week's supply. The importance of preventing any overproduction is therefore obvious without any further comment. Let me here make some suggestions to those who aim to exclude all drone-comb from most of their stocks. I say *suggestions*, for, after having been precluded by sickness from the practical management of bees for most of my time during the past fifteen years it would ill become me to speak in too confident a manner.

In limiting the production of drones to just as few as we think will be needed for the fertilisation of our

queens, may we not err against that wise precept, 'There is that withholdeth more than is meet, but it tendeth only to want?' It is easy to take for granted, that every bee in a healthy populous colony will do all that it can to enrich its home, even in the entire absence of any drones; so it is easy to assume that every worker in an artificial swarm will work just as well as it would in a natural one; but who, after a large experience with both methods, can deny that, for the production of comb honey at least, the natural swarm has that spur in the head which it never gets from our artificial processes? Is it not reasonable to think, that, for its highest prosperity, every colony of bees should be in a normal, that is to say, a natural condition? What can be more certain, than that strong colonies with few or no drones, in the very height of the honey-harvest, when such colonies show that they crave them so much, are not in a condition which stimulates them to do all that they are capable of doing? Their owner may know that, in the apiary, there are drones enough for all needed purposes; but how is he to impart this formation to his droneless colonies, when, by the fiat of the Creator, every healthy stock seeks to be in a condition that would be best for it, if there were not another family of bees on the face of the whole earth? So far, therefore, from grudging to any colony a goodly number of drones, I prefer to see that one-third of one central comb in each stock hive has choice drone-cells.

I will conclude this article by giving some facts which show that, to ensure the mating of queens, many more drones seem to be needed than are commonly thought enough.

During the period of my observation in 1885, a drought had so cut off the secretion of honey that I had no reason to suppose that any drones could be found for the mating of my queens, except such as I had bred, and kept alive by daily stimulative feeding. For over two weeks I had more than a dozen young queens which flew nearly every day, and some of them, I knew, made several excursions on a single day. I had over two hundred drones, and yet only one of those queens laid any eggs. When the weather became too cool to expect any favourable results, I found, by dissecting the other queens, that none of them had mated; yet when my apiary was largely devoted to queen-breeding, and I had thousands of drones, I had good success at the same season, under circumstances in no respects more favourable.—L. L. LANGSTROTH, *Dayton, Ohio, Feb. 10. (Gleanings.)*

CHEAP AND EFFECTUAL FEEDER.

[1560.] Take a common round tin coffee-canister, stick a piece of rough brown paper on the bottom, to give the bees foothold, and with a darning-needle lightly tapped, make a tiny hole (or holes, as required) through the brown-paper and bottom of the canister, place it over the feed-hole in the board, remove the lid of the canister, and pour in syrup as and when required. There is no need to remove the canister to replenish the syrup. It will only have to be taken off if it is required to make more holes, or to stop a hole with a fine wooden peg. Cover the canister with a good-sized flower-pot, with the hole stopped. This answered with the writer last autumn as well as the regular feeders, and cost practically nothing, and it was thought that the hint might be acceptable to those who have to take care of the pence.—T. H. H.

A SMALL COTTISWOLD APIARY.

[1561.] I have been a bee-keeper more or less since March, 1871, also a slight contributor to the *B. B. J.* in its early days. In 1875 I had some forty stocks in Woodbury hives: I had purchased eight Ligurian queens, joining seven successfully, and had bred queens from them, but could not keep them pure. This year

(1875) was fine until June, and they increased fast; then it set in wet until September, and I had to feed them all from July onwards. In the autumn foul brood appeared, and I lost them all; since which I have kept a few stocks of Blacks.

In 1876 I came to the conclusion that the 'Woodbury' would be better deeper; that a strong stock required more brood space; so I experimented on two stocks by deepening the frames to 10½ inches; last summer No. 4 stock, which had wintered on eleven of these frames, and No. 2 on eight, each gave me somewhat over 100 lbs. of honey in 1 lb. and 2 lb. sections and other supers, leaving them a winter supply; besides which No. 2 worked out the three frames of foundation.

Finding these two were my strongest stocks last spring, I lifted up three more and placed similar hives (only containing ten frames instead of eleven, and which I have christened the 'Bannut Hives') under them. They treated the upper ones as supers, and drew out the foundation and filled the Bannut hives with brood and honey, and, so far, have stood the winter well. Besides these five I have one Woodbury containing three driven stocks, and one skep containing one driven in July last; they gave me last season 3 cwt. of honey, the surplus of which I disposed of at 9d. per pound. I do not, as a rule, allow them to swarm, and if I want a swarm I make one out of two hives, as recommended by Langstroth. I do not find a ready sale for honey in sections, and generally extract it, leaving stock hives undisturbed.

I make my own hives and appliances, place the hives on separate fixed stands, with loose floor-boards and outside cases fitted over the stands, and very similar to an illustration in *B. B. J.* of April 8th, 1886, on doubling. I keep these outer cases on always, well painted, lowering them to top of hive in autumn. The air circulating round the hive keeps it dry. The hives are not painted, the inside planed, and the outside left rough. The honey-flow last year lasted about five weeks.

My principal object in writing to you is to relate what seems to me an extraordinary occurrence. On the 6th February last, being a fine, warm day, the bees were flying freely; and as I was watching them with great interest I heard the buzz of a drone, and saw one enter No. 2, amongst rather a large flight of young bees; and on 6th inst. I saw another in the same hive, and on the 14th two drones. The queen is one of 1886, and a very prolific one, and the hive well stored.

Last September a small swarm (perhaps a pint of bees) came and settled in a small bush. I put them into a three-frame nucleus hive with some honey, but they would not stay. I lived them three or four times; my bees cleared out the honey, and I found the queen—a very small one—dead. Next day I think most of the bees joined my hives.

I have tried the Ligurian, but did not find them better honey-gatherers than the black; the largest surplus I got from one of them was 70 lbs. in supers; and as to the first cross with the blacks, I had to put on veil and gloves, and still got quite used to the stings; but with the blacks I find a whiff of tobacco or a little carbolic suffice; and I am satisfied with the returns, and then they cost but little.—FRITZ.

A VOICE FROM A COTTAGER.

[1562.] I have been keeping bees for several years on the bar-frame principle, having obtained the book of *Modern Bee-keeping*, and started to work and made all my hives (of course they were rather rough at first, being a bootmaker) from old packing-cases, which I bought cheap, and have been very successful every year obtaining first prizes at several of the shows. The first year I began I think I must have been very venturesome, not having seen any honey in sections or bottled for show. I bought one swarm, took sections off top, and

extracted from the lower frames. I entered at the Romsey Horse and Poultry Show, and was fortunate enough to obtain two prizes.

Mr. Editor, I am glad to see we have a journal that will come within the reach of everyone, and, by what I see of your first number, it is likely to be a very useful one. I hope it will be taken in largely. I hope the cottagers will take it in, and well study it and work from it, and see if they cannot find a much better plan than the old sulphur pit. I was pleased to see the account of the Village Blacksmith. In a place like this one has to do the best he can; there not being anyone keeping bees on the bar-frame principle for upwards of twenty miles round. We can get an expert twice in a year by paying a small sum, which one is loth to part with in these times. I have in all twenty stocks, that being my number last year.

Being the most experienced in bee-keeping about here, I go to some of the people round to assist them, and am willing to tell them what little I know. I went to a friend last year to look at some bees just in the height of the honey season, as he was in difficulty about them, the distance being about eight miles. When I reached there and looked into his hives, to my disgust I found some of his hives not made up full of frames, also supers put on, and no covering at all placed over. Some sections were well filled, some 4½ by 4½ by 2 were filled to the weight of two pounds, no dividers being used, some dividers only half wide enough, some crooked and broken. The bees had taken possession of the roof of the hives, and had put in a lot of honey. I asked him the reason that no coverings had been used. His answer was no one had told him, and also he had not seen any instructions in any book. The clergyman here used to take the *Bee Journal* in, and lent it to me. I thought it a most useful journal, but being too expensive I could not afford to take it in. Do you think that at these shows if a bar-frame hive was shown full of comb and bees and supers on, and show the cottagers how they are managed, it would be of service towards getting them to take to the new method?—VILLAGE SHOEMAKER.

[We think such an exhibition would be of great service at a show, and would be a practical lesson to the spectators.—ED.]

PHOTOGRAPHIC GROUP OF BRITISH BEE-KEEPERS.

Abbott Brothers are preparing a large photographic group of the most eminent bee-keepers in the United Kingdom, and they would be pleased to receive any assistance from those who take an interest in bee-keeping, so that the group may be rendered as representative and as complete as possible.

LECTURE ON BEES AND BEE-KEEPING.—On Monday, March 12th, an instructive and interesting lecture was delivered by Mr. W. J. Anstey (Oxford Secretary of the Oxfordshire Bee-keepers' Association), in the schoolroom, Yarnton. The room was quite full of villagers. The Rev. J. A. Balleine, Vicar, presided. A large supply of appliances were on view, and the lecture was illustrated by diagrams and dissolving views.

LEICESTERSHIRE BEE-KEEPERS' ASSOCIATION.—An interesting lecture in connexion with the above Association was delivered at Sheepshed, near Loughborough, on March 16th, by Mr. J. H. Howard. Mr. Ward occupied the chair. Much interest was shown by a very attentive audience. At the close Mr. W. P. Meadows advocated the cause of the Association and the good work they were doing, and advised all interested in bee-keeping to join, so that more funds might be placed at their disposal, and more lectures, &c., given. The more general use of honey was also advocated, and the advantages it possessed as a food and medicine.

Echoes from the Hives.

York, March 17.—I have done and will do my best to promote the circulation of your monthly *Journal* which was much wanted, and ought to be extensively subscribed for.—J. H.

Llanerch, March 18.—Weather exceedingly cold, with north-east wind, and an occasional shower of snow, the bees are kept in; and I think that those hives that have bred freely during February will lose a lot of their brood. During a heavy storm of wind and rain that passed over this county on the 9th instant, some of my hive-covers were blown off and the quilts got wet through, so in giving them dry warm quilts I could not resist the temptation of examining them. They had brood on several frames, one had five frames well covered with brood, several of which were hatching out while I held the frame in my hand. My stocks, fifty in number, have wintered well so far, with the exception of one Italian hive, which is suffering from dysentery. This hive suffered the same last year, and I had to unite it to another, and being in too much of a hurry to unite properly, the other bees (which were blacks) killed all the Italian workers, but kept their queen and killed their own. I find the Italians difficult to winter.—H. P. JONES.

East Yorkshire, March 20.—

Bluff Boreas breathes his bitter, biting, baneful blast,
Blizzarding with icy breath all plants and trees—
Bold Frosty Jack in iron grip holds fast
Benumbed Nature,
Blighting for the present hopes of men and bees.—
F. BOYES.

Honey Cott, Weston, Leamington, March 25.—Since my last, the weather has been very severe, with scarcely any exception. The north-east wind has been like a two-edged sword, cutting every way. In the early part of last week, I was looking round amongst the hives, and noticed one stock with a lot of dead bees at the entrance, I uncovered them, and found I was only just in time to save them from starvation. I took them into my honey place, and got a paraffin stove and warmed it, and poured a little thin warm syrup on the bees, when they soon began to show signs of reviving; then I placed a bottle of syrup over the feed-hole, which was taken down during the night, and next day they were as right as any of the others. In the autumn I had placed them in a hive composed of two sections in height, six inches in depth each of them; and as they were on Standard frames they did not reach the bottom within about three and a half inches: but at the time I placed them in I considered they had honey enough to winter on, it may have been that the empty space caused them to consume more food. At all events I do not think it advisable for so much space to be left. The 21st was a lovely day, causing the bees to be very busy, and they were out very much after water and on the crocuses, also the peafflower, which they went in for in great numbers. As it was a bit milder I looked over all my other stocks, feeding any that I could not see with sealed food in the combs when I uncovered the quilts, but not separating the combs. I consider I was very fortunate in thus doing, as on Sunday morning we had a deep snow, and it was also very cold, though it soon melted. Then again last night and this morning there was more snow, and as I had looked them over and fed where I considered necessary, I can feel comfortable about them and not be afraid any more that they will be liable to starve. As far as I could see, stocks seem in good order, more especially as we have had such sharp weather. Have been busy of an evening getting extra hives, &c., made.—JOHN WALTON.

Hutton, Rudby, Yorkshire, March 26.—We have had very bad weather since January, only had two cleansing

flights in about eight weeks. Snowing almost every day, but we have not had very hard frosts. Bees wintered very well so far, I only know of about three or four stocks dying in the district. I wish the weather would break up so as we could make a thorough examination to see if they have plenty of stores.—JOHN BAINBRIDGE.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

A. B.—*Bees proving a Nuisance.*—‘In the event of the gentleman and his friends getting stung,’ we consider that the question of nuisance should be determined by your views of neighbourly courtesy. It may be that your neighbour has no right to compel you to move your bees, but as in the course of events humans are penetrating into, and reducing, the domains where bees had once the priority of range, the result will be that the latter must succumb and go farther a-field. Your bees, however, may not prove the nuisance you seem to anticipate, and therefore there is no reason to cross the bridge before you reach it.

JOSEPH BRINE.—*Honey-comb Designs.*—You will find a communication, with illustration, on honey-comb designs in *B. B. J.* of May 12th, 1887, from William McNally, Glenluce, and in number for May 19th, the advertisement you are in search of, from Richard McNally, Longforth, Glenluce.

GEORGE E. CORBYN.—*1. Excluder Zinc.*—In Mr. Cowan’s pamphlet on *Doubling and Storing*, he says: ‘We have long since discontinued to employ excluder zinc, as we have found it interfered with the work of the bees, and that we always got much more honey without its use than with it. 2. *Carbolic Cloth Recipe.*—1½ ozs. Calvert’s No. 5 carbolic acid, 1½ ozs. of glycerine, 1 quart of warm water. The acid and glycerine to be well mixed, and the bottle to be well shaken before using. The cloth should be steeped in the solution, wrung dry, and spread over the hive on removal of the quilt.

H. INSTON.—Apply to Mr. J. Huckle (Secretary of the Herts B. K. A.), Kings Langley, Herts.

ALEX. JACK.—Sections in travelling by rail have a strange tendency of having the combs broken and separated from the wood. We should advise you to use in future a spring travelling crate: this holds twelve 4¼ × 4¼ × 2 in. sections, and it is fitted up complete with glasses, springs, dividers, &c. Thanks for your kind wishes.

J. J. SHIPMAN.—*Foul Brood Solution.*—The proportions given in *Guide Book* are quite correct. No. 8 being one ounce to one pint of water equal in round numbers to one in twenty. No. 9 is one ounce of No. 8 to one pint of syrup, also one in twenty, consequently there is one of absolute phenol to four ounces of syrup. You can get phenol in crystals for about 3s. 6d. a pound, and make your own absolute phenol, and then you will be certain to have the proportions right. The crystals are taken by weight, and in all cases of solutions the measures are fluid measures. Twelve ounces of pure phenol crystals dissolved in three ounces of water make the absolute phenol No. 7 in *Guide Book*. We do not know why Mr. Cheshire adopted the plan of introducing the phenol cure in the manner he did, but presume a certain mystery attaches to the preparation, and bee-keepers were obliged to procure it through the medium of dealers, and were supposed to only get the

genuine thing if guaranteed by Mr. Cheshire. We think every bee-keeper should make his own solution, and if he will purchase the pure phenol crystals and carry out our instructions, he will see there is no such mystery about it, and that he will effect a considerable saving, and pocket the profit.

W. W.—Mode of fixing Foundation.—Appears a good idea, but turn the prongs the other way.

LLANCAIACH.—Doubling.—We have had excellent results without any excluder zinc between. Some prefer placing the top set at right angles to the lower set. About three-eighths of an inch is sufficient space between upper and lower. The stock referred to can be increased to the extent you wish with good management. Uncap some of the honey in the hive to stimulate them to breeding. The pollen referred to can be given to your remaining stocks.

Jo. Ro. Lo.—Answers will appear in our next.

J. CURRIE.—The comb sent is very suspicious. We should advise you to destroy it.

H. S. H.—Transferring.—This is not the time to transfer bees from a skep to a moveable-comb hive, and any interference now they would not get over until quite late in the season. We would strongly recommend that the bees should be left in the skep until they show signs of being crowded, when an artificial swarm could be made or the skep could be placed on the top of the frame-hive (as you suggest), which must have full sheets of foundation in the frames, or they will build a large proportion of drone-comb in them. If the skep is a bought one, or is not in the exact position it is wished the frame-hive to stand, it should at once be placed there just before dark; a piece of board should be put before the hive that the bees leaving may take notice of the altered position of things, and so find the hive on their return. The bees will be better able to keep up the warmth of the skep, and will increase faster than they would in a larger hive, and with increased numbers and fine weather, will soon make up for the delay in being placed in it.

QUERY.—What is the experience of those who have used 'Heddon's' or other invertible frame-hives, during last season? Give results.—A. T. A.

Received from Messrs. Abbott Brothers two samples of fancy cardboard boxes for holding sections, lined with tinfoil, which will render them honey-tight, and capable of being washed.

AMERICAN CLOTH QUILTS.—I have tried these for the first time this winter, and find them not nearly so good as the old bed-tick ones—those colonies wintering under them have lost far more bees from death than those wintered on the old-fashioned plan, especially have large numbers of dead bees been thrown out after severe frosts—out of all proportion to what have been ejected from hives with ordinary quilts and chaff-cushions.—F. BOYES.

Editorial, Notices, &c.

IN-AND-IN BREEDING.

'To breed from closely related animal of the same stock.'—WEBSTER.

Our valued correspondent, Mr. W. B. Webster, favoured us recently (pp. 33, 48, 61) with a series of articles on 'Consanguinity,' the gist of his argument being, that it is detrimental to the interests of the bee-keepers whose object is to 'make his bees pay,' if he force (or allow) them to continue inter-breeding in near relationship, and that to prevent as much as possible this consanguinity it is advisable to import (not necessarily from abroad) new blood into the apiary occasionally—*Cela va sans dire*.

Truly our *Journal* has been read to little purpose these many years if it has now become necessary to hammer this fact home to British bee-keepers of 1888.

It is well said that 'Nature abhors self-fertilisation,' and she takes sure steps to prevent it all through the range of animated things, from the bacterium to the elephant, from the jelly-fish to the oak. In the botanical world we are astounded at the devices made use of by the plant, under Providence, to prevent self-fertilisation, or any reasonable approach to consanguinity; and as our honey-bee is perhaps of all agents the most-used cross-fertilising instrument, surely bee-keepers ought to be the last to deny her the benefits of a system by which she confers good upon so many varieties of beautiful and useful plants—benefits palpable to every thinking mind. Even atheists admit the operation of great fundamental laws which pervade the whole of the animal and vegetable kingdoms, one of which is that of which we are speaking, *e.g.*, that in-and-in breeding is deleterious, and cross-breeding beneficial, if we seek for the development of higher powers. When we instance the breeding of domestic animals in support of the in-and-in breeding argument, we stultify ourselves by admitting an imperfect acquaintance with the customs of breeders. The Chillingham wild cattle have been mentioned, but these animals, through continued in-and-in breeding, have degenerated (so we were told by a recent eye-witness) into a herd of only some fifty or sixty comparatively small animals. In breeding short-horns the parentage is so arranged that consanguinity in a near degree is avoided.

The very particular animals themselves, so much prized by connoisseurs, are the results of studied crosses, the original of which are resorted to at times for the re- importation of typical points.

We are sorry to find Mr. W. Woodley the parent of

the following remarks on page 90:—'I feel sure that in-and-in breeding *does not deteriorate* the race of English bees as regards their size, working qualities, or prolificness, though it should run on decade after decade, generation after generation;' and we think he will, after a little further investigation, admit his error, or that he misunderstood the meaning of the term in-and-in breeding as used by him and Mr. Webster. It is too late in the day to doubt the firmness of the ground on which Mr. Webster's articles are based, now that we obtain 'honey by the hundredweight' from bees, which, according to excellent authorities, have ceased any longer to be the old English or German brown bee by reason of the numerous importations from abroad.

It is difficult to see how any objection can be taken to Mr. Webster's argument when he distinctly tries to protect himself from misunderstanding by saying on p. 63: 'I do not mean to assert that an apiary in the British lands could be annihilated through the owner neglecting to introduce fresh blood, but each consanguineous cross militates (against) the chances of successful venture in bee-keeping.' Indeed we will go further than our correspondent, and assert that the owner of a single hive of bees would not have to wait many years for the extermination (or, what is quite as bad, the worthlessness to be proved) of his bees, supposing it possible that they could be perfectly isolated. Mr. W. Woodley's case (p. 91) of the old man whose 'father and grandfather in the lone valley,' left him a pure, inbred, immaculate strain of bees, tells somewhat against his argument in our opinion, for they did not 'go forth and multiply' much if, after a century and a half, they only yielded the owner an annual profit of 6*l.*; whereas if an occasional queen had been introduced from beyond them, we suppose that valley would have been full of somebody's bees by this. Then, again, we are led to infer that there was a proximity of stocks, for 'the farmer's widow gave the man a *second* swarm of bees, and we have had them ever since.' This argument is little support in favour of in-and-in breeding unless there be some evidence (beyond that of the old bee-keeper alone) that no other bees had been kept within a radius of six to eight miles during the century and a half.

Mr. F. Boyes (p. 144) gives us one of his usually interesting articles: but we take leave to say he misunderstands the question at issue. The question of keeping to the English bee as it is, or of importing foreign bees, is scarcely germane. Our native bees can be used for cross-fertilisation to any extent without the necessity of importing a single foreign bee; such would not be consanguineous breeding, the germ of Mr. Webster's argument. If Mr. Boyes exchanged any special variety of pigeon with Mr. Webster for breeding with his own, such a mixture could not be called in-breeding, and would be productive of good, indeed it would be a most advantageous infusion of new blood such as is not only advocated in these days of high breeding, but insisted upon; it would be, in fact, just such an importation of fresh

vigour as is advocated by Mr. Webster, and is recognised as one of the canons of scientific bee-keeping. But if we interbreed the two *first* relations of any animal, we probably find some sign of degeneracy at once; and if the system be adhered to, of narrowing the parentage, so to speak, instead of expanding it, for a few generations, we accentuate such signs and enforce either the necessity of infusing new blood, or being face to face with what means ultimate extermination. A good, all-round bee might be produced from an admixture of Ligurian, Carniolan, Cyprian, and English blood in fifty apiaries at once in this country, and in one or fifty years, if such bees were interbred this would not be consanguineous breeding, exactly as our own English bee in its wild or domestic state can intercross without interbreeding.

Mr. Webster's position will be much simplified if we take him to mean that the interbreeding of different families of the same (or different) variety of bee is to be commended and advocated, whilst the interbreeding of blood relations (near or remote) is to be deprecated and condemned. Those who do not agree with us on this point find the grossest fault with that All-wise ordering of things which brings about by natural selection 'the survival of the fittest' (that common and much-prostituted phrase). Else there were no necessity for either queen or drone to retain their wings for the purpose of taking their well-known high and wide flights. This great circuit-flying alone shows us the efforts made by the bee to secure cross-fertilisation, as also does the impossibility of obtaining fertile queens in the hive and the difficulty of accomplishing artificial fertilisation. It is also shown in the evident necessity of aerial fertilisation in order that a queen may have a distinctly probable chance of meeting a strange drone.

We have no desire to stifle the discussion in our columns of any moot points, the ventilation of which may give new ideas to our readers, and throw new light into dark corners, but when we see old and valued contributors mistaking the points at issue, and meandering away from the true subject; by this means also somewhat puzzling those who are trying to follow them as to their real meaning, it is only meet and right that the points in dispute should be sifted out and re-iterated in such a manner that there should be no mistake possible on the part of those who are likely to be affected by the nature of the correspondence.

CELLAR AND CLAMP WINTERING OF BEES.

In northern countries, where Winter holds high revel, and Frost seizes everything in its icy grasp, cellar or 'clamp' wintering of bees is an absolute necessity. Nowhere is this system more extensively practised than in our own Colony of Canada, as well as in the northern parts of the United States. We have, fortunately, a winter climate usually of so mild a character that any necessity for bee-keepers to go to the expense of a bee-cellar rarely presents itself. In Canada and the United States the bee-keeper, at the approach of winter, removes all his colonies from their summer stands, and with a deal of labour packs them away in a frost-proof house, leaving them thus until the advent of summer weather; they are then removed, and placed again in the positions occupied by them during the preceding summer. Often it happens that, even with these great precautions, many colonies are lost; the reason of such is mostly an enigma. Many colonies also, after removal, are subject to that bane of bee-keepers, spring dwindling, though the cause of this latter is mostly traced to the unsuitable quality of the food stored by the bees during the preceding autumn.

Until the year 1887 we had no record of the presence

of a properly-constructed bee-cellar in England; in this year Mr. W. B. Webster, being introduced when on a lecturing tour to a gentleman, Mr. Greenhalgh of Newton-le-Willows, Lancashire, an old Canadian colonist, was informed by him that he had constructed a cellar upon the same lines as those used in Canada, and of which he had had considerable experience. Mr. Webster, having received an invitation to view this cellar, availed himself of the opportunity, a report of which visit was published in this *Journal* (p. 279 of last volume). Unfortunately, Mr. Greenhalgh neglected to weigh his colonies before placing them in the cellar, but he expressed an opinion, upon removing them in February that there was a scarcely perceptible difference in the weight, perhaps from two to three pounds each. The foregoing led Mr. W. B. Webster to try, during the winter just passed, what would be the effect upon a colony placed in a 'clamp' in much the same manner as potatoes and other roots are preserved in England in what are called 'graves.' For this purpose he dug a circular hole in the earth 3 ft. 6 ins. in diameter, and 1 ft. in depth upon the clay—we should consider this, being damp, rather an unsuitable place for such an experiment, but Mr. Webster had no other—the bees, in a straw skep, were, without floor-board, placed upon four stakes driven into the clay, the ends being four inches above the level of the bottom of hole; over the hive were ranged some rough branches in the form of a dome, then a layer of straw, about two inches, and over all the earth piled to the depth of eighteen inches. This was done on the 10th of last November, and the bees left quite undisturbed and without any ventilation, except that obtained through the porosity of the earth, until a fortnight ago, when, upon removal, they were found in a most flourishing condition, and, that which is of the greatest moment to us in England, had only consumed two pounds of stores during their four and a half months' incarceration.

We do not feel inclined upon these experiments to recommend an universal system of cellar or 'clamp' wintering in England, but to direct attention to a subject that has engaged the attention of apiarists for many years as to the least amount of stores a stock of bees can be safely wintered upon. It has been universally recommended that from 25 to 30 lbs. is the safest amount, though 20 lbs. will mostly suffice for a good colony; but if these same bees were 'clamped,' and only consumed 2 lbs. in four and a half months, they would have more stores than could be consumed before the advent of spring, and as a consequence this surplus might be confiscated by the bee-keeper. The question would then arise, whether the surplus thus obtained would be sufficient to pay the apiarists for, first, the trouble of removal into winter quarters and subsequent placing on summer stands; and, secondly, the expense of building a cellar or constructing 'clamps?'

Our opinion at the present time is that these proceedings, taking into consideration the price of honey, would not pay at least to 'clamp' them, as each year these 'clamps' would have to be renewed, though the expense would simply be the labour. A cellar if properly constructed would last for years, therefore this expense would be distributed over an almost indefinite time.

Our American friends in more southern latitudes rarely cellar their bees, where, owing to the mildness of the climate, they are not necessitated so to do, we may therefore take a hint from them, remembering at the same time that honey fetches in the United States but a little more than half the price it does in England. We will therefore leave this interesting subject to the consideration of our readers, who in making further experiments may discover some method whereby a colony can be deprived of a larger amount of stores, and yet at the same time be safely wintered, thus bringing in a little more profit to the bee-keeper.

BEE-KEEPERS' VOCABULARY;

OR, GLOSSARY OF TECHNICAL AND SCIENTIFIC WORDS
USED IN WORKS UPON BEE-KEEPING.

Abdomen. *n.* (*L.* from *abdo*, to conceal.)—The lower part of the body, united to the middle part, or thorax, by a stalk or petiole. It is divided into segments and rings, on the sides of which are small spiracles, by which the insect is enabled to breathe.

Abdominal distension.—This is a swelling of the abdomen produced by the bees eating too much pollen during winter, which they are forced to do to keep up the temperature in hives not properly protected, and are unable to fly and discharge their faeces.

Abdominal plates.—The upper and lower plates of the abdominal rings. In the worker only, there are on each of the ventral plates, except the first and last, two irregular-shaped discs or depressions called 'wax-pockets,' because it is here that the wax produced by the wax-glands collects.

Abdominal rings.—The belts of chitine forming the abdomen, each composed of two plates—the dorsal (on the back) and the ventral (on the lower side). Drones have seven rings, whilst workers and queen have only six.

Adductor muscles. (*L.* *adduco*, to lead away.)—Those which pull one part of the body from another, in opposition to the adductor muscles, which draw together.

Aberration of instinct. (*L.* *aberratio* from *aberro*, to go astray.)—Wandering from the right way. Sometimes bees will swarm without making the usual preparations by commencing queen-cells, by trying to raise a queen from a drone-producing egg; or a queen will refuse to accompany a swarm. Such cases being out of the usual course are assigned to aberration of instinct.

Abnormal bees. (*L.* *ab*, away from, and *norma*, a rule.)—Irregular, deformed, sometimes containing the characteristics of the two sexes in one individual; hermaphrodite.

Abnormal swarms.—Such as leave the hive under unusual conditions or contrary to known laws.

Aborted. *p.p.* (*L.* *aborior*, to miscarry.)—An organ whose development has been arrested at an early stage is said to be aborted or atrophied.

Absconding colony. (*L.* *abs* and *condo*, to hide, *i.e.*, to withdraw.)—A colony of bees which deserts its hive in a body.

Absconding swarm.—Part of a colony which swarms in a natural manner, and goes away to some distant place either before or after first settling in a cluster, or sometimes even after being hived.

Absorption. *n.* (*L.* *ab* and *sorbeo*, to suck in.)—The act or process of taking in or imbibing by the mouth or other parts, as in the case of the larvæ. The imbibition by the tissues of nutritive materials.

Acarus. *n.* (*Gr.* *acares*, a morsel.)—A genus of Arachnida belonging to the order Acarina, usually called mites.

Acarus favorum.—Found on old honeycombs, which are sometimes entirely eaten up by these mites, leaving a dust and their cast skins.

Accepted. *p.p.* or *a.* (*L.* *accepto*, to take or receive.)—Sometimes applied to the favourable reception of a strange queen by the bees of a queenless hive;—kindly received.

Acclimatise—Acclimate. (*Gr.* *clima*, a zone, climate.)—To inure, or to habituate to a climate different from the native one (or not indigenous).

Accommodation cells.—Irregular-shaped cells of variable size placed between worker and drone cells. *Transition cells.*—In building comb bees pass from worker to drone cells by constructing from one to six rows of such cells, and these sometimes have from three to seven sides. In joining two pieces of comb together bees build accommodation cells to fill up the interstices.

Accouplement. *n.* (*Fr.* *couple*, to couple.)—A coupling, or connecting, or pairing between drone and queen.

Acherontia atropos.—Latin name for death's head moth, a lepidopterous insect of the family Sphingidae, an enemy of bees, doing much damage in southern Europe, where it enters and plunders bee-hives with perfect impunity.

Acid. (*L.* *acidus*, sharp, sour, literally piercing; *Gr.* *akis*, *akidos*, a sharp point.)—Sour to the taste. Honey after fermentation turns acid, and may be made into vinegar. Honey also contains a minute quantity of formic acid, but not in sufficient quantity to make it perceptible to the taste. This acts as a preservative.

Aceton. *n.* (Butler gives its derivation as *Gr.* *a*, not, and *kaitos*, a bed, hence without lees or dregs' which form the bed or ground whereon wine and such liquors lie; virgin honey, so called because 'it runneth of itself as new wine and oil.')—Name given by ancient writers to virgin honey—the very first that is taken from new comb. 'This aceton or finest nectar, for his incorrupted purity, is called virgin-honni.'—C. BRILLEN.

Acrid. *a.* (*Fr.* *acre*; *L.* *acer*; *Gr.* *ak-e*, a point.)—Pungent, bitter, sharp or biting to the taste.

Adapting board or Adaptor. (*L.* *ad*, and *apto*, to fit.)—A board placed on the top of a hive, with holes or slits in it to allow the bees to pass into the supers placed upon it.

Adaptor zinc.—Sheet of perforated zinc with holes just large enough to permit workers to pass through into supers placed there, but too small to allow the passage of the queen.

Adductor muscles. (*L.* *adduco*, to draw to.)—Those which draw one part of the body to another.

Adjustable entrance.—Entrance to a hive which can be enlarged or contracted by means of slides or blocks.

Adjustable floor-board.—Loose floor-board used in hives on legs, which can be raised or lowered at will.

Adulteration. *n.* (*L.* from *adulter*—*ad* and *alter*, other.)—To corrupt or make impure by an admixture of less value for the purpose of deception or getting a greater profit. Substitution of a cheaper article for the genuine one.

(To be continued.)

ASSOCIATIONS.

BRITISH BEE-KEEPERS' ASSOCIATION.

The first meeting of the newly-elected committee was held at 105 Jermyan Street on Wednesday, January 21. There were present the Hon. and Rev. H. Bligh, the Rev. Dr. Bartrum, the Rev. G. Rayner, the Rev. F. S. Slater, Captain Campbell, J. M. Hooker, W. O'B. Glennie, Treasurer, and the Secretary. A letter was read from Captain Bush regretting his inability to be present on account of illness.

Mr. T. W. Cowan was elected chairman, and the Hon. and Rev. H. Bligh vice-chairman, for the ensuing year.

The following sub-committees were also appointed, *viz.*, 'Finance': the Rev. Dr. Bartrum, Rev. R. Errington,

and Mr. H. Jonas. 'Educational:' Hon. and Rev. H. Bligh, Dr. Bartrum, the Rev. G. Raynor, and the Rev. E. Clay.

Exhibitions: Captain Bush, Rev. R. Errington, J. M. Hooker, H. Jonas, Rev. F. S. Selater, Rev. J. L. Seager. County Associations: Rev. F. S. Selater, Captain Bush, Rev. G. 'Oddie, Rev. J. L. Seager, and Captain Campbell.

The chairman was elected an ex-officio member of each sub-committee.

It was resolved that committee meetings be held on the third Thursday in each month.

On the motion of the Rev. F. S. Selater, it was resolved, 'That a sum of ten pounds be voted for prizes in classes (open to members of the British Bee-keepers' Association only), at the county shows of affiliated county associations—such prizes to be offered only in cases where county associations will give facilities free of charge for the staging and care of the exhibits, the same total not to exceed 2% in each case.' The matter was referred to the Exhibitions Committee to make the necessary arrangements.

The Secretary reported that he had received a communication from the President in reference to the bills about to be presented to Parliament relating to the teaching of agricultural and kindred subjects in elementary schools. Her Ladyship considered that it was very desirable that the Association should endeavour to obtain every possible information which would tend to demonstrate the benefits which the nation derived from the industry of bee-keeping.

GLoucestershire BEE-KEEPERS' ASSOCIATION.

NOTICE TO LOCAL DISTRICTS.

The Hon. Sec. of the Gloucestershire Bee-keepers' Association desires to draw the local secretaries' attention to the following new rule, and will be glad to hear at once from those that wish to avail themselves of it:—

That all local secretaries who are not appointed by the district associations shall be appointed by the general committee for the districts where they may be deemed desirable, and that the general committee may fill up all vacancies in its own body which shall occur during the year.

Moved by Mr. Brown, seconded by the hon. sec., That members of the Association be recommended to form themselves into district associations, mutually arranging the boundary of their districts, should any difficulty arise as to the question of boundary, the matter shall be referred to the general committee, whose decision shall be in all cases final.

That district associations shall subscribe to the county Association one-fifth of the total amount of their annual subscriptions, and render an account of all their receipts and expenditure to the general committee.

That each district association shall hold an annual meeting early in January, when it shall appoint a local secretary and other officers it may deem desirable, but subject to the approval of the general committee.

That the Association shall aid the district associations as follows, and in any other manner within its power; viz., by lending its bee-tent on conditions fixed by the general committee, by providing sufficient annual reports, and by supplying receipt-books, and members cards.

WORCEstershire BEE-KEEPERS' ASSOCIATION.

The address of Mr. E. Davenport, Expert to the Worcestershire B.K.A. is 'Tontine Buildings, Stourport, not Stockport.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal," c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, Kings Langley, Herts (see 2nd page of Advertisements).

**. In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.*

GLASGOW INTERNATIONAL EXHIBITION, 1888.

[1563.] Having had full charge of negotiating with Irish bee-keepers, in connexion with samples of Irish honey for above, allow me, on behalf of my brother and myself, to thank all those who kindly sent samples from Ireland. Our best thanks are due to the hon. secretary of the Irish Bee-keepers' Association, Henry Chenevix, Esq., who kindly supplied a list of the best known bee-keepers in the various counties. I put myself in communication with many of these, and am happy to state I have received samples from Ireland sufficient to prove that they are advanced in the science of bee-keeping, and are keeping pace with their English and Scotch friends. Of the various lots I purchased I would specially mention the samples received from Miss E. E. Rutherford, Ghan House, Carlingford, and Mr. George Turner, Revlin House, Donegal. Of the other samples I received, I have to state many of them arrived in a terrible state of havoc, which was due in many cases to careless packing. Altogether, the Irish produce will have a creditable appearance. Should any Irish bee-keepers have any specialities, which they would like included in the Irish collection they will kindly forward the same at once to the under-noted address.—JOHN D. McNALLY, 30 Millarbank Street, Springburn, Glasgow.

SECTIONS.

[1564.] Much has been written in your columns as to the most suitable size and width for sections, and also as to the desirability of four bee-ways or two bee-ways; but as far as I have seen the question of the most suitable width for these openings has never been discussed. I would much like to get the opinion of some experts on the subject. My own opinion is strongly in favour of full bee space sections. Last year I tried, by accident rather than by design, half bee space and full bee space both two and four way, and came to the conclusion that the best were the two bee way with full bee space. The separators need only be plain strips of tin or wood. I found that the cutting out for the half bee space very much weakened the separators, and as a consequence they required more time and care expended on them in manipulation. Besides I thought—for on this point I am not certain—that with full bee space the sections were better finished. Unfortunately last year very few of my sections were really well filled, owing I suppose to the peculiar season. Though it was only last year that I took notice of the difference arising from the different bee spaces, yet I have had full space section in use for three years, and always liked them, but last year settled me in the belief that they were best. Another thing I would like to mention, viz., that no firm of dealers, so far as I know, state in their catalogue the width of this bee space in their sections. This must have caused much trouble to buyers who sometimes have to order in a hurry without seeing samples. I know it has to—GEORGE D. CLARK.

QUEEN REARING.

HOW SOME OF THEM DO IT IN AMERICA.

[1565.] Noticing the query by Mr. Stevens and your reply thereto in the Feb. 9th No. of the *British Bee Journal* I am constrained to offer the following, chiefly because it is very different from the method laid down in the article referred to, and is withal so very simple, only expressing the hope that it may be new to some of the readers of the *British Bee Journal*, and may help Mr. Stevens or others in the rearing of their own queens.

Every *Yankee* is supposed to be in a hurry, and I believe we apiarists are no exception to the rule. From April 1st to October 1st finds every day filled full of work for the man with 100 or 150 colonies on his hands, in a good locality for honey production. But queens must be had to prevent in-breeding, to replace old or worn-out queens or inferior ones, or to remedy queenlessness. Here queens cannot be reared and fertilised much before June 1st, so if we need queens in spring we buy *tested* queens of those who have them for sale. This gives us new blood, and from these and two or three others of our best queens we must prepare to rear all queens needed for the summer's use. Of course, since they are the best queens we have, their stocks will be strong, but they can be stimulated by a little syrup-feeding, or by giving them extra sealed brood from other colonies. When the time comes put on the supers, but do not give them all the room they want, crowd them a little. With this management one of the three or four will be sure to swarm early, casting a fine swarm. Hive this and give them all they can do gathering honey—we are now after the queen-cells to be found in the old stock. At the end of six days they will be ripe, when we go over the hive and cut them all out except one, to provide this colony with a queen. Handle the cells thus obtained very carefully, for they contain *royalty*. These cells are then placed in the 'nursery.' This is simply a brood-frame one and a half inches wide, divided into compartments thus:—

On one side of this frame is tacked wire-cloth over the whole side; on the other are slides for each row of boxes. The cells should then be carefully placed one in each compartment. It is not necessary to suspend them. This frame is then to be placed in the centre of a good colony in such a manner as not to interfere with the supers much. Examine this daily, and as soon as a queen hatches remove her through the slide door at the back to a queen-cage, and introduce her to any colony which from any cause needs a new queen.

As the colonies from which you have prepared to rear queens swarm one at a time, we are supplied with cells for our nursery frame until the close of the honey harvest. Last season I introduced some twenty queens from one mother, reared in the manner described above. With us *hurried Yankees* the loss of time to the colony until the new queen is fertilised is more than compensated for by having to make no nuclei. Then, again, the loss in brood to the colony, to which the virgin queen is introduced, is not felt (with us) until after the honey season is over, and the young queen will provide a good strong colony for winter, which is all we desire.

But how do we obtain the few queens needed in the autumn? Why we just return some natural swarm having a good queen, and if her wing is not clipped we first place perforated zinc over the entrance, and watch for her as the bees go in, and when we find her make a

nucleus with two frames of bees and brood and the queen from the parent stock. Two or three of such nuclei will generally supply all queenlessness in the fall of one hundred colonies.

Of course, the method outlined above must be carried out on a smaller scale in a small apiary; but I have practised it with as low as sixteen colonies. We find it the simplest and the cheapest, both in time and money, as well as the best, for the queens are all reared by natural swarming, and we can pinch off the heads of small queens or those leaving no jelly in the cells.

By buying a few tested queens each spring and breeding from them we avoid that in-breeding so much discussed in your excellent paper the *British Bee Journal*—J. H. LARRABEE, *Larrabee's Pt., Vt., U.S.A.*

FIRST ATTEMPTS.

[1566.] I am much obliged for your comments in the *B. B. J.* of January 26th, 1888, on the sample of honey I sent you. When writing you with sample, I promised to send you later on an account of my first attempts at bee-keeping. Here it is, if you think it will serve any good purpose in your interesting *Journal*.

I had been reading your valuable *Journal* the whole of the winter preceding my beginning a start with bees in the spring of 1887, obtained Mr. Cowan's *Guide*, and Root's *A B C*. In April I bought from a bee-dealer two lots of condemned bees in a twin hive, described as strong, healthy, and brooding. On arrival, I had them examined by a friend of mine, a large bee-keeper in this neighbourhood, who gave me the consolation that one stock was too weak to pull through the spring, the other, he *thought*, would be all right; and so it turned out. I thought I would start with two stocks, so ordered a swarm which came late in June: and now my troubles began. I had never hived a swarm in my life, and only saw it done once, and then by an expert. I was quite alone the evening the bees arrived, and could not possibly turn them out of swarm-box before 9.15 p.m.—rather late. After unscrewing the cover, in my haste to get them out, I forgot to bump the box so as to get the bees into the bottom of the box before throwing them out. I turned the box over, and the bees being close to the unscrewed wire gauze, their own weight bent the same, and they rolled out 4 $\frac{3}{4}$ lbs. strong. I saw my mistake instantly, and though in anything but a confident mood, with hundreds of bees flying about me, gave the box a good thump to get out what remained, and stuck to my standing. I next helped them towards the entrance of the hive with nearest tool to hand—a stick—and then did a little painting with a feather and some carbolic to keep them within boundary-line of the sheet in front of the hive. It was now getting dusk, and to help them cluster quicker, I sprinkled them with a little water from a rose-water pot: when doing this the handle came off, and half a pot of water went over the bees. Oh! I thought, if this lot gets through all right, it certainly will not be due to any help I have rendered them. However, the dry ground and sheet soon absorbed the extra moisture, and in about twenty minutes they were all in.

At ten o'clock I lifted the hive on its stand and bade them good-night. Lost a good teacupful of bees—dead. Result of my evening's performance—bees on the brain; could not get a wink of sleep. A fine beginning this, I thought. But how about the queen? Had I drowned her Jubilee Majesty?—that's the rub! I put them on ten frames of full sheets of foundation. When I examined for the first time, which was in the course of five days (could not get near them before, they had been so badly handled that they fairly drove me off the first two attempts I made to examine them), I was very pleased to find proof of her majesty's presence. At the end of the season the swarm had drawn out twenty combs, and

gave me 17 lbs. surplus beautiful honey, such as sample sent you. By the time they had the super combs well out, the honey glut was over, and then it simply became hand-to-mouth work with them. I may say I did not take but one outside frame from brood-nest, which was without brood, leaving the rest for the stock to winter, and in September gave them 15 lbs. of syrup in addition.

The condemned lot before referred to filled my four-teen-frame twin-hive with bees, and gave me but one frame of honey. This was through another blunder of mine. If I had limited the brood-nest, surplus honey, instead of a box full of bees, would have been the result. However, I packed this lot also in September, and fed rapidly. To-day, March 2nd, the bees are out in large numbers for a cleansing flight, and looking remarkably strong and healthy as far as a novice can judge. I intend to-morrow, if as fine as to-day, to give them a cake of candy for safety, though I do not think they are short.

'How many stings did you get in living your swarm so clumsily?' asks some one. 'Not one!' 'Did you use gloves?' 'No.' 'Veil?' 'Yes.' Further, to encourage the timid—of whom I am one—I did all the manipulating throughout the season without a sting. Perhaps I should have said, both lots of bees are blacks—the swarm not of the sweetest temper by any means.—J. W. PAUL, *Westbrook Villa, Neath, South Wales, March 2nd.*

'WITH THE AID OF MODERN BEE-KEEPING.'

[1567.] As your correspondent, 'A Voice from the Cottage,' I have taken the *B. B. J.* for twelve months, and have not seen anything of a *bona fide* cottager. Well, sir, I don't think we can expect much from them if it is the same all over the country as it is in this part—West Sussex. There are a great many cottage bee-keepers about here, but all on the old style. They winter one or two stocks and destroy the rest. I had the good luck to save six stocks from death last year. An old cottager, who is past work, asked me to take his honey for him; after a good deal of talk I got him to let me drive the bees out and have them for my trouble. He was very doubtful about it; he has kept bees all his life and had never seen such a thing done. However, with the aid of the *B. B. J.* and *Modern Bee-keeping*, I drove them very well and pleased him much. He says the honey is the best he ever had. But to myself. I am a cottager, groom to a farmer two years this summer. I bought a late swarm of bees and a straw skep; gave 7s. for the lot, and was told that it was bad luck to give less than 10s. I did not know anything about bees. I had a mile to carry them. I got them home all right, placed them on the stand, and left them all that summer. The next spring I got *Modern Bee-keeping*: in that little book I found out all about bees. I made a super to fit the top of my hive with eighteen sections, crown-board, and roof. At the beginning of June I placed it on and had a glass to look in. In three days they were up and at work. I had quite a show for a while, people kept coming to see the bees work; and by changing the sections I took thirty-one pounds of nice white clover honey. I had no trouble to sell it at 10d. per pound.

I had never seen a frame-hive, and I could not afford to buy one, so, with the aid of *Modern Bee-keeping*, I made a very good cottage hive to take eight frames; I only put six in, and when I put my driven bees in I tied some unfinished sections in the frames; but I put the frames too wide apart, and the bees have built up between them. I put two lots into that hive, as I had no time to drive any more then. The next week I bought a straw skep and put the other four lots into it. Then I wanted a feeder; I got an empty syrup tin, made some holes in the bottom, tied a piece of coarse paper

over them, placed it on the frames, and another over the hob of the straw skep. I only had to pour in the syrup and put the lid on, and it has answered well. I could put on two pounds at a time, and so far my bees have done well. I have three stocks to work this summer, and as there is a lot of white clover sown about here, I think I shall get a nice lot of honey. I have made a good frame-hive this winter; it has ten frames, one dummy, quilts, two section-erates, moveable floor-board, and porch. Next month I shall drive one of my straw hives, cut the combs out, and tie them into the frames with tape. I have got a good smoker, and can manage them pretty well now.—E. RAVEN, *Norton, Selsey.*

WHAT IS A COTTAGER?

[1568.] Now when many people want everything at least possible expense it is absolutely necessary to pass a rule defining the cottager. With keen trade competition, appliances, &c. are within the reach of all. The principal point, therefore, I consider, is time to give the bees the necessary attention when required. Take, for example, an agricultural village: the schoolmaster, the shoemaker, carpenter, and blacksmith, are in a certain sense their own masters, are always at home; yet these enter as cottagers. What wonder if the labourer complains that he stands no chance at the local shows? I believe there is nothing like fair competition for keeping up an amount of interest necessary for success in bee-keeping, but the man who is always at home has an advantage over his neighbour who is away the whole day.—NORTH DEVON RUSTIC.

NOTES FROM MALTA.

[1569.] I have at last hit on a satisfactory method of driving the bees from the native pots, but not until I almost lost two stocks. The combs are built sometimes across, but more generally very nearly fore and aft; and my plan was this, I gave them a puff of smoke at each end, and followed up by sprinkling from both ends with thin warm syrup. After some minutes I stood the pot, big end up, in a broken chair, and put my smoker underneath with its mouth just inside the small end or muzzle of the pot, so that the smoke went curling up slowly through the combs. A skep being held above as in 'open driving,' the bees ran up beautifully, and in a very short time I had the pot clean, and then lifted them. I have never had to do with bees before, but can't help fancying that these are smaller than usual, because after hiving I stood the pot above the hive as a super, in order that they might hatch out the large quantity of brood there was, inserting excluder zinc between; but, lo and behold! when some days after I opened up to examine, the hive was deserted, and the pot full. Queen and all having gone up, and the performance had to be gone through again, and this time I cut out and transferred three combs. They have drawn out almost all the foundation, and her majesty appears to approve as she is not content with a patch in the centre, but has literally filled the frames from top to bottom. I never saw such sheets of brood, and as level as a board, and the young bees somehow seem bigger. May it not be that foundation causes them to build larger cells than they naturally do?

I find great difference in their temper—one hive I can hardly go near unless fully gloved and veiled, while another got from the same apiary are like lambs, and I find that smoke enrages them to an extent that I have almost given up using it. The scirocco wind makes them heavy and dull. Drones are already flying, and white capping is visible over honey here and there. Clover being now in blossom.

I have just ordered a hive on Hedden's plan, as I find

trouble with the eight-inch sheets of foundation; they warp so, and when really hot weather comes I think his shallow boxes will act better, but I doubt his system of contracting and wholly trusting to artificial feeding in winter, especially for an amateur who cannot always be among his hives.

I have discovered a carpenter who has frame-hives, about twenty, and gets his things from Turin. He was astonished at my whole sheets of wax, as he had only used starters, and I don't fancy has any section super arrangements.—MALTA.

DRONES AND THE FERTILISATION OF QUEENS.

[1570.] Last year I had a stock of Carniolans headed by an unfertilised queen. This queen was reared late in the autumn, and the weather turned out very cold so the drones refused to come out.

About the end of March I examined my hives and found this hive with plenty of drone-brood, but no worker brood. As I wanted to get purely mated Carniolan queens, I thought it would be a good chance to have them mated with these drones before other drones appeared, so raised queen-cells at once, and by the end of April they were placed in nuclei to be mated.

There are no bees within two miles of my apiary, and I attend to those, and I did not see a single drone. The queen did not begin to lay until the end of May, but she must have been mated with these drones. I intended to give it a further trial this spring, but the queen that I reared late last autumn got lost, as I cannot find her in the hive. I should like to have the experience of others.—H. P. JONES.

WELSH BEES AND FOUL BROOD.

[1571.] Having acted as an expert for the Montgomeryshire Association, and having been all over Merionethshire, and parts of Denbighshire and Cardiganshire, and having manipulated several hundred stocks of bees, I have not seen the slightest trace of foul brood, except in one case, and that I am glad to say was not a bar-frame hive, but a skep; nor were there bees kept in bar-frame hives within eight miles. This goes far to prove that the bar-frame hives are not the cause of foul brood.

Having noticed the great difference in colour of our native bees I do not wonder as to there being a dispute as to whether to call them black or brown bees. I have noticed that there are two distinct kinds in Wales, one black and the other brown.

The black bees (or the darker-coloured) are more fierce; their queens are not so prolific, but the workers are better honey-gatherers, and are fearful robbers, nearly as bad as Italians which attacked one of my stocks, and actually met the workers on the alighting-board and made them deliver their honey, and if they refused, they killed them.

The brown (or the lighter-coloured) are very amiable, their queens are very prolific and beautifully marked, very much like Carniolans, and their workers have light bands around them, but are much smaller than Carniolans, their only fault is they do not defend their hives well. I think that one of these queens mated with Carniolan drones would make a good useful bee.—H. P. JONES.

PAINTING HIVES—WIRED FOUNDATION.

[1572.] I doubt whether Mr. H. Adcock may think my practice any better than 'painting' the inside of hives. However scorned, years' experience proves that it answers. It is to give two dressings of boiled linseed oil. The first dressing will sink into pine wood and

entirely disappear in a few hours. The second will dry in a day or two, and make the hive impervious to wet or damp, and is much to be preferred to any kind of paint, the base of most of which is either white lead or white zinc, and this, I think, is injurious to bees. Probably this may partly account for so many of Mr. A.'s bees dying, but more was owing to the hive being set perfectly level. No matter what the kind of hive, whether on the rectangular or parallel system, to carry off the water, it should be inclined a little to the front, but only very slightly. But if Mr. A. wishes for a hive in which it is impossible for wet to gather, let him try a modification of Mr. Blow's Anglo-Cyprian. I made myself one a few years ago by way of experiment, but instead of placing the flight-hole at the end of the hive, and entirely closing the lower angle, I made the flight-hole at that angle, and along the whole length of the bottom of the hive with corresponding slides, and an alighting board nailed to the legs on the front side twelve inches broad, coming down nearly to the ground. Although it might be objected to in another respect, it certainly has the merit of being always thoroughly dry, and the bees have done very well in it.

A good deal has been written and done about wired foundation. I entirely object to it, except in the case of sending a hive and stock (especially a recent swarm) to a distance by rail. If you want, as is not unfrequently the case, to cut a comb out of a frame, it is most inconvenient to have cut through five or six wires at top and bottom. The same object, viz., keeping the foundation sheet straight can be much easier effected as follows:—Bore two small holes a quarter of an inch apart in both ends of the frame exactly equidistant from the middle of the end, and about an inch above the lower edge of the foundation sheets. Then with a needle draw a piece of strong cotton or linen thread through the holes from end to end of the frame, but taking care to cross the thread as soon as it is through the wood end, so as to clasp the foundation close by; return the thread to the end you began at, and tie tightly. This will keep the foundation quite straight and in the centre. The bees will draw it out, and when they come to the thread will gnaw it in two, and drag it out of the hive, or the bee-keeper may do that for them. Under this method I have never known the foundation to buckle or twist. The dark line represents

the foundation, and the dotted lines the thread crossed at each end; the whole a section of foundation, thread, and frame ends.—J. H. York.

DROUGHT NOT THE ONLY CAUSE OF A LIGHT HONEY-CROP.

[1573.] It appears to be a very general complaint from almost every quarter that the honey-crop of 1887 has been unusually light, and the cause is almost unanimously attributed to drought, but I apprehend that the dry weather was not the only cause, nor do I think it was the principal cause of the failure of the honey-crop. If such were the case, how could it happen that the best flow of honey that we had last summer came during a few days right in the very driest time in the whole season? while just before and immediately after there appeared to be very little or no nectar in the flowers. That is the way it worked in this locality as near as I could discover, and I watched things pretty carefully, or at least I tried to. I think it was the late Moses Quimby that said that the best time for bees to store honey is

when the farmers begin to complain of the need of rain, or words to that effect, and my experience coincides with that sentiment. Now, in this immediate vicinity it was not so extremely dry during the past summer as to effect the field-crops very badly, although more rain would, no doubt, have been beneficial to them, yet the honey-crop was no better here in June and July than in many other places. And the same condition of things appears to have existed in other localities also. In the *American Bee Journal*, page 613, W. J. Cullinan, of Mt. Sterling, Ill., makes the following statement:—'We have had this year, without exception, the largest wheat and oat crop that was ever known in this section of the country, and I see the same recorded for Missouri and other States. We had a fair crop of hay, and will have more corn than we had last year. We have double the yield of clover seed than was ever known before. It is true the honey-crop has been a partial failure.' I desire to call special attention to Mr. Cullinan's statement wherein he says, 'We have double the yield of clover seed than ever was known before.' Now, the complaint is almost universal from Illinois, Iowa, Wisconsin, and many other places, that the yield of honey from white clover was very light indeed, notwithstanding the fact that clover bloomed profusely and yielded seed abundantly, at least in some places where the honey-crop failed. From the foregoing, I draw the conclusion that it was not altogether the lack of rain that cut the honey-crop short the past season. A pertinent and interesting query very naturally arises at this point: What then is the reason the flowers did not supply their usual quantity of nectar? If I were called upon to answer this question I should freely admit that I do not know. But judging from appearances, I have formed the opinion that the failure did not result altogether from the want of rain, but was also equally due to some peculiar state of the atmosphere, which I do not fully understand, and therefore cannot explain satisfactorily even to myself. I am not a scientist. The secretion of nectar in the flowers is a very delicate process, achieved only by the spontaneous action of natural laws which are dependent upon suitable atmospheric conditions for the fulfilment of their functions; and are very sensitive to any interruption of, or changes in, those conditions. Even the changing of the wind from one point of the compass to another will sometimes appear to suspend the operation altogether for the time. We can understand the effect, although we may not be able to comprehend the why and wherefore concerning it.

Every one that has had much experience with maple sugar is, doubtless, familiar with the fact that the flow of sap from the trees is governed almost wholly by the state of the atmosphere. When the conditions of the atmosphere are just right there will be an abundant flow of sap; when they are not right no sap can be obtained, although there may be no visible difference in outward appearances. Is it not reasonable to suppose that the flow of nectar in flowers is equally as much affected by atmospheric conditions as is the flow of sap in the sugar maples?

With your permission, friendly editor, I should like to see this matter mentioned through your columns. Perhaps, some of our scientific people will be kind enough to enlighten us upon this interesting subject.—JOSHUA FULL, *Seymour, Wis.*—(From the *American Bee-keepers' Magazine*.)

A PLEA FOR LARGE FRAMES.

[1574.] It seems to me that the most important feature of bee-culture is either ignored or carelessly overlooked, in the bee-lore of our best modern apicultural writers. It is a fact that none will dispute, that we measure our harvest by the strength of our colonies numerically; and to achieve the best results in this direction should be the guiding star of the apiarist, and

the brood-chamber should be constructed in accordance with the natural laws governing the household economy of the honey-bee.

Let us take a peep at the bee in its natural habitation, where they become their own architects in the construction of their own combs, and what do we find? I have transferred hundreds of colonies, in all kinds of hives, nail kegs, log hives, box hives, and from bee-trees in the woods, and the same principle that governs one governs all, in the main, and that is large, deep, roomy combs, with stores above, brood beneath, and combs spaced from one and a half to two inches from centre to centre. In the early part of the season sealed brood can be found in the centre of the combs, next to which can be found larvae in all stages, and on the outside of all, eggs, showing conclusively that the queen first commenced her laying near the centre of the comb, and, like a spider spinning her web, she plies her vocation from centre to circumference—Nature's most economical method of time-saving to the queen in her vocation of reproduction.

We should imitate Nature in the construction of our hives, especially in that of the brood-chamber, that we may bring about the greatest strength possible, numerically from the prolificness of the queens. To accomplish this, I contend that the most essential point in apiculture is, our combs should be so arranged that not one second of time need be lost by the queen in her onward march from cell to cell, depositing in the height of her fecundity about two eggs per minute, or nearly 3000 eggs in twenty-four hours. In order to do this, she should not be confronted with horizontal bars and bee-spaces in the centre of her brood-nest, as they are certainly a great barrier against her fecundity, being contrary to the laws of her natural domain. Being thrown out of her natural circuitous orbit, she loses time in passing over bars and bee-spaces, and shifting from side to side, thus losing the benefits of the queen's functions, which means a serious detriment to the strength of the colony.

Mr. Heddon has the lasting gratitude of the apicultural world for his many discoveries and substantial inventions, and we certainly have no desire to rob him of his justly earned fame; but we do take issue against a shallow, sectional brood-chamber, for reasons heretofore mentioned, and sincerely believe that had he exercised his ingenuity and inventive powers on a hive with combs of larger dimensions, he would have come nearer 'the hive' that will *come to stay*, and would have opened a new era, far in advance of that realised by his present device.

My argument is not altogether from the reasoning of Mr. H.'s departure from the theory governing their household economy, but years of practical experience with small and large hives has confirmed my statements in every particular, as regards the superiority of large combs over small ones, for obtaining strong colonies.

Let those who doubt my statement try an equal number of colonies with queens of equal fertility, and report. It is said that 'the proof of the pudding is in the eating thereof,' and if Messrs. Heddon, Hutchinson, and others, can give reports of larger yields of honey from the sectional brood-chamber than can be given from hives of large, roomy combs, I will have to acknowledge the fallacy of this article. I wish to get at facts, and if 'the new must give way to the old,' and the time is near at hand when 'we will manipulate hives more and frames less,' we wish to know by actual test the reasons, whys and wherefores.—J. M. HAMBROUGH, *Spring, Ills.*—(From *American Bee Journal*.)

NOTES ON BEE-HIVES.

FERTILE QUEEN INTRODUCTION.

[1575.] The art of queen introduction may be explained by considering the subject under two heads, or cases—(a) A stock of bees queenless; (b) A queen subjectless.

A stock of bees may become queenless naturally or accidentally, or may be made so artificially; among the former cases a queen leaves the hive and is then subject to the dangers of being destroyed by birds, insects, or reptiles; or it may miss its way, or may not be hived, &c. It may die of old age or disease, or may become a prey to some parasite. The weather, the time of year, or a lack of drones, may be against the successful union of the sexes, and so make the queen useless and worthless—merging into so-called fertile workers.

Amongst the reasons for artificially deposing the queen may be mentioned the desire for a queen of greater prolificness, bees of greater amiability or other qualities, or of a different race.

When bees discover that they are queenless (either artificially or naturally so made) they at once set upon the work of raising a queen from any worker larvæ in the hive not more than three days old, if virgin queens are not being raised. If they are rendered queenless while eggs or larvæ less than three days old are in the hive, and they begin to raise queens or build queen-cells upon those, it is difficult to queen them, but still this is not impossible. The queen-cells should be allowed to develop until a day or two before the queens are likely to hatch, and should then all be cut out—*i.e.*, the queen-cells—and the place brushed over with carbolic acid solution, except one cell, upon which the alien queen might be caged after the larva, or nymph, has been destroyed. The queen may be liberated at dusk the next day. This deceives the bees, so far as we are able, and causes them to believe their own endeavours have been successful.

There are objections to cages of all kinds—*e.g.*, the queen is confined, and so valuable time for egg-laying is lost; but this must be sacrificed for safety by this plan of introduction. There is an alternative method for those who object to cages, but which, from very careful experiments, I cannot do otherwise than condemn; in fact, I have not had a single success by it, nor have I known one by any of my friends who are keen and careful observers. It has been denominated 'Pond's,' sometimes 'Simmins,' method; the latter claiming to have added extra to the procedure. The method I allude to is as follows:—'Upon receipt of queen, go to the hive and remove that one to be superseded (or otherwise). At night take the new queen *quite alone!* after keeping her so for not less than thirty minutes previously, but quite warm, and, moreover, without food meanwhile; smoke the bees as usual, and then permit the queen to run down. Close the hive and make no examination until after forty-eight hours. Leave the operation until so late that a lamp is necessary. In early spring let the queen run down exactly where the cluster is situated. The queen should on no account be inserted in a colony from which bees have been taken to form a nucleus until three clear days have elapsed.

'N.B.—A "safety" match-box will do to keep the queen in alone, but the same must not be used twice over. For our own use we have tubular perforated metal cages, half-inch diameter and about one and a half inches long, one end permanently closed and the open end pressed into foundation after inserting the queen. These cages are then placed in the vest pocket, and can be carried round to the hives. Remove the wax end at the appointed time, and allow the queen to run down between the frames. The bees are not to have access to the queen until she is free from such receptacle, which must on no account be left in the hive. Thoroughly cleanse such cages by scalding before using them a second time.'

Last year I experimented with a large number of queens on 'Simmins' (?) system, and in no instance did I find the queen missing on the third day, though fully half were on the tenth day; the others I found dead, or on the outside of the cluster quite alone, &c.; therefore the system seems a very valuable one for queen-dealers,

as they can guarantee safe introduction, telling their customers to look on the third day to be sure, and yet prepare to send them another on the fourteenth, by which time she will be lost in some unaccountable manner.

Often these queens so introduced will drop a few eggs, and through some peculiar instinct of the bees these eggs are often, if not always, selected to rear the fresh queens from. By the way I might mention an experiment I have several times tried which proves that bees have the power to carry those eggs.—A Ligurian queen was caged upon a comb in a stock of black bees, after a few days the queen was removed out of the hive, queen-cells were started and yellow queens hatched; therefore, if the apiarist is busy, and does not happen to frequently examine the hive, taking things for granted, he will have a hybridised daughter reigning, and think she is the one he introduced, if he had not marked her. I might also say I have several times, upon the ninth day, found the poor queen upon an outside comb in a starving condition quite alone. Upon microscopic examination, in a few cases, a very poor condition of the ovaries, &c., has presented itself, through neglect of the subjects, although in other cases neither neglect nor disease could be traced. Moreover, I have for some years, upon quite a number of occasions, tried the 'Hallamshire law,'† and having tried this at various periods of the year, I can truly say, provided the instructions are faithfully carried out, a 'fertile' queen presented, &c., I have never found this method fail, and I have staked some expensive and pet queens on it. I do not, however, like the idea of withdrawing all the new-laid eggs and unsealed brood, which is so very necessary, but 'the shortest way across is the longest way round.' Nevertheless, the Hallamshire law is based on natural lines, while the other cannot be reconciled at all, except that we might consider the alien undergoes such a state of subjection by fright and hunger that she is glad to get 'board and lodging,' but this we can plainly see drives her into such a gons-back egg-laying condition, that she is, sooner or later, rendered quite unfitted for her motherly duties.

I have been very successful by a method that can be used at any time of the year. I allude to the method of shaking the bees off their combs in order to get them into the condition of a swarm. This exposes brood to the atmosphere unless performed in a manipulating house, but of course eggs and unsealed brood could, perhaps, be fixed in some other hive in the apiary in the case of this method, as also in that of the Hallamshire law. This excellent method I will describe as follows:—

Near the close of the day, when there is no danger of robber bees, subdue the colony with smoke, find the old queen, and remove her. Have a large platform, sheets of paper, or blanket in front of the hive. Remove every

* First select a stock of old black native bees, end of April, remove all their brood combs and queen, be sure you get every egg and grub out. Now cage a fertile and laying queen of a yellow race on some food, say in a pipe-cover cage, keep her caged for, say, twelve days, by this time you will find sealed queen-cells in the hive; you can take the queen away and let the cells develop, and you will find them hatch out queens of the same race you put in the cage.

The experiment will prove conclusively that bees have the power to carry eggs.

† The law referred to:—'If a hive of bees have no queen, or means of rearing one (that is, have neither queen, eggs, unsealed brood, nor queen-cells, in their hive), they will invariably accept a fertile queen at the entrance or dropped in from the top, providing they have been deprived of such means of requiring themselves forty-eight hours.'

No matter how long they have been queenless, or how old the bees may be, or what time of the year it is, nor even if fertile workers be present, unless they have begun to lay eggs, no failure will ever result. So that there is no exception whatever to the law; nor must the queens ever be caged; the application of it can be varied scores of ways.

comb out of the hive with the bees adhering. As the last frame is taken out, shake the bees from it on to the platform near the entrance, and replace the frame. Now take the second frame and shake the bees from it some distance from the entrance on the previously prepared platform; when the bees are all off put the comb in its place in the hive; and treat the third and fourth and all the rest of the frames in a similar way, shaking the bees about three feet from the entrance. This shaking from the combs completely subdues and mixes up the bees, and causes them to exhale the peculiar scent that bees do when shaken from a limb of a tree, &c., in swarming time in front of a hive. When all the frames have been shaken and replaced in the hive, drop the new queen at least two feet from the entrance, and she will at once move on with the marching legions toward the entrance, and in thus mingling with the mass she at once becomes impregnated with the peculiar odour of the colony, and becomes one of them; and by her queenly sound and motions among the bees she is at once recognised as the mother-bee, and enters the hive joyously with the rest, and at once proceeds to her work of egg-laying. A few whiffs of smoke among the moving mass will cause a more hasty entrance, and also add its scent to that of the bees. By doing this late in the afternoon, or evening, everything is quiet and in working order in the morning, and there will be no trouble from other bees.

With regard to the 'Hallamshire' law and the reason why bees prefer eggs or larvae to raise their own queens rather than accept a strange or alien queen, I have often thought that the force of habit is too often either not recognised or overlooked in dealing with bees. All my experiments in faithfully trying Simmins' proposed method of queen-introduction have resulted in the desired queen being 'put out of the way' when means of raising a successor were present in the hive, for the bees have invariably raised a queen after their own sweet will. I have carefully marked a few of those queens, and have watched the proceedings of the bees most attentively; in fact, I believe Burnens could not have been more attentive than those who so kindly have assisted me when I could not be actually present myself when trying experiments requiring prolonged watching and attention, and the final has each time been the same when eggs or larvae have been in the hive at the time of introduction. As I have already stated, immediately the cluster is broken to withdraw the queen to substitute an alien the colony is disorganised. I might say I have never placed another queen on the identical spot, the original queen was parading at the same moment of removing it. There is no doubt about the bees sometimes suffering the queen to remain within the hive, apparently uninjured, for a period of time when ushered in upon the Simmins' (or Pond's) system. This period I have not found to exceed nine or ten days; the poor insect gradually moving from comb to comb to the outside of the cluster, there to perish and be carried out of the hive, though sometimes it is highly probable it may leave the hive alive through mere lack of homage. I have observed the bees carrying the deceased queen out, and I have seen the queen take refuge from one hive to another.

It may be interesting to you for me to relate that I have on three occasions found alien queens so acting in this latter manner, and that in each case, although the queen entered another hive, a few bees seemed to accompany, but their courage or love seemed to falter as they clustered on the handle of a garden spade, on a post, and on a pen-stick on each occasion respectively. In each case the alien was balled or encased on the floor-board, and no doubt would soon have been despatched had I not rescued them. As they receive so little homage or attention they thus quickly present the appearance of non-laying queens and are nearly as

capable of flight, as no partly or wholly digested food is offered them (the food bees feed the queen with being about the same as they feed to the brood).

But why is she superseded? It is no use saying dethroned, as she never had the honour of reigning. Of course I am now speaking about alien queens, and if she was in a stimulated condition eggs would be deposited or dropped, and while there is an egg in the hive (whether queen-cells are present or not) the bees will try to develop it into a queen, so that if the first started cells were on the old brood the new queen might destroy them as soon as they become nymphs. Then if she left the hive in disgust or because she got no homage, why, of course, a daughter of hers takes her place.

I have found by repeated experiments that so soon as a queen is taken out of a seam of bees operations are commenced to raise a mother-bee, and by even placing the queen on to another frame these operations will be commenced. Sometimes she will then be crushed to death. By means of the so-called dummies, as used in bar-frame hives, a number of queen-cells may be started and completed in the same time and hive, providing each comb or cluster is separated. I do not mean cork-packed or great thick dummies, but perforated zinc. The main point being to place the queen on to a different frame after a few eggs are laid in a few cells. But why is she so seldom destroyed on the new frame? Simply because the whole family is working in natural harmony or habit. It is the habit for the queen to move from frame to frame; but, mark well, it is not the habit of the queen to do so until the whole of her business is transacted upon that particular frame, hence the break appearing it is the habit of the bees to perform the operation of raising a new queen. During the summer so many of the brood-cells become clogged with stores, that the queen wanders from comb to comb, which causes the same thing to be done—hence the swarming fever. The queen gradually becomes of a non-laying appearance and quite capable of flight, owing to the want of the necessary amount of feeding and attention she should have to keep up her former state, and leaves the hive as an insect a little removed above the habit of a worker. If this is not so, for why do they do it? Moreover, no attention is paid to an alien, as it is not her, or the custom, fashion, or habit for queens to fly, nor to be carried, from one hive to another.

Now, suppose there are neither eggs, larvae, nor queen-cells in the hive, how can the bees raise a queen? They cannot do it—twice I have had a stray queen take possession of such a hive, and in each case the queen has been of a different race to the bees. Place a frame containing a few eggs into the hive. Why do the bees recognise this gift? It is their habit to obtain all they can, which we all know perfectly well, and, as I have already stated, it is their habit to raise a successor from the egg. They therefore gladly commence operations upon this frame of eggs. The same conditions as above being present, that is, a disorganized state. Again, suppose the whole of their eggs and means of raising a new queen are withdrawn, or, more naturally, their queen dies. In a state of nature, perhaps, there is at no time of the year a hive without eggs in a normal state. But in the case of a stock that has swarmed, virgin queen after virgin queen might meet with mortal accidents, and so this hive would become queenless; even if a virgin queen should survive unfertilised, or be raised after all drones were dead, or if the weather happened unfavourable for fertilisation, all other conditions being favourable the hive would die out. But should a stray fertile queen fly to the hive, the habit is (we challenge any one to contradict this) that this queen is accepted. Hence the Hallamshire law is based on natural, rational, and correct lines.

I have no hesitation in saying, from my own experiments and experience, that if the law is truly and faith-

fully tried, it will invariably succeed, excepting those few persons who believe and state their own way is best, and who omit, or cannot discern, some of the particulars and conditions of the law.—T. BONNER-CHAMBERS, F.L.S., *Tref Eglwys, Caersus, Montgomeryshire, March 22nd.*

[The above contains much that is opposed to the experience of some of our most practised apiarians, but as our correspondent has bestowed much pains on the preparation of the paper, we have given it insertion in our columns.—Ed.]

‘EXPLANATION REQUIRED.’ (See page 142, March 15th.)—I will give my idea of the required explanation. It is a very simple one, but perhaps not on that account less effective. Assuming the statement to be a fact, which I see no reason to doubt, I think the strange conduct of the bees was the result of the marvellous sensitiveness of their olfactory nerves. We know how they seek out and follow for miles the faintest odours from limes, clover, and other scents pleasing to them; and also how powerfully they are affected and seek to avoid what is unpleasant. The superstition alluded to by ‘E. C. P.’ is very ancient and very widely diffused. We may rest assured that in almost all cases of this kind there are some particles of truth at the bottom of them. I believe, then, that the exhalations from a dead body are most repugnant to bees living near. In this case the body had probably been lying in their vicinity some three or four days, and would have become almost unbearable to them. Being thus thoroughly aroused, it is by no means wonderful that they should seek by a flight in the fresh air to escape from what tormented them. Most likely this is not an isolated case, but that there have been numerous instances of the same kind, and thus has been laid the foundation of this old superstition. Now I think I hear ‘E. C. P.’ saying, ‘But how do you account for the return to the hives when the lid tapped them?’ Simply thus:—I don’t believe their return depended in any way upon this tapping. When I was a boy (alas, how long ago!) all of our household used to sally forth at swarming time to ‘ring the bees.’ Nothing was said to be so effective as a copper warming-pan (out of date now) hammered with a key; and when the bees settled in a bush or hedge near, as they almost always did, the good people used to say, ‘There is nothing like ringing the bees to make them settle!’ But you know we have got beyond all that now; the copper warming-pan has gone, the key is hung on the wall, and still the bees settle as well as ever! So, I say, that tapping or no tapping, the bees in question would have returned to their hives after having shaken off, as far as possible, the unpleasant odour that assailed them. If this explanation is not a satisfactory one, it has at least this merit, that neither ‘E. C. P.’ nor any other person can say for certain that it is not the true one!—C. C. P., *Valentia, Co. Kerry, March 20th.*

WATER FOR BEES.—I noticed our friend ‘Useful Hints’ advocates the old mode of giving water to bees in vessels with wooden floats. May I ask him to try the plan I adopt, and which I have previously mentioned in the *Journal*, viz., a good thick stratum of cork-dust on the water? It has many advantages over the old plan, which did not act unless the sides of the vessel were perpendicular, even then it was liable to disarrangement; for instance, the wind would blow the float to one side and there it would stick, whilst the bees drowned themselves by the score, whereas the cork-dust is simplicity itself in its application, and can be used on any kind of vessel or tub and answers to the very last drop of water, even after the water is done the bees sip at the moist dust for a long time.—P. BOYES.

DRONES FLYING.—I have seven stocks in frame hives, strong and in good condition. Four of the seven had

drones flying to-day—one Carniolan, one Ligurian, and two Ligurian hybrids. For such a season is this not extraordinary, especially in a county like Northumberland? On March 10th—a very warm day here—I first noticed them in the Carniolans. Until to-day the bees have not been flying since.—MORPETH, *March 26th.*

Echoes from the Hives.

The Hill, Corbridge, March 31.—This month has been the coldest of the year. Snow and hard frost nearly every day. I expect a good many hives will lose their number when they come to be overhauled. I have not been able to look at mine yet.—R. L. RICHARDSON.

Beverley, April 1.—A fine day at last; bright sunshine but cold wind, thermometer 48° at noon; very cold whenever the sun is crossed by a cloud. Went into winter quarters with sixty-eight stocks, all told, and to-day, I see all are alive, and, judging by the activity of the bees both in fetching water and pollen (pea-flour chiefly), none are queenless. Vegetation remarkably backward here.—F. BOYES.

North Leicestershire, April 2.—Bees are still pretty closely confined to their hives by the snow and blow. In reality they have had only three or four days’ work on the aconites, snowdrops, and crocuses. Pea-flour has been freely taken, when the weather permitted the bees to fly. The buds of currant and gooseberry are still unexpanded, and there will be little forage to be gathered yet for a fortnight. Snow sixty-three days old still on the ground.—E. B.

Burr-Oak Apiary, Angelica, N. Y., U. S., March 23.—Bees appear to be wintering well upon this side of the ‘great pond.’ Last fall, as an experiment, I left about a dozen of my old stocks upon their summer stands—without any winter protection whatever, and during *mid-winter*, upon a warm sunny day, those colonies were moved to a new location, some seven or eight rods away. I expected to find twelve middling weak stocks in the spring. But I am happy to say that upon examination this morning I found them all in a ‘prosperous and contented’ condition.—W. M. BARNUM.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication. All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

NOVICE.—1. *Transferring.*—Three weeks after swarming when there is less danger of injuring the stock, there then being little or no brood in the combs. 2. *Excluder zinc.*—We never use excluder zinc under a section rack. 3. *Artificial Swarm.*—The method proposed would be bad. When the hive is ready to swarm remove three frames of brood and bees without the queen, place these in a hive with two sheets of foundation; shift the old stock to a fresh stand and place new hive in the position thus vacated. By introducing a new queen to the new hive much time is gained, and as a consequence, honey gained.

J. G. SNOOK.—1. *Dead Stocks.*—You give us no particulars as to condition of stocks when found dead. If you transferred one stock soon after it swarmed, no doubts there was not a queen, and in the transferring the queen-cells, containing the immature queen, got damaged. 2. *Transferring.*—As you have already transferred some stocks, you can do so as soon as warm weather sets in, say, May; with novices it is

advisable to wait until three weeks after swarming. See answer to 'A Novice.' Thanks for your kind remarks.

THOS. ADAMS.—*Bees and Blast Furnaces.*—Bees do not gather pollen from refuse of blast furnaces. No doubt they were drinking the moisture which would be sure to be held after rain by such material.

R. L. RICHARDSON.—We should consider it would be perfectly safe to use your frames of honey as they are.

K. M. S. A.—1. *Painting Hives.*—Get the requisite number of makeshift, or new, hives, and stand them in the place of the old hives you desire to repaint, transfer the combs from one hive to the other, take away the hives, clean and paint them, and in the course of a few days return them to their former position. This may be done at any convenient time. 2. *Stimulation.*—In frame-hives the amount of consumption may be noted by gently turning aside the quilt and seeing the quantity of sealed cells in the upper and hinder parts of the combs. Some of these cells in the immediate proximity to the cluster of bees may be uncapped with a sharp knife, or may be bruised, when the bees will at once make use of the contents, and the queen be stimulated to ovipositing. This should be done on mild days. Or you can give Good's candy, or frames of honey, or liquid food of proper consistency, but we prefer uncapping the cells. 3. *Best Extractor.*—We must on this point refer you to our advertisement columns.

E. O. B.—*Bees dying in the midst of Stores.*—In the absence of any bees or comb forwarded, we cannot say that the bees died from any disease. It is most probable that the bees, unwilling to leave the cluster in search of the honey in hive, died in consequence of there being no winter passages. The broken wing of the queen would not be the cause of her death.

J. S. W.—Barbadoes sugar, equally with Porto Rico, will be found suitable for dry sugar feeding.

Received from the Speciality and Novelty Seed Company, Newton-le-Willows, Lancashire, their Catalogue of Seeds. This catalogue will be found of special interest to our numerous horticultural readers.

Received from Messrs. Neighbour and Sons their Catalogue of Hives and Apicultural Appliances. This is a very comprehensive catalogue, and with its numerous illustrations covers the whole ground of bee-keeping.

Received from Simmins' Bee Company, Limited, Rottingdean, Brighton, their Annual Circular (48 pages). This is a full catalogue of all the appliances required by bee-keepers of the present day, with some special information respecting queen-introduction.

Received from the British Stores, 6 Dionis Yard, Fenchurch Street, their catalogue of prices of hives and other appliances. This catalogue contains some practical and useful instructions as to successful bee-keeping by an old bee-keeper.

ERRATUM.—P. 171, col. 2, line 13 from bottom—for one of absolute phenol to four ounces of syrup, read four hundred of syrup.

Communications to the Editor to be addressed 'STRANOEWAYS' PRINTING OFFICE, Tower Street, Cambridge Circus, W.C.

[No. 303. VOL. XVI.]

APRIL 12, 1888.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

PRACTICAL WORK IN THE APIARY.

MAKING WAX GUIDES AND FIXING FOUNDATION.

It may not be generally known that it is not absolutely necessary to have comb-foundation impressed with the bases of the cells in order to secure straight combs, although time is saved by using such foundation, and all advanced and practical bee-keepers now use whole sheets, much to their advantage. Many devices have been tried from time to time to induce bees to build their combs in the centre of the frames, and amongst others was the idea of using plain sheets of wax, or, we should say rather, strips of plain wax. Later these were made stronger by dipping sheets of paper or other material in wax and then cutting it into strips of about one half to two inches in width. The bees took to this scooped out the bases for the cells as far as the embedded material, and constructed the cells' walls in due course. This was a great improvement on the pieces of comb formerly used, but the wax-sheets invented in Germany, impressed with the bases of the cells, have displaced this simple method. In these days of cheap, and we may say almost perfect foundation, it would hardly be any use mentioning the former methods, except for the fact that a great many beginners, and others who are taking to bee-keeping, are obliged to economise and would be glad to know of any simple and effectual plan of securing straight combs.

A simple guide of plain wax-sheet is easily made and fixed by an old method recommended some years ago by Mr. Abbott in this *Journal*. For this purpose get a piece of soft wood for a 'guide-block,' 1 inch wide $\frac{3}{4}$ inch thick, and 14 inches long. Shave off the front bottom edge, as shown in Fig. 1, and cut a corner out of

Fig. 1.

each end so that the front part will be just long enough to go into the frame, and of a width to bring its face where the line of wax is wanted. For a standard frame it may be fully $\frac{3}{8}$ ths of an inch from the projecting ends to the front face. Let it soak in cold water while the wax

is melting. The wax is best melted in an ordinary glue-pot, or stand a preserve-jar containing the wax in a saucepan of water, which should be kept boiling. Take the frame in the left hand and introduce the 'guide-block,' with its wet face and grooved edge, on the under surface of the top bar. With a painter's brush apply the hot wax along both the wet guide and dry bar of the frame, giving one or more coats according to the thickness it may be desired to make the wax-guide. In a few seconds it will be cool enough to remove, when the frame can be turned over top bar uppermost, and the guide-block removed, pulling it away from the top first. We then have a plain wax-guide $\frac{1}{2}$ to $\frac{3}{4}$ of an inch wide. Success is insured by having the block well soaked, the frame bar perfectly dry, boiling wax, and a clean brush. This plan is also recommended in *Modern Bee-keeping*, and is much more simple and less messy than using plaster casts.

If ordinary foundation is to be used in strips of 1 to 2 in., it must be fixed in its proper place on the under side of the top-bar, and for this purpose we use a wider wooden guide-block. A board, A, Fig. 2, $\frac{3}{8}$ ths of an inch

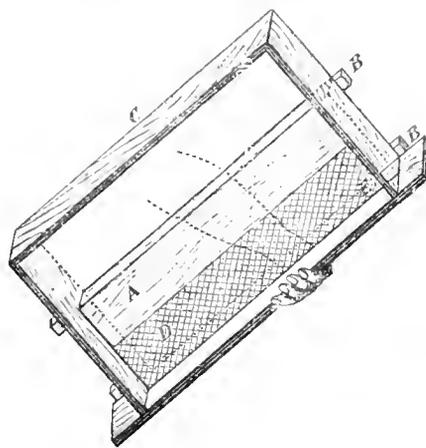

Fig. 2.

thick, is made to fit inside the frame C, and two strips, B B, are nailed along the back of it, and, as will be seen, project at both ends. The board is placed in the frame, C, the two firmly grasped in the left hand, and held slopingly as shown. The strip of foundation, D, is laid in its place, and molten wax poured at the point, E, where the foundation joins the top-bar. If the inclination is just right, and the wax at the proper temperature, it will run down the angle as down a gutter, and firmly fix the foundation to the bar. In Fig 3 we also have an old acquaintance, which those who have known the *British Bee Journal* long enough will recognise, and which is used for pouring out the molten wax in a fine

stream. It is simply a metal spoon with the sides folded over so as to form a funnel-shaped trough, from the pointed end of which the molten wax may be poured where wanted. It will cool in a few seconds when the

Fig. 3.

wax comes in contact with the cold wood of the top-bar, and then the frame can be turned over, placing the top-bar uppermost, removing the guide-board, and the frame can then be hung on one side until the wax becomes cold and solid. In fixing foundation in this manner, it is also absolutely necessary that the wax be quite hot and the bar perfectly dry.

Full-sized sheets of foundation may be fixed in the same way, but the board, A, Fig. 2, should nearly fill the frame. Some prefer to run a little wax along the junction on the other side also, but we have never done this, and found that the sheets are less liable to give way if only fixed on one side, to say nothing of the saving of wax. The bees seem to realise the fact that the foundation is only secured on one side, and at once set to work and attach it firmly. The cause of sheets of foundation giving way when this method of fixing is adopted is generally from not having the wax hot enough so that it sticks neither to the wood nor the foundation. It should be hot enough to melt the foundation where it comes in contact with it, then it will also be just right to adhere firmly to the wood. Wired foundation may be also fixed in the same way. Where a large number of sheets have to be fixed instead of the glue-pot and spoon we prefer to use what is known as Abbott's wax-smelter. This is a spouted boiler on the glue-pot principle in which the wax is kept at boiling water heat until it is poured out at the fine spout. Fig. 4 illustrates the one

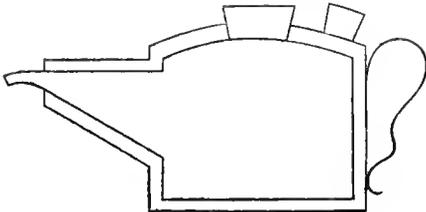

Fig. 4.

we use, it is made of copper, and with proper care will last a lifetime. The outer vessel is for water, and the inner one for wax. Thin wax-foundation may also be fixed in sections in the same manner, using a smaller guide-board.

THE IRISH EXHIBITION IN LONDON.

We are sure that all Englishmen will be pleased to hear that an exhibition of the products of Ireland will be exhibited in the ensuing summer at the Olympia, Kensington; and perhaps no exhibition of recent years is likely to prove more practically useful. Ireland possesses great natural resources and many important industries, and a full display of her products and manufactures will do much to assist the revival of trade in Ireland, and will prove of the greatest interest to the people of Great Britain. The Exhibition is begun under the happiest auspices, and its Executive Council and patrons contain the names of the most distinguished representative men. With the view of giving every facility to the Irish artisan of exhibiting the produce of

his skill, the Council have determined to make no charge for space occupied, except in very special cases. Among the interesting features will be a representation of an Irish village, with the veritable peasants at work upon their cottage industries—the dyeing of yarn, making lace, knitting, &c. Under the section of Agriculture, honey will be represented; and we trust that Irish bee-keeping associations will use every energy to make this feature of the Exhibition a success. (See letter from Mr. J. M. Hooker, page 193.)

USEFUL HINTS.

'Athens, the eye of Greece, mother of arts
And eloquence, native to famous wits:
There flowery hill Hymettus, with the sound
Of bees' industrious murmur, oft invites
To studious musing.'—*Paradise Regained*.

Long as we may for 'flowery hills' and 'bees' industrious murmur,' the sole representatives of flora within reach of our bees are a few miserable-looking, weather-beaten crocuses; and from visiting these the poor bees are prevented by cold winds, sleet, and snow, and their 'murmur'—complaining, rather than industrious—is confined to the hives. So relentless are the weather gods.

We English are said never to be satisfied unless we have a grievance, and, certes, our chief and standing one is the weather. But is it a true and just one? and can we expect 'perfection' in climate in this world—even if we obtain it in bee-feeders and other appliances? Let the following extract from 'Cold Winds' (*Longman's Magazine*) answer these questions:—

'The *Bora*, an intensely cold, violent, boisterous wind, which visits the north-eastern shores of the Black Sea, at the foot of the Caucasian range, renders it too dangerous to move about on shore, as the risk of injury is so great from falling bodies, stones as large as one's fist, slates, &c., while the strongest buildings are shaken by the fearful force of the wind. The *Purga*, a north-westerly wind which visits the plains of Siberia and the district of the Lower Yenissei, in its fury takes up the frozen snow, and being too cold and dry to absorb the icy particles, the air becomes filled with a dense cloud of dust, and heaven and earth become one chaotic mass of finely-powdered ice, which fills the eyes, stops the breath, and insinuates itself through the smallest openings in the clothing. During the storm the thermometer falls to from 90° to 110° Fahr. below freezing-point, causing numerous deaths, and bringing untold miseries to the inhabitants of this frigid climate. The cold is so intense that were we to lay hold with our bare hands on a piece of iron of the same temperature, the flesh would be, to the sensation, burnt off as if the iron had been red-hot.

'In the north-western States of the American Continent we have an almost exact counterpart of the *Purga* of Siberia in the *Blizzard*. While a brilliant sun is shining over the snow-clad prairies, and a light southerly breeze gently wafted along renders the air most delightful and exhilarating, a few minutes suffice to alter the whole scene. A cloud is seen advancing from the north-west, and in a short time spreads with fearful rapidity. It is another *Purga* cloud of ice-dust, and its effects are the same. It is death to any one who ventures out-of-doors. Those who are unfortunately caught in it are either instantly suffocated or driven mad, and in the piercing blast tear off their own clothing—utter despair depriving them of their reason. In the blizzard of January last hundreds of human beings, and thousands of cattle, were lost. Marvellous changes of temperature occur with these furious hurricanes,—for instance, from 74 degrees above zero to 28 degrees below—a change of 112 degrees in 24 hours, took place in the blizzard referred to above.'

Cease, then, to complain, oh, fellow-countrymen, since the same authority tells us of the fortunate position of the British Isles tending to ameliorate the severity of the coldest winds. The warm ocean immediately sur-

rounding our shores insures us a milder climate, and it is a very rare circumstance to have a strong east wind blowing when the thermometer is many degrees below freezing-point; otherwise, we should experience a wind of the severity of some of those which visit the climates mentioned above. Truly, contentment is a great gain—a great blessing—and well may we exclaim,—

‘England, with all thy faults, I love thee still.’

OVER-HAULING and thoroughly examining all colonies—a spring work of no little importance—has scarcely been practicable up to the present time, but should be done as soon as the weather will permit. For directions refer back to previous ‘Hints.’

Taking the stereotyped period for bringing a colony up to ‘boiling-over point’—*i.e.*, six weeks—as to population, if our hives are set in order about the middle of this month and measures taken, by stimulation, uniting, removing brood from strong to weaker colonies, spreading brood, &c., for equalising and increasing population, June, the month of white clover, honey-storing, and natural or artificial swarming, will be close upon us, so that we have no time to lose—*always* weather permitting. But the spring *must* be a late one, consequently the honey-flow will be late also; and yet we know enough of the weather to be aware that we cannot forecast the seasons. Therefore it behoves all bee-keepers to take time by the forelock, and to be ever ready for sudden changes. If a warm, growing, showery period succeed to the long, cold, sunless months which have confined the bees to their hives, they will, in well-managed apiaries, put forth all their energy, and swarming will soon begin. At the risk, therefore, of being premature, we may at once refer to swarming,—Nature’s method of increase.

NATURAL SWARMING.—That veteran bee-master, Langstroth, in a late communication to the *American Bee Journal*, remarks: ‘It is easy to assume that every bee in an artificial swarm will work just as well as it would in a natural one. But who that has had a large experience with both methods can deny that for the production of comb honey, at least the natural swarm has that spur in the head which artificial processes never seem to give? Is it not reasonable, then, to think that for its highest prosperity every colony of bees should be in a normal, that is to say, in a natural condition?’ The veteran is arguing in favour of allowing drones in all hives as being in accordance with nature, but his testimony to the superiority of natural over artificial swarms is so striking, and so strictly in agreement with our own experience, that we cannot resist making the quotation. Whether increase be desired or not when working for comb-honey, we always allow the bees to swarm whenever Nature prompts them to that course; and by placing the swarm on the stand of the parent hive, and giving to it more or less of the brood, as well as by removing the supers from parent to child, we gratify the swarming instinct, and procure far more energetic work than is possible from an artificial swarm. The depleted parent stock is placed beside the swarm, and is used as a nucleus for queen-rearing, or, increase being desired, is built up into a strong colony. For full details of this system see *B. B. J.*, vol. xv. p. 204.

FOUL BROOD.—Every bee-keeper during the spring examination of colonies should keep a strict look-out for the first symptoms of foul brood; and if the least suspicion exists—being well certified of the fact—let him make short work of any diseased stock by committing it to the flames—hives, bees, combs, and all—at the same time feeding all his remaining colonies on phenolated syrup, and using freely around the entrances, alighting-boards, and the entire outsides of the hives, carbolic acid solution or salicylic acid as a disinfectant. By adopting stringent measures on the first appearance of, instead of dallying with, the foul pest in the almost vain endeavour to cure, he will perform a duty to his

neighbours and save himself expense and trouble in the end.

FEEDING must also be carefully continued. The consumption of food in good colonies is now greater than ever.

PLANT.—Let sections, crates, hives, foundation, and, indeed, all appliances likely to be required, be procured and kept in readiness against the busy time which we all hope is near at hand.

HIVES AND SURPLUS CHAMBERS.—Our contemporary, the *Record*, for this month, has an excellent article entitled ‘Landmarks for Bee-keepers,’ in which the standard frame receives its due meed of praise for use in the brood-chamber, and a sort of quasi standard-frame 14×5½ in. which works admirably with the standard when tiered above or beneath it, is strongly recommended. The plan of using shallow frames, of from four to six inches in depth, over brood-chambers, for obtaining surplus honey—comb or extracted—we have practised for many years with great success, and can therefore give in our adherence to Mr. Carr’s views. We would, however, make one addition, *viz.*, that a zinc-excluding adapting-board be used between hive and surplus chamber. Of the precise form of such adaptor space forbids us now to treat, but in our next we hope to give some hints on its construction. These honey-boards are extensively used by our American cousins, and we venture to prophesy a revival on the same lines in our own country.

OLLA PODRIDA.—*In-and-in breeding.*—There is now no necessity for us to recur to this subject, as we had intended to do, since our views are so fully expressed in the excellent article published in last issue under the same heading, every word of which we fully endorse.

Third-class Certificates.—In the correspondence lately carried on in our columns, respecting the examinations for these certificates, it was stated in a foot-note to a letter (1512, p. 120) signed ‘Queen,’ that in the ‘Instructions’ no specified time is laid down for driving the bees from skeps; and although this is literally correct, nevertheless, we think in fairness to the judges who have endeavoured strictly to carry out the rules in regard to points, some further explanation is due. There can be no doubt that the construction put upon these rules by various judges has differed materially.

The time occupied in driving the bees and capturing the queen has by some been considered material, and by others more or less ignored. So difficult is it to act justly upon a hard-and-fast rule! So true is it that *summum jus saepe summa injuria est!* Take the case of a candidate who takes thirty-five minutes to drive out all the bees and misses the queen, although she is present. He loses twenty-five points (one for each minute over ten), and forty points for not capturing the queen as she ascends. He has lost, therefore, sixty-five points out of his hundred, and, consequently, has only thirty-five points left; whereas his required *minimum* is fifty points. Some examiners ignore all this, and pass their candidate. Others, as certainly, refuse to pass him or her. Hence, a certain amount of injustice is perpetrated, but with the best intention on the part of the judges. Now we are decidedly of opinion that—always provided the judges are most capable, and thoroughly well qualified men—it is desirable to leave a great deal to their discretion, and to avoid strictly tying them down to judging by points. At all events, a thorough revision of these rules seems to be imperative, and we commend the subject to the consideration of those in authority.

WATER FOR BEES.—We thank Mr. Boyes for his suggestion of filling the water-troughs with cork-dust, which we shall certainly try. When the wooden floats are cut to fit the troughs there has been no loss of bee-life with us, the vessels always being kept full. We have tried filling with sawdust and gravel, both of which answered well.

Where there are ponds, lakes, or running streams in the immediate vicinity of apiaries, an artificial supply of water is unnecessary, especially if the above are covered by water-lilies, or other aquatic plants, on which the bees may rest while sipping.

BEE-KEEPERS' VOCABULARY;

OR, GLOSSARY OF TECHNICAL AND SCIENTIFIC WORDS
USED IN WORKS UPON BEE-KEEPING.

Adulteration of Honey.—Glucose is used by unprincipled dealers either as a substitute for honey or mixed with it, and this mixture is sold under various names. Sugar syrup, starch, chalk, plaster of Paris, and pipe-clay, are mentioned as having been used. There are heavy penalties for adulteration, and every bee-keeper should use his best endeavours to bring such fraudulent dealers to justice.

Adulteration of wax.—Ceresin, paraffin, starch, clay, resin, tallow and suet, are used to adulterate wax, which alter its melting point and specific gravity. Wax having a melting point below 145° Fahr. may be considered as impure.

Adynamic. *a.* (*Gr. a*—not, and *dunamis*, power.)—Weak, destitute of strength owing to disease.

Aerate. *v. t.* (*L. aer*, air.)—To put air into. To supply with carbolic acid; to subject to the influence of the air by the natural organs of respiration through the spiracles and tracheæ.

After-swarm.—A swarm of bees which leaves the hive after the first swarm, and is accompanied by a virgin queen.

African bees.—Bees natives of Africa only, such as *Apis Adansonii*, *fasciata*, *unicolor*, *nigritarum*, *scutellata*, and *Caffra*.

Air-sacs or vesicles. *n.*—These are enlargements of the tracheæ, or air-tubes, and lie in the fore-part of the abdomen. They can be filled with air at the will of the insect, and enable it to alter its specific gravity, thus rendering it better able to support itself on the wing with as little muscular effort as possible. They are very large in the worker and drone, but much smaller in the queen, owing to the room occupied by the ovaries.

Air-space. *n.*—Usually called dead air-space. This is the space in double-walled hives filled with air, and constructed in such a way as not to admit any external air. Although such hives are preferable to single-walled, they are not as good as those packed with chaff and other materials, for air will circulate and does not remain stationary, therefore the heat carried from one side to the other becomes dispersed and wasted.

Albino drones. (*Sp.* from *L. albus*, white.)—Drones with white heads and white eyes, quite devoid of colour. Sometimes the eyes are red. They are not uncommon amongst crosses of black bees and Italians, are perfectly blind, and are supposed to be diseased. (*British Bee Journal*, vol. xv. p. 18.)

Albinos. *n.*—The term is applied to a variety of Italian bees lighter than usual, and which have distinct rows of white hairs. Professor Cook says they are not a distinct race, and that he has often noticed among Italians the so-called albinos.

Albumen. *n.* (*L.* from *albus*, white.)—This enters largely into the composition of the body, and is that form of nitrogenous food which goes to construct the nerve substance. Bees derive it from pollen. Albumen, in the shape of white of egg, has been long used by the Germans as a stimulant in spring.

Alcohol. *n.* (*Ar. al*, the, and *kohl*, fine powder.)—A pure spirit which can be produced by distillation from fermented honey, and is the intoxicating principle in mead, metheglin, and hydromel. It is used by bee-keepers to dissolve salicylic acid or thymol (remedies for foul brood), and being a ready solvent of propolis is also used for the removal of this from the hands.

Alien queen. (*L. alienus*, fr. *alius*, another.)—A foreign queen, or one belonging to a strange hive.

Alighting-board. *n.* (*A-Sax. lihtan*, *alhtan*, to descend, alight.)—The projection of the floor-board in front of entrance; that part on which the bees alight before entering the hive.

Aliment. *n.* (*L. alimentum*, fr. *alere*, I nourish.)—Nutriment; food which nourishes.

Alimental. *a.*—Supplying food that nourishes, as *chyle*, is alimental.

Alimentary canal.—The duct by which the food is conveyed through the body and the useless parts evacuated. It commences, in the bee, at the mouth, and consists of the cesophagus, honey stomach, chyle stomach, small and large intestines, and ends with the anus.

Alternate. *a.* (*L. alternatus*, fr. *alternus*.)—Distance-pins and broad shoulders are put on opposite sides of the ends of top bar, and are said to be placed *alternately*.—To change one frame for another reciprocally, as in uniting two colonies.

Alveole—alveolus. *n.* (Fr. *L. alveus*, a hollow vessel.)—A cell in a bee-hive.

Alvine. *a.* (Fr. *L. alvus*, the belly.)—Relating to intestinal excrements.

Ambrosia. *n.* (*Gr. ambrosia*, food of the gods, supposed to give immortality, fr. *a*, not, and *brotos*, mortal); *ambrotos*, immortal. It was often confused with nectar, the drink of the gods, one of the ingredients of which was honey.—The name given to pollen and bee-bread by C. Butler and other ancient writers; also called 'leg-honie,' because of the pellets of pollen carried on the legs.

Ammonia. *n.* (So called from Jupiter *Ammon*, near whose temple it was first discovered.)—A volatile alkali used in solution in water and called *liquid ammonia*. Used by some to relieve pain caused by the sting of a bee.

(*To be continued.*)

ASSOCIATIONS.

IRISH BEE-KEEPERS' ASSOCIATION.

The annual general meeting was held on the 5th inst. The chair was taken at first by Mr. Tipping, afterwards by Rev. Thos. Lindsay. There were present also Miss E. E. Rutherford, Rev. P. Kavanagh, Dr. Knight, Mr. Millner, Mr. Read, Mr. Sproule, and the Hon. Sec. Mr. Chenevix. The report and balance-sheet for the year 1887 were adopted with a vote of thanks to the auditors. Votes of thanks were unanimously passed to Dr. Traill for the gratuitous use of his rooms for meetings, and to the press for great services kindly rendered to the Association. Lord Ardilaun was re-elected President. The Vice-Presidents, Treasurer, and Secretary, were also re-elected. Miss E. E. Rutherford was elected as an additional Vice-President, and Messrs. Gillies and Read were elected auditors.

Mr. Sproule and Mr. Read were appointed scrutineers to examine the voting papers for the election of the new committee. This was no light task, as fifty-four of these papers had been sent in. The result of the examination was that the following were declared elected as the acting committee for 1888-9:—R. Sproule, Rev. P. Kavanagh, A. Traill, LL.D., J. M. Gillies, J. K. Millner, E. P. O'Farrell, M.D., M. H. Read, S. K. Twigg, C. F. Knight, M.D., John Jones, M.D., J. O'Reilly, D.L., T. G.

Barlow, E. Byrne, J.P., Rev. R. Seymour, J. Barnes. After some discussion it was resolved that in Rule VII. for the words 'in the second week in February' be substituted the words 'not later than April.'

There was an interesting debate as to the best method of forming depôts in various parts of the country for the sale of members' honey, in addition to the depôt which already exists in Dublin, and the Committee were authorised to grant sums of money in aid of such local depôts. Copies were distributed at the meeting of a circular, which Messrs. Abbott Bros., the Association's agents for the sale of honey, are issuing, with the sanction of the Committee, to grocers and other dealers in Dublin.

The following have been appointed Hon. District Secretaries for the counties prefixed to their names. For Cork, Mr. C. E. Beale; King's Co., Mr. R. T. Crossdale, J.P.; Fermanagh, Rev. D. E. Dickson; Waterford, Mr. W. E. L'Estrange Duffin; Wexford, Mr. T. Elderkin; Sligo, Miss L'Estrange; Mayo, Mr. W. Morony; Tipperary, Mr. T. G. Barlow; Louth, Miss E. E. Rutherford; Meath, Rev. R. Seymour.

BEDFORDSHIRE BEE-KEEPERS' ASSOCIATION.

A meeting of the above Association was held in the Blue Ribbon room, Bedford, on Saturday afternoon, March 24th, under the presidency of the Rev. Dr. Wray, of Bedford. Amongst those present were Mrs. Edwards, Messrs. E. E. Dymond, Sydney Street, W. James, Turtle, Johnson, J. Pestell, and the Hon. Sec. (Mr. W. Rushton, of Felmersham).

The Chairman stated that the meeting was called mainly for the purpose of drawing up the schedules of prizes to be offered at the various shows during the season. On the motion of Mr. Johnson, seconded by Mr. Street, it was agreed 'That there be an additional class for cottagers, in which prizes shall be offered for the best six 1-lb sections of comb honey.' Mr. Street proposed, Mr. Johnson seconded, and it was carried unanimously, 'That prizes in Classes I. and II. be all of money as in the other classes, and that the silver medal be offered for the best exhibition of comb honey in any class, and the bronze medal for the best exhibition of extracted or run honey in any class.' Mr. Johnson moved and Mr. Turtle seconded, 'That two prizes in money be offered at the Bedford Show for the best exhibition of bees-wax.'—Carried. It was resolved on the motion of Mr. Johnson, seconded by Mr. Pestell, 'That the prizes offered at the Sandy Show be equal in amount to those offered at the Bedford Show.' Mr. Johnson then suggested 'That the medals (silver and bronze) given as prizes by the B. B. A. be offered elsewhere;' but it was decided to discuss the matter at a future meeting. Mr. Johnson proposed, and Mr. Dymond seconded, 'That the same amount in prizes be offered at the Woburn Show as last year.'—Carried *nem. con.* A short discussion then ensued in regard to the entry fees, and it was ultimately agreed on the proposition of Mr. Johnson, seconded by Mr. Pestell, 'That the same entry fees be charged at the Woburn Show as at other shows.' Mr. Johnson moved the following resolution, which, having been seconded by Mr. Pestell, was carried unanimously:—'That the expert be requested to report any cases of "foul brood" he may meet with, and ascertain on what terms the owner would allow the infected stocks to be destroyed, and that the Secretary be authorised to pay a fair amount in compensation.'

Foreign.

BELGIUM.

An interesting Apicultural Exhibition will be held in Brussels from the 11th to the 23rd of August next. There are seventeen classes in six divisions, and the

prizes consist of medals and money. We hope some of our manufacturers will make a show because, owing to the circulation of the French translation of our *Guide Book* in Belgium, many bee-keepers have there adopted our plan of hives and methods. Application for space must be made before 15th May next, and full particulars may be had by addressing Monsieur le Secrétaire des Concours Internationaux d'Apiculture, Jardin Botanique, Brussels. Exhibits coming from other countries than Belgium pay half rates on Belgian lines.

SOUTHERN CALIFORNIA.

The honey-bee was introduced into Southern California in March, 1855, by Mr. O. W. Childs, who purchased a few colonies in San Francisco, paying \$100 per colony for them at that port. Under his care and management, the bees multiplied and produced large quantities of comb honey, which he sold readily at \$1 per pound. His success started a boom in the bee business, and in three years afterwards nearly every American resident in Los Angeles city had bees to sell, but the price was a shade lower than that paid by Mr. Childs in San Francisco, for many were anxious to sell their bees at \$5 per colony. The price of honey had gone down to 15 cents per pound. Swarms of bees had escaped from the apiaries and located in hollow trees, clefts in the rocks and holes in the ground, so that the land was literally flowing with honey. About this time the fruit-growers began to complain that the bees destroyed fruit, and most of the bees were removed to a distance from the city and located in the foothills and at favourable spots, along the foot and sides of the mountains. In their new homes the bees produced a better quality and a much greater quantity of honey, found in the bloom of the black and white sages that abounded in the hilly and mountainous regions, besides the nectar-yielding indigenous shrubs and plants so abundant in Southern California in those days. From 400 to 500 pounds of honey per hive was considered a fair yield: and as the quantity of honey increased the price decreased, so that 4 and 5 cents per pound was about all that good honey would command. Most of the honey was shipped by sea to foreign countries. A small quantity found a market in New York. The crop of honey in 1876 was enormous, thousands of tons being gathered in Los Angeles county alone, and equally large yields were produced in San Diego county, one person being credited as the owner of 6000 colonies of bees and producing \$50,000 worth of honey and beeswax. The next year, 1877, proved most disastrous by reason of an extremely dry season. Thousands of colonies of bees perished for want of food, and the spring of 1878 found many apiaries entirely destroyed. Discouragement took a fast hold of the average bee-keeper, and to such an extent that he quitted the business in disgust and never embarked in it again. Low prices for honey have been the rule since 1876 until the present year, when, by reason of a short crop, and the meagre supply of honey on hand, both in California, the eastern States, and the West Indian Islands, the price of honey has gone up nearly one-half more than it was one year ago, and this right in the face of low-priced sugar, an article that has heretofore governed the price of honey to a great extent.

Amongst the men of means now pouring into Southern California in search of a salubrious climate and a rich soil, that has never failed to give a fine crop of fruit in a hundred years, no doubt many may be found who have in their old homes handled the honey bee, either for profit or pleasure—that pleasure derived from investigating the habits and peculiar instincts of the most wonderful creature in animated nature, seemingly endowed with an intelligence that man himself can hardly measure. To such men, coming, as they mostly do, from northern latitudes, where winter care of bees is often greater than the care and labour bestowed in summer, I

would say, Take hold of the bee business in this land of sunshine, where, on an average, there are not 15 days out of the 365 of the year in which the bee is not on the wing—in this land of perpetual bloom, where the honey bee may gather nectar every day in the year. Take hold with your experience, and, keeping step with the progress and advancement that permeates every other branch of business, help the honey bee to gather and store the unlimited quantity of nectar that burdens the bloom of millions on millions of flowers in this favoured land of ours, and save from the wild winds this wealth of sweetness that would otherwise be for ever lost to mankind. The health-seeker can hardly find a business so conducive to perfect restoration of health, and the student of science can nowhere find a field that will afford a more interesting and absorbing study than that furnished by the apiary. Very many of our prominent bee-keepers have turned their attention to town sites and corner lots, quitting a business that has heretofore yielded them health and wealth, without the risks of speculation, and to-day there are fewer men in the business than there were fifteen years ago.

The orchard and vineyard, the grain field and town site have displaced many a splendid apiary that was considered a good property three or four years ago. Our extensive mountain-ranges afford an abundance of bee pasture in localities where the plough, the orchard, and vineyard can never go, and the very best use that such places can be put to is to make them the home of the honey bee. San Diego, Ventura, Los Angeles, Santa Barbara, and San Bernardino counties ought to maintain 500,000 colonies of bees, that would produce \$5,000,000 worth of honey and half a million dollars' worth of bees-wax per annum. Nature furnishes the raw material; the honey bee, under proper handling, will throw in the necessary amount of industry, if man will take the trouble to throw in a little industry and skill to give to commerce this vast amount of wealth that would add so greatly to the pleasure of the palate, as well as to the health of humanity. For it is a fact that pure Californian sage honey contains medicinal properties that, properly used, will add greatly to the health of most people.—C. N. WILSON.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to "The Editor of the 'British Bee Journal,'" c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C." All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, Kings Langley, Herts (see 2nd page of Advertisements).

* * * In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

OUR HONEY IMPORTS.

The value of honey imported into the United Kingdom during the month of March, 1888, amounted to 284. [From a return furnished by the Statistical Department H. M. Customs to E. H. Bellairs, Wingfield, Christchurch.]

CYPRIONS AND CARNIOLANS.

[1576.] From Great Britain and from America letters similar to the following have so often been received by me that I deem the answers of sufficient general interest to warrant their publication on both sides of the Atlantic. They are given in accordance with my experience and honest convictions, I would explain that I sent Mr. Group

¹ imported Cyprians in 1885, and again in 1886, direct from Cyprus by letter-post.

Ranctown, Penn., U.S.A., Feb. 23rd, 1888.

MR. FRANK BENTON, *Laibach, Carniola, Austria.*

Dear Sir,—1. Are the Carniolan bees as good honey-gatherers as the Cyprians?

2. Will they at all times defend their hives?

3. Are the queens as prolific as the Cyprian and Syrian queens?

4. Do you consider them as well a defined strain or race as the Cyprians? The Cyprians, according to my experience, are a far better defined race than the Italians. When crossed their markings are transmitted much farther. I am inclined to give the Germans the next place. I have experimented with the German, Italian, and Cyprian races.

5. How do the Carniolans winter in confinement?

I would like to have this information as early as possible, but should Mr. Benton not be at home, I will esteem it a favour if the receiver hereof will transmit it to him.

Respectfully,

JOHN W. GROFF.

ANSWERS.

1. No; but they are good both as honey-gatherers and comb-builders, and they seal their honey in such a manner that the combs look whiter than those sealed by Cyprians, Syrians, Palestines, or Italians.

2. No. If made queenless, they are thrown into greater excitement than are other bees under the same circumstances, and if deprived of their brood at the same time are frequently so disconcerted as to neglect for the time being the defence of their hives. At other times, that is, under ordinary circumstances, they are most excellent defenders of their hives.

3. Carniolan queens are not, as a rule, as prolific as Cyprian and Syrian queens, but are far more prolific than black or Italian queens. The best Carniolan queens do not fall far short of Eastern queens as regards prolificness.

4. I do not. Mr. Group is quite right in saying that 'the Cyprians are a far better defined race than the Italians, and when crossed their markings are transmitted much farther.' And the same thing is true of Cyprians as compared with Carniolans or any other known race. Cyprians are the 'thorough-breds' among bees—the only ones whose pedigrees are pure, and their long line of ancestors bred in pent-up Cyprus, under conditions that must necessarily have produced a wonderful race of bees, reproduces its individuals to our admiring and covetous gaze,—admiring because these bees transmit their markings and great beauty, and covetous because they transmit also, even should their pure blood be adulterated by several generations of cross-breeding, their wonderful energy in collecting honey. Among European races of bees, Carniolans, according to my experience, are, in all points of importance, decidedly superior, no matter whether we consider their qualities as honey-collectors, or their ability, if their working-force be so directed, to increase rapidly; their readiness to enter surplus receptacles and ability to build and seal over snow-white combs; their gentleness of disposition—their quietness under manipulation, and inclination to adhere to the combs, yet the comparative ease with which they can be brushed or shaken off; their ready defence of their hives under all ordinary circumstances, both against moths and robber bees; their quiet submission when confined for shipment; their readiness in constructing numerous queen-cells; the great prolificness of their queens; the indisposition the workers show towards gathering propolis to daub up sections and glue frames solid; the greater size and individual strength of the workers; their ready submission upon the application of smoke, if perchance they may have been aroused by rough manipulation; their disinclination to attack any one who merely enters the apiary; their hardihood, enabling them to withstand the severest climates and

their quietness and compactness in their winter clusters making them remarkably good winterers; if we test them in regard to any of these points, side by side with any other commonly cultivated European race of bees, all must yield the palm to the silver race of Carniola. Mr. Samuel Simmins, in his excellent work, *A Modern Bee-Farm*, published last autumn, tells the whole story in one sentence when he says of Carniolans, 'Scarcely a fault can be found with them.'

I concede for the blacks what Mr. Group intimates he is inclined to credit them with, viz., transmitting power. The Carniolans are also well endowed in this respect, but if the blacks or Germans have, in comparison with them, nothing that is superior to transmit, pray of what use is the bare power to transmit, even supposing that to be greater than is possessed by any race except Cyprians? To transmit, forsooth, their fawny, shaggy coats, their black tails, their proclivities for robbing, their kindly disposition toward moth-larvæ, their keenness in spying out, the moment they stick their heads forth from between the top-bars of the frames, a soft spot in the back of any man's hands, and their agility in getting there, while their fellows left in the hive do mostly come on the scent of their predecessors' tails? Or is it to hand down to the coming bee that transcendent quality or sense whereby this aforesaid German bee invariably and instantly becomes aware of the intrusion of a stranger's nose within twenty rods of its alveary domicile, and the unexampled self-forgetfulness it exhibits in the punishment of this offending but otherwise very respectable human member? But enough of this. Americans should have no prejudice in this matter, for we have no *native* race of bees: all are imported foreigners; and it only behoves us to select the best to build upon. And are we to remain idle, while breeders of horses, of cattle, of sheep, of swine, of poultry, of fancy pigeons, and even of pet stock, by importing, selecting, and combining, are producing almost any and every form and quality desired? And for us to commence with the common black bee—the 'scrub' among bees—would, I consider, be equivalent to the cattle-breeders going back at the present time to the 'scrub' among bovines, because forsooth he may have discovered that his developed breed will not bear the neglect that his common stock would, and still preserve the character it had when he first made its acquaintance; or it would be like the horticulturist who should ignore the splendid fruits already existing, and persist in cultivating the sour, gnarly natural fruit; or the woollen manufacturer, who should go back to the spinning-wheel and hand-loom, because the steam-loom costs a deal of money and eats up tons of fuel, or because, perhaps, its tremendous clank and clang do not please him! No, friends, though all these old things had their uses, and, doubtless, there are many still for whom such things are best adapted, those who lead must have what produces the best result—what yields the greatest returns. These cannot afford to ignore any of the progress the world has made in their respected branches. No more can the breeder of bees, who, by selection and combination, expects to attain greater and more satisfactory results than have heretofore been reached, afford to ignore the great value of the breeding material which the past few years have placed at his disposal. And as Nature herself has kindly done part of the work, he cannot afford to go over it again, but should begin with the races she has partly perfected.

5. Excellently. They have been developed in a cold, mountainous region, where snows are deep in winter and rains often prolonged and even cold during the summer season. The past winter bees have been confined here without a good flight for four months continuously. Snow has been over two feet deep in the open country, while mountain ravines are drifted full. The thermometer several times indicated 13° Fahrenheit

below zero. Very possibly this question is meant to refer to wintering in cellars or special repositories. In Carniola bees are not wintered in cellars, so far as I know. The native bee-keepers pack their shallow box-hives (which are 6 to 8 inches deep, 12 to 18 inches wide, and about 3 feet long) side by side and one above another in old-fashioned bee-houses or sheds, and surround them with moss or fine hay, letting a mat or trap-door close the front during intense cold or when the ground is covered with light snow and the sun is bright. In this sort of repository colonies, with abundant stores, winter well.—FRANK BENTON, *Laibach, Upper Carniola, Austria.*

GRIQUALAND BEES.

[1577.] I send you some bees from this district, and would you kindly inform me, through the columns of your *Journal*, what kind they are? They work fairly well, but are very troublesome when the hive is doing well, as they sting a good deal then. Another question I should like answered, and that is, I found, on opening a queen-cell on two occasions, a worker-bee only inside, and dead, and on another occasion only some stuff inside which appeared to be a mixture of wax and pollen; these cells were sealed, and to all appearance just the same as the ones that contained queens. Only this summer have I and a few others gone in for bee-keeping. I think we shall do well when we get into it. Both your *Journal* and book are of great assistance. We have no foul brood to contend against, nor the wax-moth. I only hope foul brood won't be brought into the country through foundation-comb, some of which we have on the way out.

We have about seven months' summer (our seasons are not well marked here, and we have practically only summer and winter) and a dry, though cold winter. So I think in time, and with experience, we will go ahead.—REGD. TYRRELL, *Griqualand East, Cape Colony, South Africa, January, 1888.*

[The hive-bees forwarded are the same as those described by Dr. Stroud, Port Elizabeth, South Africa, see *B. B. J.*, vol. xiv., p. 188. Dr. Stroud would be pleased to give any advice required as to treatment. Most of the bees have three yellow bands, as Ligurians, Cyprians, &c. The queens and drones are the usual size. Like Dr. Stroud's South Africans, the workers are smaller than those of any other cultivated race, and the presence of darker bees shows them to be hybrids, though generally well marked. It is not unusual to find workers in queen-cells. After the queen is allowed to hatch, the worker goes in to clear up; its 'friends' kindly seal the covering, and the poor inmate, forgetting its first cradle, fails to find an exit—and dies.—ED.]

RAILWAY RATES.

[1578.] Our thanks are due to Mr. Griffin for bringing this subject so practically to our notice. It is one which presses very heavily on all our home productions. I am glad to hear he has been so successful in his negotiations with the Railway Companies in his district, but I fear so long as Railway Companies are allowed monopolies—and they take precious good care to be well represented in Parliament—we shall never see the tariffs put on a much more liberal basis.

With respect to Railway Companies and their rates, I will, with your permission, Mr. Editor, mention a case where your humble servant was nearly made to smart dearly for the carriage of his hives and bees. Well, I wanted to send some of my hives to the heather—over fifty miles away—so I ordered a van for their conveyance in the usual way, and at the usual cost, and took thirty hives to the moors through which the Company's line

one advance a little further? I never let my dovetail be seen on top. How shall I keep them at the bottom, and yet have as much security for a full piece of foundation as is given by the new inventions? I do not think I have one slip in a hundred of the (about) half-size pieces which I use, but I might wish to use full pieces and not show the dovetails. I think of a plan, but I have neither leisure nor appliances to work it out.—S. C.

AN IRISH EXHIBITION IN LONDON.

[1581.] An Irish exhibition is to be held at Olympia, Kensington, to open on the 4th of June, and to close on the 27th of October. Lord Arthur Hill is the Secretary. Department A is devoted to Agriculture; hives, and bee-appliances, manufactured by Irish firms, will be admissible in section 4, and in section 5, 'Products,' the following are named:—Milk, cream, butter, cheese, eggs, HONEY, bread, biscuits, flour, vegetables, cereals, roots, hops, seeds, tinned meat, compressed animal food, foods of all kinds.

This will be a good opportunity for the Irish Bee-keepers' Associations to show how the country has benefited by the visit of Messrs. C. N. Abbott and W. Carr, who, under the auspices of the B.B.K.A., made a lecturing tour through Ireland, the expenses of which (some 80*l.*) were borne by that Association. It will be early for this year's honey, but that of last year will be eligible, and can be supplemented by this year's honey later on.—J. M. HOOKER, *April 7.*

KOERBS' COMB FOUNDATION.

[1582.] With regard to the new Koerbs' comb foundation, has it occurred to any of your readers, that inasmuch as there are cells on one side only, not more than one half the number of bees usually working on the ordinary comb, would be able to work on the Koerbs' foundation; and moreover, that it is probable that the bees would be prevented from manipulating either the comb or their honey on cells of double depth with that speed which they would be able to exercise on the foundation now generally employed?—W. J. MUCKLEY, *Loweswater.*

SUGGESTIONS.

[1583.] In your issue of March 1, your correspondent, Mr. Shea, gives a few useful hints to bee-keepers in his communication (1510) under the above heading, and I hoped some one more capable than myself would have given in return a simple mode of shading the entrances from the glare of the sun; but as no one has replied to his request I shall be pleased to give him my experience if he will accept a hint from a working man. He says, 'Porches I have discarded as not necessary;' true, they are worse than useless as often made, but if they comprise a slanting board not less four inches wide, and are placed rather low across the entire front of the hive, you have always a shade on the entrance and a dry promenade for the bees in all weathers.

Another plan, very effective, though not so simple as the above, is to make the alighting-board work on hinges, fastened to the floor-board, and which may be hooked to the porch as soon as winter commences, and which need not be lowered until spring, as the bees can go in and out freely at either end of porch.—YORKSHIRE NOVICE.

GARDENERS AS BEE-KEEPERS.

[1584.] I have just been reading your new monthly paper, and most heartily congratulate you on its issue, and also wish you every success. I was much pleased with the letter of the 'Village Blacksmith,' and it put the idea in my head that perhaps you might find space in a

future issue for my experiences as a *bona fide* cottage bee-keeper.

I am a gardener, and I think every gardener ought to keep bees. I have kept some now for six years, the first four of which I kept them in straw skeps, and used supers on the top, but got but little honey. Then a change came o'er the scene. A shining light arose in the shape of a new school-master, who not only knew something of the modern systems of bee-keeping, but was willing to share his knowledge with anyone else. Under his tuition I learned some of the mysteries of the bar-frame hive, and also how to make one—rough, certainly, but still it answered for a time. I have made several since then; but I now buy 9-inch deal boards, and make them 18 × 20 outside measurement, and use a doubling box on the top.

In the autumn of 1886 we commenced driving, and I got stung so badly that I thought I would give it up, but still I persevered, and can now drive bees with anyone. I had four lots, which I placed in two hives; they wintered well, and came out very strong last spring. One I worked for sections, and the other for extracted honey. I commenced extracting June 21st, and got 26 lbs., and by the end of July my hive had yielded me 95 lbs., and the other about 50 sections, so I think on the whole my first season turned out well. I am now the happy possessor of seven colonies, and hope to give you a further account of my experiences later on.—KENTISH BEE.

[We shall be most pleased to receive the account of your experiences, and we would fain hope that the day may soon arrive when all gardeners will be bee-keepers.—Ed.]

FIXING FOUNDATION.

[1585.] I forward you a description, with sketch, of the way I fix foundation in my frames for insertion in the *Journal* if you think it of sufficient interest.

Cut two strips of wood $\frac{3}{4} \times \frac{3}{4}$ × length of inside of frame, and nail them to the top of the inside of frame on each side of the foundation, *pressing the strips well against the foundation.* Nail with $\frac{3}{4}$ in. wire shoe nails. If half sheets only of foundation be used, this plan works perfectly. I have never tried it with whole sheets without wire, for I always wire the whole sheets with diagonal wiring, one wire passing on each side of foundation. I embed the wire with an *Sd.* brass wheel, which cooks use for cutting out pastry devices. There could not be a better embedder, so I think. The $\frac{3}{4}$ in. strips need not be the full length of inside of frame; 8 in. in length works well, if wire be used, or three blocks 2 in. in length spaced along the frame would do. Strips the full length of frame have the advantage of strengthening the top-bar. In my opinion no part of the frame should be of less than $\frac{3}{4}$ in. stuff.—HIVE.

WIDTH OF SECTIONS.

[1586.] In discussing this subject, in which we find considerable diversity of opinion, we must carefully weigh the advantages, or otherwise, of narrow *v.* the two-inch width. For my own part, I am strongly in favour of the latter, for reasons which I shall briefly endeavour to point out. It has been decided that the $4\frac{1}{4} \times 4\frac{1}{4}$ section is the best for many reasons. The $1\frac{1}{2}$ -in. and $1\frac{3}{4}$ -in. width sections have their supporters; they look neat and are a handy package; but the cost will be the same as a 2-in. section. The foundation, &c., will be the same, and as the quantity of comb-honey they contain is less, the cost of production will be greater. If the bee-keeper works his bees for exhibition purposes and his honey for home consumption, then he will be the best guide as to which width is preferable: but if the apiary is to be a paying concern, and the sections

are worked for sale, then my experience would strongly be in favour of the full-width sections. We have noticed that the cost of production is the same for a narrow and wider section; therefore, if the chances of all were equal, then the 2-in. section would produce the best profit. But where a sale for one narrow section is obtained, a market is open for six of the wider. Many firms will not look at a narrow section, and as supply and demand must be considered, it devolves on bee-keepers to take the wants of the public as a criterion, and to decide on only having $4\frac{1}{2} \times 4\frac{1}{2} \times 2$ sections. As I am now only alluding to which width section will find the best sale, I will not speak of the merits of two or four bee-way sections, as long as the 2-in. width is adopted, either of these plans will not be against their market value; and this allows the bee-keeper some diversity of methods of working.—WM. N. GRIFFIN.

QUEEN INTRODUCTION.

[1587.] I have read with much regret Mr. Bonner-Chambers' letter (1575) in last *B. B. J.* in which he so strongly condemns the Simmins' method of direct queen introduction. I have adopted the system throughout my apiary of fifty stocks, and have never had a failure when I have strictly followed the directions. As Mr. Simmins is the only dealer to my knowledge who guarantees safe introduction, I think it only fair to give an instance which to unbiassed minds will surely negative Mr. Chambers' sentence:—'The system seems a very valuable one for queen-dealers, as they can guarantee safe introduction, telling their customers to look on the third day to be sure, and yet prepare to send them another on the fourteenth, by which time she will be lost in some unaccountable manner.' Having safely introduced five Carniolans to stocks whose queens I had killed as being of a second-rate quality I proceeded to examine hive No. 6 with the intention of killing the queen so as to make room for the sixth Carniolan which had just come to hand. Being struck with the fine appearance of the black queen, I removed her with a frame of brood to a spare hive intending to utilise her as occasion might require. Although at the time I did not recognise the fact, yet I was virtually constructing a nucleus, which is expressly forbidden by Mr. Simmins. This queen was balled and killed on the eighth day by the old bees, returning from the nucleus. I wrote Mr. Simmins a post-card informing him that the queen was killed, but giving no details. By return of post I received a note saying that 'Mr. Simmins will certainly send you another so soon as more come in.' On thinking it over I saw in what way I had departed from the instructions, as explained above, and of course declined Mr. Simmins' offer to replace the queen. Surely the above is strong proof that Mr. Simmins or any other dealer who may guarantee safe introduction is not actuated by any motive so base as that suggested by Mr. Chambers.—E. J. GIBBENS, *Neath, Glamorganshire, April 6.*

ALIGHTING-BOARDS.—GIVING SUGAR CAKE

[1588.] I enclose sketches of two devices that might interest some of your readers if you think them worth inserting. Fig. 1 shows one of my hives arranged to prevent young bees being lost by dropping from the edge of the alighting-board, and also to give the young pollen-gatherers an easy entrance to the hive when they alight on the ground. Two small nails are driven into one side of the board (*d*), and a stone or brick underneath supports it, so that there is a run without break from the ground to the hive—the floor-board being, by this means, kept from contact from the ground. A large board is used in a similar manner for hiving a swarm. The common floor-boards are not well adapted for applying such a board, although with a little contriving

something similar could be managed without placing the hive directly on the ground. On a warm day, after a spell of cold, the loss of young bees is considerable; and

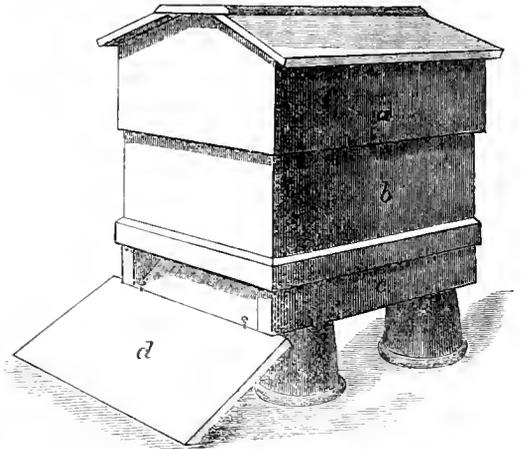

Fig. 1.

then just at a time when they cannot well be spared. The arrangement illustrated provides in the best way against such loss. I find the following a handy way of giving sugar-cake to the bees. A sardine tin has a circular hole cut out of the bottom; this hole is placed over a rounded block C, and the hot cake is poured in to just fill the tin. When set, the block is removed and the cake placed over feed-hold. A piece of glass then forms the cover; the glass allows you to see when the cake is coming to an end. The saw-cut edging of the top of the tin should be removed by melting the solder in a flame cautiously. The hole is cut with a large gouge on a wood-block; 5×4 photo negatives that accumulate as 'wasters' form good covers where available. An inverted cup answers for the block.—SILKE.

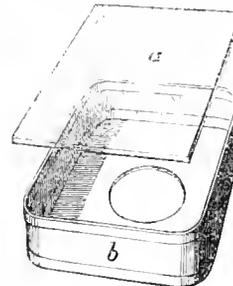

Fig. 2.

IN-AND-IN BREEDING.

[1589.] As a bee-keeper of several years' experience, I can quite agree with Mr. Webster and the writer of 'Useful Hints' on the above subject. I have four races of bees in my apiary, and can now more than double the quantity of honey from the same number of stocks. My hybrid bees last season proved the most productive, some giving over 100 lbs. per colony. I have one frame-hive that contains four races of bees, and the amount of honey they collected last year was astonishing. It is very strong now, and the queen breeding vigorously. It will be a test hive the coming season.

I have read Mr. Boyes' letters with interest at various times for over a couple of years, for we live in the same riding, but I do not know him personally, but this letter may form a sort of introduction to our acquaintance. I do not wish to enter into a paper war with him, but our views certainly differ in point of issue. I think if he once crossed his bees with Eastern races, he would derive the same benefit that myself and many others can prove. In conclusion, we, as bee-keepers and stock-breeders, are very much indebted to Mr. Webster and the writer of 'Useful Hints' for their sound and practical information.—PAUL BIELBY, *North Grimston, Yorkshire, April 9th.*

Echoes from the Hives.

Cottingham, April 2nd, 1888.—Up to the present date the poor bees here have had a bad time of it. High north winds, rain, snow, frost, and an occasional gleam of sunshine is the state of the weather, so that nothing is going into the hives—even when they can get out—only what we put in ourselves. I have placed a frame of wheat-flour next each brood-nest, with a bottle of syrup on the top, and a few eggs are being laid, I believe, in the middle of each day by every queen, or nearly so. I have Carniolans, Italians, and blacks, and by how they are going on now I much prefer the Carniolans to either of the others; they are hardier, stronger on the wing, queens more energetic, and, in fact, far preferable to either Italians or blacks in every particular.—CHAS. HOWES.

NOTICES TO CORRESPONDENTS & INQUIRERS.

E. C. P.—*Obtaining Fruit Blossom Honey.*—Your plan would result in the 'crowding out' of the queen. If there is a sufficiency of orchards—which we, to the best of our recollection of your neighbourhood, doubt—the following plan would be preferable: Stimulate the colonies until they become crowded with bees, then just before the trees are in full bloom, put on the racks. Before doing so, contract the body-box that the bees are forced up into the sections.

T. D. S.—1. *Fastening Brown Paper to Tin.*—Glue will do this very effectually, but we doubt whether this would stand the dampness from the food. We never use such feeders. 2. *Zinc and Syrup.*—Storing syrup in zinc vessels is to be condemned, but in moderately quick feeding from feeders having perforated zinc over feed-hole it is of little consequence. 3. *Queen Introduction.*—See pamphlet advertised in this *Journal*. 4. *Candy.*—Candy cannot be made by boiling fermented honey. We should make vinegar of it. 5. *Echoes from Hives.*—We are always pleased to receive same.

G. J. D., *Barnes.*—1. *Transferring.*—The transferring must not be done until warm weather sets in, say, middle of May. There will then be plenty of time for the bees to repair combs before the honey-flow sets in, which in your district is about the third week in June. 2. *White Substance in Combs.*—The substance seen is mouldy pollen. This is often observed in spring time. The honey which bees usually place over stored pollen has been consumed, consequently it has turned mouldy. The bees will remove it.

REV. F. W. PUDSEY.—*Drone-comb.*—A preferable plan to the one you suggest is: Place two frames half filled with drone-comb outside the cluster of bees, one on each side. Remove any similar remaining frames containing drone-comb from the brood-nest, and store them ready for use in an upper storey when the honey flow commences. Fill up the vacant space, thus caused in the centre of brood nest, with frames containing full sheets of foundation, and close up the cluster of bees by division boards. Insert more foundation when required. Be careful that the drone-comb left in the hive does not contain eggs in the drone-cells. When putting on the upper storey use the Heddon excluding honey-board, and remove the two frames of drone-comb from the lower hive, supplying its place with foundation, to the upper, having first cut out all drone-comb and brood.

HIBERNICUS.—*Solidified Honey.*—We are not prepared to assert that scientific chemistry cannot supply an effectual remedy for the prevention of granulation in extracted honey, but we think very doubtful that such a remedy has been applied to the honey you mention as offered for sale under the condition of 'warranted not

to solidify.' Honey which has been submitted to a temperature of 200° Fahr. will not granulate as a rule.

C. HOWES.—*Drone-breeder.*—The chances are about even that the expert is mistaken, that the queen is really an old one, or that she is unfertilised. Any of these three positions may be the correct one in the case you describe. We advise that the queen remain at the head of the colony another fortnight, and if at the end of that time there is no worker brood in the hive, remove her and unite the bees to another colony.

JO. RO. LO.—*Box Hive.*—You have no alternative but to remove the top of this hive and transfer all straight combs into a bar-frame hive. You will find ample details in last year's volume, pages 89, 112, 124, 134, 188, 273, 294, 315, 416, and 512. From April to September is the extreme period for transferring, and during that time no prosperous stock would be without brood. Place all brood-combs in the new hive if at all straight. Fighting will certainly take place if more than one queen is left when uniting. Queens, like ladies, are any age unless you happen to know.

C. HOWES.—We are pleased to note your exertions on behalf of the Yorkshire B.K.A., and wish you all success in your work.

RODORO.—*Plants to cover Wall and Fence.*—We should advise planting *Cotoneaster microphylla* on the wall facing west. As to the wire fence you mention being so much in the shade, it would be useless to plant creepers, for honey secretion. Anything might be planted, such as honeysuckle, jasmine, Clematis, climbing roses, &c.; but as the sun has not much access to the screen, little or no honey would be elaborated.

T. H. BUSH.—*Parasites.*—The parasite on your bees is, from your description, the *Braulta caeca*. It is not often found on bees in this country; but in Southern Europe and in Cyprus it is very frequently met with. It will most probably die off. They are very active little creatures, and you would have a difficulty in removing them individually from your bees.

A. W. C.—*Moving Bees.*—If the bees have not been overhauled this year, we would simply place a piece of perforated zinc over the flight-hole, and secure another piece of perforated zinc over the hole in the quilt used for feeding, and pack them securely, so that the quilts could not get removed during transit, and send them by the pantechmicon, taking care that they were not covered up by other packages or a tilt. You will find they would then travel all right, as the weather is so cold. But if the frames have been taken out and the bees overhauled this spring, then—No. 1, Yes; No. 2, No; No. 3, Either.

H. S.—1. *Flour Candy.*—We find our stocks continue to consume the flour candy after stimulative bottle-feeding has commenced. No other plan entails as little waste. 2. *Syrup in Winter.*—Syrup must not be given in winter, being too watery it would induce dysentery, as the bees cannot exercise sufficiently to drive off the water. Sealed stores and candy are the only permissible foods in the winter. 3. *Queens raised now.*—Of no use whatever unless they mate in about 5 to 10 days after hatching. 4. *Position of Cluster.*—Not at all unusual. Fresh air is quite as important as warmth and warmth as fresh air. 5. *Hive-maker.*—There used to be a maker of the name you mention advertise in these columns.

D. R. DALY.—1. *Sections on Swarms.*—Yes, at once, with excluder zinc between, and only starters of half an inch foundation in the frames below. 2. *Preventing Swarming.*—Yes. See answer to T. Nixon. 3. *Position of Hives.*—We would advise you to move your bees away from your cow-yard for the sake of the cows; there might be 'ructions' in the hot weather. The hives should, if possible, stand in a sheltered

position, and face any way between east and south or south-west. Thanks for your appreciation of our publication.

HORACE.—*Replacing Old Combs.*—In view of the persistent cold weather, you can wait, say, a fortnight before carrying out your substitution.

J. WALTON.—*Transferring Bees from Box.*—On a mild day—if we ever get one—you should cut the combs out of the frames, and tie them in the Standard frames with about three pieces of tape each, keeping the combs close up to the top-bar. In about three days they will be fixed, and the tapes should then be removed. All bees should be carefully shaken or brushed off each comb before attempting to cut it out. After you have a comb in the new hive, brush the bees into that one.

T. NIXON.—1. *Preventing Swarming.*—Yes, if you adopt Simmins' non-swarming system, i.e. put half-inch starters only of foundation in bottom box, raising the combs already there up into the doubling-box. Extract from the shallow super as may be advisable. 2. *Sugar.*—The sample of sugar will do for dry feeding, but not for syrup-making. It is known by the name of 'Demerara Syrups.'

QUERY.—Some years ago I saw several sections at a show worked entirely in glass, which looked beautiful. Will some reader kindly tell me how they are fastened together, as I should like to work a few this year? Also, is it a fact that honey extracted from *old* combs, or combs that have been bred in, is not so clear as that stored in new; and, if so, why? This is a question of great importance to those who have a lot of spare combs, which are given in upper storeys for extracting purposes; besides which I think all bee-keepers will admit that light honey sells much better than dark, for the simple reason that it is more pleasing to the eye: therefore it behoves us all to produce it as clean and light as possible.—**LORDSWOOD.**

QUERY.—I should like to ask Mr. Broughton Carr if he finds it necessary or best to wire his 6-in. extracting frames to prevent damage in the extractor?—**J. S. W., Plumstead.**

Received from Mr. William McNally, Glenluce, Scotland, his Illustrated Catalogue of Bar-frame Hives and Bee-keeping Appliances (24 pages.) This is a very compact catalogue of the requirements of bee-keepers, without any redundancy of pages or illustrations.

Received from Mr. S. J. Baldwin, of Bromley, Kent, 'The Bee-keepers' Instructor, with a Catalogue of Appliances' (48 pages.) This 'Instructor' will be found of great service to beginners, as it embodies the very large experience of Mr. Baldwin, and is full of sound information. The catalogue is very extensive, containing a list of all the appliances in use by bee-keepers.

Received from Mr. Rice, of Norwich, a solid-wood feeder, with centre cone and saucypan lid. We consider this would be preferable to the ordinary tin-feeder, as it would tend to retain the heat of the cluster. The price has not been communicated.

Communications to the Editor to be addressed 'STRANGEWAYS' PRINTING OFFICE, Tower Street, Cambridge Circus, W.C.

[No. 304. VOL. XVI.]

APRIL 19, 1888.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

ROYAL AGRICULTURAL SOCIETY.

We beg to call attention to the announcement in our advertising columns relating to the Bee Department of the Royal Agricultural Society's Exhibition, which takes place at Nottingham in July next, the entries for which close on May 12th. The schedule contains several improved features, notably a class for Appliances, in which the articles to be exhibited are definitely stated. Provision is made for lodging protests against the decision of the judges, and for all exhibits to be staged on the day previous to the opening of the exhibition. We venture to hope that this rule will be most rigidly enforced by the executive; the delay which has hitherto taken place in the commencement of the judging, owing in a great measure to the late staging of the exhibits by a few exhibitors, has been detrimental to the exhibition.

The regulations also provide for returning all fees paid for entries in the Honey Classes providing fourteen days' notice has been given by the exhibitor of his inability to send these exhibits.

The schedule is a considerable improvement on previous years, and will, we feel sure, result in a large number of entries.

COUNTY ASSOCIATIONS.

If there be anything wrong in the working of these useful and valuable societies, now is a fitting opportunity to discover, and to rectify, the mischief. That there is something at fault with the machinery we have not the slightest doubt. We cannot agree with one of our correspondents, that it is wiser to hide our faults. If disease exist, better use strong remedies, and eradicate it before it becomes chronic. Good cannot but result from friendly discussion. We do not offer a panacea for all the ills existing or imaginary; but by exposing deficiencies in some societies, and naming topics for consideration, we may, ere the busy bee season arrives, have once more our County Associations in a position to surmount all difficulties, and sweep away every obstacle.

Besides the wrongs mentioned by our correspondents we know of one Society, of whom the

Hon. Sec. is really the only shining light. A large Committee exists (on paper), meetings are called, but the members never put in an appearance, and thus it will be seen that if the Secretary did not move, this Society would soon collapse.

Then another Association has in the past accomplished much, and bee-keeping was raised in that county to its proper footing. It possessed a hard-working Secretary, whose heart was in the work, and who treated obstacles as a pleasure to be overcome. This Association now differs from the former instance, in that it has an indefatigable Treasurer and a good Committee, but the present hon. sec., taking but a slight interest in the cause, does little to further its advancement.

Then, again, we know of several other Societies, whose Secretaries, having to do all the work, are gradually losing heart. More enthusiasm is evidently wanted somewhere. Away, all ye bee-keepers that say the Associations have done you no good! How would you have learnt to keep your bees on scientific principles? How would you have adopted the present system of producing comb honey in a saleable form? How the improvement in the quality of extracted honey? How the meetings where you have met your fellow-apiarists? How the hints for disposing of your surplus produce? How the knowledge of new and improved inventions? How bee-keeping has become a national industry? Nay, how your very existence is owing in a thousand ways to the County Associations of whom you now say, 'They are no use.' Our bee-masters have striven in the past; the books they have written, the rules they have framed, constitute the very essence and basis of an existence as bee-keepers.

These organizations, 'County Associations,' must not, and cannot be allowed to quietly drop. During the past months most of the annual meetings have been held, and it must rest with all true-hearted bee-keepers to consider carefully the present state of affairs, to note their respective deficiencies, and to place their Societies on sound commercial principles.

The bee-keeping industry will flag and retrograde if County Associations are allowed to be a thing of the past. We believe that a certain portion of the work assigned to the Societies has been accomplished; but must this be a reason for inactivity? There is still much work before you to grapple with,

fresh ground to break, new objects to be obtained, and advancement, when attained, will open up new schemes for attainment.

BEE-KEEPERS' ASSOCIATION FOR HULL AND DISTRICT.

On Friday, April the 6th, a meeting was held at the Station Hotel, Hull, for the purpose of forming a branch of the Yorkshire Bee-keepers' Association. There was a fair attendance, and Edward Harland, Esq., who presided, explained that some correspondence had taken place between the Secretary of the Y. B. K. A. (R. A. H. Grimshaw, Esq.) and some one then present, and it was thought that from the large number of bee-keepers in Hull and its immediate neighbourhood a very good branch association could be formed. After a considerable amount of discussion had taken place, a resolution favourable to the formation of the Association was submitted and carried *nem. con.*

The meeting adjourned until Wednesday April 25th, when it is hoped all interested in the project will attend, for the purpose of electing officers and committee.

Mr. H. Harland, The Elms, Cottingham, Hull, will be glad to receive copies of rules from secretaries of various associations.

CAPE COLONY.

A NEW HONEY-PLANT.—In Cape Colony, Africa, grow about sixty different species of *Portea*. Some of them give honey, the most from *Portea mellifera*, by the natives called zuykerbosches, zuykerboom, or tulpboom. It has so great a quantity of nectar that the same is gathered and evaporated to a syrup, which is sold and used as medicine by the natives. This syrup has a flavour similar to bananas. The plant blossoms in the fall, and the flowers are half full of this nectar. I think it would be very desirable to get this plant from Cape Colony, and to try its cultivation in the United States.—L. STACHELHAUSEN, *Texas*.—*American Gleanings*.

THE COTTAGEE'S (BRITISH) BEE JOURNAL.—The publishers of the weekly *British Bee Journal*, in view of the fact that the price of the weekly at 10s. 10d. is beyond the reach of the poorer classes, decided to issue the *British Bee-keeper's Adviser, and Cottage Bee-keeper*. This is issued concurrently with the weekly, once a-month. The price is 1s. 6d. a-year. The first copy is now before us, and we feel quite sure that it will meet the expectations of the publishers. It has for its editor none other than our good friend Thomas William Cowan.—*American Gleanings*.

THE DEATH OF MRS. TUPPER.—We note by the *Prairie Farmer*, that Mrs. Ellen S. Tupper, well known to our older readers, died suddenly, March 12, at El Paso, Texas, while she was visiting her daughter. At one time Mrs. Tupper was considered not only a standard authority on almost all questions pertaining to bee-culture, but she was also remarkably successful as a honey-producer. She finally went into the supply business in company with a Mrs. Savery, under the name of the Italian Bee Company, at Des Moines, Ia.; but in consequence of financial troubles and overwork it is said she became partially deranged, since which time we have heard little or nothing from her.

AN EXAMPLE FROM IRELAND—WILL OTHERS DO LIKEWISE?—If you send me a few copies of the *Bee-keepers' Adviser* I will send it to any of my neighbours who keep bees. There are very few bar-frame hives in this part of the country, nearly all straw skeps. I get the *Bee Journal*, and when I read it I send it round to all my neighbours who keep bees. I wish the *Adviser* every success.—W. J. ANDERSON, *Ards, Caledon, Co. Tyrone, Ireland*.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'THE EDITOR of the "British Bee Journal,"' c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, Kings Langley, Herts (see 2nd page of Advertisements).

* * * In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

BRITISH AND AMERICAN JOURNALS.—FOUNDATION FASTENERS.

[1590.] The visits of your *Journal* are as regular as they are welcome. It is read by some of us with an interest greatly enhanced because of our good fortune in having made the acquaintance of many of the leading contributors to its columns. To know the Editor, to have met with the gentleman who week after week gives us so many 'Useful Hints,' to have conversed with such men as Mr. Grimshaw, Mr. Hooker, 'Amateur Expert,' and a host of others, is to appreciate the regular visitations of the *Journal* to which they are frequent contributors.

The British bee-keepers are privileged above their fellows on this side the Atlantic in having a journal published exclusively in their interest, that is, the mouthpiece of no man in particular, nor the medium through which he trumpets the merits of the goods he has to sell. In this the *B. B. J.* differs from every bee paper published in either Canada or the United States with which I am acquainted. The publisher of every one of them has a direct interest in the manufacture and sale of bee-keepers' supplies. This may be a necessity to their existence, but it has its objectionable features. It fosters narrowness and jealousy among the rival claimants for public patronage, which frequently show themselves in the columns of their respective papers, and are sometimes manifested by the absence of information which their subscribers have a right to expect and ought to insist upon getting. I am reminded of this by the perusal in your last issue over the signature of 'R. F. Holtermann, Brautford, Canada.' The subject of Mr. H.'s letter is Mr. Eden's foundation-fastener, and appears to be called forth by a paragraph in 'Useful Hints,' published in your issue of January 5. It appears Mr. Eden contributed something on the subject of foundation fastening in the *American Bee Journal*, which referred to his own device. In referring to this Mr. Holtermann says, 'It might be interesting to know that Mr. Eden was simply working in an advertisement for his own ingenuity, and to draw attention to the subject so that it might pave the way for the fruits of his own thoughts.' All your readers have gathered from Mr. Holtermann respecting Mr. Eden's machine is found in its last sentence, where he says, 'An important feature in the machine here is an iron plate heated by a lamp. Upon this plate the edge of the wax is melted. It works well and rapidly.' I am no apologist for Mr. Eden if he has attempted to secure a free advertisement for his machine by instituting comparisons between it and others in an ordinary communication. His machine possesses merits superior to anything of the kind brought out in this country, and if he wants to make money out of it he ought to advertise it in the usual way. The strangest feature about the matter is that Mr. Eden exhibited his machine at the annual meeting of the Ontario Bee-keepers' Association held at Woodstock last January, and showed it working to the great satisfaction of every one who witnessed the work; and, although both our bee papers had a representative present at that meeting, who saw the machine in operation, yet neither of them has

condescended from that day to this to tell their readers that such a man as Eden exists, or that a foundation fastener has been invented by him which does the work 'rapidly and well.'

What would the readers of the *B.B.J.* think if they knew that something for which they had long looked—something calculated to lessen their labour, and make a perfect job when but an imperfect one could be made by appliances hitherto available—had been invented and exhibited at one of your Board meetings, and the Editor omitted to tell them of it? What excuse would the *Journal* offer if its Editor conveyed the information to the people of another country, and concealed from the readers of his own *Journal* the fact that a long-looked-for want had been met by a machine which did its work 'rapidly and well?' I fancy I hear you say, 'The Editor of the *B.B.J.* would be guilty of no such dereliction of duty,' yet such is the position Mr. Holterman occupies. He is the Editor of the *Canadian Honey Producer*, that carries on its title-page the following motto: 'Published in the interest of the Honey-producer exclusively.' But, then, Mr. H. is connected with a firm that deals in supplies, and so is the Editor of the other *Journal*, and this may 'account for the milk in the cocoanut.' Possibly they think they have a right to remain silent on all inventions, however useful, unless they control their sale. We have now two of the best section foundation fasteners in America. Of Mr. Alpaugh's you already know something. After seeing Mr. Eden's working, I ordered one of them, but it is not yet forwarded, so that I shall not attempt a detailed description of it. Suffice it to say that I think it is about as complete as it is possible for a machine of the kind to be made. It works not only 'rapidly and well,' but it does its work neatly, truly, and strongly. Unlike Mr. Alpaugh's, it works on both four-piece and one-piece sections, either closed or unclosed. What more can be desired in a machine of the kind? But there is a serious drawback to the general introduction of both machines. The price is too high. It is not every bee-keeper who can afford to pay five dollars, *U.*, for a foundation-fastener, however perfect it may be.

I am pleased to learn that your Mr. Lee is working along the same lines. His inventive genius, I doubt not, will enable him to give to the British bee-keepers what Messrs. Alpaugh and Eden have produced for us. If he succeeds in producing a machine that will do the work of fastening foundation in brood frames, he will have accomplished that which is 'devoutly to be wished,' and that for which his brother bee-keepers will owe him a debt of gratitude.—R. MCKNIGHT, *Owen Sound, Ontario, March 15th.*

WIRING COMBS IN SHALLOW FRAMES.

[159L.] In reply to your correspondent 'J. S. W.' who, on p. 196 of last issue of *Bee Journal*, asks if 'I find it necessary, or best, to wire my 6-in. extracting frames to prevent damage in the extractor,' let me say:—There is not the least necessity for wiring combs in shallow frames such as I use. I extract some hundreds of these combs annually, never have a breakdown, and have never wired a sheet of foundation in my life. When combs are built in shallow frames over the brood nest, the bees nearly always attach the comb to the frame along the full length of bottom bar as well as the sides, and when built thus—as 90 per cent of such combs will be—no breakage can occur, seeing that the face of comb lies close on wire of the cage, and the strain is equal over its whole surface. The sectional boxes I use are 6 in. deep, and the frames $5\frac{1}{2}$ by 14, not 6 in. as stated by your correspondent. It is important to bear these measurements in mind, because I frequently use two of the boxes as a brood-chamber, so that with eighteen frames 14 by $5\frac{1}{2}$ we have a larger breeding surface than

ten standard size combs give, and any addition to its capacity is, on this account, objectionable.

At the present time, when shallow frames are meeting with such general approval for surplus chambers, it is quite a misfortune to find differences in dimensions creeping into use. I have used these frames successfully for the past thirteen or fourteen years, and would express an earnest hope that our hive-manufacturers will adopt the 14 by $5\frac{1}{2}$ as a standard size, in such hives as they turn out with frames for surplus chambers. It is the best size in every respect for extracting purposes.

The esteemed writer of 'Useful Hints' also refers to these frames on p. 187 of your last number, and, while approving of their use, says:—'We would, however, make one addition, viz., that a zinc-excluding adapting board be used between hive and surplus chamber.' In the concluding portion of my article in *Record*, to which reference is made, these words occur:—'Queens should be rigorously confined to their own department, and never be permitted to enter surplus chambers. Excluder zinc accomplishes this (for us) without failure, and a supply of the article is an indispensable item of our working plant.' It will thus be seen that I am entirely in accord with Mr. U. H. on this point, though he has apparently overlooked my words as quoted.—W. BROUGHTON CARR, *Higher Bebington, Cheshire.*

IN-AND-IN BREEDING.

[1592.] I read your leading article in last week's issue with considerable pleasure, which was, I confess, much enhanced by finding we were so nearly agreed on all the chief features in this discussion. It, however, seemed to me that you must have somehow overlooked Mr. Webster's second article, which was the one to which I took exception. There are a few minor points, too, requiring a little more elucidation; and, lastly, as you state that I have misunderstood the question at issue, I beg you will allow me to say a few more words, as I am most anxious to put myself right with your readers, amongst some of whom I fear your article may create the impression that I am against the introduction of fresh blood into our apiaries.

To begin, let me say that I had no general objection to Mr. Webster's first article, page 62, only that I did not accept his examples of degeneration brought about by supposed isolation and in-and-in breeding, which he gave in support of his case. However, I allowed that to go by unchallenged. It was to his second communication that I so strongly demurred, and must ask your readers to judge whether I was right in supposing Mr. Webster's article was intended to favour the importation of foreign bees as a cross with our native ones or not. I quote from his letter, page 131: 'Would our cows, our sheep, our fowls, our bees, our trees, bushes, and plants, produce what they do if they had been allowed to revel in a state of nature?' 'Has no foreign variety of tree or plant been imported to improve and has improved our own?' &c. 'How have our fancy pigeons been produced? How our useful or pretty dogs, cats, rabbits? Why, each and all of these have been produced by a judicious crossing of varieties—in every case of *foreign* varieties.' 'Why, then, should not we do the same with our bees?' Now, with regard to the above quotations from Mr. W.'s article, I can only say that I very much regret he did not confine himself to bees and bee-keeping instead of wandering into the wide regions of biology, for there is not the slightest analogy betwixt man's selection or crossing animals and plants with a definite object in view and natural selection or the crossing of animals and plants naturally, which with bees we cannot at present prevent.

So far as his article relates to the infusion of fresh blood into our apiaries, I am fully in accord with him; it is only to a cross of *foreign* blood that I object,

because I don't believe the foreign bees are a superior race to our own, nor is it likely they will withstand our fickle climate nearly so well.

After this little digression, perhaps you will allow me to return to your article.

You state, 'Our native bees can be used for cross-fertilisation to any extent without the necessity of importing a single foreign bee.' This is just my own argument, and so far from my being opposed to a cross, I stated that I was not against it 'if such could be got from a bee in all points better than our own,' but that I was 'against crossing with any degenerate race the foreigners chose to send us.' Also (page 158), 'I have driven bees thirty miles away, on purpose to get a cross.' But you see I am for crossing with a *better* bee, just in the same way as our raisers of stock, fruits, flowers, &c., set up an ideal of perfection in their minds, and carefully breed and select from those which most nearly approach it, until eventually they attain their object; and I would in the same way wish bee-keepers to improve their bees, but it, unfortunately, cannot be done—not until we have a certain method of mating them, and until we get that for which we are groping in the dark.

What the advocates for the introduction of foreign bees contend for is simply a cross, with a bee whose characteristics in its native land they know nothing about; and when such cross is obtained, what then? No matter what new feature it presents, whether good or bad, they they cannot be perpetuated or eliminated until we discover a sure way of controlling the mating of queen and drone. Therefore, the only advantage, if any, that can be claimed for crossing with foreign bees is, that there is an infusion of fresh blood, although that blood may be from a very inferior stock to our own; whilst I contend we can get an infusion of fresh blood from widely different districts in our own country, with the advantage of knowing their good qualities, and avoiding the spread of disease.

You state, sir, 'that a good all-round bee might be produced from an admixture of Ligurian, Carniolan, Cyprian, and English blood.' Quite possible. I do not doubt it, but it would possess traits of character either for viciousness, or what not, which might take years to eradicate. Besides, have we not a good bee in our natives, both for hardiness, for temper, and for honey-gathering, which will put into the shade all the foreign bees, either pure or crossed? Let the advocates of foreign bees give their best results, Mr. Editor, and I will give mine.

You state, 'It is too late in the day to doubt the firmness of the ground on which Mr. Webster's articles are based, now that we obtain "honey by the hundred-weight" from bees, which, according to excellent authorities, have ceased any longer to be the old English or German brown bee, by reason of the numerous importations from abroad.' Surely, such a contention as this ill becomes the Editor of the *Bee Journal*. Are you, sir, going to ignore the benefits derived from keeping bees on modern principles, and ascribe all the benefit to a haphazard cross of foreign blood? Surely not.

I have much more to say, but I dare not; I fear I have already trespassed beyond ordinary limits, but cannot close without expressing a hope that your remarks on breeding stock, and what is and what is not consanguinity, are not intended for me. I had hoped I had passed that elementary stage some twenty odd years ago.—F. BOYES.

CONSANGUINITY.

[1593.] Under the above heading, page 101 (1498), a case is brought up of bees being 'nearly two miles in a bee-line' distant from others, and swarming 'say a fortnight earlier than any other neighbours' bees, these circumstances being considered sufficient proof that this

must have been a case of in-and-in breeding. I should very seriously doubt—in fact, feel positive that this cannot be considered such a case. I know positively by island experiments on Georgian Bay that the queen may meet the drone five miles from the hive. Then as to their early swarming, this would not be sufficient proof that matured drones might not exist in other hives, and your bees and honey seasons must be very unlike ours if they did not have later swarms.

I can say nothing very positively as to the evil or good effects of in-and-in breeding; if not evil, why has their Creator ordained it that the queen should be impregnated on the wing? Then may we not make a mistake by in-and-in breeding, whilst we have few strains of bees as yet which have reached that state that we cannot improve them by judicious crossing?—R. F. HOLTERMANN, *Brantford, Canada*.

CONSANGUINITY.

[1594.] In returning to this subject again, I trust I shall not be accused of *cacoethes scribendi* if I add a short *résumé* to what I have written before in previous letters. Our worthy Editor, having endeavoured in last week's issue to place the salient facts before the readers of the *B. B. J.* in the editorial (page 175), has taken a short excerpt from one of my letters, and italicised the salient point, or the offending words; whereas in Mr. Webster's case he gives a paragraph with the gist of his article, which I do not consider fair. Taking my previous letters as a whole, I have nothing to retract; probably, if I had more time to spare for ink-slinging, I might often word some of my paragraphs differently, but under existing circumstances I have to send off my communications as first written.

Now, my contention is, and has been—*vide* my previous letters—that when a recognised writer on bee matters like Mr. Webster makes a statement, and then backs that statement with examples, the inexperienced novice in bee-keeping would accept his deductions without the customary *granum salis*, and believe it as an established axiom or dogma. Though I am bound to admit that Mr. Webster, like some 'Old Parliamentary Boys' once limned in *Punch* as running away after they had chalked up on a notice-board, 'No Popery!' he too had to recede from the position he had taken up in his article, and the examples he recorded, and admit the remote possibility of the consequences he predicted ever being realised. If Mr. Webster had not appended the two examples of the old woman's apiary in the 'Lone Valley' and the one in the Pine Woods as instances coming under his own actual notice, I should not have replied to his article, but with such positive instances of alleged deterioration incident on in-and-in breeding, I felt it a duty to bee-keepers generally, and the new converts to the modern system especially, to publish two (among many similar) instances that have come under my own notice, diametrically opposed to Mr. Webster's ideas—instances of continued and continuing prosperity in equally isolated apiaries to those mentioned by him. Yet Mr. Webster's ideas are lauded to the skies as axiomatic dogmas, while my instances (tangible, truthful ones though they be) are relegated—with the words I used to emphasise the actual fact—to the cold shades of pity, evidently because they happen to prove the futility of Mr. W.'s examples and the very antithesis of his deductions.

The instance I mentioned of the same strain of bees being in the possession of grandfather, father, and son, was not in a lone valley but on a hill-side, and they must have gone forth and multiplied abundantly year after year for many years,—though I do not remember stating it to be 150, but in the matter of prolificness of the strain of bees mentioned by me I would like to mention the cottager obtains his harvest of honey by the brimstone pit, which is a salient reason why the said bees

had not peopled the hill-side, aye and the valleys beyond. Then as to the amount of 6*l.* cash and twenty gallons of mead, which, at a low estimate would be worth 1*l.* more, making 7*l.*, as the profit in five stocks. I opine there are many bee-keepers who have the best and latest improved appliances, coupled with the best advice the *B. B. J.* can give them, and who have invested in the finest selected strain of foreign bees, and yet fall short of that amount of profit when they tot up accounts at the end of the year. I mentioned the farmer's widow gave the old man the *second* swarm, at the sale of the farmer's effects, implying that the bees were sold with the other farm stock, which is the fact—but I do not assert that no bees were kept within a radius of eight miles of the apiary, evidently the district would have been full of the same strain of bees if the men had sold one swarm per year to their nearest neighbours, without any introduction of queens from other strains from a distance. Here we leave the matter with the eddying circles of dates and distances still enlarging, like the enlarging ripples produced by throwing a pebble in the centre of a placid pool of water. Mr. Webster fairly conjectured the time of three generations at ninety years, our Editor at 150, a wide difference between two authorities; and we find the radius enlarging also in which a strain of bees can be kept pure and immaculate. It seems like a waste of time to write on consanguineous subjects, nature appears too prodigal in our small island to allow of close in-and-in breeding if radii of eight miles are everywhere overlapping each other.

Then again as to obtaining honey by hundredweights with the mongrel strain of foreign bees, I, too, have accomplished the same results with my English strain; and if I was boastful I have no doubt that both my average and profit on (say) fifty to seventy stocks, would compare favourably with any like number of stocks in any apiary in England, be they Carniolan, Ligurian, Cyprian, or the Holy Land bee, or a hybridised mixture of all and sundry. I can also say, Mr. Editor, I have stolen a march on you while your hybridised strain enables you to write of hundredweights, I am able to write of honey by the ton, and all gathered by the English strain of (not immaculate) bees and equal in my estimation in every point to any race of bees existent in Great Britain to-day. I am sorry I was not more lucid or explicit in a previous letter *re* the grafting and budding, so that Mr. Webster may have grasped my meaning when I mentioned the 'amber heart cherry' and pippin apple as instances and kinds it would be impossible to produce from the wild cherry and crab-apple by cultivation, and Mr. Webster's antistrophe was misapplied to me, for though I do not sit under my own vine and fig-tree I gather fruit yearly from trees grafted by myself, proving I am quite conversant with both budding and grafting.

When may bees be said to be wild? when a stray swarm locates itself in some hollow tree, or are there some strains of wild bees existent in England that refuse to be domesticated, *i. e.*, to dwell in hives: if so, where or in what part of the kingdom are they to be found? If our Editor is referring to a stray swarm located in some tower or roof, that took themselves to flight from (say) my apiary two or three years ago, I fail to see the advantage accruing to my bees inter-breeding with these bees beyond the occupants of hives still remaining in the apiary.—W. WOODLEY.

[According to statisticians, the average duration of a generation is thirty years, but in an ordinarily healthy family 150 years is not an uncommon duration for three generations. Sometimes these extend to 200 years, and even beyond that term. William Penn, the founder of Pennsylvania, was born in 1644; his grandson, Granville Penn, died at Stoke Pogis, near Windsor, in 1844.—Ed.]

BIRDS AND FRUIT-BUDS.

[1505.] We are not much troubled with the bull-finches here, the bird-catchers are always on the look-out for them; but we have a curse nearly as great in the sparrows, which swarm everywhere, to the great injury of all fruit-growers. When snow is on the ground they attack the gooseberry, red currant, and plum-trees, pecking out the blossom-buds for the sake of the small quantity of saccharine matter which they contain, and which would develop, if unmolested, into the future honey for our bees. Not only do they do this, but as soon as the gooseberry-trees come into *flower* they cut off the flowers and incipient fruits wholesale. I believe an old cock sparrow will destroy at the rate of nearly a stone of gooseberries per hour if undisturbed. Any one can see the destruction they cause by this means if they will only take the trouble to lift up the branches, when they will see all along the bearing shoots—especially such as are horizontal, and on which the birds can easily perch—the flower-stalks, or, perhaps, half of the young fruits, remaining, the other portion having been cut off and the sweet part eaten.

I am glad to see Mr. Hiam call attention to this, as, of course, if we allow the birds to peck out the blossom-buds, we cannot expect to have the blossoms for our bees.

Sparrows, I find, take my bees, too, worst of any birds we have, except the great tits (*P. major*). They also destroy the crocuses, and do other mischief,—'drat 'em!'—F. BOYES.

REMINISCENCES.

[1506.] Reading the pages of our *Journal* the other night I determined to write an account of most of my misfortunes—all I can remember—and mismanagement of the honey bee, also known as the sting bee. My readers will kindly remember that I was very young to start bee-keeping, and knew no one to whom I could appeal in case of any mishaps: and I did have several, as you shall hear.

It was about the year 1875 we lived, and had been living for several years, in a beautiful valley about ten miles from Birmingham. There was not a fence, tree, hedge, or bush, that was unclimbable, as the birds knew full well. My brother Harry and I went to the rock-shop and to school at the nearest village, three miles off, or rather town, as the inhabitants proudly called it. When we were not there we were either up some tree, or roaming about the fields and woods in quest of another egg to add to our collection, which was a very good one. According to the report of one who should know I was a fair sample of a boy; but judging by a peculiar smile which followed after that saying, I should infer that a great deal is meant by that, and I say at once to anyone who has read *Sandford and Merton* that I was a wicked boy indeed.

Now I have described myself let me describe our hive, which contained the first bees I ever remember. It was a large, box hive, and at one corner the bees used to hang out in a cluster every summer, while we, at the risk of a dumpling eye, used to pick off with great skill the straggling bees with a catapult, and wonder vainly what it was like inside. Every autumn on the path beneath we found some morning that it had been raining drones in the night; never since have I seen so many turned out of one hive. Our interest increased with our years in those bees, and much more so when my father conceived the noble idea of fixing a straw hive against the wall for them to swarm into. Our old friend the gardener was told off to perform this feat. He bought one of the smallest hives I ever saw, which he made very sticky inside with beer and sugar, and, as a further inducement (?) constructed a network of sticks

inside 'for the bees to lodge on.' It was then placed on two iron supports some two yards from the bee box. Total abstinence principles were at once forgotten, and I regret to say many bees were soon wandering about on the path thirty feet below, trying in vain to find the entrance of their home. I fancy those bees had many a laugh over that straw skep, but it was destined to become very useful in twelve months' time; for one lovely evening, as my brother and I were out gathering clover for our rabbits, we came across a large swarm, bending to the ground a stout hazel bough. Our hearts beat wildly with fear, hope, and joy. Being dusk, at first we were in doubt whether it was not a swarm of flies or wasps, but at last decided it must be bees. So, while Harry kept watch, I fled for the gardener, and finding him managed to stammer out enough for him to understand what was wanted. The hive that had kept such a long, faithful watch was brought to earth, and after some little delay in putting in a fresh supply of stickiness to gum their wings for a space to stop them from flying and throwing their stings away, we started with the hive, a table, a cloth, and various feelings, in which fear predominated, to hive our first swarm. We arrived and watched the busy insects for several minutes, during which time my knees knocked together more than I would own afterwards. We prepared for action; Bunn, the gardener, held the hive under them, Harry was to hit the bough sharply (it was getting dark), and I held the cloth ready. Everything was now ready, the signal was given, a very weak tap broke the stillness of the bees and of the evening, half the bees fell into the skep, the bough released of most of the weight, like a piece of elastic, shot at Mr. Bunn, who caught a great many of the bees with his coat and hair, and who called the bees, bough, and Harry, several naughty words for some moments afterwards.

When we had got our breath and our instructions afresh, the hive was again placed beneath the remaining bees, and Harry, now more used to it, knocked every bee off at one try. The hive was nearly full of bees, and so was the grass round about. Singularly, not a bee lifted his stung against us; whether it was the sugar and beer that made them so tame, or the trembling of the hive confused them, or maybe the funny old face of Bunn peering down upon them, inspired confidence and implied that all would be well, I know not; but I know we were glad to get them on the table and covered with the cloth, and then, after 'flicking' all the bees we could find on Bunn—some scores—off him, we carried them home in triumph, leaving thousands behind to their fate, and, luckily for us, to mourn the loss of their 'leader.'

The hive was placed in the garden, and next morning, some hours after the bees had started work and well marked their position, we put up a stand the other side of the garden, and got the hive on it and a milk basin to cover all. There they worked splendidly, and were soon clustering outside for want of room. But even now we were not content. It was tantalising to think of all the wonders going on beneath one inch of straw and nothing to be seen. But a bright idea struck us, which was to cut a hole in the crown and put a piece of glass over it. This we did, and were delighted with the extensive view of comb obtained. We now would gaze by the half-hour at about seven cells, and as many bees, who were not in the least afraid of us, but by their expression seemed to say, 'Our time is not yet come to make you run.' Strange as it may appear at first sight, that hive was the innocent cause of many a terrific fight between Harry and me, during one of which our collection of birds'-eggs, the result of many a hard climb, was knocked over and smashed. The necessity for this warfare was, that I contended we ought to go shares in that swarm, having both clapt eyes on it at the same moment, but my brother, in virtue of being older than I (some sixteen months), claimed it as his. After awhile, being unable to decide

by force, I tried persuasion, which was successful, for he promised to make an artificial swarm and let me have it. We learnt by heart the instructions contained in a book by the Rev. J. G. Wood, which happily my father had bought. Then being quite prepared with veil and gloves, &c., and having chosen a dark night so that the bees could not see to sting—we found afterwards that they can feel to sting quite well enough for all practical purposes—about ten o'clock we went to work. With fear and trembling we approached the hive, and having blown in a little smoke and a great many sparks from a piece of rolled-up rag, we turned the hive over, and immediately put an empty one over it, wrapping a towel round the junction. Now we know bees are wonderfully knowing creatures, and I firmly believe they took advantage of our youth, for we could not get them to run up. It may have been because we gave a few taps and then ran off to extract the stings (there was a leak in that towel) and then back again to give a few more, only again to bolt, so giving the bees thinking time. Enough to say we never got that swarm. True there were some hundreds of bees and drones in the upper hive, which were put on a new stand, but they returned next day to the mother bee. Well, I was not going to be outdone by such a small insect, so I drew out of a secret recess one pound, the result of much self-denial, and straightway went to a bee-keeper, six miles off, and bought with the money a very weak stock. It survived the winter, and in the spring by feeding at the entrance every night with syrup in a spoon, I got them very strong.

About this time I came across the picture of a bar-frame hive, and was so struck with its advantages that I at once went to some expense to get a very wide piece of wood to make one. I thought it must be a good depth, so secured a piece one inch thick and sixteen inches wide, then made a box with a groove at the top for the ends of the frames; these latter were 15½ in. depth and 10 inches wide. When it was made I thought about it all day long, dreamt of it at night, and even in church my thoughts would wander to it. I pictured myself taking out the frames, watching the queen egg-laying, and all sorts of things. How many times I took the frames I cannot say; but by the way, I could not get the frames to hang true; but it did not matter, because that hive was destined never to see a bee inside it, the only wonder is I did not break it up for fire-wood. Why? Because I came upon a book by A. Pettigrew. I read it once, I read it twice, in fact I read it until it was imprinted deeply in my memory. I made all haste to increase my stock; three swarms were bought at different times, two were off an old man, who had more than twenty rotten old skeps, on stands at such an angle that anything else would have rolled off them. Three long weary miles I had to carry them. The other one was from a cottager who had hived them four days before I got there, of course all the combs broke down and killed a lot of bees, but fortunately not the queen: they afterwards got very strong.

In the meantime Harry had taken a very nice super of honey and drone-brood off his hive; so, to be equal with him, I determined to drive a stock and take the honey. Having selected a very dark night. I did my best to get them out, but did not succeed; they forced me to retreat, for they had found a breach in my veil, and formed into a false swarm on my throat. I brought away a lot of stings as a trophy, and my relatives spent some time in collecting them. When this was done, they used the greater portion of a blue rag, part of a bottle of ammonia, and several onions, which were very successful, for the stings had little or no effect on me at all, although as a rule one is enough to close both eyes.

I have driven scores of hives since then, but never again at night. Well, seeing that was a failure, I next sent them to sleep with smoke, while I appropriated the

side combs of honey; but I evidently did not give them enough, for they came *very* much awake before I had finished, and stored their stings away in me right and left. The next day there was a great commotion amongst those bees, for all the hives in the neighbourhood were kindly helping them to clear the honey up, and they did it fairly well, for no honey or bees were left in the hive by the next evening. But before this I had tried Nutt's Collateral system: on both sides of a strong stock an empty skep was placed, connected with the stock by a wooden tunnel; it was rather exciting work cutting the side holes, and in the end we suffered for nothing, as they never took to them.

Some time before this Harry was seized with a splendid idea, which was to take the honey out of the box hive. He mounted a ladder, drove all before him with burning sulphur, and took out all the honey he could reach, which was about twenty pounds, then nailed it up again; and there those bees are to this day, I believe. His old hive gradually got weaker, and at last died out; and, luckily for me, his interest in bees died out with it. But my chapter of accidents is not finished yet. That same summer, one June morning, I hived a cast, covered it up, and some weeks after left home for a month. Coming back one hot day in August, of course I was anxious to see how they had fared, so I turned the hive up, and was pleased to find it full of comb and very heavy. I turned it over to replace it, when out fell the bees and combs in a soft mass, something like currant pudding; here was another hive killed. I began to doubt the saying that bees were so profitable. I stood afar off behind a hedge and watched them; if any one had passed by wanting bees I should have sold at an enormous sacrifice. At this time my advice to the poor clergy would have been—'Don't keep bees! Don't keep bees!!' I went about with a dejected countenance, and sitting on the grindstone handle wept aloud as I thought what a 'delusion and a snare' bee-culture was. But there was a fascination about it I could not withstand—yes, before long, I began to look forward to another year! Little did I think how different it was to be for me and the bees, for that same autumn my uncle, a well-known and successful bee-master, hearing of my troubles, sent for me, and from that time my trials were all over. Thirty stocks were at my service to practise on, sections and scores of other things to be examined, also a large exhibit to get up and mind at the show. There I pored over, read, and re-read several volumes of this most interesting *Journal*, besides several books on the same subject. There I met that great man, Mr. A. Pettigrew, whose book at one time gave me such pleasure and caused me no end of stings. He lived just by, and was rather 'put out,' I thought, because my uncle had joined the 'new-fangled' party, for Mr. Pettigrew had started my uncle with the barn hives.

But this pleasant time came to an end at last. With my pockets full of sketches of all kinds of appliances, and with a bar-frame hive, which my uncle had very kindly given me, in the luggage van, I hied back home a happier boy. That winter I made several hives, section crates, and a lot of other things. I carried an almanac about with me, and struck out each day as they came. The time went very slowly, but May came at last, when I transferred most successfully all my bees into the bar-frame hives.

After awhile I took nearly a dozen sections, as well as extracted every bit of honey they had, and fed them up with syrup. Driven bees were added, and several new stocks made; and every year since I have been more and more successful; my take of honey increases, and my customers take it all. Lastly, every one is much interested and astonished at my annual exhibit of honey and appliances at our village flower show—not the village, I regret to say, we used to live near, but one not

two miles from Birmingham, so that I am unable to astonish the readers of the *Journal* by any great take from one hive. My best stock in 1886 yielded sixty-two pounds, and in 1887 fifty-six.

Perhaps later on I may give an account of my success, but I hope even the foregoing lines, faithfully recording my adventures with the honey-bee, will be enough to save some from giving up in despair, and others from doing things that ought to be left undone. By joining the Warwickshire Association, I now write five letters behind my name; the cost is only one shilling each letter, not taking into account the other advantages. Let every bee-keeper take in the *British Bee Journal*, it is generally most amusing and always interesting; and in conclusion, I say, follow the French bishop's advice to his poor clergy—'Keep bees! Keep bees!!'—LORDSWOOD, M.W. B. K. A.

WAR! PESTILENCE!! FAMINE!!!

A CHAPTER OF FAILURES.

WAR.

[1597.] 'Please will you come to look to my bees?' Being district adviser, this was part of my duties, so I went; and before I tell you what I found, I will tell you the history of the stock under consideration.

Last autumn the bees were given to the party that addressed me as above on conditions that he 'took them up.' Consequently, he borrowed a neighbour's horse and spring cart, drove five and a half miles, gave them the necessary amount of 'bumping' and driving, packed the bees into three empty straw skeps and returned home. The road was the usual parish lane in a country where flints abound, consequently the bees had a fair amount of jolting, and arrived home looking pretty black, with a large amount of them dead through over-gorging and suffocation. The best queen was selected, and the hive bees placed with her, and crammed on seven bars well supplied with sealed food.

My experience of driven bees when united at home in this way is, that they invariably 'ball' the queen given them, but if united on the spot, they accept the one given them without question. Whether this was so in this case, I am unable to certify; certainly she was alive later on when I helped pack them up for winter, and she had bred a goodly number of young bees. But I noticed what I never care to see under such circumstances—a few queen-cups, or undeveloped queen-cells.

Spring came, and the owner, to be on the safe side, gently fed them a little syrup, and then the war commenced! He had no opportunity of seeing them during the day, but being suspicious, he called on me for advice. 'The wife says this hive and the next to it are always busy when others scarce work at all.' Examination told me that evidently early in spring this queen had succumbed to stimulation for breeding. Robbing had ensued, a gentle resistance at first, eventual surrender, and take common cause with the assailants and accept the 'fortune of war.'

Query.—Are driven bees when carried long distances and submitted to excessive nervous (?) exhaustion worth the candle?

PESTILENCE.

This was an application for advice from another party. Not a labourer, as in the last case, but a professional man. He had kept bees for years, and one year got twenty-five well-filled sections from one hive, but only once, and then only from one hive. He is a good sort of fellow, he has a try at everything, and is good at nothing but his profession. Carpentry! His greatest achievements are done in putty, certainly not in wood. Painting! If you saw his work you would imagine he laid it on with a trowel. Gardening! He has a greenhouse, but he always has to buy his bedding-out plants, because the

heating apparatus that he fixed himself never will work. Poultry! He buys sittings of the most famous breeds, and you should see his fowls penned up! You would imagine his last investment was in those famous American patent eggs, which not only could not be distinguished from hen's eggs when cooked, but would hatch out chicken, only they had the serious fault that they are always featherless.

It will not be difficult for you to believe that his bees were no exception from his general lack of thoroughness. When I first knew him, he owned half-a-dozen stocks; by degrees they dwindled down to one. For the past three years he has done his best to keep them alive; he has united 'driven' bees to them each autumn, each spring he has given them a good cake of candy. Yearly have the snows and rains of winter soddened the hive and the winds of spring blow through them. The quilts are well daubed in propolis in patches—happy hunting-ground for wax-moths. The dummies never did fit, and a handful of miscellaneous pieces of rags does yearly the duty for winter packing.

This spring has seen the end of the 'one ewe-lamb.' Mildew, dysentery, and the webs and grubs of the wax-moth, have done their work. Our friend—a fair representative of a large class of subscribers to our county Associations—is no longer a bee-keeper. His pets have succumbed to Pestilence!

FAMINE.

'Well, "A. E.," you are fast in talking about others. Do you never get a failure?' Come home with me into my garden, I will tell you one or two little tales. You see the hive at each end of the row; each of them contains a home-bred Carniolan queen, the gift of my friend John Walton of Leamington. He was good enough to give me two last July. How blithely I introduced them *à la Simmins*. I had recommended it to others, having always been successful since I followed the half-hour starvation plan. But you should have seen my look of mingled astonishment and disgust when I found one was dead and the other 'balled' beyond all hopes of recovery. Friend Walton doubled his gift by sending me two more, which I caged, and succeeded in getting them accepted all right.

That is confession of failure number one, but I have not done yet. I was especially careful to give these two hives ample sealed frames of food, so that nothing should prevent them from doing well. I packed them snugly for winter, promising to work them on the 'let-'em-alone' principle in spring. During their winter flights, I noticed a good sprinkling of Carniolan blood, more in one hive than the other. The other stocks I looked too and fed where necessary, but comforted myself that these two 'Waltons' were all right. A few days since I noticed a few bees crawling out of one of them. This alarmed me. Bees were flying around the entrance also. I found on examination that the hive was one mass of crawling, helpless bees. I did not remove the frames, nor break up the cluster, but I put three fire-bricks in the kitchen oven, and proceeded to warm a pint of syrup. About a gill of the syrup I gently poured down between the combs, one hot brick I placed outside the dummy in the place of the cork-dust cushion, and two bricks I put on the top of the quilt over the frames, placing three more bricks in the oven. When the first set of bricks were cooled down, I replaced them with hot ones, and placed a feeder full of warm syrup in position. It was 7 p.m., but they soon began to 'hum,' food and heat were doing their work. At 8.30 p.m. I placed on the last set of bricks for the night, amidst the inquiry as to whether the bees 'had caught cold and wanted hot bricks to their feet and chest. Would a linseed or mustard plaster be of service?'

Next morning I found quite a pint of dead bees, a disposition to rob on the part of the neighbouring hive, and to ball the Carniolan queen on the part of her

famine-stricken subjects. They will pull through with care, and will be united to the first swarm I get. But a few hours more, and I should have to record a loss on the score of Famine!—AMATEUR EXPERT.

PORCHES.

[1598.] I beg to thank 'Yorkshire Novice' for his hints. I have already tried what he recommends, but the result of the experiment did not give me satisfaction. I tried porches 2½ in. by 4½ in. and placed 4 in. above the entrance. The first improvement I made upon the porch was to deprive it of its roof. The next improvement was the removal of its sides. My experience is that porches give shade just when it is not required. They retard the bees in getting to work in the morning; they are the homes of spiders and other insects. The fewer angles about a hive the better.

In very exposed positions side protection would be of advantage. I have two alighting-boards hinged on to the floor-boards, but I prefer them disconnected, although they serve as partial shades from the snow. If the alighting-board is 6 in. from the hive it acts well as a snow-shade; in my case it is too near the hive; the sun's heat passes on to the hive. A perfect snow-shade would be a piece of wood, say 2 ft. square, with two iron spikes attached to it to fix it in the ground, and placed one foot from the hive. The air in front of the hive would in this case be kept at such a temperature as to prevent the bees flying.

The expert of the Essex Bee Association paid me a visit yesterday. He examined four colonies; one he pronounced 'very good.' I mention this because they were wintered on twelve frames in a 6-inch hive with a 9-inch hive below. They have never been touched since September, beyond placing a cake of candy over them in January.—R. T. SHEA, *Little Wakering Vicarage, Rochford, Essex, April 14.*

BEEES IN NORTH WALES.

[1599.] Seeing several accounts of different associations I thought I would like to give you a little account of the North Wales Association, which I am afraid is going to collapse. I have heard nothing of it for two years, for which I am very sorry indeed.

Having a few days' holiday during Easter week, I thought I would take a walk and see some of my brother bee-keepers. I made my little tour not three miles from my own home, and visited over thirty bee-keepers. I found many of them willing to join an association. Most of the stocks were in fair condition, with exception of a few that had died through the want of food.

Having six stocks myself I thought it was time for me to be looking at my pets. On Easter Monday, April 2. I found them in very fair condition, with the exception of one, and that was a hive I had robbed a great deal. I took eighty-two pounds of honey from it last season, it having swarmed on the 29th of May; I made an extraordinary swarm of it.

Having seen a great deal of talk about the Ligurian bees, I do not think they possess any advantage over the common English bee. One disadvantage they certainly possess is that a good swarm costs 2*l.* as against 15*s.* for a common one.

I hope that in the course of a few years the North Wales Association will be second to none in the country.

O Wales! why dost thou sleep?—J. D. W., *Wrexham.*

NOTES FROM MALTA.

[1600.] *April 12th.*—First natural swarm yesterday in almost a gale of wind, but hived successfully, to the great astonishment of the native gardeners, and this morning they filled six frames. Supers on four hives, and one

obliged to be tiered up, some of the sections being sealed over. I expect another swarm next week. Wax-moth pretty nearly defeated.—*MALTA.*

STINGS.

[1601.] I desire to put on record a few facts on this subject, drawn from my own experience while in the bee-business. I always worked with my bees bare-handed, merely guarding against bees passing up inside of my sleeve. In the course of a year I received many stings on my hands. When I began keeping bees I dreaded a sting very much. It was not only painful, but usually followed by swelling which often lasted over twenty-four hours. After a time I ceased to dread them, and noticed them as little as possible, and they seemed to be less painful, and scarcely ever caused swelling. If during the day I received a number of stings I would feel drowsy in the evening, and desired to retire early. At least, I imagined that my drowsiness was caused by the stings. I also thought severe stinging caused a burning, itching sensation in my eyelids, and it seemed to me that each year I could notice this soreness in my eyelids increasing.

Once a bee-sting made me sick and faint. I was stung in the small of my back, the bee stinging through my shirt. It caused me intense pain, and I grew sick and faint, and with difficulty reached the house. The day was sultry, and I was very warm at the time, and therefore I could not say how much of my illness was owing to the sting. After an hour's rest I felt all right. My wife often assisted me in my apiary, and frequently received stings with no serious inconvenience; but one day as she was busy about her housework a cross bee darted at her and stung her on the neck. She complained of intense pain, and soon became so ill that she had to lie down. Her whole body was somewhat affected, as a rash came out all over her body. Her sickness lasted probably six hours.

One day I was taking off combs to extract. My little daughter, then about twelve years old, was blowing the smoker for me. She was well protected, but in some way a bee crawled inside her hat and stung her, when she suddenly dropped the smoker and made tracks for the house. About half-an-hour later my wife called me to see the effects of the sting. She had been stung on the neck, which was somewhat swollen; but the most swelling was about her eyes, which were swollen so much she could scarcely see. She also seemed drowsy, and after a couple of hours' sleep seemed as well as usual, but her eyelids were still somewhat swollen at bedtime. She has had frequent stings since, but none produced anything like a similar effect.

I remember being in the house of a physician one evening when he returned from visiting his patients. He said he had been called into a house in the village to see a boy who had been stung by a bee, and was surprised to find him quite sick and his body covered with a rash as though he had scarlet fever. The boy's parents were alarmed, but the physician told them the lad would be all right by morning. My experience has led to the conclusion that the effects of bee-stings are not always the same. The anger of the bee, the amount of poison injected, the place stung, and the condition of the system, all have an effect. If a person is stung, and the sting proves troublesome, he need not infer that it will be always so, and thus be deterred from ever looking at a hive of bees. The effect of the next sting received may be quite different.—*W. D. RALSTON (American Gleanings.)*

VENTILATING HIVES DURING THE WINTER.

[1602.] Three winters ago I purchased a hive (wooden box) of bees from an apiarian, who was selling his stock pending his removal to a distant part of the country. On going to see the bees prior to purchasing I

found all his boxes, eight in number, thoroughly ventilated, the doorway being left open to its full width, and a four-inch square opening in each crown-board, only covered by a piece of perforated zinc; the hives were in a small wooden bee-house open to the front. This starvation state of affairs of course elicited from me a few questions as to the cause of such apparent carelessness for his bees, when I was informed that such had been his practice for a number of years. Some years ago he had been in the habit of keeping his bees free from ventilation during the winter, but not unfrequently he had the mortification of losing his bees. As a last resource he seems to have adopted a directly opposite plan, by ventilating them in a manner above described, and, singularly enough, he never afterwards lost a hive.

Without, then, seeing the reasons for this success, the facts were too plain to admit of doubt; I therefore adopted his plan, and up to the present have been favoured with similar success. Many bee-keepers of the old style of skep without opening at the top (and there are a goodly array of them in this neighbourhood), have seen my hives, and their greatest cause of wonder seems to be that the bees are not perished. My experience so far indicates that bees kept in a comparatively dry atmosphere by thorough ventilation will come through the most severe winter in our climate in a better condition than when ventilation is prevented.

I may here say I think it is advisable to ventilate early in October, but not continue it longer than the middle of January or the commencement of February, although I have ventilated until the middle of March; and after this the hive so ventilated, without being fed, has sent out its first swarm only second in the neighbourhood, the first being thrown off only a day or two earlier from a stock which had been fed during the whole of the spring.

There is also another point worthy of notice—namely, when ventilated they require a considerably less quantity of food. As an illustration of this—I, and a friend near, at the beginning of last winter had each a hive very similarly situated in most respects, except that mine had only twelve pounds of honey as their winter stock, while his had upwards of twenty pounds. I ventilated mine in the manner before described; whilst my friend, I suppose out of kind consideration for his favourites, added a bell-glass over the perforated zinc by way of making comb-side a little more congenial. Before our bees were able to provide for themselves a fresh supply, in the following spring my friend's stock was bankrupt, he having to eke out their supply by feeding, while mine paid more than twenty shillings in the pound, and sent out a prime swarm three days earlier than his.

Numerous instances have come under my own observation during the last two winters of hives perishing (in one case seven) through the severity of the frost, while the hives through want of ventilation have been saturated with moisture.—*W. JOHNSON.*

STARVATION IN THE HIVE.

[1603.] Among the common class of bee-keepers a good per cent of loss occurs every year from starvation. Some colonies perish while there is yet plenty of honey in the hive, but the greater part of the loss is from colonies that have run out of stores. Beginners in their anxiety to increase their number of stocks are too apt to try to winter colonies that are too light in stores, but with those of greater experience there is less excuse for loss from this cause. *Guessing* at the amount of honey by lifting the hives in the fall is an uncertain guide. Even *weighing* does not in all cases give a correct idea of the amount of available winter stores on hand. The dependent and helpless condition of the bees when their stores are exhausted requires that an abundant supply should

be on hand at all times. To put away light colonies and depend on feeding them as their supply of food becomes exhausted during the winter is a poor plan and should not be encouraged. The bee-keeper who has to resort to feeding in the midst of winter is in an unenviable predicament, and when such condition of things is the result of a neglect to make the necessary preparation for winter at the proper time he deserves censure rather than sympathy.

The variability of winter, too, is such that sometimes much more than the average amount of food is consumed, and it may therefore happen that colonies which apparently had plenty at the beginning of winter are found almost at the point of starvation in early spring. It is important that a close watch be kept at this season and not let such colonies perish after having come through the hardest part of the winter, and thus become a total loss. A few pounds of food may bring them through until natural stores can be gathered; and if in all other respects in a healthy condition, they may prove among the most profitable stocks in the apiary, and all the trouble and expense will be amply repaid. Whatever form of food is supplied the relief must be given before they have reached the stage beyond which their case is hopeless. A few pounds of honey in small frames, laid on top of the brood frames immediately above the cluster, and so arranged that they can have free access to it, have always given good results in my experience. After putting on the honey, they should be covered up snug and warm, and, if much benumbed, a little artificial warmth judiciously applied by placing a warm brick in the upper storey, will have a very beneficial effect in reviving them. This method of warming the hive when there comes a pleasant day after a long continued cold spell may save many a colony that is too numb and weak to get out for a cleansing flight. One or two warm bricks wrapped in a cloth and laid in the upper storey will have a surprising effect in cases where they otherwise might not have vigour enough to get out. But a little help of this kind enables them to cleanse themselves and rearrange their position in the hive. My experience in thus giving relief with artificial warmth has always given good results, and more extended experiments may show that many a colony may be saved in this way.—H. D. STEWART, (*American Bee-keepers' Guide.*)

BRINE FOR SOAKING DIPPING-BOARDS.—Use salt brine, weak or strong, warm or cold, for soaking the dipping boards and the wax will not stick to them. It matters not about the condition of the boards—whether rough or smooth, of soft or hard wood, nor whether the edges are sharp or square. Temper the wax-sheets in warm brine-water before running them through the machine. Try this, and it may in the future help you to dispense, in a measure, with lye, starch, washing fluid, and all other lubricators. Brine water is both inexpensive and unobjectionable; besides, it is precisely what the bees like and should have.—M. M. BALDRIDGE.

HIVES WITH TOP ENTRANCE.—I observed one of your correspondents asks if a hive with top entrance has been tried; it is twenty years since I first tried it and I still use it with satisfactory results. I find the bees winter well in it, and with careful management very seldom swarm; in using sections the bees enter at once the section holder on the top, so no occasion to pass through the hive to get at them. For a small apiary, I can recommend them.—G. F. PERKINS.

FEEDING.—Mr. Simmins has told us of a very simple manner of feeding,—dry sugar, if rendered into paste with a little honey all the better, on a piece of cheese-cloth over the cluster pressed down hard between the frames, ready at hand for them to make use of at once, reminding us of the system up in the North of an inverted basin full of dry sugar on top of a skep, with a piece of perforated paper over the hole.—J. R. POWELL.

Echoes from the Hives.

Meldon, Morpeth, April 4.—I have been keeping bees on the bar-frame principle for some years. I have thirteen stock hives all right after the hard winter we have had here. On March 26 I had to cut seven of them out of a snow-wreath five feet deep, after being embedded a week, one an Italian, the queen I got in October. She is all right, as I see the young bees appearing on a fine day. I got a recipe out of the *B. B. Journal* in 1885, and made some mead in March 1886, of which I enclose a sample. Will you please let me have your opinion of it? During the summer, a friend of mine came to play at cricket, and being rather hot and the mead good to take, it made him forget his Blue Ribbon.—GEO. BRITAIN.

[Having Blue Ribbon proclivities, we thought it advisable that the sample of mead should be submitted to a connoisseur in honey drinks. His reply is, that the mead was very good, and he thought a few glasses a-day would be beneficial to his system.]

Langford.—My first swarm of bees for this year on April 6, rather early, but it was through some men having felled an elm-tree, and finding a stock of bees in it asked me to get them out that they might get the honey, thinking there would be a good lot of it; but we are all subject to disappointments, so were they. After sawing the bole, above and below the nest, I gave them a little smoke. I got the combs out as best I could, four or five of them, the longest about three feet. I shook them on the ground and let them run into a small straw hive, with a little honey in a section tied to the top. There would only be one or two pounds of honey, no pollen or brood. I brought them home and put them into a nucleus hive on three frames of honey and pollen, and started them as my first swarm of this year, and they are now (April 16) going on all well. Such a change in the weather!—all stocks busy taking in pollen.—J. WILSON.

Cheriton, Hants, April 13.—This is the first spring morning; neighbour Harfield's bees are out as though they are going to swarm, and I counted no fewer than eleven butterflies in the lane, remarked a gentleman to me this morning. On returning to my small apiary of nine stocks, I find the musical hum—than which there is no sweeter music—in pleasing plenty. Well, 'better late than never,' saith an old saw; and I readily adopt it, waiting for the fruition of my hopes. Thousands of tiny labourers are going to and fro, in the act of finding their food stores, but the modicum of pollen adhering to their legs is indicative of floral paucity.—AGED AMATEUR.

South Cornwall, April 14.—Young bees are flying, and there are solid patches of brood almost ready to be hatched, but not on more than two frames in a hive, as far as I have seen. There does not appear to be a graduated succession of grubs and eggs. Milder weather has set in and hopes are reviving. I regret to say that I have lost a stock—dead, all dead—leaving pounds of honey, and with, I should have thought, ample protection, in a house in which two others are doing well. But too often 'there is no accounting.'—C. R. S.

Honey Cott, Weston, Leamington, April 16.—Friday and Saturday last were grand days for the bees, which made them go off to the woods to fetch the pollen which was brought in in large quantities. In looking over hives on Saturday night, I found, what appeared to me, new honey in the cells, in stocks that had not been fed and that had no chance of getting any that had been fed to other stocks; as I have often proved before, stocks that have been wintered in temporary $\frac{1}{2}$ -inch hives have survived and appear as healthy and well as others that have double walls, thus in my case seeming to point contrary to what 'U. II.' said awhile back about cheap and nasty hives. It appears to me the chief thing is, for them to be kept dry and have plenty of food.—JOHN WALTON.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

H. W. HARRIS.—*Honey Plants.*—All the plants you name are grown for the production of honey. Buckwheat is an annual and may be sown from April to July; the same may be said of mustard and borage. Mustard secretes honey of rare quality. Borage is a good all-round honey plant, as it may be grown in any out-of-the-way place, dry banks and ballast hills may be profitably used by growing borage on them; it is not affected by drought as most honey-secreting plants are. Catmint and figwort are both herbaceous plants. The seed should be sown in March or April in the open; when the seedlings are large enough to handle plant two feet apart. Phacelia is an annual, and may be sown from March to May, and again in September to stand over the winter; these autumn-sown plants flower from March to May; sow where the plants are to remain. Phacelia is an excellent bee-flower.

O. B. T.—*Perforated Separators.*—These have been tried, and found to be either of little advantage or a serious disadvantage; in the latter case, when made from excluder zinc, the sections are finished with waved surfaces.

HONEY-FLOW.—*Drone Brood.*—Your bees are in a very unsatisfactory condition, having a drone-rearing queen. At this season, and with so little brood, no such thing as a drone capping ought to be seen. If you examine more carefully you will perhaps find that all the brood capped over have these cappings; if so, destroy the queen and unite with another stock.

R. L. RICHARDSON.—*Site for Apiaries.*—Anywhere much further south than your present abode. Heather gives little return. There are in the Midland or Southern Counties plenty of districts where large crops of honey can be obtained, but little heather. We know of one district where there are acres and acres of heather, and have painful experience of moving our bees to it—our expenses vastly exceeding our takings. Mid or West Berkshire is a fine county for bees. We know of one bee-keeper in West Berks who, last year, took over 400 lbs. from four colonies—all he had.

SCOTSMAN.—1. *Observatory Hive in a Shop.*—For each shop there should be two observatory hives, with crates conveniently arranged for transit. One hive will be at home in readiness to make an exchange every fortnight more or less. For further particulars see Simmins' *Modern Bee Farm*. 2. *Cloth underneath Feeders.*—Common glue will answer; but it is not desirable to place such material under the stand where the bees cluster and are annoyed by its presence. Open feeders, if we understand you to mean those of wood tongued at the joints, should always have such parts painted with white lead when putting together.

M. ORMOND.—*Nadiring.*—Your plan of placing standard frames beneath the smaller frames now occupied by bees and brood, would probably end in both hives being utilised as brood-chambers. When honey begins to come in freely, place a hive with standard frames having full sheets of foundation, on the stand of your present hive, setting the full hive beside it. Place a board, covered by a sheet, sloping to the entrance of the new hive. Take out each frame from the old hive and shake, or brush off with a goose-quill, the bees on

to the board, when they will all run into the new hive, wedged up a little in front. Cut out all drone-comb and drone-brood from the old frames and replace them in the old hive in the same position as before, and cover up warmly. Now put a sheet of excluder-zinc on the new hive, over the bees, and set the old hive upon it. The bees will rebuild the combs in the upper hive, and as the young worker bees hatch out, they will join the colony below, and the upper hive will be used for storing honey only. The operation is very simple, and should be performed on a fine evening when all bees are at home.

J. STRADLING.—*Dwindling.*—If the bees in these hives would not cover more space than three sheets of note-paper, you must not expect to get much honey from them. Move these three hives gradually near to each other, and unite, reserving one queen only, and that the youngest and most sprightly in appearance—probably the one having most brood in its hive—and destroy the other two, unless you have use for them. In uniting cage the selected queen under a pipe-cover cage, on a brood-comb, in the centre of a clean empty hive, and place all other combs from the three hives, which contain eggs and brood with bees on both sides of this centre comb, alternating them from each hive, and close up with division-boards covering up warmly. Brush out any few remaining bees from the other hives on to a board sloping to the entrance, and they will run in. Perform the operation on a fine evening. On the following evening release the queen, and you will have one good colony out of three weak ones. Feed above with honey or syrup.

CHESHIRE.—The sample of comb submitted, in its transmission through the post, has been compressed together into an agglomerated condition, from which it has been impossible to extract a single bee entire. The only portions removable were heads, with occasionally a thorax attached, and these were in a condition so dry as to be wholly unfavourable to microscopic examination. There are, however, no symptoms of disease; the comb is very old, and it is desirable that it should be replaced by foundation.

C. N. PARKIN.—*Reducing Thick Combs.*—If your frames are seven-eighths of an inch wide on the bar, shave the combs down level to the bar with a sharp knife that has got well warmed in hot water.

R. DRIVER.—*Excited Stocks in Skeps.*—Short of personal examination, we should say robbing has been going on, and in the m \acute{e} lée a queen has been thrown out. If you are quite sure which stock is queenless, you might let her run in at the hole in the top of the skep; but most likely she is seriously injured. We should strongly advise you to have all your bees in frame-hives, then any necessary examination could so easily be made. Have the mice got into your skep? Do not mind writing again if you think we can help you.

* * Several Replies to Queries postponed to next week.

PRACTICAL WORK IN THE APIARY.

PREVENTING SAGGING OF FOUNDATION.

One of the great obstacles to the use of full sheets of comb-foundation has been from its stretching and sagging which caused it to become wavy, and the resulting combs would not be always just within the frame. The first sheets we used, of German manufacture, were so fragile, that it was difficult to fix them in the frames. However, by persevering, we managed to secure straight combs from full sheets, which were in those days the wonder and admiration of all who saw them. The sheets were obtained from Messrs. Neighbour, who were the only importers of them at that time; but subsequently we obtained a pair of type-metal plates, which enabled us to make our own of much stouter material. The imported sheets were generally very brittle, and often had incipient cracks, causing the sheets to drop down when the weight of the bees was upon them. To secure them in our frames we split the top bar in two, and after inserting the flat part of the foundation with which these sheets were always provided the two halves of the bar were screwed together. We tried brads, but found that the jar caused by the hammering would crack the foundation near the top bar. The frame was then placed between two frames of brood, with the result that every sheet would be worked out perfectly straight. Unless this precaution were taken it was found that the foundation was not strong enough to have a swarm upon, but by placing a frame of foundation and a frame of comb alternately the weight of the cluster was so distributed as not to affect the foundation. This difficulty has been overcome by the use of much thicker and stronger sheets of from four to six square feet to the pound.

When a swarm of bees is placed in a hive filled with frames of foundation, the heat generated causes the wax to soften and the weight of the bees pulls the sheet down, which causes the cells to be elongated and distorted. For this reason it has always been recommended to use thick

sheets and to allow for the stretching; they were not brought down nearer to the bottom bar than within about three-quarters of an inch. Besides the sagging there is also the waviness of the sheets to be guarded against. This is caused by the bees working at different parts of the sheet at the same time and drawing it out unevenly, and always results when there are more frames of foundation than the bees can comfortably cover. To remedy these defects many devices have been tried.

For some time we used the Cheshire foundation-fixers, and although we obtained straight combs with them, there were so many objections to them, and we found them such a nuisance, that we were forced to give them up. In the first place, they were expensive, as it required at least six for each frame, or sixty for a hive of ten frames. Then the foundation had to be secured in the usual way by means of molten wax to the top bar. After a couple of days the fixers had to be removed, and in doing so, even with the greatest care, the cell-walls close to the points were broken causing the bees much extra labour to repair them. Then where the points pierced the foundation the bees would gnaw away the wax in their endeavour to remove the obstruction and cause holes in the combs which were never filled up. Such things are all very well when there are only two or three hives, and the bee-keeper has nothing better to do than to be constantly fussing with his bees, but when hives are kept for practical purposes and time is an object, the bee-keeper must find more simple and practical methods. Various substances have been tried embedded in the wax, such as paper, silk, thread, calico, wood, and glass, which have been used with more or less success; but it was Captain Hetherington who conceived the idea of introducing wire into the wax-sheets. For this purpose the foundation was made with a flat midrib so that the bases of the cells were flat and the wire was embedded in the midrib during the process of manufacture. The wire used is tinned and runs in parallel rows about one inch apart. This foundation, known by the name of 'Van Deusen foundation,' is readily accepted by the bees and is not liable to stretch. Captain Hetherington uses no other, and when we visited him we were delighted to see with what regularity his combs were built out, and to have ocular proof on a large scale that the brood suffered in no way from the wires.

This foundation may be fixed with molten wax in the same way as described on pages 185 and 186, or the top bar may have a saw kerf down the middle (Fig. 1), and the wax-sheet inserted into this. The simplest method of

inserting the wax-sheets into such top bars is to drive two nails into a board about one inch apart, allowing them to project three-quarters of an inch. The heads are cut off and the ends filed flat like a brad-awl. Place the frame with the top bar downwards, so that the

Fig. 1.

nails enter the saw-cut; then give the frame a slight turn so as to open the slit to allow the foundation to enter easily. Turn the frame back until the nails nearly touch the foundation and pull up the bar, when it will be found that the top-bar will grip the foundation securely. This plan can also be adopted in fixing ordinary foundation, and its only objection is the waste of wax, but for rapidity it cannot be excelled.

The foundation is now secure at the top but is loose at the bottom, so that new combs require great care in manipulation. Captain Hetherington has, however, hit upon another device, which makes the combs built within his frames as solid and as secure as if the wires had been attached to the top and bottom bars. This he accomplishes by using thorns, which are put through the bars of the frames. Ordinary thorns from blackthorn or acacia, about one and a half inches long, are selected, and holes are bored through the bottom and side bars at intervals of about two inches apart. When the foundation is in its place the thorns are driven through the holes, so that the projecting point of every alternate one touches the foundation on one side and the others on the opposite side. This effectually prevents wavy combs, and when these are built out the thorns become embedded, so that even rough usage will not loosen the combs. Many will prefer to use natural-based foundation, and this can be firmly fixed by wiring the frames.

There are various ways of doing this, and in Fig. 2 we give the method most generally adopted. The frames

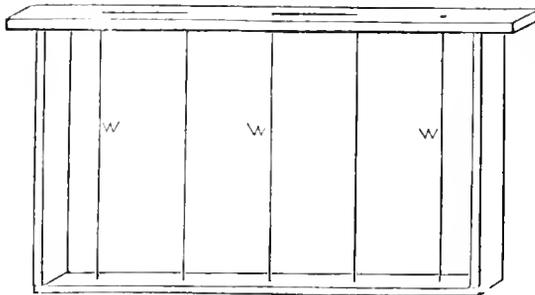

Fig. 2.

have to be wired with No. 30 tinned wire. The top and bottom bars are pierced with small holes, and the frame placed over a guide-board similar to that used in fixing wax foundation; but it must fit the frame well, otherwise, when the wires are drawn up, the bottom bar is likely to bend. Pass the wire W through the holes, as shown in Fig. 2, and draw pretty tightly. Turn down the ends and secure them by means of pegs of wood driven into the holes. Lay down the guide, and place on it a sheet of foundation, then over it put the wired frame so that the foundation touches the top bar. We may now embed the wire, and it can be done simply by using the flat end of a bradawl and forcing the wire into the wax-sheet. Even an ordinary wheel pastry cutter has been used successfully, but by either of these methods the wire is only forced into the wax and not completely covered by it.

Where a number of hives are kept much time may be saved by using what is known as the 'Woblet spur-embedder.' It is essential for the proper use of this instrument that it be *hot*, for if used cold it is no better

than the bradawl and the expense of getting one may be saved. The wheel is made of brass, and is of such a substance as to retain a certain amount of heat. The circumference has twenty-six teeth, a little more than one-sixteenth inch apart, and each of these teeth has a V groove on the outer edge. The wheel is heated in the flame of a spirit-lamp, the V groove is then placed on the wire, and the wheel ran rapidly along it from one end to the other. The heat melts the wax at each point, which cools as fast as the wheel travels forwards, and the wire will be found covered with wax. There is no necessity to fix the foundation to the top bar if this plan of wiring be adopted.

We would caution those who are going to use this style of embedder to get a proper instrument, as there are some in the market perfectly worthless. We have been shown one made of tin working on a pin driven through a piece of wood. We need hardly say such a thing could not be heated without burning the wood, and even if it could it would not embed the wire properly. We were also shown another made with a wheel about $1\frac{1}{4}$ inches in diameter, and teeth $\frac{1}{8}$ of an inch wide instead of $\frac{1}{16}$, and $\frac{3}{8}$ inch from point to point. We may say such an article is about as useless for the purpose as the one with the tin wheel. With a proper instrument we know of no method more rapid or more effective for fastening foundation.

Another way of wiring the frames is shown in Fig. 3,

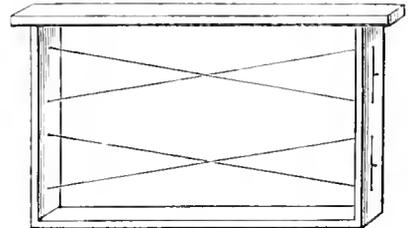

Fig. 3.

where the wires stretch diagonally from one side bar to the other and cross each other in the centre. The foundation is placed between the wires so that there are two on each side of it. In using wires in this way the foundation must be fixed to the top bar. In America, where the frames are rather longer than ours, an upright support of wood is used about the centre of frame, but we have never found this necessary. We have used shallow frames for extracting and also the Carr-Stewarton frames, but never found any necessity for strengthening the foundation in any way in these; and Mr. Carr recently sent us a specimen of one of his shallow extracting combs, which was beautifully worked out within the frame without any strengthening whatever. Wiring large frames is a saving in wax and an economy of time in manipulation.

USEFUL HINTS.

WEATHER.—Thunder-storms, copious showers, and a higher degree of temperature, are causing the meadows and corn-fields to assume a brighter green than hitherto. The fruit-trees are showing well for bloom, and after the long and dreary winter Nature is putting on a brighter garb. But there is a lamentable lack of forage for our bees. Literally, there is nothing within reach of our own save a few willows, and until the elms blossom, and the fruit-bloom opens, our bees will return with empty sacks and unladen legs. Many a hive around us is now tenantless, and we shall expect to hear that the loss of bee-life during the late inclement season has been exceptionally large.

FEEDING must still be carried on, or bees will starve, their stores of late having rapidly disappeared.

ROBBING should also be strictly guarded against, the bees showing a strong disposition to pilfer wherever a chance is offered; hives, in consequence, should be examined at evening only, or most certainly loss will accrue.

SPARROWS, we are inclined to think, are the worst of all the enemies of the feathered tribes to our bees. The destruction wrought by them is almost past belief, where they congregate in abundance. Our house and outbuildings are covered with ivy, and although the net has been freely used, and from twenty to thirty sparrows taken on many a dark winter's evening from their favourite roosting-place, yet we have abundance left. The nests are destroyed once a fortnight all the summer through, and yet the sparrows are as numerous as ever, fresh immigrants, we suppose, taking the place of those removed. Fruit-buds disappear beneath their piercing ken, and depredations are committed on all sides. During our boyhood every parish beadle was deputed to purchase adult and callow birds and eggs, so that there was a strong inducement to every village urchin to collect them, and thus to repair the inroads on his purse made by his disposition to visit the sweet shops. But this, like many other good old customs, has ceased to exist, and the farmyards and corn-crops of our thriftless farmers are laid under heavy contributions by this sparrow pest. The best scare we have found to be a stuffed sparrow-hawk, with outstretched wings, suspended over our apiary. These pests too often take our young queens when on their marriage-trip.

ADAPTING BOARDS, or *Queen-excluding Honey-Boards*, as they are now called, are confessedly an English invention, although never brought into general use in this country. Since the introduction of the American 1-lb. and 2-lb. sections into this country indeed, they have entirely fallen into disuse, the general opinion being that the queen rarely enters a crate of these sections, and, consequently, there is little or no inducement to the bees to store pollen there. The American idea is the very reverse of this, and in Canada and the States these excluders are almost invariably used beneath sections, and between doubling or tiering hives. Climate, and a more copious and lengthened honey-flow, may in some degree account for this difference between the American and English practices.

The first English frame-hive, largely used, was the 'Woodbury,' with its crown-board, and three-eighths of an inch space between that and the frames. As a rule, when supers were placed on the hive the crown-board was removed and an adapting-board took its place. But the late Mr. Pettitt of Dover, about twenty-five years ago, converted the ordinary crown-board into an adapting-board, by cutting through it queen-excluding slots, having the same direction as the frames below, the slots being closed by zinc slides when supers were not in use. The large shallow supers in vogue in those early days were generally used by the queen partly as brood-chambers, which the adapting-boards of the period in no way tended to discourage, since they were simply thin square boards fitting the top of the hive, with a slot on each side, and a two or three inch hole in the centre, all large enough for the passage of queens and drones. Hence arose the adaptation of the crown-board as a queen-excluder. Then came queen-excluder zinc, with circular perforations, which proved a failure in the hands of our foremost apiarists, the bees either refusing to enter the supers, or, having entered, perishing in large numbers, apparently unable to retrace their steps. The next step in advance was the introduction of rectangular perforations of $\frac{1}{2}$ inch in length by $\frac{3}{8}$ in width in the zinc sheets, in lieu of the $\frac{1}{2}$ in circular perforations, and this has been largely adopted by our Transatlantic brethren in their queen-excluding honey-boards and drone-traps. For some time they imported largely from this country, but now they manufacture their own zinc. In an amusing satirical

article, by Mr. Heddon, in the *Canadian Bee Journal* of March 7, p. 1010, on English apiarian inventions, he says:—'We notice that you have not yet discovered the advantages of honey-boards: but know that you will by and by, and when you do, we fear you will forget how you opposed them in 1888, and claim them as a new and novel invention. We are sorry the queen-excluding metal won't work over there, for in our apiary it works like a charm.' Now why this wide divergence of opinion amongst practical apiarists re the advantages of queen-excluding honey-board between brood and surplus chambers?

We suspect the cause to be that we English have used plain sheets of excluder zinc laid flat upon the brood-frames, while the Americans have used the Heddon and other similar honey-boards, in which strips of zinc are introduced between slats of wood, and a full bee-space is allowed below and above the zinc. We had several similar boards in use last season, and the sections built upon them were simply perfection: moreover, the bees entered the crates and worked through the perforations as freely as those colonies over which no excluder was used. *Fas est ab hoste doceri*. Not that we consider Mr. Heddon an enemy, but rather the best of friends, because he does not hesitate to tell us the plain truth, and, good-naturedly, to laugh at our overweening self-confidence. But that honey-boards will again come into use in English, as they have in American, apiaries, we have not the shadow of a doubt. In a merry mood, Mr. Heddon addresses our well-known humorous correspondent respecting slotted dividers, thus:—'Why, Amateur Expert, I am surprised that you should "claim" anything, good, bad, or indifferent, for the "old chestnuts," called "slotted dividers" by you, and "perforated separators" by Yankees, for lo, these many years. . . ! Hadn't you better come over here and see what we have, and not get so far behind us as to be newly discovering our old discarded implements and well-advertised inventions?' Bearing in mind the Carr-Stewarton hive, the progenitor of the 'Heddon Invertible,' surely 'A. E.' may well reply by a *tu quoque*. And then, let Mr. Heddon note Dr. Tinker's admission in the *Apiculturist* for March last, where he says (p. 65): 'English bee-keepers used the zinc-honey boards before they were used in this country, but the general verdict was against them, and they were finally discarded as being a hindrance to the workers. Now I venture that their boards were not properly constructed, as they never used a wood and zinc honey-board. I do not regard their tests as affecting, in any way, the merits of perforated queen-excluding zinc.' This is exactly what we ourselves have been saying for the last two or three years; and we have at the present moment in course of registration a perforated queen-excluding zinc, which we hope will remove all further objections to the use of these 'honey-boards' when rightly constructed.

And this leads us to the subject of Mr. W. B. Carr's letter (*B. B. J.*, 1591). To him we apologise for having overlooked, in our hasty glance at his article, the statement that 'he trusts to excluder zinc for confining queens to their own department.' This is as it should be, and the bee-world is under a great obligation to Mr. Carr for having taught, by the splendid quality of the prize honey at the late 'Colinderies' Exhibition, that the only way to obtain the finest quality of extracted, as well as comb, honey is by using shallow frames (or sections) over queen-excluding zinc.

SHALLOW FRAMES, $14 \times 5\frac{1}{2}$ inches as the standard size for a smaller or tiering-up frame, we, therefore, with him, strongly advocate; and we trust that when another Standard-frame Committee shall be appointed (not for altering the dimensions of the rectangle of the present standard frame, but for considering a few details in connexion with it) this shallow frame may receive the sanction and seal of the B. B. K. A.

HIVES, SECTIONS, AND RACKS, should now be procured without delay, and prepared for use by the insertion of foundation. Hives of ten standard frames, well filled with brood and bees, should be ready to receive the small surplus chambers, six inches deep (which take the small frames mentioned above), or crates of sections, by the time the fruit-bloom is well out, which must be late in this late season, and will therefore afford a greater promise of honey-yield than is customary from this source. Our bean-fields, except the winter-sown, will be a month later than usual, and, to all appearance, clover and hawthorn bloom will be unusually late. So much the more need, therefore, to have our hives boiling over with population when at last the good time arrives.

EQUALISING STORES should be attended to when looking over colonies, as it will often be found that one colony can well spare a comb or two of honey and pollen for replenishing another which is populous but short of stores.

VENTILATING QUILTS, where not previously removed, should at once give place to non-ventilating of enamel cloth, above which they should be placed for affording warmth.

CHEMICAL PROPERTIES OF POLLEN.

By PROFESSOR COOK.

Pollen-grains are really cells, and consist of protoplasm within a cell which has two layers. Professor Goodale, who is excellent authority, says that the contents of pollen-grains are:—1. Protoplasmic matter. 2. Granular food materials, such as starch and oil. 3. Dissolved food matter, as sugar and dextrine. Sach says that protoplasm, which we know, fills the pollen-grain, is rich in proteids or albumenoids. These substances, which are well illustrated in the white of an egg, the albumen of the blood, the casein (or cheese) of milk, are often called nitrogenous substances, as they contain nitrogen as well as oxygen, hydrogen, and carbon, which last three chemical elements are found without the nitrogen in starch, sugar, and the oils, or fats. In addition to the proteids, pollen also contains much water and several inorganic elements, such as the alkalis, lime, magnesia, phosphoric acid, and sulphuric acid. It would be impossible to give an exact chemical formula for pollen. Like our grains, which it somewhat resembles, the composition varies with the kind, and probably, somewhat even in the same kind. Thus I find these formulæ for oats and wheat:—

	Oats.	Wheat.
Water.....	12.7	12.5
Albumenoids	10.1	13.5
Starch.....	56.0	68.4
Oil	2.3	1.2
Fibre	16.6	2.7
Ash.....	2.3	1.7

While these are much alike, we see a marked difference, especially in the amount of oil and proteids. I presume pollen is richer in proteids than either of the above; and so, while flour will serve as a substitute for pollen for our bees, I dare say pollen is richer and hence better. As food is not perfect unless it contains all these different elements: Proteids, carbo-hydrates (starch and sugars), and oils, and as honey contains only the sugars, we see why our bees must have the pollen. This last supplies the proteids and oils. We also note how desirable that they have a nitrogenous food particularly rich in the proteid elements. As we could get along without much albuminous food, such as muscle, cheese, beans, &c., for a time if we exercised very little, and possibly be the better for it, so our bees may go for weeks—yes months, in winter—when they are so inactive, with no pollen, and so with no proteids, except the very little existing in the honey, and possibly they are the better off.

(1.) *What proportion of the food of the larvae is pollen?*

The larvæ of the bees are, I think, fed almost on pollen. The old view of Swammerdam and Dufour, that bees digest their food, and feed it, thus digested, to the larvæ, is still entertained, in part at least, by such able authorities as Mr. Cowan, Schonfeld, Planta, &c., (see *British Bee Journal*, 1887, p. 185). On the other hand, Leuckart, and his able student, Schiemenz, believe that the food of the queen-larva, and most of that of the other larvæ, and that of the laying-queen, is not digested food, but really a secretion from the large glands of the head of the worker-bee. This view, which it seems to me is the more rational one, makes the food of the larvæ like milk, instead of chyle. We would not say we fed the young calf on hay and oats because these formed the rations of the mother cow; so we do not say that pollen is the food of the larvæ because bees need it to form or secrete food for them. The cow must have albuminous food, or she can give no milk very long. So the bees must have the pollen to elaborate food for the larvæ.

Dr. Planta shows that the food of worker larvæ differs from that of queen and drone larvæ. Schiemenz showed that the worker-larva, just at the last, was fed on pollen, and, presumably, honey. Thus quite likely the composition of the food is thus changed. Thus we might say that the queen-larva was fed profusely with exclusive bee-milk, while the workers were fed scantily of the same, which at last was adulterated with honey and chyle. Schonfeld shows that it is not impossible for the bee to regurgitate the chyle. Indeed, the pollen in the worker larva's intestine, just before it pupates, or before it sheds its alimentary canal with its last larva moult, shows that it is fed on chyle in some part. As Schiemenz shows, there are good reasons to think that the laying queen is fed on the same bee-milk.

(2.) *Is pollen a part of the regular food of the mature bee?*

I have already answered this question. The imago or mature bee must have pollen, not only to nourish its own tissues, but the nurse-bees are equally dependent on it to form the bee-milk, or secretion which they feed to the queen and all larvæ. If we feed a cow simply on starch or sugar, she would soon pine away, and her milk-glands would cease to secrete; so if we feed our bees simply on honey, they likewise, when active, would soon waste away, and, as all observing apiarists know, they could not care for brood. Pollen is absolutely necessary for bees when functionally active.—*Agricultural College, Mich.—(American Gleanings.)*

ACCIDENT TO A BEE-KEEPER.—Mr. Roberts, a bee-keeper at Gosmore, near Hitchin, who some little time back went over to New Zealand, to start bee-farming, &c., while climbing a tree to take a swarm of wild bees, the bough broke, and he fell with such violence that he broke both arms and a leg. He is now doing as well as can be expected.—G. J. B.

GRIMSBY NATURALISTS' SOCIETY.—On April 5th, a lecture was delivered before the members and friends of the above Society in their museum in the Masonic Hall building, by Mr. H. O. Smith, of Louth, upon the 'Hive and its Wonders.' The chair was occupied by Ernest L. Grange, Esq. Before introducing the subject, Mr. Smith referred at some length to the usefulness of societies of this description, affording, as they do, such ample means of improving the minds of young men who are inclined to follow natural history pursuits or investigation, and such a charming mode of obtaining knowledge should be more fully taken advantage of. The lecturer then gave a very interesting account of the habits and management of 'Bees;' and from his long practical experience, aided by diagrams, hives, and other illustrations, he was able to thoroughly describe their history and process of working. He was listened to with the greatest interest and attention throughout, and a vote of thanks, proposed by E. Bannister, Esq., J.P., seconded by F. Wood, Esq., was carried, and terminated a very successful meeting.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal," c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, Kings Langley, Herts (see 2nd page of Advertisements).

*. In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

IN-AND-IN BREEDING.

'Ce n'est pas par le raisonnement mais par la connaissance d'un nombre considérable de faits que la question de consanguinité sera élucidée.'—DR. RASCOL.

[1604.] I have read with some interest the correspondence on this head appearing in the *B. B. J.*, over the names of Mr. W. B. Webster and Mr. Woodley, which culminated in your own leader in the issue of the 5th instant. I am willing to join the heterodox on the question, and to combat, as far as my abilities allow me, the views of Mr. Webster and yourself. I think I may say, without wishing any offence, that this matter of consanguinity is by no means so clearly understood in its physiological aspect as it should be, and that in the case of your own article wisdom has nodded, and you have slightly confused cause and effect.

Let us look at the facts—not exactly as bee-keepers, but as amateur physiologists, anxious to obtain information upon the subject as it affects all animals (using the word in its largest sense) from man downwards. I agree with you in the axiom that 'Nature abhors self-fertilisation,' if by that you mean the fecundation of a plant from its own seed; but there is a wide difference between this and intimate consanguineous relationships.

Further, your (if you will permit me to call it so) rather *ad captandam* argument of the Providential interference to prevent in-breeding is somewhat far-fetched. In all the Sacred Writings there is no direction to the contrary. But, on the other hand, if it were seemly and germane to the subject, I could cite numerous instances from the Scriptures to show that no Divine wrath has followed the infringement of what you assume to be an immutable law. If you take the chosen people as a guide on the point (and we may fairly assume that, as they were the recipients of the Mosaic law, they should know the Divine will), then you have consanguineous marriages between uncle and niece, aunt and nephew, at which modern civilisation shudders. Are the Jews, on this account, notorious as a physically or mentally degenerate race?

As against your axiom I am prepared to quote another, viz., 'Consanguinity *per se* is not injurious.' This is not mere boldness, as I hope to make apparent before I conclude. We are all anxious, I hope, to arrive at the truth, and in dealing with the subject, I will, in addition to my own remarks, quote from one or two writers, well qualified to speak, and I trust we shall find that the view I take is not by any means a *petitio principii*.

In a question of this kind it is necessary to start from a firm basis, upon which all parties are agreed. It will not be denied, I think, by the greatest opponent of in-breeding, that, given two perfectly healthy non-related animals, the produce of those animals must (accidents and usual faults excepted) be healthy also. Why should this fact cease to be a fact, because the producers are blood-relations? Is it not a fact that this question has been debated on unscientific lines, and an unbalanced and hastily considered judgment has been arrived at? Take

two known consumptive or scrofulous human subjects and unite them, and the chances are, many thousands to one, that the progeny will be consumptive to a greater degree than their parents. Again let two of the lower animals be allowed to breed, one being healthy, and the other having some organic or physical defect, the produce will be healthy and defective in a varying degree. It matters not one whit that the parents are utter strangers in blood. Natural laws cannot be altered or defeated. But where an evil of this sort is apparent between strangers, it is ten times more apparent when the parents are nearly related. Why? For a simple natural reason. First cousins are the produce of a pair of grandparents. Presume one or both grandparents to be suffering from an organic disease, does it not follow that both the cousins have the seeds of it in their own bodies, and that the bodies of their progeny are favourable incubators for its propagation? Such a result is natural; but it is no *more* natural in the case of cousins than it would be in that of complete strangers, given a like defect in each. To refer, in passing, to bees. What bee-keeper would willingly mate a queen the produce of one of known bad qualities to a drone from a hive possessing similar or equally bad qualities? Would he stay to consider whether they were nearly related or not, or would he strive to mate his queen with a drone of known strain qualities? I venture to say that, given a queen—of all those good qualities which we bee-keepers so much covet, and having some of the defects we seek to avoid—fertilised by a drone from the same hive, and therefore her brother, the resulting progeny, instead of being a deterioration from the original stocks, would be an improvement upon them. I say so because the qualities would be fused, and therefore accentuated. The converse argument holds good, and defects would be similarly demonstrated and accentuated.

In birds and the lower animals effects are as strongly marked as in the human species; but inasmuch as more care can be exercised in their mating than that of *genus homo*, those effects can be seen, and, if bad, guarded against. I have, myself, to a small extent, proved that there are no evils to be feared from consanguinity, but my experience is hardly lengthy enough to allow me to dogmatise, and I therefore content myself with giving the opinions of men who have devoted years to a study of the question, which opinions are diametrically opposed to those of yourself.

Such of your readers as are canary fanciers will know what 'Sib-bred' birds are. Can they say that there is a deterioration in the 'Scotch fancy' because the birds have for (bird) generations been in-bred? I think our canny Scottish neighbours know quite sufficient on this point not to suffer their birds to lose ground for any attachment to in-breeding for itself. They do it to fix certain good qualities, at the same time courageously sacrificing every weakling, and persistently refusing to breed from birds displaying any weakness or defect.

The first writer I shall refer to on this question is Mr. V. la Perre de Roo, in his work, *La Consanguinité et les Effets de l'Ucédité*. M. de Roo was about to marry his first cousin, and being then anxious to ascertain the facts regarding consanguineous marriages, he consulted his 'family doctor,' who happened to be a courageous man, not hide-bound by the beliefs of certain of his fellows, and he distinctly advised the union. Dr. Herr-boudt informed M. de Roo that the story of deaf-mutes being the result of consanguineous marriages was moonshine (only he used a more polite French equivalent), and requested him to call at the Deaf and Dumb Institute at Bruges and make his own inquiries. He did so, and found that *not one child in the Institute was the issue of first cousins or related parents*. After his marriage, M. de Roo again became uneasy, and he then began his experiments to prove the falsehood of the general opinion, being personally, as he frankly confesses, much in favour of the general opinion. The result of

his researches, therefore, is against his views, and entitled to all the more weight. In the course of his remarks, he says:—

‘In the face of these facts, which all the world can verify, the theoretical statements of the adversaries of consanguinity may be lightly esteemed, for all my observations are based on facts which, for the most part, took place under my own observation, and which I can conscientiously affirm. . . . Therefore, whilst the opponents of consanguinity waste their time in interminable and fruitless discussions, which can never throw the slightest light on the subject before us, let us employ our time more usefully in examining the results of numerous direct and indirect experiments . . . which alone can solve the difficult problem of consanguinity in man and animals.’

It would be too great an infliction on your readers to set out at length the whole of Mr. de Roo's experiments: suffice it, that for a period of about twenty years he carried on these experiments with nearly all the breeds of poultry, pigeons, and canaries; and, so far from finding that in-breeding was injurious, he testifies that after many generations of pairing, brother to sister, parent to child, and so on, the points of the various breeds became more definitely fixed, and their physique was wonderfully improved. Naturally this gentleman, in trying an experiment of so delicate a nature, took that care that one would expect from an ingenious and upright man, notwithstanding that the results were against his former convictions. He did what every man does who wishes to guard against disease or deterioration in his domestic birds or animals, viz., he persistently killed off all those showing any taint or physical defect, and so his experiments produced the result that one who studies this subject with an unprejudiced mind would expect. It may be said that it was this care of Mr. de Roo that to a great extent accounts for his results, but, as against this, I would ask whether the greatest enemy of consanguinity would willingly allow bees, birds, or beasts, to breed where the parent on either side was unhealthy. If, therefore, in non-sanguineous unions this care should be exercised, why should it be denied in the other? I again repeat, at the risk of being thought tiresome, that given the same condition in sanguineous and non-sanguineous unions, the former will produce progeny as healthy and perfect as the latter. I would almost go farther and say that the chances of perfect breed in the lower animals are greater in the former than the latter.

The next authority I refer to is Mr. W. T. Greene, M.A. M.D., of Peckham, a Fellow of the Zoological Society, and a man who, to judge from his published writings and his qualifications, is not likely to run after a fad, particularly one which runs counter to much public opinion. He says that for five years he has bred from the progeny of a single pair of fantail pigeons, and that their offspring instead of degenerating has decidedly improved, and the latest batch is finer than the original pair from which all are descended.

He then says:—

‘Consanguinity alone will not produce disease in the offspring. If the related parents are strong, healthy, and without blemish, the tendency will naturally be to establish and confirm those valuable and desirable qualities; but on the other hand if the consanguineous parents are undersized, cachectic, or rachitic, it will as certainly follow that their progeny, should there be any, will inherit their deficiencies with re-duplicated intensity. In such cases, however, Nature provides her own remedy, for after a time the race thus produced will fail from sheer lack of vigour to maintain it, and the great principle enunciated by Darwin, of the survival of the fittest will deliver the world from a burden, and the lover of beauty and harmony from an eyesore; but to argue that consanguinity *quæ* consanguinity is productive of deterioration is an absurdity that needs only careful consideration to be cast aside as an utterly untenable delusion I have inbred cockatills for the

last ten years and yet perceive no indications of a deterioration.

‘It is said that the marriage of cousins produced diseased children, I do not believe it at all. If the cousins are thoroughly sound their children will be healthy; if they are not, their offspring will be diseased, just as happens when two non-related consumptive people marry. Heredity is a potent factor in the determination of health, no less than of disease, and so far as I can judge it does not matter an iota whether it is derived from one side or the other, but when it comes from both, the tendency to either strength or weakness is increased to an appreciable extent, or in the ratio of 1 to 4, and so on in geometrical proportion.’

These are weighty words for a man, who by culture, profession, and knowledge of the subject he deals with, is entitled to respect.

I need not enter at any length into my own experience on this subject with fowls, pigeons, canaries, and rabbits, and I, therefore, simply record the fact that so far as it goes it certainly corroborates the results of M. de Roo and Dr. Greene. That these results are not isolated is shown by the following extract from the editorial notes in a journal devoted to the poultry and pigeon fancy:—

‘The late Mr. Jayne, a celebrated and successful breeder of short-faced Almond Tumblers, used frequently to boast that he had not had any fresh blood in his loft for fifty years.’

According to Mr. Webster this stock of pigeons *must* have died out, because all the breeding pairs would of necessity be nearly related. I venture to say, as M. de Roo observes, that in a state of nature birds and animals seem to prefer a consanguineous union to a non-related one. On this head I dissent directly from the propositions of Mr. Webster and yourself.

One cannot with insects like bees carry on a series of experiments as with domesticated animals, but, arguing from the greater to the less, is it not reasonable to suppose that what is true in the cases quoted, and arguments used in respect to other animals, is true of bees? It will require in the bee world a second Lubbock to arise and demonstrate whether bees are subject to the same natural laws as other animals. Until some better evidence is adduced I for one prefer to stand by natural opinions backed by men who have spoken so boldly as those quoted, and I would suggest that no bee-keeper should, out of mere fright at the bugbear of in-and-in breeding, introduce into his apiary fresh blood from a source of which he knows nothing. Let him not think, if his stocks be perfectly healthy and good workers, that he has anything to fear from the fact that the fertilising drone and the young queen are from the same mother.—*THEA, Withington, 14th April, 1888.*

[We should have been glad if ‘Theta’ had favoured us with his views a little earlier, for then his arguments could have been dealt with *seriatim*: as it is, the subject must remain in the region of ‘Correspondence,’ where there is room for much divergence of opinion.

Lifetimes of observation and study, instances and experiments without end, have confirmed scientific men in the general truth of what appears to be a law, viz., that in-and-in breeding (the continued crossing of near blood) is detrimental to the race, variety, or strain; and if Mr. de Roo's or Dr. Greene's opinions to the contrary obtain for ‘Theta’ any converts, we raise no sort of objection, but we opine that some day they will find they have something to unlearn.—*Ep.*]

IN THE HUT.

‘He is not worthy of the honeycomb,
That shuns the hive because the bees have stings.’
SHAKESPEARE.

[1605.] I think about the most *uninteresting* heading that could be found for an article in our *Journal* is the one of ‘Railway Rates’ (perhaps, excepting ‘Poor

Rates'), and about the most *interesting* paper we have had for some time is on this subject, from the pen of Mr. F. Boyes; it is quite an artistic composition, working up as it does to such an acute climax—'all through the obstinacy of an official who, I afterwards heard was—shall I say it?—yes, a jealous bee-keeper.' Will not Mr. Boyes favour us with some letters of his name, so that every bee-keeper in Yorkshire may identify him, and—bless him, or better still, pronounce on him *Anathema maranatha!* He is a cad whoever he is.

Some time ago I got a hint from Mr. S. Abbott as to the best means of preventing the propagation of one part to another, which I hope he will pardon me for making public. It is, to rub a little vaseline on the parts likely to touch, when making the first spring examination, or using new frames. The bees won't have anything to do with the stuff, and manipulation is rendered easy all through the season.

Who the gentleman is who sends you the valuable contribution, 'Bee-keepers' Vocabulary,' is, of course, a mystery, but he has dashed from the lips of poor 'X-Tractor' a cup he hoped some day to sip of; and this is how it is:—I have during the leisure evenings of the past two winters burnt the midnight oil in preparing material for a bee-keepers' dictionary, knowing such a thing was much wanted, and now we have the very beau-ideal appearing in weekly numbers in the *B. B. J.* Coming in this form, we are bound in time to swallow the dictionary. It is a capital idea, and if my MSS. be of any use to the author, it is at his service.

I have come across a capital tool for uncapping in extracting or stimulating, and also for scraping propolis and wax off sections or frames: it is called a plumber's scraper (purchased of ironmongers) and is a triangular piece of flat steel, bevelled to a sharp edge on each angle.

each angle being about two inches; in the centre is fitted a wooden handle about eight inches long. A pulling motion uncaps beautifully, the cappings rolling downwards, and nooks and corners can be got into with facility. When one edge gets soiled, the other two are ready at a turn of the wrist. In extracting, we often find the usual uncapping-knife scarcely what we require, by reason of the waxiness of some combs, and to make all things equal some honey has to be levelled down, *i.e.*, long cells much shortened. As there are *varieties* of plumbers' scrapers, be sure to get them right-angled triangle, no kind of oval.

As Mr. 'Useful Hints' hinted a week or two ago that he was on the track for a true definition of the word 'Blizzard' (blessed Blizzards!), I read his remarks to an eminent American, and he said they were 'exactly there,' but *falling snow* is not a necessary condition.—X-TRACTOR.

[We shall be much obliged by our correspondent lending us his MSS. We shall no doubt find it of great service in our compilation-work.—Ed.]

AN ESSEX RECTORY.

[1606.] My new home in Essex has one feature about it that I certainly did not anticipate. My hives at Berkhamsted were reduced to three, and sent at great trouble and expense into Essex. Since spring has appeared, I find that there are already three colonies inhabiting the upper part of my house! They have settled, curiously enough, all of them on the north-

eastern side. We cannot get at them from the inside, as they have settled just under the eaves in a very inaccessible position. They have evidently entered by a hole in the plaster. A very high ladder would be required to reach them. My Essex gardener seems to think they ought to be dislodged, if only to prevent other bees from following their bad example! I am rather puzzled to know what course to adopt. Is it advisable to allow them to remain? Were they accessible from the interior, there would be no difficulty; but they are not. I don't care to mount a high ladder and try the effect of puff-ball or carbolic acid. I cannot ask others to run a risk which would be a serious one to a person at all afraid of bees. Perhaps, the best way, after all, will be to let well alone. But I shall be glad of any hints.—E. BARRUM, D.D., *Wakes Colne Rectory, Essex.*

[If the bees are not a serious inconvenience, their residence may be permitted. If at any future time it be desirable to evict the tenants, it would be advisable for an expert to make a reconnaissance on the spot, and act accordingly. No general directions can be given for getting bees from 'an inaccessible position.'—Ed.]

HONEY.

[1607.] Honey consists of the saccharine substance collected by the bee (*Apis mellifica*) from the nectaries of flowers, and deposited by them in the cells of comb. While this is the commercial article, yet the production of honey is by no means limited to the bee, for there is a honey-ant in Mexico which stores a nearly pure syrup of incrustable sugar. A Vieiliers has reported also a honey from Ethiopia, which is the product of an insect resembling a large mosquito, which, like our wasp, makes its nest in cavities in the ground. The natives call the honey 'tasma,' and ascribe to it medicinal virtues, especially using it as a cure for sore throat.

The composition of honey is complex, but the essential constituent is a mixture of dextrose and levulose; and a solution possesses the physical property of turning the plane of polarised light to the left. This property furnishes an easy and accurate method for the detection of the adulterated article; and, while I have never met with a known pure honey which was not levo-rotatory, yet there are statements on record which claim that honey has been met with which was dextro-rotatory.

Honey is adulterated as much, if not more, than most articles of food, and, while the adulterant is harmless, yet the fraud to the purchaser remains. The substances generally used are glucose and cane-sugar. The former, on account of its low price, has been the most common, and, mixed with enough of the genuine article to give it a flavour, is sold extensively as 'pure extracted honey.' One will also find a small piece of genuine comb honey in a jar which is filled with glucose syrup. The honey in the comb gradually diffuses itself through the mass, giving the required flavour.

I have examined forty-three samples of honey, the purity of which was unknown, and have also examined two samples of known purity. The method of analysis was as follows:—A Soleil-Scheible polariscope was used, the normal weight of which is 26.048 grams; that is to say, 26.048 grams of pure cane-sugar (sucrose) dissolved with 100 c. c. water, and a tube 200 m. m. in length filled with the solution, will indicate 100 on the scale. Cane sugar and glucose will therefore indicate 'plus' and 'levulose,' or honey will mark 'minus' the zero. The same weight of glucose will turn the plane so far to the right (or plus) that it will exceed 100. The commercial glucose, when the normal weight is used, will indicate from 155 to 170, according to the greater or lesser amount of dextrose present. Pure honey will indicate from .4 to .15. Seldom, however, as low as .15, but I have found this figure in old honey of undoubted purity. It will, therefore, readily be seen that owing to

the high dextro-rotatory power of glucose, that a comparatively small amount will neutralise the levo-rotatory power of the honey, if added. The same, of course, is true, if cane-sugar syrup is added, but in this case the indication will not exceed 100, as will be the case if a sufficient amount of glucose is present.

The mode of procedure is as follows: 26·048 grams of the honey are taken, dissolved in a flask of 100 c. c., and the solution filtered through a small quantity of bone-black in order to clarify the solution. A tube of 200 m. m. is then filled with the solution and placed in the instrument, and the instrument adjusted, the indication of the scale being noted. If 'minus,' we may assume that the sample is genuine, for while it is perfectly possible to produce a honey which is adulterated, which will indicate 'minus,' yet at present, after conversation with and inquiry from those engaged in the business of manufacturing honey, I am of the opinion that the adulteration consists in the use of dextro-rotatory substances. If the indication of the scale is 'plus,' however, that will indicate that either cane sugar or glucose has been used; and if the scale indicates more than 100 the presence of glucose is conclusive, but if not, we must proceed to learn which. This is accomplished as follows:—A solution is prepared as stated, or 50 c. c. of the original solution is taken and treated with one-tenth volume of hydrochloric acid, heated at a temperature of 80° C. for a few minutes, cooled, and repolarised. If now the scale still reads to the right the presence of glucose is assured, while if to the left cane sugar is shown to have been the cause of the original reading being to the right.

The action of the acid is to 'invert' the cane sugar—that is, to change it to a substance which no longer is dextro, but is levo-rotatory, and which is termed *invert* sugar, and acts in the same manner as honey. While cane sugar can be added to a honey, which will not indicate 'plus,' yet practically the amount used is so great that such is not likely to be the case. If such should be, however, by what is known to chemists as 'double polarisation' would yield the amount, this being the method for determining the small amount naturally present, and if more than 5 per cent was obtained it would indicate a *probable* addition.

Temperature has more or less effect on the rotatory power of invert sugar, consequently all the readings of the solutions should be at a uniform temperature in order for a proper comparison.

As an adulterant, however, invert cane sugar, if made without the use of acids, and not added in too great an excess, would prove a substance rather difficult to positively detect. If used to a large amount, its great levo-rotatory power—a pure invert sugar solution marking at 23° C. 32·5—would indicate its presence. It has been tried, but, I understand, has not given satisfaction, and when used has been used with glucose, no honey whatever being used. It has been suggested by some that an examination of the ash of honey would indicate as to its purity. This is a mistake. I have found the ash alkaline even when glucose has been present, and I have found phosphoric acid to be present in a sample claiming to be 'virgin honey,' and containing no honey whatever. The amount of ash is so variable in known pure honey that this is no guide.—SHIPPEN WALLACE, *Analytical Chemist*.

NOTES ON BEE-HIVES.—SECTIONS.

[1608.] In my former notes I have stated reasons for my preference for wide frames in working for sectional honey, and in continuing my notes I might say I find these frames are admirable for working glass sections.

The following is a very easy way of producing them at the lowest cost, and at the same time showing one of most enticing, interesting, and beautiful objects that can be put upon the table. Four pieces of glass are fixed or kept in place within a wooden section by means of a

small quantity of gum or china cement. When whole sheets of foundation are used gum is unnecessary. Whole sheets of foundation are fixed by painting molten wax very neatly round all the edges of the foundation by means of a sable hair pencil, the surplus wax being removed with a penknife as soon as possible before the wax gets quite hard.

When the section is placed on the dish for the table, the wood section is removed, and—!

Glass without a green tint (observed by looking at the edges) should be used, and all edges should be polished. Both the cutting of the slips and the polishing of the edges can most easily be performed.

A more beautiful but more expensive glass section is one I have lately designed. It is a simple rim of one piece of glass accurately made and having a small ridge on all the four inner surfaces to fix the foundation against by means of a very small quantity of molten wax.

The dotted lines in Fig. 1 show the position of the ridge, and Fig. 2 is part of a side showing the shape of the ridge alluded to. I need not make any comment upon their attractiveness in shop-windows,

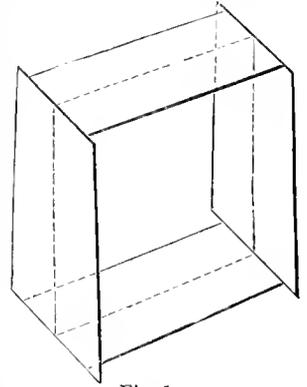

Fig. 1.

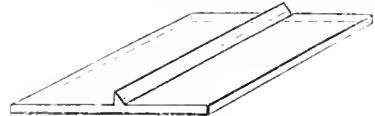

Fig. 2.

for I have never seen anyone that could resist admiring them.—T. BONNER CHAMBERS, F.L.S., *Tref Eglwys, Caersus, Mont., April 12.*

POOR QUALITY HONEY—THE EXTRACTOR—HONEY A LUXURY—THE SUCCESSFUL HONEY PRODUCER.

[1609.] We sometimes affect righteous indignation toward those who adulterate honey. No words are caustic enough to express our wrathful ebullitions. But did it ever occur to you that the possibilities of such nefarious practices are greatly enhanced by the poor quality of *unadulterated* honey, especially extracted, often found on the market?

Probably more injury has been done the bee-keeping interest by putting upon the market poor honey—unripe, sour, thin, or detestable in quality—than by commercial adulterations. I only pretend to voice my own convictions when I say that the extractor, regarded by many as the greatest invention in modern apian appliances, has done the industry more harm than good. It is an easy matter to concoct a mixture, independent of the aid of bees, that will taste better to the average purchaser of sweets than some of the so-called honey got with the aid of the extractor. When a novice first gets an extractor and finds how easy it is to 'sling' honey, he is, perhaps, anxious to astonish his neighbours by his wonderfully superior bee-lore. He is after large yields with no thought of quality. He extracts early and often—as the trained ward politician in the next precinct votes. Instead of honey, he extracts nectar. Instead of a rich, oily, aromatic delicacy whose fragrant memories will linger long after the joy has passed, he has some

sweetened water that will hasten to convert itself into vinegar, as if ashamed to attempt to counterfeit what it can never equal.

If nothing but the best were sold, it would be impossible to imitate it successfully. Honey is considered a luxury in America. Luxuries for the table must appeal to the eye, or the taste, or both. If we want our honey on the tables of the rich it must win its way there on its merits. It must be proved in the same manner as the pudding—in the eating. Honey that is good enough to go into the dining-rooms of the wealthy will find its way into the kitchen of the labouring man—for there is nothing too good for the working man in this country to eat. His taste is educated. He lives more royally than royalty itself a hundred years ago. We can no more deceive the taste of the poor than the rich, and the former, or at least the middle class, are among the best customers. Now if we want to cater to the taste of the consumer, we must produce such an article as will please when bought. The time was when honey was honey, and little was known of the different grades. Not so now. The successful honey producer of the future is to be the one who not only sells nothing but a ripe article, but who puts it in such attractive packages as the buyer delights to take home with him when he has company to tea.—EUGENE SECOR, Iowa (*American Apiculturist*).

FIXING FOUNDATION.

[1610.] In perusing the *Journal*, April 12th (p. 193, No. 1585), I find a friend's description of the way he fixes foundation in frames, which I may state is very similar to the plan on which I have constructed my frames for the coming season. I beg to forward you particulars of the slight difference, for insertion in *Journal*, if you think it likely to be of any benefit or worthy of consideration.

In the place of the two strips of wood $\frac{3}{8} \times \frac{3}{8}$, length of inside of frame, I take two strips of wood $\frac{3}{8}$ wide, and $\frac{3}{8}$ thick by $13\frac{1}{2}$ long, bevelled on one edge at an angle of about sixty degrees; one of those strips I fix firmly to the inside of the top bar with the bevel inclining to the bar. Then place the frame flat on the bench and insert a piece of wood $7\frac{1}{2} \times 13$ inches, and $\frac{3}{8}$ stout in thickness, inside the frame; on this place the foundation, taking care that the upper edge is brought well up to the top bar, then take the other bevelled piece and press the foundation firmly between the two and fasten with half-inch wire nails. The bevel acts similar to a wedge, and holds with a slight pressure, very firmly. The sharp edge of the bevel should be slightly taken off or rounded to prevent cutting the wax.

I should be pleased to know if the method I have endeavoured to describe in the hope that it may be of some benefit meets with your approval. Thanking you sincerely for the great assistance I have received through the medium of your valuable *Journal*, which is weekly anxiously looked for.—W. HORNER, 30 Cumberland Street, Skipton-in-Craven.

HIVING SWARMS.

[1611.] Now that the swarming season is approaching, I think that the following remarks may prove acceptable to the readers of the *Journal*. In most of the modern works on bee-keeping the advice given to those about to hive a swarm is, first, to place a straw skep under the bees when they have settled, and then either shake or sweep them into it. For several seasons I have adopted what appears to me a far simpler and more advantageous plan. It is to reverse the old order of things, and suspend the skep by means of a strong cord over the swarm,

taking care that the branch on which the bees have settled comes in contact with the inside of the skep. In a short time the bees will be seen going up into their new home.

The advantages I claim for my plan are, total absence of anything which irritates the bees, as the old plan of shaking or sweeping generally does, and that all danger of crushing the queen is done away with. I do not use a smoker at all during this process, but let the bees take their own time about going up, which I find they do in about half an hour.

Sometimes it is necessary to shade the skep if the bees have swarmed on a spot much exposed to the sun, as there is a chance of their going off on a second excursion if very heated and allowed to remain so.

I trust you will find space for these remarks in your valuable paper.—EDMUND J. JONES, *Ysgubor-Fawr, Penderyn, Aberdare, South Wales, April 18th.*

DRIVING BEES.

[1612.] I am quite a beginner at bee-keeping, and if it is not trespassing too much on your space, I should like to relate my first experiences of driving last year. I commenced with a stock and a swarm in the spring of 1887, and made up my mind when the autumn came, and with it my holiday, that I would devote part of my time to driving condemned bees, so as to gain a little experience and increase my stocks. August duly arrived, and I started away about the middle of the month to spend a fortnight or so, as is my custom, under the parental roof in one of the eastern counties. I soon found that I should have plenty of work to do, as there were any number of skeps in the neighbouring villages, and no sooner had my fame (?) got abroad than the cottagers were sending up nearly every day to say, 'Would I come and take their bees?' My father caught the bee-fever of me, and I was very glad, as in him I had an able pupil and assistant. We, first of all, started to get hives put together, and in a short time we had several in readiness. They were made square with single walls to take standard frames, and so far have answered admirably. My first venture was in our own village. The sexton had three hives, and, as he was getting somewhat aged, had determined to give up keeping bees, so I had permission to take the lot. I started operations, my pupil taking his turn at the drumming, and we had a very successful drive, the bees going up splendidly, and we put the three lots together on one of the old stands, fed them, using one of Simmins' frame syrup feeders, and left them. In about a week all the combs were drawn out, stored, and sealed. The next bee-day was at a farm-house about two miles off in the next village, so I requisitioned a donkey and cart, and having got skeps, &c., together, started off with a boy to act as coachman. Here I found I had got somewhat a big job on, seven skeps to drive out of a total of eight, and my former assistant not present. To get it over as quickly as possible, as it was rather late in the afternoon, I pressed the boy into the service. He 'worn't' afraid of bees, and we soon had them tied up securely in our empty skeps. I despatched my coachman home with the load, took the honey out, and then sat down to a substantial tea with my friends in the farm-house.

This was a fair illustration of the succeeding days' driving, of which we had several, and drove in all about thirty lots without a hitch of any kind. We made of these eight stocks, and it was arranged that I should send four to my own home and leave the others behind. We thought matters over, and as we had no experience, and no advisers at hand, we had to make arrangements for the railway journey in the best fashion we could—and we evidently went wrong somewhere at this stage. Two hives were selected, the bees of which had been driven about a week, that had comb extended and syrup

stored, and the frame we fixed at top with wooden blocks, so that they could not move out of position, and the lids to all were arranged with a strip of perforated zinc let in along the centre for ventilation. These hives stood the journey very well, but the other two we selected contained bees that we had driven the day before my return. They were sent off in the morning by passenger train and arrived before I did in the afternoon, when I at once unpacked them, to find much to my disappointment that the contents of these two were thoroughly mixed up with broken foundation in a heap at the bottom of the box and dead as door-nails. Will some experienced bee-keeper kindly advise me the best way to pack driven bees for a railway journey, so as to be prepared for a similar campaign next autumn?

I forgot to say we varied our performance one day by trying to drive some bees out of a hollow tree. In this we were unsuccessful, as they would not leave; so we contented ourselves by taking out as much honey as the openings we could make with a chopper would allow us, and this weighed fifty pounds. The bees had been in the tree for years and were a very savage lot. We got plenty of stings for our honey.—W. J. S.

ONE SIZE SECTIONS—OVERSTOCKING.

[1613.] Every producer should of course study the wants of his own market, and govern himself accordingly. If two-pound sections are received with more favour by his customers, two-pound sections are the ones for him to use, no matter if one-pound bring a higher price in other markets; and so with other sizes. But to a great extent it lies largely in the power of the bee-keeper to decide upon one size or another of section, just as may suit his convenience, without protest from his customers. Anyone who has tried having different sizes of sections in his apiary at the same time need not be told that the nuisance is something like that of having different hives and frames in the same apiary. One year as a matter of experiment, I tried sections of five different sizes or widths, and part of them remained unfilled to annoy me for two years afterward.

If there were no other reason for uniformity there is a strong one in this, that supply dealers and manufacturers are more apt to have on hand a standard article, and if the bulk of bee-keepers use a section of a given size, manufacturers can make them up in large quantities at a lower price. They will feel safe in working ahead of the demand and getting a stock on hand. Whatever in this direction is for the interest of the manufacturer results in a lighter demand on the purse of the bee-keeper.—DR. C. C. MILLER (*American Apiculturist*).

LECTURES ON BEE-KEEPING.—On April 27th, at the invitation of a lady whose unobtrusive work is well known and appreciated in the parish of Upper Hatherley, Cheltenham, the schoolroom was filled with upwards of 200 people, bee-keepers and their friends, to hear a lecture by Mr. Slade, Hon. Secretary Gloucestershire B. K. A., on 'Apiculture, and how to make Bee-keeping profitable as well as interesting.' The lecture was illustrated by about sixty slides, with the limelight, showing the bee scientifically, and bee-keeping at home and in other lands; also diagrams, and hives, supers, extractor, wax-melter, and appliances used in bee-keeping. A table was laid out, exhibiting cakes and confectionery, from George, of Reading, honey drops from Huntley and Palmer, specimens of English and foreign honey, and chocolate, honey creams and tablets, from Messrs. Fry—all kindly contributed by the various manufacturers, which were much appreciated and enjoyed by those present. Rev. Mr. Griffiths opened and closed the meeting with a few kind and encouraging remarks. A similar lecture was given on the following Tuesday at the Workmen's Hall, Silver Street, Worcester.

'REMINISCENCES': A CORRECTION.—In the article last week entitled 'Reminiscences' (No. 1596, p. 201), there is a mistake which should be rectified. It is said: 'The first hive I ever saw was a large box hive.' Whereas it was not a hive at all, but a large box spouting, or cornice running all along the front of the house, and about thirty feet from the ground. This will explain 'The bees hanging out at one corner;' 'Placing a straw hive against the wall to catch a swarm;' 'Getting up a ladder, taking the honey out, and nailing up again.'—LORDSWOOD.

Echoes from the Hives.

Welwyn, April 16th.—The weather is very trying, and everything is very backward, though I had drones on the wing from a very strong hive on the 9th.—GEO. J. BULLER.

North Leicestershire.—Beautiful weather here last week, and bees flying and gathering pollen well, but the wind has shifted to east, and all is at a stand again, except feeding.—A. E.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

F. T. G.—*Moving Stock.*—Leave perforated zinc uncovered. It does not matter which time of day, morning or evening, so long as, if you elect the morning, it is *early morn.*

W. B.—1. *Rearing Queens.*—Unless you have capped drone brood now, it will be unwise to attempt queen-raising, and your better plan would be to wait the young queens you anticipate at swarming time, either uniting the queenless lot to another, or purchasing a queen for them. 2. *Clipping Queen's Wings.*—If they really persist, in spite of every precaution, then of course clip the queen's wings. 3. We believe Mr. Simmins sends out queens now with a guarantee of safe introduction. 4. *Cross between English Drone and Carniolan Queen.*—The first cross between Carniolan queen and black drone is excellent for honey gathering, but temper suspicious.

ENOX.—1. *Commencement of Honey Flow.*—When you see the top cells of combs becoming elongated with white new wax. 2. *Doubling.*—See Cowan's *Bee-keeper's Guide Book*. 3. *Strengthening Stock.*—Commence stimulative feeding at once and shortly give a frame of brood from your strongest stock to weakest, so equalising the colonies. Treat the colony deprived of its combs as a swarm; you may get a little surplus from it. 4. *Lee's Sections.*—Full sheets of foundation can be fastened into other makes of sections, but in all the foundation is seen from the outside; this is very little, if any detriment. 5. *Cleaning Floor-boards of Hives.*—This should be done now. Lift hive off floor-board and place it upon a piece of calico, damped with weak carbolic acid solution, then scrape floor-board, afterwards replacing hive. Take floor-boards away quietly from other hives; little disturbance will ensue. 6. *Honey Harvest.*—Your main crop would be from sainfoin and clover. Unless your bees are very strong the fruit blossom will be too early. 7. *Cultivating Plants for Bees.*—It does not pay to cultivate plants specially for bees, the land in England being far too valuable, but if honey-producing plants can be grown that are useful as feeding stuffs for

- cattle, &c., it will pay to plant them. In our own flower garden we plant 'bee flowers' as we must have flowers of some sort or other, and therefore discard all mediocre honey-producing ones. If we had a farm we should not plant red clover, but a honey-producing variety.
- MALTA.**—*Supers and Swarms.*—When a stock swarms, remove the parent stock to new site. Place the swarm on the original site, put queen-excluder on the frames (which should have starters only), take the supers off the stock, and place them on the swarm.
- J. W. BARKER.**—*Drone flying on April 8th.*—We should say the stock referred to is queenless, and should advise a close examination on the first mild day. (See 'Echo' from Welwyn.) Be very careful not to chill the brood should there be a queen.
- WOOD GREEN.**—*Skep not Filled.*—Considering the weather last season, your bees did as much as could be expected. Feed about quarter of a pint of syrup every evening. You will hardly get much of a honey flow in your locality till the limes come on in July.
- J. F. CLEEVE.**—*Bees vacating Hives.*—During spring it is not an unfrequent occurrence for colonies to vacate their hives and join others near. This is frequently the result of shortness of stores, but in your instance it is not so. The cause cannot always be traced. No doubt the colony was weak—strong ones never do so if they have plenty of stores—and the smell of the paint (turpentine) drove them away.
- S. W. R.—1. Queen Nursery.**—Any appliance manufacturer who is acquainted with the American system of queen-rearing would make you one. They are frequently used in America. 2. *Removing Queen before placing Nursery in Position.*—There is no necessity to do so. 3. *Virgin Queen Introduction.*—They can be introduced direct with even greater ease than when fertilised.
- JOHN BAINBRIDGE.**—*Bees fixed in Combs.*—During the winter a portion of the cluster has got separated from the main body, and has been prevented by the cold from joining them. They have thus, after consuming the stores near them, died from starvation and cold.
- T. D. M., Anwell, Burma.**—1. *Apis dorsata.*—We are not aware of any successful attempt to domesticate these rather pugnacious bees, but we should like to have a good try were we situated as you are; probably they would resemble the Cyprians in resenting smoke. Quietness and nerve would be essential. — 2. *Apis Indica.*—We should think your stocks are queenless, judging by our *Apis mellifica*, or it may be you gave them so much food that the queen has nowhere to lay. Remove a centre comb, and the bees will soon build another, that is, presuming you have no foundation to put in. Do not fail to favour us with the opportunity of helping you in the future. Any notes on bee life and culture in your far-distant home would be appreciated.
- H. I. A.—1. Wiring Frames.**—You can use a centre bar as you suggest, but we should certainly prefer to remove it *after* getting the wire threaded in. There is no need to strain it so tight.—2. *Transferred Bees.*—Unless the weather becomes very much warmer, we should certainly wait the period you name before disturbing this stock. You put enough foundation.
- ENQUIRER.**—The shrubs and trees referred to are not of much use as honey producers, but some pollen is gathered from them.
- W. F. A.—Prevention of Swarming.**—For preventing colonies from swarming when arranged on the tiering-up principle, consult our *Guide-book*, p. 58, or our pamphlet on *Doubling and Storifying*.

CONSTANT READER.—*Best Hybrid.*—Try a cross between a Carniolan drone and a black queen. This makes a good honey gatherer of robust constitution.

R. CURTIS.—*Stock not Working.*—On the first mild day examine this hive closely, and note whether you can see the queen, whether there is any worker brood, and how the stock is for strength, and write to us again.

BEE-KAY.—*Uniting.*—Bring the hives to be united close together, about a yard a-day, reckoning only those on which the bees are flying freely. When the weather is suitable unite the lots, placing a piece of glass before the entrance so that the bees may note their new location. If you fancy one queen more than another the worse queen should be removed at the time of preparing the hives for uniting.

W. C. THOMAS.—*Syrup.*—We should not advise using syrup made last year, it would make assurance doubly sure by making it afresh. Syrup should now be given rather thinner in consistency; and in average weather a quart weekly will generally be sufficient to keep a strong colony advancing.

H. W. T.—*Spring Dwindling.*—Spring dwindling is often attributable to too early and frequent manipulation and stimulating by giving food irregularly. The queen being in the condition you represent, it would be desirable to procure another stock and unite. By judicious feeding, and attention and care, a populous colony may be created by the arrival of the principal honey harvest.

ELLIS E. CRISP.—*Bacillus depilis.*—The bees have not reached us, but from your description we are inclined to consider that the bees are affected with *Bacillus depilis* or *Gaytoni*. We advise you to raise the hive slightly from the floor-board by means of small wedges, so that a current of air may pass beneath the combs. Feed also on phenolated syrup, and do not open the hive or attempt to manipulate. Under this treatment the colony may soon recover.

Wanted, a list of the honey shows or fairs, with dates and places of meeting, to be held in England during season 1888, with classes 'open' to the United Kingdom.—**VIRGIN HONEY.**

RECEIVED from F. M. Atwood, Rileyville, Saline Co., Illinois, his Catalogue and Price-list of apiarian supplies in general.

RECEIVED from Messrs. Abbott Brothers samples of honey labels. These are lettered 'Honey,' 'Pure Honey,' 'Heather Honey,' 'Irish Honey,' &c. These labels are very pretty, and the designs neat and appropriate. They will be found effective for their purpose. There is a large variety of them for selection. Well-designed labels add much to the attractiveness of honey.

FIRST-CLASS CERTIFICATES.

The annual first-class examination will take place on Thursday, May 17th. Candidates intending to compete are required to give notice to the Secretary on or before Saturday, May 12th.

ARE BEES WORTH KEEPING?

In some form or other the title of this article will be crossing the minds of the majority of our readers during the present season of apiculture. This subject can be viewed from so many and distinct points that, starting with such a wide basis, the enumeration of a few of the subjects of interest may prove of pleasure as well as profit.

First, we have the man who keeps bees for pleasure, eager to possess himself of any new race, anxious to try any fresh invention. Apiculture to such is a hobby, but this apiarian is of great use to the cause, as, money being of no object, his facilities for proving novel ideas enable others to know if this or that appliance possesses any real merit.

Secondly, we have the experimentalist, who loves his bees as a study, ever striving to advance science and acquire some fresh knowledge concerning the natural history of these most industrious insects, useful in a thousand ways to man. In these ranks from age to age have been found men who have devoted their lives and fortunes to the cause, teaching us the anatomy of the bee, pointing out the wonderful adaptation of this part of the insect for certain work, and that part for the advancement of the wonderful economy in nature, showing us the loving forethought of the Great Creator who fashioned all things, however simple or complex in their construction, for an all-wise purpose. From such men we know the habits of bees, their diseases and cure, their methods of collecting honey, and their power of transmitting pollen from flower to flower, insuring the fertilisation of blooms, providing for us a larger harvest of both grain or fruit than could have been obtained without their instrumentality. Thus true philanthropists have given to the world the results of their tedious experiments and laborious observations.

Thirdly, we have the agriculturalists and fruit-

growers, who keep bees, not with the primary object of obtaining honey, or because they are particularly fond of bee-keeping, but because they have learnt from the experimentalist that no bees mean no fruit. It is now becoming a recognised fact that where fruit is cultivated to a large extent and bees are not kept in the vicinity an apiary must of necessity be added to the garden; and, profiting from the experience of our bee-masters, these apiaries have been made to yield profitable results in honey harvests.

Fourthly, we come to the class who form the greatest number of our bee-keepers, viz., those who keep bees to increase and help out their incomes; these are recruited from all classes of society: and we are glad to see the cottagers, profiting by the experience of their neighbours and the teaching of the Associations far and near, are now swelling the ranks of the advanced apiculturalist. To this fourth section of those who keep bees a few words of advice may here not be out of place. If you wish your bees to pay, and if you intend them to succeed, conduct your apiary on strictly commercial principles, leave the proving of new hives and new ideas to those who can afford it and have the time; depend upon it if they are worth anything you will soon hear of it. In the present day, with County Associations, shows, and Bee Journals, you can with patience reap the experience of others' experiments. Be careful, but do not have a hive because it is inexpensive; such may prove 'cheap and nasty.' Take full advantage of comb-foundation, and do not neglect feeding when necessary, as such a principle would prove false economy. Have only such appliances as are of actual service, avoiding such things as you can do without, as, if your bees are to pay with the present competition, the strictest economy must be observed.

A word here as to the width of section. Much is said and written about $1\frac{1}{2}$ and $1\frac{3}{4}$ inch sections. Before adopting these widths, be sure that they are the best. Our experience is rather in favour of the two inches; they are, without doubt, the favourites for selling honey in; many shops absolutely refuse to have anything to do with the narrower. Two or four bee-ways are a matter of opinion and choice, as right-angled and parallel frames are; both have their strong advocates, as well amongst scientific as with practical bee masters.

Fifthly, and lastly, we come to the man who

makes bee-keeping a speciality, devoting his entire time and attention to their management, making apiculture his sole source of income, either by selling swarms and queen-raising, or working his apiary exclusively for the production of honey; or else, when circumstances permit, he may include all three in his scheme.

We have thus briefly traced the five different reasons 'why people keep bees;' from which it is easy to reply that bees are worth keeping. As a hobby and a study the pursuit will ever abide; but as a source of income the industry must ever continue to advance. Large apiaries are the rule in America and Canada, but with our changeable climate we do not consider that such undertakings will be greatly adopted by us. Apiaries of from ten to fifty hives will pay in the British Isles when worked as aids to incomes. Honey is steadily taking its right place as a household requisite: it was, of old, considered man's proper food. Some authorities inform us that Pythagoras the philosopher used to be contented with honey and the honey-comb and bread.

BRITISH HONEY COMPANY.

We very much regret to announce that we have received a circular intimating that a meeting of the above Company will be held at Charing Cross Hotel on May 10, when the following resolution will be proposed, 'That it has been proved to the satisfaction of the meeting that the Company cannot, by reason of its liabilities, continue its business, and that it is advisable to wind up the same voluntarily.'

ASSOCIATIONS.

BRITISH BEE-KEEPERS' ASSOCIATION.

Meeting of the Committee held at 105 Jermyn Street on Thursday, the 26th ult. Present—Rev. Geo. Raynor (in the chair), Rev. F. T. Scott, Rev. R. Errington, Captain Campbell, J. M. Hooker, W. O'B. Glennie (Treasurer), and the Secretary. Letters were read from Captain Bush, Rev. E. Clay, Dr. Bartrum, and the Rev. J. L. Seager, regretting their inability to be present. The finance business and the Secretary's correspondence having been considered, the Exhibitions Sub-Committee reported that they had held a meeting previous to the General Committee Meeting, and had resolved that the following arrangements be made in respect to the awarding of prizes to members of the B. B. K. A. at the county shows of the affiliated Associations:—(1.) That priority be given to those counties which had made the earliest application, subject to suitable arrangements. (2.) That two classes be arranged, one for comb honey in small sections, and one for run or extracted honey, with two prizes of 12s. 6d. and 7s. 6d. in each class. (3.) That the exhibits be subject to the B. B. K. A. Exhibition rules where they applied. (4.) That no competitor be allowed to take more than one prize in each class. (5.) That an entrance-fee of one shilling and sixpence be made for each entry, the entrance-fees to be handed over to the funds of the County Association. The report of the Exhibitions Sub-Committee having been considered, it was approved and adopted.

In the absence of Dr. Bartrum, who had placed the notice on the agenda paper, it was resolved, 'That copies of the reports of the quarterly meetings and papers read be forwarded to each member.'

A meeting of the Educational Sub-Committee, called for the purpose of considering some modification of the rules relating to third-class examinations, could not take place. Only one member was present, the remainder being absent through illness.

The next meeting of the Committee, also the quarterly meeting of County Representatives, will take place on Thursday, May 17th.

LOWESTOFT BEE-KEEPERS' ASSOCIATION.

The annual meeting of the members of this Association took place at the Public Hall on Thursday, April 26, when the following report was presented by the Hon. Sec., L. Wren:—

'The committee are again able to present a very satisfactory report and balance sheet for the year 1887.

'There are now forty-five members against forty-six last year. The year closes with a balance in hand of *£* 12s. 5d.

'It was resolved at the last annual meeting not to hold an exhibition during 1887; but in lieu thereof the members to have two visits from the expert, viz., spring and autumn. In accordance with that resolution, the expert visited the apiaries of members during April and May, examined 159 stocks, giving advice and assistance where required. The visit was repeated during September and October, when 162 stocks were examined and put in order for the winter.

'It has been a long and trying winter for bees, and many stocks have died, some from starvation, others through old worn-out queens. All stocks need great attention just now where they are strong. Much food is consumed in rearing brood, and it will be some time before the bees will gather sufficient to supply their daily needs.'

The report and balance-sheet, showing a balance of *£* 12s. 5d., were unanimously approved and adopted. The following committee for the ensuing year were unanimously re-elected:—Rev. T. A. Nash, Rev. C. T. Scott, Mr. S. Cox, Mr. R. J. Colman, Mr. J. L. Clemence, Mr. G. S. Everitt, Mr. K. Rix, Mr. L. J. Peto, Mr. F. Morse. Mr. L. Peto was also elected chairman for the year. Mr. L. Wren was re-elected as honorary secretary, expert, and treasurer.

It was also thought advisable that in connexion with the Blundeston and Corton Horticultural Shows prizes should be offered for cottagers, and it was resolved there should be two classes of prizes as under:—1st. For the best exhibition of honey in the comb, taken without destroying the bees. 1st prize, 5s.; 2nd, 2s 6d. 2nd. For the best exhibition of extracted or run honey, in clear glass bottles or jars, taken without destroying the bees. The honey should be exhibited in a saleable form. Any exhibitor destroying the bees to take the honey will be disqualified.

The proceedings then terminated.

MIDDLESEX BEE-KEEPERS' ASSOCIATION.-- SOUTHGATE BRANCH.

A general meeting of the Southgate Branch of the Middlesex B. K. A. was held in the Village Hall, Southgate, on April 25th, 1888. Chairman, Mr. H. Matthews. The Hon. Sec. and Treasurer (P. P. Hasluck) reported that up to date *£* 10s. 6d. in subscriptions from sixteen members had been received, of which sum *£* 9s. 6d. had been paid over to the Provincial Secretary, leaving 1s. in hand. The show for the N. E. division of the county was held in the grounds of P. P. Hasluck, Esq., The Wilderness, Southgate, on the 20th August last. In spite of the bad weather the attendance was fair. Southgate branch was well represented at the show, and the B. B. K. A. medals were awarded to Mr. J. H. Belton and Mr. P. P. Hasluck respectively. The autumn tour

conducted by the expert-in-chief to the B. B. K. A. (Mr. S. J. Baldwin), was, on the whole, satisfactory. Three cases in all of foul brood were reported, of which one was so far advanced that the expert recommended its destruction; his suggestion was carried out. The Association appears to be making way in the district, and the Secretary has strong hopes of a considerable addition to the number of members during the coming season.

ESSEX BEE-KEEPERS' ASSOCIATION.

Spring Visits.—The expert is working, as weather allows, near home, but has been constantly stepped by the continued cold and wet. Distant journeys are left last for the sake of longer days.

Cottagers' Apiary Competition.—Notes will be taken on spring visits of the stocks in cottagers' apiaries, so that results may be judged on autumn visit for the prize of 10s. offered by Mr. Ed. Durrant for the best-kept cottage members' apiary giving largest returns in comparison with the number of hives kept.

Hives for Cottagers.—To encourage labourers and cottagers now using skeps to purchase bar-frame hives, Mr. Bovill has generously placed a sufficient sum at the disposal of the Association to enable the purchase of six hives at 12s. 6d. each, to be delivered to cottage members recommended by the expert as sufficiently advanced in bee-keeping, and unable to purchase unaided. The cost to be repaid by anyone who takes a hive, as he can make it out of the honey produced in the hive so purchased. A recognition, in the shape of a section or bottle of honey, to be made yearly by each purchaser as long as any portion of his amount remains unpaid.

County Show at Ilford, June 28-29.—F. H. MEGGY, Hon. Sec., Chelmsford.

Selected Query.

[7.] *What is the best thing to do with queenless colonies in spring? Should they be united to those having queens?*

In the afternoon of a fine day, on which the bees have been flying, move the queenless colony close up to another having a queen, for the purpose of their being united. Give both a little smoke and jar the hives a few times. After waiting a minute or two to allow the bees time to fill themselves with honey, take off the quilts or covering, remove the frames of comb with the bees on them from the queenless colony, and alternate them with the frames in the other hive. Any bees remaining on the sides or bottom of the hive should be shaken on to the frames before putting the quilts on, when a little more smoke may be given at the entrance. A feeder filled with syrup can be put on for a few days. If the queen is a valuable one, and the bees are bad-tempered, she should be caged; but this is not generally necessary.—JOHN M. HOOKER.

United. Yes. — JOHN H. HOWARD, *Holme, Peterborough.*

If a colony lose its queen in March or April unite the bees to the next hive, and let the hive stand midway between the original position of both hives. The uniting had better be done as follows to prevent fighting:—Shake both stocks of bees into a straw skep, or on a wide board or cloth, in front of the hive you intend them to occupy, and as they run in together sprinkle them with some very thin syrup with a few drops of peppermint in it; it is also a safe plan to cage the queen for twenty-four hours. But if a colony should lose its queen in May and there was a fair lot of bees, I should give them a frame of brood containing eggs from a good working stock and let them raise a queen.—W. WOODLEY.

Queenless colonies in spring should be united to moderately strong colonies which possess queens.—H. WOOD, *Lichfield.*

If the queenless colony in spring be a weak lot it should be united to another stock having a queen, as they are hardly worth looking after. Or should the colony be queenless and still strong in bees, at end of April or beginning of May a frame of brood may be given to it from another stock to hatch a queen, provided, also, that precaution be taken to have drones flying at the time for successful mating. In most apiaries will be found in spring one or two stocks having a young queen with few bees. When a stock is found to be queenless, these small lots with queen may be united to queenless colonies; this I believe to be the best way.—WILLIAM McNALLY, *Glentworth, Scotland.*

Unite by all means.—WM. N. GRIFFIN.

Unite them to other stocks near, except they are very strong in bees; then, if any queens be obtainable, give them one by caging from twenty-four to thirty-six hours. — JOHN WALTON, *Honey Cott, Weston, Leamington.*

Either unite to those having queens, or unite two or three queenless colonies after introducing a queen.—W. B. WEBSTER.

If queenless recently, I should regard it as no great evil, particularly if bees covered four frames; give a frame containing eggs from queen whose good qualities have been proved, and proceed in usual manner with cells. It frequently happens that stocks are queenless earlier; if strong, should proceed as above and protect the nucleus by artificial heat. Do not regard uniting early in year as advantageous, and only practise it as a last resort. By this method I have queens now ready to fly, and can thus practise 'select' rearing.—JOHN EDEY, *St. Neots.*

I think so.—W. E. BURKITT.

This depends upon circumstances. If the colony is large enough to cover four or five standard frames, and a nucleus headed by a last year's queen is available, unite the latter to the former, caging the queen for twenty-four hours. Of late years I have wintered nuclei of three and four standard frames, and find them very useful at spring. Colonies, populous and headed by young queens, when put into winter quarters well prepared, will rarely be found queenless at spring. Failing a queen, union with another colony is the only alternative.—GEORGE RAYNOR.

Nothing is gained by uniting strong colonies. Take a queen, if good, from a weak lot, and then unite latter stock to one near it, should the weaker lot not stand near the queenless hive.—SAMUEL SIMMINS.

Foreign.

THE EAST COAST OF FLORIDA.

The usual winter losses of bees in the Northern States cause many apiarians to turn their thoughts to Florida, believing that in this sunny land, where flowers are blooming the entire year, there would be a field open for the enterprising apiarist which, if occupied, would result in satisfactory returns for the trouble and expense that might accrue in removing to so favoured a locality. There have been good reasons in the past for the inquiring mind to dwell upon this subject, as the apicultural journals have contained numerous reports relative to this and other localities, as especially favoured by nature for the production of honey. Believing there are other localities in the State that are suitable for establishing apiaries with a fair prospect of success, it is not necessary in this article to make any reference to them, but rather confining the subject to the locality

embraced in the mangrove district of the eastern coast of the State, of which New Smyrna has long been considered the centre. With the exception of St. Augustine, it is claimed to be the oldest town in the State, and one of the last to receive the benefits derived from railway transportation, and as a consequence has been deprived of its share of emigration compared to other portions of the State.

Previous to the freeze of January, 1886, this locality was considered to be a most desirable location for securing large yields of honey. The mangrove flourishes for miles up and down the river, and in the season of its blooming, the amount of honey secreted was sufficient for thousands of colonies. The bee-keeping industry began to attract the attention of specialists, quite a number of whom possessed flourishing apiaries numbering from fifty to two hundred colonies and over. After the freeze, which killed and blighted from seventy-five to ninety per cent of the mangroves, a feeling of despair secured a firm hold on many of the bee-keepers, and they either sold out or removed to more promising localities. To those who remained the future proved anything but encouraging. The lack of honey to subsist the colonies upon caused many to die of starvation, and a general indifference to the result was common. Bees have been shaken upon the ground, the honey extracted, and the combs melted into wax in order to secure a portion of the amount invested in them by their owners previous to removing. The result is, there are at the present time but one-third to one-fourth as many colonies here as were in the fall of 1885, and to the best of my knowledge, no one is relying on their apiaries exclusively for a subsistence. There are individuals here who desire to dispose of their apiaries; others who realise if the impression goes abroad that apiculture is a failure, it will prove disastrous to the disposal of their real estate. It is from persons of this character that the misleading reports emanate that are seen in the Northern bee journals. The season of '87, like the year previous, has proven a failure, the colonies barely securing sufficient to winter upon, but not a few of the bee-keepers have extracted at the rate of from fifty to eighty pounds of honey per colony. The result at present is the bees are either starving or are being fed at much trouble and loss to the owner. While this is transpiring, the Northern bee-keepers are rearing of a third of a crop in this locality, of nine barrels of honey from forty-five colonies, and reports of a like nature, which are intended to mislead for reasons mentioned above.

Possibly many who peruse this article may inquire in what way does apiculture differ in Florida from what it does in the North, and if the absence of winter is a benefit to the apiarist? Replying to the first, can say so far as my opinion on the subject is concerned, The only feature that is identical in both localities is the *instincts of the bee*. Of the second, the best interests of the colonies are only secured by the constant vigilance of the apiarists during the winter months. The climate, the humidity of the atmosphere, the variety, time, and duration of the blooming of the flowers, must be familiarised. The fact that colonies require about thrice as much honey to keep them in an active condition, the necessity of strong colonies to secure surplus, and, unless they are destroyed at the close of the season, the increased amount of bees are of but little value except to consume honey. The prevalence of the mosquito hawks renders queen-rearing extremely uncertain at times; the moth-worm, active at all seasons of the year, makes the preservation of combs extremely difficult. The ease with which robbery can be started during a dearth of honey, and the persistence of the bees in keeping it up, are among the many objectionable features of the profession. Our honey is also liable to ferment if not given the best of care, and the result is sometimes the bursting of the barrels while undergoing transportation. Another great detriment is that our

best grades of honey, known as 'mangrove' and 'palmetto' honey, are classed in the Northern markets as Southern honey, which reduces it to the level of the strained product of Georgia and other Southern States, greatly to our disadvantage. Had the interests of Florida apiculture been taken into consideration by the representation of the national society during the past four years, instead of seeking to promote personal aggrandisement, a better state of affairs could have been reported, notwithstanding the many disadvantages under which we have laboured during a portion of that time.

It will be seen that with the many desirable features of this location, among which are an enjoyable climate, the natural food resources of the country, and an almost perfect exemption from diseases, there are objections here as well as in other States.

Honey production in the Northern States is more profitable and requires less labour than in this locality, and there is not the least doubt that it is so over the entire State. Our home market is comparatively nothing to what is possessed by the apiarists of the North, except in some favoured localities near the large cities. The winter problem, or the loss of colonies, is not taken into consideration as in the North, if the colonies have not been deprived of their stores, and the ambition to secure a large yield of honey has ruined many a promising colony of bees.

The future prospects of this locality appear to be good, as the new growth of mangrove secreted a small yield the past season, and it is expected the yield for 1888 will enable all to secure a full crop.

Through the solicitation of a number of the more prominent apiarists of this locality, the North American Bee-keepers' Society have been induced to appoint Professor G. W. Webster of Lake Helen as the Vice-President for Florida for that Society for 1888. Having an extended apicultural experience in the State of Iowa, and also in this State, coupled with his reputation as a botanist of distinction, fits him to a great degree for the position which he now holds, and all interested can rest assured that no visionary or misleading article on Florida apiculture will emanate from his pen. The above description of our honey interest and the condition of affairs pertaining thereto, are as near the true facts of the case as circumstances will warrant in asserting at the present time.—JOHN Y. DETWILER, *New Smyrna, Florida, January 4th (American Gleanings)*.

JOTTINGS BY AMATEUR EXPERT.

'Mel Sapit Omnia.'

'What a time since we saw that!' 'X-tractor' will say. The truth to tell I have two or three things to write about, so I thought I had better 'run up the old flag' and do it.

The first is 'honey boards.' I need not assure our faithful monitor 'Useful Hints' that I had seen the article written by Mr. Heddon to the *C.B.J.* that he ('U. II.') has classified as 'amusingly satirical,' nor that I know a good *quid per quo* for Mr. Heddon. Unlike 'U. II.,' I took that article as intentionally offensive, and on principle I answer such with silence, however much I should have enjoyed to break a lance with our 'invertible' friend over the water. But I started to write about 'honey boards,' not about Mr. Heddon, and what I should like 'Useful Hints' to tell us is, why he wishes us to use honey boards? By our present methods of working with young queens at the head of our colonies, and expansive hives allowing us to give room as required, I can get sections without the queen attempting to lay in them *without a queen-excluder* far easier than I could do with the zinc in position. I do not get two per cent of my sections laid in without an excluder, and am never troubled with pollen in sections, consequently

I consider it scarce worth while to give the bees unnecessary trouble for the sake of what, under the circumstances, can only be classed as a 'fad.' I get more brace-combs than I like. If 'U. H.' can tell me how to still further reduce them, I shall be pleased to listen if he thinks he knows of a more excellent way than I have tried, and accord to him the thanks he will merit.

The next is the word 'blizzard.' 'Useful Hints,' on page 163 *B.B.J.*, gives the Americans the credit for coining the word on the strength of Nuttall's Dictionary. 'Right here' let me say that a very large number of the quaint, and to us, witty expressions, used by our cousins over yonder, are simply very old English ones, long since forgotten by most 'Britishers,' whose language is being so constantly affected by importations from the Continent. In reading, as I often do, newspapers published in small rural towns in the States, the similarity of many expressions used in rural districts of the States to others used in West Cornwall often strikes me, living as I did for many years in 'West Barbary.' (West Barbary, allow me to explain, is that portion of Cornwall lying west of Truro, and witty, humorous expressions is the hall-mark of a native.) Rural districts, far removed from the centres of civilisation (?), are always the last to be affected by change, and phraseology is no exception to the rule, especially previous to the days of School Boards. I do not claim the word 'blizzard' as a Cornish one, but here is what a correspondent writes about it to *Notes and Queries*: 'The word "blizzard" is well known through the Midlands, and its cognates are fairly numerous. I have known the word and its kin fully thirty years. Country folks use the word to denote blazing, blasting, blinding, dazzling, or stifling. One who has had to face a severe storm of snow, hail, rain, dust, or wind, would say on reaching shelter that he has "faced a blizzer," or that the storm was "a regular blizzard." A blinding flash of lightning would call forth the exclamation, "My! that were a blizzomer!" or, "That wor a blizzer!" "Put towthry sticks on th' fire, an' let's have a blizzer"—a blaze, "A good blizzom"—a good blaze. "That tree is blizzared"—blasted, withered. As an oath the word is often used, and "May I be blizzared" will readily be understood.'

A BEE-KEEPER IN PRISON.—Here we must 'haul down the flag' to the Yankees. We have 'invented' nothing like that as yet in this fossilised old country. Mr. L. A. Clarke, of Arkadelphia, Arkansas, U.S., is in prison for contempt of court. A neighbour indicted his bees as a 'nuisance,' and Mr. Clarke was ordered to remove them beyond the corporate limits of the city. He refused, and was put into 'durance vile.' Mr. Newman, the editor of the *American Bee Journal*, who is also manager of the North American Bee-keepers' Union, is making strenuous efforts to raise 500l. to defend the case. If this is a sample of local government in the 'land of the brave and the home of the free,' save us from such local government!

The *B. B. J.* of last week and the *American Bee-Hive* for April came by the same post. I looked at the *Bee-Hive* first, and on turning to the *B. B. J.* discovered that the scraper illustrated by our friend the 'X-Tractor' is shown in the *Bee-Hive* also, but the latter has the advantage of cheapness. This is what the *Bee-Hive* says:—'We are using a scraper for scraping separators, hive bottoms, &c., made by drilling a hole in the centre of a mower "section," and putting on a handle with a screw. Try it, and you will cry, "Eureka!"' A section that is worn out for mowing will answer the purpose admirably. Almost every village smith throws quantities of them annually on the scrap-heap, so no one need be without a scraper; or, failing to get one there, come and fetch one from the scrap-heap under the 'chestnut-tree' of—AMATEUR EXPERT.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'The Editor of the "British Bee Journal," c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, Kings Langley, Herts (see 2nd page of Advertisements).

*. In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

COUNTY ASSOCIATIONS.

[1614.] The Secretaries of County Associations have no light duties to perform to keep the Societies going, and I am sure we are all greatly indebted to them for the labour and time they bestow in the interest of apiculture. In these times of apicultural and general depression it is most difficult to get the support that the societies have a right to expect, and there is great trouble in getting in subscriptions and keeping up the number of the members.

In addition to this, it appears that in some counties the secretaries are complaining that they cannot get their managing committees to attend the meetings, and that they have to do all the work themselves.

I feel that I am guilty of not having attended the meetings of the committees of the county of which I am a member, and I am sorry that this is so. I will tell you the principal reason, and it is not unlikely that others have been absent from similar causes. In my case the meetings have been called by the secretary—very properly no doubt—at towns which are at a considerable distance from me, the journey there and back taking up a whole day; this, the railway fare, and other expenses, are more than I can afford. It is difficult to see how this can be obviated, as the committee are generally chosen from different parts of the county; some on account of the known interest they take in apiculture, others on account of the position they hold in the district; and wherever the meetings are held, the majority would have a considerable distance to go.

This will, I think, be the case in all the counties, and I would suggest that as soon after the appointment of the committees as convenient, the secretaries should send a letter to each member of the committee for the purpose of ascertaining, first, the day in the week that would be convenient, and the particular day preferred, and the time of day; second, what places or towns they could attend, and which they would prefer. The secretaries would then be able to select the day in the week and the place most convenient to the majority, and in this way would, in all probability, get a better attendance.

This is the way the meeting of the committee of the British Bee-keepers' Association is arranged.—JOHN M. HOOKER.

THE DRONE.

OUR POOR, SLANDERED DRONE ASKS FOR HIS DAY IN COURT.

[1615.] 'Virgil, who was a great poet, but not enough of a practical bee-keeper to know a laying from a virgin queen, was the first writer of much note to have his fling at me. To him I was only an idle knave, born to consume the fruits of others' labours, and deserving no better fate than death, by ignominious expulsion from the industrious commonwealth. Ever since he so grossly libelled me, to compare one to a drone is the most orthodox form of denunciation for laziness, gluttony, and what has been called "general cussedness."

Now I am proud to say to this Court, that I can disprove every charge brought against me by simply proving that, to the best of my ability, I fulfil the express object for which I was born. Surely no creature can do an better than this, and excuse me for thinking that few men do as well.

CHARGED WITH LAZINESS.

If any of my enemies had authority to call the roll of my demerits, he would surely begin by accusing me of being too *lazy* to gather any honey. But an expert in points of this kind could remind him that if he examines my proboscis, he will see that it is much too short for sipping nectar from the opening flowers.

MAKES NO WAX.

I am free to admit that I make no wax, but even Cheshire himself, whose microscopes have fairly turned me inside out, will tell you that I have not a single wax-secreting gland, and am also without those plastic, trowel-like jaws, which enable the worker-bees to mould the wax into such delicate combs.

GATHERS NO POLLEN.

Now do not insinuate that I might at least employ some of my leisure time in gathering pollen? Can you not see that my thighs have no basket-like grooves, in which it could be packed, and are quite destitute of the hairy bristles by which the workers hold the pollen in place?

ACCUSED OF BEING A LAZY COWARD.

No doubt you have often denounced me as a big, hulking coward, that leaves to the women the whole defence of the State. Are you not aware that I have no sting to fit me for acting on the offensive? Would that I had one proportioned to my bulk! if only that I might make proof of it upon all who berate me for not accomplishing impossibilities!

I am not at all ashamed to admit that I spend the most of my time not given to eating, either in sleeping, or in what you are pleased to call listless moping about the hive. Has it never occurred to you that if I should try to assume the restless activity of a worker-bee, I could be nothing better than a meddling busybody, perpetually interfering with the necessary business routine? I guess the silly meddler who would put me up to such nonsense ought more than once to have had a dish-cloth pinned to his rear, to teach him not to bother the women in their work!

MISUNDERSTOOD.

I am sorry to number Shakespeare among those who have misconceived me, by calling me 'the lazy, yawning drone.' But as one of my maligners have likened me to Falstaff, I may be allowed to quote in my own defence what this great braggart, when accused of cowardice, says of himself to the Prince: 'Was it for me to kill the heir apparent? Why, thou knowest I am as valiant as Hercules; but beware instinct; the lion will not touch the true prince. Instinct is a great matter; I was a coward on instinct. I shall think the better of myself and thee during my life. I for a valiant lion, and thou for a true prince.' I lie not, like the false knight, when I say that what you call my laziness is a matter of pure instinct.

With all your boasted reason you seem to have entirely overlooked the doctrine of the conservation of forces. You upbraid me with consuming so much of the precious honey, to the gathering of which I contribute nothing! Well, if I made a single uncalled-for motion, would not that necessitate an extra consumption of food? What better can I do, then, than to keep as quiet as possible? There is nothing either inside or outside of the hive which calls for any other line of conduct until the young queens are on the wing, and as they do not sally forth until long after noon, why should

I go abroad any earlier? I can assure you that if bridal excursions were in order as many hours in the day as the flowers secrete honey, no worker would ever be earlier to rise, or later to go to bed, than myself.

MISREPRESENTED.

I, an idle, lazy, listless loungeur, forsooth! Does any one wish to witness the most perfect embodiment of indefatigable activity? Let him then look at me, when at the proper time, with an eager, impetuous rush, and a manly, resonant voice, I sally from the hive! See with what amazing speed I urge, what our old friend, Samuel Wagner, called my '*circumvolating*' flights! For aught you know I may cover greater distances in describing these vast circles than the busiest worker in the longest summer day. There is great need, then, that I should be abundantly provisioned for such exhausting excursions, and it is only a law of nature that on my return from them all that I carried out with me should be found to have been used up. If you taunt me either for the full or the empty stomach, I merely ask you if you have never heard of honeymoon trips among your own people, which began with extra-full purses, to end only with uncomfortable light ones?

SAVAGE DELIGHT OVER MY DEATH.

To cap the climax of your abuse, what savage delight you take in seeing the workers drive me from my pleasant home! And how glibly you can moralise over what you call a righteous judgment upon a life spent in gluttony and in glorious ease! Just as if you did not know that the whole economy of the bee-hive is founded on the strictest principles of utilitarianism. Is not a worker-bee, when disabled by any accident, remorselessly dragged out to die, because it can no longer contribute to the general good? Even so exalted a personage as the queen-mother herself, as soon as it is plain that her fertility is too much impaired, she has a writ of *supersedeas* served upon her, in favour of one of her own daughters.

Knowing well the law under which I was born, I urge nothing against being put to death when Shakespeare's 'pale executioners' deem the day of my prospective usefulness to be over. Truly the sword of Damocles is suspended over my head, and from the hour of my birth till that of my death it may fall at any moment. Many bitters are thus mingled with my sweets.

I have time to mention only one more. While I know that most of the young queens come safely back from their wedding excursions, I cannot help sometimes foreboding the worst when I see that no drone ever returns to tell us of his experience.

APPRECIATED BY BONNER.

I will close my defence by reminding you how the good father of the great Scotch bee-keeper, Bonner, showed his appreciation of our persecuted race. It was his custom to watch every year for the first flying drone. Its cheerful hum so filled him with delight, as the bappy harbinger of approaching swarms with their generous harvest of luscious sweets, that he called an instant halt on the work of his busy household, and devoted the rest of the day to holiday feasting. The patron of the drones ought forever to bear the honoured name of 'Saint Bonner.'

THE DECISION OF THE COURT.

Sir Drone:—This Court having heard your defence, declares it to be a true and manly one, all those to the contrary notwithstanding, who would further injure you by calling it nothing more than crafty, special pleading. It only regrets its want of power to punish adequately your slanderers. But, alas, my worthy fellow! you must not expect too much from this acquittal. Remember how difficult it is for Truth to overtake a Lie that has got a start of only a single day. No doubt the

time will come when those who have been stigmatised as the

'LAZY FATHERS OF THE INDUSTRIOUS HIVE'

will be held in due honour by the world; therefore console yourself with this bright hope for the future of your race, while you protest against the lies that have had so many centuries the start of your true story, that you may well despair, in your short lifetime, of ever overtaking them.

MORALS FROM THE DRONE'S PLEA.

It were easy to draw more than one good moral from the drone's plea, such as, 'Do not give even a dog a bad name, unless you are quite sure he deserves it;' but the moral which I think at the present time can hardly help suggesting itself to well-read bee-keepers, may be very fairly styled the

MORAL OF THE PROF. WILEY SCIENTIFIC-PLEASANTRY LIE.

It is only too well known, to the sorrow of most of our large honey-producers, that some years ago Professor H. W. Wiley, an entomologist in the service of the Government at Washington, published substantially this statement, viz.: That honey-combs, after being manufactured, filled with glucose, and sealed over, all by human skill, so nicely as to escape detection, are largely sold as genuine bees' honey; when the bees have had nothing to do with a single step in the whole cheating process. This absolute falsehood having got a good start, as coming from a *scientific man* (?), has widely, at home and abroad, prejudiced the public against buying the purest honey in the most beautiful combs.

Many times have I heard the above story spoken of as either undoubted truth, or have been asked if it were not the truth. It has been refuted again and again, and large sums of money have been offered by responsible parties to any one who will produce even a small specimen of such a man-made product; and yet the story is constantly appearing in print in America, Europe, and not long ago even in Australia. It has found its way into a periodical of as high repute as the *British Bee Journal*, and it sometimes seems to have a greater vitality for mischief than when it first started out on its hurtful career.

Professor Wiley, when called to account for fabricating such a story, thought it a sufficient excuse that he meant it only as a '*scientific pleasantry*.' Could any one wish him a harder task than over his own signature to try to stop the march of such an inexcusable utterance? Could there be a stronger condemnation of his conduct in this matter than the words of Holy Writ?—As a madman who casteth firebrands, arrows and death, so is the man that deceiveth his neighbour, and saith, Am I not in sport?' Prov. xxvi. 18, 19.—L. L. LANGSTROTH, Dayton, O., March 8th.

BIRDS AND FRUIT TREES.

[1616.] I was truly sorry to see the letter from J. Hiam on 'Birds and Fruit Trees;' the gentleman is not content with destroying bullfinches himself, but wishes others to do the same. I am happy to know there are some human members of Parliament who are trying to put a stop to the catching of wild birds during breeding season. I read in the Old Book that God made the firmament and the fowls to fly in it, and God pronounced *all* very good, which must include birds as well. Now some men seek to destroy the beautiful plumaged songsters, which enliven the fields and woods of merry England, but I may venture to say in my humble opinion, that the country would lose one of its sweetest charms were our little feathered friends absent.

Mr. Hiam goes on to say the blossom of peach and plum trees have been a great loss to his bees. I have

been a bee-keeper for a good many years and my father before me, and I venture to assert, a hive of bees could not support themselves from peach and plum blossom, if they had not other stores; even if bullfinches do harm, they make up for it during the rest part of the year. I do not wonder at the birds coming when he had a call bird to allure them, doubtless many visited him that would not have done so; if he had some small bells in the trees and attached string and set them ringing when the birds came they would soon have decamped, or better still, could not nets be used to prevent mischief. I sincerely hope and trust no bee-keeper will follow his example to destroy the poor birds, but to rather copy the example of the great and good Lord Shaftesbury, who thought it not beneath him to feed them during the hard, frosty weather. Who being dead, yet speaketh to us all, lessons of kindness and love.—T. HILL.

LOCATING THE APIARY—BEST HIVE—BEST BEES FOR ALL PURPOSES—WINTERING BEES—SPRING MANAGEMENT.

[1617.] Nearly all, if not all, the older bee-keepers have laboured under the disadvantage of having commenced the pursuit of bee-keeping at the place where they were located at the time they received the first stroke of the 'bee fever.' This made the business of bee-keeping very uncertain with many of them, to say the least. Let me illustrate this point. My location has a good white clover range for bees, and this is the main source for surplus in all the older states; but my location is surrounded by a closely cultivated district, and a nice state of husbandry. All weeds are cut from the pasture lands and waste places, and my bees are deprived of fall pasture except from heart-sease (smartweed) which flourishes only in wet seasons. Hence I must feed my bees in the fall more or less, and this is a heavy draw on the profit side of the account kept with the bees. Some years ago I advised a friend of mine to start an apiary at his place—he lived but seven miles from me—as he had about the same white clover range that I had and the hills about him were covered with the little white and purple asters which would supply his bees with winter stores. He took my advice, and time is proving that his location is twenty per cent better than mine on account of the waste lands about him which abound with fall honey-producing flora. Let us pause here and take the 'hint' that the difference in a good and a poor location may make all the difference between success and failure.

THE HIVE BEST FOR ALL PURPOSES.

My views on this subject are not radical. The bee-literature of the past clearly shows that men have succeeded well, and equally well, who have used hives that differ as much in construction, as any of the new hives differ from the old ones and from each other. These facts are a broad 'hint' to the honey producer, that the difference in hives is not so great as many profess to believe. Any good moveable frame-hive, by the application of a little ingenuity, will give satisfactory results. I will not consume space by discussing this point here, as a description of my favourite hive has already been given in your pages. If the hive is light and substantial, and capable of being 'tiered' to the best advantage, without giving too much room at one time, no other hive, no matter how costly or complicated, will beat it. The 'tiering up' system is essential to the largest yield of the best quality of honey, and I believe the best way is to tier above the brood department of the hive.

THE BEST BEES FOR ALL PURPOSES.

It is generally conceded that Italian bees are the best bees for all purposes. But as it requires time and money to keep the race pure in any vicinity where there are

black bees we are induced to say that Italians and the first cross between them and black bees make a strong working apiary. But all subsequent cross with hybrids should be avoided. Such crosses have never failed to be inferior to the first crosses, in my apiary.

WINTERING BEES ON SUMMER STANDS.

To winter bees safely on the summer stands the apiarist should study the climate of his locality and prepare his bees for winter to suit his climate. But there is one condition in wintering bees that is common to every place, and that is plenty of winter stores. This I discovered years ago when transferring bees from box-hives. I found that plenty of honey in the box-hive means a strong colony of bees, and light stores always brought through the winter a small colony of bees. Bees do not waste and dwindle away when surrounded with an abundance of honey as they do when their stores are limited. We may take a 'hint' here and have strong colonies in the spring, if disease does not overtake our bees in their long winter confinement.

SPRING MANAGEMENT OF BEES.

I want my bees to have such a bountiful supply of stores that they do not have to be disturbed in the early spring till they begin to gather honey and pollen from the early bloom. After this no harm will come from any necessary manipulation. All upward ventilation through absorbents or otherwise should be prevented as soon as spring breeding commences. Bees will manage any accumulation of moisture at that season of the year. In fact they need water to carry on breeding and must have it, if they have to carry it from a distance. The surplus cases should go on the hives as soon as the weather will admit with safety to the bees, for if bees once get the habit of cramming the brood-chamber with honey they will lose much valuable time in starting work in the surplus cases. I suspect that bad management along this line is at the bottom of the complaint of those who 'can't get their bees to enter the surplus cases.' Bees are governed more by 'habit' than any of the domestic animals with which we have to do, and they must be watched closely. When bees get in the habit of storing their honey in the surplus cases they will neglect the brood-chamber in the fall; for this reason I confine my bees to the brood-nest at the close of the heated term so as to have the brood-chamber supplied with honey, if there is a fall flow.

EMPTY SECTION COMBS BROUGHT OVER.

Quite a number of persons have complained that the empty sections when used again do not give them first-class honey. This trouble can be overcome by shaving the combs down till the cells are about one-half inch deep. If managed in this way the sections will be first-class every time. The job is easily and rapidly done by a Bingham uncapping knife if kept hot by immersing it in hot water.

TAKING SURPLUS HONEY.

I am never in a hurry to take surplus honey from the hives, if I have a supply of surplus cases. By the tiering-up plan I keep the honey at the top where the finishing process can go on without the bees soiling the combs. Honey managed in this way will ship better and look better in the market than if it was a little whiter at the start by reason of being taken from the bees the moment it is sealed. And its superior quality will compensate for the slight difference in appearance. *Good quality* will win in the end.

HOW TO BUILD UP A HOME MARKET.

Perseverance is the main factor in accomplishing this desirable end. Some small circulars sent out by the apiarist, explaining the manner of taking pure honey from the comb, and some directions about its management to keep it fresh and free from fermentation, how to reduce

granulated honey to its natural or liquid state, its different uses for cooking and table purposes, its healthfulness, &c., should be delivered, one to each family in the circuit of the 'home market,' and above all, samples of pure honey taken from the comb, should be left with every family that is not acquainted with the article in that shape. If the name 'extracted honey' is good enough for you, you can put that 'hifalutin' name in your circulars, but it will be a 'mill-stone' about the neck of your enterprise, so far as your home market is concerned. If such is not the case your experience will differ from mine. A smart boy can be trained to sell honey in and out of the comb, from a light spring waggon provided with all the necessary conveniences for handling and weighing the honey. He should be directed to leave some honey at every new home he enters and fails to make a sale of honey. A circular should be left at each house he visits. In this way hundreds of dollars can be taken in, at prices enough better than city market prices to pay the extra expenses of disposing of honey in this way. After the home market has been well established, the spring-waggon system will not be necessary, except to widen the business and to deliver orders for honey in the towns, &c.—G. W. DEMAREE (*American Apiculturist*).

NOTINGS ON SECTIONS AND FOUNDATION.

[1618.] *Glass Sections*.—I noticed a question a week or two back about glass sections exhibited a few years ago. As the querist probably referred to an exhibit of my own at one of the British Bee-keepers' Annual London Shows, I may inform him that they were formed of four pieces of glass, the sides two inches wide, and the top and bottom pieces one and three-quarter inches, to give bee-space, and were held together by narrow strips of gummed paper. The foundation was fixed by warming the top piece of glass and pressing the edge of starter on it, not making it so hot as to make the wax run. Dividers were used as for the ordinary wood sections. Both sides of sections were afterwards glazed, the squares fixed by narrow strips of paper. It would be advisable to work them in a well-made crate, and wedge up tight, to insure that they were quite square when filled. I remember I sold the dozen for 21s., or about 67. each more than the usual wood sections at that time (but then we did not get our sections made from such nice white wood as we do now). Possibly, it would pay to produce a few for sale in an aristocratic neighbourhood, or to give away as presents to grace the wedding breakfast-tables.

Speaking of sections, I have just received by post a sample of Blow's new patent grooved sections, which for utility, neatness, and strength, cannot be surpassed; in fact, it is the *ne plus ultra* of sections for those who wish to use full sheets of foundation. I do not know if Mr. Blow has any special frame or block for holding the sections while inserting the foundation. My idea would be a long trough with rectangular sides, about four inches high. Fold three sides of your sections, leaving one side or top unfolded, place the section in the trough or block, say long enough to hold six, insert the sheets of foundation, then close down the top piece, and with a tap of the hammer drive the toothed ends together. It has everything to commend itself to bee-keepers who have a large apiary; it is strong and rigid when folded, and although not quite so large (inside dimensions) as the ordinary section, the wood being a little thicker to allow of the grooving, yet, if we get sections without the numerous popholes, the grooved sections in the future will contain more honey; at the same time, will be stronger for transit and handling.

And now a word to foundation-makers. I hope the makers of foundation will keep abreast of the requirements of bee-keepers, and supply foundation of a size that will cut up into sheets to fit sections without so

much waste as we have been accustomed to in the past. Take the usual size, viz., stock size, as an illustration. Now, it has been a mystery to me why super foundation should be cut as though it was intended to be put into supers or sections same size as the standard frame. A bee-keeper using full sheets in his sections will have a strip off each end to waste in each sheet, or if he cuts his sheet into eight squares he will most likely get eight nice little pieces of honey-comb hanging from top of section independently of any attachments to the side. This happens more especially towards the end of the honey season, notably when the limes are in bloom.

I myself have taken time by the forelock and have had my stock for the coming season cut 12 in. by 8 in. full, so that I can cut up without waste (and I should like to mention that I have never seen a finer lot of foundation than Messrs. Abbott have made up for me this season). Now, I think a good size would be 12 in. by 8 in. or 8 in. by 8 in., so that we should not get any waste foundation, costing the bee-keeper 2s. 9d. to 3s. per lb., and when remelted have to sell again as wax at 1s. 3d. per lb. Taking into consideration the prevailing low prices for honey the last year or two, it behoves bee-keepers to work on the closest lines of economical management if they have any wish for a fair margin of profit for their labours at the end of the year when they make up their annual account.—W. WOODLEY.

THINGS I HAVE LEARNT.

[1619.] Of course I had learnt most of these things in print before, but only during the latter part of the past winter and the early spring has the knowledge been hammered into me by experience. Having a faint hope that the repetition of a few familiar hints may be the means of inducing a beginner or two to take means to avoid disaster in his early bee-keeping career, I give a list of my lessons.

First lesson.—That if the bee-keeper wish to avoid the risk of starving his stocks he will take care in autumn that each is provided with not less than twenty pounds of stores. I am ashamed to confess what this lesson has cost me.

Second lesson.—That late breeding is prejudicial. One of my stocks bred largely as late as December, and succumbed, I believe from exhaustion, in January.

Third lesson.—That it is unwise to winter weak stocks. If other beginners feel as I do then they are very loth to unite, especially if they be ambitious to build up a considerable apiary. I think I may define a weak stock as one that does not crowd at least four frames.

Fourth lesson.—That it is worse than useless to give, even in April, a frame of brood to a very weak stock. I did this in the second week in April, and a few days afterwards found the weakling defunct, and a full frame of brood sacrificed into the bargain. I ought to have known better. I have now ten fairly strong stocks—the best with brood in six frames—and trust that I shall so succeed with them during the coming season that I shall be warranted at its close, in relinquishing my present name of—WELSH NOVICE.

TOOL FOR UNCAPPING COMBS.

[1620.] Seeing in the *Journal* of April 26, a tool for uncapping combs for the purpose of stimulating, recommended by 'X-Tractor,' I should like to describe a stimulating tool which I think will beat 'X-Tractor's.' My tool can only accomplish one thing, so in this respect it is inferior to 'X-Tractor's.' But I think there are few tools, which can be used with comfort for more than one purpose. The tool is made thus: Cut a piece of tin, $1\frac{1}{2}$ long by $\frac{3}{4}$ wide, cut teeth $\frac{1}{4}$ deep, and $\frac{1}{4}$ apart. Nail the tin to the end of a piece of $\frac{1}{2}$ wood, 8 by $1\frac{1}{2}$. Shape

the wood into an elegant handle. The comb need not be removed from the hive when stimulating, it only requires to be drawn a little apart from its neighbour.—R. T. SIEA, *Rockford, Essex.*

FROM A JUNIOR BEE-KEEPER.

[1621.] I have often wondered whilst reading this *Journal* that we do not hear more from its junior readers (and I should judge from answers to 'Useful Hints' problem in December numbers that there are a good few). Darcy R. Grimshaw bravely broke the ball, but no one else had the pluck to back him up (self included). I propose, instead of 'Children's Column,' we call it 'Junior Column,' in which the sayings and doings of junior bee-keepers shall be inserted. I hope to hear soon how 'D. R. G.' has been getting on with his humble bees, and whether he has been successful in wintering of them. Stimulated by 'D. R. G.'s' letter (356, page 207) last spring, I searched everywhere, but could not find a nest of humble bees. Shall try again this year. I saw the first humble bee this year on April 16th; it was black, and was working on the polyanthuses. I have been rather unfortunate with my bees this year, having lost three stocks out of six, through loss of queen and consequent dwindling, two being last year's queens and the other an old one. The other stocks are doing well. I am the only bee-keeper in this district, and all I know about bees I have learnt from this *Journal* and other publications.—FREESTONE (age 16), *Odd Down, Bath.*

THE SO-CALLED TRUMPETER IN NESTS OF HUMBLE BEES.

Nearly two hundred years ago (1685), the Dutch painter and able observer of insects, Mr. Van Goedart, reported having noticed that colonies of humble bees had a trumpeter among them, who every morning climbed up to the top of the nest, whence he summoned the other humble bees to their work by constant humming. Having become acquainted with a great many peculiarities among hymenoptera that live in communities, especially bees and ants, which resemble social arrangements of human beings, it would hardly have surprised us to find among them something similar to the vigilant trumpeter of our barrack yards. But from the time of Van Goedart to the present day, all endeavours to hear the trumpeter again proved futile, and, following the example of Réaumur, people pretty generally began to look upon Goedart's statement as a fable.

Recent observations made by Professor Dr. Edward Hoffer, of Graz, however, have fully confirmed the fact, that several kinds of humble bees, which build their nests under ground, have a watchman who calls the colony in the morning to their labour. In his work on the humble bees of Styria (1st part, Graz, 1882), which is now being published, and which contains most charming descriptions of insect life, this excellent observer of insects relates, how last year he had presented to him a three-storied nest of *Bombus argillaceus*, containing about 150 workers, which he placed in a box, provided with an entrance, and having a cover of smoked glass, in which the humble bees continued their work uninterruptedly, a couple of hours' journey not having disturbed them in the least. The very next morning at half past three o'clock, Professor Hoffer heard a peculiar loud humming in the box, and after carefully removing the wooden lid which covered the glass roof, he observed a so-called 'small female' standing erect on the top of the comb, its head, however, turned aside, and beating its wings with all its might, the humming which this caused being apparently increased by the air forced through the breathing tubes. The small creature continued this music till nearly half-past four o'clock, i.e., for about three quarters of an hour, during which

time the humble bees came out of their nest one after another, and flew off into the fields. And this went on every morning, the trumpeter rose from its nest at the same hour, and continued humming, sometimes uninterruptedly, for a whole hour, until it fell down completely exhausted. After lying quietly on the ground for a few minutes, it recovered sufficiently to be able to crawl into its nest again.

Professor Hoffer, who, of course, was highly delighted with his discovery, was able during the following days to invite his family and various friends interested in humble bees to this wonderful morning concert. One of his visitors, Mr. Zirtsch, afterwards discovered a trumpeter in colonies of *Bombus lapidarius*. It is probable that only those humble bees which build their nests underground have such a trumpeter, and among them perhaps it is only to be met with in large colonies. The ancient observer of insects being thus completely vindicated, Professor Hoffer determined to find out what would happen if the trumpeter were removed. He therefore caught it and pinned it on a card for his collection, and on the following morning everything remained quiet till eight minutes past four, by which time a few humble bees, tired of waiting for the customary signal, began to crawl out of their nest.

At the same time, however, another 'small female' crawled up the side of the box and commenced humming just as loudly and continuously as the previous trumpeter, whose duties the little creature henceforth discharged regularly every morning.

It will be seen from this that the life and doings of humble bees are deserving of a little more attention than has hitherto been bestowed upon them, and that like ants, in which Sir John Lubbock takes such a great interest, they are well worth a place in our study. Their whole behaviour is most amusing, and they are not by any means so ill-natured as their hot-tempered relations, the wasps and hornets. Huber assures us that he himself had seen them carrying their good nature so far as to allow some bees which paid them a visit to carry away the last drop of honey they had.—*Translated from the Gartenlaube*, No. 51.

Echoes from the Hives.

North Leicestershire, April 30.—To-day is splendid day for bees, and they are well at work carrying in pollen from the willows. Nectar, however, is so scarce that robbing is going on in all directions. Saturday last was an excellent day, making the sixth nice day this spring. Neglect of feeding means at present death to the strongest of stocks. Two more fine days and all will be changed.—E. B.

Honey Cottage, Hawes, North Yorks, April 30.—The weather so far has been very unfavourable for the bees. When I wrote my last 'Echo,' February 9, the weather was, to all appearance, promising us an early season, but about February 11 a change came for the worst, snow began to fall, and until March 25 never a bee was able to fly, and ever since then it has been so cold that I have never been able to examine a single hive, because during the few fine days that we have had the bees have been so inclined to rob that it has not been safe to open any hive, and the evenings have been so cold that to open them then means to give them a chill. Of course, I have taken a look under the corners of the quilt to see how stores are, but have never lifted a frame. I am feeding those that are anyway running short, and I have artificial pollen near at hand ready for them when they can get out. There is not a flower to be seen in the fields, even the willows are not out yet. The only flower to be seen is that useful bee-plant, *Arabis Alpina*.—JOHN WHARTON.

NOTICES TO CORRESPONDENTS & INQUIRERS.

QUERIES.—I have six stocks of bees:—

Nos. 1 and 2.—Old stocks in straw skep; strong.

No. 3.—A last year's swarm. The owner, in attempting to move them in October, lifted the skep off the stand, and left the bees and honey behind. I drove the bees out of the honey, and had them for my trouble, together with the hive, and about one-quarter of the comb, which was not disturbed. I am feeding them, and they are doing fairly well, though not a strong lot.

No. 4.—A stock driven rather late last autumn, and put in a frame-hive. Very weak. Feeding them with syrup.

No. 5.—Last year's swarm, in bar-frame hive; strong, and have plenty of stores.

No. 6.—Late swarm of last year, in skep; not very strong. I feed them.

Question 1.—Should you advise me to transfer the bees from the straw hive to bar-frame? and when?

Question 2.—I live in a fairly good honey district, woods all round; clovers and sainfoin in abundance. I do all carpentering myself, and can get materials at as cheap a rate as any one. Would it pay me to increase my stock? and to what extent? I have nearly 600 acres of land, so it would not be necessary to have them all in one place.

I have troubled you with a fairly long rigmarole, and to sum up: I took the bee-fancy into my head rather last season, and I want your opinion as to whether it would pay me to go in for them strong. I fear the difficulty would be to dispose of the honey. Hoping I have not trespassed too far on your kindness, I beg to sign myself—COTSWOLD.

REPLIES.—1. Your object being to establish your bees in frame-hives, we would advise you, instead of transferring in the old way, to proceed as follows:—Allow the bees to remain in the skep in the position they now occupy until they swarm, or until they show signs of swarming, when you can make an artificial swarm if you prefer it. In either case, put the swarm into a frame-hive, each frame having a piece of comb-foundation about two inches deep fixed to the top bar. Remove the skep to a new position, and put the hive containing the swarm on the old stand, with the entrance as nearly as possible where that of the skep was, so that any bees that are flying may return to and strengthen the swarm. (*See answer to 'Malta,' page 219 in our last number.*) On the twenty-first day after the bees swarmed, the brood in the skep will have, with the exception of a few drones, all hatched out, and there will be a young queen ready to lay. The bees should now be driven, and put into a frame-hive prepared with foundation as before, and in order to build it up quickly, it should be fed with a quarter of a pint of syrup every evening. In this way, you will obtain two good colonies with good, new combs, and some honey and wax from each skep. The combs should be taken out of the old skeps, the honey extracted, and the old combs melted, and the wax separated from debris. 2. Your district being a good one, it would pay you to increase your stock, but we would not advise this being done too fast, until you have had the experience that this year should give you. If those in skeps are treated as above, and those in frame-hives swarm, we think you will (if a novice) have quite enough to attend to for this season. You should get a strong hive with *standard-sized frames* from a good maker as a pattern, and those you manufacture should be all exactly alike.—J. M. H.

REPLY TO QUERY BY 'LORDSWOOD,' PAGE 196.—I made a crate of glass sections and exhibited them at South Kensington show some years ago, the same year as the Princess Christian was to have distributed the prizes. I afterwards let my bees fill them with honey, and exhibited them at our local Flower Show.

Perhaps these were the ones 'Lordswood' saw; they were made thus:—two pieces of glass about 6 x 3 for the sides, two pieces $1\frac{1}{2}$ x 3 for ends, these four pieces were fastened together with coaguline, the ends between the sides, the top was 2 x 6 and not fastened on, but had a very narrow strip of glass fastened on at each end so as to just fit inside of ends and sides, and which kept the top in its place. To get at the honey it was only necessary to pass a knife round sides and ends, and the honey would then lift out with the top glass, and by having a spare top the same sides and ends could be placed on the hive at once.—W. T. JOYCE, *Farnborough, Hants.*

AMATEUR.—1. *Live carrying in Pollen.*—Sometimes, but very rarely, pollen will be carried in, but if so, it is in much smaller pieces. 2. *Means of knowing when a Hive will Swarm.*—Not as to the particular time the swarm will leave the hive. 3. *Colony covering Three Frames.*—Yes, with proper care and adding brood occasionally.

A. L. Y. M.—*Moving Bees.*—It is a very bad time now to move them so short a distance, but if they must be moved do so at once—there will be much greater losses if you move them later on. Cannot you arrange to allow them to stay until winter?

GARDENER.—1. *Hunger Swarm.*—You could not have stopped the fighting. The stocks, no doubt, were strengthened, but we have no means of knowing how many entered or were killed. 2. *Centipedes.*—They will not injure the bees or honey.

ST. IVIAN.—1. *Spring Treatment of Colony.*—Your treatment has been very good. Feed slowly until fruit-blossoms, and between them and the time of white clover blooming. 2. *Wired Foundation.*—Yes; but by wiring ordinary foundation into frames by means of the Woiblet Spur Embedder it costs much less, and is more effective. 3. *Flying Foundation in Sections.*—There are various methods of doing this. See advertising columns, also notices in this issue. 4. *Drones.*—Examine the colony you saw drones issue from a fortnight ago. We should look upon such an early appearance with the greatest suspicion. If it is very strong it will be all right, but if weak in numbers, the queen is a drone-rearer. Are you sure they were worker larvae on the floor-board? Drone larvae reared in worker-cells are very small, and may by a novice be mistaken for worker.

N.—*Drone-rearing Queen.*—The queen sent is a Carniolan. We should say that during the winter the introduced queen has died, the one received having been reared from eggs left by her, but no drones being about, has failed to get fertilised.

ERNEST.—*Rack left on all Winter.*—Remove rack at once, and clean up for use when honey flow comes on. If there are any sections with honey in them, uncap and place behind dummy board for the bees to clear out, as if they are allowed to be completed this season, the honey of last season, already in the section, will be darker, making what is termed a 'piebald' section.

THOS. GILHOLM.—The piece of comb consists of very old comb, but there is no foul brood. It would be advisable to use comb-foundation.

ROBERT DRIVER.—The queen was not among the bees forwarded. The bees are black bees. We are sorry you have been so unsuccessful in wintering your bees. If you desire to have a Carniolan stock, you cannot do better than proceed in the manner you suggest.

WILSON.—The piece of comb forwarded is sweet and wholesome. Many of the cells are pollen-clogged, and a few of them covered with mould, but of foul brood there is not a trace. The bees have most probably lost their queen some time ago, and gradually dwindled away. The vitality of a superstitious idea is very great.

CLUTHA.—1. *Artificial Swarm.*—Refer to replies to 'Cotswold'; you will find there instructions which will meet your case. 2. *Staples.*—Staples are used for equalising the space between frames. Metal ends, or broad-shouldered frames, are now used for the same purpose.

T. NIXON.—By the time the queen is hatched there is every probability of her being fertilised, as there should then be plenty of drones flying.

FAWKHAM.—1. *Cross-built Combs.*—You will find it a tiresome job to put the stock straight. Your only plan now will be to lift out the whole of the frames as they are after having driven the bees up into a spare box or skep; then quickly cut out the combs and fasten the straightest, and also all with brood, into the frames with tape; then shake the bees back into the hive, cover up warm, and feed gently. In three or four days the tapes may be cut and removed. 2. *Stocking New Hives.*—You cannot do better than purchase swarms from a reliable dealer. Try a cross between Carniolan drone and black queen.

Received from Mr. J. H. Howard, of Holme, Peterborough, a section with foundation, as produced by the block figured in his advertisement. The block is secured to a table receiving a section cut as illustrated, and on the centre-bar the full sheet of foundation is guided into the three grooved sides of section, and the upper half of section top rail (cut at an angle of 45 degrees) is brought into place by the hinged door of block. We are highly pleased with the wax foundation used in section.

Received from Mr. W. B. Webster, Binfield, Berks, a section with wax inserted and a block for keeping the section perfectly square. The method invented by Mr. Webster for fixing whole sheets in sections is very effective. The foundation is gripped securely on top and both sides, and fills the section so perfectly that the existence of 'pop-holes' or sagging will be well-nigh an impossibility. The means whereby these results are obtained are:—Three sides of the section are in halves, the third side having sufficient pliability to form a hinge; upon pressing these two halves apart, after folding the section, they form jaws, within which the sheet of foundation is placed: it is then put into the block, a board, part of the block, is pressed upon it for the purpose of holding it firm and true; two little tin staples are then squeezed or knocked in, rendering the whole secure.

Received from Simmins's Bee Company (Limited) their Catalogue of Bee-keepers' Appliances (48 pages). This is a well-arranged catalogue; it is divided into various departments; viz., Queen and bees, hives and implements, and the specialties of Mr. C. T. Overton, whose business has been purchased by the Company. It also contains a list of flower-seeds for bee pasture, besides a large amount of practical information.

Received from Doctor Angelo Dubini, of Milan, his catalogue of bee appliances with price list, together with an illustrative sheet of his manufactures.

BRITISH BEE-KEEPERS' ASSOCIATION.

QUARTERLY MEETING AND CONVERSAZIONE.

The next Quarterly Conversazione will be held at 105 Jermyn Street, on Thursday, May 17th, at six o'clock. Members being desirous of introducing subjects for discussion, or to submit new, improved, or interesting appliances, are requested to communicate with the Secretary not later than Monday, the 14th inst. County representatives will meet at 149 Regent Street, at four o'clock. The Quarterly Conference of the County Representatives with the Committee of the B.B.K.A. will take place at 105 Jermyn Street, at five o'clock.

The Committee have decided to forward copies of the Reports of the Quarterly Meetings to each member of the Association.

ROYAL AGRICULTURAL SHOW.

Entries for the Bee Department of this Exhibition to be held at Nottingham in July, close on Saturday next, the 12th inst. Prize Lists will be sent on application to Mr. J. Huckle, Kings Langley.

ADULTERATION OF HONEY.

We have long been aware that American dealers adulterated honey, but we must confess that we were not prepared for the revelation made in the *Bee-keeper's Magazine* for April. It appears that the Dairy Commissioner of New Jersey has had honey purchased in different towns in the State, and has had it analysed. Out of *thirty-one* samples of honey put up by packing-houses, only *six* were found to be pure! We reprint the list furnished by our contemporary, and commend it to the careful study of every bee-keeper. We have never suspected bee-keepers to be guilty of adulteration, and we are glad to find, as of course we expected to do, that every sample supplied by bee-keepers was pure. We have very good reasons for complaint against American honey-dealers, for did they not flood our British markets with adulterated stuff, to the great detriment of American as well as our own bee-keepers? It will be still within the recollection of many of our readers that in 1879 Messrs. Thurber & Co. imported into England a large quantity of honey. They exhibited it at Kilburn,

and certainly up to that time no single exhibit of such magnitude, or presented in so saleable a form, had been seen in London. W. Hoge, who was their honey-man at that time, said there were ten tons, but although there was not even half this quantity, the exhibit was a fine one, and gave a good idea of the capabilities of America in the production of honey. The market for American honey was now open, and prospects were most brilliant; but it was not long before Thurbers, through Hoge, introduced adulterated honey, and, notwithstanding the attractive labels, the British public soon learnt to look with suspicion on any honey bearing the name of Thurber. The British Bee-keepers' Association also did good service to bee-keepers in having honey supplied by dealers analysed and publishing the results.

Hoge left Thurber's, and started business on his own account with an office in the City, a honey refinery (?) at Islington, and all the paraphernalia necessary for the sophistication of honey. He advertised extensively, and his honey was to be seen in many shop-windows; and had he dealt honestly in pure honey, probably his career would not have been such a short one. Adulteration, however, proved for him too great a temptation, and when analysed, of all the samples of honey emanating from Hoge's establishment under various names, there was not one pure. We do not wish to enter into details of how he imposed on the credulity of the public by assuming what he was not, and why he and his fraudulent exhibits were turned out of the Health Exhibition; nor how he imposed on his countrymen a story of which there was not a word of truth, pretending that he had got his honey on the Queen's table, and how this story, with various additions and variations, made the tour of the American papers. Knavery may serve a turn, but honesty is the best in the long run. Probably Hoge has found this out now in his wanderings no one knows where in America, and his firm have lately paid a first and final dividend, a most remarkable one, of '65 of a penny, or 2*l.* 14*s.* 2*d.* in 1000*l.*!

We mention these facts merely to show the harm that adulteration has done and the reason that American honey is now a drug in the British market. Bee-keepers, both here and in America, have reason to cry out against these adulterating practices of dealers and should decline to supply them with honey. We have before us a letter written to us a few years ago by Hoge & Co., asking us to supply them with our honey, and they said they were

prepared to give us our own price. Suspecting the purpose for which it was intended we declined to sell to them at any price. We hope others will do the same, and thus induce shop-keepers to purchase direct from the bee-keeper, instead of through a dealer. The list is rather an instructive one, and is worth a careful study, as it makes clear two very important points. First, it will be noted that in most cases the adulterated honey is labelled in such a way as to make one suppose it was pure and something extra good. For instance, No. 57, 'Choice comb honey,' No. 62, 'White clover honey from the apiaries of Central New York, warranted pure,' No. 78 is also 'warranted pure;' and one, No. 90, has actually the audacity to state 'Pure orange-blossom honey; is absolutely pure, no glucose,' and yet this is found to be adulterated. The gaudy label and the warranty therefor of an American honey-dealer appear to us in the vast majority of cases very much like a badge of its impurity. The second lesson is that honey in the comb is also adulterated. By referring to Nos. 57, 58, and 60, it will be seen that these are all comb honey, yet they are adulterated.

Where does this adulterated comb honey come from? Not from respectable bee-keepers, of that we are quite sure. We have the authority of Mr. Shippen Wallace, Ph.D., for the fact that this comb honey is adulterated, and it is therefore produced. How? That is the secret. Shall we be also told that this is a *Wiley lie*, or is there any other explanation than that this adulterated comb honey is manufactured on some of the adulterating farms by feeding bees? We are glad to notice that not a single sample of honey purchased of bee-keepers was adulterated. Further comment is unnecessary.

The *Bee-keeper's Magazine* has done bee-keepers good service in exposing this adulteration, and, in a vigorous article condemning the practice, winds up with the following remarks, which we commend to our readers:— 'So long as Messrs. F. G. Strohmeier and Co. continue adulterating honey, they should be shunned by all bee-keepers who have any respect for themselves or their pocket-books. The same is to be said of Messrs. McCaul and Hildreth, and the rest of the gang of adulterators. They should be made to feel that they are outraging the rights of the bee-keepers of this country, and for the few paltry dollars they may make in this nefarious trade they are ruining hundreds of bee-keepers, and rendering hundreds of others poor, with their families perhaps, in want.'

Mr. A. Todd, whose kindness to us when at Philadelphia we shall never forget, cried out, and truly, against this practice, and said the competition was so great that there was very little chance of making a living by dealing only in pure honey, but that rather than adulterate he would give up the business. We are glad to find that he has been true to his word. This is what the *Bee-keeper's Magazine* says:— 'It is a lasting monument to our friend, the late Arthur Todd, that, amid all the adulterating dealers about him, he stood aloof, and never soiled his hands with the dirty business, and that when he preached "Deal in pure honey," he also practised it.'

We subjoin the Report referred to from the *Bee-keepers' Magazine*.

ANALYSIS OF HONEY.

The forthcoming report of the Dairy Commissioner of New Jersey will contain notes on the quality of strained honey as usually sold in bottles and jars. Forty-two samples of bottled honey were analysed, and it was ascertained that out of thirty-one samples put up by packing-houses only six were pure. The samples

purchased in small towns and villages, representing strained honey put up by farmers, were all pure.

Below is a table of the samples analysed and the result of the analysis:—

STRAINED HONEY.			
Office No.	Where Purchased.	Name on Label.	Result of Analysis
57	Paterson	Wm. Thompson, Wayne Co., N.Y., 'choice comb honey'	Adulterated
58	"	McCaul & Hildreth Bros., N.Y. City, 'white comb honey'	Adulterated
59	"	Samo as 58	Adulterated
56	Hoboken	Ritter, Philadelphia; no label	Adulterated
60	"	Wm. Collins, Worcester, N.Y., 'choice comb honey'	Adulterated
61	Jersey City	J. V. Sharp Canning Co., Williamstown, N.J., 'clover honey'	Pure
62	"	Wardell & Watson, Brooklyn, N.Y., 'white clover honey from the apiaries of Central New York; warranted pure'	Adulterated
76	Newark	J. T. Dunham, 'superior quality of clover honey'	Adulterated
77	"	Thurber, Whyland & Co., N.Y., 'pure California white sage'	Pure
78	Hoboken	E. A. Walker, Greenpoint, L.I., 'superior XXX honey, warranted pure'	Adulterated
79	Jersey City	Wm. Collins, Worcester, N.Y., 'choice honey'	Adulterated
80	Hoboken	E. A. Walker & Bro., 135 Oakland St., Brooklyn, N.Y., 'choice honey'	Adulterated
81	Newark	Charles Israel & Bro., N.Y., 'choice California honey'	Adulterated
82	"	C. G. Leshe & Son, Pittsfield, Mass., 'choice extra clover honey'	Adulterated
83	"	No Name, said to be Ritter	Adulterated
84	Hoboken	Geo. D. Powell, 'choice extracted North-ern'	Adulterated
85	Newark	Wm. Thompson, Wayne Co., N.W., 'choice golden rod honey'	Adulterated
86	Hoboken	E. F. Watson, Brooklyn, N.Y., 'pure California honey from groves of San Diego; there is none better'	Adulterated
87	Paterson	McCaul & Hildreth, New York, 'choice extra honey'	Adulterated
88	"	Code, Effelt & Co., San Francisco, 'extra choice Los Angeles'	Pure
89	"	Frank Charters, New York, 'white clover honey'	Adulterated
90	"	F. G. Strohmeier & Co., New York, 'pure orange-blossom honey; is absolutely pure, no glucose'	Adulterated
91	"	Wm. Thompson, Wayne Co., N.Y., 'choice golden rod'	Adulterated
92	"	Andrew Jackson, Deposit N.Y., 'pure honey'	Pure
1416	Burlington	R. J. Dutton	Pure
1417	"	Sleeper, Wells, & Aldrich	Adulterated
1418	"	Arthur Todd, Philadelphia	Pure
1424	"	Arthur Todd, Philadelphia	Pure
1425	"	Western honey	Adulterated
1427	Bordentown	R. K. Allen, farm honey	Pure
1429	"	Wm. Collins, Worcester, N.Y.	Adulterated
1431	"	Shipp & Son, farm honey	Pure
1432	"	S. Garrison, farm honey	Pure
1434	Trenton	Wm. E. Johnson, Moorestown, N.J.	Pure
1435	"	S. P. Robinson, farm honey	Pure
1436	"	S. Holcomb, farm honey	Pure
1437	"	F. E. Erends, Dentsville	Pure
1438	Camden	Brown & Bros., State honey	Pure
1439	"	Arthur Todd, Philadelphia	Pure
1440	"	W. Collins, Worcester, N.Y.	Adulterated
1441	"	Gifford & Stiles, State honey	Pure
1442	"	Philadelphia Pickling Co., 'virgin honey'	Adulterated

—*Bee-keepers' Magazine*.

USEFUL HINTS.

WEATHER.—After several days of boisterous wind and most ungenial weather we are enjoying calm and sunshine, of which the bees are making the best use. Fruit bloom in abundance is bursting forth, and willows, elms, poplars, furze, &c., are now affording forage. Let us hope, then, that at last the trying winter is past, and a plentiful honey-yield is approaching. But of many a colony, alas! it may be said, *Mortua est*.

BACILLUS DEPILIS.—On all sides we hear of colonies dead, colonies queenless, colonies diseased, *Bacillus depilis* being very prevalent. For the latter disease we have found the best treatment to be plenty of ventilation

below and feeding on salicylised syrup. This should be done immediately the disease is discovered—by the number of dead bodies, bloated, black and shiny, being cast out—otherwise in a few days the population becomes so reduced, that death or gradual dwindling speedily follows. With the exception of the loss of a few weak colonies and of several aged queens—which ought to have been superseded before going into winter quarters—our bees have passed through the winter well, under enamel cloth and free from dampness or mouldy combs, the entrances being kept at full width until the time of pilfering arrived.

QUEEN WASPS have not appeared at present in our locality. We have not noticed a single specimen, which is somewhat remarkable at this advanced period. The absence of queens now does not, we fear, forecast the absence of their offspring throughout the summer.

FEEDING on thin syrup is still carried on vigorously in our apiary, and is thankfully and freely accepted by the bees. Apparently, they prefer it much to winter stores of candied honey, and are actively clearing out the latter. Pollen is now abundant in the fields, and with water and syrup supplied at home the bees have all they can want, and will amply repay the expenditure, we trust, by the future storage of surplus honey.

NATURAL SWARMING, if the weather continues bright and warm, will soon commence; and forward colonies, especially if surplus cases are not in use, should be carefully watched. Our own practice, as we have before stated, is to allow natural swarming, and to place surplus cases on the swarms which occupy the position of the parent colony, a part of the latter being used simply as a nucleus for queen-rearing (*vide B. B. J.*, vol. xv, p. 204). By these means we keep up a sufficient supply of young queens of superior quality—raised under the swarming impulse—for superseding old ones, and have a few over for our friends at the *minimum* of trouble and expense. The average yield of honey under this system will also bear comparison with most other systems. Of course there is no forcing swarms, the bees being allowed to follow their own instinct, surplus cases being placed on all colonies, as a rule, when they are sufficiently populous, at the commencement of the honey-flow. To those who prefer artificial swarming, we say, consult Mr. Cowan's book, p. 89, last edition.

HIVES AND SUPER CASES should now be held in readiness with foundation inserted. The best hive we consider to be one containing two similar equal and interchangeable chambers, each capable of containing ten standard frames and two division-boards or of taking a case of sections, with substantial roof, and four stout legs *not* splayed. Splayed legs are so apt to be kicked by the manipulator, unintentionally of course, that the temper of the bees, especially if they chance to be Cyprians, is not improved thereby. Two additional boxes, each taking ten frames of $14 \times 5\frac{1}{2}$ inches outside dimensions, are also very useful and desirable when working for extracted honey, or as a divisional brood chamber by those who prefer a deeper frame than the standard for wintering upon. In all cases we advise the trial of an excluding honey-board between brood chambers and surplus compartments.

REALLY GOOD SECTIONS, in our opinion, will always hold their own against extracted honey. But to combs intended for extracting neither drones nor queen must be admitted, if we desire to produce a first-class article. Last season we worked several cases of sections, both 1-lb. and 2-lb., in hanging frames, whose four sides were two inches wide, entirely covering the four sides of the sections, which being crowded into the frames were thus kept clear of propolis, and when finished were as clean and white as when first inserted in the frames. The frames were suspended in a plain four-sided case, just as we suspend brood frames in a hive, with a bee-space below them, and slotted dividers between the sections.

The method proved successful, and we hope to recur to it again.

EXPERTS.—We earnestly exhort experts to be very cautious as regards spreading foul brood. We always advise cottagers to destroy diseased colonies by burning hives, combs, bees, and all surroundings. Calvert's carbolic soap, used by the medical profession, and sold in small tablets in tiny tin boxes, is useful for washing the hands after manipulating foul brood. The clothes likewise should be disinfected, which may be effectually and cheaply accomplished by dredging over them a little of the Government Carbolic Powder, sold by all chemists in tin cases, perforated at one end, and holding about a quart, for sixpence. A cheaper and better disinfectant cannot be procured, and it ought to be used in every apiary.

WEAK COLONIES.—If a very weak colony, possessing a young and fertile queen, be made to exchange places with a strong populous colony about midday, on a fine warm day, when the bees are at full work, it may quickly be metamorphosed into a strong and prosperous one. The only caution necessary is to cage the queen of the weak colony until the following evening when she may be liberated without any fear of being attacked.

There is no more simple and easy method of equalising colonies at this time of the year than this. If the hives are similar in appearance and construction there need be no fear of failure, but under any circumstances we have never known the plan to fail.

OLLA PODRIDA.—*Honey-boards*.—Friend 'Amateur Expert' wishes to know why we advocate the use of honey-boards. In our last 'Hints' we said, that over the slatted honey-boards last season we had obtained sections which were simply perfection, and moreover the bees entered the crates and worked through the perforations as freely did as those colonies over which no excluder was used. That, to our mind, was sufficient reason for advocating further trial. We also suggested that non-success in the use of excluder zinc, in this country, had arisen from laying the zinc sheets upon the top bars of brood frames, instead of using the slatted boards, and allowing bee-space above and below them. This was our own experience, and we have in time past condemned the use, under the former conditions, of excluder zinc, as loudly as any one. Our experience differs from that of 'A. E.' as to the amount of brood and pollen liable to be deposited in sectional and other supers when exclusion of drones and queens is not practised. In moist seasons, when the population increases fast, and honey comes in slowly, we have repeatedly seen sections filled with brood, and pollen placed around it; and although 'A. E.' gives it as his experience that less than two per cent of his sections are defiled by brood or pollen, nevertheless, he has, in days gone by, mentioned the case of a 'leading light' in his 'adopted country,' who said to a friend, 'Come and look at my super, the bees have filled it and sealed it over in no time. Splendid! it is fit for the show!' 'Yes,' said the friend, 'it is the handsomest specimen of drone brood I ever saw; all the sections are complete; I hope you will get first prize, you deserve it.' (*B. B. J.*, vol. xiv, p. 188). So then *sometimes*, at least, the instinctive yearning for drone brood leads to defilement of sections. Wherefore, if, as our American cousins say, and as our own experience points in the same direction, bees work sections of superior quality, and, to say the least, as quickly, over excluding honey-boards as they do without excluders, why should we debar ourselves from the use of these? Surely not because our American friends succeeded where we ourselves have failed.

Additional reasons—to those we gave in last 'Hints'—in favour of 'excluders,' we venture to think are, (a), exclusion of drones from congregating in sections, and to a certain extent discolouring them; (b), prevention of the building of drone-comb in sections, which

frequently takes place, even on the thinnest worker foundation, and spoils the appearance of the sections; (c), prevention of the discoloration of the central sections, immediately over the centre of the brood-nest, by the ascending heat, and the close clustering of the bees.

With regard to the last objection, we rarely take off an ordinary case of sections without finding the central ones of a dirty brown colour, unless 'excluder' has been used. This, however, is not the case where the 'Raynor-divisible-section-cases' are used; and we are bound to say that in them we have never met with a single instance of deposition of brood. Nevertheless, in future practice our intention is to place these divisional cases on the excluding honey-boards; so convinced are we of the certainty of thus obtaining more perfect sections than when the admission of drones and queens to super cases is allowed. Indeed the testimony of such ardent and experienced bee-keepers as Mr. W. B. Carr, and others, together with the foremost apiarists of America and Canada, should not be lightly esteemed, or quietly ignored, without a full and fair trial. Superior sections, the case with which they are removed from the brood-chamber, and other advantages enumerated above, induce us to forecast for the slatted excluding honey-boards a great future in the production of comb-honey. Restriction of the brood-chamber—sufficiently large, of course—solely to the raising of brood, without expansion or contraction after the honey flow sets in, and storage of surplus above it, with an intervening honey-board, and tiering up, as required, both for comb and extracted honey, we believe will be the 'system of the future.'

BLIZZARD may or may not be an Americanism, but Nuttall certainly gives it as such. As 'A. E.' states, there are no doubt many obsolete English words, or words whose meanings have been entirely changed in the old country still in use in the United States, *e. g.*, the words 'sick' and 'sickness,' which still retain the old signification in the U. S., while here they have been superseded by 'ill' and 'illness,' the later usage of sick and sickness conveying the idea of nausea only. To the derivation of the word 'blizzard,' suggested by the correspondent of *Notes and Queries*, we prefer our former suggestion of Blinkard, Blizard, Blizzard, meaning a 'Blinder.' We were born, bred, and educated, during the first quarter of a century of our life, in a Midland county, and freely mixed with all classes—high and low, rich and poor, educated and uneducated—in three or four Midland counties, having kept up acquaintance with the localities for more than forty years since that period, and few if any provincialisms have escaped us, but we never heard the word 'Blizzard.' Blast and Blazer, are common enough, and the former is frequently used as an oath, but Blizzer, for Blazer, we never heard, nor the verb Blissom, which has a widely different meaning. We incline, therefore, to Nuttall's view, that 'Blizzard' is of American coinage to express the violent storm for which they had no word.

Selected Query.

[8.] *What should be done with weak colonies in spring? How can they be strengthened? What is best to be done with mouldy combs? Can they be prevented?*

Two colonies may be united in the manner described by me in Query No. 7. They can be strengthened, first, by contracting the frames of comb to the number the bees can well cover by feeding, to stimulate brood-rearing, and then, when there are sufficient bees to protect and care for it, by exchanging a frame of empty worker-comb for one of sealed and hatching brood with a strong colony, another frame of brood may be added from time to time; but great care must be taken not to do this too fast, and to first ascertain that they are strong enough to cover it and prevent its being chilled. It is

best to cut out the mouldy portion of comb, and fill in the space with clean worker-comb or foundation. If simply cut out the bees will usually fill the spaces with drone-comb. It can be prevented by the entrance of the hive being left open the whole width during winter, thus giving better ventilation and circulation of the air at the bottom of the hive, and keeping all dry.—JOHN M. HOOKER.

Allow no more combs than actually needed, place the dummies close up to same, have all well packed and judiciously fed, with entrances contracted; such will hold on till strengthened by a frame of hatching brood. Mouldy combs, if not unto rottenness, can be brought back into use by heat, or hanging in a dry, airy room, and when dry the mould, so far as possible, brushed out; but if combs are placed to a winter distance of 2 in. apart (centre to centre) at right angles to a full entrance with plenty of bottom air-space, they will not mould provided that the roof and hive-walls are sound.—JOHN H. HOWARD, *Holme, Peterborough.*

(1.) If very weak I would unite two or three together; but if only moderately reduced in strength and possessing young queens, I would strengthen with brood from strong colonies, being careful to only give it in such quantities as the weak colony would cover with bees. (2.) By adding frames of eggs and hatching brood from strong colonies able to spare them, removing spare combs, and gentle feeding. (3.) Brush off all the mould possible, and then place the combs in the centre of strong stocks, and the bees will soon complete the cleaning. (4.) Yes; by giving them to the bees to clean off the loose honey after extracting, and then hanging them in spare hives, or boxes, and storing in a dry room until wanted for use.—H. WOOD.

Unite them, and, if possible, give one or more combs of sealed brood—taking care not to give *more than the bees can cover at once*—and pack up warmly. Melt them down and use foundation, unless the combs are very even and clean; then dry in the sun and brush as clean as you can; spray with salicylic acid, or phenol, and fumigate with brimstone before re-using. Combs covered with bees in a dry hive I have never found mouldy.—W. E. BURKITT.

Build them up by giving hatching brood in such quantity as they can cover easily, if the queen is of any value; cover up warmly and reduce entrances. To prevent store in *dry* condition, half an inch apart in autumn, and paint box with solution of carbolic acid; if good in other respects should utilise them later in strong stocks. Fumes from burning sulphur, or weak carbolic solution, are both excellent preventives of disease.—JOHN EDEY.

If a weak colony possesses a prolific queen and has commenced breeding, I would confine it between division boards and give it a frame of sealed brood from a strong colony, feeding gradually on warm syrup, and covering up warmly, until it attained to the average strength. But in cases of this kind everything depends upon surrounding circumstances, and it is impossible to give any but general rules. Melt down mouldy combs.—GEORGE RAYNOR.

Having weak colonies in spring, I should prefer to unite two or more together so as to make one good colony. They may be strengthened by adding frames of brood from other hives as the bees are able to cover, but I doubt much if the latter would be profitable. Combs found to be mouldy, and not clogged with pollen, should be softly brushed and sprayed with salicylic acid solution, after which they may be hung up in a dry, airy place for further use. If the combs are very mouldy, I would put them into wax basket for melting down. In these days of cheap comb-foundation no risk should be run with old and doubtful-looking combs.—WM. McNALLY, *Glenluce, Scotland.*

Unite them to others; or if the queen is worth saving they can be strengthened with frames of hatching brood from other colonies. If only slightly mouldy the bees will clean them out, but if very much so the melting-pot is the best place for them: can be prevented by dry hives of sufficient thickness and allowing upward ventilation, or wide entrances during winter.—WM. N. GRIFFIN.

It would depend on the queen: if she was worth saving I should contract the brood-nest to three or four combs, feed with 'Good' candy, to which some meal was added; and if I had a frame of brood I could spare from a strong colony I should add that with as many young bees adhering as possible; but if the queen was aged I should unite to next stock. I find a strong stock of bees will soon clean out mouldy combs. Those combs that are pollen-clogged and got mouldy had better be melted down, as a strong colony of bees would work out a sheet of foundation as quickly as they would clear the old comb of mould besides leaving many of the cells full of useless pollen: the new comb would be far more useful in the brood-nest than the old one under such circumstances.—W. WOODLEY.

If there is a stock standing near, I find it a good plan to take the queen away, and unite the bees to the stock, putting what brood there is in the centre, and move the stock midway between where the two stood before. If they are not too weak they might be shut up close and stimulated by continuous gentle feeding; giving occasionally a frame of brood from stronger stocks that could spare them, and inserting in their place a frame of foundation. Where there are any mouldy combs it is best to take them out and hang them to dry, and as the stocks increase in strength give sheets of foundation. I have found some mould in my hives where there has been too much covering on the tops of the frames, while in other stocks that had not so much the combs were quite dry.—JOHN WALTON, *Honey Cott, Weston.*

Unite and utilise spare queens by giving them to queenless stocks. Great impetus can be given to mediocre colonies by reducing space between combs about end of April or beginning of May if weather is fairly warm. Give frames of brood from strong colonies after weak ones have somewhat recovered. If rotten with mould cut part out, but if only superficially mouldy, dry and then brush off as much of the mould as possible, then spray with salicylic acid solution, and return to bees. Combs will never get mouldy if hive is dry and thickly populated. Combs that have been removed from hives will keep free from mould if properly cleaned out by bees in autumn, and then put away in sound boxes in dry position.—W. B. WEBSTER.

Wait until a few young bees hatch, and then unite; or hold them until swarming time, then unite and use one queen for a stock that may have swarmed. It is very bad practice to rob the strong to help the weak; better far let the weak help each other by uniting judiciously. Mouldy combs do not occur in a dry, well-ventilated hive.—SAMUEL SIMMINS.

ASSOCIATIONS.

IRISH BEE-KEEPERS' ASSOCIATION.

The Committee have made arrangements for exhibiting hives and other bee-keeping appliances and honey at the Irish Exhibition in London. Samples of last year's honey will be shown at the opening of the Exhibition, and in August it is intended to make a substantial exhibit of new honey. Prizes will be offered to members for the best contributions to this latter exhibit.

Since the Report published in the *Bee Journal* of 12th April, the two following District Secretaries have been appointed:—For Co. Leitrim, Rev. J. Garnier Digges; for Co. Donegal, Mr. George Turner.

MONMOUTHSHIRE BEE-KEEPERS' ASSOCIATION.

At the Flower Show to be held at Monmouth on the 15th and 16th of November next the following prizes for honey will be given:—Section Honey, best six 1-lb. sections—(1) 10s.; (2) 6s.; (3) 4s. Run Honey—best six 1-lb. bottles of this year's honey—(1) 10s.; (2) 6s.; (3) 4s. Further particulars may be had from Geo. Tucker, Esq., Hon. Sec., The Shubbery, Monmouth.

HULL AND DISTRICT BEE-KEEPERS' ASSOCIATION.

A meeting of this Association was held at the Station Hotel, on Wednesday evening, May 2, when Mr. David Wilson, J.P., was unanimously elected President of the Association, the Rev. R. M. Lamb of Burton Pidsea, and Mr. E. Harland, were elected Vice-Presidents, and Mr. Charles Howes and Mr. Henry Harland, hon. secretaries. The objects of the Association, which is under the patronage of Mr. Arthur Duncombe, M.P., are the advancement of rational and modern bee-keeping in place of the old and barbarous sulphur-pit method, and the spread of a profitable method of bee-keeping to the advantage of cottagers and others in the East Riding. The prospective arrangements include, amongst other things, a lecture on some subject of interest connected with bee-keeping at an early date, and a honey fair in the autumn.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

Communications relating to the literary department, reports of Associations, Shows, Meetings, Echoes, Queries, Books for Review, &c., must be addressed only to 'THE EDITOR of the "British Bee Journal," c/o Messrs. Strangeways and Sons, Tower Street, Cambridge Circus, W.C.' All business communications relating to Advertisements, &c., must be addressed to Mr. J. HUCKLE, Kings Langley, Herts (see 2nd page of Advertisements).

In order to facilitate reference, Correspondents, when speaking of any letter or query previously inserted, will oblige by mentioning the number of the letter, as well as the page on which it appears.

OUR HONEY IMPORTS.

The value of honey imported into the United Kingdom during the month of April, 1888, amounted to 250*l.* [From a return furnished by the Statistical Department H. M. Customs to E. H. Bellairs, Wingfield, Christchurch.]

IN-AND-IN BREEDING.

[1622.] 'Theta' (1604) takes the bull by the horns with a vengeance when he so courageously rushes in to show your readers how much they are mistaken when they imagine it possible to improve their bees (or, indeed, the breed of anything) by a judiciously carried out system of crossing; or that they can reinvigorate waning or expending force by a timely infusion of fresh blood. He plunges *in medias res* and boldly tells us that as he has, to a small extent, proved that there are no evils to be feared from consanguinity; that as Mr. Greene has 'for five years bred from the progeny of a single pair of fantails;' and that as M. de Roos married his cousin without any serious results (if any), in-and-in breeding is to be commended, and whole generations and aeons of historical record are to be by these means falsified, and rendered worthless by this absurd new doctrine.

The letter of 'Theta' is so well written and thought out, that on that account it is worthy of consideration; but the germ of his communication would lead me to dismiss it from very serious argument, so much am I

convinced of the instability of the foundation on which his structure is built. And this is more consideration than is shown to *their* opponents by M. de Roos and Mr. Greene; for while M. de Roos says, 'The theoretical statements of the adversaries of consanguinity MAY BE lightly esteemed' . . . He also states, 'The results of numerous direct and indirect experiments alone can solve the difficult problem.' Mr. Greene characterises 'the belief that consanguinity is productive of deterioration' AS AN ABSURDITY, and is thereby inconsistent with his subsequent statement:—'Heredity is a potent factor in the determination of health no less than of disease . . . but when it comes from both (parents) the tendency to either strength or weakness is increased to an appreciable extent, or in the ratio of one to four, and so on in geometrical proportion.' He also says that 'consanguinity alone will not produce disease in the offspring.' Neither will an open drain near one's house, but both will offer a specially prepared alighting place—a happy hunting-ground—for just that very disease which goeth about like a roaring microbe, &c. Yet Mr. Greene himself tells us further on in 'Theta's' letter that 'consanguineous parentage transmits to posterity with reduplicated intensity' certain diseases and characteristics; 'in such cases Nature providing her own remedy, for, after a time, the race thus produced will fail from sheer lack of vigour to maintain it.' In order for this gentleman's experiments to be of service in an argument in favour of in-and-in breeding, it would be necessary for his fantails of to-day to be the descendants of *nearest* relatives in each generation; for, in a question of this sort, we cannot allow breeders to look around for the finest birds and keep breeding from them. We should have consecutive generations of *nearest* kin crossed, and to prove an argument 'the nearer the better' in opposition to the opinions we hold of 'the further away the better,' make us *avoid* relatives and proceed to the other extreme—yourself to give point to *your* argument. I imagine the pigeon-fanciers of the future won't have many of 'Greene's strain of fantails.'

Let M. de Roos carry his human experiments a little closer to the argument and intercross in nearer relationship (of course *the nearer the better* according to these three authorities) for generations, giving nature at least a chance, in point of time, to improve the race; and I think she would 'leave not a wrack behind.' The directories of the period would be ransacked in vain for, at least, male representatives of the family.

Even if the instances given of alleged improvement by in-and-in breeding could hold water as proving *bona-fide* improvement, they are so meagre and few compared to the myriads of examples to the contrary we see in a rough survey of animated nature, that they could only be adduced as 'exceptions which prove the rule.' Besides, it has yet to be proved that abnormal sports and freaks of Nature, which are all right to 'the fancy,' are at all improvements on original ancestors as to vigour, size, fecundity, and hardness of constitution, just as it has yet to be shown that M. de Roos' male grandchildren (or even children) are improvements, mentally and physically, on this celebrated author. Nearly every man of middle age has seen instances of human degeneracy or deterioration resulting from the marriage of cousins in *one* generation; and I have a well-authenticated instance of cousins marrying for *four* generations, the result being that all the progeny were devoid of hair and nails, and were either imbecile or blind. On the other hand, instances of benefit resulting from judicious crossing of varieties are indeed 'too numerous to mention;' they occur all through the animal and vegetable kingdoms.

I regret that 'Theta' instanced the Jewish race in support of his theory: it is bringing Bible history into the argument, and that should have been avoided; but so long as it has been introduced, it is necessary to meet

the charge that interbreeding is, or has been, beneficial to the Semitic race by the distinct statement that true in-and-in breeding has not been faithfully carried on by them, and even so far as it has been partially practised it has been detrimental to them in my opinion. In fact it is, in all likelihood, one of the causes of the peculiar position of that people amongst the nations of the earth,—wanderers, without organization or head, over the whole surface of the habitable globe, subject to persecution and misery everywhere; not remarkable, to say the least of it, for those vigorous qualities which go to make strong nations, and which are characteristic of peoples of mixed ancestry.

Your correspondent says that in all the sacred writings there is no direction to *prevent* in-and-in breeding. I will not contradict him, as it will open up a religious discussion; but as he is evidently interested in this aspect of the question, I may be pardoned for asking him to search out where Cain found his wife, driven out as he was into the land of exile (Cain, the first man born of woman!). Certainly not in a consanguineous union, of which there is, I believe, no instance amongst the children of Adam. And though there is nothing to *prevent* in-and-in breeding in the following passage, yet the inference, to my mind, is decidedly in a preventive direction:—'When men began to multiply on the face of the earth, and daughters were born unto them, that the sons of God saw the daughters of men that they were fair; and they took them wives of all which they chose. There were giants in those days; and also after that, when the sons of God came in unto the daughters of men, and they bare children unto them, the same became mighty men which were of old, men of renown.' Let us leave the Bible alone, please, 'Theta,' for we may not, all of us, take it as being a history of the origin and growth of the whole human family.

It seems to me that 'Theta' says a great deal to upset his own argument, *e.g.*, 'Take two known consumptive or scrofulous human subjects and unite them, and the chances are, many thousands to one, that the progeny will be consumptive to a greater degree than the parents.' Just so. That is exactly the point. You emphasise a taint in the blood of the union, and if one parent member of a family have a taint in the blood, his or her descendants are likely to receive it hereditarily; *ergo*, to lessen the risk, relations should not intermarry, and, *q.e.d.*, the marriage of near relations is to be condemned because of this danger. Again, he tells us, 'An evil of this sort is ten times more apparent when the parents are nearly related,' because 'first cousins are the produce of a pair of grandparents. Presume one or both grandparents to be suffering from an organic disease, does it not follow that both the cousins have the seeds of it in their bodies, and that the bodies of their progeny are favourable incubators for its propagation?' Here we get Truth itself; but I certainly read it as being condemnatory of consanguineous unions.

'Theta' asks for a second Lubbock to arise. Why not let the first Lubbock arise (a second Frankenstein) and speak for himself? In his work *The Origin of Civilisation* (p. 125), Sir John Lubbock says: 'The inferior energy of children sprung from in-and-in marriages.' 'The advantage of crossing, so well known to breeders of stock, would soon give a marked preponderance to those races by whom exogamy was largely practised.' On p. 123: 'The evils of marrying near relatives.' 'Exogamy a reformatory movement to break up the intermarriage of blood relations.' To quote further would be to give you pages of marriage laws showing how too near consanguineous unions were avoided. Every one will, I think, admit that the lower we go in the scale of humanity the more barbarous and rude are the customs of the race as regards the relationship or otherwise of parents towards each other, and, per contra, the higher the civilisation the greater is the care exer-

cised to prevent what may seem too near consanguinity (witness the action of the bench of Bishops with regard to the Bill for legalising marriage with a deceased wife's sister).

Sir John Lubbock, in his book, comes to the following conclusions:—

1. That existing savages are not the descendants of civilised ancestors.

2. That the primitive condition of man was one of utter barbarism.

3. That from this condition several races have independently raised themselves.

And I gather from the many instances given in his book that those races which practise, or have practised, consanguinity in their breeding do not advance, but either stand still or decline into mere savagery, and ultimately die out, while the converse is the case with those whom we observe as avoiding in-and-in breeding.

Without being insulting to any civilised race, I will take the Australian nation, the Bosjesmen, and the Redskins as illustrating the one practice, and the English, French, and German speaking people the other.—R. A. H. GRIMSHAW, *Horsforth, near Leeds.*

BEES COLLECTING HONEY.

[1623.] Saturday, the 5th of May, I visited my bees at Farnborough in Kent, about ten miles from my house. It was a beautiful day, and quite a treat to be away from London, to realise that the recent rains and the warmer nights had at last started all trees, shrubs, &c., into active life. The fields are green, and the buds of the fruit trees are beginning to open, the gooseberries are in full bloom, and my bees were busily at work on them, bringing in honey quite fast, and had evidently, from the appearance of the combs, been doing so for the last few days, when the boisterous winds would allow. The nightingales were singing close to me during the examination of four of my colonies. The hives were in splendid condition, they had wintered well, and three of them full of bees, and the majority of the frames of combs nearly filled with sealed and hatching brood on both sides, just in the condition to have the advantage of the whole of the fruit-blossom as it comes out, if the weather is only propitious. In shaking the bees from some of the combs during my manipulations the thin honey positively poured out of the cells drenching the bees as they left the combs; the hives smelt quite strongly of the gooseberries, the peculiarity of which no doubt many of your readers have observed. The upper part of many of the combs had been built out with nice white comb, a hint that supers must not long be delayed, and had I not been pressed for time I should have at once put them on. Fortunately professional business calls me into the neighbourhood again on Wednesday, when I hope I shall get time to super them.

Being at a distance it is impossible to give the bees the attention they would otherwise have. I think, however, that nothing that I could have done, had I been on the spot, would have improved their condition. I am a great believer that the majority of bee-keepers over-manipulate and meddle too much with their bees; robbing them too much of their natural stores. Feeding late in the autumn, however judiciously done, excites the bees, stimulates the queen to lay, when, if left to herself, she would be resting. Many of the old bees die from overwork and undue excitement, leaving the hive in many instances 'to perish in the cold'; the young bees hatching late are often unable to take the necessary cleansing flights, spring dwindling and dysentery being the result.

My bees were left with abundance of natural stores, were not fed in the autumn, or anything done to them since the beginning of October until about three weeks ago, when I just looked under the quilts to see they had

sufficient food left after the long winter, and they have not been fed this spring; nevertheless they are in as good a condition for honey-gathering as I could wish them to be. I am sure that in leaving plenty of natural stores in the autumn we get amply repaid for so doing the following season.—JOHN M. HOOKER.

SELECTED QUERIES: INFORMATION DESIRED.

[1624.] I was very much pleased and instructed by the answers to your 'Selected Query' of May 3rd, 'What is the best thing to do with queenless colonies in spring? Should they be united to those having queens?' I should like to ask a few questions, perhaps some one will answer. If they were queenless before May, or if they were weak colonies, then the answers generally were, 'Unite,' with the exception of Mr. Edey, who would form nuclei, giving artificial heat. If queenless in May and strong, the opinion which carries weight, but needs further instruction, is, that brood or eggs should be given for queen-raising. Probably in the south no difficulty would be felt in having drones flying so early, but in some districts to the north there would be danger of not having any flying. Yet, by the answer of Mr. McNally, that difficulty in his case is got over. Are the drones produced naturally, or are they produced by giving empty combs to selected stocks? Mr. Edey's answer has the appearance of increasing this difficulty. It is true he applies artificial heat to the early nuclei for queen-raising. Does he produce the select drones by the same method? If so, are they kept under cover? Are they allowed to fly in the open for fertilisation?

I was very pleased to find that Mr. Raynor had been able to successfully winter nuclei of three or four frames with young queens. They are of great value in spring to replace the loss of queens during winter, or to build up into stocks for summer work. To do this, is any extra protection needed? Would it be necessary to have them in the house? Would they be wintered in the open garden? We think answers to the above would be of great service to many of your readers, and could be given with the greatest satisfaction by the parties named.—R. M.

BIRDS v. FRUIT-BUDS.

[1625.] I am pleased that 'Birds v. Fruit-Buds' has been revived in the pages of the *Bee Journal* by Mr. Hiam. Although the subject is not strictly speaking an apian one, yet it affects the bee-keeper more closely than it at first appears.

The culprits of bud devastation are our old enemies, the blue-tit, tomtit, and the bullfinch, a most accomplished bud-consumer. It is simply incredible the amount of damage two or three of these birds are capable of doing in a few days. The buds are not safe from their voracious appetites until almost ready to burst into flower. It is not only fruit-buds that they have an affection for, but hawthorn, bird-cherry, sloe, blackthorn, myrobellia plum, &c., all come within their bill of fare. The damage, of course, is done in winter and spring, and we do not know of it until the time flowers should appear, then we solace ourselves by blaming the weather, or that it is not a fruit year.

As fruit-blossom forms a considerable item of bee-forage it behoves the bee-keeper to use every means to take advantage of it, and also to lessen the chance of any of it being destroyed by birds, which ought to be shot whenever they are seen at their destructive work. Many people think that they are looking for and destroying insects, when in reality they are simply and completely relieving the trees of a valuable crop of fruit.

It is decidedly monstrous that so much legal and moral protection should be extended to such numbers of

our bird fauna. This protection is, I am sorry to say, rapidly increasing, and, too, at the expense of agricultural occupations (including bee-keeping).

It is very delightful no doubt, and I can thoroughly understand the enthusiasm a suburban resident would exhibit should there perchance visit his garden either a bullfinch or blue tit, but should his feathered visitors insist on acquainting their hungry stomachs with the quality of his gooseberry buds, the suburban resident, I opine, would (unless ignorant of the damage they were doing) think, after all, that it was rather too much of a joke that his crop of mellow gooseberries should be at the mercy of his gay visitors.

In the country where these pests are more numerous, it is a real nuisance to many a small holder, market gardener, &c., to be always in the *qui-vive*, gun-in-hand state, as it is to him and to many others means a vast deal more than those kind (?), hearted folks (some of whom tie pieces of suet on a string and take pleasure in watching the trying evolutions of the bird in his endeavour to get a mouthful) are aware of.

I can put on record here the fact of a five-acre orchard's produce being totally destroyed by these birds two years ago.

I am glad that the sparrows here have not acquired a taste for fruit-buds. I have watched them very closely for years past, but have never detected them eating any. They, however, destroy crocus and primrose flowers and revel in green peas.—HENRY DOBBIE, *Thickthorn, Hethersett*.

SHALLOW FRAMES.

[1626.] I am much interested in Messrs. Carr and 'Useful Hints' opinions on shallow frames, but has it not come too late for them to lay down the bounds of measurement seeing that there are so many thousands of such frames in commerce already? Mr. Carr declares his conviction that a 6-inch box with a 5½-inch frame is the best surplus chamber extant for all purposes connected with working for extracted honey. Now why is the above measurement of frame the best? Is not a 6-inch frame equally as good?

Mr. Howard, of Holme, exhibited at Norwich in 1886 super boxes containing frames of the usual standard length by 6 inches in depth, and since then this practical manufacturer must have sent out a great number,* and I believe was the first maker to offer them to the public. I use them myself and can find no fault whatever in the size; and no doubt there are many more bee-keepers like myself to whom the Howard shallow frame is of some interest; and should the B.B.K.A. decide on any given measurement for a shallow frame I trust the 6-inch Howard size will not be ignored.

I fail to see the advantage or the reason of Mr. Carr's 'firm conviction' as to his measurements being 'the best.' No doubt his size is very convenient, and may work well, but I claim for the other size the same good qualities.—HENRY DOBBIE, *Thickthorn, Hethersett*.

RUST FROM SYRUP CAN.

[1627.] Not long since I purchased from a well-known bee-keeper's supply firm a 'Bee Proof Syrup Can,' for which I paid 6s., hoping thereby to save time and trouble in carrying syrup about. The first time I used the said can everything appeared to go well. A day or two since I placed a second lot of syrup in it, and filled my feeders therefrom. To my surprise this morning on going to replenish the same I found that all my stocks (eight) had not taken any of the syrup, so I took off the said feeders to ascertain the cause, and discovered that the syrup had

* I have communicated with Mr. Howard and learn from him that he has sent out some 35,000 shallow frames of 6 inches in depth.

a brown yellow tint instead of pure white as syrup ought to have. I find that the hinge of the can lid and the spout had rusted, and the rusty liquid running down the sides of the can had polluted the syrup. The result being that I had to throw away twenty lbs. of syrup, and the can I can't safely use again, so that there is a dead loss of at least 9s. No wonder amateurs get tired of bee-keeping when such things happen, and I think the above should be made public as a warning to amateurs like myself.—LEX, *Sussex*.

SAVED!

[1628.] In passing along amongst my hives at 2 o'clock yesterday, I found, on the alighting-board of a stock recently sent me in a present, and which I had not had time to examine, four bees evidently in a weak state. My suspicions of starvation were aroused. The hive was still, no work going on. All the other stocks busy. Plenty gooseberry blossom to attract them.

Lifting the heavy wooden cover, I found the bits of carpet in a disordered state, freely admitting bees through, these were crawling about in a half-dead condition. A further examination showed me a hive well stocked with bees, but nearly exhausted for want of food. Hastily bringing two sections from the 'bee-shed' I laid them flat side down over the frames covering all over with fresh warm carpet, packing well all around. Above, I laid across the sections (carpet between of course) a large hot iron, covering over with more carpets, then the wooden cover, stuffed the six little ventilating holes, blocked up the entrance entirely. Across this and resting upon the entrance blocks, I placed another very hot iron keeping it in that position for half an hour. By that time there was a lively hum inside, removing this iron to one of the side walls supporting it upon bricks, thus warming the walls of the hive. Then gave space at entrance for one bee to pass.

The bees were rejoicing, and gave every evidence of returning vitality by a noisy hum, clearing out some young chilled, well-advanced brood. But for the timely arrival of artificial heat of food a good stock would have been lost. To-day they are busy and active even in the midst of showers. The hot irons were procured from a friendly tailor's workshop near at hand.

The reader will notice the bees were not allowed to touch the irons.—THE BRAES, *Downe, N.B. May 1*.

CAUTION.

BEES-WAX FOUNDATION & PURE COMB FOUNDATION.

[1629.] Being one of your regular readers and a well-wisher to all concerned in honest bee-ology, I thought a word or two of caution to those intending purchasers of comb-foundation, who, like myself, are not overdone with ready cash, and at the same time are anxious to buy in the cheapest market, might be seasonable and acceptable if you will allow me the space in your paper.

When comb-foundation was almost a novelty, I adopted it, and was delighted with the benefit derived from its use. Since then I have used it freely; by freely I mean full sheets, everywhere instead of starters and half-sheets. When I commenced I believe the foundation-makers in this country might be numbered on the fingers of one hand; now, according to what one can gather from the different advertisements, there is quite an army of them, no doubt called forth by the demand for their produce; but I am afraid the competition engendered thereby has not been of any benefit to the interests of bee-keepers.

The reformation of bee-keeping was advancing with rapid strides from the dark ages of sulphur pits, and honey looking like that juvenile corrective mixture treacle and brimstone, with a flavour not much better,

and medicinal properties producing results most delightful from a motherly point of view, to the time of our lovely tiger-like (in more senses than one) bees, sections transparent, and honey brilliantly clear and tempting.

I am sorry to say these improvements have not gone on all round, for, as the demand for comb-foundation became greater, the makers—not all of them—have produced an inferior article, and deliberately advertise it to the public as pure comb-foundation. To my own chagrin I have used this horrible stuff, foundation is a misnomer, as that is exactly what it is not. The bees—poor deluded creatures, like myself—take to it like ducks to water, and when warm and partly laden with brood, honey and bees, the cells which should have all sides equal will be quite oval, and of no use whatever for brood or honey. This is not the whole of the trouble; if it happens to be hot weather, nineteen out of every twenty sheets will fall down and curl up, forming a roly-poly bee-and-wax pudding on the lower bars of the frames, binding them all together, to the disgust of bees and bee-keeper.

I know of nothing more provoking than on a warm evening you wish to extract some surplus honey, and, upon opening a hive, you find your bees all in a mess at the bottom; your queen (a beauty) rolled up in the general wreck. If others can refrain from saying words that ought not to appear in a Sunday-school primer, they are more clever than myself.

Moral.—Get your foundation from some reliable, honest, old trader, who is too anxious about his fair name and reputation to risk compromising it by selling such rubbish. Ask for pure bees-wax comb-foundation, and see that you get it! If it is a little more expensive, pay and grin. Better pay and grin now than stamp and swear after you have wasted your money and ruined your colonies.

As a test for the quality of comb-foundation, experience has taught me that if you can wrap a piece round your finger like the roll gingerbread sold by confectioners it is utterly worthless; but, on the contrary, if it will snap or split off upon being bent, you may safely accept the sample. I am aware a few sheets get shaken to pieces in transit, but I prefer to see it so, as that proves, to my mind, its fitness for foundation. These remarks more especially allude to the thick body foundation, and not to super foundation, as my experience has been highly satisfactory with respect to supers.

The prime cause of my writing this article is the derisive, sneering, and jeering look of an old-fashioned croaker, who has seen the mess I am in, and who says, 'Yah'll not catch me putting onny o' that 'ere darned stuff to my bees!' The same man, a few years ago, presented himself, all fragrant with tobacco-juice and smoke, in my shop amongst a lot of ladies, and propounded the very solemn question, 'Do yah want to buy onny honey?' at the same time producing a sample of candied stuff out of his coat-pocket in a piece of brown paper. It is needless to say there was no trade between us. But if we wish to assist the poorer classes and the class from which this man comes, I think we ought not to adulterate our appliances, and so weaken our chance of proving to them the advantages of bee-keeping as taught in your very valuable *Journal*.—LANCOLNSHIRE.

BEEES AT SHOWS.

[1630.] I am glad to see suggestion made by 'Village Shoemaker' in a recent issue of your paper. I have kept bees in bar-frame hives for the last three years, and have attended several shows during that interval, at which there are bee experts. They drive the bees from one skep into another and stop at that point, not further showing how to transfer from skep to bar-frame. Neither do they show how to place sections in their proper position, nor how to fix comb-foundation. We

know there is a right and a wrong way of doing everything, and the poor cottager, converted from straw skeps and sulphur, yet unaided by the expert's superior knowledge as to the proper fixing up of bar-frames, would, in all probability, hit upon the *wrong* way. I sincerely trust your note at the end of 'Village Shoemaker's' letter will have the desired effect, and that in future at shows will be seen cottagers leaving the expert's tent enlightened and not mystified as to the proper management of bar-frame hives.—EDMUND J. JONES, *Ysgubor Fawr, Pen-dergyn, Aberdare, May 5th.*

SOFT CANDY FOR SPRING STIMULATIVE FEEDING.

[1631.] Take seven pounds of lump sugar (white crystallised will do), two table-spoonfuls of vinegar, one teaspoonful of salt, boil together with one quart of water, crush any lumps that may be still undissolved and continue boiling until the mixture attains the heat of 240° to 245° Fahr. If you have not a thermometer registering these high figures take a pipe stalk and dip it into the sugar, after having drawn off what adheres to the pipe between the thumb and finger, try if it will stretch out a fine thread between the thumb and finger about an inch long; if it is not strong enough to do that, it is not quite ready and must boil again a little longer, perhaps five minutes, according to the fierceness of the fire; but great care must be taken not to pass this degree, which is called 'The Feather' by confectioners, as the candy would then be so hard the bees could not use it. Upon the desired degree being reached add eight ounces of flour, and stir upon the pan sides until it looks like so much thick cream, in which condition it should be poured upon a slab or smooth table, or, failing these, a doorstep, and with a long flat stick work it about *thoroughly* for fifteen minutes, and then put it into any old cardboard box lids or sardine-boxes. Allow it to cool, and it will be ready for using under the quilts of the hive.

This candy is about as stiff as candied honey and looks very much like it. For spring feeding it is excellent (especially in a cold spring like the present one). There is no fear of it running down among the combs as it is tenacious and tough like a piece of soft putty, or the beautiful white cream we get in the finest quality chocolate creams; the manner of preparation is the same, of course without the salt, vinegar, and flour.—H. S. F.

MODERN BEE-KEEPING.

PROGRESS IN BEE-KEEPING.—The last fifty years have amply compensated for past neglect by the enormous progress which has been made in our acquaintance with this extremely interesting study. The anatomy of the bees themselves, whether queens, drones, or workers, has been minutely investigated under the microscope; the old straw hive, or 'skep,' has been abandoned in favour of the wooden 'bar-framed' hive with moveable combs; instead of suffocating his bees the bee-master merely takes out one or more combs, brushes off the bees, extracts the honey, and replaces the combs to be refilled. It has been discovered that the most vindictive bees may be subjugated and made perfectly tractable by blowing among them a few whiffs of brown-paper smoke, or the vapour of creosote, or by touching the tops of the combs with a feather dipped in carbolic acid. The bee-keeper, instead of leaving his hives undisturbed until the autumn, is for ever opening them, manipulating the combs, increasing or diminishing the space, feeding the bees, or extracting the honey. The bees, instead of having to make their own wax, at a vast expenditure of time and labour, have sheets of wax provided for them, in which the rhomboidal bases of the cells are ready stamped by machinery, and the net result

is that the annual yield of honey from each hive is from five to ten times as great as under the old system, with the further advantage that the lives of the bees need never be sacrificed. No bee-keeper, in a favourable part of the country, is now-a-days content with a harvest of less than a hundred pounds from each hive, and even in the suburbs of London as much as forty or fifty pounds per hive may be realised.

Why, then, is the army of bee-keepers so small? The price of honey is not so high as it was, but it is still possible to sell it in most country districts at a shilling a-pound, and as the original cost of a bar-framed hive stocked with bees, together with all the necessary appliances in the shape of comb-foundation, smoker, veil, extractor, and so forth, need not exceed 3*l.* at a liberal estimate, it will be seen that modern bee-keeping offers to amateurs the agreeable inducement of a handsome profit; and it is much to be regretted that in spite of the praiseworthy efforts made by the British Bee-keepers' Association the advantages of bee-keeping as now practised are not more widely known among the poorer classes. It is true that cottagers as a rule have not much spare time, but it is wonderful how little time need be taken up in attending properly to a hive. Five or six hours a month in the summer season, and five or six minutes a-week, at certain periods of the spring and autumn, should be ample; and a man's circumstances must be very unusual if neither he nor any member of his family can find this little leisure. In every poor man's garden there is room for a beehive; the flowers of the field produce a store of nectar plentiful enough to supply (without any appreciable competition) at least a hundred times as many hives as are now in existence; and apart from the pecuniary profit, the study of bees yields a peculiar pleasure of its own, opening up revelation after revelation of minute wonders in endless succession. . . .

WORK YET TO BE DONE.—Although on the whole a great advance has been made in apiculture, a study of the *British Bee Journal* for the last two years reveals the fact that much still remains to be done. That the science has arrived at a stage from which avenues of improvement open themselves in all directions is evident from the fact that in matters of detail there is a singular want of unanimity among its exponents. On almost every point rival theorists are fiercely at variance. The champions of the Ligurians, Carniolans, or Syrians, will not listen patiently to the slightest detraction from the merits of their favourites. The advocates of salicylic acid laugh to scorn the champions of phenol or camphor. If by any mischance a hive becomes queenless and it is necessary to introduce a new queen, the puzzled amateur is confronted by conflicting recommendations as to the proper course to be adopted. If he desires to establish a new hive, and wishes to obtain the best possible kind, he finds himself in doubt between the 'combination' system, the 'storifying' system, the Stewarton principle, the Heddon principle, and many others, between which, after all, there is very little to choose. When it becomes necessary to feed the bees he is distracted by the advocates of dry-sugar feeding on the one hand and syrup-feeding on the other.

However much they may differ in other matters, all bee-keepers will agree that bee-keeping is a most fascinating pursuit. An old French writer, De Gélien, once remarked that he had never met a bee-keeper who loved his bees moderately, they were all enthusiastic devotees. Certain it is that a beehive is a little kingdom filled with the most astonishing marvels. The study of it is endless. If it is a source of pride and of gain to its possessor, it is above all a wonder of wonders to the naturalist. So exquisite is the mechanism of a bee's organs and muscles, so varied and complicated, so mysterious and well-nigh inexplicable are its instincts, and so faithfully and beautifully does it perform its

appointed work, that we can think of no branch of science the study of which is better calculated to arouse an inquirer to enthusiasm.—*Good Words for May.*

Echoes from the Hives.

Appleby, Doncaster, May 1st.—This ought to be the beginning of the bee's spring, with the thermometer at 50° by breakfast time; but no, the wind is very high, and so it has been bad weather of some kind the whole winter. In consequence I have scarcely seen my workers out, and knowing that I added driven bees to my stock somewhat late last year, I expected, as has proved true, that I should have blanks in my rows. I only looked through the hives a few days ago, and found plenty of food, but in no case more than two patches of brood, the size of the palm of your hand. Curiously the best and strongest hive consisted of one packed away in the worst manner. It was late and I put a lot of driven bees into a Carter's seed-box, $\frac{1}{2}$ inch thick of wood only, holding six frames, placing a poor old quilt and tiek over, and spare roof by way of an umbrella. Another also in an inner box of a Cowan hive, barely quilted and roof stuck over, is at least as good as any if not better, although in extra strong hives. So I lose faith in double walls and chaff packing, thinking a good, dry, taut hive will do as well as a better! The two hives I lost were the only ones I have on the right-angled system, and I have never had bees do so well as in the parallel style. I fear we shall, with difficulty, build up our stocks for the white clover, unless it, like the whole chapter, be late too. My best hive last year was a Cowan piled up, and to try every recommendation I kept the old brood nest at the top, thinking, as written in the *Journal*, that the queen would descend; but no, she stopped at the top, never leaving the original box to lay. I am much pleased with the wire embedder, figured in the *B. B. J.* last year, it has saved me many a comb when extracting; in consequence, I advise all to use wire if working for extracted honey.—**EASTERN COUNTIES.**

Cottingham, May 7.—Since my last 'Echo' a great change has come over this part of the bee world. The bees get out every day, or nearly so, and pollen is going in the hives with a 'rush,' eggs are being laid fast, especially by the Carniolans and Italians; and if the bright weather continues, we shall soon be at boiling point. To-day I examined all my hives, and found combs already whitening at the top, which is the result of a large area of gooseberry bushes near at hand. I received a Carniolan queen on Friday last from Mr. F. Benton, and made up a nucleus for her in the following way:—Placed three frames in a hive, one of food, one empty, and one brood from a strong stock, on which I caged her majesty in a cage $6 \times 4 \times \frac{3}{4}$. I then removed a very strong stock of Italians one foot from its position, and placed the nucleus six inches on other side, so that the flying bees got pretty well divided between the two. This morning I released her, and noticed how kindly she was taken to by the bees. To-night, at six o'clock, I took a quiet look again and found the empty frame filled with eggs on both sides, and from end to end. Am trying both, 'right-angle' and 'parallel' hives, and find, up to now, the brood-nest is the largest in the 'parallel' hives in every case.—**CHARLES FLOWES.**

Honey Cott, Weston, Leamington, May 7.—The weather here seems to have changed for the best this last few days. The bees are rushing off to the woods and gardens where there are any blossoms for them to rife, a great contrast to what it was a week ago. Yesterday, though it was a dull day, they were off by thousands, and I might say tens of thousands; indeed they were

going so thick and fast that a young man said to me, as he stood looking, that a swarm of bees had passed over him. He seemed rather astonished that they still continued passing and re-passing. Though this has been a backward spring, I think bees have progressed very well, and appear to be in good order to take advantage of this favourable change in the weather.—JOHN WALTON.

Killarney, May 1st.—My bees did very well last year. I got 600 lbs. from ten hives, and only two swarms. I got 130 lbs. from my best stock, the queen of which is four years old. From the same hive I got 120 lbs. in '85 and 75 lbs. in '87, which was a very bad year. We have no foreign bees in this locality, and no *new blood* has been introduced at this side of the 'flood'.—F. J. M'DONOGH.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

G. DOWNER.—*Honey.*—We do not think so slightly of the honey as you appear to do. Its peculiar flavour is not to us objectionable. There is no disagreeable smell about it. The bees no doubt will be glad to have it. It will not in any way be injurious to this year's crop.

THE VILLAGE BLACKSMITH.—1. *Working Sections.*—Your plan of working sections appears to be a simple one when two bee-way sections are used. With you it would be found easy of practice, but with others the question would be, What is the cost of the hoop-iron frame and the screws; how are these to be procured by one who is not a 'village blacksmith'? 2. *Frame for Extracting.*—With regard to the frame, something similar has been suggested by Mr. W. B. Carr, of which we hope to hear a report further on. There is no object in using a middle bar unless to steady a full sheet of foundation. If a triangular piece of foundation is used as you suggest, the probability is that the lower corners and sides would be filled with drone-comb.

E. CLOWES.—*Bees Deserting Skep.*—From particulars given we should say your bees were unable during a sudden chill to keep up the necessary warmth, consequently many deserted, and, joining other hives, so weakened and disheartened the remainder that they swarmed out; a few of the more loyal bees would be sure to remain with the queen. The queen might, after being in a warm room for an hour or two to get lively, have been introduced to a queenless colony, but the probabilities are she would have proved of little real use.

W. RIGDEN.—*Doubtful Queens.*—We should recommend you to unite the two doubtful hives, and if in a week's time you still find the eggs placed irregularly, as detailed by you, remove the queen, introduce a frame of eggs (just hatching) from your other colony on the third day, cut out all queen-cells which may have been commenced on any of the old original combs. Repeat on the sixth day if any more have been started on any comb except the one introduced. Destroy all except two on that comb.

W. TRUSLOVE.—*Transferring.*—Do this on the very first favourable day. Stimulate gently, but *regularly*. Sorry to hear of your unsuccessful wintering. Your bees had dwindled owing to the continued bad weather preventing breeding. You did wisely to

unite. Better one strong colony than two weak ones.

F. W. PUDSEY.—*Andrena.*—The specimen forwarded belongs to the family *Andrenide*, of which there are about eighty British species. The specific name of the one sent is *Andrena fulva*. The specimen is the female; the male is a small black bee, very different in appearance from the bright, golden-tinted colour of his mate—so dissimilar, indeed, are they that entomologists at one time were very doubtful as to their relationship, but by observation of them in their burrows this was satisfactorily established. These bees appear in great numbers about the time of the apple-blossoms. After a time the fulvous pubescence, through exposure to the atmosphere, wears off, and the female's colour fades into a pale yellow, and that of the male into a dull gray. They burrow in the earth, their tunnels varying from five to six inches in depth. The architecture of their cells, and their provision for their young, are an interesting study.

E. H. LATTY.—The name of bee forwarded is *Melecta armata*.

H. J. S.—1. *Excluder zinc.*—In our pamphlet on *Doubling and Storifying* we say, 'We have long since discontinued the employing excluder-zinc, as we have found that it interfered with the work of the bees, and that we always got much more honey without its use than with it.' 2. Allow not less than a quarter of an inch, and not more than three eighths, between rack and frames.

RECEIVED from Mr. C. Redshaw, South Wigston, Leicester, his Catalogue of Hives and Bee-keepers' Appliances (20 pages). This catalogue is a well-assorted list of the various appliances required by the bee-keeper. Our attention was especially drawn to a very simple wax-extractor, with directions for use; also to a suitable exhibition section case for shows, grocers' shops, &c. With the catalogue we received a sample of Mr. Redshaw's honey labels, which are neat and effective.

RECEIVED, the schedule of prizes for the fifth annual show to be held at the Market Place, Aberdare, on Thursday, August 16th.

CORRECTION.—We omitted to state that the letter on 'Honey,' p. 215, was taken from the *Bee-keeper's Magazine*.

* * * Several replies are postponed till next week.

BRUSSELS APICULTURAL EXHIBITION.

We are requested to announce that the time for application for space at the above exhibition has been extended from the 15th of May to the 20th of June. We may remind our readers that this exhibition will be held from the 11th to the 23rd of August.

PRACTICAL WORK IN THE APIARY.

CROWDING HIVES.

If the instructions we have given for stimulative feeding have been properly carried into practice, hives should now be crowded with brood in all stages of development, and the numbers of the bees will be rapidly increasing. We examined two hives a few days ago which were crowded with bees and had thirteen frames of brood. These hives had racks of sections placed upon them as the bees were already gathering honey from the fruit bloom. The next day two frames of brood were removed, and it was found the bees had taken to the sections, in which they were busily at work. In districts where there are orchards, bees should be by this time sufficiently forward to take advantage of the honey flow. All strong hives should be immediately supered, otherwise, if they are cramped for want of room, and have no place to store what they collect, they will make preparations for swarming. If we wish to take advantage of the honey flow coming on now, strong colonies may have two frames removed, and the space closed up with division boards. This will crowd the bees in the lower storey and force them up into the sections placed above. The frames that have been removed may with advantage be given to hives that are not so strong. Notwithstanding the addition of supers the now rapidly hatching bees will soon require more room, and this we can give them by moving the division boards and giving them an empty frame on either side of the brood-nest as they need it, not increasing beyond ten frames. As soon as the sections are two-thirds full they should be lifted and another set placed beneath. A third can be given if required, and should be placed beneath the two first. In this way room will be provided slightly in advance of their requirements and swarming prevented.

It must be borne in mind that when the bees have once got the swarming fever and make preparations by constructing queen-cells, it is very difficult to prevent

them from swarming. They do not usually make preparations until honey is coming in plentifully and they feel cramped for want of room. Give them plenty of room above, and although crowded below they will not think of swarming. Some recommend removing frames of hatching brood, but this we do not like because the queen requires empty cells in which to deposit her eggs, and it is these hatching bees that supply her with such cells. Weak hives should still be encouraged to develop in readiness for the main honey-flow, and empty frames should be added as they need them on the outside of brood-nest.

Warmth is necessary now more than at any season. The nights are still cold and many are not aware how closely the bees cluster at such times. We have insisted on the hives not having more combs than the bees could crowd upon. An examination during the day, especially if it be a very warm one, is deceptive, and some imagine that if they see bees on all the combs they are sufficiently crowded. This is not so, and if the same hive were again examined late at night or very early in the morning, it would be found that probably there would be few, or even no bees on the outer combs. We construct our division-boards so that they come within half an inch of the bottom board, giving bees room to go into the space on the other side. We then crowd the bees so that they not only cover the combs but overflow into the space beyond. At night if we still find a few bees on the outside we are satisfied that there are enough to cover the combs and all the brood. Should we find that there are no bees on the outside, we take away a frame or two as may be required from the brood-nest and push up the division-board. We are then quite certain that we have made all safe and that the brood in the combs is not likely to become chilled by the cluster of bees receding. Chilled brood occurs only in hives badly protected and when the brood-nest is too large for the number of bees. It is a fruitful source of disease, and every precaution should be taken to guard against it. Put plenty of blankets over and round the sections to keep them warm.

GLASGOW INTERNATIONAL EXHIBITION.

This exhibition was opened on Tuesday, the 8th May, in the finest of weather, and under the most favourable auspices. The Prince and Princess of Wales had a most enthusiastic reception, and were so fascinated with the exhibits that their stay in the exhibition was much longer than intended. Bee-keepers will be interested in knowing that it was arranged, had time per-

mitted, to draw the attention of their Highnesses to the exhibit of honey and appliances, shown in Court 21, by Messrs. E. and J. D. McNally, of Rutherglen and Springburn. The executive considered that the design in honey-comb, 'God save Queen Victoria,' was specially worthy of being brought under their notice. Although this part of the programme had to be cancelled, the Messrs. McNally had the honour of presenting H.R.H. the Princess of Wales with a beautiful case containing three samples of Scotch honey. Mr. E. McNally was introduced to the Prince and Princess by Sir Archibald Campbell, Bart., M.P., and on handing over this unique little present, they seemed greatly pleased, and remarked that it looked very pretty.

On the opening day, a small observatory hive on the Messrs. McNally's exhibit caused considerable attraction, and altogether this venture on the part of these gentlemen seems likely to result beneficially to themselves and to bee-keepers generally.

BEE-KEEPERS' VOCABULARY;

OR, GLOSSARY OF TECHNICAL AND SCIENTIFIC WORDS
USED IN WORKS UPON BEE-KEEPING.

American cloth.—Oil-cloth more or less glazed on one side, which is used on the tops of the frames under the quilt. Eramel cloth.

Amœboid. (*Gr. amoibe*, change, alteration, and *eidos*, form.)—Applied to the blood-corpuscles of the bee from their constantly changing their form similar to an amœba.

Anal. a. (*L. anus*, the fundament.)—Pertaining to the anus, or excretory opening.

Analogue. n. (*Fr. analogue*, fr. *Gr. ana-logos*.)—A structure which corresponds with, or bears a great resemblance to, some other structure depending upon similarity of function. Called *analogous*, or *analogues* of each other.

Analysis. n. (*Gr. analysis*—*ana*, up, and *lysis*, fr. *luco*, to loosen.)—Separating a compound body into its constituent parts. The component parts constituting pure honey and wax being well known, any admixture of adulterants can be detected by analysis.

Analyst.—One who analyses; a chemist expert in analysis.

Anatomy. n. (*Gr. anatome*—*ana*, up, and *tomos*, a section, fr. *temnein*, to cut.)—The study of the structure of animals and the nature and general properties of the separate substances of which the body is composed.

Andrenidæ, Andraenidæ. n. pl. (*Gr. andrôn*, an apartment.)—A family of solitary bees varying much in size and habits. They make their nests in sand-banks, decaying wood, straw, and burrow in similar places. Nearly seventy species of *Andrena* are found in England, and their tunnels with nest at the end may generally be found in dry and stony soils.

Androgynous—Androgynal. a.—Uniting the physical character of both sexes; hermaphrodite.

Androgynus. n. (*Gr. aner*, a man, and *gune*, a woman.)—A hermaphrodite.

Anguiculi. n. plur. (Probably a corruption from *L. unguiculus*, a little finger-nail, dimin. of *unguis*, a claw.)—The claws on the foot of the bee by which it clings to rough surfaces, and which enable bees to hang on to each other and suspend themselves in clusters.

Anomalism. (*Gr. ana*, not; and *homolos*, even.)—Irregularity; deviation from the common rule.

Anopsy. (*Gr. ana*, without, and *opsis*, sight.)—Want of sight. Albino drones are said to suffer from anopsy.

Antagonist muscles. (*Gr. anti*, against, *agonistes*, a combatant.)—Those which act in opposition to each other, such as abductors and adductors, flexors and extensors.

Antenna. n. plur. antennæ. (*L. antenna*, a sail-yard).—Commonly called feelers or horns. Slender jointed bodies appended to the head of bees and other insects containing the organs of smelling, feeling, and considered by some to be also those of hearing. They comprise the *scape*, or basal joint, and the *flagellum*, the terminal part consisting of a number of smaller joints. Collectively these joints number twelve in the workers and queens, and thirteen in drones.

Antenna-cleaning apparatus.—This consists of a semi-circular notch, furnished with a comb or *pecten* situated on the upper part of the *tarsus* of the leg. On this falls a spur with a projection, or *velum*, attached to the lower part of the tibia, or next joint, above. The two combined form a circular opening into which the antenna is placed, and when drawn through is cleaned of all adhering pollen. (*British Bee Journal*, vol. xiv., p. 43.)

Aphides. n. plur. (*Mod. Gr. aphid*, a plant-louse).—Small insects known as plant-lice, living by sucking the juices of plants. At the extremity of the abdomen, they have two horn-like spines from which exudes the saccharine fluid called honey-dew.

Aphidian. a.—Pertaining to aphides as applied to honey, a sort of saccharine fluid, or honey-dew, deposited by a small insect called an aphid and collected by bees.

Aphis. n. (*Mod. Gr. Limæus*.)—Plant-louse, see *Aphides*.

Apian. a. (*L. apianus*, adj.)—Of or belonging to bees.

Apiarian. (*L. apiarium*, neuter of *apiarius*.) Should properly be used only as an adjective, although sometimes used as a substantive.—Pertaining to bee-hives; a keeper of bees.

Apiarist. sb. (*L. apiarium*.)—One who keeps an apiary; one who takes care of bee-hives; a bee-keeper.

Apiary. (*L. apiarium*.)—The place where bees are kept; a stand or shed for bees; a bee-house.

Apiaster. n. (*L. apiastra*, fr. *apis*, a bee.)—A bird called Bee-eater, a species of *Merops*. Merops apiaster is very common in southern Europe, where it does much damage to hives, being a voracious feeder on bees, but is unknown in Great Britain.

Apiator. Macaronic, and should never be used, being formed on the analogy of *piscator*, though no Latin verb *apiari* is found.—Used sometimes improperly to designate a bee-keeper.

Apiculture. (*L. apis*, bee, and *cultura*, tending.)—The culture of bees; bee-keeping; the art of cultivating bees for practical purposes.

Apiculturist.—One who devotes himself to the care of bees; a bee-keeper.

Apidæ.—The name of the family of insects to which the honey-bee belongs. The characteristics of the family are that they feed their larvæ on pollen, or honey and pollen. It includes several genera, of which *apis* is one.

Apifactory. Obs., rare.—An apiary kept for economic purposes.

Apifecture. Obs., rare. (*L. apis*, bee, and *factura*, making.)—The work of bees.

Apiology. A hybrid word (*L. apis*, and *Gr. logos*, discourse.)—Bee literature; literature of bee-keeping.

(To be continued.)

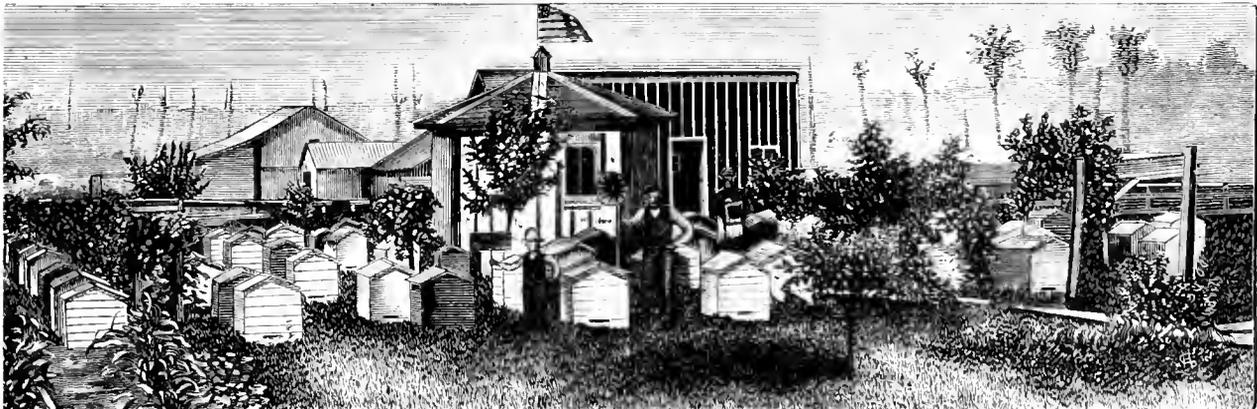

GEORGE E. HILTON, OF FREMONT, MICH.

The accompanying illustration shows the apiary of Mr. Geo. E. Hilton, of Fremont, Mich., which contains about ninety colonies of bees. The octagonal building in the centre is the honey house and extracting room. The little piece of walk at the right leads to the dining-room door, and the walk running to the honey-house runs close to the dwelling, which is just cut off at the right of the picture.

The tallest person in the foreground is Mr. Hilton with his favourite living basket in his hand. The boy at his right is his little nephew and namesake, Geo. D. Hilton, while Mrs. Hilton stands on the walk further back. A new factory now stands to the right of the

little workers,' and enjoyed it much better than the sports usually indulged in by other boys.

His first colony of bees was a present from his wife; the parties of whom she bought it had another, and he bought that. This was in the summer of 1877; the two were increased to four colonies, but being on odd-sized frames they were soon transferred to the American frame, and increased to six colonies; but finding too much honey along the top bars, and hearing of the Langstroth frame, they were again transferred, and from that time until the present his success has been very gratifying. His honey crop was largely in the comb, and for the past eight years his average per colony has been about seventy-five pounds. The past season was the poorest one.

buildings, at the back of the lot, and has been built since the picture was taken.

The hives are painted, and so arranged that there is first a red, then a white, then a blue one in every direction, the rows running straight east and west, and north and south; the hives facing the east.

Mr. Geo. E. Hilton is an energetic and progressive apiarist, and we present an illustration to show his per-

sonal appearance, and have secured a biographical sketch, from which we extract as follows:—

Mr. Geo. E. Hilton was born August 25, 1846, in Bedfordshire, England, near the spot where John Bunyan wrote the world-inspiring book, *The Pilgrim's Progress*, while incarcerated in Bedford jail. His parents moved to America when he was between five and six years old.

He says that he was always attracted to bees, and was never afraid of them from his earliest remembrances, and that he 'lined' a bee-tree from bees working near the kitchen when only twelve years of age, and the cutting of that tree resulted in his having all the honey he wanted for the first time in his life. He often said that when he became a man he would keep bees. He often sat by the side of an old log-gum watching the 'tireless

Mr. Hilton has a good library of books by the best authors on bee-culture, and takes nearly all the bee periodicals. He put the first sections of comb honey on his home market which were ever seen there, and now has a large trade with surrounding towns, seldom having to ship to the large cities. He has helped many to start in the business, and Newaygo county is fast coming to the front as a honey-producing county.

A local organization, called 'The Fremont Progressive Bee-keepers' Association,' exists, of which Mr. Hilton is President. He has always taken great interest in Convention work, believing it to be one of the best sources through which to receive and impart knowledge. He has attended the 'North American' whenever it has been within his reach, and has never missed a meeting of the Michigan State Convention since his first attendance in 1881. He was elected President of that body in 1886, and re-elected in 1887.

Mr. Hilton, in the *Fremont Indicator*, remarks as follows concerning East Saginaw, where the last Michigan State Convention was held:—

'Space will not permit me to speak of all the favours shown us while there. For cleanliness of streets East Saginaw is next to Detroit. For modern architecture in public and private buildings, taste and ornamentation, certainly she stands at the head. The newspapers, too, gave us every attention, devoting nearly a column morning and evening to the proceedings, and none but favourable comments appeared on their pages, which showed their reporters to be gentlemen in their profession, whether we deserved it or not.

'The bee-keepers of Michigan will long remember their visit to East Saginaw. The address of welcome by Mayor H. M. Youmans was enough to make every one happy all through the session. But, not satisfied with this, he invited us in a body to look over the fire department. Here an alarm of fire was sounded two and a half miles away, and in the twinkling of an eye the gas lighted, the horses attached to the hose cart, the doors flew open, and away they went—the whole thing, except the muscles of the men and horses, being moved by electricity.'—*American Bee Journal*.

Foreign.

HOLY LAND.

During our detention at Jaffa, occasioned by a violent storm which prevented our embarkation on the day appointed for the commencement of our voyage by the Syrian coast to this city, we were enabled to make exploration into various matters connected with this key to the Holy Land; and I hope the incredulity of your readers will not be called out when I tell you that there are in the famous groves of Jaffa 500 gardens and the enormous aggregate of 800,000 orange and lemon trees, from which there were last year exported to Europe 20,000 boxes of oranges of the peculiar, oblong, lemon shape now so well known in England, besides an enormous number of smaller, round oranges not adapted for distant exportation, but extensively consumed nearer home. Out of this enormous exportation and extensive consumption, showing the vast extent of these groves, there has arisen another special industry in the collection of orange-blossom honey from 500 bee-hives, under the control and management of five brothers, very active and sensible men who came from Germany. On our arrival at Jaffa the air was perfectly laden with the perfume of orange-blossoms, on which was being displayed the activity of, I suppose, some millions of little active workers, who were

'Gathering honey all the day
From every opening flower.'

The bee-farm is located on the margin of the groves and Plain of Sharon, but in addition to this extensive farm of orange-blossom cultivators, these spirited five brothers have established other farms on the hills of Judea, where wild thyme gives another opportunity of gathering honey of a somewhat different character from that of Jaffa; the wild-thyme honey is brown, while the orange-blossom honey is white. Of all honeys I ever tasted, whether that of the heather of Scotland, the white or brown honey of Switzerland, or the far-famed Hymettian of Athens, I never tasted any so delicious as that of the orange-blossom honey of Jaffa, of which last year 30,000 lbs. weight was collected. This year, as with many crops of agricultural and other produce, there is a falling off in the supply, owing to the long, dry season of the district. Nevertheless, I was so impressed with the value of this article, and its new feature of industry, that I purchased 100 lbs. for distribution amongst my home friends and the connoisseurs in honey, and especially with the view to the opening of a new feature of commercial enterprise which the bee-farmers earnestly desired.

In addition to this interesting information relating to the orange groves, I learned from the same informant (to whom I have referred) that special colonies are now being planted in the plains of Sharon, and all round this old city of Jaffa. Four of these colonies have been established by the eminent bankers the Rothschilds, who have bought lands and have built houses upon them, one of which colonies has been especially provided for, and is occupied by poor Jews driven out of Russia. In other cases German settlers are located, and one colony in particular, at Saron, on the Plain of Sharon, is appropriated to the keeping of cows for the supply of fresh and pure milk and butter to the inhabitants of Jaffa, thus realising the old interesting ideal of a 'land of milk and honey.'—*Extracted from a letter in the 'Glasgow Herald' signed THOMAS COOK.*

BEEES IN QUEENSLAND.

It is not generally known that Dr. Roberts has within his grounds one of the best collections of bees and bee-hives in Queensland. Although exceedingly busy in his

profession, the Doctor finds time to devote an hour or two now and again to his bee colony, which has now assumed considerable dimensions. There are more than fifty hives in the group. They are nearly all on the Langstroth principle, and for convenience, appearance, and the comfort of the bees, these cannot be excelled. Some of the hives are three storeys high, or, perhaps more correctly speaking, divided into three sections. All are fitted with small frames, and on these are machine-made foundation sheets of wax, upon which the honey-comb is built. Another development, which has been fully availed of by Dr. Roberts, is the section boxes, four of which fit into the ordinary-sized frame and each of which holds exactly one pound of honey. These sections are extremely convenient, either for exhibition or for the sale of honey in the comb. The whole of Dr. Roberts's hives contain Italian bees, which he has bred from an imported queen. This mother-bee was imported at a cost of three guineas some time ago, and although she presents a somewhat ancient and dilapidated appearance, she has been an excellent breeder, and some of her progeny in the surrounding hives are much better looking than their progenitress. Some of the hives contain a few hybrids, but, as a rule, the bees are uniformly Italian, and very pretty, hardworking, and prolific little workers they are. Dr. Roberts is a great believer in Italian bees, and he is of opinion that they are as much at home here as in their native country, because of the similarity of the climates and food obtainable. The supreme advantage of these foreigners is that they have been moth-proof ever since their arrival in this colony. The native bee had become almost extinct in this district, because of the fatal ravages of the bee-moth; but now truant swarms of Italians have taken up their residence in the bush and are rapidly multiplying without interference from the enemy which had been so fatal to the native bees of the bush. Dr. Roberts has bred the whole of his present stock of queens from the imported bee, and he is yet hopeful that many more of her progeny will pass through his numerous nucleus hives before presiding over the larger swarms in the Langstroths. The yield of honey is great, a full hive averaging fully 1 cwt. per year. The means of extracting the honey are very simple. The operator, clothed with a veil and gloves, removes the top of the hive, and, in the majority of cases, the bees are remarkably good-tempered during the process. The frames are gently lifted from the hive and the hundreds of bees gently brushed from the comb with wing or tail feather. An empty frame is replaced, and the bees then set to work and fill it. Dr. Roberts possesses a honey extractor—a very simple but effective piece of machinery—which works on the centrifugal principle. The extractor is in shape like a large milk-pail. It is made of tin, and contains a centrifugal frame made of iron. Into this frame the honeycomb—and each of these combs contains 4 lbs. of honey when filled—is placed. A handle is turned, the comb is whirled round at a tremendous speed, and the honey is thrown out on to the sides of the extractor. It drains to the bottom, and is then drawn off through a tap. The comb, being cleared of the honey, is used again and again until too far gone for further work by the bees. This saves the bees an immense amount of labour in rebuilding the combs, and therefore the yield of honey is greater. This is the system followed by Dr. Roberts, and the only wonder is that a greater amount of bee-keeping does not exist in this most favourable district. The pursuit can easily be made profitable, and it is certainly most interesting and instructive.—*Toowoomba Chronicle, March 8.*

[We are indebted to the Rev. Astley Roberts for the newspaper containing the above description of the apiary of his nephew, Dr. Roberts.—Ed.]

QUEEN WASPS are on the wing abundantly in many parts of the country. They should be destroyed.

ASSOCIATIONS.

NORTH OF SCOTLAND APICARIAN SOCIETY.

This Society has just issued this year's prize list with every prospect of a successful show and competition to be held on 23rd, 24th, and 25th of August, and for which the Town Council has granted a site in the Duthie Park. Special prizes, given by the Hon. Lady Aberdeen, the Highland and Agricultural Society, and others, will be competed for, and special efforts are being made by this Society to promote apiculture in the North of Scotland.

YORKSHIRE BEE-KEEPERS' ASSOCIATION.

A very interesting Committee Meeting of the above Association was held at the Church Institute, Leeds, on April 28th. Dr. Dodgson (Hon. Sec. Craven Branch), in answer to the Secretary, said he would make further inquiry, and report, respecting the proposed formation of Branch Associations at Crosshills and Bolton. The Hon. Secretary reported correspondence with Mr. C. Howes, of Cottingham, resulting in the formation of a Hull Branch under very influential, and, consequently, useful patronage.

Mr. W. Dixon, Beckett Street, Leeds, was appointed manipulator at the forthcoming show of the Yorkshire Agricultural Society at Huddersfield.

A new departure was taken with regard to tent manipulation: It was resolved, bearing in mind that skep-driving, &c., formed an important item in the Schedule of Competitions and Prizes of the Yorkshire Agricultural Society, that the lessons taught in the beehive should be accompanied by manipulations of frame-hives, sections, and other objects used in scientific or modern bee-keeping, instead of the almost monotonous skep-driving, thus teaching and exhibiting 'the right way.'

The Secretary reported that at the suggestion of Mr. A. W. Henderson he had written an appeal to Yorkshire bee-keepers, which was printed in the columns of the *B. B. J.*, a copy of the *Journal* being sent to every member and to others. The object of this being the formation of district Associations. It is pleasing to notify that since this meeting, still another Branch has been formed, at York, chiefly through the energy of a veteran bee-keeper, the Rev. J. Hodgkinson.

Selected Queries.

[9.] *What size and width of section is the most saleable? Do you consider the two or the four bee-way sections the best, and why?*

The $4\frac{1}{2} \times 4\frac{1}{2} \times 1\frac{3}{4}$ are in my opinion the best for all purposes. The four-way sections are best, and I believe will be better filled if slotted dividers are used and a passage-way left at the ends and between sections. The bees can then get readily from one side of the comb to the other without leaving popholes.—JOHN M. HOOKER.

$4\frac{1}{2} \times 4\frac{1}{2} \times 1\frac{3}{4}$. Two-way are better to handle, better to pack, and are worked cleaner.—SAMUEL SIMMONS.

Weight 1 lb., size $4\frac{1}{2} \times 4\frac{1}{2} \times 2$. Theoretically four bee-way would appear to save time and labour, but whether this is so or not cannot say from experience.—JOHN EDEY.

The ordinary 1-lb. section $4\frac{1}{2} \times 4\frac{1}{2} \times 2$ I find the most saleable. I have worked a large number of both two and four bee-way sections, in some instances mixed in same crate, and have not been able to decide which are best as regards popholes, but I consider the two bee-way sections far preferable for handling, glazing, and storing, to those having four bee-ways.—W. WOODLEY.

$4\frac{1}{2} \times 4\frac{1}{2} \times 2$. Four-way—as less impeding work.—W. E. BURKITT.

I have found the 1-lb. section ($4\frac{1}{2} \times 4\frac{1}{2} \times 2$) the most saleable size, but during the last year or two there has been a readier sale for really good and evenly worked 2-lb. sections ($6\frac{1}{2} \times 5\frac{1}{2} \times 2$) than formerly. Judging from the short experience I have of the 'four-way sections,' used with slotted dividers, I prefer them to the 'two-way,' since the comb-surface is more evenly finished and sealed and there is an absence of passage-ways at the corners, when the former are used.—GEORGE RAYNON.

1. The 1-lb. section $4\frac{1}{2} \times 4\frac{1}{2} \times 2$ in my opinion is the most saleable at present, and likely to remain so. 2. The four bee-way, proper separators being used, the bees have free passages from section to section, diminishing the probability of popholes, as well as inducing the bees to take more readily to the super.—ROLAND GREEN.

During the past season I found the $4\frac{1}{2} \times 4\frac{1}{2} \times 1\frac{1}{2}$ inch section by far the most saleable. Should the demand for them be the same this year I would never hesitate to work almost exclusively the narrow section. Yes, by all means the four bee-way section is the best, they are quicker filled, have fewer popholes, and consequently look neatest.—WILLIAM McNALLY, *Glenluce, Scotland*.

$4\frac{1}{2} \times 4\frac{1}{2} \times 2$ wide is the best, *vide* my remarks on the subject p. 193. If divisional trays are used the two bee-way sections are best, but if not the four; equally good harvest can be obtained with either.—W. N. GRIFFIN.

I think the $4\frac{1}{2} \times 4\frac{1}{2} \times 2$ inch sections sell the best. I have quite discarded the 2-lb. sections as I could not sell them. I only experimented with one crate with four bee-way sections last year, and then rather too late in the season to give it a fair trial, so cannot say; I like the two-way sections best for handling.—JOHN WALTON, *Honey Cott, Weston, Leamington*.

1. $4\frac{1}{2} \times 4\frac{1}{2} \times 2$ inches wide, I find the most saleable. 2. Two bee-way, as they are not so liable to damage by being bruised in handling as four bee-way sections, and they have a better appearance when complete.—H. WOOD.

$4\frac{1}{2} \times 4\frac{1}{2} \times 2$. The four bee-way sections are the best, but is not of sufficient importance to warrant a bee-keeper going to the expense of altering all his present plant. They are finished off more neatly.—W. B. WEBSTER.

$4\frac{1}{2} \times 4\frac{1}{2} \times 1\frac{3}{4}$. If the operator has no confidence in working these, then $4\frac{1}{2} \times 4\frac{1}{2} \times 2$ wide are next best. If sections two inches wide are used, and of necessity dividers, the two bee-way are filled equal to the four bee-way. The breaking up of a wax-secreting and comb-working cluster is too effectually done by dividers to be compensated (?) by additional centre end passages and slotted dividers; but if $1\frac{3}{4}$ inch wide sections are worked dividerless, four bee-ways are indispensable, and with outside end passages only as fair a chance for perfect work is given to clustered bees as is possible in sectional work.—JOHN H. HOWARD, *Holme, Peterborough*.

[10.] *Does it pay best to use full sheets of thin foundation in sections, or starters only? Do you like the flat-bottomed or the natural base best? Which will the bees commence to work on and draw out first? How many superficial feet to the pound do you think the best thickness?*

Full sheets of thin foundation will pay best to use in sections. I prefer the natural base, and I think the bees take to it better, and work it out first; although the flat bottom is less liable to sag. There should not be less than ten feet superficial of thin foundation to the pound. Messrs. Dadant supply some extra thin twelve feet superficial to the pound.—JOHN M. HOOKER.

1. Full sheets by all means. 2. Natural base, though I do not condemn Van Deusen's excellent foundation.

3. They commence on either readily, but always convert thin flat base to the natural shape. 4. Nine feet, or slightly more or less according to the mill it is made on.—SAMUEL SIMMINS.

1. Full sheets except when sections are three inches wide in a case, then it is preferable to use sheets two-thirds the depth of section in the centre ones only. 2. Natural base. 3. Natural base. 4. About twelve superficial feet.—JOHN H. HOWARD, *Holme, Peterborough.*

1. Full sheets. 2. Natural base. 3. The natural base foundation. 4. Twelve.—W. WOODLEY.

1. I consider full sheets pay best; if starters only are used drone-comb is invariably built, this has not such a nice appearance when finished, and it also offers a strong inducement to the queen, especially if there is very little drone-comb below. 2. Natural-based. 3. From my experience natural-based. 4. About eight feet.—ROLAND GREEN.

Yes, it pays best in nearly all cases to use full sheets in sections. When honey is scarce in coming in, but sufficient to keep the bees drawing out comb, starters may be used in sections then to advantage. I prefer the foundation with natural-base cells, bees will take to either quickly during the honey flow. Ten to twelve superficial feet to the pound is to be preferred.—WILLIAM McNALLY, *Glenluce, Scotland.*

Full sheets of foundation are much the most profitable. Have used both with equal results, if it is good and pure foundation do not think it matters much. The thinner it is for sections the better.—WILLIAM N. GRIFFIN.

Yes. Full sheets in preference to starters. I like the very thin flat-bottomed foundation best; have not noticed particularly which kinds the bees work on first, nor how many feet superficial to the pound.—JOHN WALTON, *Honey Cott, Weston, Leamington.*

1. In my opinion full sheets. 2. Natural base the best. 3. Natural base. 4. Twelve feet to the pound.—H. WOOD.

Full sheets. Either natural base or 'Pelham.' The bees will commence to work on either at the same time, but will draw out the natural base or 'Pelham' first. With flat bottom there is more chance of 'popholes,' the septum being very frequently removed by the bees. Flat bottom is more easily made. Any thickness so long as the septum is sufficiently thin. With 'Pelham' if properly made, ten feet to the pound gives good thick walls and thin septum.—W. B. WEBSTER.

I cannot answer this, having only used starters of thin foundation hitherto.—W. E. BURKITT.

Full sheets. I much prefer the flat-bottomed. The bees have no preference. Strong colonies in normal condition, and a plentiful honey flow, are the only requisites. I use the thinnest American flat-bottomed foundation, which can be procured, transparent, and about twelve square feet to the pound, and would use a lighter if obtainable.—GEORGE RAYNOR.

Use full sheets every time. Natural base best, have used both, but do not notice any different as to time. Twelve feet superficial to 1 lb.—JOHN EDEY.

Correspondence.

SELECTED QUERIES: INFORMATION DESIRED. (1624.)

[1632.] 'R. M.' desires information as to Query 7, at the same time misquotes me. 'If *strong*' stocks (not weak) were found queenless, say at the latter end of April, rather than unite I should put them into a queen nursery, and heat by lamp or gas to about 20° over outside temperature, and keep supplied with food. This would

probably cause them to start cells. By the time the queens would fly drones would be ready, and the young queens come in very useful if helped with brood at first. Bees of course fly in the open. Have not found it necessary to do more than feed drone-rearing hives on warm syrup.

Probably queen-nurseries would not pay every bee-keeper to use, but we have found them handy for a variety of purposes during three or four seasons. They cost from 25s. to 50s. to make, according to size, &c.—this by the way.

I think select rearing might be practised to greater extent than it is with advantage. Two years ago we reared thirty per cent of queens pure, and this year I found drones on an examination on April 30th. This in a late year, when swarming will be at least a fortnight later than usual.—JOHN EDEY.

SELECTED QUERIES: INFORMATION DESIRED.

[1633.] Your correspondent 'R. M.' at page 239 of *B. B. J.*, asks a few questions under the above heading. Permit me to reply briefly to the questions more particularly connected with my name. Referring to my answer of selected query No. 7, I said, 'At the end of April or beginning of May a frame of brood may be given to a queenless colony from another stock, to hatch a queen, provided also that precaution be taken to have drones flying at the time for successful mating.' By giving a strong queenless colony at beginning of May a frame of brood to raise a queen it will be well-nigh the end of May before the queen will be hatched and ready to meet the drone. Living in the south-west of Scotland, which may be considered as enjoying the mean temperature of the British Isles, I have during the past ten years noticed that drones were flying in my apiary from the 20th to the 28th of May each year. The drones were all produced naturally. I based my reply to query referred to according to conditions existing in my own district. If 'R. M.' desired drones from a special stock to mate the queen, he could insert in middle of the brood-nest a drone-comb, about a week previous to the time of giving the queenless stock, the comb of eggs and brood wherewith to raise the queen. He will thus ensure drones to be flying at the right time. With our very limited space in answering these queries, it is impossible to go into detail, but for my part I am always willing to clear away any mist that may be hanging over my answers.—WILLIAM McNALLY.

SELECTED QUERIES.

[1634.] Your selected query for May 10th.—The questions are appropriate and well timed, the answers cannot fail but to be of great service to your readers. Your correspondents having said so much we would ask them to say more. The first question, 'What should be done with weak stocks in spring?' A great proportion of the answers are, 'Unite.' The exception, 'Should a young breeding queen be at their head, then preserve the stock.' If it would be profitable to keep a nucleus through winter to save a young fertile queen to replace winter's losses then it would be equally profitable to keep a weak stock with a young breeding queen to repair losses during the summer. Mr. Simmins would give the queen to the first stock which sent off a swarm. Would he give a queen's cell to the weak stock from which the queen had been removed?

The second question, 'How can they be strengthened?' Answer:—Contract brood nest, pack warmly, feed quietly, narrow the entrance. Mr. John Walton says, 'If not too weak, shut up close.' Does he propose to close the hive and not allow the bees to fly? It would save the bees from being robbed, and the bee-keeper from some trouble, if they could be kept healthy under such treat-

ment. What is Mr. Walton's experience with such management? What is the experience of bee-keepers in general?

Some would strengthen by giving 'bars of brood.' Mr. 'Useful Hints' would 'change the stand of the weak stock with a strong one,' when the bees were flying on a fine day. This, no doubt, would strengthen the weak stock, but how would the other fare? Would there be two moderately weak stocks? Can the stocks be too strong at the opening of the season? If so, why should the hives be doubled to improve the yield of extracted honey?—R. M.

WEAK COLONIES IN SPRING.

[1635.] In the answers to Selected Query No. 8, all the authorities advised one or other of two courses, viz., either to unite or to strengthen the weak colony at the expense of a stronger one.

In 1886 I used a different plan and it seemed to me to be successful. The spring was a very late one, and I had one weak colony, on 24th of April, on four combs with brood in two of them. I had also another colony which was pretty strong, and I thought I should endeavour to try and utilise both queens by letting the queen in the weak colony lay eggs, but removing the young brood to the other hive to be fed up. I therefore, on the 24th of April, removed the brood comb which contained the youngest brood, replacing it by an empty comb. On the 8th of May, and again on the 10th of May, I did the same thing. This enabled me to super the stronger hive on 17th of May. On the 30th of May the weak colony was on eight combs with brood in five of them, and on the 3rd of June I returned the stronger colony on foundation, leaving two brood-combs and gave the remaining seven brood-combs to the weak lot, doubling them, there being enough bees to take charge of the additional combs. The season was a bad one, but the weak lot gave me over fifty-five pounds of honey. The stronger lot which I worked with sections, gave me forty-two pounds. Both queens were pure Italians. I think this plan if worked out properly might lead to good results.—T. F. L., *Brondesbury.*

BEE TEACHINGS.

[1636.] The bee, from our childhood, has been set before us as a model of industry; but even Dr. Watts himself—whose simple verses embody this useful lesson—unless he kept bees, could have had but little conception of the ceaseless activities of these busy little creatures. The valuable lesson thus taught requires—in these columns at any rate—no further dilating upon, but not to have alluded to it at all would have been as reprehensible as the conduct of the players, who, professing to play 'Hamlet,' left out of the play all mention of the illustrious Prince of Denmark!

The thoughtful bee-keeper must often have been struck with the *unquestionable unselfishness* of a bee's work. Here, at any rate, is a less repeated lesson, that it would be well for many of us to lay seriously to heart. The bee is no miser, no lover of self. The welfare and the comfort of others enter into their consideration. For whom does the happy virgin toil? Certainly not for herself! She builds a house of marvellous design, but not for her pleasure alone! She 'gathers honey all the day,' but not for her consumption! Bees that are yet unborn, whom she may never see, shall eat the fruit of her industry when the toiler shall lie on the cold, bare ground, shrivelled up, forgotten, dead! for as Homer, ages ago, wrote:—

'Like leaves on trees the race of bees is found,
Now green in youth, now withering on the ground;
Another race the spring or fall supplies,
They droop successive, and successive rise.'

Naturally all animals love their young. They would lay down their lives in gallant defence of their little ones, would they not? But the bees teach us to care for the offspring of others. In early spring virgin-sisters brave the biting wind, leaving the warmth and comfort of the hive, in order to procure pollen for the baby-bees. How tenderly they care for them, how zealously they guard them, how faithfully they feed them! And the point to be borne in mind is, that *they are not their children*. Sons and daughters of their mother-queen, heirs of the treasures of the hive—true, but not their offspring! But, all the same, greater love they could not show towards them than they do.

The foolish question is often asked in these days of ennui: 'Is life worth living?' The question comes, not from the lips of those who toil from rising sun till evening shadows for daily bread, but from the surfeited sons of earth, who would do well to take their answer from the hive. *A bee's work is a bee's happiness*. There is the grand secret! No talk of ennui, of collar chafing, of bad seasons, of unpropitious weather, of want of ease. Happy bees!—happy in their work, singing at their daily toil, fulfilling their allotted tasks, till working-days are o'er!

Politics seem out of place in a journal devoted to bees and, unfortunately, I risk the Editor's wrath in venturing to draw political principles from the hive. Spare me, O mighty journalist, if our opinions happen to clash! My knees tremble as I pen the next few paragraphs, feeling conscious that I have got on dangerous ground. How loyal the bees are to their sovereign! How they venerate her, provide a royal palace for her abode, obey implicitly, unquestioningly, all the laws of her wise administration! One happy community—under the sceptre of one sovereign lady. No cries of 'Dismemberment!' of 'Disintegration of the Empire!' 'Down with royalty!' 'We are all equal!' But stay, I thought I heard the buzz of some angry reader in my ear. I will pull up ere I get stung!

Punch's well-known advice to those about to marry is, 'Don't!' The bees say, 'Don't marry on love. Don't rush into an improvident marriage. Be wise. Cut your garment according to your cloth, for—

"The prescient female rears her tender brood
In strict proportion to the hoarded food."

Shakespeare avowed that 'home-keeping youths have ever homely wits;' and however true this may be, there is also an opposite truth. The domestic work of the hive, I believe—such as the construction of cells, the making of bee-bread, the feeding and sealing up the larvae—is entrusted to the care of the young bees. The collecting of the pollen and the honey is undertaken by their elder sisters, who 'not only know their way about,' but are able to withstand the temptations and allurements of their enemies, who dwell outside the camp.

Here, surely is a lesson for the daughters of England. Mothers, give your young daughters work to do in the family hive. Entrust the minor domestic duties to their charge. However rich or talented a young lady may be, she will be none the worse wife or mother for a thorough training in simple, but essential, household work.

Young lady readers, please don't scold: I am only telling you what the bees say: it's *their* advice, not *mine*.—J. EATON FEARN.

COUNTY ASSOCIATIONS.

[1637.] My great interest in the matter, and placed in similar circumstances, must be my excuse for presuming to answer Mr. Hooker's letter (1614). I believe the question is not so much the most suitable day and date and place of meeting of the county representatives, but the *distance and expense*.

Take this county—Glamorgan—for instance. The

chief centres of the members of the Bee Association at the present time are. Cardiff, where the meetings are held; Aberdare, 24 miles from Cardiff, where the Hon. Secretary resides; Bridgend, 20 miles from Cardiff; Neath, 38 miles; and Swansea, 45½ miles. With the exception of Aberdare and Cardiff the rest of the county is practically not represented, and know nothing of the Association except when called to pay towards its support.

If the County Associations are to do any further good the parent society must take the initiative and issue rules and regulations for the formation of sub or district associations. I believe this is already done in some counties, and in others again there are district and separate associations from the county. I do not favour the latter, but better so than as we are now; and this is what ultimately it will lead to if the former is not carried out, or the Society will collapse for the want of interest and funds.—BEE-KEEPER.

NOTES ON BEE-HIVES—SECTIONS.

[1638.] As I have had numerous inquiries respecting the glass sections, described in last week's issue of the *British Bee Journal*, kindly permit me to say the outside dimensions are those of the $4\frac{1}{2} \times 4\frac{1}{2} \times 2$ -in. section; the sides are 2 in. wide, and the top and bottom $1\frac{1}{2}$ in. wide. Fig. 1 showed the shape or form only, but, of course, the size could be made to order. They may be purchased when advertised in your advertising columns. What I have had made are for my own private use.

When glass dividers are used in connexion with my glass sections, the super is 'a dish to set before a king.' The edges of the glass dividers should be polished, although this is not absolutely necessary; wood, tin, or other dividers may be used.

In looking over bee-keepers' appliance-suppliers' catalogue, I notice in that of Mr. John H. Howard's a section with a groove on all the four inner surfaces in order to hold whole sheets of foundation. I notice in that of Mr. T. B. Blow a section with a groove on all the four inner surfaces in order to hold whole sheets of foundation, and that Mr. T. B. Blow has applied for a patent for his.

Months before Mr. T. B. Blow applied for this patent I noticed Mr. John H. Howard give a description in the *British Bee Journal* and in the *Bee-keepers' Record* of a grooved section as an invention of his own—i.e., of Mr. Howard's.* As the grooved section in wood contains the best method of fixing or holding whole sheets of foundation that can be devised, I shall be glad to know exactly in what way the sections differ. This will also be found interesting most likely to many of your readers.

I have already stated I had made and used a groove on all the four inner faces in order to hold whole sheets of foundation long before Mr. Blow applied for a patent, but I never gave a description in the *British Bee Journal* until I began my notes under the above heading, and I might say my sectional honey gained first premiums wherever exhibited, and astonished everyone who saw it, being quite free from pop-holes and other defects.

I also notice Messrs. Abbott make the following statement:—'The plain groove (not dovetailed) as advertised by other makers, cut free of charge.' Perhaps they will be so good to make all this plain to us.—T. BONNER-CAMBERS, F.L.S., *Tref Eglwys, May 1.*

THEORY v. PRACTICE.

[1639.] Unfortunately for the best interests of bee-keepers, the expression has gained to some extent in the

* For date of descriptions I allude, *vide B. B. J.* for April, 1887, and *Record* for May, 1887. I understand Mr. Blow applied November 1887.

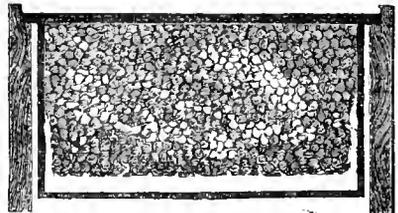

outside world, that they are a lot of theorists, who instead of working for the greatest good to the greatest number, are trying to feather their own nests, by attempting to show (or some of them at least), that they alone know it all, and their appliances are the only ones of value; that their theories alone are worthy of acceptance, and by the use of their hives alone, can bee-keeping be made a success. As to honesty and integrity of purpose, the matter is not at all considered; all that is thought of, being that the theories don't pan out as anticipated, and the hives don't bring in honey when there is none in the fields to be gathered. The great trouble has been that some one of little practical experience, but with a fair knowledge of bee literature, gets an idea into his brain and elaborates it therein, till finally he thinks he has discovered something new and valuable; then without testing the matter, he rushes the idea into print. No harm would be done if experts only read the matter; but amateurs who read the article are impressed with the way it is put, and in testing find to their sorrow and disgust that failure follows; then comes the trouble, but bee-men of intelligence are condemned as well as the author of the humbug, and bee-keeping suffers thereby.

Patent hives and traps of various kinds have been offered that possessed no merit whatever, yet were claimed to make the man rich who bought them. The 'Cottons' of the bee-world are still alive, and every season we find them putting in their work. The remedy against all this is for bee-keepers to take a reliable journal, and follow its teachings; by so doing they will steer clear of the humbugs, and save enough in a single season to pay for many years' subscriptions.—J. E. POXB, *No. Attleboro', Mass., U. S. A. (Canadian Honey Producer.)*

FRAMES WITHOUT SHOULDERS OR ENDS.

[1640.] Having several times seen notices in the *Journal* that yourself and other bee-keepers used frames without any shoulders or ends, &c., to keep them distanced one from another, I cut the broad shoulders off my frames last year, so as to be able to close the frames to $1\frac{1}{4}$ inches, as advised; but on the expert visiting me in the autumn he asked how the heat was retained, and prevented escaping between the ends of the frame? I could not tell him, but having thought of the matter again lately, I write to ask you what you do to meet this point. I do not know that my bees have suffered, but it does seem to me a good deal of heat must escape between the ends of the top bars, and thence along inside the hive side under the quilts, until it communicates with the space behind the dummies, which would not escape were broad-shouldered frames or metal ends used. Supposing I reverted to the old practice, would you advise broad-shouldered frames (as Abbott's) or metal ends? and if the latter, whose pattern?—EAST DULWICH.

[You would certainly lose a large amount of heat unless you adopt measures to prevent its escaping. The

proper way is to have a piece of wood fixed to the hive, running along the ends of the frames. This will form a rabbet, as shown in the illustration, and closes the ends of frames. The division boards are also made to fit this rabbet, so that when the quilt is on the frames no heat can escape. This rabbet is also useful if you use

metal ends, as there is always an escape owing to the conduction of the metal. Your hive being constructed for broad shoulders is better suited for such. The Carr metal ends we think the simplest and best, because they at any rate give you the choice of two openings, $1\frac{1}{4}$ and $1\frac{1}{2}$ from centre to centre.—Ed.]

BEEES AND FLOWERS.

BENEFITS OF BEES TO AGRICULTURE AND HORTICULTURE.

[1641.] From the very 'pointed' argument used by the bee in self-defence, either real or imaginary, the masses believe that the sole occupation of the bee is to sting; and we often hear the remark that 'a bee will go ten rods out of its way, any time, to sting me.'

Let us see if this be true. The bee is never more happy than when hard at work, and at a time when honey is coming in rapidly. There is nothing stingy about them. At that time of the season I have taken from the hives hundreds of pounds of honey without the least protection of either smoke, veil, or gloves.

Why is nectar placed in the flower or blossom? Is it necessary for the setting and maturing of the fruit? The scientific horticulturist says No! Was it placed there for the bee? Again the scientist says No! Then let us examine the mysterious construction of the blossom, and see if we can solve the problem.

The blossoms are composed of one or more leaves called petals. The base of this is called the corolla, and there, as a rule, nectar is deposited. The stamens or pollen-bearing stems—in other words, the male organs of the plant—protrude beyond this nectar, and in order for the bee to secure this much-coveted sweet she must brush by these stamens, and to a greater or less extent the pollen adheres to the legs and body of the bee. It no sooner drains the cup that Nature has filled for a twofold purpose, than it hies away to another, and here is where the wise economy of Nature is being performed. The bee, in coming in contact with this second blossom, mingles the pollen of the two, impregnation takes place, and all fruits and vines are made to bring forth fruit, 'each after its own kind.' If any doubt this assertion, next spring when your fruits, vines, and clovers blossom, just before they open, with a bag having the meshes small enough to exclude insects, see how much fruit and seed you get from the blossoms thus treated.

In the West, in some sections where the bee and hornet do not exist, they fail to raise pumpkins, for the want of something to fertilise the blossoms. In some of the mid-ocean islands they could not raise red clover seed until they imported bumble bees to impregnate the blossoms. Now the Italian bee is aiding in this grand work.

The bee is the friend of horticulturists and agriculturists, and as there is no insect that increases in such vast numbers so early in the spring when their services are so much needed, they are of more value to the farmer, gardener, and fruit-grower than all other insects.

A man near Boston makes a business of raising cucumbers for the winter markets. I am informed that he has several acres under glass, and until within the past few years he did all the fertilising by hand. This was a most tedious and expensive piece of work, reducing the profits to a minimum. But now, in each section of this vast winter garden, he has a colony of bees, and while the mercury is sporting with zero outside, these little helpers are gathering honey from cucumber blossoms, and at the same time doing the work of many hands; and one great advantage is, that they do their work so much better. The proprietor says that by the old method they never succeeded in fertilising over 50 per cent of the blossoms, but that the bees fertilise at least 80 per cent, thus advancing his industry from a basis hardly paying expenses to one that is profitable.

I might dwell for hours upon things connected with this very interesting pursuit, but I will not tire you, for what may seem interesting to me may be idle talk to you; but let us learn a lesson from the bees, to do all the good we can in this life. The bee that gathers the nectar from, and fertilises, the blossoms, never lives to consume the honey stored for the winter months; but toils on uncomplainingly, and if the season be favourable it not only stores sufficient for the winter's supply, but a surplus sufficient to compensate the bee-keepers for the attention given during the summer months besides, and giving us the only pure sweet known to the civilised world.—*Read at the Fremont Mich. Convention by Geo. E. Hilton.—(American Bee Journal.)*

Echoes from the Hives.

Aberdeen, May 8th.—Notwithstanding the fact that we have had a very cold and almost wintry spring, bees are now in fairly good form and give hopes of a few May swarms after all. The rather dry and frosty winter has been favourable, and where good stores and comfortable wrapping had been provided, hives have wintered well. Fruit blossoms and spring flowers are now beginning to unfold to the ever-increasing strength of sunlight as the days lengthen, and in nooks sheltered from the strong winds of the last week good work has been done. In more exposed positions the strength of hives has been considerably reduced by the bees being tempted out by the bright sunshine, and then being overcome by the strong winds. Reports from this district in general are hopeful, but the lateness of the season is everywhere felt, and reckoned to be over three weeks behind the average. We may now hope that with brighter weather and an absence of frost, flowers may not be blasted in the bud, as in recent years, and that after all some leeway may be made up.—*G. B. B., Hon. Sec. N.O.S.A. Society.*

Biroh Vale, Derbyshire, May 13.—In North Derbyshire here everything is very late. I wintered with one stock and three of last year's swarms, packing with earth, dust, &c., early in October, as the heather keeps us going here pretty late. One swarm was originally a poor one, and should have been united; this was wintered on four (parallel) frames, the others on seven frames each—two parallel and one right-angled. On 24th March—fine warm day—I changed the weak lot to a new hive, and found them only sufficient to cover three frames, and short of food. I gave them sugar, and on the 8th April gave them warm syrup, but up to the 6th instant found no trace of brood, and found no pollen going in, and had given them up as queenless; but on the 11th instant had another look at them and found the queen, but still no brood. The bees were now very much reduced, so I got a frame of brood from another hive, some yards away, put it with weak lot, reduced them to three frames, and changed the hive to the place of the one I took brood from, putting the robbed hive on site of the weak lot. The bees were flying freely at the time. The other three hives have wintered well, including the one from which I have taken the drone-breeding queen. As I can get no queens about here yet, I have put in the last-mentioned hive a frame of brood and eggs, hoping a queen may be raised to meet the drones now hatching out in this hive. I see your correspondents talking of blossom being out some time ago. We have none out here except gooseberry bloom, which have come out within the last three days, and is now covered with *Apidae* in all their various forms—my bees, though, being conspicuous by their overwhelming numbers. By the way, I saw the first queen wasps of the year, hereabouts, yesterday—a very fine bright summer day—and killed twelve of them and ten more to-day, the Sabbath notwithstanding. They seem numerous this year here. I found no eggs or brood in my hives up to the 15th April, after which I was absent

till the 6th instant, on which day I found patches of sealed brood. I may say I paint my hives inside and out, floor-boards, and everything, with three coats of oil paint, and find the bees do very well with this. I should be glad of some views as to the best way of working hives for the heather. I don't move to the heather, as we have it close to us here.—'TH. ASPEN.'

Brondesbury, May 14.—Bees hard at work in outer sections—working on gooseberries and fruit blossom.

Springburn, Glasgow.—Since the 1st of May, we have had glorious bee weather. The warm sunshine has allowed examining operations to be carried on without risk or injury to the bees. Should this and next month continue as at present, you may reckon on hearing good reports from Scotland, and I hope also from our friends across the border.—J. D. McNALLY.

NOTICES TO CORRESPONDENTS & INQUIRERS.

Letters or queries asking for addresses of manufacturers or correspondents, or where appliances can be purchased, or replies giving such information, can only be inserted as advertisements. The space devoted to letters, queries, and replies, is meant for the general good of bee-keepers, and not for advertisements. We wish our Correspondents to bear in mind that, as it is necessary for us to go to press in advance of the date of issue, queries cannot always be replied to in the issue immediately following the receipt of their communication.

All queries forwarded will be attended to, and those only of personal interest will be answered in this column.

WM. MITCHELL.—1. *Dysentery.*—The Eastern races of bees are frequently subject to dysentery. In your case, as there are plenty of young bees, you need have little fear now the weather has improved, of there being an increase of brood-rearing and a cessation of dysentery. We presume the queen is alive, you do not give that information. 2. *Foundation.*—Steep it in warm water at least 90° Fahr., but not much over that temperature; old foundation is very unsuitable.

HERBERT LIVERMORE.—*Queenless Hive.*—You acted very unwisely in transferring so early in the season. When bees are much disturbed in early spring the queen is frequently 'balled' and so killed; it is so in your case the bees raising others from larvæ left in the hive; they would not cease carrying in pollen while there were larvæ and queen-cells in the hive. Continue stimulative feeding and see that the queen is properly fertilised, which now the season is so far advanced is most likely to take place.

A. EVERETT.—1. *Excluder Zinc.*—We never use it, although there is a growing tendency to do so when using any other but sectional supers. 2. *Distance between Bottom and Top of Body Box Frames.*—Three-eighths of an inch.

J. S. LAWTON.—*Bees leaving Hive.*—These proceedings of bees are not infrequent during spring; such swarms being called 'hunger swarms,' though they do not always proceed from shortness of stores. A weak colony is more likely to do so than a strong one, in fact we have never come across a case happening with a strong colony in a normal condition.

MRS. W. W.—1. *Storing Honey in Earthenware Barrel.*—It is a most unsuitable vessel. Clover honey is sure to granulate more or less according to the temperature after being once exposed to the air. 60 degs. F. is a very good temperature to retard its granulation. 2. *Trifolium incarnatum.*—This being an annual, is never sown on pasture land. The time for sowing is autumn, as a crop for the following spring for green food, or allowed to grow for hay. Bees obtain a fair amount of honey of a light colour from it. The proportion to be sown is 25 lbs. to the acre. 3. *Doubling.*—Your plan would answer very well, as you would not very materially weaken the other stocks. 4. *Cyprians and Syrians.*—Both these varieties are of an irritable disposition.

W. H. GOING.—*Dead Stocks.*—There are no symptoms of foul brood in the combs sent. One of the pieces had evidently come from a hive that had been robbed. We should therefore suppose that robbing was the cause of death of the colonies, but with no further data than you give it would be impossible to state with certainty.

JOHN HEPWORTH.—1. *Dysentery.*—A slight case of dysentery which will disappear now fine warm weather has set in. 2. *Bees carrying out larvae.*—The colony requires feeding.

A. H.—1. *Stores.*—Your hive is without doubt in a very prosperous condition. 2. *Transferring.*—Now. 3. *Placing on Crates.*—As soon as honey flow sets in. 4. *Keeping body-box free from Stores.*—Yes. 5. *Excluder Zinc.*—We do not use it under sectional racks. 6. *Tiering up.*—Place first rack on top of second with the bees in it. 7. *Queen Cells.*—Yes, if there are any. 8. *Answers by post.*—Yes, if of a very urgent nature.

J. E. ORPHE.—*Suspicious Comb.*—This is foul brood.

JAMES HOUSTON.—*Dead Brood.*—Arrived in rather a mixed condition, but appear to be only chilled, not foul brood. Feed gently and regularly, and keep them warm and comfortable. Give them syrup in the evening only, and then at the temperature of new milk. Contract the brood-nest so that the combs are covered, and make all tight and cosy.

WOOD GREEN.—*Living Swarm.*—Put inch starters only in the frames, and full sheets in the sections. If honey is coming in, put sections on at once, and do not feed; but should the honey not be coming in, then feed very gently for a day or two, and put the sections on after you remove the feeder. It is the exception for natural swarms to come off except when honey is coming in pretty freely. Ohlong excluder is best. As you only put starters in the frames, you can put all the frames in when living the swarm.

J. P.—*Moving Stocks.*—Your only safe plan now is to move the stock some cool evening to a place quite two miles from their present, and also from their future stands. Allow them to remain for a week or two or more if you can, then remove them to their new location. If you were to remove them one mile only, you would be sure to lose many.

ENTHUSIAST.—*Removing Bees from Chimney.*—It is very difficult to advise without seeing the exact position they occupy. Can you send a sketch, and we will help you if we can?

H. MARRS.—1. *Supering Skep.*—You might get some nice sections from apple blossoms, also from gooseberry. Therefore super at once, and keep warm. 2. *Supering a stock that has swarmed.*—We should prefer to set the swarm on the stand of the parent stock and super it as soon as hived, placing the parent stock elsewhere, but not supering it, as owing to the shift it will have lost all bees that were on the wing when the swarm issued, and thus be greatly reduced in numbers. This mode tends to prevent casts.

F. H. W.—1. *Grubs thrown out.*—This is a sign of starvation, feed at once on either syrup or dry sugar (Porto Rico). 2. *Dead Queens.*—Without knowing where you kept the box containing the queen we should say she died from cold. 3. *Placing swarm on stand of parent stock.*—(See answer to H. Marrs.) Those on the wing would take to the new hive. They are heavily laden, and being given ready admittance at once adopt it as their home.

T. NIXON.—1. *Delaying Swarming.*—Your plan will not do. Why not make an artificial swarm on Saturday,

thus preventing a watch on Sunday? 2. *Several Eggs in one Cell.* The present cold snap caused the cluster to contract. The queen has been fed to lay, and must extrude the eggs somewhere. Warm nights should adjust matters. That is our experience. 3. *Excluders.*—Adjusters are best. The zinc should never rest on the frames, there should be $\frac{3}{8}$ -inch space between. 4. We have not tried the articles you name; they are said to be effectual.

A. J. R.—1. *Doubling.*—You will find your questions answered in our 'Practical Work in the Apiary,' of this week. 2. Old queen-cells are of a darker colour, and more rugose than those recently formed.

G. E. CORBYN.—1. *Poor laying Queen.*—Unite and remove defective queen. Super under the circumstances you quote. 2. *Norfolk Association.* Apply to Mr. Jethro J. Rice, 16 Wensum Street, Tombland, Norwich.

W. L. BIRD.—*Extracted Honey from Skep.*—Try a shallow super with frames $14\frac{1}{2} \times 5\frac{1}{2}$ placing excluder-zinc over the hole. We should prefer transferring them to a bar-frame hive as the more profitable plan.

RIP VAN W.—*Queen thrown out.*—We should say your bees have superseded the old queen. We would advise you to make an early examination to ascertain if *worker* brood is being raised. This is in case the queen may have missed fertilisation.

AMATEUR.—*Dead Queen.*—This was so smashed on arrival that no opinion can be given. (See reply to 'Rip' above.)

H. J. SAVORY.—1. *Wax-moth.*—The 'maggot' forwarded is not the larva of the wax-moth. It must have dropped from an overhanging tree. If you should see the larvæ of the wax-moth, you must promptly destroy them either by crushing them, or, if they are wriggling out of the comb, by pricking them out with a pen-knife. 2. *Casting out Brood.*—Casting out brood at this time of the year indicates either the want of food, or, it may be, the removal of brood that has become chilled.

WRITE FOR CATALOGUE.

THE 'SIMPLICITY' HIVE.

Registered No. 98332.

No. 1 B. Fig 1.

In placing this Hive before
the public I venture to say that
it is one of the most simple and
practical yet brought out, and
possesses many advantages over
the ordinary Bar-frame Hive.

The Floor-board is hinged to
the back of the Hive as shown
in Fig. 2, and, when in position,
is supported by a simple bar of
wood across the centre, held in
its place by two cleats. The
floor-board, as will be seen, can
be let down in an instant with
the least possible trouble, and
as quickly replaced, completely
doing away with any difficulty
in cleaning, &c.—a great ad-
vantage.

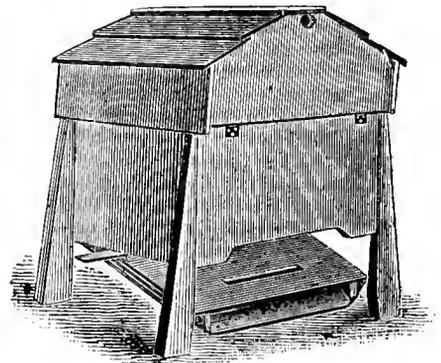

Fig. 2.

The outside walls fall 1½ ins. below the floor-board all round, thus ensuring freedom from damp, as it is absolutely impossible for rain to drive into the Hive.

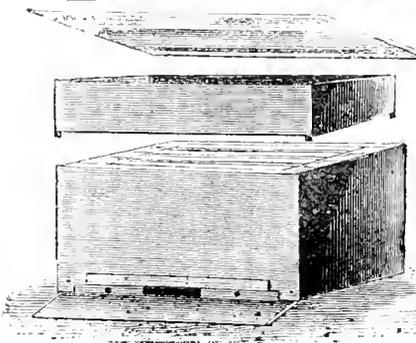

The entrance to the Hive is through a slit cut in the floor-board about 4 ins. from the front wall, and the alighting board being directly underneath is protected from wind and bad weather, and is always dry. The bottom bar of the third frame from front wall hangs just over the entrance slit, thereby preventing any direct upward draught into the cluster. By means of a metal slide the entrance can be contracted in winter, or in the case of robbing.

There are no projecting pieces on the Hive, such as alighting boards, porches, &c., to get broken in transit.

Price 10/-. Fitted for a Swarm, as No. 1a, 14/-. A reduction allowed if three or more Hives are ordered.

THE WORKING MAN'S HIVE.

Registered No. 98331.

The Hive contains nine frames, Standard size, with metal ends; one dummy; one quilt; has a stout body made of sound red deal; is double walled, and grooved, and has a water groove down each side underneath to exclude wet. The floor-board is hinged, and can be removed by two screws be let down for cleansing purposes. There are also a good landing board and two entrance contractors. Price—Body, Frames, and Roof, 5/-.

The rim shown between body and cover is made to drop exactly on to the body, and is kept in position by a block at each corner. It is for the purpose of carrying a section crate of twenty-one 1-lb. sections, and thus the whole form a complete and compact Hive. The rim and section crate can be had for 2/6 extra, making the complete Hive 7/6. Six of the frames can be fitted with half sheets of brood foundation for 1/-.

Customers buying the above Hive at 5/-, can at any time obtain the rim and super when wishing to raise section. They are all made to a size, and a fit is guaranteed.

MAY 24, 1888.

[PUBLISHED WEEKLY.]

Editorial, Notices, &c.

THE REV. L. L. LANGSTROTH.

There is, perhaps, no man living to whom bee-keepers of the present day owe more than to the Rev. L. L. Langstroth, or, as he is termed by our American friends, 'Father Langstroth.' How often in the progress and development of a science or industry the pioneers, those who were amongst the first, and who worked the hardest, very soon become forgotten. It is so in bee-keeping; those who have done the most, and by their exertions have enabled many in the present day to become not only bee-keepers but successful honey-producers, are forgotten and ignored. But this is not all, for those who have benefited by others' brain efforts and experiences are frequently those who do their best to crush them. Do we not find repeatedly that claims are made to inventions and improvements without regard to what has been done before? Names of inventors, discoverers, and benefactors, are frequently forgotten in the eagerness to benefit at their expense. We might mention numbers of instances at the present day, where inventions are used with but slight alteration, and the users deriving a pecuniary benefit, whilst the originators, to whom the invention cost a large expenditure of brain power, many sleepless nights, and perhaps a large sum of money into the bargain, are completely ignored. We have a most striking instance of this in the case of the Rev. L. L. Langstroth. We do not wish to enter into the question of whether Langstroth, Munn, or any one else, was the first to invent the frame, but what we wish to point out is that Langstroth was the first to make the moveable comb hive a practical success, and by his work, *The Hive and Honey Bee*, which is still the standard on the subject, he opened up to the world the improved methods of bee-culture, which have led to the enormous success witnessed at the present time. Does every bee-keeper realise that in using a moveable comb hive he is morally indebted to Mr. Langstroth for the benefit he is deriving from it? And if he does, is he prepared to make some acknowledgment and return for this obligation?

For many years Mr. Langstroth, who is now seventy-seven years of age, has suffered, and only from time to time, and at long intervals, has he been able to take up with his favourite pursuit. We

regretted that when we visited America last summer he was not in a condition to see us, and nothing would have given us greater pleasure than to have grasped this veteran's hand and looked into his benevolent face. Ever devoted to the science he loves so well, according to a friendly letter we received from him a few days ago, he was even then, during a period of convalescence, at the apiary of Mr. Heddon studying the capabilities of the Heddon system. His head troubles have prevented him from earning his living, and it is because this master of bee-keepers has been robbed of his means of livelihood by some of those who have reaped the benefit of his labours that he is not now, in his old age, in comfortable and independent circumstances. From time to time small sums have been subscribed, and in 1879 'The Langstroth Fund' was started in America. In that year Mr. Newman visited England, and at a meeting of British and Foreign bee-keepers held at our residence in Horsham, a subscription was started which amounted to about 6*l.* 6*s.*, the whole amount collected here and in America barely reaching 10*l.* Since that time small sums have been remitted to him, but how out of all proportion is this to the benefits conferred by him on the world! It is now proposed in America to raise a sum of money in order to purchase an annuity, and every bee keeper there will have an opportunity to pay some tribute to his great leader.

But why should we stand aloof and do nothing? On another page our correspondent 'Amateur Expert,' in his pathetic appeal, says, 'Let us, as British bee-keepers, give practical expression of brotherly feeling by subscribing to the fund; it will only stimulate his countrymen to do more, and make the annuity the greater.' These sentiments we heartily approve, and think it the duty of the many who have benefited by Mr. Langstroth's labours to do something on his behalf, so that this good old man may pass the remainder of his days in comfort, cherished by the thought that there are noble and honest minds on either side of the Atlantic that do appreciate his efforts, and prove a brotherly love and feeling are ready to recognise them. We shall be pleased to open a subscription list to be called the 'Langstroth Fund,' and earnestly hope that our appeal will be heartily responded to. Let us bear in mind that 'he giveth twice who gives in a trice.'

Donations sent to us, or to Mr. Huckle, Kings Langley, Herts, will be acknowledged in the *B. B. J.*, and forwarded to America. The list of contributions is headed :—

PRACTICAL WORK IN THE APIARY.

HIVING SWARMS.

The bee-keeper must have hives and all he may require for his swarms in readiness for their reception. If he has decided to have natural swarms, and has made his arrangements accordingly, now is the time when they are usually to be expected. He must keep a look-out for them, for strong hives will frequently throw a swarm without the usual clustering outside, which is the general outward sign with skeps. The signs of the approach of swarming are the crowded state of the hive, and the presence of drones and queen-cells. The first swarm usually issues between ten o'clock in the morning, and four o'clock in the afternoon on a fine day; and although we have known swarms occasionally to leave the hive earlier and later, it is not often that they do so. When bees swarm they will after a short time settle and form a cluster, which will gradually grow in size as the bees join it. As soon as most of the bees have joined the cluster, we generally sprinkle them with cold water, using for this purpose a garden syringe. This cools them, close clustering is the result and very much facilitates after operations. If they have clustered on a bush near the ground, and the hive be one without legs, they can be hived in the following manner:—Spread a sheet, cloth, or even a large newspaper will do, directly under the cluster on the ground, and at one end of it place the floor-board bringing one end of the sheet over the edge of the board.

The object of using the sheet in this way is to prevent the queen and the bees running under the floor-board, which they would be liable to do if the board were stood on the sheet. The prepared hive is then placed on the board and the front raised about $1\frac{1}{2}$ inches by means of a block of wood or a stone placed under the hive. The frames will be placed at right angles to the front of the hive so that the comb-foundation will hang perpendicularly; otherwise, if placed parallel to the entrance, the inclination of the hive will cause the foundation to be displaced, when it becomes warm and consequently soft. The front of the hive should be as near as possible to the cluster. Then give the branch on which the bees have clustered a smart jerk so as to dislodge them and cause them to fall on the sheet in front of the hive. In a few seconds the bees will make a start towards the hive, which some of them will enter, and by their joyful hum will let the others know that they have found a suitable dwelling. Their call will be answered by the others following, and nearly all will enter. Like human beings, some will be late, but after a little time the stragglers on the sheet and those flying about will join the rest. If they are a long time in entering the hive a sprinkling

with cold water will make them go faster. When the weather is very hot it is as well to shade them with a leafy bough, or a towel-horse with a sheet spread over it will answer the purpose. If the branch is not a valuable one and is small it will sometimes facilitate matters to cut it off; but be very careful to avoid all jarring. Then shake off all the bees by a sudden jerk in front of the hive. When all the bees are in, give a puff of smoke to drive in the stragglers or those that are fanning; remove the block, and the sheet and carefully lower the hive on to the floor-board. Then carry the hive steadily, place it on the stand it is intended to occupy and adjust it. As we prefer frames at right angles to the entrance, our floor-boards are always arranged to have an inclination towards the front, the hives being set level across the frames.

Those who place their frames parallel to the entrance will have to arrange their hives so that they stand perfectly level. If the bees have clustered on a branch too thick to be cut off or too high to admit of shaking the bees on the ground, they should be first shaken into a skep, box, or pail, and then from this into the hive. Hold the skep bottom upwards in one hand under the cluster, and with the other give the branch a smart shake so as to dislodge the bees into it. They can then be shaken out on to the sheet by inverting the skep and giving it a sudden jerk. Bees do not always settle on a branch, and sometimes choose very awkward places, frequently trying the patience of the bee-keeper to secure them. Sometimes they will settle and spread on the trunk of a tree, and in such a case we must either brush them gently into the skep or place its edge near the upper part of the cluster and persuade the bees to ascend into it; and if a piece of comb containing brood can be placed in the skep it will be more attractive. Occasionally the queen, which accompanies the swarm, will alight on the ground; and when this happens the bees will also settle with her, and spread out for a considerable distance. In this case put the hive as near the bees as possible, and with a spoon carefully place some bees near the entrance.

With hives on legs, and those too heavy to move, we have only to take the bees in a skep, or, what we think still better for this purpose, a pail, and then introduce them into the hive in the following manner:—Turn up the quilt, push back a division-board, and remove three or four of the frames. The bees are then poured out of the pail into this space and covered over with a quilt. They will not be long before they run in and cluster amongst the other frames, when the division-board can be pushed up into its place. Swarms should always be placed on the stands they are intended to occupy, and the hives adjusted as soon as possible after they have clustered, because as soon as they have found a dwelling they at once commence work and mark the spot where they stand. If left until the evening before they are removed to their stand many bees will have already got used to the spot where they were first hived and will be lost. This, however, does not apply to swarms which have to be sent to a distance. These had better be left where hived until the evening, and when all the bees have settled down quietly they may be taken to their destination and at once hived.

In a future article we shall speak of catching swarms and the appliances used for that purpose.

USEFUL HINTS.

WEATHER.—After a gentle, refreshing rain we have a day (May 18) of brilliant sunshine, and our bees are wild with excitement, several colonies showing signs of swarming, although doubled, and drones flying in abundance. Our supers are not yet on, as we have little fruit bloom from which to gather early surplus honey.

Some of our Kentish brethren, we hear, have sections in position which the bees are rapidly filling, but Kent is a county of orchards and abounds with sainfoin, both producing early first-class honey. We less favoured apiarists must bide our time, and patiently await the hawthorn and white clover bloom, building up our colonies until they overflow with population, and preventing swarming as best we may by nether ventilation, and getting on our surplus cases ready for action when the good time arrives.

SHALLOW FRAMES.—Mr. Dobbie, in his letter (1626), p. 240, makes reference to shallow frames $5\frac{1}{2}$ inches deep as advocated by Mr. W. B. Carr and ourselves, and mentions the fact of Mr. Howard having sent out 35,000 shallow frames 6 inches deep, deprecating the establishment of a standard of the former depth. Now in Mr. Cheshire's *Bees and Bee-keeping* (Vol. II, p. 111) the depth of Mr. Howard's 'Small body-boxes,' as used in his 'Holme Wood Hive,' is stated to be $5\frac{1}{2}$ inches, and the small frames used in these boxes are said to have no bottom rail. We do not understand, therefore, this apparent discrepancy of using 6-inch frames in $5\frac{1}{2}$ -inch boxes (unless the frames were sent out independently of the boxes), or how Mr. Howard can be said to advocate a shallow frame of 6 inches deep.

WEAK COLONIES.—'R. M.' (1634, p. 250) suggests that our plan of strengthening a weak stock at the expense of a strong one by changing positions might result in the production of two moderately weak stocks. No doubt, such *might* be the case if the exchange were made without thought or foresight. The time of exchange, the *time* of the honey-flow, and the *fecundity* of the queens, must all be taken into account. With a late honey-flow the exchange should be made not later than the end of April; and the weak colony should be *moderately* weak only, while the strong one should be *very* strong. A colony covering two frames only is not worth preserving; and a strong one, having given its flying bees to a weak one, recuperates more quickly at this season perhaps than 'R. M.' supposes, unless he has made the trial. In a former letter 'R. M.' expressed a desire for further information as to the wintering of nuclei. During several winters—notably the last—we have wintered nuclei, both in houses and in the open, successfully and without loss. Each has consisted of three or four frames, well covered with bees, and having sufficient sealed honey for winter store. Our hives contain four frames only—of course, we prefer four to three for wintering—are well made of inch pine, and protected by ample roofs, with quilts, &c., just as our other hives are wintered. Such nuclei, well prepared for winter, with young and prolific queens, will come through the winter better than they would if packed in a ten-frame hive between division-boards. Thus, in fact, we prefer to winter our small 'after-swarms,' and find them most useful when spring arrives for uniting and other purposes.

For strengthening a *deserving* weak colony at the *expense* of a strong one—for that is the only alternative—many advise, and with reason, to take from the strong one a comb of hatching brood, with adhering bees, to jar it slightly, causing the older bees to take wing and return home, while the young remain on the comb, and then to insert the comb and bees in the centre of the weak colony, at the same time uncapping a little honey around the brood-nest, and removing all other combs which the bees are unable to cover, and finally closing up the division-boards and covering up warmly. The process to be repeated as occasion shall require. In lieu

of the frame taken from the strong colony, a frame of clean worker-comb, as new as possible, is inserted in its place, and is quickly filled with eggs. But we again say that if a colony does not possess four frames, well covered with bees at the end of April, it is most advantageous to unite it to a moderately strong one.

GIVING ROOM in the brood-chamber is now a matter of importance, if we wish to prevent swarming, with a view to honey-production. During fine and warm weather a frame of nice clean comb may safely be inserted in the centre of the brood-nest, and may often be done with advantage immediately before putting on the section case. Colonies should be occasionally examined in order to ascertain their wants during the latter portion of this month, as the objection to manipulation is less now than in the early spring. By a careful examination in suitable weather, bees now suffer no disadvantage, and where the desire for pilfering has disappeared, manipulation may be carried on during the hours of flight, but care should be taken to keep the hive open for as short a time as possible, since the hatching larvæ are quickly chilled. 'Giving room,' as recommended above, will be understood to apply only to colonies which have not yet attained to the maximum of population. Where such is the case, 'crowding' the bees before putting on surplus cases, is generally advised at this early period, but there are so few districts in which early surplus can be gathered, that there is a wide margin for discretion here. In fact, bee-keepers, perhaps more than any other class, must act in accordance with surrounding circumstances.

SWARMING will no doubt have commenced in southern counties before these words are in print, and all apiaries, whether worked for honey or for increase, should be carefully watched during swarming hours—say from 9 a.m. till 3 p.m. Apiaries left to themselves often lose swarms which are never missed by their owner. It must also be borne in mind that some seasons are far more productive of natural swarming than others are.

Showery weather, with frequent gleams of sunshine, and a scarcity of honey, are conducive to swarming. A large skep, or pail, a sheet or cloth, a pail of water, a garden syringe, a short ladder, or steps, are all useful aids towards capturing swarms. When the swarm is well out, and soaring aloft, a few well-directed shots from the syringe will generally prevent its departure to some distant pre-selected rendezvous, and prevent its loss. As a rule all swarms settle, and remain a short time, in the neighbourhood of their hive before decamping. But to this, as to all other rules, there are exceptions, and we have often witnessed the departure of a swarm, especially a second swarm, direct from the parent hive, without the slightest delay or settlement. Such swarms usually rise aloft at once, sufficiently high to clear the tops of the tallest trees, and then dart away in a straight line to the selected spot, at a pace very difficult for any biped to maintain.

To hive a swarm when settled, having first sprinkled it with water from the syringe, take the skep, mouth upwards, in the left hand, having the cloth lying across the left arm, and its edge grasped, together with the skep, by the fingers of the left hand, shake the swarm with a good hearty shake, into the skep and cover it quickly with the cloth. Tighten the cloth around the skep mouth, and at once invert the skep in a well-shaded spot, near the place of settlement, and allow it to remain thus for a couple of minutes.

Next raise the edge by placing under it three thick wedges, by which it is raised a couple or three inches, all round, from the cloth. Shade well with rhubarb-leaves or green boughs, and sprinkle frequently during the day with water, and at night remove the swarm to its future stand, shaking it out in front of the frame-hive which it is intended to occupy, wedging up the front of the hive, and using the carbolised feather to

hasten and direct entrance of the bees. By brushing a little carbolic solution on the branch where the swarm settled, stragglers will be prevented from congregating there. If a swarm settles upon a post, a stump, a wall, or similar place, set an empty skep above it, and by the application of carbolic solution, drive it up into the skep by passing the feather repeatedly around the post, close to and beneath the bees, until all are in. The speed with which the bees will run upwards into the skep will astonish a novice in the art. Be careful, however, to allow no smear of carbolic on the *skep*, or a sudden exodus will follow.

QUEEN-INTRODUCTION to the parent hive, after the departure of a first swarm, is easily accomplished by cutting out all queen-cells and caging the new queen for a short time.

THE POND METHOD.—Mr. J. E. Pond, writing to the *Canadian Bee Journal* (current vol. p. 68) on this subject, gives concisely the method which he has practised successfully for many years, thus:—‘On the afternoon of a fine day, when the bees can fly freely, I remove the old queen, taking care at the time to see that no queen-cells have been started. On the evening of the same day, after the bees have all returned to the hive, I allow the new queen to run in at the entrance of the hive, taking no further precautions. I then allow the hive to remain unexamined for four or five days, except carefully examining the entrance to assure myself that the queen has not been killed and carried out. As yet I have never met with failure, and, so far as I can learn, no failures have resulted with those who have tried the plan by following exactly the method I have briefly outlined. No time is lost in the introduction, which is of considerable importance in the honey-gathering season, or the season preparatory therefor.’

ZINC EXCLUDING HONEY-BOARDS.—In the current number of the *American Bee Journal* (May 2nd), in answer to the query, 538, ‘Have you demonstrated in practice that the zinc queen-excluding honey-board is a hindrance to the free passage from the brood-chamber to the supers? In other words, Have you found any difference in the quantity of honey stored where such boards were used?’ The answers given were fifteen in number. Of these, ten are highly in favour of the zinc excluder. Of the remaining five, three report that they have not sufficient experience to give a decisive answer; one, Mr. Hambaugh, says that he ‘has not experimented largely, but he thinks there was a difference;’ and the fifth, Mr. Brown, states that ‘the disadvantages over-balance the advantages.’ The ten approvers are Professor Cook, Mrs. Harrison, Messrs. Mason, Eugene Secor, Doolittle, Heddon, Taylor, Pond, Demaree, and Newman (the Editor). Mr. Heddon writes:—‘I have demonstrated, by the use of several hundreds of them, and for three years, that they are not a hindrance.’ Mr. Taylor says:—‘I had several colonies with excluding honey-boards that stored more surplus honey than any colony which did not have them.’ Mr. Pond states:—‘I have satisfied myself that they are a great advantage. I do not find that less stores are secured when zinc excluders are used.’ Mr. Demaree says:—‘The perforated excluder is a success;’ and the Editor remarks:—‘The zinc queen-excluders are no hindrance to the bees.’ This is important testimony, and we hope some of our leading English bee-keepers will make trial of these honey-boards during the coming season, and report thereon.

ASSOCIATIONS.

BRITISH BEE-KEEPERS' ASSOCIATION.

The usual monthly meeting of the Committee was held on the 17th inst. Present, the Rev. Geo. Raynor (in the chair), the Rev. Dr. Bartrum, the Rev. F. S. Sclater, Rev. R. Errington, H. Jonas, J. M. Hooker, and the

secretary. The minutes of the last committee meeting were read and confirmed.

The consideration of amendments in regard to the mode of conducting examination of candidates for third-class certificates was under discussion, and various suggestions in reference thereto were considered. It was resolved, that a special sub-committee, consisting of the Rev. Geo. Raynor, Mr. Hooker, Rev. F. S. Sclater, and Dr. Bartrum, be appointed to consider and report on the proposed amendments, and that the secretary do prepare a tabulated statement of the examinations which have been held under the present rules. The secretary reported that upwards of 250 entries had been made for the bee department of the Royal Agricultural Show, to be held at Nottingham. The several arrangements for this exhibition having been considered, the meeting resolved itself into

THE QUARTERLY CONFERENCE.

There were present the following County Representatives, namely, C. H. Haynes, Worcester; W. Rushton, Bedford; J. P. Sambels, Herts; Rev. W. E. Burkitt, Wilts; W. Lees McClure, Lancashire and Cheshire; J. Garratt and F. Cudd, Kent; W. B. Webster, Berkshire; F. H. Meggy, Essex.

The minutes of the last Quarterly Conference were read and confirmed. In reference to the proposed amendments for conducting third-class examinations, the Chairman reported that a special committee had been appointed to consider the question and to report at the next meeting of the General Committee. The suggestions already sent in to the Committee on this subject were calculated to strengthen the present system adopted, more especially in regard to the knowledge of the candidate in reference to foul brood. On this point the Chairman mentioned the fact that recently some candidates competing for the higher honours in the examinations had never met with a case in their lives. They, however, possessed a good general knowledge of apiculture.

Mr. Meggy was of opinion that there were many good experts who were not thoroughly acquainted with the subject of foul brood, and that if candidates were expected to have an intimate knowledge of this subject he feared that many might be found who would fail to satisfy the examiner in this respect, and yet be good sound practical bee-keepers and thoroughly competent to teach others how to manage an apiary. Mr. Sambels supported the views of Mr. Meggy, he thought it would be very hard upon the candidate who showed a good general knowledge of bee-keeping to be plucked in his examination simply because he had never met with a case of foul brood. Providing the candidate showed a knowledge of the subject and how it should be treated, he considered that his certificate should be granted. A discussion ensued in regard to the regulation for catching the queen in these examinations. Mr. Garratt considered that the queen should be pointed out when ascending even if she were not caught. Circumstances might prevent the candidate from actually handling the queen without injury, and if the examiner's attention were called to the fact and noted by him this might be considered sufficient. The meeting was generally of opinion that if the candidate failed either to catch or point out the queen, the examiner should take some trouble to ascertain whether the queen was present and if not to make allowance to the candidate accordingly. The Chairman promised that the suggestions given by the county representatives and others on this subject should have every consideration.

Mr. McClure reported that the subject of the prizes offered at county shows, which were open to members of the British Bee-keepers' Association only, had been considered by the county representatives at their preliminary meeting. The following resolution in reference thereto having been passed—viz., ‘That the exhibitors

competing for these prizes should be members of the County Association where the show was held, in addition to being members of the Central Society—the Secretary read the minutes of the Quarterly Conference held in July last year, from which it was gathered that the regulations made in regard to these prizes were considered and approved by the county representatives.

Mr. Garratt suggested that it would be well to modify these regulations, so as to include the members of all county associations, similar to the rule of the Bee Department of the Royal Agricultural Show. At the time the regulation was made the impression prevailed that at some future time many of the present county Associations' distinctions would cease, and that it was very desirable to strengthen the Central Society as much as possible.

Mr. McClure was of opinion that the present arrangement was calculated to draw off the exhibiting members from the County Associations, and he considered that it was very desirable to retain these members in the County Associations, whilst the larger county gentlemen subscribing their guinea annually might be handed over to the Central Society. The Lancashire and Cheshire Association would most certainly work to this end. He hoped next year that the Central Society would increase their grant under this head very considerably and under more suitable regulations. The Chairman pointed out the amount granted for the purpose must depend upon the Central Society's income. If the County Associations would act on the lines laid down by Mr McClure, then the Central body would be in a position to do more for the Counties.

CONVERSAZIONE.

The Rev. G. Raynor, upon being elected chairman, expressed his regret that a county representative had not been chosen to fulfil such duty. However, he accepted the office with pleasure, and hoped there would be an interesting and instructive discussion. There were several appliances and inventions for inspection, but the proceedings would commence with the reading of a paper by Mr. Sambels, entitled, 'The Future of County Associations.'

Mr. Sambels apologised for the hasty way in which his paper had been prepared. He thought the subject would be an interesting one for discussion, but had not decided to commit it to writing until that very day. He then read as follows:—

The subject of the future of our county associations is one that is occupying the minds at the present time of most of us who are interested in them. The question that requires answering seems to be—Have they attained the ends for which they were established? Is their work done? Is there any object to be gained in continuing their existence? They were established, as all are aware, to make for bee-keeping a fit and proper status as a national industry, and to especially benefit the agricultural labourer. These are objects in common with our august parent the *British*, and, of course, the affiliated associations have brought bee-keeping home to the doors of the cottager in a way that the *British* never could; but my observation of *Hodge* and his susceptibilities to be benefited in the way of what you can teach him towards helping himself leads me to the conclusion that the philanthropic work of our county associations must in the main—I say in the main—be dropped, and if we continue these organizations in the future, it must be chiefly for their commercial importance. Depression is everywhere complained of, but chiefly in the rural districts. The clergy complain, and justly, tithes are low and increasingly difficult to collect; the landowner complains, too, rents are lower even than tithes. Settled incomes are and have been diminishing, consequently everyone is looking around for opportunities of reducing their expenses, and in many

cases the subscription to the bee-keeping associations has to go. Moreover, the idea that if you invested in the best hive and a colony of the best bees—which in most cases were the greatest novelty and the race known least about—and set them down in your garden, they not only looked pretty, but a return of 100 per cent per annum was assured, is exploded; as also is the other—that bees are as harmless as flies. The truth is out. Bees have stings, and some people have unhappy ways of handling bees to induce them to show their stinging powers; and I know of few easier ways of losing money than for a slipshod person who is not methodical and who does not pay due regard to details to invest in bees, and persist in trying the newest inventions in spite of repeated failures.

The last three years have seen the loss of most of the above class from our associations as well as a large number of subscribers who supported us in our endeavours to benefit the labourer. This brings me to 'Hodge' again. There are not a few agricultural labourers who are good bee-keepers and are making money by their bees. We have the wife of one in the Association of my adopted county that comes to my mind at once. But these are exceptions. As a rule, they have not the money to invest. If you set them up most of them are too slow to learn to help themselves, and their ideas so centre around the old straw skop with its small returns and simple methods of management that very many of them slip back into the old method, only allowing an advanced man to 'drive' their condemned bees, instead of calling in the old barbarous sulphur-pit. We in Herts did at one time succeed in getting large numbers of such to subscribe 1s. per annum, but they are dropping off; and nothing seems to induce them to continue to subscribe, and so we are even better off, financially, by their withdrawing, however much we desired to retain them. Then, again, the novelty of the thing to the general public is gone. The bee-tent has long ceased to be a source of profit to us. Everybody has seen what can be done by the expert, and has failed to repeat the operations so successfully themselves with their own bees in their own gardens. Shows, again, are a source of deficit to us: they are not of sufficient general interest to draw a crowd, and no, or at least few, horticultural societies care to amalgamate with us, as they will get just as much gate-money without us as with us.

Then you argue that our associations have done their work, and are of no further practical utility? No! On the contrary, I argue they can be made of very great service to bee-keeping in the future; and I would call your attention to the fact that bee-keepers' associations are being largely increased and extended on the other side of the Atlantic, both in Canada and the States. But they will consist almost exclusively of people who make bee-keeping pay, and are more what our Transatlantic cousins call 'Specialists,' and they must in future be conducted on lines more suitable to the altered position of things. In place of the one large organization embracing the whole county with a large central committee with its members living thirty or forty miles apart, we must have something more compact. The county must be divided into districts, and instead of spending a lot of money on the expert's tour and the circulation of the *Journal*, each individual member must subscribe to the *B. B. J.* or *Adviser* privately if he wants it, and the districts must hold frequent conferences. We are nothing if not fraternizing. And what even would the *British* be to us but for these quarterly conversaziones? Each district must have control of its own funds, a small committee and a secretary, who will find his own smaller area quite as much as he will care to look after, and then a general committee formed from the most enthusiastic members of each district for special purposes, with *perhaps* a paid county secretary, and the organization is complete. From henceforth only the real honey-

getters will care to belong to it, because the meetings will only be of interest or profit to them, except they be lovers of natural history. Then again, we ought to increase our efforts to get bee-keeping recognised as a legitimate branch of agriculture. The Royal and other larger societies may well be copied by many of the county agricultural societies, and as many of them have sub-committees for poultry, butter-making, &c., so they may well add another for bee-keeping. I am sure if this was pressed upon our vice-presidents, who, as a rule, are large subscribers to agricultural societies, they would see the wisdom of the proposal, and bring their influence to bear in this direction to the benefit of both agriculture and apiculture.

I am especially sorry to raise this question now, because I fear those counties that have not been sufficiently worked will use it as an excuse for relaxing their efforts. We want the whole ground covered and worked by the expert and the bee-tent, that will find out the bee-keepers that are really worth their salt, and bring them together for future mutual edification and profit; but without this I fear in some parts the sulphur-pit will still reign. Whatever comes, I believe the British will not suffer. Having fairly established Apiculture throughout the kingdom as a national industry it will ever be her part as parent to guide and control everywhere. To open up new fields, to advance the scientific aspect especially, and when necessary, to claim, protect, and watch over our interest in the legislature and the schools. The counties were always a source of outlay to her, not of profit, and if the affiliated associations were dissolved to-morrow many of their best members would at once join the British, who would thus be swelled by the ablest and best of the county bee-keepers, and would continue to pursue its course of usefulness with even greater dignity and lustre. I have been induced to put these few remarks together since I came to town this morning, in hopes that it may raise a discussion on a subject which has not only been under serious consideration in Hertfordshire, but I find is also being considered by many others in various parts of the country.

The Chairman thanked Mr. Sambels for his able paper, which bore traces of careful thought, although produced hurriedly. Many points therein were of great importance, and well worthy of consideration.

Mr. Garratt thought it was not a little curious that the views expressed in the paper came from the County of Hertford—the first county to form an association, or, at any rate, the first to achieve any prominence under the able and energetic guidance of the late Mr. Peel. As an impromptu effort he considered Mr. Sambels' paper very praiseworthy. He had for some time past endeavoured to form a definite idea as to what the immediate future of County Associations would be. In reading the *B. B. J.*, one could not but discern the notes which had been sounded in different counties, and those were indicative of a diminished interest on the part of not only the officials and managers, but also of the general body of supporters and of the public in general. While that feeling existed it would do much to lessen the efforts and reduce the enthusiasm of those who had the interests of the Association in their keeping. Some counties were in a flourishing condition, but the bulk were not so. Some of the counties which had been foremost in the movement had disappeared from the field entirely, which fact compelled him to admit that Mr. Sambels' paper raised a subject which was ripe for discussion. In his own county of Kent, a periodical meeting of the Committee or Council had been summoned for the purpose of deciding upon the advisability of holding an annual show. No member attended the meeting, nor was a single response to the summons received. Under such circumstances the Secretary and Treasurer could not assume the responsibility of any

action in the matter. That state of things was extremely regrettable, nevertheless it was too significant to be ignored. It would be a good arrangement if the district branches could by some means be maintained as units, and be held together in the different counties by some simple tie.

Mr. Webster trusted they were not officiating at the obsequies of bee-keeping in England. He attributed the failure or success of the county Associations to the apathy or energy of the executive officers thereof. Some secretaries made light of obstacles and difficulties, which they always surmounted, and in such cases the counties prospered. He knew of one such secretary who had obtained no less than thirty-two members that year. His own county of Berks had not been exhaustively worked, nevertheless it was fairly successful. The old custom of bee-driving and catching the queen in the bee tent was out of date, and something new must be substituted in order to maintain public interest. The counties should be divided into districts, and small periodical conversazioni held in each locality, when matters of interest relating to apiculture could be discussed and appliances shown and examined.

Mr. Slade dissented entirely from the desponding opinions expressed by Mr. Sambels. In his own county of Gloucestershire, interest in bee-keeping was kept up by means of district branches, which were all allowed the privilege of home rule, and were therefore satisfied. At Wotton-under-edge the subject was not permitted to languish, for a monthly meeting was held throughout the winter. In Gloucestershire bee-keeping was a profitable investment, as many of the cottagers could testify.

Mr. Meggy said, as secretary to a neighbouring county to that of Mr. Sambels, he was much surprised to hear the doleful account emanating from Herts. He had always looked upon Herts as the pattern county, and had endeavoured to follow its example, especially in the matter of one shilling subscriptions from labourers. He could not endorse Mr. Sambels' views. The fact that the labourers were not willing to reap the advantages they might from the County Associations proved that it was necessary to work among them more persistently and educate them. Neither could he allow that shows and bee-tents were played out. In his own county the bee-tent did not pay financially, but there was no lack of interest in it when manipulations were exhibited free of charge. He thought efforts should more generally be made to hold shows in connexion with the County Agricultural Associations, and he prided himself on managing to obtain a good show in Essex on an expenditure of not more than 2% or 3%. On the question of committees, he quite endorsed the remarks of Mr. Garratt as to the difficulty of securing a meeting. No doubt the work mainly depended on one individual; the Secretary should not fail in his duty if the Committee did. If the plan proposed of allowing district branches to carry out their own work in their own way came into force, he could only say that the duties of a County Secretary would be considerably lightened. As regarded Essex, he felt sanguine of continued success.

Mr. Sambels said in reference to the remarks of preceding speakers that the Associations represented by those gentlemen were about three years behind the Herts Association. About three years ago the latter Association was flourishing, new members entering its ranks in great numbers. Then the institution was new and popular, but as time went on there was a difficulty in keeping up the interest. Nevertheless, the Herts Association had worked hard. It was the first to map the county out into districts, and appoint a secretary and local advisers. The latter were instituted at the suggestion of the late Mr. Jenyns. Then, as to the Secretary, it was not possible to find a more energetic one than the Rev. Mr. Seager. That gentleman had actually spent

one summer holiday in his dogcart visiting every bee-keeper in the county. Every parish in which it was possible to give a lecture had been lectured in. Not only had the bee-tent been shown free of charge in all local flower shows, but it had been exhibited on gentlemen's lawns, and the mysteries of the bee-hive explained over and over again to labourers invited there for that purpose. The subject had also been worked through the Natural History Society. He had known cottage bee-keepers, who were full of enthusiasm at first with the bar-frame hive afterwards go back to the straw skep. He did not think the rôle of county Associations was played out; nevertheless, he could not help believing that in future these bodies must be worked on different principles. Recent experience in Herts showed that, except in the case of enthusiastic persons, it was difficult to obtain attendances at quarterly conferences held for the purpose of mutual education. In the United States and Canada matters were different. There the Associations did not work from any philanthropic motives—it was entirely a matter of dollars and cents; but they contrived to keep up the interest in bee-keeping by treating the subject entirely from a commercial point of view. They held periodical meetings, and mutually encouraged one another. He did not wish it to be supposed that Hertfordshire would relax its efforts; the executive would always be glad to assist any one in the county to learn apiculture, and do its best to promote the same. They had been considering a scheme of management by which the district branches would be allowed control of their own affairs, and be permitted to appoint one—and in populous districts two—members to act on a Central Committee, which would work for the benefit of the whole county. The local Agricultural Society had not given them unstinted support, and they were determined during the present year to press on that Society the importance of bee-keeping as a recreation and means of livelihood for the agricultural labourer.

Mr. McClure was sorry to hear the unsatisfactory account of Mr. Sambels. In his (the speaker's) own county (Lancashire) not much had been done up to the present. That county was rather too large to be conducted on the same principles as Herts, and he would be glad to hear what plan of action Mr. Sambels would recommend for Lancashire. They had had applications from six districts, which had not even seen a bee-tent. Their local Agricultural Society had asked them to write a paper for insertion in the journal published by that body, and appeared willing to render every assistance.

Mr. Sambels said the district of Herts in which he resided comprised eight or ten parishes. The local secretary lived in the town of Hertford, and his business caused him to travel over a considerable portion of the country once, and sometimes twice, a-week. Knowing all the bee-keepers individually, he seldom passed any by in his journeys without calling on them. Thus he kept himself in touch with them; and besides that he never lost an opportunity of urging clergymen to give facilities for lectures in their parishes during the winter months, and the exhibition of the bee-tent in their grounds during springtime. Many of the lectures he (the speaker) had given, often driving seven, eight, and even ten miles to carry out such work, sometimes journeying through deep snow for the purpose. Quarterly conferences had been regularly held, at which all local bee-keepers were invited to come and bring their appliances, no matter how simple and primitive these might be. At one of the meetings referred to the Canadian gentlemen were good enough to be present, much to the satisfaction of the crowded audience which assembled in the schoolroom at Hertford. He recommended Mr. McClure to adopt some measures of the kind he had indicated.

Mr. Slade said his county had only one tent, and would be glad of more. He argued that bee-keeping

was a prosperous undertaking, and, in fact, paid much better than most businesses; therefore he could not understand the doleful view taken by Mr. Sambels.

Mr. Sambels said that Mr. Peel, who was a far-seeing man, shortly before his death, remarked, 'The bee-tent in Herts has had its day; sell it, and use the money for other purposes.'

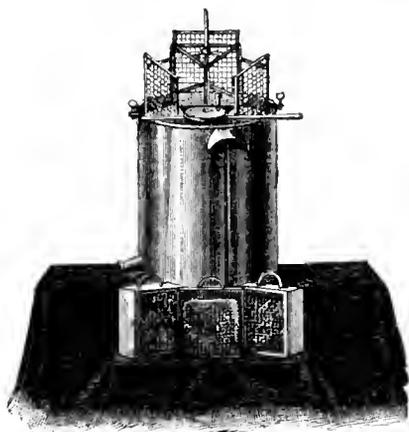

Mr. Meggy said that in Essex they considered it best to send the expert to every bee-keeper twice a-year. He believed that for cottagers it was better to introduce a modern skep than the bar-frame hive. He thought it would be impossible to advance much further with the labourer until bee-keeping was made a subject of education in elementary schools.

Mr. Garratt, while admitting the force of Mr. Sambels' remarks, advocated continuous endeavours to popularise bee-keeping. Nevertheless, the experiences of that evening should teach them that the work could not be carried out exactly on the old lines.

Mr. Sambels said he had entered on the subject with great reluctance, although convinced the difficulties he had alluded to would have to be faced by all of the Associations sooner or later. He trusted that his remarks would tend towards increased and judicious energy rather than desponding apathy.

The Chairman thanked Mr. Sambels for the information he had supplied respecting the management of county Associations. Mr. Webster's remark about individualism they would all endorse, but the difficulty was to find in each county the required individual. He could bear testimony to the energy of Mr. Meggy, who had done a great work in Essex for the County Association. He had let the Agricultural Society have no rest until they supported the movement in favour of bee-keeping. He was glad to see that Mr. Jesse Collings was about to introduce a new bill into Parliament which, if passed, would, from an educational point of view, advance the interests of bee-keeping. He quite agreed with those who thought that the driving of bees in the bee tent and catching the queen was out of date. He thought the frame-hive had not been sufficiently introduced to cottagers. It needed more explanation and demonstration in the methods of handling and manipulating. Interest would not flag among the cottagers if an expert were to visit them twice a-year for that purpose.

Mr. T. Lowth, of Brunt Broughton, Newark, Notts, exhibited his 'Lowth's Unique Extractor.' This extractor

is specially made for the purpose of extracting honey from the comb made in unshapely, unfinished, and unsaleable one-pound sections. The machine will be found handy for extracting honey for exhibition purposes, the honey being easily ejected from delicate comb without a risk of damage in breakage, and with a minimum of waste, the quality and brilliancy of the honey being preserved.

Bee-keepers with small apiaries, who work on the section principle, will find this extractor desirable. The machine is provided with three extra cases for the purpose of holding comb honey to be extracted other than that of sections. The extractor can also be adapted for the reception of two-pound sections. The illustration will furnish an explanation of its mode of working.

The workmanship of Mr. Lowth's extractor was highly applauded, but it was thought that the work it could do could also be effected by the larger extractors.

Mr. Webster showed his new method of fastening whole sheets of foundation into sections. This is done with the aid of a specially made block. Three sides of the section are in halves, so that when folded the fourth side acts as a hinge or joint to a pair of jaws formed by the other three sides, these jaws being opened by the thumb and forefinger of one hand, a sheet of foundation is dropped in with the other, the section is then placed in the block, which keeps it perfectly square, a lever pressed to shut the jaws close together, which fastens the foundation very securely. We think quite secure enough for the purpose wanted, but Mr. Webster pushes two little tin staples into the section. This renders the section a deal more rigid, and the foundation more secure than any means that we have at present seen adopted. This invention was much approved of by those present.

Mr. James Ross, of Stranraer, N. B., exhibited an improved Feeder. This feeder is of wood, and therefore is not so susceptible of changes of the atmosphere as glass or metal. It has no corners into which the bees have no access, and therefore they clean out thoroughly. It can be shut against bees entering without removing it, and it can be easily filled while on the hive.

Mr. W. H. Jenkins exhibited his Reversible Section-crate, for which he claims the following advantages:—That sections can be quickly inverted and reversed. A finished section can be taken out and replaced by an empty one in a few minutes; the state of the sections can be ascertained and the whole crate cleared without taking it off the hive, with no jarring, and with far less disturbance of the bees than with the ordinary section-crate. There is a bee space left at the ends, sides, and between the rows, so that bees can pass to the upper crate without having to walk over the lower sections and soil them. They also offer a safe means for transit, sections being kept clear of the sides of the travelling box by the projecting edges of the holders.

The Rev. G. Raynor exhibited some sections of honey which had been built by the bees without the aid of separators. The sections were particularly fine specimens, being perfectly straight and even.

Mr. McClure moved, and Mr. Hooker seconded, a vote of thanks to the Chairman, who briefly acknowledged the compliment, and the proceedings closed.

EBOR BEE-KEEPERS' ASSOCIATION.

A meeting was held at the Commercial College, York, on Friday, May 11, the Rev. J. Hodgkinson in the chair, when the 'Ebor Bee-keepers' Association' was started. Mr. Samuel Peel was appointed Secretary and Treasurer. A few resolutions were passed relating to subscriptions, and it was also decided to hold a honey fair in the autumn, when it is proposed to offer prizes to the members of the Ebor B.K.A. for honey exhibited in its various forms. Mr. Jemison has kindly consented to act as travelling expert to the Association.

Correspondence.

'FATHER' LANGSTROTH.

[1642.] Dear Editor, you have given us in last week's *Journal* the long letter in defence of the poor drone, from the pen of the one whom 'all the States own.'

Blood is thicker than water, and the whole Anglo-Saxon race is one people, moreover 'one touch of Nature makes the whole world kin.' The dear old man has been afflicted, and with the saddest of all sorrows—head trouble. He is so far restored as to be able to write what you gave us last week, but as an actual fact he is past work in the way of bread-winning.

He has been defrauded of the results of his brains by his fellow bee-brethren from lack of power to defend his rights, and being worn out and in poverty they have decided to buy him a small annuity. Surely we can endorse the sublime words of C. Mackay:—

'I love you, if your thoughts are pure;
What signifies your poverty,
If you can struggle and endure?
'Tis not the birds that make the spring—
'Tis not the crown that makes the king.
If you are wise, and good, and just,
You've riches better than all other!
Give me your hand—you shall—you must—
I love you as a brother!'

Let us, as British bee-keepers, give practical expression of brotherly feeling by subscribing to the fund; it will only stimulate his countrymen to do more, and make the annuity the greater. What if the Maloney's, 'Amateur Experts,' and Heddon's do occasionally have a 'rough and tumble,' let us show we are one mother's children by giving our mite. Here are two dollars to start, from—AMATEUR EXPERT.

SHALLOW FRAMES.

[1643.] Referring to the letter, No. 1626, in your last issue, I have no desire to engage in any lengthened controversy on shallow frames, and so will content myself with a simple answer to Mr. Dobbie's query as to why I consider a 5½-inch frame better than a 6-inch one—this being the real point at issue.

It is well known by all who have read anything I have written on shallow frames in 6-inch boxes, that I use these boxes and frames for brood-chamber as well as for surplus honey. I have also asserted, very confidently, that any bee-keeper who adopts them as surplus boxes will, under certain circumstances, use them for brood-chambers, as I frequently do myself. In proof of this, and as Mr. J. H. Howard's name has been mentioned, I may say, in passing, that that gentleman is coming to the same conclusion himself, for he wrote me a month ago to say,—'Shallow brood-chambers I have found very good, and methinks I shall prove them ahead.' Here, then, we have the fact that Mr. Howard and myself are as one in adopting shallow frames for brood as well as for surplus.

The boxes in which *my* shallow frames are worked are six inches deep, each holding nine frames; and as two of these are required to form the hive body or brood-chamber, we have eighteen frames in the latter, with a comb-surface of about 265 inches more than that of a ten-frame standard hive. I call this extra 265 inches a fault rather than an advantage; ten standard frames of comb being abundant for all breeding purposes. But if we adopt a 6-inch frame, we get about 500 inches in excess of what is justly considered a full-sized brood-chamber, so the fault is increased in the same ratio. Should the shallow frame be so fortunate as to merit discussion at the hands of the committee of the B. B. K. A., I don't doubt but weighty reasons can be given for preferring the 5½-inch size; indeed, even Mr. Howard's only objection to it lies in the fact that he has made and sold a large number of the 6-inch ones, and so must, perforce, keep to it in the interest of his customers. Curiously enough, Mr. Cheshire, describing the 'Holme-Wood' hive of Mr. Howard in *Bees and Bee-keeping*, p. 111, says the frame is 5½ inches in depth.

In conclusion, and since your correspondent has raised

the question, I can assure him that Mr. Howard was not the first maker to offer a shallow frame of standard length to the public. For myself, not being either a maker or dealer, I can only speak as a user of these frames, and I believe I was the first person in the kingdom to use them. I had them in my apiary for some years prior to the Norwich Show in 1886, both as surplus chambers for working over standard frames and as sectional brood-chambers on the Carr-Stewarton plan.—W. BROUGHTON CARR, *Higher Bebington, Cheshire.*

SHALLOW FRAMES.

[1644.] There have been advocates of the 5½-in. frame, and there have been advocates of the 6-in. frame. These both may be very good, but I cannot see one special advantage of the size claimed for either of them, whereas I think you might almost as well have an 8½ as a 6-in. frame. Every one praises his own, of course, so I offer another size which I think best, and can mention positive advantages in its favour. Instead of having the side pieces 8 in., as in the large frames, why not have them 4 in? Advantages:—(1.) For getting super foundation pulled out before the honey-flow, it would cut out for sections without any waste. (2.) Two half-body boxes would make one big one, and could be used for standard frames. (3.) Two shallow frames would fit in each cage of extractor, thus four could be extracted at once where two large ones were before, whereas, with an awkward size of shallow frame, no more could be extracted from at once than of the standard frame, and there would be waste in cutting out for sections. (4.) Of course there would be still less need for wiring foundation in, than in a larger. (5.) This could be put on before the bees were strong enough to bear a larger box. Of course I am too unimportant to cause that my frame should be adopted, but still, why shouldn't I have my say?—F. G. BEZZ.

I should like to ask 'X-Tractor' about the plumber's scraper. If one angle is a right angle, what are the others to be? The figure looks as if it is an equilateral triangle.

SPREADING THE BROOD.

[1645.] From several tests made by leaving whole rows of hives through the bee-yard undisturbed, while a row alongside had the brood spread as about to be given, I find those manipulated gave results above the others more than double enough to pay for the extra labour. The trouble with most of those who try the plan for the first time is that they begin to manipulate the brood too early. There can be nothing gained where there are three or four combs, one-fourth full of brood, by spreading them apart and putting an empty comb between: for by so doing we simply spread the brood out in an unnatural position, and work on the plan of scattering the heat instead of concentrating it. Besides, as long as this state of affairs exists, they have already got brood in more comb than they should have; for all will see that, if all this brood were put in one comb, and that comb placed in the centre of a chaff-hive made for only one comb, the bees that hardly covered it before could hardly crowd into the space it now occupies.

To get at what I wish to illustrate, let us suppose that we could get that ordinary colony of bees with its brood in four combs as above, all on one comb, and no room for the bees except in this space, it will be seen that quite a proportion of the bees would be obliged to cluster outside. To obviate this outside clustering we would enlarge our hive so as to take one more comb, which comb is put in. Now having our heat and bees condensed to the right proportion, we would find that the queen would lay in this comb at the same rate she would in July, filling it with eggs in three or four days; while, had we not done this, the brood in the four combs

with a whole hive to carry off the radiating heat, would not have advanced to the amount of one-sixth of a frame. In a few days, more young bees from our first frame have hatched to such an extent that they are again crowding out at the entrance, when we once more enlarge the hive and put in another comb (putting it in the centre this time), which is filled as quickly as before, and so we keep on till our hive is enlarged to the breeding capacity of the queen. Does anyone doubt but that we shall have a hive full of brood and bees long before we should if nothing had been done? If such doubt exists, an experiment or two along that line will convince any.

Well, now to practical work. As soon in spring as the first pollen appears, shut the colony on to the number of combs containing brood, using sometimes to confine the heat as much as possible for a division-board. If these combs of brood do not contain honey enough, use a feeder such as I described a few months back for that division-board, and feed, or leave combs of honey beyond the board so the bees can have access to it. Now leave them till the two central combs have brood clear down to the bottom outside corners of the frames; for manipulation previous to this would not help a bit, as they already have all the chance for spreading their own brood that is needed. As soon as you find the two central combs thus filled, reverse the brood-nest; by which I mean put these two central combs of brood on the outside, and those outside in the centre, when, in a very few days, we shall have our combs and colony in just the shape of the supposed colony we spoke of above, and are to proceed in the future on the same plan.—G. M. DOOLITTLE, *Borodino, N. Y. (Gleanings.)*

COMPENSATION ON EVICTIONS, &c.

[1646.] Will any of your numerous readers kindly give me some idea of the amount (if any) per hive which can legally be claimed for forced removal of bees? I live in a direct line with the Manchester Ship Canal, and have received from the promoters three weeks' notice to quit. As I am a yearly tenant, compensation in the shape of twelve months' rent has been offered me in common with others of my neighbours, but as I have four fine stocks of bees, I think I am right in claiming some compensation for the loss which will ensue if they are removed to a fresh site which I have taken less than a quarter of a mile away. If they were removed to a location, say, five miles distant, there would be the cost of moving back and to; also rent of ground (though small) to pay. Could this be claimed for? I expect to get a few days' grace after the expiration of notice, so any advice from legal or other readers will be in time and thankfully received. No one in our part expected them to begin work here before next spring.

Turning to other matters, I am extremely pleased to see published in the *Journal* a biographical sketch of Mr. George E. Hilton of Michigan, U.S.; but could you not also arrange to give us some sketches and photographs of prominent British bee-keepers—those with whose writings and names we are so familiar and yet many of us have never seen? Take, for instance, 'Amateur Expert.' I have long enjoyed this gentleman's letters, appearing from time to time in the *Journal*, and have often wondered what he is like, whether old or young, and what is his real name, and in what part of the country he lives;* and there are many others as familiar in name whose history as regards bee-keeping would to me be of lasting interest. I have seen very few of the scientific bee-keeping fraternity. I am unable to go to the great shows and places where the great leaders of the craft do

* In the first number of this year's *Journal* we gave an illustration of the apiary of 'Amateur Expert,' with some particulars of his life.—ED.

congregate, hence my proposal could, if adopted, make up somewhat for such disadvantage. I am exceedingly fond of my bees and all connected with them, and live outside the town away from my work at a sacrifice purposely that I may indulge my fancy. The bees are a great comfort to me, and have taught me many of the useful lessons mentioned by Mr. J. Eaton Fearn in his letter in last *Journal*.—F. PEARSON, *Stockton Heath*.

NON-ALCOHOLIC DRINK.

[1647.] Will you kindly allow me to ask, through your columns, if any of your readers will favour me with directions to prevent a drink made with honey from fermenting? I have been looking through a number of back years of the *British Bee Journal* and find several recipes for mead, &c., but as they all 'work' or 'ferment,' or have yeast introduced, none of them will suit us, as we are thorough abstainers, and want to get a good non-alcoholic drink. As the summer is coming on, no doubt many would be glad to know how to make a light beverage from their honey.—THE WIFE OF A SUSSEX BEE-KEEPER, *Ticehurst, May 15th*.

[We should be specially obliged by some bee-keeper replying to the above.—ED.]

TEN TONS OF HONEY.

[1648.] I have received numerous letters since the above advertisement appeared, and I have found it entirely impossible to reply to one half of the inquiries as to price, &c. Allow me to thank all those who have written on the matter, and to say that during the season I shall be very pleased to quote for new season's honey as per advertisement; also sections.—J. D. McNALLY.

Echoes from the Hives.

North Leicestershire, May 21st.—From the 4th to 21st inst. inclusive, the bees have been hard at work without a day's interruption. Some little rain fell on the 17th, but the weather was so warm that the bees continued work through all but the heaviest showers. On Friday, 18th inst., the thermometer went up to 68° Fabr., and a copious honey-flow set in, and still continues. Saturday, the 19th inst., was a wonderful day for bees. The thermometer stood at 75°, and the busy workers were carrying in pollen, nectar, and water for fifteen hours. Stocks are rapidly increasing in strength: some few are abnormally strong, and nearly all are crying out lustily for more room. Supplies of pollen and nectar are just now being drawn from wild cherry, plum, sloe, sycamore, currant, gooseberry, arabis, dandelion, chickweed, shepherd's purse, gillyflower, ribes, and celandine.—E. B.

NOTICES TO CORRESPONDENTS & INQUIRERS.

- TIT ASPEN.—The queen forwarded was unfertilised.
- G. BEESTONE.—*Wax-moth*.—The larvæ forwarded were those of the wax-moth. They should be destroyed whenever seen by crushing them or extruding them by aid of a pen-knife. They may be avoided by keeping stocks strong, or having Ligurian bees.
- P. T. C. BOX.—*Fumigator*.—We believe this can be purchased of most dealers. Please consult our advertisement columns, as we do not recommend one dealer in preference to another.
- J. P. O'FLAHERTY.—*Swarming*.—We cannot recommend the plans you suggest, but consider that under the circumstances it would be best to make an artificial swarm in the manner pointed out in *Modern Bee-keeping*. If the swarm is put in a frame-hive and placed on the old stand, the super should be placed on it. In this case it would be better to use starters only.

2. *Fanning*.—Fanning is to reduce the temperature of the hive, and evidently there are signs that your bees will swarm before long. 3. *Painting Hives*.—The whole hive should be painted.

R. AULD.—1. *Full Sheets of Foundation*.—It is advisable to use full sheets of foundation if properly secured in the frames, care being taken that they hang perpendicularly and that there are sufficient bees fully to cover both sides of all frames. Starters may be used at all times, but if the honey flow is at hand and large, drone-comb will most probably be built. 2. *Old Combs having Honey*.—Old combs with honey in them may be utilised for swarms, the cells in which there is honey being first uncapped.

ENQUIRER.—If your candy is wholesome and sweet it may safely be re-liquefied.

C. GILBERT.—*Moving Bees*.—We would recommend you to allow your hives to swarm, and get the swarms forwarded in swarm-boxes, and sell the stocks on the spot. Frame-hives will travel well on the railway if there is some person to see to the hives being so placed in the train that the combs hang in the direction the train is going, and not across the carriage, or the combs may probably be dislodged from frames by a sudden jerk or stoppage.

R. J. SANKEY.—*Bees Dying*.—The queen is at fault, being constitutionally weak. Introduce a new queen and the mortality will cease.

H. BISHOP.—*Joining Association*.—Apply to Mr. J. Huckle, Kings Langley, Herts, who is Secretary of the British Bee-keepers' Association.

J. F.—*Doubling Hive*.—The upper portion ought to be the exact size of the lower and interchangeable with it, viz., $17 \times 15\frac{1}{2} \times 8\frac{1}{2}$ inches, inside measurement. This size allows of a lateral movement of frames, which is important.

BEAULY.—1. *Arrangement of Bar-frame Hive*.—Your surmises are correct as to arrangement of boards. We very much object to the narrow entrances in such hives; the entrance should be the whole width, with arrangements for contracting, on the outside, when robbing is rife. 2. *Uniting Cast*.—You would keep the youngest queen, which would be with the cast. If two colonies of bees are separated from their hives, combs, and brood, and are while in this condition thrown together, they will unite peacefully.

G. FIELD.—*Hybrids*.—The bees sent are Ligurian and English hybrids. When the bees hung out last season they were superseding their queen, and the dead queen found was the old one; the virgin queen left was fertilised by either a Ligurian or a Ligurian-English hybrid, hence the bees now are imperfectly marked. When an English stock is hybridized a portion only of the population have yellow bands, and many have the three yellow bands; but where an English stock is crossed by a hybrid, a greater scarcity of bees with the distinguishing marks of Ligurians are noticed, and so on as each successive cross increases or diminishes these marks.

STRONG PLANTS of STOCKS, ASTERS, PE-TUNIAS, LOBELIAS, VERBENAS, &c., &c., ready in May, from 1d. per dozen. Orders booked and forwarded in rotation. Strong, well-rooted Celery Plants, red or white, 1s. 3d. per 100, post free. All Plants carefully packed in wooden boxes. Address H. DOBBIE, Hethersett, Norwich.

NEW BEE DRESS, COOL AND COMFORTABLE.

See Advertisement in Bee Journal of May 3.

CHARLES BARNETT, Tailor, Godalming. A3968

MANIPULATE WITHOUT SMOKE.

Webster's Fumigator

(CARBOLIC)

With Bellows complete, 46. Bottle of Agent, 6d. A Piece of Carbonate (common crystal form) of Ammonia should always be kept behind Sponge.

FIRST PRIZES: Indian and Colonial Exhibition; Royal Agricultural Show; Royal Counties Agricultural Show.

BEE SUPPLIES of all Descriptions.

CATALOGUES FREE BY POST,

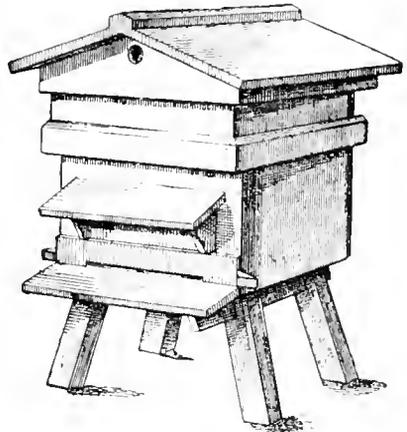

QUEENS, STOCKS, NUCLEI.

WEBSTER'S NEW SECTIONS.—The only Method yet invented of Securely Fastening Three Sides of the Foundation, thus entirely preventing Sagging and 'Pop-holes.' 6d. per 100 extra.

WEBSTER'S BOOK OF BEE-KEEPING. Fully Illustrated. 'The most practical that has yet appeared.'—Field. Price 1s., Post free.

W. B. WEBSTER, BINFIELD, BERKS. (192)

THIS Hive has Bar-frames, Standard size, and Section-body containing 24 1-lb. Sections, Divider, Quilt, &c., all complete, except legs 1s. extra, free on rail, 66.

BEST METAL ENDS,

3/- per 100.

Send 1d. Stamp for Sample, and see for yourself.

USEFUL ARTICLES FOR BEGINNERS.

1 Prospect Hive . . . 6/6	1 Smoker, best . . . 3/-
1 Bee Veil . . . 1/-	1 Pair Gloves . . . 1/6
½-lb. Foundation . . . 1/-	1 Feeder . . . 1/-
½-lb. Super ditto . . . -/9	1 'Modern Bee-keeper' /6

The Lot for 15'. Returnable if not approved.

FOUNDATION and SECTIONS at lowest price when ordered with HIVES. CATALOGUES FREE.

JOHN MOORE, Prospect Farm, Warwick.

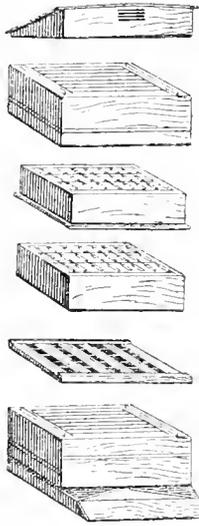

Fig. 7A,
with Reversing Arrangement and Honey Board.

Perfect Sections of Comb Honey can be obtained in Perfect Crates.

EDEY'S HONEY BOARD and REVERSING ARRANGEMENT

OPENS A NEW FIELD TO COMB PRODUCERS.

Price: Each with 21 four bee-way Sections, with bee-space round each Section, 7/- per pair; for two bee-way Sections, 6/6 per pair: full sheets of Foundation fixed, 6d. per pair extra.

In Flat: Lots of Five subject to 33 per cent discount. Sections, &c., complete.

EDEY'S DOUBLER

Is fitted with Honey Board and Crates, &c., two bee-way Sections, complete as Engraving, 16/-; cheapest hive sold. In Flat: In lots of Five, less 33 per cent.

Send for Catalogue of Bee Furniture. Specially Good Foundation now rolling.

EDEY & SON, Steam Joinery Works, St. Neots.

W. B. BAKER,

MUSKHAM WORKS, NEWARK.

OUR NOTED 1 A HIVE.

Contains all necessary Fittings,

Price **10/6**

As originally made by this Firm, and Advertised for several Seasons.

If with six sheets of Foundation in Frames, and Foundation in Sections, ready to receive a Swarm,

Price **14/6**

Too well known to need description.

PRACTICAL WORK IN THE APIARY.

CATCHING SWARMS.

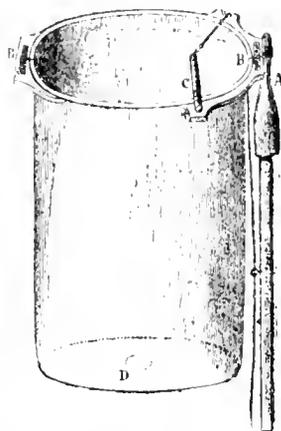

If swarms were always to settle near the ground, or within easy reach of the bee-keeper, hiving them would be easy enough, but sometimes they select places on trees too high to reach in the ordinary way, or even conveniently with a ladder. When hives are kept in lofts or in places above the level of the ground, swarms usually settle on high trees. We at one time kept nearly 40 hives in lofts above our stables, and during the whole time they were there every swarm settled high and out of reach, and we had not one that we could hive without a ladder or some special contrivance for the purpose.

We have sometimes been able to get a swarm away together with the branch of the tree on which it alighted if this was not too large. The branch is cut off without jarring by means of an instrument called a 'sécateur,' and which we use for tree-pruning. This instrument is found in every gardener's hands on the Continent, and is gradually coming into use in this country. A branch, $\frac{3}{4}$ or even 1 inch in thickness, can be easily cut through without the slightest jarring, therefore it is very much better for the purpose of getting a swarm than a pruning-knife. When the branch is much thicker and assistance can be had, a pruning saw could be used. The assistant mounts a ladder, and with the 'sécateur' prunes away

the small twigs surrounding the cluster. Then he takes hold of the branch while the bee-keeper from below saws carefully through it with a pruning saw. A pruning saw is generally made to fix to a long handle, and has the teeth set in such a way that they cut through green wood rapidly and without clogging up, as an ordinary saw would do. Our pruning saw has a long handle of four joints which screw together so that the length can be adjusted to the height of the branch from the operator.

An assistant is not always at hand, and to enable bee-keepers to take their own swarms with little trouble a number of contrivances have been introduced. The oldest, and one we have used for upwards of twenty years, and the pattern generally used on the Continent, is shown in the illustration. It consists of a jointed hoop fixed to a ferrule A, which fits on to the end of a pole.

The hoop is hinged at B, B, one half of it is rigid and attached to A, while the other half C is connected to a cord which passes through a hole on the fixed portion of a hoop, and through eyes along the pole. To the hoop is fixed a bag, something like a butterfly net, only made of calico. Ours is made of glazed calico, with the glazed surface inside. The bottom is not sewed up, but it is tied round a couple of inches from the end by means of a piece of tape. We preferred this arrangement

because we found it much easier to hive the swarm than when the bag has to be turned inside out. The glazed surface also dislodges the bees much more easily. The way of using this appliance is very simple. Bring it up to the swarm, holding the pole in one hand, and with the other gently pull the cord. This will draw the two halves of the hoop together and enclose the swarm in the bag. Lower it gently, and remove the bag from the pole by pulling off the socket A. Bring it to the hive you wish to introduce the swarm into, and untie the tape at the bottom of the bag. One smart jerk will dislodge all the bees, as the sides of the bag are parallel and the opening at the bottom the full width of the bag.

A very simple contrivance, which we saw when visiting Mr. Root, Medina, and which is described by him in his *A B C of Bee Culture*, is the invention of Mr. Shephard. It is simply a box made of $\frac{1}{2}$ -inch basswood boards, 8 inches square by 16 inches deep, the bottom closed and top open. The sides are bored full of $\frac{3}{4}$ -inch holes. The

box is then fixed to a pole which passes through two of the sides; and fastened in this way it can be turned in any direction and brought in position to receive the swarm. Another pole with a hook is sometimes useful to shake the bees from the branch into the box. A so-called improvement has been advocated by Cheshire, more theoretical than practical, in which he proposes to have a thin iron rod pass 'loosely through the box above the centre of gravity so that the latter always rights itself whatever may be the position of the pole;' but the fact seems to have escaped notice that the centre of gravity of a shifting cluster of bees is moveable, and such an apparatus would be very likely to precipitate the bees on to the operator's head when he least expected it. It is also a much more expensive contrivance, and more likely to get out of order, than the Shephard apparatus, whose extreme simplicity is its recommendation. The rigidity of the box constitutes its safety.

When visiting Mr. McKnight, at Owen Sound in Canada, he showed us a very simple and ingenious device he used for taking swarms from trees. This consists of a stick, the end of which for about 18 inches is planed, six-sided pieces of lath are cut in lengths varying from 6 to 10 inches, and are nailed at right angles to the stick on the six sides. Close against the stick these laths touch each other, but from the fact of there being six sides to which the laths are nailed, the ends are from 3 to 4 inches from one another. About a foot of the end of the stick is furnished with these laths, and at the other end there is a ferrule, by means of which the stick can be fixed to a pole. When the cluster has partly settled the bristly end of this pole is pushed in among the bees, which cluster on and between the laths and can be brought down and shaken off. In this way Mr. McKnight told us he had never failed to secure a swarm.

Mr. J. B. Hall, of Woodstock, uses a contrivance made of a cheese-box fastened to a pole. A piece of cheese-cloth is fixed to one side of the box, and by means of a cord is drawn over the opening of the cheese-box, and in this way the swarm is secured. Mr. Pettit uses a box in which a couple of frames of comb can be placed. This, held up to the cluster, induces the bees to run in amongst the combs. There are many other ways of securing swarms that have settled high besides these, but they are all based on the same principle. Sometimes it will be noticed that bees are not inclined to settle at all, but will rise higher and higher into the air. When this happens the bee-keeper should arrest their movements by throwing water from a syringe over them in such a manner as to resemble rain. Some use sand or earth, but we have found water much more effectual for this purpose.

EQUALISING STOCKS.

The spring is the best of all times for getting bees to mix freely, because most, if not all, of them are comparatively young; consequently, they fraternise more freely than in the autumn. But if you wish to make a comparatively weak stock strong at the expense of the stronger, the chief requisite for success is *brains*.

To exchange places on a bright day, thus giving the weak stock the foragers that did belong to the strong, is a simple method, but the queen of the weak stock must be first caged, or she will probably be ruined by 'balling' for some hours; and I am disposed to think that 'balling' does more harm to full-laying queens than most of us are disposed to think. To find and cage one or two queens when hives are full of bees and brood is an operation likely to take some time in the hands of people who are likely to profit by any good advice I may be able to give in this article, and the experienced will not require any from my pen—they always have means

and 'short cuts' of doing things ready to hand. Then again, the queen or queens have to be liberated, which means another overhauling, and over-manipulation is the bane of unsuccessful bee-keepers; consequently, I do not suppose this method is likely to be popular, but it is workable in some hands.

Another method is, if the weak stock has a comb in which the queen has not laid, and there are sufficient bees to cover it, take a comb of brood from a very strong stock and give it to the weak one in place of the comb that has no brood in it, giving the strong stock the empty comb—making an exchange, in fact, if the empty comb is clean; if not, give a clean comb or a sheet of foundation—thus keeping the strong stock at work and its queen egg-laying. In making the exchange, do not give a comb containing eggs only, let the brood be sealed if possible; at all events, let it be above five days old, past the 'weaning' stage, as young brood is always a greater strain on the colony to prepare food for it than the older.

Another plan still is, to smoke and gorge a weak and strong stock, or, perhaps, two strong stocks if necessary, and taking a comb with its adhering bees from the strong stock, carrying it out well in front of the hive, and gently jarring it on the top bar with one hand, while you hold it firmly with the other. This operation will cause all the old foraging bees to leave the comb by taking wing and flying home. The bees remaining adhering to the comb will thus be young; and if you cannot spare comb and all, they may be shaken off the comb on to the top of the frames in the weak stock or outside the dummy, if your dummy has a bee-space underneath it, as all mine have. By the way, let your dummies fit well at the ends, but always have a bee-space underneath them. Some recommend shaking the young bees in front of the entrance on to a board, and allowing them to run in. You may do so, but young bees, especially the very babies, are intensely silly and will run all ways but the right, and, moreover, can ill bear being chilled.

If one stock cannot spare enough young bees, some may be taken from a second and added in precisely the same way; and I know of no readier method of building up than this, as some of the bees thus given soon become foragers, thus bringing in a greater amount of food, and the very young become nurses, and thus the weak colony is strengthened on all hands.

If you have two weak ones, of course the simplest method is to unite them, reserving the best queen, or if both queens are good, disposing of one of them. Queens are always marketable, especially in spring.

A few words of caution as what *not* to do are generally far more important than what to do. First, a really good strong stock at the commencement of the honey-flow is worth three moderate ones. Next, equalising is of no practical value when the honey-flow has begun. Again, if you have a stock very strong some time before the flowers are ready, to give some of the bees and brood to a weak one is the very best thing you can do, because it is more than probable if you do not divide them they will swarm. And if they swarm they are not so likely to give large results. Once more, do not attempt to give native bees to foreigners, except Carniolans. In the old days, when I was enraptured with the Syrians, I knew a mere handful to kill and carry out all the black bees on six frames that were given them in one night—the savages! Once more, it is a simple but wise precaution to feed stocks over night with a little scented syrup if you are going to unite or add to them, thus making both lots *taste* alike. Above all, what you have to do do quickly, firmly, and resolutely. Avoid over-manipulation; it is a long double word, but four letters spell it for bee-keepers, it is R-U-I-N.—AMATEUR EXPERT.

Selected Query.

[11.] *Do you advise the use of separators? Are wood or tin best? What is the proper width when they are to be used with $4\frac{1}{2}$ in. sections to prevent the comb being built, so as to project beyond them at top or bottom?*

Yes, if you wish to glaze or handle the sections without damaging the honey-comb. I prefer tin to anything, but it should be a good thickness. 'Taggin tin,' used by some makers of slotted dividers, bends, and is much too thin for the purpose. The width or depth should be $3\frac{1}{2}$ in. in the narrowest part.—JOHN M. HOOKER.

No. Separators should be $3\frac{1}{2}$ in. deep.—SAM. SIMMINS.

1. Yes, particularly on sections over $1\frac{1}{4}$ in. wide. 2. Wood. 3. Cut the separator to the size of section, and take the bee-space out of top and bottom nearly half inch deep, or all round for four bee-way. Latter are preferably cut from tough English wood to prevent splitting.—JOHN EDEY.

No, but I admit real practical knowledge and confidence are necessary; without therefore, beginners, and old hands who will not admit by advanced practice the better way, must use separators, which should be of wood only. Separators should never be more than $3\frac{1}{2}$ in. nor less than $3\frac{1}{2}$ in. wide, and kept at equidistance from the top and bottom of a $4\frac{1}{2}$ in. section.—JOHN H. HOWARD, *Holme, Peterborough.*

1. Yes, most certainly, if marketable sections are required. 2. I have used wood separators, but have discarded them as they were so easily split and damaged. I use zinc dividers only; some with slots and some plain. 3. As the openings in sections vary very much from half to a full bee-way, there should not be more than quarter inch top and bottom. The bulk of my dividers in use are $3\frac{1}{2}$ in. wide. Some I cut years ago are not quite so wide, and I have occasionally had a few projecting cells. I mark the divider, and if it occurs again it is thrown out.—W. WOODLEY.

1. For 2-in. sections, yes; for narrow sections, not so necessary. 2. Taking all things into consideration, I prefer tin. 3. $3\frac{1}{2}$ in.—ROLAND GREEN.

I advise the use of separators for either wide or narrow sections. Tin is better than wood, and zinc is better than either, as it is not so liable to rust. The proper width of separator to fit $4\frac{1}{2}$ in. sections is, full depth, $4\frac{1}{2}$ in., at corners; at centre, $3\frac{1}{2}$ in.; that is, $\frac{1}{2}$ in. taken out of top and bottom edges of separator.—WILLIAM McNALLY, *Glenluce, Scotland.*

Yes, certainly. I find tin the best for many reasons. I use the $3\frac{1}{2}$ in. wide, and find this width succeeds. The distance allowed at top and bottom coming opposite the piece cut out in the section, gives the bees ample room to pass.—WM. N. GRIFFIN.

Yes, decidedly. I prefer tin to wood when honey is coming in and stocks are strong. I never find any difficulty with getting bees into supers. About $3\frac{1}{2}$ in. wide, placed equidistant from top and bottom.—JOHN WALTON, *Honey Cott, Weston, Leamington.*

1. Yes; I always use separators, and consider wood the best, being the warmest. 2. $3\frac{1}{2}$ in. wide, placed so as to give a $\frac{3}{8}$ in. passage top and bottom on face of section.—H. WOOD.

Yes. Metal separators (No. 5 zinc) are the best and cheapest, especially with four bee-way sections, in which case they must be slotted. Four inches from bottom of foot to top, or $3\frac{1}{4}$ in. if without feet.—W. B. WEBSTER.

Decidedly. Tin of course are more durable, but I think the bees prefer wood, and they are certainly warmer, so, on the whole, I prefer them if, like Abbott's, *thin enough*. Thicker ones are an abomination. To secure an even face to the combs, only $\frac{1}{4}$ in. should be allowed top and bottom, *i.e.* the separators should be $3\frac{3}{4}$ in. wide.—W. E. BURKITT.

Yes, and I prefer tin to wood, as being more durable, not liable to warp, and better adapted for cutting slots, but the tin should be light and thin. With 'four-way' sections I use dividers of $3\frac{1}{2}$ in. wide, which allow a space of $\frac{3}{8}$ in. at top and the same at the bottom of the sections. This allows passage for the bees and prevents bulging of combs.—GEORGE RAYNOR.

Correspondence.

The Editor does not hold himself responsible for the opinions expressed by his correspondents. No attention will be taken of anonymous communications, and correspondents are requested to write on one side of the paper only, and give their real names and addresses, not necessarily for publication, but as a guarantee of good faith. Illustrations should be drawn on separate pieces of paper.

'RAYNOR EXCLUDING-HONEY-BOARDS.'

[1649.] As the slatted-honey-boards, for excluding queen and drones from surplus boxes, now in general use in America, are likely to gain an introduction into the apiaries of this country also, I should be glad to say a few words respecting the one I use. As the time for their use has arrived, and unavoidable circumstances have prevented an earlier reference, I would say that without an engraving it is difficult to give a full description, but they are very similar to the American boards, and are made by Mr. Neighbour of 149 Regent Street, and by Mr. Dines of Maldon, Essex, either of whom will supply a pattern with full particulars and price. The board is made to cover a ten-frame standard hive, outside dimensions 17 x 16. It consists of a framework containing eight slats and nine interspaces corresponding in width and direction with the top-bars of the brood frames and the interspaces between them. The latter are fitted with queen and drone-excluding zinc slides, having two rows of perforations of a new pattern, which allow perfectly free passage to worker bees, but effectually exclude queens and drones. This new 'zinc-excluder' is manufactured and supplied by Messrs. Harvey & Co. of the Kent Zinc Works, Lewisham, S.E., and has been registered by them under the name of 'Raynor's Queen and Drone Excluding Zinc.' The under side of the honey-board has a full bee-space of three-eighths of an inch, being intended for use on hives whose frame-bars are flush with the sides of the hives, and the slats on the upper side are flush with the outside framework of the honey-board, to which it is intended that all section-cases or crates in use at present having a bee-space below their framework may be adapted, as it is considered that a bee-space both above and below the honey-board should be afforded for the freer passage of the bees. I may add that I obtained sections last season worked on these honey-boards better in quality, brightness, and colour, than any I had previously obtained without the use of queen-excluding honey-boards, and the bees manifested no indisposition whatever to pass freely through the perforations, nor had I a single swarm from hives on which the boards were used.—GEORGE RAYNOR, *Hazeleigh Rectory, May 26th.*

BEES AND FLOWERS.

[1650.] Possibly many of your readers are expecting to see a few lines from me once again, having promised last autumn that it should be so. By your permission I will first say a few words about the bees. I closed up for the past winter with seven old stocks, seven swarms, and three lots of driven bees. Thirteen lots weathered the winter well and came out this spring nice and strong. Three lots were rather weak, and one lot starved to death with plenty of stores in their hive. Well, say you, that is strange talk, but permit me to relate the circumstances. Most of my hives hold fourteen standard frames, and this lot was packed for the winter on seven frames, and having some frames of comb which had lately had the honey extracted from them. My dummies don't reach the bottom of the hive by $\frac{1}{2}$ of an inch, and behind this I left four of these empty combs for the bees to clean, and by some means the queen got in with these empty combs and the weather set in cold, so I did not disturb them, not thinking, of course, that the queen had got out of place; but I suppose the fact of her being behind the dummy all the bees followed her, and there they stayed and starved to death with abundance of stores on the other side of the dummy.

Now I had three queens which were in their third year and I decided to unite these three weak lots and so utilise the two spare queens, they being young and healthy. And I will here relate that I decided to follow some of Mr. T. Bonner Chambers' advice, which he gave us in *B. B. Journal* for April, 1888, pages 180 to 183. The advice which I followed is that which he calls an excellent method, on page 181, for 'queen introduction.' Now two of these weak lots were in one hive with a close-fitting dummy (only) between them, with a piece of board to divide the entrance on the flight-board; I had previously brought the single weak lot up to the double one. I did not take quite so much pains as our friend 'T. B. C.' advised, but I will tell you just what I did. I got two ordinary lucifer-boxes and put one in each waistcoat pocket, opened all three lots of bees and spread a carbolic cloth on the tops of frames for about one minute, then lifted frames one at a time until I had caught two of the queens and slipped one in each lucifer-box and back into, this time, my trousers pocket to keep them warm. I then took one frame from No. 1 hive and shook the bees on the platform in front and replaced it at one end of the hive which had the two lots in; I then took a comb from No. 2 hive and No. 3 hive and treated them all in a like manner, one by one, until I had been through all three lots, and then covered the frames with a quilt and left the bees to run in while I went with my two queens to two other stocks, first arranging the platform and then taking the combs one by one, and caught the old queen and gave her a pinch with the thumb and finger and threw her down (of course dead). Then I began in like manner to shake the bees from the combs and replacing them in the hives: so here you see, that I did not at any time have more than one comb out of the hives at one time. I did not take any notice of the loose bees which were on the sides and bottom of the hives when I had been through all the combs, and of course as fast as I could handle them I dropped the queen on the heap of bees from the lucifer-box and they all ran in.

The next day one would not think the hives had been disturbed unless they were acquainted with the fact. I have changed many queens for myself and neighbours in this same way, and all have gone to work as though nothing had interfered with them in the slightest way. But here I will mention, if there is much fresh and thin honey in the combs, I should not introduce queens in this way, as a deal of the honey would be shaken out of the combs, and, of course, nearly drown, and perhaps quite drown, many bees. I myself used a cage in intro-

ducing one in a hive on the 12th of May, this hive having much thin honey in it. In this case I let the queen remain in the cage twenty-four hours. I use a long cage to go down between the combs. This is put directly under feed-hole, so you can release the queen without even disturbing quilts, and you can take the cage out when it suits you, or, say, after the queen has had twenty-four hours' liberty. I never remember losing a queen, either with or without the cage, so I think either of the above is a good plan, and perhaps many others are as good, but I have not tried them, so must leave it to those who have. I may say that Mr. R. Green, the Kent Bee-keepers' Association expert, called on me on the 14th of May, and found this cage in the hive. He wanted to know why I used a cage. He was satisfied with my explanation, but he says he has long practised, and recommends the shaking bees from combs in the front of the hive, then dropping queen, as above, and it is the safest plan he knows of.

I am afraid I am trespassing too far on your space, but if you can spare me I should like to say a few words upon bee-flowers. I told you before that many of our friends have sent me different kinds of seeds, cuttings, and plants: I beg to return thanks to all. I have done my best with them, but upon my soil I find nothing to equal the borage and *Nepeta Mussini*, therefore they are still my favourites. I had many applications for the latter last autumn which I could not supply, I therefore promised to strike large quantities this spring and offer them to our bee-keeping friends. Now I have done so, and I think I have supplied all my last year's orders, so I have advertised in the advertisement column of this issue a fresh batch. Cuttings and seed will be free as before, namely, applicants paying postage.—C. H. W., *Aylesford, near Maidstone, Kent.*

JOTTINGS BY WOODLEIGH.

[1651.] There has been a great deal written during the past year or two on improving our race of bees, and I think it is quite time some one should say a few words in favour of the drone bee. Writers on bee matters are generally in favour of using full sheets of foundation in the brood nest, or at least of leaving a space in some outside corner of the comb for the bees to build if they like a patch of drone-comb; and if they do not think fit to build their drone-comb at that particular spot, they will in the near future be under the necessity of raising drones in elongated worker-cells. Looking at the fact from a physiological point of view, could there ever be a more fallacious proceeding on the part of present man who prides himself on improving his race of bees. Recent writers have compared stock-raising, &c., to bee-culture, yet what stock-raisers would ever think of introducing foreign blood into their strain as a means of improving the breed, and neglect the first and greatest desideratum, viz., a sire of the noblest and amplest proportions? Yet the tendency of modern bee-culture is to prevent drone-brood raising in the natural way, i.e., in natural built cells; and consequently if drone bees are raised by a colony in elongated worker-cells, they must of necessity be smaller than if raised in a larger natural size drone-cell. In the first place, the nurse bees would not have room for the insertion of so large a quantity of food as in the natural cell; then the bee itself could not grow and thrive so well as in the natural cell by reason of its restricted dimensions, the cocoon from which it emerges being small, how can the baby bee grow to a normal size, where if we are advancing it ought to be a little larger rather than smaller than the drone of twenty years ago? I commend this little jot to the thoughts of bee-keepers, and the query rises to my mind, Are we really advancing in excluding natural drone-combs from the modern bar-frame hive? I fear our greed for gain by raising worker bees only is in an opposite direction as

regards the improvement of the race of bees. Then by every means let us look to the improvement of the drone bees as the first stepping-stone to an improved race, for unless the sire is in good form and condition, the progeny must deteriorate.

We have had a beautiful rain in our district during the week, and on Friday, May 18th, our first honey flow for the season. Every colony was in a state of excitement, as though they had discovered some deserted hives replete with stores. They continued to work with a will until very late in the evening, in fact, till darkness prevented them. In the evening I started in quest of their newly-discovered Eldorado, to discover, if possible, the source from which they were busy extracting their sweets, and a walk of about a quarter of a mile from the apiary I found some large sycamore-trees literally covered with flowers and bees at 7.15 p.m., also some beech-trees had a great abundance of blossom and attracted a considerable number of bees even at that late hour of the day, though not so many as were on the sycamore-trees. There are large fields of permanent grass yellow with the dandelion in our immediate vicinity, and this Saturday morning I walked across one of the fields and found large numbers of bees sipping honey from the flowers. I was tempted very much to super some of my strongest colonies, but to-night it is much colder, and so I shall leave the supering until late in next week after the holidays (weather permitting); the earliest date I have put on supers has been May 23, and in an early season. I would caution young hands in bee-keeping not to super too early, also to well wrap up their crates whenever they do super to conserve the heat of the hive and keep up the normal temperature of brood-nest. Saw first drone this season on May 9th.

RECORDS OF QUEENS AND SUPERSEDING THEM.

[1652.] In the *American Bee Journal* just to hand there is the following query (540):—‘*Is it best to keep a record of the queens so as to supersede them when they are two or three years old, or let the bees manage in their own way?*’ Some prominence was given to this subject in your article of June 17th, 1886, when you say:—‘*When queens are stimulated to their utmost, and as much as possible is got out of them, they are of little use after the second year.*’ The following week (399) I took exception to this, and pointed out that many prominent apiarists preferred leaving the superseding to bees themselves. I say that ‘my experience tells me that there are many things that bees do much better than we can, and I think this superseding of worn-out queens is one that, if left to themselves, they will do at the right time. If a queen during her second year has been as prolific as we could expect her to be, and has shown no signs of want of vigour, it appears to be a cruel as well as an unwise thing to depose her to put a young and untried, artificially bred queen, in her place,’ and run the risk of introducing foul brood into your apiary with the queen, which, if bought or imported, may possibly be as old, or older than the one superseded, for all we know.

The following are the answers reported in the *A. B. J.* from men whose names will be familiar to many, particularly to you, Mr. Editor:—

It is best to keep a record.—J. P. H. BROWN.

Let the bees do it.—DADANT & SON.

Let the bees take care of that matter.—G. M. DOOLITTLE.

Perhaps so, but I never have superseded my old queens.—EUGENE SECOR.

Keep a record of everything, and supersede the queen when she ceases to be prolific.—A. B. MASON.

I have never kept a perfect record, but I am inclined to think that is the best way.—MRS. L. HARRISON.

Keep a record anyway; but I do not know what is best as to the superseding.—C. C. MILLER.

It is much better to keep a record. Supersede the queens when they begin to fail—it makes no difference if they are one or three years old.—P. L. VIALLOX.

I let the bees manage it in their own way with all valuable queens.—G. L. TINKER.

Deeds, not days, determine a queen's usefulness. With experience you can tell when a queen becomes unprofitable by looking into her hive, and I should assist the bees as much as possible to supersede worthless queens.—R. L. TAYLOR.

I prefer to keep a record of all queens, including pedigree, so far as ascertainable. But I let the bees supersede a good queen. They know when to do it.—M. MAHIN.

I keep a record only of my fine breeding queens, and the older they are, the better for breeding purposes. I let my bees supersede their own queens.—G. W. DEMAREE.

No; let the bees manage it. I keep records of sale queens only. The bees do it better than we can, cost considered.—JAMES HEDDON.

Keep a record always. Thus you will know the pedigree, &c., and be able at any and all times to know the age of every queen in the apiary.—J. E. POON.

Yes, keep a record of queens, but supersede them only when they decline in vigour. Superseding by rule would often depose queens of great value. The bee-keeper must have brains as well as a record.—J. M. SNECK.

I think that the bees can manage the matter for themselves. If queens are found that are doing very poorly, it pays to supersede them; but age is not the test. Our vision will serve better.—A. J. COOK.

As a rule the bees will attend to these matters more satisfactorily than you could possibly do, and before you are aware that such was their intention. It is well enough to know which hive your best queens occupy, and if you have many colonies it will necessitate a record.—J. M. HAMBAUGH.

I find that the bees manage that thing very successfully if you let them alone. You will find many cases where it is best to supersede, and you will not be obliged to keep a record to find it out. For a beginner in the business a record of all work is an excellent help.—H. D. CUTTING.

I think that it would be a good idea to keep a record of the age of queens. I do not think, however, that it would be advisable to supersede queens less than four years old unless they prove inferior; in that case, do so at once. I supersede only such as fall below my standard.—C. H. DIBBEN.

It is certainly best to keep a record of queens, but as to superseding the queens, the bees will manage that more satisfactorily themselves.—THE EDITOR.

I would call particular attention to the answer of Mr. Doolittle, who is himself a large breeder of queens, as evidence in favour of the let-alone plan.—JOHN M. HOOKER.

SHALLOW FRAMES.

[1653.] A word or two explanatory as to the frame 6-inch deep sent out by myself.

Having convinced myself of the utility of a narrower frame than the standard for the purpose of storifying, &c., I was sufficiently bold to introduce it at Norwich Show in 1886 at a time when the standard frame was the *sine qua non*. The depth of shallow bodies (for use either above or below the standard body) was ruled for the working of 2-lb. sections, 5½ inches deep, suspended in a divided hanger or frame, and side-spring dummies brought all work in that direction together as though crated in the ordinary manner. It may be now seen how a frame 6 inches deep was necessary to take the place of the 2-lb. section and its hangers of necessary strength, to keep all in position when stored with honey. Soon after the Norwich Show, ‘Useful Hints’ wrote, describing even such a hive as I had exhibited, and asks

—or to the effect—Who will give us such? and here we had a good recognition of the shallow frame. About such time the DEEP FRAME of Mr. D. A. Jones was acknowledged by some to be far ahead, and in an 'Universal' hive such a frame was to be used, which also admitted the standard and W. B. Carr frames if preferred. Hence 'Universal' and Bebington hives followed to have a place in the bee world market.

I do not wish to infer that these frames and systems did not exist prior to my 6-inch frame, but rather to show that when I knew they were to be put into the Market, was I willing to meet, if possible, the size of our friend, W. B. Carr, and more especially as 2-lb. sections were then (1886) at a discount. Therefore a shallow body, differing from the original, was sent with my 'Holme Wood' hive to Mr. Cheshire, and from this Mr. Cheshire gave his figures no doubt.

At the end of that year I ran through orders executed during the past two seasons, and found it would be too much to ask of my customers to accept a 5½ in. frame; so I kept to my original depth, and the great numbers of 6-inch deep frames I have sold bear testimony of their utility, as well as many written acknowledgments received. With Mr. Dobbie I think that my patrons must feel from vested interests the 6-inch frame of as much importance as the 5½, and especially so as 2-lb. sections (now reascending) can find a place side by side with the former. Surely the B. B. K. A., having once set up 'A STANDARD,' will not weaken its position by another, but rather let its significance be shown in the clustering around it of the many divergencies before and after its adaptation.—JOHN H. HOWARD, *The Model Apiary, Holme.*

VALUE OF SMOKE IN MANAGING BEES.

[1654.] When honey was at the highest price ever known in this country, viz., from 1863 to 1866, little use was made of smoke by the greater number of bee-keepers. Even Rosewell C. Otis, the veteran who mainly introduced the Langstroth hive in New York and the West, only used a cigar in his demonstrative work. It is true that Mr. Langstroth had explained the action and value of smoke in the control of bees, and the principle on which its effect rested, in his most efficient work, *Langstroth on the Hive and Honey Bee.*

Hunters of bees had used burning straw about bee trees when cutting them down, and found the cloud of smoke a protection against stings. But the main conception of the value of the smoke in the management of bees was associated with the common pipe or cigar. This fact, no doubt well based, came from the prompt action of tobacco-smoke,—an action more efficient than any other smoke, and also more convenient with the means then in use, especially when the bee-keeper was a tobacco smoker. (And such habit was likely to prevail with bee-keepers whose aversions to the habit of smoking were not strong.)

The invention and application of the direct-draft principle in bee-smokers at once revolutionised the management of bees. Tobacco-smoke was no longer of value because more condensed and in use by pipe and cigar smokers. The great abundance—a cloud of smoke enveloping the user of a Bingham smoker, and the fact that such smoker never went out, and that smoke in clouds could be instantly applied to bees—at once supplanted the tobacco, pipe, and cigar in their management. While it is not the province of this paper to discuss the tobacco habit, the direct-draft smoker plays an important part, as there is no excuse for a bee-keeper smoking tobacco so far as bee-keeping is concerned.

The fact that bees fill their honey-sacs with honey when frightened, and do not, when so filled, volunteer an attack, and the ease with which smoke is applied, has led, no doubt, to the abuse of smoke in managing

bees. Bad habits are common from superficial methods of reasoning, when a more thorough analysis of apparent results would eradicate or modify them. This is especially true in the use of smokers, and the smoker in the case of the apiary. The fact that a cloud of smoke around a bee tree reduces the anger of the bees, and removes the danger of attack from them, leads directly to the conclusion that such cloud of smoke would have the same effect in an apiary. Circumstances which have come under my observation lead at once to this conclusion. As an evidence of the fact allow me to cite the sale of smokers at certain seasons of the year, and the sizes most sold at such season.

The inference from the sale of any particular sizes of smokers, at a season when smokers are not much in use, is that the most experienced bee-keepers provide themselves with such tools as they are likely to need before they are actually required for use in the apiary, while the amateur waits till the case becomes urgent before he decides, and then is likely to consult the first cost (which he sees clearly) rather than the results and principles underlying his purchase which he does not so clearly understand.

Early in the spring, and also in autumn, our sale of smokers is as five of the two largest to one of the smaller sizes; while in the middle of the season, when the young bee-keeper is obtaining his urgent outfit, the small and medium-sized smokers lead in sale the three largest sizes somewhat, so that the entire season wings round with about the same total number of each as sold. As the larger sizes hold more wood and make as much more smoke in proportion, it is safe to infer that bee-keepers of experience do not object to an immense volume of smoke in handling bees.

This conclusion, providing the premises on which it is based are correct, leads to the decision that bee-keepers, whether they understand the principle or not, recognise the value of a continuous cloud of smoke in the apiary at all times when bee-keepers are of necessity or choice among the hives and bees.

It is idle to presume that a peaceful, non-aggressive apiary can be found where gloves and veils are resorted to instead of constant and overwhelming smoke. With abundance of smoke, the eye of the bee-keeper holds the temper of bees as the experienced horseman holds the vicious horse, and any careful manipulation may be made without a puff of smoke, provided always the smoke is abundant in the air, and at the service of the operator should occasion require.

The above leads directly to the most discussed fuel for smokers. Of course circumstances alter cases, and the means of obtaining fuel of any particular kind will play a conspicuous part. One thing, however, will be found advisable under all circumstances, viz., to consult the smoker. It is useless to try to burn anthracite or hard coal in a box stove designed for burning wood. It would be equally futile to attempt to burn stove wood in a smoker not having a strong, continuous draft. This being understood, a clear understanding of principles leading to results desired, it seems to me but one conclusion can be reached, viz., that sound sun-dried or other perfectly dried maple stove wood, meets, in the highest degree, the needs of the bee-keeper using a direct draft smoker.

Some of the reasons why perfectly dry hard wood is preferable for use is that it burns only at the bottom or lower end. That is, it renders the direct-draft smoker a base burner. (Rotten wood burns all over and is soon gone.) Wood in sticks does not obstruct either the draft or blast, both of which render quick and continued action easy. Sound wood which has live coals left after it has ceased to smoke, maintains sufficient heat to prevent unpleasant sooty accumulation, and furnishes hot, dry, strong smoke all the time without working the bellows, thus rendering it ready for use every instant. Of course

the direct-draft smoker will burn anything combustible, and he who uses it may choose his fuel according to circumstances and tastes.

It may be asked here if it would not be better to have cold smoke. Such an idea has been advanced very much, but as the object of smoke is to frighten bees, not convert them into bacon, anything that will accomplish the fright in the easiest and most effective manner will serve the purpose best. Hot air will do this just as well as smoke, as far as it goes, but the air cools, so quickly it is of no value except just as it leaves the smoker. The making of smoke goes on fast or slow just in proportion to heat, so that when there is little heat there is little smoke, and *vice versa*, where there is much smoke 'there is some fire.'—T. F. BINGHAM (*From the Beekeeper's Guide*).

EXPERIENCE.

[1655.] I have twelve hives of bees. Last year I bought some starch and salmon boxes, as I could not afford 8s. to 10s. for bar-frame hives, so I made some makeshift hives out of these boxes. I bought a bit of $\frac{3}{4}$ in. board for making the frames; the frames are as near standard size as I could make them. The salmon-boxes had to be cut shorter, 16 $\frac{1}{2}$ in. in length. The swarms I had last year were put into them. They were dummied up to six frames. A crate of twelve sections was put on the same time as hiving. The first swarm gave thirty-six one-pound sections, the last gave twenty. I gave one-inch starters of foundation on the frames, and nearly filled the section. In the autumn I bought some boards and made some good standard hives holding ten frames. I bought the little book *Modern Bee-keeping*, and consulted it, and made the hives as near as possible to those in it. It is a useful little book: I think every cottager ought to buy one; its cost is only 6d. As soon as my hives were finished and painted, I brought the bees into a warm room and shifted them into their new hives, and packed them up for winter; and now, May 17th, I think they are in good order, one hive especially. They are on ten frames, drones flying freely. Three of the straw hives are full of bees. I am expecting them to swarm every day. The other frame-hives are on six frames. I am going to give extra frames next week. I will give you a few names of flowers near me. My bees have been working on palm, wild anemones, wild cherries, and blackthorn; next come the May and maple trees. I shall write again a little later on.—HAYBINDER.

GIVING A LAYING QUEEN TO PARENT COLONY IMMEDIATELY AFTER SWARMING.

[1656.] For years we have been told that no colony should go without a laying queen for a single day, if it were possible to give them one; and plans of introducing queens which required that the hive should be queenless a few days previous have been severely criticised. We have also been told, for years, that the bee-keeper who wished to secure the best results from his bees should have a laying queen ready to give to each old colony as soon as they swarmed, as the time lost to them, by rearing a queen, is equivalent to a swarm of bees. Being eager to know for myself all the plans which would give the best results, I have experimented largely; and the truth of the statement, that the time lost to the bees in rearing a queen in natural swarming was equivalent to a swarm of bees, is the first reason that the plan has not been a success with me. If it were bees I were after, the case would be different. With us white clover yields enough honey to keep the bees breeding nicely, and prepares them so that they mainly swarm from June 20 to

July 1. Our honey-harvest is principally from basswood, which blooms from July 10 to 16.

Now, all who are familiar with natural swarming know that the bees are comparatively few in number in the spring, and increase by the rapidly increasing brood produced by the queen, which, in due time, hatch into bees, until a swarm is the result. By giving a laying queen to a colony immediately after it has cast a swarm, we bring about the same result (swarming), as before, or we place the bees in the same condition. The only difference is, that, having plenty of brood, they built up quicker, and are prepared to swarm in a shorter time. As this second swarming, brought about by giving a laying queen, comes right in our basswood-honey harvest it cuts off the surplus honey; for it is well known that bees having the swarming fever do little or no work in the section boxes; and, if allowed to swarm, the object we have sought after (section honey) is beyond our reach. Having given my experience on this point, let us see how the same colony would work had we not given the bees a laying queen.

Eight days after the swarm has issued, the first young queen will have emerged from her cell, as a rule, when the apiarist should remove all the other queen-cells from the hive, so that second swarming is entirely prevented. In ten days more our young queen is ready to lay, which is about the time basswood begins to yield honey largely. During the period between the time the swarm issued, and the young queen commences to lay, the bees, not having any brood to nurse for the last half of the time, consume but little honey; hence, as fast as the young bees emerge from the cells, they are filled with honey; for bees not having a laying queen or unsealed brood seldom build comb in the sections. Thus, when the young queen is ready to lay she finds every available cell stored with honey. At this point the instinct of the bees teaches them that they must have brood or they will soon cease to exist as a colony, and a general rush is made for the sections. The honey from below is carried above, so as to give the queen room, and in a week we have, as a result, the sections nearly filled with honey. I have had such colonies fill and complete section honey to the amount of 60 lbs. in from eight to twelve days, while those to which I had given the laying queen immediately after swarming did little but swarm during the same time. Bear in mind, we are talking about producing comb honey, not extracted. Different locations may give different results; still, I think that nearly all sections give a large flow of honey at a certain period during the season, rather than a steady, continuous honey-harvest the whole season. To such sections these remarks are especially applicable. My second reason is, that after basswood we have a honey-dearth, hence the bees from the introduced queen are of no value, but, on the contrary, become consumers. On an average, it takes twenty-one days from the time the egg is laid to the perfect bee. Then if the colony is in a normal condition, this bee does not commence labour in the field till sixteen days old; hence, the eggs for the honey-gathering bees must be deposited in the cell thirty-seven days before the honey-harvest ends, or else they are of no value as honey-producers. As the basswood is all gone before the eggs of the introduced queen become honey-producing bees, and as the larger part of them die of old age before buckwheat and fall flowers yield honey, it will be seen that a great gain is made by letting each old colony, having cast a swarm, rear their own queen; for thereby we save the expensive feeding of the larvæ, which are to become expensive consumers of the honey of the hive. Also the chances are, that, when the colony rears its own queen, they will be stocked with younger bees for wintering in November than where a queen was introduced immediately after swarming.

The one point worth knowing above all others in bee-keeping is a thorough knowledge of the location we are

in, as to its honey resources, and then getting the largest amount of bees possible at that or those times to gather honey, having just as few at all other times as is consistent with the accomplishing of this object.

In working so that we get the bees out of season, we have to pay the same price for them that we would to get them, so that each one becomes a producer instead of a consumer. If all who read this article will study their location, and then rear their bees in reference to that location, I think they will find their bees will do as well as their more successful neighbours'. We often hear it said, that one colony in the apiary did much better than the rest, and, had they all done as well, a rousing crop of honey would have been the result. The reason that one colony did so well was because it happened to have a large proportion of its bees of the right age to gather honey just in the honey-harvest; and if we can get all in this condition we can assure a like result from the whole apiary.—G. M. DOOLITTLE, *Borodino, N. Y., April 2, 1888.*

SELECTED QUERIES AND REPLIES.

[1657.] Replying to 'R. M.'s' query, it may not be amiss for me to give him my plan of wintering bees on three or four frames, as he asks Mr. Raynor to give his plan on page 239. I get driven bees, saving those queens that I know to be young, and put them on about four frames (some more), and feed them up in the autumn. They are placed in hives only $\frac{1}{2}$ inch thick, and shut up close at side with one dummy, the other comb goes up near to the side of the hive, with an entrance about $1\frac{1}{2}$ inch or 2 inches long. These lots I place in pairs about my garden, and in spring I take queen away from one lot, when I get orders for them, and join the bees and combs to the next lot, and by that means I get a fair stock. I wintered over twenty in this way this last year, and did not lose a single lot. I merely cover the top up warm with two or three quilts and a folded rice-bag, and lay a roof right on top, and tie them on so that they cannot get blown off; there is no protection at the sides. In answer to same questioner of May 10th, by my saying 'shut up close,' I do not mean the bees were not to be allowed to come out, but to only have a small entrance, but to be shut up close with a dummy, and fed and stimulated. I had in my mind a case, about three years ago, when I sold sixteen stocks to a gentleman at Cheltenham. I offered him at a price these stocks, and included this same nucleus with a Carniolan queen and bees only on two frames, and a few others on the third. However, he did not have this said nucleus, and it was quite at the end of April. I fed them and inserted a frame of foundation in the centre of the brood-nest, and looked to them, so that they never wanted for food, and as soon as they had filled the frame of foundation and sealed up brood, I gave others, till I got ten frames well covered with bees, just in time in June, when honey was coming in well; and I supered them, and took over thirty 1-lb. sections from them. I did not give any brood at all from other hives.—JOHN WALTON.

AFTER THE WINTER.

[1658.] After reading with interest the notes of a correspondent from Farnborough, in a late edition of your *Journal*, I feel anxious to describe a somewhat opposite state of things to those which he was fortunate enough to find in his colony. Of four good stocks last autumn, but two are left to start this season. One of the survivors was from a straw skep, and the other from a bar-frame hive. Now, why are the others dead? not because, as your correspondent remarks is often the case, too much honey was taken last year, for there were at least two bars in each hive with two or three pounds of

sealed honey in them. Why had the bees not helped themselves? or may it be that the extreme coldness of our early spring prevented them from coming on to the bars for food till it was too late? If so, what could have saved their lives? An extra supply of honey would in this case have been of no avail. You may be interested to hear that the stock from the straw skep was most successfully transferred into a frame-hive one fine day last week. There was not much brood-comb to be removed, but one or two pieces were wired on to the new bars, and by now they seem to have settled down to their new quarters most comfortably. With best wishes for a good honey-bee season, my notes from the Anerley colony must be concluded.—BRATHAY.

NON-ALCOHOLIC DRINK.—No. 1.

[1659.] One ounce of citric acid dissolved in two pints of water, this gives us a fluid about the strength of lemon juice with its good chemical action on the liver and stomach. A tablespoonful of this, ditto of honey, in a tumblerful of water, gives a perfect cooling summer drink, but having the objection that it will not keep. It should be kept prepared in its acetous form, honey and water being added when mixed for drinking.—R. A. H. GRIMSHAW.

NON-ALCOHOLIC DRINK.—No. 2.

[1660.] One pound of clear extracted honey to one bottle of the Montserrat pure lime-juice. These can be mixed a few bottles at a time. The writer has used this drink the last twelve months continuously, but for a summer beverage it cannot be beat. Mix three parts of water to one part lime-juice and honey; some prefer more water. If mixed in cold weather, the honey must be warmed.—ANOTHER BEE-KEEPING ABSTAINER.

INFORMATION DESIRED.

[1661.] Will experienced bee-keepers give me any information they can? First: On the possibility of beginners being able to procure bees in the neighbourhood of Queenstown, Cape Colony, and about what price should be paid for them? Second: As to the likelihood of colonists being able to take out stocks or swarms safely from England, and the best way to pack said stocks?—M. E. EYTON.

WHAT MAY BE DONE IN A CASE OF EMERGENCY.

[1662.] If I shall not be trespassing on your valuable space I should like to say what experience has taught me last summer and this winter, as I think it may be interesting to some of your numerous readers. I live on the border of the remnant of Sherwood Forest, there being several apiaries in the village, my small one amongst the rest. Last summer there was a swarm left my next neighbour's apiary and took up its abode in an unused chimney. The owner not wishing to fetch them out, I asked if I might do so. Having got his consent I at once went to the occupier of the premises and asked his leave, and it was given at once. In examining the place, I found it was a chimney belonging to an out-building, the gable end to the orchard, with a parapet wall about twelve feet high, flat top, running from the gable end. I took with me an empty straw hive, also some scorched rag. The chimney was built up from the inside of the room, but fortunately there was a hole into the chimney I could use. I at once set fire to the rag, and with a thin rod of wire pushed it into the chimney, smoking the bees out at the top. I then placed a ladder on the wall and rested it against the gable end of the building. When at the top I found a flat stone covered

the top of the chimney, to the underside of which a previous stock of bees had built comb, but had died and left it unoccupied. The swarm had taken possession of the comb and had been working in it for several weeks. When I lifted the stone I broke down some of the comb, but there was a good quantity left attached to the stone, which I turned upside down and carried down on my head, and laid it on the wall the same side up I had carried it down the ladder. I then pulled up some long grass and brushed the bees that had settled on the outside of the chimney into my skep, brought them down and placed them over the stone. In an hour they had settled to the skep. In two hours I took a cloth and laid it on the grass in the orchard, carried down the stone and skep, placed them in the centre, tied the four corners above, putting a strong stick through. With the assistance of my son I removed them to my apiary, where I had an empty bar-frame hive with comb worked out. I shook the bees out on the bars, having set them about two inches apart, covering quickly with an empty sack; they settled down in a short time. The next day I put the bars the proper distance, the bees all the time being very busy. I examined the hive this morning, and find that they have gone through the winter well, and cover about six frames two inches deeper than standard size. Being the first bar-frame hive I possessed I still keep it, the bees always working fairly well in it.

If you think it will interest any of your numerous readers I shall be glad to say in another letter how I succeeded in transferring a stock the last week in November.—*W. ROBINSON, Mansfield, Woodhouse, Notts.*

[We shall be pleased if you carry out your promise.—*Ed.*]

WAX SECRETIONS.

[1663.] All bee-keepers know the origin of wax. It is secreted by thin membranaceous glands just beneath the ventral segments of the abdomen. These glands take elements from the blood and form the liquid wax; which, by osmosis, passes through the eight wax-plates and is moulded as thin scales on the outside of these plates.

In most all cases secretion is wholly involuntary. From analogy then we should suppose it would be in this case. The cow has no control over the milk secreted in the milk-glands as to time of secretion, quantity, or quality. No more have we as to whether our salivary glands shall secrete spittle or not, or whether our liver shall form bile, or our pancreas its peculiar liquid. In case of bees then the burden of proof rests with him who believes that the wax-glands of bees are under the control of the will.

Some years since, when foundation first came into use, I felt that this was an important question, and I attempted its solution as follows: I hived three good prime swarms; one on empty frames, one on foundation, and one on empty combs, and then weighed each, each day, after the bees had collected in the hives for the night. I found that the colony without either comb or foundation gained in honey much more slowly than either of the other two, and that far less bees flew. The other two colonies increased nearly the same, but the gain was slightly in favour of the colony with combs. Since then I have had my students try the same experiment, with similar results; except, in one or two cases, the colony on foundation has done the best.

Now one of two things must be true. Either the bees have control of this function, or else, by their action, whether of rest or motion, they indirectly control secretion. The horse that works very hard raises a poor colt, because she cannot do so much muscular work and secrete enough milk for her off-spring. I wish to fat my fine shorthorns for the shambles at Christmas time. I shunt them up in a warm, comfortable, quiet stable, and give them no exercise. If they have to eat to supply

muscular force they can furnish less for fat. Now, it would seem that this might explain the fact given above. When combs are to be built the bees hang quietly from the top of the hive, eat much; and, as no muscular force is to be expended, much wax is formed. When the mare works hard she forms little fat or milk; when quiet she may produce much of both. Likewise the bee; only the condition of the hive is what induces the action or quiet.

But there is one more tangle to this knot: when bees are hived in an empty hive, we find that even the field bees are secreting wax. Nearly every bee will show the scales. On the other hand, put a swarm into a hive full of empty combs, and it is difficult to find a bee within or without with the wax-scales in the wax-pockets. I have repeatedly noticed this in looking for bees with the wax-scales to show my class. Here it must be voluntary, unless the bees do less outside work in the one case, and so use vital energy to produce wax, and more in the other, and so do not have any vital force remaining to secrete wax.—*A. J. COOK, Agricultural College, Mich., (American Apiculturist).*

BIRDS AND FRUIT TREES.

[1664.] Sparrows destroy buds and catch bees, too, and will soon destroy peas, when they are beginning to appear above the ground, unless they are protected. Some people say they destroy crocuses, &c.; others say the great tits destroy bees; I have often watched, but have never seen them take any but dead bees; they feed mostly on insects. I should never think of destroying them. Surely in these days of invention those gentlemen could think of something to scare away birds: there are imitation birds of prey to be bought from Hickman and Clive, Wigan. There are directions given in *Gardening Illustrated*, May 26, to frighten sparrows. We never know the want of water till the well is dry, and birds will never be missed until they are gone. When I see the mischief done to plants by insects I often wish there were more birds. Bullfinches do not take hawthorn, wild cherry, sloe, blackthorn, myrobella. Here I have fed them during the severe weather in winter. Cherries were only about two hundred yards away, but they never touched them.

I have had the management of many stocks in this neighbourhood. If short of food I feed my bees until the white clover appears. I always think of what an old bee-keeper said to me when talking about flowers; I asked him why he did not grow them, his reply was, 'I leave the farmer to do that.' I think we may conclude the same. It is the acres of clover, trefoil, and alsike, and the ten thousand blooms which we must depend upon: at least such has been my experience. When the snow is on the ground I have seen the bullfinch clinging to the black-berry cane, and his lovely colour contrasting with the snow, one of nature's lovely pictures which ever present themselves to the eye of the observant traveller. I have also seen the goldfinch eating the thistle-seed, and the woodlark up in the clouds, the music falling to the earth: alas, you look and listen in vain! for the birdcatchers have caught them up in Staffordshire. The Psalmist sang of them in his day: 'By them shall the fowls of heaven have their habitation, and sing among the branches,' and Solomon rejoiced to sing of the 'birds of spring.'—*T. HILL.*

THE JUNIOR COLUMN.

'SOMETHING FOR THE BOYS.'

[1665.] I also think from the contributions we got to the Tom-tits Problem that we could muster a fairly good staff to our Junior Column, and I feel it my duty to reply to Master Freestone. The readers of this column will be sorry to hear that I have been unsuccessful in my pursuits of last summer. I had half my stocks of humble bees ruined last autumn during

my absence from home by boys coming and playing with them, and when the bees flew round them, they struck at them with their hats. I fear also that I didn't keep my stocks strong enough, and had not plenty of bees to keep up the temperature.

For fear of starving them, I bored a hole in the top of the box, and put a section over it, and a piece of glass over that, and the syrup in a tin-lid inside. The drones are easily distinguished by a light yellow stripe down between the eyes (*Bombus terrestris*), which I notice neither the workers nor the queen have got. I find the workers get so that they don't care where they go and ramble away—I think to find a place in which to die in peace.

One time I kept my bees in an attic, and had no queen, so all the workers died off, and the drones, as they hatched, were so miserable that I could not keep them prisoners any longer.

I have tried catching a queen early in spring with the intention of persuading her to build with me. She would fill her honey sac with syrup, but would not build under observation. No doubt she had a home of her own already made elsewhere. My book on humble bees says:—'My observation of the colonies I have kept has always dated from about this stage. I have never been able to induce a queen to commence house-keeping under observation. I have kept the young queens from my nest till the following spring, as well as those captured in the fields late in the autumn, and I have also tried with two caught in the early spring. My colonies have always been taken from the meadows.' I got a nest last autumn without a queen, thinking if I kept workers all the winter, I could introduce a queen in spring, and have kept them in a glass tumbler, putting bits of an old nest round the sides of the comb to keep them warm. In the middle of the day we used to let them fly out in the house, and they would take bearings, and then go to cull nectar from the flowers on the wall-paper. I am certain they went for the flowers, because they avoided the leaves, which were not so brightly coloured as the flowers, therefore not so attractive to the eyesight; and when they found there was nothing to gather, they seemed to rest awhile (I fancy they looked disappointed), and then either flew to the light or back to their tumbler home.

I trust we shall have some more contributions from junior bee-keepers interested in our column.—DARCY GRIMSHAW, *Crag Hill, Horsforth, near Leeds.*

A LETTER TO AN UNCLE.
