THE CIVIL ENGINEER AND ARCHITECT'S JOURNAL.

WROUGHT-IRON TUBULAR BOW BRIDGE.
(With an Engraving, Plate 1.)

In consequence of the tubular form becoming a favourite mode of constructing bridges of wrought-iron for railway purposes, we are induced to give an engraving of a wrought-iron tubular bow suspension bridge for crossing the Ouse river in Norfolk, designed by Mr. W. C. Harrison, who has had considerable experience in the construction of some large timber bow suspension bridges on some of the Norfolk railways.

Mr. Harrison observes,—"The facility with which a bow bridge of this construction, with boiler-plate, could be put together, appeared so evident, that he felt convinced of its practicability and usefulness for railway purposes, in crossing rivers and valleys, to almost any extent. A bridge of this kind could be easily put together, by the same kind of workmanship as in steam boilers, in a manufactory in any part of the country, and in certain convenient lengths of 10, 15, or 20 feet each, for the purpose of transporting to its destination, so that there will be but a few joints to rivet up when put in its place. The bow being hollow, and also the tie-beam, or string as it may be termed, gives the opportunity for a man to get inside to hold up the rivets for the workmen outside to rivet the parts together.

The bow and string are to be made of plate-iron, of such a thickness as is most suitable to the size of the bridge intended to be constructed, and joined at the angles with angle-iron; and it will be perceived from the engraving how perfectly well connected the extreme ends of the tie-beam and bow will be by the manner shown, which is a plate extending over the tie and bow, firmly rivetted to each, thereby answering the purpose of an abutment to the bow, and giving perfect security in a vital part.

The elevation of the bridge shows both the suspending and cross-brace bars, being all of plate-iron, from the facility of getting bars in this shape so easily made, and requiring so little workmanship—namely, the rivet holes made in their ends.

The design is for a span of 170 feet and two lines of rails; consequently, there are three bows. Fig. 1 is the elevation of one-half the span, with the suspending bars a a and b b; d d, the abutment plates, as they may be called; c, the cross-beams, which may be of iron or timber. Fig. 2, a view on the top of the bow, with some of the cross-beams, c, extending outside (as also seen at fig. 3, the end elevation), to receive the lower ends of the struts going up to the top of the outside of the bows, to give steadiness to the whole; but these can be used or not. Fig. 3 shows the distance-pieces and cross-frames between the bows. Fig. 4 is a section of the cross-beams or girders, which may also be made of wrought-iron plate and angle-iron, or wood, to carry the timber sleepers of the rail. Fig. 5 is an enlarged section of the bow and string, and the distance-piece between the suspending bars.

Mr. Harrison proposes for a bridge of the span shown in the engraving, that the bow should be constructed of half-inch plate-iron, 4 feet deep by 3 feet wide; and the tie-beam or stringer 2 ft. 6 in. deep by 3 feet wide.

Next month we will endeavour to offer some remarks on the construction of bridges of the tubular form, as to their applicability for railway purposes.

A DEFLECTION OR VIBRATION GAUGE.

By George Howard Fenwick, C.E.

The accompanying engraving, fig. 1 (drawn to one-third the full size), is a gauge for registering the vibration or deflection of railway girders. A is a piece of wood or metal, made to slide in another piece, B, which is held in position by a slight pressure of two springs, G and F, as shown on plan fig. 2 (drawn full size). On the face A are two arrows at C, which can be moved to any of the holes at D for adjustment. It is supposed to be set at zero, and as it receives the pressure from the girder E it is pressed down, thereby registering the deflection of the girder on a decimal or mechanical divided scale on B. This gauge may be applied by being supported by a frame let into the sides of the walls which the girders span, and so made to travel to any particular place, such as the centre or springings; or may be placed upon a staff for convenience, similar to a levelling staff.

G. H. F.

[This simple and ingenious contrivance might, perhaps, be improved by fixing a vernier on the slide D, divided so as to indicate the hundredth parts of an inch; the side scales being divided into inches and tenths. —Ed.]
NOTES ON ENGINEERING.—No. VIII.

By HOMERSHAM COX, B.A.

On the most Economical Forms of Suspension Bridges.

Of all kinds of bridges suspension bridges are capable of being constructed with the greatest span. Notwithstanding this advantage and the facility of construction, the use of these structures has been restricted by their flexibility and tendency to undulate. They have fallen into disrepute in the modern practice of engineering, on account of the difficulty (generally deemed insuperable) of making them sufficiently rigid for the purposes of heavy traffic, such as that upon railways. Another, though less obvious, objection is that the ordinary methods of calculating the proper form and dimensions of suspension bridges, and the different strains to which they are subjected, are exceedingly complicated. The intricacy of the investigations leaves a degree of uncertainty and distrust as to the actual strength which the several parts of a suspension bridge may be assumed to possess.

The object of the present paper is to examine how far these difficulties may be removed, and to show what method of arranging the different parts of the structure secures the greatest amount of strength for the whole.

Suspension bridges may be distinguished generally into two classes: 1st., those of the ordinary form, that of a main chain or catenary, with the roadway suspended from it by vertical rods; 2nd., those in which the roadway is suspended directly from the abutments by straight rods, the catenary or curve chain being altogether dispensed with. It will be shown, on strict statical principles, that the first method involves a great waste of material, and that, by a proper arrangement of straight rods, a given amount of strength may be secured with a smaller quantity of iron, or a greater amount of strength with a given quantity of iron, than by the use of a main catenary. Of course, methods of using straight rods may be employed which involve greater waste of material than even the employment of the curved chain. The most economical arrangement of straight rods is not a merely arbitrary matter, but depends, like every other branch of engineering, on sound deductions from the laws of mechanics.

Before proceeding with the investigation, it may be as well to remind the reader that the object of these Notes on Engineering is to simplify the practical applications of theory, and to explain them, as far as possible, in familiar, untechnical language. This important rule should be constantly remembered by all who teach and all who study the mathematics of engineering—that long formulae are never put into practice. In practice, simple general principles are far more useful, because capable of being applied with far more certainty and facility, than the most elaborate results of scientific researches.

We now proceed to establish the following important general proposition.—In a suspension bridge the material required to sustain a given load will be the least when each point of support in the roadway is directly connected with a point of suspension in the nearest abutment by one independent straight rod.

To begin with the simplest case, it will be first of all supposed that only two points of support in the roadway are connected with the point of suspension. Suppose that B (fig. 1) is the point of suspension; A and D the two points of support in the horizontal platform AC. Then it will be shown that to sustain a given load, the most economical arrangement of the suspension bars consists in connecting B with D independently and directly by two rectilinear rods, AB and BD. If, however, as in fig. 2, the connection be indirectly made by suspension rods meeting at an intermediate point E, more material will be required for a given amount of strength.

In order to prove this proposition, which has so important a relation to the most usual methods of constructing suspension bridges, it is necessary to ascertain the quantities of material in the rods AB and BD (fig. 1), and the rods AE, DE, and BE (fig. 2), and to compare the aggregate amount of material used in both cases. It is, of course, presupposed that the strength of the rods is proportioned to the strain upon them. In ascertaining the thickness to be given to the rods of a suspension bridge, the first point to be settled is the amount of strain which the material will bear on each square inch of the sectional area. For the purpose of mere comparison, it is indifferent what amount be assumed: it may therefore be supposed that the rods are to be calculated to bear a strain or tension of \( t \) lb. per square inch of their sectional area. Consequently, multiplying the sectional area of any rod by \( t \), we have the whole strain to which it is subjected. Further, for purposes of comparison it is indifferent what be the load on the bridge, so that in both cases the weights at corresponding points of the platform may be supposed the same; let it therefore be assumed that both in fig. 1 and fig. 2 the point A has to sustain a vertical weight \( w \), and also (for the sake of simplicity) that the point D in both figures has to sustain the same weight \( w \).

It will (at least) be taken for granted that the platform contributes nothing by its rigidity to sustain the load; that the whole weight is borne by the suspension rods, which are kept in their oblique position by the connection of the platform. The amount of material requisite to support \( w \) at the point A will first be considered.

Commencing with the case of fig. 1, we have, since the rod AB supports the weight \( w \) at A, the vertical component of the tension of AB equal to \( w \). Supposing the sectional area of this rod to be \( k \) square inches, its tension, by what has been already said, will be \( kw \).

\[ w = kt \sin BAC = kt \cdot \frac{BC}{AB}; \quad k = \frac{w}{BC} \cdot \frac{AB}{AE} \]

Consequently, the mass of the rod = sectional area multiplied by its length = \( \frac{w}{7} \cdot BC \cdot \frac{AB}{AE} \) \[ (1) \]

Proceeding now to the case of fig. 2, and still confining attention to the suspension of the point A, by reasoning exactly the same as that for fig. 1, the mass of the rod AE = \( \frac{w}{7} \cdot AE \cdot \frac{Ee}{Ee} \), (Ee being drawn vertical.)

It is clear that the connection between the point B and the point E may be supposed to be established, not by a simple bar, but by a compound bar of two or more parallel lengths. In fact, this method is that usually adopted in actual practice, the several links of the chain commonly consisting of several bars or iron plates laid side by side, and connected at their extremities. Their relative thickness is a matter of indifference, but their total thickness must be sufficient to sustain the strain. In fig. 2 the rod BE, provided it have the thickness necessary to sustain the united effects of the two weights at A and D, may be supposed to be made up of any number of parallel bars of whatever thickness whatever. Now, supposing BE to be a compound bar, let \( k' \) be the sectional area or thickness of metal due to the effect of the weight at A, \( k' \) the thickness due to the weight at D: \( k' + k'' \) will be the total thickness of BE.

Taking the thickness \( k' \) to be that requisite to sustain \( w \) at A, and the consequent amount of tension of that part of the compound bar, we have the vertical component of \( k' t \) (= vertical component of tension along AE) = \( w \). Hence, if BE be drawn horizontal, \( w = kt \sin BBE = k't \frac{BE}{EB}; \quad k' = \frac{w}{EB} \cdot \frac{EB}{BE} \).

Multiplying this quantity by the length EB, and adding the mass of the rod ascertainment above, we have the total mass of metal required to connect A and B = \( w \left( \frac{AE}{7} + \frac{EB}{7} \right) \) \[ (2) \]

Hence subtracting the expression (1) from the expression (2), it will be easily found by simple analysis, that the material here omitted for the sake of brevity, that is, the mass required for the indirect connection AEB, fig. 2, exceeds the mass required for the direct or rectilinear connection, ABE, fig. 1, by a quantity \( \left( \frac{BC}{7} \cdot BE - \frac{AC}{7} \cdot AE \right) \cdot \frac{w}{7} \)

which is positive in all cases. Hence, more material is always required for the indirect than for the direct connection of A and B.

The same mode of reasoning applies to the weight suspended at D.
The form of the analysis is such that it applies to this case as well as the last, and leads to a similar conclusion—that the indirect or bent connection, $D \neq B$, requires more material than the direct or rectangular connection, $D = B$. Now it is evident, that what is true of the several parts of the system individually, is true of the whole collectively—that if less material be required for each of the direct connections than for each corresponding indirect connection, the total material required for all the former will be less than the total material required for the whole of the latter. In other words, the system of suspension in fig. 1 is the most economical.

The same result might have been obtained by supposing $B \neq E$ to be a simple, undivided bar, and the amount of material given by that hypothesis would be the same as that on the hypothesis here adopted. But the method of investigation given above leads more easily to the general results for which we are seeking. It has the advantage of admitting immediately, and without any more mathematical analysis, the following important

**Corollary.** The method of suspension (fig. 1) is more economical than the method (fig. 2), for any number of points of support in the platform.

For the reasoning given above is not affected by supposing the rod $E = B$ to divide at $E$ into three or more radial bars proceeding to as many points of support in the roadway. Whatever might be the number of indirect connections by this method, each of them would require more material than the corresponding direct connection of fig. 1; and therefore the total quantity of metal required by the former method exceeds the total quantity required by the latter method.

We have hitherto considered, in the second or indirect method, only one point of divarication, $E$; the inquiry will be completed by considering several other such points to exist—as at $B$, $B'$, $B''$, &c., fig. 3.

The connection of $A$ and $D$ with $B$, by bars meeting at $E$, has been already considered. Less material would have been required to support the weight at $A$ and $D$, if, in the manner of the former method in fig. 3, there had been separate straight rods from $A$ and $D$ to $B$. In this last case, $B'$ (the next point of suspension) would be connected with the three points $A$, $B$, $B'$, by three straight rods, divaricating from the end $B$ of a common rod $B''$. The inquiry above given shows that this triple divarication involves a waste of material. Had there been in the place of it, three straight rods from $A$, $D$, and $B'$, less material would have been required to support the corresponding weight. But this triple divarication itself requires less material than the method shown in fig. 3. Hence, a fortiori, the direct connection with $B$ would require still less material than the method shown in the figure. And so, by concluding the same mode of reasoning for the other points, $B''$, $B'$, &c., we come at last to the general conclusion that, if all the points of support had been directly and independently connected with $K$ (the ultimate point of suspension), less material would have been required to sustain given loads than by the method shown in fig. 3.

This conclusion is independent of the inclination of the rods $E = B$, $B'$, $B''$, &c., and remains true when they are vertical. Hence, in the common suspension bridges, such as those at Charing-cross, Hammersmith, &c., with a main chain or catenary hanging between the abutments, and connected with the platform by vertical rods, there is a waste of material. The same conclusion applies to all suspension bridges having radial bars radiating from any point except the point of ultimate suspension at the abutments—and, therefore, hold with respect to the bridges on Dudgeon's principle, some of which are erected in the Regent's-park, and of which one recently gave way and was destroyed near Calcutta.

The analogy may be extended by supposing all the points in the platform, with the abutments by independent straight rods, may be best shown by an example. The Hungerford bridge, at Charing-cross, may be taken as a familiar example—and we will, therefore, proceed to compare the material required for that bridge by the method actually adopted, and the quantity which would be required by the method here advocated.

The quantity of material required for suspending the bridge by a catenary and vertical rods will first be considered. The position of the centre of gravity of the half-span depends on the form and weight of the chain, and the manner in which the load is distributed along the platform. When the load is small compared with the weight of the chain, the centre of gravity of half the bridge and load will be nearer the abutment than the centre of the bridge; for the curvature of the chain, its increase of thickness near the point of suspension, and the increased length of the vertical rods, all tend to make the weight preponderate towards the abutment. But when the bridge is supposed to be loaded with a breaking weight greatly exceeding the weight of the chain, and uniformly distributed along the platform, it may be assumed, without sensible error that the horizontal distribution of the weight of the whole system is uniform. In this case, the centre of gravity of the half-span will be midway between the abutment and centre of the bridge.

At this latter point the tension of the catenary is horizontal. Let moments be taken about the point of suspension for the equilibrium of the half-span; then, since the horizontal tension in question acts below the point of suspension, at a vertical distance equal to the deflection of the chain, and since the weight acts at a horizontal distance from the same point equal to the quarter-span, the products of each of these forces into the corresponding distance will, by the Principles of Moments, be equal. Hence, calling $W$ the total weight of the half-span (including the half-chain), $T$ the horizontal tension, $d$ the deflection, a the quarter-span, it follows that

\[ W = T \cdot d; \quad \text{or} \quad T = \frac{W}{d} \quad \text{(1)} \]

That is, the horizontal tension is the weight of the half-span multiplied by the ratio of the quarter-span to the deflection; a simple rule, from which the horizontal tension of the chain of any suspension bridge loaded with its breaking weight may generally be calculated with sufficient accuracy.

It has been assumed that the load is uniformly distributed, or that any portion of the weight is proportional to the length of the corresponding portion of the platform. It follows, that if any distance, $x$, be measured along the platform from the lowest point of the chain, the weight corresponding to that distance is $W \cdot x$.

Also, if $y$ is the vertical ordinate of the chain at the same distance, a known principle which applies to catenaries of every form gives

\[ \frac{dy}{dx} = \frac{W}{a} + T = \frac{W}{d} \quad \text{(2)} \]

By another known principle which also applies to all kinds of catenaries, the tension at the point $(x, y)$ is equal to

\[ T = \frac{1}{2} \left( \frac{dy}{dx} \right)^2 \]

And since the sectional area of the chain at any point is supposed proportional to the strain at the same point, we have, if $k$ and $k'$ be sectional area at point $(x, y)$, and the lowest point of the chain respectively

\[ \pi = k \left( 1 + \frac{1}{3} \frac{dy}{dx} \right)^2 \]

The mass of each small portion of the length of the chain is the product of the element of length, and the corresponding sectional area; hence it will be easily shown that the mass of the half-chain is $k' \int_0^a \left( 1 + \frac{1}{3} \frac{dy}{dx} \right)^2 \, dx$.

And this quantity by substitution from (2) will be found equal to $W \cdot \frac{a}{d}$.

Finally, if the tension per square inch be $t$, and consequently $T = k't$, and if $a$ be put $= 170$ feet, and $d = 50$, it will be readily ascertained that the mass of the half-chain is $W \cdot t \times 1189\frac{3}{4}$.

(Which are almost exactly the values of those quantities in the Hungerford Bridge.)

To obtain the whole quantity of material required for the purposes of suspension, we must add to the quantity last obtained, the
mass of the suspension rods. The length of these increases from the centre to the abutment, and is equal to that of the vertical co-ordinates of the catenary.

The integration of equation (9) gives the relation of \( y \) to \( x \), which will be found such that the proportion between any two vertical co-ordinates is equal to the square of the proportion between the corresponding horizontal co-ordinates—a very simple rule for determining the form which the chain will nearly assume when subject to its breaking weight.

It follows from this rule, that when
\[
\begin{align*}
&x = \frac{1}{3} \text{th of the half-span, } y = \frac{1}{5} \text{th of the deflection} \\
&x = \frac{1}{5} \text{th of } y = \frac{1}{15} \text{th of the deflection} \\
&x = \frac{1}{15} \text{th of } y = \frac{1}{3} \text{th of the deflection} \\
&\text{&c.}
\end{align*}
\]

Now, if we suppose the half-platform attached to the half-chain at every 20th of the length of the former, we shall, by adding up all the \( y \)'s in the above scheme, get the total length of all the vertical rods together, which, therefore, is equal to
\[
\frac{w}{20} \left( 1 + \frac{2^3}{3} + \frac{4^3}{5} + \cdots + \frac{19^3}{19} \right) \times \text{deflection};
\]
and this by actual calculation is equal to the deflection \( \times 6175 \).

Therefore, since the deflection is 50 feet, the total length of all vertical rods is 308.73 feet. This supposes that the platform meets the chain at the centre, the value of \( y \) at that point being zero.

Each rod sustains one-twentieth of the weight of the half-span, and therefore has a tension \( = \frac{w}{7} \). Therefore, if, as before, \( t \) be the tension per square inch of the sectional area, that area, by principles already laid down, equals \( \frac{w}{t} \). The mass of all the rods equals
\[
\frac{w}{10} \times 308.73 \text{ feet, just obtained } = \frac{w}{t} \times 308.73 \text{ (A).}
\]

Adding this to the mass of the half-chain, we have finally
\[
\text{the mass of the half-chain and its rods } = \frac{w}{t} \times 1904.7 \text{ (A).}
\]

Next, let it be ascertained what is the quantity of material required when the load is supported by straight rods exclusively. It has been shown that if \( \frac{w}{t} \) be sustained at \( A \) by a straight rod \( AB \), the mass of that rod is
\[
\frac{w}{20} \frac{A B}{BC} \text{ (B).}
\]

This expression (since \( ABC \) is a right angled triangle, and therefore \( A B \) = \( AC \) \( + \) \( BC \)) is equivalent to
\[
\frac{w}{20} \left( \frac{AC}{BC} + BC \right) \text{ (B).}
\]

Adding up all the values of \( AC \), we get for the total mass of the rods
\[
\frac{w}{20} \left\{ \frac{1}{20} \left( 1 + \frac{2^3}{3} + \frac{4^3}{5} + \cdots + \frac{19^3}{19} \right) \frac{w}{10} \right\} = \frac{w}{20} \left( 175 \frac{w}{800} + 19 \frac{w}{10} \right) = \frac{w}{20} \left( 175 \frac{w}{800} \right) = 761.3 \text{ (B).}
\]

Comparing the expression (B) with (A), we see that the material required in one case is about \( \frac{w}{7} \) the of what is required in the other case. In a suspension bridge, of the dimensions of the Hungerford bridge, were independent by straight oblique rectilines, instead of a main chain and vertical rods, a saving of nearly half the material would be effected.

It will be hereafter shown, that great as is this advantage with respect to the power of the bridge to sustain a statical load uniformly distributed, still greater advantages belong to the method of suspension here advocated, when the effect of movable loads is taken into consideration.

---

**THE OBLIQUE ARCH.**

On the Focus to which the Joints on the Face converge.

Suppose a right-angled plane triangle formed of any flexible material, having its two sides respectively equal to \( L \), the axial length, and \( \pi r \), the semicircle obtained by taking a section of the bridge perpendicular to the axis. If the side \( L \) be placed along the top of the abutment of an oblique bridge, and the triangle wrapped over the laggings, the hypotenuse will form a spiral line, which is the intersection of the couring joints and silt. If a straight line move along the axis of the cylinder, so as always to intersect it at right angles, and pass through the hypotenuse of the above triangle, it will generate the twisted surface proper for the bed of the stones. Mr. Buck was the first to show that the joints that appear on the face of the arch, pass through a point \( O \), below the centre \( C \), when the "section on the square," or section perpendicular to the axis, is a circle. A similar expression for the length of the line \( CO \) may be obtained when the sections of the intrados and extrados, made by a plane perpendicular to the axis, are similar ellipses.

Let the figure represent the elevation of an oblique bridge, circular or elliptic "on the square"-if it be segmental, the ellipses must be supposed completed. Take the axis of the cylinder for the axis of \( y \), and let the plane \( xy \) be horizontal. \( A \); \( B \); \( a \); \( b \), are the semi-axes, major and minor, of the extrados and intrados respectively. \( A \times E \); \( a \times E \), the lengths of these semi-ellipses. \( S = \text{arc } AP \), where \( CN = AC \text{ cos } \phi \); and \( s = \text{arc } aP \), where \( CZ = \text{arc } aP \).

\( L \) = axial length. \( \alpha \) = acute angle between the directions of the roads. \( \phi \) = angle of extrados; and, therefore, \( \tan \phi = \frac{AE}{L} \).

The equations to the extrados and intrados spiral are, respectively,
\[
\begin{align*}
X &= A \cos \phi \\
y &= L \frac{E}{A} \frac{s}{E} \\
z &= B \sin \phi
\end{align*}
\]
and the equation to the face of the arch is \( y = \frac{s}{\cos \alpha} + d \).

Let \( X'Y'Z' \); \( x'y'z' \), be the co-ordinates of the points in which the corresponding extrados and intrados spirals meet the face of the arch. Then \( X'Y'Z' \); \( x'y'z' \), are co-ordinates of a point in the face of the arch, and must satisfy equation (3).

\[
X - x' = (Y' - y) \tan \phi = \frac{L (S - s)}{E (A - a)} \tan \phi \]

In order to determine the length of \( CO \), it will be sufficient to confine our attention to the projection on the plane \( xz \), of a straight line passing through \( X'Y'Z' \), \( x'y'z' \). The equation to this projection is
\[
x - X' = \frac{Z - z'}{Y' - y} (x - X') \\
and if \( x = 0 \), \( z = CO \), \( x' = 0 \), \( z' = CO \), \( x' = 0 \).
\]
II. The fresco scheme for the decoration of the Palace of Westminster does not, it seems, answer expectation,—at least so does not what has been done in the House of Peers, where the experiment has been first of all made; instead of the artist acquiring proficiency in that mode of painting, by being employed in less important parts of the building before touching that which ought to display, not the efforts of "prentice hands," but the mastery acquired by matured proficiency. Among other defects and oversights of which it has been now discovered that, particularly in the transference of gilding and vivid colours of the decorations, the frescoes do not produce the anticipated effect, they being in a great measure overpowered and eclipsed by what is mere embellishment. Thus, they are in a manner converted from principal objects as works of art, into quite secondary ones as regards the general ensemble,—a serious defect, that will be further increased when all the windows shall have been filled with stained glass, whose brilliant hues will inevitably cause the frescoes to appear, by contrast, feeble and faded, more especially as the windows occupy such a large proportion of surface. The only remedy which is now left, is to moderate the scheme of colouring for the windows, by executing them nearly entirely in chiaro-scuro, with only a few touches of positive colour here and there. Yet even this would be unsatisfactory in another respect, because such sparing applications of colour in the glass would be out of keeping with the showiness in regard to colour of much of the ornamental work. The fact is, the decorations of the "House" have been studied only piecemeal, and those employed upon them have considered no more than their own pieces of work in all, and not the general effect. As far as the frescoes are concerned, it would have been easy enough to ascertain their effect beforehand, by filling in all the six compartments with the cartoons for the respective subjects. Yet, obvious and simple as such mode of preparatory trial was, it seems, somehow or other,—perhaps owing to the latitude which hangs over all our public undertakings in so to have been overlooked. Bold as it may be thought to say so, a determined system of blundering seems to be established for them. Certainly not the slightest pains are taken to prevent blunder, by proper experiment previous to the work being actually commenced. Moreover, not in the least, the chief precaution taken is to keep matters entirely in the dark, until some irreparable mischief has been committed; and the only satisfaction left us is to amuse ourselves by wondering that they should have been managed so perversely.

I. Of so-called religious subjects in painting, some are audaciously profane, others the most trivial in matter, and all equally fabulous; giving us only the fancies of artists for the representations of historical events. Religion may have been the patron of art, but art has been but a very questionable, if not positively treacherous, ally to religion. It served Popery during the Inquisition, and for that very reason, with the escape of the imposters of the latter. But for pure Christianity, art can do just as much and no more than it can for the advancement of pure mathematics. There is a great deal of very palpable and maudlin cant ascribed to the art of religious art. Practically, every artist was not only having something to say, whether it was anything or not, but exercises their pencils on the few traditions of pagan mythology with quite as much gusto as they did on the traditions of the Church. Medieval art has, besides, contributed not a little to that fundamental superstition of popery. Monotony, against which we have to compete with the pretended "Queen of Heaven," the Salic law ought to be enforced amongst Catholicks.

IV. Notwithstanding their piddling and minikin pedantry, architectural writers are apt to be exceedingly careless in their language and expressions. Some, as the Germans say, condescended to exemplify harmony of colouring in decoration by a few positive instances—both such as were distinguished for the observance, and others which proved its value by showing the errors arising from neglecting it—he would have supplied his readers with some really useful lessons; whereas now he leaves them entirely to themselves to take their chance for making out what he, as their professorial instructor, should have carefully explained step by step. Where he ought to have been most of all full and explicit, he is more vague and brief than elsewhere. On the whole, he is somewhat less than marking technical work done by him at Abbotsford, notwithstanding that it does not in the slightest degree serve to illustrate the Laws of Harmonious Colouring, the painting being there confined to the mere imitation of oak and wainscoting. In short, the book is a rather humbugging affair, for the light which Mr. Hay has thought proper to afford us amounts to no more than "darkness visible," and there he leaves us to grope about...
column—or rather the rejection of the latter altogether, notwithstanding they are quite distinct in meaning—is peculiar to English writers, those of other countries properly observing the distinction between them. Just as well might we use the word "Colonisation" in the sense of "Column," and speak of a portico as consisting of so many colonisations, as call "Intercolumnus" "Intercolonisations"—the latter term signifying, not the actual spaces between the columns, but the mode of spacing adopted for the columns. The inaccuracies of language will be thought to have no consequence; yet, as it is just as easy, it is surely just as well to employ terms correctly as not; and the correctness thus recommended is surely also far less finical than that puerile affectation of antiquated orthography, which insists upon a final k in the word "Gothic," instead of the written "Gotic." The architects themselves upon their orthodoxy; the k serving as a badge of it—perhaps, like other badges, as a substitute for it.

V. If Bunning's design for the new Coal Exchange be not wildly caricatured in a wood-cut of it that has been published, it must be deemed respectful; but in the exalted style by which he is exhibited by him in the City of London School, the taste displayed in which can be accounted for only by supposing that Guildhall disperses an architectural malaria throughout the whole of that neighbourhood—a supposition rather confirmed than contradicted by the sight of a frontage designed for the corner of King Street. To go to the Coal Exchange, it seems the design of some architectural coal-heaver. I say "seems," for though it is made to appear such, it may prove the contrary; and that is all the more likely because, as has been said, the design is a great deal better in reality than in the wood-cut, and is room, therefore, for suspecting that it has been greatly misunderstood and misrepresented. According to what, it is to be hoped, is a very gross caricature, Mr. Bunning's design is absolutely architectural run mad—madder than any of Borromini's freaks. In short, it is impossible to believe that such extravagant unorthodoxy and unmeaningness of forms as are there exhibited, will be actually perpetrated; therefore judgment ought to be suspended until the work shall have been executed. Still, it is difficult to conceive how such a degree of misrepresentation could have occurred. Surely the wood-cut in question must have taken the most excedingly rough and random sketch indeed, or have been the work of some arrant bungler.

VI. A story is told of a lecturer who was cut short in a long-winded rambling preamble, consisting of truisms and commonplace dressed up in high-sounding words by one of his hearers. The lecturer got not only impatient, but also getting up and saying: "You will excuse the interruption, Sir, but I must beseech you to bear in mind that we have not come provided with nightcaps!" This silly was succeeded by such a grand chorus of laughter, that before it had subsided the lecturer had begun his lesson. Like many other so-called anecdotes, the above may be pure invention, it being, perhaps, too good to be exactly true. Its moral, however, is a tolerably significant one, and deserves to be attended to. If it be not an Hibernianism to call that strange which is so generally common, it might well be urged, why the mere school-boy stuff should be served over and over again in lectures and written essays; sometimes to the exclusion of anything besides such frothy matter, it being poured in so unmercifully, that there is actually no room for what would be substantial and nutritious. Now, people may be excused for not caring more than what is already familiar to everyone at all acquainted with the subject so professedly treated of; but there is no occasion for them to betray to others that such is really the case. It was not very long ago that conversing with an acquaintance who had been to hear some lecture on architecture, he told me that little himself knew of the subject, he knew enough to be able to engage to produce something infinitely more to the purpose than what he had heard, it being utterly stale, and barren of the least fresh information; much of it consisting of mere metaphorical moonshine, better calculated to mystify than to enlighten the auditory.

VII. It may fairly be questioned whether sculpture for the pediment of the British Museum might not just as well be spared, inasmuch as such partial decoration will only serve to render the absence of ornament in the rest of the structure all the more painfully striking. If, however, there is a most unartistic wish of keeping between that and the wings,—a defect which it is now so utterly beyond the power of any mere ornamentation to remedy, that it is more likely to be increased by attempting it. At present it is not so apparent as to be worth in the old buildings, which serve in some degree as a foil to the new ones, shall have been completely cleared away, and the entire line of the latter become fully exposed to view. What sort of a tout ensemble may easily enough be guessed, since it may even now be plainly foreseen. If there be any doubt at all in regard to it, it is only because it still remains to see how it is intended to inclose the court from the street. Should any such sort of palisading as that before the Post-office, the effect will be mean and tasteless in the extreme. Whatever it is to be, and the sentry-boxes were probably not included in the model, which, it might reasonably be fancied, did not even so much as exhibit the wings, otherwise the whole artificial structure could hardly have failed to be noticed and objected to by those to whom the model was submitted—at any rate, if they were at all qualified for exercising any judgment in the matter. One question not wholly undeserving deliberate consideration there is which does not seem to have occurred to any one, namely, whether it would not have been more advisable, instead of adhering to the arrangement of the original edifice, to advance the new façade up to the street or nearly so, thereby extending the plan, by taking in the court-yard. That would have provided the accommodation that is required, should the collections continue to increase as they hitherto have done. Much available space has also been thrown away elsewhere, since without entirely filling up the inner court, it was obviously practicable enough to occupy a portion of that quadrangle (317 and 258 feet) by one or more galleries, as the case might be, and thereby, among other things, to obstruct the windows towards the court, which are besides at a considerable height from the ground. Or the apartments there formed might have been on a somewhat lower level than the court itself. It will, perhaps, be said that should it be found requisite, the windows might be done in bybuilt windows, but that could not have been, had it been planned at first, since it would call for some alterations in what is already built; besides which, had it been thought of at first, the cost of the inner façades of the quadrangle might have been spared, since plain brick walls—quite shut out of view, as they have been—might have been as well as such a situation as the present ones faced with stone. Even had the court been partly built upon below, the upper part of it—that is, as much of its sides as could be seen from within through the windows, might still have been finished as at present, with the omission however of the columns and ante, so that the general appearance as viewed would have been quite as satisfactory as it is now; nor need buildings within the quadrangle have been at all visible from any of the surrounding galleries or other apartments.

VIII. The plan of the new building is a great measure sacrificed to the unlucky and obstinately-persisted-in whim of letting St. Martin's church be seen from Pall-Mall East. Since it has been thrown open by the removal of the Mews, that building, said the wisecracks, must on no account be shut out of sight again as it was before galleries were really hand above, and not so high as to obstruct the windows towards the court, which are besides at a considerable height from the ground. More trees might have been planted at first, since it would call for some alterations in what is already built; besides which, had it been thought of at first, the cost of the inner façades of the quadrangle might have been spared, since plain brick walls—quite shut out of view, as they have been—might have been as well as such a situation as the present ones faced with stone. Even had the court been partly built upon below, the upper part of it—that is, as much of its sides as could be seen from within through the windows, might still have been finished as at present, with the omission however of the columns and ante, so that the general appearance as viewed would have been quite as satisfactory as it is now; nor need buildings within the quadrangle have been at all visible from any of the surrounding galleries or other apartments.

IX. "Eminent" must be an epithet of extremely doubtful meaning when we find it applied to an individual recently deceased, who, as an architect, was of no note whatever. However eminent Mr. Wilkins may have been in the profession, he was certainly not at all eminent out of it, his name being totally unknown to the public. Rather was he eminently obscure, since so far from being quoted in evidence of his talent, not a single building by him has ever obtained notice at all. As a man, he may have been a very worthy character: so he might, had he been an "eminent cheesemonger," in which case eminence and obscurity might have been allowed to go hand-in-hand together. Truly great men and harmless nobodies should be so viably daubed over as soon as they are dead. It looks too much like thanking them for going out of the world and leaving their snug places and appointments for others. The profession of the eminent architect alluded to, would, I fancy, form a more curious than interesting contribution to the biography of artists.
BUCKINGHAM PALACE AND THE MARBLE ARCH.

But one opinion has been expressed of this unfortunate Palace, for if it finds favour at all with any, they have not the courage to utter so much as a syllable in defence of it. We may accordingly spare ourselves further censure of what is actually done, our present purpose being to point out what might have been done, and doubtless would have been, had aught like due or decent consideration been given to the matter, the idea here submitted being so very obvious a one that it is difficult to conceive how it could have by any possibility been overlooked. Or if it was not overlooked, but purposely rejected, it becomes the more regrettable, inasmuch as the reasons must have been more than ordinarily cogent ones to lead to its rejection.

Looking at the Palace as it stood before the alteration was commenced, no one would have ever imagined that the blocking it up by another building, merely in order to obtain additional rooms and thereby depriving all the original portion of the building of those advantages of situation and prospect which in some degree atoned to its occupiers for its architectural deficiencies, would have been resorted to without all other expedients being first tried. The preserving the same view as before into the Park should have been made sine qua non; instead of which Mr. Bowes seems to have had carte blanche to do just as he pleased, and he seems to have studied nothing more than merely providing the extra accommodation required, in an additional building merely tacked on to the first one. To say that he at all considered the circumstances of the case—the opportunity which it held out for architectural improvement, would be to accuse him of downright incapacity. The most prudent excuse for him is that he was called upon so suddenly to prepare drawings for the purpose, that he had no time to collect his thoughts, much less the idea of which might else have had being put to flight by the expeditiousness imposed upon him. Whereas had he been allowed to apply himself to the task leisurely and quietly, he would have devised some means of preserving the Marble Arch, and not only retaining it, but giving it increased value and importance, as the focus point of a new façade.

General, vague suggestions of this kind, it will perhaps be said, are very easily made, but we here offer somewhat more than a mere shapeless, unembodied idea, by showing in the annexed cut how the Arch could have been retained and connected with the advanced line of new buildings. We would have continued the stylobate and order of the Arch by two sweeping double colonnades (quadrant in plan). This would not only have been given sufficient height to the central arch, this being sufficiently high to prevent its being lost into, but would also have given it greater apparent space than before, when that space was so indistinctly defined by the pallading, that as seen from the Palace the Arch appeared to stand as quite a distinct and independent object in the Park. According to the plan here shown, it would, on the contrary, in connection with the colonnades attached to it, have formed a highly scenic piece of architecture, full of play of light and shade and perspective effect, and admitting a view of the landscape scenery in the Park in the background. As an embellishment to the court there might have been parterres in the quadrant portions of it, with a fountain in the centre of each quadrant. To specify other matters of decoration not indicated in the plan,—statues and can- delabra for gas-burners placed alternately in the intercolumns of the colonnades on the figure of Britannia on the summit of the Arch, giving to the latter what it has all along wanted, a pyramidal termination to its mass, would have produced a more than ordinarily striking architectural picture, whether viewed from the Palace or the Park. As seen from the latter, it would have been a sufficiently complete and distinct object within the court, and after the sun had passed off from the east side of the Palace, would have been continually lighted up by its rays striking upon some of the columns during the whole day. In combination with additional buildings carried out to the right and left in extension of the original wings, such a colonnaded centrepiece might have been made to produce a façade not at all inferior to, perhaps even more picturesque, than that of any other royal palace in Europe; whereas now—but we can hardly speak with decent patience of the miserable and truly contemptible pretensions which Bowes has perpetrated, both to his own disgrace, and the disgrace of those who employed him. Had such a design for enlarging the Palace been sanctioned by William IV., though our mortification would have been the same, our surprise would have been considerably less. His taste and feeling for art never extended beyond the figure—head of a ship. That it should have been perpetrated under the auspices—at least under the very nose of a Prince who affects the character of a connoisseur and patron of art, fills us not only with astonishment, but dismay. We account for it only by supposing that he was overruled in the matter, he being no more than Prince Consort.

To show, as we have, what might have been done, when the opportunity for doing it has passed away, may seem ungracious. Our reply is, it is no fault of ours that the opportunity was not afforded us, and not ourselves alone, but others also perhaps far more able, of making suggestions at a time when advantage might have been taken of them. At any rate, we hope that Buckingham Palace will now prove an efficacious lesson for the future; and it is also some consolation to find that it is not only poor, but so desperately bad, that there is very little danger of its corrupting public taste, because it will be now more mocked, and more an object of general derision than ever. Admiration it will excite none whatever, that's certain; but then it is equally certain that it will excite a vast deal of astonishment. It will completely astonish the natives, and all foreigners into the bargain.

As the Marble Arch—which might have been so easily retained, and not only retained but greatly improved, and made the nucleus of an extended piece of decoration in the foreground of an extended line of façade—is to be taken down, the question now is, is it to be destroyed, or re-erected on some other spot? Nobody except those actually in the secret, knows; though why it should be made a secret at all nobody can tell, unless it be because in regard to it is so preposterous that were it divulged it would excite strong opposition. Our idea is that the street front of the Horse Guards would be a very suitable situation for it. It would there fill up what is now too much of a gap, and the two are much of a gap, and the two are much the same, and would serve admirable as the recesses for the student's on horseback. It has, indeed, been rumoured that both the Horse Guards and Admiralty are to undergo architectural transformation by Mr. Barry. But instead of that interfering any obstacle, it would rather facilitate such application of the arch, since Barry would only have to bring it into his design, and treat the rest of the composition in accordance with such feature.

BUCKINGHAM PALACE.

Six.—It seems not a little singular that none of the critics who are disposed to animadverb in such severe terms on the new front of Buckingham Palace, not even your lynx-eyed "Candidus" himself, should have discovered that it is only a reduced copy (about two-fifths in length) of the Palace at Caserta; so that the faults or merits, be they which are not Mr. Bowes's, but Vanvitelli's. In proof of which, I beg your acceptance of tracings of the perspective view of the front and of the plan, after Vasi.

It is to be feared that the imitation will be confined to the part of Vanvitelli's design upon which he appears to have bestowed the least pains, that is the outside, and that there are but faint hopes of any internal imitation of the noble design of Vasi.

Vasi states the length of the north and south fronts of Caserta to be 918 palms (Neapolitan, I presume), which, at 10½ inches,
would give 873 ft. 10 in. for the length of the front. The east and west fronts, by the same reckoning, would be 618 ft. 10 in.; and, as the length of Buckingham Palace is stated in the Journal at 350 feet, the proportion is exactly two-fifths. The height of Caserta is 190 feet, that of Buckingham Palace, 77 feet.

I visited Caserta thirty years ago, in company with Mr. Woods and M. Soiss, the eminent Belgian architect, and the notes of that day are now before me.

"The central passage or vestibule leading from the entrance is 24 feet wide, and rises high to the springing of the semicircular vault. The steps of the middle flight of the stairs are 22 feet long, and the two return flights each 14 feet long (100 steps in all), and are of white and reddish variegated marble: there are statues, trophies, &c. The vestibule above is handsome, but (in my eyes at that time) in bad style. The chapel (which is opposite to the staircase) has coupled columns, of Sicilian marble. The lower part of the chapel is lined with slabs cut from the Giallo Antico columns, removed from Porruli, &c &c.

Let Mr. Blore give to the Palace a staircase at all resembling this, and the world will forgive him the faults of his front; many of which have, no doubt, been forced upon him, as upon his great predecessor, by the necessity of providing accommodation for so many people.

I have read Mr. Elmes's Epitome of the Lives of English Architects with great satisfaction, and beg to express my hope that he will carry out his "present intention" without delay. I would take the further liberty of suggesting to him that the illustrations he promises ought to consist mainly of unedited specimens, or at least of those of which the engravings are least accessible, or the works containing them least known. A list, referring to the buildings in which the most meritorious of each architect's productions are to be found, would be very valuable.

It should be remembered that size is not the criterion of excellence. How many of our country architects are forced, to take the counsel of our excellent friend, Percyer, and in despair of executing large works, to bestow greater care upon lesser ones?

York, Dec. 12, 1847.

COWPER'S INVERTED ARCH BRIDGE.

Sir,—In reflecting on the construction of Mr. Cowper's bridge, I think it is interesting to notice that the boiler plates are riveted together, so that the pressure on the piers and abutments must now be vertical instead of oblique, as in the common suspension bridge.

Hence, when it is said that the bridge may be said to coincide with the ordinary gilder bridge, but its alteration in form suggests an important advantage, which it possesses; for, in the gilder bridge (and especially when dealing with long bearings), there must always, viz., the gravity of the material itself, independently of any additional influence of a load placed upon it, is constantly tending to assume a curved form, and such curved form not being the natural position of its particles, it is constantly tending to rupture; but in the "inverted arch bridge" the material is thrown into that form (or nearly so) which it would take if perfectly flexible, and then is made perfectly rigid.

So that, as regards its own gravity, there is no further alteration of form, of any practical importance, to be apprehended.

With regard to the alteration of form which might result from a load being put upon it, Mr. Cowper has already pointed out the preventive measure, viz., the giving to the vertical dimension of the plate such a magnitude as to bring the line of strain within the plates.

Thus, it may be said that the weight of the arch might be more aptly chosen: "Inverted arch" is suggestive of form, and not of principle, and might (it seems to me) with equal propriety be applied to the ordinary suspension bridge.

G. W. Richard.

* * * It is not clear that it would be practicable to make the "inverted arch bridge" so rigid as to exert only vertical pressures on the abutments, and to act as a curved girder.

Supposing the height 60 feet, and a weight of 30 tons (engine and tender) rests at its centre. Then, by the ordinary principles of statics which apply to girders, we may easily find the horizontal strains of tension and compression which this weight alone produces at the centre. Considering the arch as a separate statical system, the forces acting upon it have equal moments about the point of support in the abutment; or half the weight X the half-span = the moment of the couple of tension and compression created at the centre of the bridge. The length of the arm of couple is indeterminate, but (since the total depth is 4 feet) it is a favourable supposition to take it at 3 feet. Hence, calling the horizontal strain $F$, we have

$$ F \times 3 = 15 \times 100, \text{ or } F = 500 \text{ tons!} $$

The metal must be considerably thick to resist five hundred tons pressure on the upper, and tension on the lower, side of the bridge at its centre! This difficulty is formidable enough when the structure is considered as all one piece, but becomes insuperable when the effect of joints is taken into account. It is not to be overcome by a system of riveting, and loading, however intricate.

Though it be easy to calculate the amount of the horizontal strains at the centre of the curved beam, it is not easy to estimate the sectional or transverse dimensions necessary to resist those strains; for our knowledge of the transverse strength of wrought-iron is very imperfect. Some idea may, however, be obtained from analogy. The "inverted arch," if it sustains itself by its rigidity as a girder, may, for all purposes of calculating the strength at its centre, be considered as a horizontal beam 200 feet long and 4 feet deep, with an effective width of 1 foot to 1 foot 6 inches at the utmost. Now, the proposed Menai tubular bridge will be 440 feet long, but its depth will be thirty feet, and width fifteen feet: also its upper and lower sides will be composed of several thicknesses of metal, as the former will consist of two, and the latter of one, series of cellular compartments. The analogy between the two bridges and the iron in the compartments is complete; both are tubular, both are to be composed of rivetted wrought-iron plates, and both are designed for railway traffic. The sectional dimensions of the Menai bridge are suggested by actual experiment, and are never considered too great. Is it not, therefore, strange, a mere hypothesis, that it is deemed unsafe to sink the span of this Menai tube, but with only an eighth or twelfth its depth and width, would not be rigid enough to sustain itself as a beam?

If suspended, from instead of resting upon, the abutments, it might perhaps be prevented from actually falling, but it would certainly bend. If the point of suspension be to be at the upper edge of the beam, the transverse strains of deflection will be somewhat reduced by the curvature of the beam; but it would be difficult to show that this advantage would not be far more than compensated for by the increase of length, and therefore of material, which the curvature demands necessary.

It is important to remark, that if the only requisite for security were that the depth of the chain should "include any alteration in the curve of the chain," that depth should not be uniformly 4 feet. It should be nothing at the centre of the span and the point of suspension, and gradually increase up to some intermediate part. The highest and lowest points of a catenary may be always chosen arbitrarily.

The argument that the chain would not be distorted because it is so much depth as "to include any alteration in the curve," is vague and inconclusive. It cannot certainly stand against the fundamental equations of statical equilibrium. The remaining given above is a simple, ordinary application of the elementary principles of mechanics; these are not to be opposed by a mere hypothesis which is not susceptible of rigid investigation. All that can be said of this hypothesis is, that it is not necessarily true.

A number of independent chains might be hung from the abutments, and to each might be given that form which it would, if perfectly free, assume of itself when the load acted; at some particular stage of its transit hung from that point alone. Then it is clear that, while no connection existed among the several chains, the load acting on each in succession would not tend to distort any of them, i.e. would not produce transverse strains. But it does not follow that this would be the case when all the chains were bound up together and hung from a central point.

The "inverted arch bridge" does not seem to be an advantageous compromise between the principle of the gilder and the suspension chain. An intermediate condition misses the advantages of each; those structures: an inverted arch be only partially rigid it is subject to needless and prejudicial strains; if it be as rigid as a gilder, why unnecessarily increase its length by curving it? The idea of our correspondent that the curvature obviates its tendency to deflect by its own weight, seems to us unfounded; for however much the structure was bent when first put up, it would tend to bend still more when it was merely rested upon the abutments. We cannot positively undertake to assert that the suspension of a curved beam has no peculiar advantages; but they have not yet been pointed out, and we are unable to discern them.—Encrons.
ELECTRIC TELEGRAPHHS.

It is extraordinary that we should have had to wait so long for the introduction of a system of electric telegraphs, considering that a century ago it was known that the liquid fluid could be sent through a coil of wire two miles long, as was done in the experiments at Hampstead, while a coil had also been carried across the Thames. Papin, too, in the beginning of the last century, had sought a means of communicating power and motion to a distance. Had, however, such a means of communication as that by the electric telegraph been adopted, it would have languished in the then state of the roads, and the then state of society, for it would not have answered commercially, and its failure might have been most prejudicial. It has been reserved for our day to apply this invention, and to give one to the many characteristics which make it an era of progress. Beside the locomotive, the steamship, and the daguerreotype, the electric telegraph may take its place; and the day is perhaps not very distant, when our furthest islands will be by the telegraph be brought under our immediate rule.

Having been among the first in the field, and having by the Slough line proved the practicability of the system, we have allowed the Americans to get in advance of us, for they had in 1846 sixteen hundred miles in practical commercial working, while we can hardly be said, even at present, to have got to the greatest extent of telegraph in use, although we have a great length laid down. Next year will redeem us from this charge, for we shall have two thousand five hundred miles, but it will not excite the government for having so long neglected this admirable invention. It is some comfort that we are now ahead of European knowledge, and it is the want of machinery for extending electric telegraphs we have to regret the neglect of the government in withholding the introduction of railways in India, where the telegraph would be invaluable in governing territories so vast, and where the number of English functionaries is exceedingly limited.

We have now arrived at an era in the telegraph, for at the date of this publication, the metropolis has been brought into immediate communication with Liverpool, Manchester, and many of the great centres of trade and manufactures. The Electric Telegraph Company have brought out operations on the ground that they can convey intelligence to sixty great towns, and this seems an appropriate time for laying some account of their proceedings before the public, the more so as the full effect of this admirable invention does not seem to be so well appreciated as it might be in comparison with its vast capabilities, and the influence which it will exercise upon every class of the community, both morally and physically.

The operations may be considered as having begun with Mr. Cooke and Professor Wheatstone, who, after labouring singly for some years, put out their joint patent. It is known that Professor Wheatstone applied himself more to the purer philosophical experiments, and that Mr. Cooke has taken charge of the practical detail, and at last brought the invention to its present bearing. Of any nothing of other parties who have laboured on this subject, for both the Electric Telegraph Company. Soon after Messrs. Cooke and Wheatstone took out their patent, they laid down a line nineteen miles long on the Great Western railway, between London and Slough, the working of which was most successful, although of course it did not satisfy those who thought the system might be extended to Liverpool or York. It took many years to urge the system forward, and it was not till 1846 that a company was incorporated, called the Electric Telegraph Company, for carrying it out on a large scale. Contracts had however been made, and works carried on, so that before the end of 1845 there was already a line laid down and had by the end of 1846 laid down 1000 miles of telegraph. At the same date Professor Morse, in America, had laid down 1600 miles. The system has been chiefly carried out in connection with railways, because the advantages are all the telegraph to the railway companies has induced the latter to adopt it, and to make advantageous arrangements for laying it down. The years 1846 and 1847 have therefore been chiefly employed in laying down the wires, and their working on a large scale has been retarded until now by the non-completion of the wire between London and Rugby, on the North Western railway. On the 13th November this link was completed, and the London prices were at once conveyed to Manchester. The new metropolitan station has likewise been partially opened, and by the new year the whole plan will be in full operation. During the present year, the metropolitan station has been in the Strand, and the working has been chiefly for government purposes along the South Western line to Gosport, although latterly much general business has been transacted. The organization of a new system has called for the exercise of much labour and ingenuity in the engineering and the signals departments, the principal officers of which are Mr. Hatchett, formerly of King's College, and Mr. Whisah, author of the "Railways of Great Britain," and the inventor of the hydraulic telegraph. In the standard work on the "Railways of Great Britain," Mr. Whisah proposed uniformity of railway time, and a mode of communication between guard and driver, which in many other practical suggestions are now carried out. At a given time every morning a signal will be made from the central station, and the needle will be brought to the vertical indicating Greenwich mean time, by which all the telegraph clocks will be set. As this arrangement, most important to the traveller, who is carried out over the country, we may observe that local clocks and watches can be made with a double minute-hand, so as to show local time and mean time. Although much controversy has been raised about mean time, and many eminent men have opposed it, it has received the sanction of the astronomers, who has proposed the adoption of it for the great clock at the palace of Westminster, which is to be set by electric telegraph from Greenwich. The system of codes adopted by the Electric Telegraph Company, has been, we believe, entirely constructed and arranged by the same gentleman. On account of the extent of the operations, and the number of the company a great many mechanics have been employed in making the various apparatus and in laying down the wires, and many works of great nicety in their execution have been carried out.

The company is not restricted to Messrs. Cooke and Wheatstone's patents, but has power to avail itself of all inventions in which electric power is used. They have therefore purchased many patents and inventions, among the chief of which may be mentioned Bain's electrical clock, an invention, the full value of which is far from being known. At the offices in the Strand is a model-room, which contains a large collection of telegraphy, various apparatus, and of clocks. This model-room does great credit to the company, and is a museum of great value to the practical man. It will be recollected that at Sir John Rennie's conversazioni in the spring, among the many novelties which the learned president had before his guests, was the apparatus of the model-room. This was contributed by the Electric Telegraph Company, and formed not the least interesting contribution to the temporary museum in Whitehall Place.

A model-room in the Strand, the collection in which will, we presume, be removed to the city, there is every thing necessary to illustrate the subject, though of course it does not contain every telegraphic invention. Several apparatus show the improvements which have been gradually made in the needle instrument, so as to make it capable of being connected with ingenious telegraphs communicate by sound. One of these is Professor Professor Wheatstone, strikes two bells of dissimilar sound, the combination of the two producing the letters, as in the double needle telegraph. Another, the discovery of a workman, gives a humming noise from a bell, the effect is produced by electricity. At present it is of no moment, but the preservation of a model by the company serves to encourage the spirit of discovery, while what is now merely trivial may become the germ of a valuable application. It is deserving of note that already the officers and workmen employed on telegraphs have been making many useful suggestions, and we may anticipate the best results from an energetic body of employees, if the company are liberal. Notwithstanding all that has been said about railway improvements, it is well known to practical men that very great improvements have been effected by railway offices, and that a large amount of talent is constantly and energetically directed to the perfection of the system. The names of George and Robert Stephenson, Brunel, Brathwaite, Booth, Gooch, Gray, Edmondson, are only a few as a specimen of those who have contributed to the practical improvement of railways. In a few years the Electric Telegraph officers will be the hope, have given equal proofs of zeal and ingenuity.

The printing telegraphs in the model-room are illustrated by several apparatus of various forms, some for printing by letters, and others by signs. The company make use at their stations of the needle telegraph, but as the working of this is doubtful, and as it is supposed that this mode of telegraphy will tend to change the nature of the telegraphs, as they have the wires laid down, and the wires are used under whatever system. While desiring to printing telegraphs, which print their message in black, we may observe that it is perfectly competent to make a telegraph which shall use different letters, and a mode of shading was long ago suggested by Mr. Hyde Clarke.

The business of the company in electric clocks will no doubt be
very large in the end, as they admit of such useful application in public and private establishments. In the course of a short time no public office will be without a clock dial in every department, and when the example has been set wide enough there will be few private houses without a dial in the drawing-room. It is a necessary evil, but it is no mean thing to increase habits of punctuality in a population. Those who have noticed in foreign countries the disregard of the value of time among unenterprising populations, know the worth of our greater luxury in time-pieces. The Electric Telegraph Company, on the contrary, has already laid many miles of line, and we have no guarantee that any similar undertaking will proceed further, without seeking further as to the public benefit they may effect. The price of a clock is at present of course rather high, namely, sixteen guineas, and of companion clocks, ten guineas each. I grant that at first sight the cost of electric clocks at present is, that depending on the electric currents of the earth or a battery, their regularity cannot be depended upon.

The metropolitan station, designed by Mr. Hunt, is very well situated. It occupies what was lately Founders Hall and the adjacent premises, having entrances in Lothbury from Founders' Hall-court, and in Moorgate street. The road in Founders' Hall-court is handsomely carved in stone, and though small makes a good façade. The central hall or counting house is one of the handsomest works lately executed. This station is within a few minutes' walk of the Bank, Law Exchange, Royal Exchange, Lloyd's, the joint stock and private banks, assurance offices, in the heart of business, and not far from the Corn Exchange, Commercial Rooms, Coal Exchange, and the seat of the Manchester warehouses and colonial produce warehouses. The newspaper offices are further removed. The means of communication from the East of this country is, the same to the west of it. The government offices, houses of parliament, courts of law, and places of west-end business are also at a distance, but the city is the district which will pay best, and it is impossible to provide for all at once. So far as the city office is concerned, the Jews and the managers has been well shown in its selectiveness.

The principle of Cooke and Wheatstone's telegraph is founded on the discovery of Professor Reuterd in 1819, that a magnetised needle has a tendency to place itself at right angles to a wire along which a current of electricity is passing. By the movements of such a needle, a current of electricity is formed, which serves as the means of communicating messages.

In the other forms of telegraph a disc is made to rotate, bearing on it letters or signs, and this is effected in virtue of the property soft iron has of becoming temporarily magnetised by an electric current being passed along a wire coiled in a spiral around it. The same principle is adopted in all the apparatus for ringing the alarum in order to give notice that the telegraph is in action. It is to be observed that the telegraphs in the United States, France, and Prussia, are on the disc system; in Baden Highton's telegraph in England are no telegraphs, that on the South Devon is a disc telegraph, and that in the Box Tunnel on Nott and Gamble's plan.

The disc telegraphs are operated either by the voltaic battery or the magnet-electric machine, power being derived from a permanent magnetic, which is arranged on the same plan as the disc. The needle telegraphs, for commercial purposes, require three wires, two needle-wires for the telegraph and one wire for the alarm.

As now laid by the Electric Telegraph Company, the best system, two wires are employed for each principal station, the wires used being of iron, of No. 8 gauge, and one-sixth of an inch diameter. These are galvanised, and come very cheap. The weight is about 38 lb. to the hundred yards, or 480 lb. per mile. The wire is welded together in lengths of about a quarter of a mile each, and are fastened to the telegraph-pole with a small plate, or a smaller one, at the principal, a distance of 45 to 55 yards apart, and at each quarter of a mile is a stronger standard, where a connection is made. The wires are kept taut by a simple arrangement, which it is unnecessary to describe. In consequence of this mode of suspending the wires on standards, which was first adopted in 1826, a great economy is effected, and the system admits of a more extensive application, as now it may be laid anywhere wherever the standards can be put up; and as the population get accustomed to this invention, it can be put up as safely in the streets, or in the roads, as gas-lamps are now left. But it is obtained as an advantage to anticipate such advancement at present. Under Brett and Little's system it can, we believe, be laid much cheaper than now.

The original method of laying the wires was to cover them with silk or cotton thread, and then with pitch, resin, casuchoce, or some other non-conducting substance, enclosed in earthware tubes, in wood trunks, or in iron pipes. At that time, there were several inventions for laying the telegraph wires in asphalt. The great expense of the system was one of the obstructions to its extension at an earlier period. Our readers will remember that pipes were used on the Great Western and Blackwall Railways. Our courses in the pipes prevent any interference with the telegraph wires; but this precaution is now considered unnecessary. The connecting wires between Nine Elms and the Strand stations, and between Euston-square and the metropolitan stations, are laid in pipes (Mr. Freeman Roe being the contractor); but, as the steam has already arrived at the end of the telegraph, the conductions of sound; but waiting till that is accomplished, it is quite easy to play music at a distance by the present resources of science. With a sufficient number of wires, a grand piano might be played in London and Liverpool at the same time; and nothing would be easier than for one organist to play in two cathedrals, or to play a set of chimes in St. Paul's and in York Minster simultaneously.

Professor Wheatstone's bell telegraph, in the model-room of the Electric Telegraph Company, gives the elements of such an apparatus. In Flanders, every town has its set of carillons or chimes, playing elaborate tunes, and having its carillonier, who plays on Sundays. In time, the whole of these may be worked together, or perhaps the towns of England supplied with the luxury of carillons. Professor Wheatstone, however, proposes to go beyond this, and to convey musical sounds to a distance.

In the country, the number of wires used. In the earliest Slough instrument, five needles were used, and double wires for each. The application of the principle that the earth could be made to serve as half of the circuit, and its adoption by Mr. Cooke in his patent of 1842, at once abolished half the wires, and by the invention of the ring, the number of needles was brought down to four, to three, and to two, and, for some purposes, even one. Thus, where twelve wires were necessary in 1842 for one station, two are now sufficient, while the cost is decreased in a very much greater ratio by the wires being galvanised instead of wound with copper, their being suspended in the air instead of being laid in pipes. Perhaps, in the end, a lighter wire will be used, and the system will be indefinitely extended. It is impossible to consider the system as being otherwise than in its earliest infancy, and we may expect, as in railways, to see very great modifications. The locomotive, after being increased in size to the magnitude of the "Great Western," is now likely to be brought down to the proportions of a steam carriage. Nothing is so dangerous in new inventions as to pre-judge.

The instruments are Cooke and Wheatstone's, and are either single or double needle instruments. The latter is preferred. They are both on the same principle, except that the latter is double the former. As seen from the outside, the double needle telegraph shows two needles suspended like clock-hands on a horizontal bar, but two needles are suspended in the instrument, and behind the dial, and which latter is the real needle. This needle is suspended in a light hollow frame of wood or metal, round which are wound two sets of fine copper wire, coated or insulated with silk or cotton. About 200 yards of wire, one-tenth of an inch diameter, is used for these purposes. This coil is connected with an electro-galvanic battery. A great difficulty of the needle telegraph is to stop the oscillations or vibrations of the needle when set in motion. This is attempted by giving a greater extension and weight to the lower limb of the needle. The whole device, at present, is, which is so formed as to turn on or break off the connection of the battery with the conducting wires, and so to transmit motion to the needle, which, according to the way in which the current is passed, may be deflected to the right or left.

In the double-needle instrument, the alphabet is formed by the production or repetition of three combinations. The needles being placed parallel, the right-hand needle may be worked or the left-hand needle, the two together, or the two alternately; accordingly as this is done once, twice, thrice, or four times, a large number of letters can be worked. Each additional needle has this additional economy over the single needle, that in many combinations the two handles are worked together; in other telegraphs of a simpler construction the saving would be still greater.

The needle being itself a magnet, is subject to disturbance from the presence of other magnets, or the approaching of other magnets, so that its working is very uncertain; and although some modifications and improvements are made, this does not obviate
the objections. To prevent the needle from traversing too far, it is confined by pins on either side. On a recent occasion all the telegraphs throughout England were deflected for so long a period that business was wholly stopped.

It is to be noticed, that the communication is carried through the instrument, which is a part of the chain of connection. At each station used, must be an instrument; but where the corres-

pondence is to be sent to a separate instrument, a wire must be provided; but of course two stations cannot be worked together,— one only can use the telegraph at a time. Where there is larger correspondence, separate wires and instruments are used for each station. An objection at present is that one instrument being dis-

ordered, which is not unfruitfully said, as in the words of the Wise Man in the end of the year 1846, says—"This method has been fully tried, and has been relinquished only upon a conviction of the greater certainty and eventual quickness of the literal communication." At the present moment, the company are again working by sig-

nals, and with great success, upon Mr. Whishaw's system. It will strike everyone who has given his attention to the subject, that each subject relating to shipping, to the stock exchange, to produce markets—will have its own technical language, in the cognate business of short-hand writing, called "arbitraries," and for which signs may be used as they are in short-hand. The merit of Mr. Whishaw's system consists in its special application, while the failure of the previous attempts was in their generalization. All successful codes of sig-

nals, or telegraph communications, have been special; and the attempt to say of short-hand arbitraries. An arithmo-

writer will find constantly recurring—"plaintiff, defendant, affi-

davits, plea," and a number of other terms, which it would be a work of supererogation to write in full; and so in each department; but this has been left to systematization by the individual rather than a work of science. It is a very simple plan, for their application to nautical purposes, though the attempts to apply them to more extended communications have failed.

In Mr. Whishaw's system for the Electric Telegraph Company, a code of signals is applied to each class of communications. Thus there is a code for shipping intelligence, a code for racing, a code for share-

lists, a code for corn-markets, and so forth. On the message being commenced, a signal is made which code is used, so that the clerk who receives the message is prepared for the nature of the signals. As the number of signals which can be made in a given time is limited, it is impossible to imagine the correspondence being cut short by the adoption of arbitraries, instead of spelling every word, letter for letter. Indeed, if an expedient of this kind were not adopted, it would be impossible to carry on the correspondence between the great towns. As it is, it may be reasonably expected that business will so far increase on the organization of the system, as to require the adoption of more than one line of telegraphs between the metropolis and such towns as Manchester and Glas-

gow. We may note here, that it will be curious to observe whether the telegraph messages will bear any corre-

spondence with the number of post letters sent to a town. There can be no doubt, however, that to give accommodation to the public new companies will be formed, as in other branches of enterprise.

On a message being delivered in writing at the telegraph office, it is translated into telegraph language, transmitted by a tele-

graph clerk, received by a telegraph clerk on the other end, re-

translated there, and written out and given to a messenger for delivery. Each message is accompanied by preliminary signals, to call the attention of the clerk to be addressed, and to signify to him the nature of the message, and the code to be used. It may readily be conceived that it is of great assistance to the clerk to know the class of message he is going to receive, as he is thereby better prepared to understand its import. It is like a writer in the gallery of the House of Commons understanding the speaker who addresses himself to him. The telegraph messages will bear any corres-

pondence with the number of post letters sent to a town. There can be no doubt, however, that to give accommodation to the public new companies will be formed, as in other branches of enterprise.

pondence with the number of post letters sent to a town. There can be no doubt, however, that to give accommodation to the public new companies will be formed, as in other branches of enterprise.
management of the Electric Telegraph Company," "Shameful Oppression," "Shameful Negligence," "Shameful Monopoly," and so forth, in which the real or fictitious correspondents declare the dreadful sufferings to which they have been exposed by the errors and delays of the telegraph clerks—how "owls" were ordered for dinner, instead of "fowls," "pigeon" for "widgeon," "reel" for "till," "list" for "lesse," "ripes" for "hippe," and sundry grievances, which could not be complained of hitherto, as there were no telegraph offices to be belaboured by the querulous, dissatisfied, and considerate. The telegraph grievances will be a great safety-valve to the railways, for the former will so occupy the Times and Punch, as to leave no room for the last case of neglect by Mr. Hudson, or the last instance of being five minutes behind time on the Eastern Counties. When telegraphs come to be abused as well as railways, it will be a sign that they have done some service, and have merited well of the public.

The lowest charge for the delivery of a message at present is half-a-crown, for which thirty words are sent thirty miles—though it is to be hoped for the public accommodation that the prices will be reduced. The charge increases, of course, in the double ratio of the number of words and number of miles. In many cases, the charge will not be greatly above what was made a few years ago for general post letters for mercantile purposes; and, indeed, merchants will have been relieved from the charge of postage, to give them a revenue for telegraph purposes. If there are any who doubt that the mercantile classes will be ready to avail themselves of the valves of the telegraph, they should be put in mind of the large sums formerly disbursed for postage, and, indeed, of the large sums still disbursed for Indian and foreign postage.

The Electric Telegraph Company, as a matter of necessity, give notice, that they do not hold themselves responsible for the speed with which messages are transmitted, nor for delays caused by the state of the weather or apparatus. At present, the state of the weather often affects the rate of working of the machines, and sometimes to a serious extent.

The rate at which messages can be transmitted is rather lower than might be thought, and this arises from using the needle telegraph. It is found that about six words a minute is as much as can be practicably telegraphed at present, the words being spelled literally. The last Queen's Speech was sent seven words a minute. By using the code, longer messages can of course be sent. The number of words which can be written by short-hand in a minute is seventy; the number of words which can be read rapidly in one minute is 280. The number of characters passed by Professor Morse is 117 as a maximum, 99 as an average. We may be prepared for the much greater rapidity of the electric telegraph in other countries, where Morse's system is the current one. Linen characters: but the present rate of speed is amply for all present purposes, though we have that faith in the extension of telegraph business, that we believe it must be shortly increased. By using well-trained clerks, and a chief and sub-chiefs, and auditing them, the utmost use will be made of the telegraphs; and they are likely to be worked night and day. For many classes of correspondence, all the words must be spelled, and no arbitratory or codes can be used; but still a large mass of correspondence will admit of probable improvement. From New York, and many telegraphers, undertake to do a much greater number of words than those assigned by us as the present rate in England; but what one individual can do in an isolated case, is very different from the working of a miscellaneous correspondence, through a public office.

That the improvement will turn out productive, we have no manner of doubt, because, in many cases, the company have not the property of the lines, which belong to the railways, but work them at a toll, while the revenue to be received must be very great. A line between two principal stations will yield five thousand a-year, and as the outgoings are chiefly in clerks, it will be seen that there must be a large surplus to pay the wear and tear of instruments, the cost of management and superintendence; and after yielding a toll to the railway companies, afford a very handsome return to the Electric Telegraph Company for all the capital they have been stimulated to employ in the management of a ready-money business. A thousand a-year, would, however, yield a dividend. At present the company have not wires enough for the public business, and great complaints are made of the delay.

The length of line laid down by the Electric Telegraph Company, or in progress, is now, we believe, about 2,000 miles; and the following is a list of telegraphs, with the date when laid down, and the length of line, though the materials from which we have compiled it are imperfect. It will, however, in some degree, serve to show the progress of the system:

</tbody>
</table>

The length of line laid down previously to 1845, was not more than 45; in that year, about 500 miles; in 1846, 600 miles; and in 1847, 1,100 miles. The total done and in hand is above 2,300 miles.

The towns to which communication will be made are above sixty, including London, Manchester, Glasgow, Liverpool, Edinburgh, Leeds, Sheffield, Birmingham, Bristol, Newcastle, Hull, Wolverhampton, Wakefield, Derby, Leicester, Norwich, Nottingham, Portsmouth, Northampton, Bradford, Coventry, Dudley, Worcestershire, Rutland, Winchester, Dorchester, Peterborough, Huntingdon, Chesterfield, Wisbeach, Lowestoft, Chelmsford, Berwick, Scarborough, Burlington, Stamford, and St. Ives. With Bristol, the communication is circuitous round by Birmingham and Gloucester, as the Great-Western, although first in the field with the Slough line, have neglected to apply the telegraph throughout, which seems to arise from dissatisfaction with the needle telegraph, for they have allowed partial applications of two other systems. Every town in the country having above one hundred thousand people, is brought into communication with the metropolis; and the only great towns still
unemployed are Plymouth, Chatham, Preston, Exeter, Bath, Brighton, and Oxford. The number of shires towns brought into connection is near thirty; all the chief seaports and seats of manufactures, and several watering-places.

Besides the places already enumerated, many considerable towns can be served, being already placed on the line of telegraph, as Worcester, Stourbridge, Wolverhampton, Shrewsbury, Chester, Chesterfield, Wrexham, Macclesfield, Wigan, St. Helens, Manchaster, Leeds, York, and Hull. Indeed, within a very short period, the company will be able to supply the prices of above a hundred market towns, if wires enough are laid down.

In the United States, New York, Philadelphia, Boston, Baltimore, Washington, Albany, Newhaven, and Hartford, have the advantages of intercommunication, and a line of a thousand miles long runs to Quebec.

With regard to submarine telegraphs their practicability is indisputable. The great essay will be the line between Dover and Calais, when the two great cities of western Europe will have instant parley. Already the money markets of the two sympathise, the capitalists of the two cities are bound up with each other, and it is to be hoped these ties will be drawn closer, and the peace of the two great nations be maintained. A continuous line between London and Vienna is talked of as in progress; at any rate, we shall see the telegraph lines of Marseilles or Trieste, the means of abridging our East Indian correspondance. The value of such correspondance to the London houses engaged in East India business and expecting remittances would have been very great during the late crisis.

If the worst threatens us with greater hazard of invasion during any future war, the telegraph comes in good time to counteract any unfavourable influence, by giving us instant intelligence of any danger to our coasts, and allowing of immediate, and as it may be called, personal communication between the statesmen of England and India, and personal influence where they have never entered, and with men they have never seen. The confidential agent or the junior partner will be a zero, and the means of safely conducting an available operation will no longer be limited by the necessity of intrusting it to a subordinate. Indeed it is imputed this very week a correspondence extends the power of wealth and enterprise, and widens their sphere of action. A Rothschild, a Goldsmith, or a Baring, may rule by agents in London, in Paris, in Madrid, and in Lisbon at once; but henceforth their most distant affairs will be under their own guidance, and personal influence, to which agents they have never had access. The means of conducting a private correspondence will be more than equal to the opening of the wires, and to which the effects of railway and steamer intercourse, great as they are, are as nothing.

To the Admiralty the electric telegraph offers the means of superseding the cumbersome semaphore, and of rapid intercourse with the naval stations. We consider the Admiralty greatly blameable in not availing themselves of the telegraph to secure the success of the Slough experiment. As it is, they have only a line to Gosport. There is none to Plymouth, Chatham, Sheerness, or Milford. We do not see why a submarine telegraph should not be carried out to the anchorage of Spithead, so as to allow of rapid communication with the laziest war-officer in England. We have no testimony in favour of government management in England and France that the clumsy semaphores, useless at night and in a fog, and useable only for a fifth of the year, should have been so long persisted in; but we entertain no doubt that so soon as the electric telegraph is electrically applied to the navigation of the navy, the whole of the government and private agents will become candidates for taking its control into their own hands, or for interfering with it as they have with the railways.

A submarine telegraph which will be of great use will be between England and Ireland, and nothing but the want of energy of the government prevents them from applying it in the present crisis; when it will be a means of economising money, and most probably of saving human life. Such a telegraph is properly a government experiment, and not a commercial experiment; and for that reason it is not likely to be done until it cannot be put off any longer, and when done will not work non profit. It is to be remembered that the telegraphic establishment will be a new post-office, operating almost instantaneously, and with this advantage—that instead of the whole business being restricted to one fixed time, or to two fixed times, communication will be made at the moment desired by day or night. The way in which such an establishment must operate on society must be most beneficial. All those interested in markets, whether belonging to the agricultural interest or the mercantile interest, will, in every part of the kingdom, wherever they may be, know the state of trade at a moment's notice, and in a few minutes a transaction will be effected, while they will have the means of making purchases or sales hundreds of miles off, whereby transactions will be much quickened, and a general and uniform rate of prices will be established throughout the country. The charge for subscription is only two guineas yearly, and the subscriber, wherever he may be, has admission to the subscription rooms, in which are posted the shipping lists, the share lists from the London and provincial share exchanges, the prices current, the prices of corn, live stock, and produce, and every event of public or mercantile interest. No one concerned in any business can well avoid this payment, for it will in the end become de facto tax, for no one will dare to be placed under a disadvantage to his neighbour. It will be as common to read the newspapers.

It will readily be seen that even the man of pleasure cannot escape contributing to the revenues of the telegraph company, for with a mere four guineas a year in full work, intelligence would have been sent of the state of the poll from sixty boroughs and thirty places of county elections, which are now telegraph stations. A parliamentary division will be known within a few minutes all over the country, and the faction which triumphs or which falls at St. Stephen's will within a brief period be brought under the comment of thousands of its supporters or opponents. Now the divisions are telegraphed to Liverpool and Manchester, and posted in the rooms.

The sending of private messages must be most various in its influence, and the effect of time and experience only can enable its bearing to be fully appreciated. New modes of doing business will spring up, new branches of business will be created, some perhaps be superseded, but that the result will be beneficial on the whole no reasoning man can doubt. Whoever has a sick relative at a distant place, and his pulse is imperiled, already lives with life quivering on the breath, in all the agony of hope and fear, will know the value of an establishment which can give him frequent and immediate intelligence of the state of one whom he holds dear. After this example it is of little moment to picture the many ways in which personal wealth and personal influence will be extended when the wires extend from London through the provinces, and when the power of the wires extends to the ends of the earth.

To the press the electric telegraph will be a new arm of power: the money which is now spent in horses and express will be applied to the electric telegraph; thousands of new employments will result, and new agents and correspondence. It may appear at first sight that the telegraph rooms by affording so much intelligence will be curtailing the sphere of the newspapers, but they will only be interfering with them in some departments to give them greater facilities in others. The electric telegraph will be the second post-office. The electric telegraph will make the postal steamer brought to Liverpool the American president's speech, and its purport, but the special edition of the Times must give its words sent up by telegraph. Country meetings of importance will be sent up by telegraph, and it is not impossible that before long such arrangements may be made as to allow of the reporter's notes being used for telegraphic transmission. The difference in the number of signs between long-hand and short-hand (discarding most of the arithmetical), is as 275 to 170, or nearly as 3 to 2; this gives a saving in favour of short-hand of two-thirds, and possibly more. It will be seen in time how many signals, observed in telegraphic communication, the great object is to economise the time used at the telegraph. The short-hand system was tried on the South-Western and found to answer. It seems by no means improbable that an influence will be exerted on the jurisprudence and policy of the country by the telegraph system. Perhaps we ought to say that it has already done so. The arrest of Tawell, the quaker, for murder, and the arrest of so many other criminals has given a greater efficiency to the telegraph; the respite and afterwards execution of the convict at Maidstone, the arrest of the murderer of the officer at Maidstone, and the arrest of the man who killed three people with a club in the central authorities. But though a telegraphic message may be a sufficient authority to arrest for felony, it will be necessary to provide some new process to make this establishment available in cases of misdemeanor and in the end it is likely to be applied in civil cases, in which already it is calculated to quicken many stages of proceeding. It may hereafter not be uncommon to have a witness at Edinburgh examined by telegraph during a trial at Westminster Hall, and other evidence be sought for five hundred miles off. It may cease to be necessary to bring up a prisoner to the superior
ON THE LAP AND LEAD OF THE SLIDE VALVE.

The slide valve is that part of a steam engine which causes the motion of the piston to be reciprocating. It is made to slide upon a smooth surface, called the cylinder face, in which there are three openings to as many pipes or passages: two for the admission of steam to the cylinder, above and below the piston, alternately; while the use of the third is to convey away the waste steam. The first two are, therefore, termed the induction or steam ports, and the remaining one the ejection or exhaust port.

The slide is enclosed in a steam-tight case, called the slide-jacket; and motion is communicated to it by means of a rod working through a stuffing-box.

The steam from the boiler first enters the jacket, and thence passes into the cylinder, through either steam port, according to the position of the slide, which is so contrived that steam cannot pass from the jacket to the cylinder through both steam ports at the same time, or through the ejection port at any time.

CASE 1.—WHEN A SLIDE HAS NEITHER LEAD OR LAP.

Fig. 1 represents the cylinder face for a "Murray slide" without lap, a and b being the induction ports, and c the ejection.

Figs. 2, 3, and 4, are similar sections of the valve, showing the slide in its central and two extreme positions. It occupies the mid-position, fig. 2, when the piston is at either extremity of its stroke; the extreme position, fig. 3, when the piston is at half-stroke in its descent; and that shown in fig. 4, when the piston is at half-stroke in its ascent.

When a slide has no lap, the width of its facing, at f and g (fig. 2), equals that of the steam ports; the lap being any additional width whereby those ports are overlapped.

That the waste steam may have unobstructed egress, the exhaust port c must be made of no less width than the steam ports; and, for the same reason, the bars d and e should correspond with the slide face at f and g. The three meeting-rod, without the bars between and beyond them, are therefore drawn of equal width; the total length of the slide being equal to the distance between the steam sides of the steam ports.

The distance through which the slide moves, in passing from one extreme position to the other, is called its true length; which, in this case, equals twice the port.

When the motion of a slide is produced by means of an eccentric, keyed to the crank shaft and revolving with it, the relative positions of the piston and slide depend upon the relative positions of the crank and eccentric.

Demonstration.

Let ab, diagram 1, represent the crank; ae being the crank-pin, and ac the centre of motion, the larger circle represents the orbit of the crank, and its diameter be the stroke of the piston. Supposing the cylinder to be an upright one, having the crank-shaft immediately above or below it, the connection between the piston-rod and crank being merely a connecting rod, without the intervention of a beam, it is evident that when the position of the crank is ab, the piston will be at the top of the cylinder, and at the bottom when its position is ac. The relative positions of the crank and piston, at any point of the stroke, depend upon the length of the connecting-rod: for the present, however, let us suppose the connecting-rod to be of infinite length, and therefore always acting upon the crank in parallel lines, so that when the crank is at dc, e will be the apparent position of the piston, and f the same when the crank is ac; the piston being represented by the sine of the arc described by the crank from either of the points b and c, in the direction of the arrow.

The diameter hf, of the inner circle of the diagram, represents the travel of the slide, and its radius the eccentricity of the eccentric; or, regarding the eccentric as a crank, the radius may be said to represent that crank, as ab represents the main crank. The travel of a slide, without lap, being equal to twice the port, the two steam ports are represented by the spaces ab and ac, but transposed, ab being the passage to the top of the cylinder, and ab that to the bottom.

Supposing the piston to be at b (the top of the cylinder), the position of the slide will be as shown in fig. 2, the direction of its motion being downward, so that the port a (same figure), or a in the diagram, may be gradually opened for the admission of steam above the piston, until the piston has arrived at half-stroke when it will be fully open, as shown in fig. 3. The direction of the slide's motion is then reversed, so that when the piston has completed its descent, the port b, figs. 1 to 4, or ab in the diagram, will begin to open for the admission of steam beneath it, and exhaustion will commence from above it through the port a, or ab, and exhaustion port c, the slide being again brought into its central position, fig. 2.

Now the slide being at half-stroke, when the piston is at either extremity of its stroke, if we make ab the position of the crank, ab will be that of the eccentric; and the axis of the crank being
likewise that of the eccentric, they must necessarily revolve in equal times, and always at the same distance apart; therefore, when the crank has reached the point d (supposing it to move in the direction of the arrow) the eccentric will have advanced to f, and e f and i m represent the positions of the piston and slide respectively; showing that when the crank has descended to the point g, the steam port a f in the diagram, or a f 1 to 4, will be open to the extent a m. Again, when the crank is at h, and the piston consequently at half-stroke, a i will be the position of the eccentric, the port a i being fully open, and the slide occupying the extreme position shown in fig. 3. The direction of the slide's motion is now reversed, and the port is again gradually covered by the slide face until the positions of the crank and eccentric are a c and a o, when the piston will have completed its descent, and the port a i will be completely closed, the slide again brought into its central position, fig. 3. The opposite steam port a f now begins to open for the admission of steam, and the direction of the piston's motion is reversed; the port continues to open until the crank and eccentric reach the points p and b, when the piston will again be at half-stroke, and the slide in its extreme position, fig. 4. Meanwhile, exhaustion from above the piston has been taking place to the same extent, through the port a i. Finally, the piston having completed its ascent, the slide again occupies its original position, fig. 2, and, its course being downward, steam is again admitted into the cylinder, through the port a i; the piston then begins to descend, and, at the same instant, exhaustion from above, and commences from below it, through the port b o.

It is sometimes urged against the use of the eccentric, as a means of actuating the slide, that the steam ports are opened and closed too slowly; but it must be remembered that the piston does not move at a uniform velocity, as the crank of the eccentric describes the arc b d, the piston descends only from b to a, the curved sines of that arc; and its velocity is gradually increased as it approaches the middle of its stroke, where it is greatest, being equal to that of the crank. Again, as the piston approaches the end of it stroke, its velocity is diminished in the same ratio as that in which it had previously increased, until the completion of its stroke, where it remains stationary during the small space of time in which the direction of its motion is reversed.

Now, it must be obvious that less steam is required to impel the piston at a slow rate than at a rapid one; and a glance at diagram 1 shows that the steam admitted into the cylinder, when the slide is actuated by an eccentric, is at all times proportioned to the velocity of the piston, the port being least open when the piston is near the end of its stroke, and fully open when it is at half-stroke. When an eccentric, instead of being set as in the preceding case, so that the steam port shall only begin to open when the piston commences its stroke, its place, is such that the port shall be open to some extent prior to the commencement of the stroke, the width of that opening being termed the lead.

The Lead.

The non-use of lead is disadvantageous, chiefly because at the commencement of every stroke, the steam has to contend with the whole force of that which had impelled the piston during its previous stroke. But, besides obviating that disadvantage, the lead is of essential service in locomotive engines, "where it is found necessary, to let the steam on to the opposite side of the piston before the end of its stroke, in order to bring it up gradually to a stop, and diminish the violent jerk that is caused by its motion being changed so very rapidly as five times in a second. The steam let into the end of a cylinder before the piston arrives at it, acts as a spring cushion, and assists in changing its motion; and if it were not applied, the piston could not be kept tight upon the piston rod."—Description of Stephenson's Locomotive Engine, "Trevithick."

Case 2.—When a Slide has Lead without Lap.

Diagram 3.

Let a b, diagram 3, represent both the travel of the slide and the piston's stroke; then c a and c b represent the steam ports. And let e f represent the lead; then c a and c e represent the crank and eccentric, the piston being at the top of the cylinder. Now, steam will enter the cylinder, below the piston, when the eccentric is at f, and the crank at g; for the arcs a e g and e b f are equal. Again, the arc a g is equal to the sine e; therefore, ig is equal to k e, and i b is its versed sine; hence

**Rule I.**—To find the distance of the piston from the end of its stroke, when the lead produces its effect:

Divide the lead by the width of the steam port, both in inches, and call the quotient versed sine; multiply its corresponding versed sine, found in the table, by half the stroke, and the product will be the distance of the piston from the end of its stroke, when steam is admitted for the return stroke, and exhaustion commences. Or.

**Rule II.**—To find the lead, the distance of the piston from the end of its stroke being given:

Divide the distance in inches by half the stroke in inches, and call the quotien versed sine; multiply its corresponding sine by the width of steam port, and the product will be the lead.

**Example 1.**—The stroke of a piston is 48 inches; width of steam port 2 1/2 inches; and lead 1 inch: required the distance of the piston from the end of its stroke, when exhaustion commences.

Here, .5 ÷ 2 = .25 = sine, and versed sine = .9002. Then, .9002 × 24 = .4846 inches.

**Example 2.**—The stroke of a piston is 48 inches; width of steam port 2 1/2 inches; and distance of piston from the end of its stroke, when exhaustion commences, .4846 inches; required the lead.

Here, .4846 ÷ 24 = .0202 = versed sine; and sine of versed sine = .0202 = .78.

Then, .78 ÷ 24 = .013 = lead.

When the lead of a slide is equal to the width of steam port multiplied by any number in the first column of the following table, the distance of the piston from the end of its stroke, when steam is admitted on the exhaust-side, will be equal to half the stroke multiplied by the corresponding number of the second column. Or, if the distance of the piston from the end of its stroke, when steam is admitted on the exhaust-side, be equal to half the stroke multiplied by any number in the second column, the width of steam port multiplied by the corresponding number of the first column equals the lead.
THE LAP.

A slide is said to have lap when the width of its face is greater than that of the steam ports, the ports being thereby overlapped, as in fig. 7.

It is to be remarked that slides should have some degree of lap on both the steam and exhaustion sides of the passage, because, although in theory an aperture may be said to be completely closed when covered by a bar of similar width, yet, in the construction of a slide without lap, we cannot insure such accuracy of fit as to preclude the possibility of steam entering or leaving both steam ports at the same time.

Lap on the steam side has the effect of cutting off the steam from the cylinder, by closing the port before the completion of the stroke, the remainder of the stroke being effected by the expansion of the steam already admitted.

Demonstration.

Case 3.—When a Slide has Lap on the Steam side, without Lead.

Let \(ab\) and \(bc\), diagram 4, represent the lap at both ends of the slide; and let \(ad\) and \(ce\) represent the two steam ports; then \(de\) will represent the travel of the slide, which, in this case, equals twice the steam port, plus twice the lap.

Supposing \(de\) also to represent the stroke of the piston, and that the piston is on the top stroke, then \(bd\) and \(bf\) are the respective positions of the crank and eccentric; for the slide, instead of occupying its central position, when the piston is at the end of its stroke (as in Case 1), must be set in advance of that position to the extent of the lap, that steam may enter the cylinder when the piston begins to move. (See fig. 5.)

Again,—when the eccentric has reached the point \(f\), the port \(ce\) will be re-closed (fig. 5), and \(i\) will be the position of the piston; therefore, the distance of the piston from the end of its stroke, when the steam is cut off, is proportioned to the whole stroke, as \(ie\) is to \(de\).

When the eccentric arrives at \(k\), the slide will occupy its central position (fig. 7), and the piston will be at \(m\), where exhaustion commences from above it; but steam is not admitted below it, for the return stroke, until the eccentric has reached the point \(n\), where the port \(ad\) begins to open, the position of the slide at that moment being that shown in fig. 8.

When the eccentric arrives at \(d\), the port will be fully open, the slide being then in its extreme position, fig. 9; and it will be re-closed when the eccentric arrives at \(g\), and the piston at \(p\), where the steam is cut off, the position of the slide being again that shown in fig. 8. Again,—when the eccentric reaches the point \(i\), exhaustion ceases from above the piston, which is then at \(e\), and commences from below it, the slide being then in its central position, fig. 7, and moving downward. Finally,—the crank having arrived at \(d\), and the eccentric at \(f\), the piston will have completed its ascent, and the slide will occupy the position fig. 3, as at starting.

The steam was shown to be cut off when the piston had descended from \(d\) to \(i\), the crank having described the arc \(dy\), and the eccentric the arc \(feh\). Now, \(di\) is the versed sine of \(dy\), and \(ec\) is the versed sine of half \(feh\); and \(dy\) and \(feh\) are equal areas. Hence

Rule III.—To find what part of the stroke steam will be cut off with a given amount of lap:

Divide the width of steam port, by itself, plus the lap, and call the quotient versed sine. Find its corresponding arc in degrees and minutes, and call it the first. If \(arc\) be less than 45 degrees, multiply the versed sine of twice that arc, by half the stroke in inches, and the product will be the distance of the piston from the commencement of its stroke, when the steam is cut off.

If \(arc\) be the first exceed 45 degrees, multiply the versed sine of the difference between double that arc and 180 degrees by half the stroke, and the product will be the distance of the piston from the end of its stroke when the steam is cut off.

Rule IV.—To find the amount of lap necessary to cut off the steam at any given part of the stroke:

If it be required to cut off the steam before half-stroke, divide the distance the piston moves before steam is cut off, by half the stroke, and call the quotient versed sine. Find the arc of that versed sine, and also the versed sine of half that arc. Divide the difference between the versed sine last found and unity, by the versed sine, and multiply the width of steam port by the quotient; the product will be the lap.

If it be required to cut off the steam at a point beyond half-stroke, divide the distance the piston from the end of its stroke, when steam is cut off, by half the length of stroke; call the quotient versed sine; find the corresponding arc, and subtract it from 180 degrees. Find the versed sine of half the remainder, and subtract it from unity. Divide the remainder by the versed sine, and multiply the width of the steam port by the quotient; the product will be the lap.

Example 3.—The stroke of a piston is 36 inches; width of steam port 14 inch; and lap 6 inches: required the point of the stroke at which steam will be cut off.

Here \(1.5 + 6 = 7.5\); and \(1.5 \div 7.5 = \frac{1}{5} = \text{versed sine}\); arc of versed sine \(2 = 36^\circ 59'\) (arc the first);

and \(36^\circ 59' \times \frac{1}{5} = 73^\circ 44' = \text{arc of versed sine, } 7198\).

Then \(7198 \times 18 = 12993\) inches \(=\) distance of the piston from the commencement of its stroke when the steam is cut off.

Example 4.—The stroke of a piston is 36 inches; width of steam port 14 inch; and extent of lap 1 inch: required the point of the stroke at which steam is cut off.

Here \(1.5 + 1.25 = 27.5\); and \(1.5 \div 27.5 = \frac{1}{15} = \text{versed sine}\) of arc \(62^\circ 58'\) (arc the first),

Then \(62^\circ 58' \times \frac{1}{15} = 125^\circ 56'\); and \(180^\circ - 125^\circ 56' = 54^\circ 04' = \text{arc of versed sine, } 4131\).

Then \(4131 \times 18 = 7443\) inches \(=\) distance of the piston from the end of its stroke when the steam is cut off.

Example 5.—The stroke of a piston is 36 inches; width of steam port 15 inches; and distance of the piston from the commencement of its stroke, when the steam is cut off, 120 inches: required the lap.

Here \(120 \div 18 = 7198\) \(=\) versed sine of arc \(73^\circ 44'\);

\(73^\circ 44' \div \frac{1}{2} = 36^\circ 59' = \text{arc of versed sine } 2\).

Then \(1 = \frac{1}{2} = 8\); and \(8 \div 2 = 4\); \(1.5 \times 4 = 6\) inches = lap.
HEALTH OF TOWNS—THE GOVERNMENT AND THE PROFESSION.

Now that the sanitary movement is likely to bear fruit, it will be well for our professional readers to turn their attention to the shares which have been in the hands of the sanitary reformers, who have borne their part of the labour. While engineers, architects, and surveyors have been working hard in carrying out sanitary reform, in improving the drainage, in reducing the cost of sewers, in mitigating the smoke nuisance, in warming, in ventilating, in the construction of dwellings, in the application of sewage manures, and in many other ways,—medical men and members of parliament have been making speeches, and claiming the honours of the campaign, as it seems they claim the emoluments. With what justice members of the constructive professions can be kept out of sight, we do not know; but in this department of the work, the medical men have kept them out, and to monopolise the merit and the patronage. Of the five Metropolitan Sanitary Commissioners, two are medical men, viz., Dr. Southwood Smith and Professor Town; and not one is engineer, architect, or surveyor. The commissioners, at page 51 of their First Report, speak as follows:

"It has appeared to be our duty to state, that we have had presented to us ground of exception against one class of appointments to the medical profession, and that of surveyors, of architects in practice, of builders, traders, agents, and professional persons connected with building operations in their respective districts."

We think the bias of this passage is readily to be seen, though it may not impugn the appointment of engineers, architects, or surveyors, but the bias lies in the omission of medical men not practitioners. There is no reason given why an architect and an engineer should not be appointed on the Metropolitan Sanitary Commission in addition to the physician and surgeon, or naturalist. We will show afterwards what reason there is why the two former should be appointed.

The following paragraph of the Report contains an insinuation, well worthy of notice, for it has its object:—

"The more the investigation advances, the more it is apparent that the progressive improvement and proper execution of this class of public works, together with the appliances of hydraulic engineering, cannot be reasonably expected to be dealt with incidentally, or collaterally to ordinary occupation, or to contractors, or to consultants, but must be the subject of special study which not only places them beyond the sphere of the discussion of popular administrative bodies, but beyond that of ordinary professional engineers and architectural practice. In justification of this conclusion, and in the evil of the present state and condition of names of high professional authority, we might adduce examples of the most defective works which have received their sanction."

The aim of this is, that the abuse shall be an argument against the use: because some architects have laid down expensive sewers, engineers, architects, and surveyors shall be excluded; because Professor Donaldson and Mr. Joseph Gwilt approve of the old system, those who have fostered and executed the new system shall not be employed. This is what the commissioners mean, though they do not say it fully; and we put it to the public whether it is fair to professions, which by their talent and their intelligence have so much contributed to the reputation of the country.

It may be taken as a matter of course that Crown Commissioners recommend the employment of the government Caleb Quotem, the Board of Royal Engineers to execute survey of the metropolis districts. This we conceive to be the finishing touch to the wrongs and insults which the Sanitary Commissioners have in this Report, and in their proceedings, heaped upon highly honourable professions.

It is needful to show that engineers, architects, and surveyors can be of some use, we shall appeal to the Report of the Sanitary Commissioners, the recommendations in which are based on the evidence of Mr. Roe, the Surveyor of the Holborn and Finsbury District, Mr. Phillips, the Surveyor of the Westminster District, and other able officers. In truth, as our pages would show, Mr. Roe has, by his indefatigable exertions, already carried out much of the plans now advocated by the Sanitary Commissioners, and has only been prevented by the Commissioners of Sewers from doing more. Surely these officers are to be balanced against those who have adhered to a practice which has only recently been opposed and condemned. What do the commissioners tell us?

"All the improvements which the public have yet obtained in this branch of public works, have been the result of the special and undivided practical attentions of well-qualified paid officers, and it appears to us that further improvement must be sought by the officers, and that the clerical and secretarial arrangements must be to secure, protect, and encourage the zealous, undivided attention and efficient labour of such officers."

If engineers and surveyors have already effected "all the improvements which the public have yet obtained in this branch of public works" and if to them, as scientific officers, the public have to look for future improvements, we can see no reason for the slur cast on them by their exclusion from the present commission, by the announced exclusion from future commissions, by the employment of the Corps of Royal Engineers, of whom—with all respect be it said—the removal is not only not European. We cannot hold the appointment of Mr. Austin to the secretarialship of the commission, nor the compliment paid to the executive officers of the Commissioners of Sewers as any alleviation of the intended slight. We hope Mr. Edwin Chadwick, as commissioner, and Mr. Austin, as secretary, both of whom have done well in the cause of sanitary reform, have had no part in the exclusive policy of the commission.

We have the highest regard for the medical profession; we have the deepest feeling of the pronouncement of the sanitary commission; but we cannot stand still while medical men arrogate to themselves the merits, the honours, and the rewards of sanitary reform. Their agitation has done good, we admit; their disinterested advocacy of the cause claims the highest praise; their service has been given lavishly by them, but it is in our professions which have worked while theirs have talked,—which have improved the forms of the sewers, and reduced the price—which have cleansed them by flushing, and which by a mass of individual labour have perfected and carried out plans of improve-
ment in every branch of construction, ministering to the public comfort, health, and life. Our pages have had their share in these discussions, and we have co-operated with our professional readers in carrying out a measure of reform, which is already great. In the Holborn and Finsbury and Westminster divisions of sewers alone, a reform has been effected, such as has not yet been seen in these parts of the metropolis, and the share the medical profession have taken in carrying them out.

Within a period not very distant, the new Sanitary Commissioners, or Commissioners of Sewers, will lay down works to the amount of half a million, perhaps a million sterling, upon the advice, it is true, of competent professional officers; but whether the supervision on the part of the commission, we are unaware. When Mr. Roe proposes his plan for spending a quarter of a million in getting a new outfall, which of the commissioners will consider it his special department to examine the estimates, and share the work of the commissioners, it will not be Lord Robert Grosvenor—it will not be Mr. Edwin Chadwick, great as is his capacity as an administrator—it will not be Mr. Richard Lambert Jones, though he is Chairman of the Bridge Committee in the City—it will not be Dr. Southwood Smith or Professor Owen. The two brothers, however, have “a degree of special study which shall not only place them beyond the sphere of the discussion of popular administrative bodies, but beyond that of ordinary professional engineering and architectural practice.”

The government have not thought it necessary to give a fair representation to the profession in the new Commission of Sewers, though the names of Mr. Robert Stephenson, M.P., Mr. Locke, M.P., Mr. George Rennie, Mr. Cubitt, and others, are well known at Whitehall. The constitution of the Metropolitan Sanitary Commission is, in reference to the sphere of its future duties, more monstrous than that of the Railway Commission, where three parties, who know nothing of railways—a member of parliament, an East India judge, and an officer in the army—and who had no interest to meddle with railway works and administrations, have so many of these absurd appointments of late, that we have a strong impression that unjustness is adopted as the government rule for office, and have some expectation of seeing Monsieur Jullien prime minister. Why the engineering professions should be exposed to so much contumely and neglect from which it suffers at the hands of the government, we do not know; but the enumeration of the Railway Commission, the Tidal Harbour Commission, and the Metropolitan Sanitary Commission, is a sufficient proof that a degree of unfairness is displayed, inimical to the interests of the profession, and that the reputation of English engineers is well known to the world—although their professional skill is sought in every country—it may be that they are thought by the home government a body too incomprehensible and contemptible to withstand oppression or demand in such a manner. The misconduct of the government on this head has reached that height, that the professions, if they wish to maintain their public character, cannot do otherwise than take instant steps to obtain justice. They have no security at present for the appointment of competent commissioners, or efficient officers, or for the employment of professional men at all; there is no security that officers of the Royal Engineers, and other branches of the army, will not be appointed surveyors of the sewers and other public works, the present system being that it is the duty of the Institutions of Architects and Civil Engineers to call meeting of their members, to memorialise the government, and send deputations to Whitehall, and take every other necessary step to vindicate the rights of their members. Aggregate meetings of engineers, architects, and surveyors, should be held in the metropolis, and in provinces petitions sent to parliament, and memorials to the Treasury. The members of parliament interested in the welfare of the professions, should be requested to take steps in parliament for obtaining explanations from the ministers. Mr. Robert Stephenson, Mr. Locke, and Mr. Cubitt, would not doubt, on application, give their cordial support to any necessary measure.

While we urge these strong remarks on the injustice done to engineers by the Metropolitan Sanitary Commissioners, it must not be thought that we undervalue their Report on the practical points to which they apply themselves. We are glad to acknowledge it as a step forward in the right way.

THE FAN BLAST.

Series of Experiments relative to the Fan Blast, presented by Mr. Buckle, of the Soho Works, to the meeting of the Institute of Mechanical Engineers, Birmingham, May 17, and October 27, 1847.

(PAPER NO. 1.)

The subject of this paper has reference to a portion of a series of experiments on the Fan Blast,—a subject which many members of this Institution are conversant with; but it is hoped that hints may be derived by the ingenious in leading to such improvements of the fan as shall insure the greatest useful effect with the least expenditure of power. The fan has become an indispensable machine in smithies and foundries, it abridges time and labour, and is otherwise a great improvement over the old system of bellows. The uniform stream of the former admits of no control, by the puffy blasts of the latter. By means of the fan the smith can heat his work with precision; he can vary at discretion the size of his nozzle twoyer, without deteriorating the density of his blast. He can conveniently heat one piece of work while shaping another.

The position of the fan in its chest, or the one preferred and generally made use of, is an eccentric position. The continual increasing winding passage between the tips of the vanes and the chest, serves to receive the air from every point of its circumference, as it was formed, as it was formed, and to give a uniform distribution of the air to the exit pipe. The particles of air having passed the inlet opening, and entering on the heel of the blade, would retain the same circular path were it not for the centrifugal force of the air due to its weight and velocity, impelling them forward towards the tips of the vanes, and this continued action is going on, particle by particle, till they are ultimately thrown against the fan chest, and are impelled forward to the exit pipe. It is by this centrifugal action that the air becomes impelled and accumulated into one general stream. But, as will be presently shown, there is a certain velocity of the tips of the fan which best suits this action.

An ordinary eccentric placed fan, 4 feet diameter—the blades 10 inches wide and 14 inches long—and making 870 revolutions per minute, will supply air at a density of 4 ounces per square inch, to 40 inches radius, each being 1 inch diameter, without any falling in density. The experiments herein detailed were made with a fan 3 feet 10½ inches diameter, the width of the vanes being 10½ and the length 14 inches; the eccentricity of the fan 1½ inches, with reference to the fan case, the number of vanes being 5, and placed at an angle to the plane of the disk, the diameter of the opening on the side of the fan chest 14 inches diameter, the inlet openings on the side of the fan chest 14 inches diameter, the space between the tips of the blades and the chest increasing from 3 inch on the exit pipe to 3½ at the bottom, in a line perpendicular with the centre. To the blast pipe leading to the uniforms a slide valve was attached, by means of which the area of the discharge was accurately adjusted to suit the required density.

The gauge to indicate the density of the air, was a glass graduated tube, primed with water, it being more sensitive and having a greater range than the mercurial one. These experiments were made with a view to ascertain what density of air could be obtained, with the vanes moving at given velocities, the outlet pipe being closed, and also at given velocities with the outlet open; but its area varied at discretion. And further, to ascertain the horse-power required to drive the fan under the varied condition.

The horse-power was ascertained by an indicator, the friction of engine and gearing being deducted in each experiment. With reference to the term "horse-power," as used in the table, it may be necessary to observe, that there is a given velocity of which a body would acquire in falling the height of a homogeneous column of air equivalent to the required density. Having given the necessary preliminary explanations of the blast above that of the atmosphere, we come to the experiments as recorded in the table, No. 1 a.

The first column is the number of experiments.

The second is the number of revolutions of the fan per minute.

The third is the velocity of the outlet pipe in feet per second.

The fourth is the density of the air in ounces per square inch, as indicated by the gauge.

The fifth is the area of the discharge pipe in inches.

The sixth is the indicated horse power.
By this paper it is intended to show that there are certain velocities with which the tips of the vanes of a fan should move according to the required density of air, and that there are certain laws which govern these velocities.

First.—Water is 867 times heavier than air; mercury is 13.5 heavier than water; consequently, mercury is 11164 heavier than air. A column of mercury, one inch in height, would therefore balance a column of air 11164 inches, or 930.3 feet in height. Let A be a column of mercury equal in height to any given density, and let B represent 930.3, and C 64°; then \(\sqrt[4]{(A \times B \times C)}\) = V or the velocity that the body would acquire in falling the height of a column of air equivalent to the density.

Second.—The centrifugal force of air coincides with the results obtained by the laws of falling bodies, that is when the velocity is the same as the velocity which a body will acquire in falling the height of a homogeneous column of air equivalent to any given density. To obtain the centrifugal force or density of air apply the following general rule.

Having given the velocity of the air, and the diameter of the fan, to ascertain the centrifugal force.—

\[ D = \frac{V^4}{N \times 0.00034} \]

where \(D\) is the density of the air in ounces per square inch, and \(N\) the number of revolutions of fan per minute, and \(V\) the velocity of the air in feet per second.

Let us now compare the results of the foregoing table. To do this, we will first take the velocity of the tips of vanes per second, and the power necessary to drive the fan. We will first take Nos. 1, 2, 3, 4, 5, and 6, and we shall find by inspecting the table that the corresponding velocities and the numbers of revolutions vary from 930.3, 900.8, 902.9, 1853.2, 1715.4, and 1441, and the corresponding densities of air per square inch are 9.9, 7.9, 6.9, 5.6, 4.5, and 3.5 ounces. The fan, it must be understood, is discharging no air; the velocity of the fan is merely keeping the air at a certain density or pressure per square inch. Under these circumstances, it requires a certain velocity of the tips of the fan to maintain a certain density of air, but not in a direct ratio.

The law which governs the velocity of the tips of the fan appears from these experiments to be \(\sqrt[4]{v}\) of the velocity a body would acquire in falling the height of a homogeneous column of air equivalent to the density. This we have called the theoretical velocity, and by comparing Nos. 1, 2, 3, 4, 5, and 6 experiments as above, that is, by comparing the velocity of the tips of the fan per second with \(\sqrt[4]{v}\) of the theoretical velocity, we shall find them to agree very nearly. Thus, if the velocity of the tips of the fan per second be represented by \(V\), then \(\sqrt[4]{V}\) of the theoretical velocity will be represented by 1:008 in No. 1 experiment,

-990 6

But we shall not fully find that the \(\sqrt[4]{v}\) of theoretical velocity governs the fan when it is not discharging air, but that the theoretical velocity governs it also when the outlet pipe is open; that is, that the maximum effect of the fan is when the vanes move from the theoretical velocity to \(\sqrt[4]{v}\) of that velocity due to the density of the air, the greater the quantity of air is discharged by the fan under these conditions with the least expenditure of power. To illustrate this more fully, let us refer to the table of experiments, and for our example we will take Nos. 9, 10, and 11; here the density in each is six ounces. In No. 10 the velocity of the tips of the fan per second, and the theoretical velocity is 211 feet per second, being nearly the same. The quantity of air discharged is 779 cubic feet per second, and the power employed in this case amounts to 19.5 horses.

We take now No. 11 experiment. Here the velocity of the tips of the fan per second, and \(\sqrt[4]{v}\) of the theoretical velocity 190 feet per second. Now these two experiments are in proportion to each other nearly, viz., in No. 11 the quantity of air discharged amounts to 35.7 cubic feet per second, and takes 6.4 horse power, while No. 10 discharges 779 cubic feet per second, and takes 19.5 horse-power. Thus the discharge of air is nearly 9 to 1, and the horse-power employed in the same proportion.

In the following examples we shall call the theoretical velocity per second unity, beginning with No. 15. In this example we shall also call the quantity of air discharged in cubic feet per second unity, and also the horse-power per second.

To give a further illustration of this part of our subject, we will take Nos. 7, 9, 12, and 16 experiments. Here the velocity of the tips of the fan is the same, which we shall denote unity. The corresponding densities are 7, 6, 5, and 4 ounces; we shall call the highest unity, also the cubic feet discharged per second, and the horse-power per second.

Nearly all the preceding examples justify our conclusion, that the greatest results are obtained when the theoretical velocity and the tips of the vanes are nearly equal. It carries its own conviction that if we increase the velocity of the tips of the vanes, and only double the cubic quantity of air delivered, that it must take more than double the expenditure of power, the density of air remaining the same.

We shall now give examples of the data dictated by our table of experiments. And first, having given the density of air per square inch to determine the velocity of the tips of the vanes per second, also the horse power requisite to drive the fan under these circumstances, the fan not discharging air, but its velocity merely keeping the air at a certain density.

Let \(D\) denote the density of the air in ounces per square inch, and \(A\) a column of mercury equivalent in height to that density. Then by the laws of falling bodies \(\sqrt[4]{(A \times 930.3 \times 64)} = V\) the velocity acquired by a body falling through a column of air of the corresponding density.

Then \(X = D\) = \(P\) the number of pounds acting on the vanes, 10 \(\sqrt[4]{V \times 60\ P}\) = \(V\) P. \(\text{H} = P\). H. P. or horse-power required.

The constant number 38 is obtained by the following formula.

\[ H \times 38000 = P \text{ Then } \frac{38000}{H} = D \]

Example.—Let \(D = 9.4\) oz. per square in.; and \(A = 1.175\) in. of mercury, to determine the velocity of the tips of the vanes per second, and also the horse-power.

Then \(\sqrt[4]{(930.3 \times 64 \times 1.173)} = 264.4\), the theoretical velocity, \(\sqrt[4]{V}\) which is \(237.96 = V\), or velocity of tips of vanes per sec.

Now \(\frac{384 \times 9.4}{384} = 22.92\) = \(P\), or pounds acting on the vanes of fan.

Then \(33000 \times 22.92 = 96\) horse power required.

Having given the velocity of the air in feet per second (or as it has been termed the theoretical velocity) to determine the density of the air in accordance with the laws of centrifugal force.

Let the velocity be 964 feet per sec., and the diameter of the fan 3 5 feet. Then by former rules we have

\[264.4 = 66.5\text{ and }66.5^{2} = 11169 = \frac{11169 \times 1.209}{3.9}\]

\[0.01\]

\[144 = 6^{2}\text{ ounces density, the answer required.}\]

By the second rule, take the velocity of the fan in feet per second, multiplied by the number of revolutions of the fan per minute, the product multiplied by 0.00034 = the density required.

Here we must remark, that according to our table of experiments, that when the tips of the vanes are to move at \(\sqrt[4]{v}\) of the theoretical velocity, that not more than 920 lb of air are discharged per minute; but this is without any attenuation in the density.
To determine the horse-power necessary to drive the fan when discharging air, the velocity of the tips of the vanes must not exceed \( \frac{V}{g} \) of the theoretical velocity, having given the density of air required, also the cubic feet of air.

First find the horse-power, as directed in former examples, when the fan is not discharging air.

Then multiply \( \frac{V}{g} \) part of the weight of air to be discharged by the fan per minute in pounds by \( \frac{V}{g} \) of the theoretical velocity, and divide by 3000, the quotient \( \frac{V}{g} \) of the horse-power necessary to discharge this quantity of air, which add to the horse-power necessary to drive the fan when not discharging air, for the answer required.

Example.—Let \( D \) be the density of air required = 4 oz. A, a column of mercury equal to the density = '5 and \( W \) = the weight of air to be discharged = 220 lb. per minute, and \( \frac{V}{g} \) the velocity of fan in feet per minute.

\[
\frac{38 \times \frac{1}{16}}{4} = 9.5 = P = \text{the pounds acting on the vane.}
\]

Then by former rule, \( V = \frac{93150 \times \frac{5}{9}}{33000} = 2'67 \) horse-power necessary to drive the fan without efflux.

Now a cubic foot of common air at 60° Fahrenheit weighs 1'029 oz., therefore a cubic foot of the given density will be equal to \( \frac{1'511}{1'029} \) oz., and

\[
\frac{220 \times \frac{1}{1'511}}{1'029} = 2330 \text{ feet} = \text{the cubic quantity of air discharging per minute.}
\]

And \( \frac{220 \times 3'66 \times 93150}{60} = 33000 \) = 1'0 horse-power necessary to discharge the given weight of air, and \( 1'0 + 2'67 = 3'67 \) = the total horse-power required.

When the tips of the vanes is to move equal to the theoretical velocity, there we have the only example as in the last one only we take \( \frac{V}{g} \) instead of \( \frac{V}{g} \) (as in former examples) of the weight of air discharged, which added to the horse-power requisite to drive the fan when no efflux takes place.

We should here remark, that when the fan is moving at this velocity, that it is capable of discharging 480 lb. of air per minute without any falling off in density.

In a recent set of experiments, the inlet openings in the sides of the fan chest were contracted from \( 1'4 \) in. the original diameter, to 12 and 6 in. diameters; when we obtained the following results.

First, that the power expended with the opening contracted to 12 in. diameter, was \( \frac{94}{1} \) to 1 compared with the opening of \( 1'4 \) in. diameter; the velocity of the fan being nearly the same, as also the quantity and density of air delivered.

Second, that the power expended with the opening contracted to 6 in. diameter, was \( \frac{94}{1} \) as compared with the opening of \( 1'4 \) in. diameter; the velocity of the fan being nearly the same, and also the area of the efflux pipe, but the density of the air increased one-fourth.

These experiments show that the inlet openings must be made of sufficient size, that the air may have a free and uninterrupted action in its passage to the blades of the fan, for if we impede this action we do so at the expense of power.

(Paper No. 2.)

In resuming the subject of the fan blast, I shall endeavour, as far as I conveniently can, to avoid detailed statements of the pneumatic laws involved in its consideration, as they would occupy more time than would be consistent with the present occasion; and shall proceed to remark on the most important points connected with the construction of the fan, viz. : the adoption of such forms and proportions, as shall insure the greatest results with the least expenditure of power; and effect a diminution of the intolerable noise that generally arises from the working of the fan. And although I have not been able to carry out such leading principles to the fullest extent, I trust that I have furnished materials that will be found of value to those members whose greater leisure may enable them to do so.

From a contemplative view of the action and apparent effect of that very useful apparatus, a blast fan, it would appear that the air in the fan case is impelled by the vanes along the transit pipe, or channel, to the chest provided for the blast; and that the continuous rapid motion of the vanes, compresses air in the pipe and chest, to a degree that may be shown and accurately measured, by a water, or mercurial gage, attached to the blast chest.

In my first communication, the principal investigation rested on a theoretical question, viz. whether the tips of the blade should partake of the same velocity as a body falling freely a certain height, such height being governed by the density of air required. Recent experiments (the results of which accompany this paper) justify the conclusions then made, as will be seen on examining tables Nos. 2, 3, and 4.

Having satisfied myself with respect to the velocity a fan ought to have, when a certain density of air is required, I purpose in this paper to examine the fan under other various conditions, the object being to establish the best proportions of inlet openings in the sides of the fan chest, and the suitable corresponding length of vanes. For this purpose, I caused the openings in the sides of the fan chest to be varied in different diameters, and enabled to vary those openings, by fitting in rings of wood; and I varied the fan by attaching to its arms, vanes of corresponding lengths. The experiments are classed in the following tables:—

Table No. 1.

<table>
<thead>
<tr>
<th>1</th>
<th>Density of air.</th>
<th>1'0 horse-power.</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>69</td>
<td>1'01</td>
</tr>
<tr>
<td>3</td>
<td>8</td>
<td>1'0</td>
</tr>
<tr>
<td>4</td>
<td>1'0</td>
<td>1'0</td>
</tr>
</tbody>
</table>

Here are the results in favour of the fan in its original shape, and similar results appear when the fan is discharging air.

I will now proceed to examine the inlet opening, and the best length of vane.

From the experiments enumerated in the tables it will be seen that the longer vane possesses a preponderating power over the shorter one, in condensing air of the greatest density, with the least expenditure of power; and the results of which will be seen on comparing the results of the former state of the fan, in table No. 1, with the present tables Nos. 2, 3, and 4.

In the first five experiments, no efflux of air takes place; and if, in these experiments, we take the mean of the density of the air and the horse-power, and call them unity, their proportions with the corresponding experiments represented in tables 2, 3, and 4, will stand thus:

Table No. 1.

<table>
<thead>
<tr>
<th>1</th>
<th>Density of air.</th>
<th>1'0 horse-power.</th>

</tbody>
</table>

The proportion a suction pipe bears to a pump, is an analogous case; for, if we drive the water at a greater velocity, the suction pipe will supply it with water, the consequence will be, that we shall not lift so much water, at the same time that we absorb more power.
In the 14 inch blade, the tip has a velocity of 26 greater than the heel; or, by the laws of centrifugal force, the air will have 26 times the density at the tip of the blade that it has at the heel. The air cannot enter on the heel with more than atmospheric density, but in its passage along the vanes, it becomes compressed in proportion to its centrifugal force. The greater the length of vane, the greater will be the difference of the centrifugal force between the heel and the tip of the blade; consequently, the greater the density of the air.

Reasoning, then, from these experiments, I recommend for easy reference, the following proportions for the construction of the fan:—Let the length of the vanes be one-fourth of the diameter of the vane. Let the diameter of the inlet openings in the sides of the fan chest be one-half the diameter of the fan. —And, let the length of the vanes be one-fourth of the diameter of the fan.

In adopting this mode of construction, the area of the inlet openings in the sides of the fan chest, will be the same as the circumference of the heel of the blade, multiplied by its width; or the same area as the space described by the heel of the blade.

The following tables give the sizes of fans varying from 3 to 6 feet diameter:

</table>

Table 1.

The dimensions of the above tables are not laid down as prescribed limits, but as approximations obtained from the best results in practice.

In some cases, two fans fixed on one spindle would be found preferable to one wide one, as by such arrangement, twice the area of inlet opening is obtained, compared with a single wide fan; and they may be so constructed, where occasionally only half the quantity of air is required, that one of them may be disengaged by a clutch, and thus a saving of power effected. In a single fan of great width, the inlet opening must either be made too small in proportion to the width of the vane, or if it be made large enough for the width of the vane, the length of the vane becomes so short as to be quite incapable of producing air of the required density.

It has been stated that the air from the fan chest is impelled by the vanes along the transit pipe, to the blast chest, &c.: I beg attention to the results of an experiment very recently made by me, with reference to the admission of air into the transit pipe, and which, I think, may lead to an important improvement in the fan. The experiment alluded to, was made to enable me to ascertain the result of varying the area of admission to the transit pipe, in proportion to the quantity of blast required for use; and I effected this by adapting a segmental slide to the circular chest of the fan, as shown in the accompanying section, by means of which, I vary the width of the opening into the transit pipe, from 12 to 4 inches.

The object of this arrangement is, to diminish the transit pipe opening at pleasure, in proportion to the quantity of air required, and thereby to lessen the power necessary to work the fan. The results will be seen by experiments inserted in tables 1b, 2b, 3b, and 4b. The inlet opening to the transit pipe having been contracted from 12 inches to 4 inches deep, so that the tip of the vane and the bottom of the outlet opening were nearly in a direct horizontal line, nearly the same quantity of air was impelled, as with the original opening; the noise produced by the fan had, however, nearly ceased. It therefore appears, that the less this opening made—provided we produce sufficient blast—the less noise will proceed from the fan; and by making the top of this opening level with the tips of the vane, the column of air has little or no reaction on the vanes.

With respect to the degree of eccentricity which the fan should have, with reference to the fan chest, 1/5 of the diameter of the fan...
has been found in practice to answer well; that is, the space between the fan and the chest should increase, from \( \frac{3}{4} \) of an inch at the top of the inlet to the transit pipe, to \( \frac{3}{4} \) of the diameter of the fan at the bottom of a line perpendicular with the centre. The tunnel, or main pipe, from the fan chest may for short distances, varying from 50 to 100 feet in length, be made not less than \( \frac{1}{2} \) times the area of the transit pipe in the fan chest; and in distances varying from 100 to 200 feet in length, \( \frac{1}{2} \) times the area of the transit pipe. The length of a tunnel may be continued to 300 or more feet, provided it be made of sufficient dimensions to allow the air to pass freely along it. The experiments accompanying this paper were made with a tunnel 18 inches diameter and 160 feet in length, and no difference could be detected in the density of the air, when the gage was applied at any part of the tunnel.

Having investigated the leading characteristics of the fan, it may not be out of place to give a few hints respecting its mechanical construction.

**First.**—It is one of the greatest essentials, that all parts maintain a just and proper balance.

**Second.**—That the arms of the fan be as light as is consistent with safety; round arms are decidedly objectionable; I have known instances when their centrifugal force has torn them from the centre boss. I prefer the rectangular arm, about the proportion of \( \frac{3}{4} \) times the width, for the depth at the centre, with sufficient taper towards the tips.

**Third.**—The bearings and journals of the fan spindle should be made of a length not less than four times the diameter of the necks of the spindle.

**Finally.**—The driving pulleys should be made as large as circumstances will admit of, so that the strap may have sufficient surface to prevent slipping.

The fan from which my experiments were collected, was made with these proportions. It has been at work nine years without any perceptible wear.

The application of the fan has hitherto been chiefly applied to smelting and foundries; and in but few instances has it been applied to the smelting of iron ore. I am aware that differences of opinion exist as to the applicability of the fan to that purpose. The principal reason urged against it being the limited density to which the blast can thereby be compressed, compared with the blast supplied by the cylinder. It remains, however, to be proved whether such high densities are absolutely necessary for the smelting of iron ore; whether we may not reduce as good iron by a diffused soft blast, as by the strong and generally applied, concentrated blast. I hope it will not be thought presumptuous on my part, in thus doubting long established practices. The old maxim of "there's no way like the old way," is not always based on unerring principles.

As I have before stated, the density of blast afforded by the fan, is limited to the force arising from the centrifugal motion of the air, in passing along the vanes of the fan; the quantity not exceeding what is due to its velocity and magnitude. But may not the density be increased by using a succession of fans, so constructed and arranged, that the air may be passed successively through each; the air from the first fan being made to enter the second; the air from the second to enter the third; and the blast finally emitted of adequate density?

I cannot here enter into a further investigation of this important subject; neither are the limits and character of this paper suited to the minute connected with the principles and practice of a smelting furnace; but I hope that the observations which I have made, and the principles I have endeavoured to enunciate, will be the means of instituting further inquiry; and, as the expense of constructing a fan can be no barrier, I trust that a fair trial will be made, where convenience is suited to its application for smelting purposes.

---

**REGISTER OF NEW PATENTS: VENTILATION OF MINES.**

**John Wilcock,** gentleman, in the county of York, for "certain improvements in the ventilation of mines."—Granted June 19; Enrolled Dec. 12, 1847. [Reported in the Patent Journal.]

The patentee, in this specification, states his invention to be for the purpose of improving, and more effectually securing, the better ventilation of mines, and consists of elongating the upcast shaft of the mine, by the addition of stacks, towers, or other similar buildings, erected above, or in connection with such upcast shaft, by which the upper orifice of the upcast shaft is elevated very considerably above the upper orifice of the downcast shaft, proportionally to various circumstances—as the relative depths of the two shafts, the velocity of the current of air through the mine, the nature of the gases, &c. The ventilation of mines is effected by the current of a stream, or current, of atmospheric air through the various ramifications of the mine, carrying with it, in its course, the various noxious gases—as carburetted hydrogen, carbonic acid, and also the vitiated air, in its course, and escapes through the upcast shaft into the atmosphere. This current is, in most cases, caused—or the velocity of it is increased—by the application of heat to the upcast shaft, either at the bottom thereof, or at the orifice at the surface. The patentee proposes, by his invention, to increase the velocity of the currents through the upcast shaft, by erecting a stack, tower, or other similar building, above, or in connection with, the upcast shaft, which forms a continuation of the shaft, and through which also continues to flow the current of air. The height to which, in most cases, it will be sufficient to raise the elongated portion of the shaft, the patentee states to be from 60 feet to 100 feet, though this will be governed by circumstances varying in different mines. The patentee gives several drawings, descriptive of his invention, as applied to several descriptions of mine shafts; as, first, to its application to mines having only one shaft; in this case, it is customary to make partitions down the shaft, thus forming downcast and upcast shafts. The patentee proposes leaving these arrangements as usual, but erecting over, or in connection with, the part of the shaft, a stack, tower, or other building, as a continuation of the upcast shaft. Secondly, to a mine in which the upcast shaft is also the working one; in this case, the minerals and workmen pass out of the lower end of the stack, or tower, by an aperture in the wall of it; and, thirdly, to a mine in which the upcast shaft is only employed for that purpose; in this case, a plain stack, or tower, is employed. In all cases, the patentee states, it is necessary that the sectional area of the stack, or tower, should be, at least, equal to the sectional area of the upcast shaft; and that, when it is necessary to have any openings into the lower part of the stack, or tower, the sectional area of the upper part of the stack, or tower, above the
CONSTRUCTION OF BRIDGES.

Stephen Moulton, of Norfolk-street, Strand, Middlesex, gentleman, for "Improvements in the construction of bridges."—Granted April 8; Enrolled Oct. 8, 1847.

The improvements are for constructing bridges in the manner shown in the annexed engravings. Fig. 1 is a side view of a bridge constructed according to the invention. Fig. 2 shows two transverse sections thereof, by which it will be seen that the top rail B, and the bottom rail A, are combined together by a series of diagonal bars D, so that the bottom rail A is suspended from the upper rail B, by means of such diagonal bars D; and the rails, A and B, are kept apart by means of the uprights C, which uprights are not fixed to the upper or lower rails B, A, but simply come in between them as supports to retain the parts A, B, at the correct distance apart; and in the event of the chain being formed to act unequally on any of the diagonal bars D, by driving in wedges, as shown at E, Fig. 1, the whole must be correctly adjusted. The diagonal bars D, proceed in opposite directions, and cross each other, as is shown, but they are not fixed to each other, they being simply fixed at their ends by means of pins passing through them; and the top and bottom rail, B, A, Fig. 1, shows part of the side framing of the bridge.

Fig. 3 shows the diagonal bars D, with the screw pins and nuts, by which they are attached to the rails A, B. The upper rail may be formed of two angle-irons, as shown at Fig. 3, the diagonal bars D passing between the parts B, B, and such parts will be held together by the pins and nuts J, as shown. The lower rail is composed of two bars, A, A, shown in Fig. 2, and the ends of the bars D are placed between them, and held by the screw pins and nuts J, as shown. K, the beams for receiving the floor of the bridge. F, the caps which cover the upper edges of the two bars of which the bottom rail A is composed. At the ends of a bridge it is preferred to use additional bars D*, D*, as shown at Fig. 1, and also holding-bars G, with adjusting screws and nuts, as at H; but these may be dispensed with. There are openings through the uprights C, for the passage of the diagonal bars D, but these bars D should be free and not confined in the openings through such uprights C.

It will be found by examining the peculiar arrangement of the parts that great strength with lightness are obtained by construct-

LOCOMOTIVE ENGINES AND RAILWAY CARRIAGES.

George Taylor, of Holbeck, near Leeds, for "Improvements in locomotive engines and railway carriages."—Granted June 3; Enrolled Dec. 3, 1847. [Reported in the Mechanic Magazine.]

The patentee states that his invention consists:—Firstly—In certain improved arrangements of the steam cylinders of locomotive engines, and the parts which communicate the reciprocating motion of the pistons of the cylinders to the axle or axles of the driving-wheels, which arrangements have for their object to concentrate the driving power of the actuated pistons, so as to communicate an even rotating motion to the driving-wheels, or to distribute the moving power (before concentrating it), in an even and uniform manner to one, two, or more pairs of wheels. The advantages which the patentee states he believes to result from this part of his invention are, diminished wear and tear of the engine, and the attainment, with safety, of a greater degree of speed, in consequence of the decreased amount of oscillation of the locomotives. The construction is as follows:—Above the boiler, and near the smoke-box, are placed, horizontally, and in just a horizontal position, two steam cylinders of equal capacity, each having its piston furnished with cross-heads sliding in guides supported by the frame of the engine. The pistons are connected by rods to two cranks, which are attached on either side to a wheel having cogs or indentations on its periphery, and which gears into another wheel fastened on the centre of the axle of the driving-wheels. The axle is placed above the boiler, and allows the employment of driving-wheels of larger diameter (say from 10 to 15 feet), with even a diminished amount of oscillation, in consequence of the weight of the engine being brought near the line of rails. All the wheels may be made to drive by being coupled in the ordinary manner. In order that the cross-wheels may be worked by a greater degree of speed, the bearings of the engine act freely, the guide, in which are supported the journals or axle-boxes of the driving-wheels, are made slanting. Two modifications of the mode of connecting the piston-rod of the steam cylinders with the axles of the driving-wheels are specified by the patentee. The first consists in forming a slot in the centre of each of the piston-rods, in which works a short vibrating link, connected to a vertical frame on either side of the engine, which is made fast underneath the boiler by means of a pin, on which it vibrates—and in connecting each of these vibrating vertical frames by rods as is usual with the axles of the driving-wheels, or in attaching one end of a connecting-rod to the outside end of the cross head of the piston-rod, and the other to the Boss of the driving-wheel. Secondly,—This invention has reference to the construction of apparatus applicable to the locomotive, tender, and carriages, which serves to retard the progress of the train when necessary, and to support, in the case of the breakage of an axle, the weight of the carriage. To effect this, two levers are made fast to the bottom of the carriage in such manner as to allow their action freely, and have each at the outer end a flanged skid placed directly over the line of rail. These skids have on the under surfaces blocks of hard wood with the grain placed vertically, and are moreover connected by a strong spring. From the centre of this spring rises a vertical shaft, from one end of which are joined by a threaded connection, whereby it can be lengthened or shortened, and by which the top of this shaft is forked, and has between the prongs at top and bottom two anti-friction rollers; between these rollers is a cam, fastened to a horizontal rod, which is made to rotate by apparatus brought under the control of the engineer, after any ordinary and well-known means. When the longest radius of the cam is brought to bear upon the lower anti-friction roller by means of the rotating of the horizontal shaft, it follows that the vertical shaft descends downwards and the flanged skids thereby depressed on to the line of rail which they had been in contact with at the progress of the train. The flanges serve to retain the carriages on the line of rails, and the skids to support the carriage in the case of the breakage of an axle; but, in order that the vertical shaft may be relieved from the weight of the carriage, stops are inserted in the lower part thereof at the extremities of the spring point, which the skids catch. Thirdly,—The patentee proposes to divide the tender horizontally into two parts, using the upper or open portion for coals, and the lower to contain the water, and to pass the axle of the wheels through the water or above it, in order that the weight
of the tender, as in the case of the locomotive before described, may be brought nearer the rails. Fourthly—To employ axles for railway carriages composed of two pieces, one solid and the other tubular, to slide over it; one of a pair of wheels being attached to each piece, so that they may revolve independently of each other.

VIBRATING PISTON-ROD ENGINE.

G. V. GUSTAFSON, of 15, William-street, Regent's-park, late engi-

er, R.N. "Improvements in the steam engine."

The improvements relate, first, to the mode of connecting a piston-rod to a piston by means of a ball-and-socket joint. The advantage of this plan over the old one (where the piston-rod is connected to the piston by means of straps and keys like the crank and connecting-rod) will easily be perceived; a large bearing surface, its facility for adapting itself in the centre of the piston, being borne and guided at the same time, and also the advantage of holding a lubricating substance, such as oil or tallow, and thereby lessening the friction, and causing a less wear of the ball and socket. Secondly, the manner of keeping the piston tight within the cylinder by the combined mechanical forces of steam and metallic springs. The advantage of this arrangement will also be perceived without difficulty: the skeleton of the piston is formed like a wheel; the nave receives the end of the piston-rod, from which proceeds the arms, to the extreme ends of which a ring is attached, and to which ring is bolted the top and bottom cover of the piston, which for lightness should be made of wrought-iron; within these covers, and at the outer periphery, are fitted two metallic rings of light construction, and kept in their places by means of spiral and horizontal springs, but not necessarily steam-tight, as that will be effected by admitting steam into the chamber, which incloses the packing-rings by means of a double acting valve; this will cause a more uniform pressure on the packing-rings than could be effected by springs alone; it also requires very little fitting and grinding, only the side of the ring nearest the cover: it has also another, though not very great advantage, of partially pulling, instead of entirely pushing the piston. Suppose the piston is moving upwards, a portion of the pressure from under it will be removed to the upper cover, which is considerably above the centre of the globe; hence the pulling property, which in such case is preferable to pushing, and the same, of course, takes place on the down stroke. Thirdly, the construction of a moveable apparatus to be adapted to the top or cover of the cylinder through which the piston-rod is to slide, and at the same time vibrate. The advantage of this apparatus over the old slide-rest shaped one is, first, being curved as to press nearly at right angles to the different positions of the piston-rod, whereby the friction is considerably diminished; secondly, having a flat bearing surface to act against, instead of the dovetailed edges in the old plan; thirdly, and lastly, its facility of keeping in contact with the bearing surface, which is effected in condensing engines by connecting the narrow chamber, between the two slides, with the condenser, whereby the slides are kept in their places by the pressure of steam and the atmosphere: in non-condensing engines this chamber should be in communication with the atmosphere, which may be effected by causing the upper slide to bear at the middle third, allowing a passage to the chamber under it, which will also lessen the friction of the upper slide; it will be perceived that the slides are portions of circles, and consequently easy of construction. And fourthly, an apparatus (or self-acting damper) for regulating the draught of the flues and furnaces, and thereby regulating the pressure in the boiler, and giving such due notice of the state of pressure in the boiler as may prevent accidental explosion. This being a distinct apparatus, may be used with or without the other improvements, and is applicable both for land and marine engines and marine engines.

The inventor states, that a plan somewhat similar in principle, though differing in details, was tried many years ago, but in consequence of the ill- adaptability of the slides—somewhat like the slide-rest of a turning-lathe—to the motion of the piston-rod, being at right angles to the latter only at the dead points of the engine, or top-and-bottom stroke, it was a very great defect.

The three first improvements are shown in the annexed engraving of a vertical section of the steam cylinder. a, the cylinder; b, the skeleton of the piston, formed like a wheel for the purpose of resting it of light construction; c, a hollow cast-iron globe, fitted to the end of the piston-rod and secured to it by a plug d, or it may be cast on to the end of the piston-rod: in the centre of the piston is a hemispherical socket, into which the globe c is fitted and secured to it by means of a cap e firmly bolted to the hemispherical socket; the arms have strengthening flanges on their under sides, and to the outer ring, at the extremity of the arms, is bolted the top and bottom covers g g, which, for lightness, may be made of wrought-iron. To render the piston steam-tight, two metallic rings are placed in the annular chamber between the covers g g, and held in their places by means of vertical and horizontal springs, but not necessarily steam-tight, as that will be effected by admitting steam into this annular chamber of the piston by means of a double-acting valve, by which a more uniform pressure on the packing-rings is obtained than could possibly be effected by springs alone: i is the cylinder, which is made spherical, with segmental pieces to complete the arc of a circle; k is a segment slightly hollowed in the middle and bolted to the cylinder-cover; l are slides attached to the cups m n. To keep the radius slides l l constantly in contact with their bearing surface, the hollow space o should be in communication with the condenser, which is effected by fixing a small tube in any convenient place: in non-condensing engines this space should be in communication with the atmosphere.

It will be seen that as the piston ascends and descends, the piston-rod will be enabled, by the lateral motion of the radius slides, to vibrate, and thereby act directly on the crank; in consequence of the angular position of the piston-rod the wear of the cylinder would be greater on one side than the other, but this may be avoided by giving to the latter an inclined position. It will be perceived that this peculiarity of the piston is of great advantage, especially for horizontal engines, as the weight of the piston would be supported by the pressure, and consequently prevent an unequalizing wear of the cylinder and piston, which in common horizontal engines cannot be avoided; hence the vibrating piston-rod is particularly adapted for the screw-propeller and locomotive engines. To prevent an unnecessary waste of steam, the space between the piston and the cylinder cover, where the former is on the top stroke, as shown by the dotted lines, may be filled up with hard wood and bolted to the cylinder cover.
BUNNETT'S SEWER TRAP.

Mr. Bunnett, of the firm of Bunnett and Corre, of Lombard-street, has invented a very simple and cheap "Self-acting Effluvia Trap," which differs from all previous contrivances. The fault of the old invention was that they were so arranged that a very small quantity of water caused the pan of the trap to fall, and consequently defeated the object of draining the sewer. Bunnett's action was intermittent, continually opening a communication with the sewer, and liable to be held open permanently by any light matter being caught by the rising of the pan. In Mr. Bunnett's improved trap this is avoided by introducing a peculiar mechanical arrangement of the lower part of the contrivance, and the form of the moveable pan, and application of the weight, which admits, under ordinary circumstances, of a constant flow of water through the grating into the pan of the trap and over the edge of the same, both into the sewer or drain, the lower part of the trap being immerged into the water, so as to prevent gases passing through a circu-

GAS IMPROVEMENTS.

(With Engravings, Plate II."

GEORGE HOLWORTHY PALMER, of Westbourne-villas, Harrow-road, Middlesex, civil engineer, for "an improved method or mode of producing inflammable gases of greater purity and higher illuminating power," &c. — Granted April 17; Enrolled October 13.

The first part of this invention relates to an improved mode of setting and arranging the retorts in conjunction with additional vessels called "regenerators," so as to insure their being heated uniformly to the required temperature (as shown in figs. 1 to 6), by which method not only an increase of volume, but also an increase in the illuminating power of the gas is obtained. The heating surface of the regenerators may be further increased by the introduction of metallic chippings, or by sheet iron partitions.

By this arrangement, the gas passes direct from the retorts into the regenerators, where it receives a second dose of carbonic, and then flows in the usual manner through the sealed pipe to the hydraulic main, and then into the mechanical precipitator, to be next explained. The patentee recommends the retorts to be kept at a bright cherry-red heat, and the regenerators at a dull-red heat, visible by daylight.

The second improvement relates to an apparatus called "mechanical precipitator," combined with a refrigerator (as shown in figs. 7 and 8), for the purpose of abstracting the vapours of tar and naphtha, as well as the gaseous ammonia and its compounds.

The third improvement relates to apparatus called "ammoniacal filtering towers," through which the gas passes before it reaches the gas precipitator, being washed in its course by liquid ammonia, descending like rain through one or more perforated plates, as shown in Nos. 1, 2, and 3, in figs. 9, 10, and 11. By this process a further portion of ammonia, contained in the gas, is absorbed without subjecting the remainder of gaseous ammonia and its various compounds; after which, the permanent gases flow from No. 1 condenser into No. 2 steam chamber, when the gas will be again saturated with steam, and will again flow into its proper refrigerator, to deposit the steam charged with another portion of the product in a liquid form. The gas then passes into Nos. 3 steam chamber as before, and hence into No. 3 condenser, where is deposited the remaining ammonia and its compounds, together with a portion of sulphurated hydrogen. All these liquid products are to be made to flow, as fast as they are deposited into the condenser, into a suitable receiver, sealed by an hydraulic joint to prevent the vapour passing through the usual water sealed joint, of sufficient depth to withstand the effects of evaporation from other matter, the water will rise in the body of the trap, until it is about two-thirds full, at which point it raises the balance-weight, and obtains considerable leverage by the peculiar formation of the moveable pan, insuring a rapid discharge of a large body of water, which by its force most effectively cleanses the trap, and flushes the sewer or drain, and instantly recovers its position, with sufficient water to form the joint again, resuming its former action till another stoppage occurs; the form of the trap also insures on the commencement of a thaw the ready ejection of any ice that may have formed therein. The annexed figure is a section view of a street grating and gully hole with the trap, which is represented in its ordinary position, the water flowing from the grating into the body of it, and over the edges of the moveable part into the sewer or drain. The lower part of the body of the trap is immersed in the water which is retained in the moveable part by the counterbalance weight, thereby forming a perfectly sealed joint and effectually preventing any smell from rising.

Another advantage attending this trap is that it can easily be freed to any gully hole, and the price is very moderate, being about £1 each.

Reference to the Engravings.

Figs. 1 to 6 show the mode of setting and heating the retorts and regenerators: fig. 1, a sectional elevation, and fig. 2, a front elevation — each figure shows one-half of a set of retorts; fig. 3, a longitudinal section; fig. 4, a plan of one of the retorts, showing the opening through which the flame rises; fig. 5, sectional plan of the retort; and fig. 6, sectional plan of the regenerators. — Similar letters refer to similar parts: — a, b, c, retorts; d, e, f, regenerators, showing the plates k to increase the heating medium, over which the gas flows from the retorts; g, g, the furnaces; h, f, flues through which the flame rises from the furnaces, and, as indicated by the arrows between and over the retorts and regenerators, to the shaft, and l, m, the blow-holes. There is one regenera-tor to each retort, of the capacity of about two-thirds the latter.

Fig. 7 is a vertical section of the "mechanical precipitator," and shows the same, and the fastened apparatus to precipitate the gas in the chamber h, — the shaft is stepped into the lower chamber and passed through an inclined plane, d, under which the gas blows through the tar passing from the pipe r, and adjoining is a chamber, e, containing a convoluted worm, or refrigerating pipe, g, to cool the gas after escaping from the chamber h, through the curved pipe f. To prevent the gas blowing through the aperture in the inclined plane where the shaft passes, the shaft is inserted in a pipe x, bolted to the inclined plane, being of an altitude sufficient to overcome the pressure of the gas; and instead of being discharged through the hydraulics, it issues through the pipe y.

The pipe is kept cool by a supply of water passing through the chamber e, by the pipe k, entering at the top and discharging by the pipe j. The pipes h and j, together with the chamber e, form a syphon; the legs or pipes, k and j, are furnished with cocks, p, to admit or cut off the supply of water. An air-pump is used to remove the small quantity of air that may be in the syphon; it is
The principal problem is to ascertain the modification due to that defect of the apparatus. The requisite data for this investigation are obtained by the following experiment:—After the tube has been exhausted to a certain extent, the whole apparatus is suffered to remain quiescent, no train being dispatched. The leakage will then be determined, the air inside and outside tube be restored. By observing the rate at which the barometer-gauge falls during the interval, we get—not the rate of leakage—but data from which that rate may be calculated.

The density of air is proportional to the weight, and therefore height, of the columns of mercury. Take 30 inches as the height of mercury corresponding to the atmospheric pressure; then, if the barometer-gauge of the exhausted tube show, for the pressure in it, a height equivalent to 10 inches of mercury (for example), the density in the tube would be to that of the external air as 10 : 30, or for words, 1 : 3 of ordinary density of air. If, after the leakage has gone on some time, the barometer-gauge show a height equivalent to 20 inches for the pressure in the tube, the density will be 20 : 30, or 2 : 3 of that of common air. The difference between the densities in the tube at the two respective periods is 20 : 30 = 1 : 1.5, or, in other words, the ratio of the leakage during any interval is equal to the cubic capacity of the tube multiplied by the fraction expressing the difference of densities during that interval. (The barometer-gauge is so graduated that, for the words, “fraction expressing the difference of densities” in the above, we may substitute, “difference of gauge-heights divided by 30.”)

If this quantity of air were divided by the number of minutes of the interval, the result would be the rate of influx per minute, supposing that rate uniform. This method of investigation is, however, liable to an objection, which our author well states as follows:—

“We have calculated for the extreme indications of the vacuum gauge, and divided by the number of minutes that elapsed during the observations, for the average leakage per minute. Now this method would be perfectly just, were it possible to get a uniformity in the indications that the quantity of leakage is constant, or of the same amount in equal times; but the idea of a constant amount of leakage is altogether incompatible with what we know to take place, when air of atmospheric density is allowed to flow into a vessel containing air of a less density. Here it is obvious that the air in the vessel is continually approaching to a state of equilibrium with that without, and consequently the velocity of influx is continually diminishing until the equilibrium obtains.”

He then proceeds to show, that in those experiments on the connecting pipe of the Dalkey line, in which the heights of the gauge were taken every minute, though the successive differences of height for any number of minutes they do not indicate a uniform rate of leakage, but lead to the directly opposite conclusion, that the leakage was far more rapid at the beginning of the experiment than at its conclusion: and he then makes the following important remark in reference to Mr. Stephenson’s report:—”We are somewhat apprehensive that, by assuming a constant amount of leakage for the connecting pipe, some very erroneous deductions must have been made.”

“But with regard to the valve tube the case is very different; for it is easy to conceive that, as the longitudinal slot or aperture is covered with a flexible substance, this substance will readily accommodate itself to the pressure of the exhausting gas, and by thus diminishing the area of the aperture as the velocity of influx increases, a constant amount of leakage, or nearly so, may happen to be maintained: at all events, it is not inconsistent with the maxims of accurate science, to admit that such may be the case, and it actually appears from experiment that the supposition is not far from the truth.”

If it be conceded that the leakage of the connecting pipe is an avoidable evil, and may therefore be assumed to be wholly remedied, we have very simple means of calculating the effect which the leakage of the main tube has on the velocity of the train. As the passage of unknown quantities of air is assumed as that dangerous, let the leakage corresponding to any proposed working vacuum be ascertained by a separate experiment with the barometer-gauge. We have explained how to calculate, from the fall of the gauge, the quantity of external air which enters the tube per minute, and this being done, may be subtracted from the total quantity of external air the length of tube this quantity of air would by itself occupy, if diluted to the supposed working density. And that length of tube is the measure of the loss of speed of the train during the minute; for

This was, however, Hosking evidently contains so much practical wisdom and cautionary matter that we do not like to dismiss it with a passing notice, but we intend to devote a little time to its consideration. Meanwhile, whatever opinion we may entertain with regard to some of its recommendations, we have seen quite enough of it to feel justified in recommending it to our professional readers.

The authors have published an appendix to these very useful tables, showing how the tables may be applied to side-lying ground, for which they give the following rule—Ascertain the ratio of the areas of cross sections of the side-lying ground to the areas of similar cross sections, that is with same height on centre line, of level-lying ground, and multiply by that ratio the complete quantity furnished by the tables.

This is a novelty for the antiquarian student, which will be very favourably received at the present season, as it contains many curious memoranda and an archaeological calendar for the year. The work is small—which may, perhaps, be an additional recommendation.

LECTURES ON GEOLOGY.

By Professor Amsted. Delivered at King's College, London.

On the Application of Geology to Engineering and Architecture, and the Supply of Water to Towns and Cities.

Professor Amsted commenced his fifth lecture, by considering the question of drainage, more particularly with reference to general engineering, which depended, in many cases, very distinctly on the geological structure of the soil. And it did so naturally, as, for instance, in an ordinary road, properly made, where the drainage would ultimately have reference to the structure of the material and to the rocks in the neighbourhood. With regard to geological structure, it might happen that the beds which came close to the surface would have a strong inclination; and, in that case, where the beds were permeable, the road would be drained naturally, and, where one part lay on an impermeable bed, and the other on a material which suffered the water to percolate through it, an attention to geological structure would enable the road to be made very satisfactorily. This would illustrate the applicability of geological knowledge, even to common road making; but that knowledge was still more directly available in the case of railways, which, running through a long extent of country, involved the necessity of frequent and deep cuttings. In the execution of which, drainage was of great importance. The engineering societies, or geological considerations, must always come in. Suppose, then, they were to take a transverse section of a railway cutting, similar to one of the diagrams exhibited—if the beds were horizontal, the two sides would be situated in a similar manner with regard to accidents arising from unequal pressure; but if they were not the case, and the bed was composed of mud, clay, sand, or any slippery earth, in beds inclined to the horizon, some parts of the superincumbent mass would be more apt to slip down than others. Some strata would carry water, and others would not; and there would be a slip through; and much of that work was done without due regard to these phenomena. In such cases, the speed would wash it away gradually, and, a portion of the support being removed, the upper mass would naturally have a tendency to slide down upon the lower part. If once it began to slide, no matter how slowly—if the speed were only an inch an hour, or an inch a day, or an inch a year, and the preventive measures were made too late, and there would be a slip sooner or later, and especially in heavy rains, or rains combined with frost. But before the superincumbent mass were set in motion, if by any means the water could be prevented from passing through it, and it might be best done by cutting a drain on the other side, by which all the water which came on the surface might be carried off before it reached the sand. There would then be sufficient cohesion to prevent the upper part from being set in motion.

A knowledge of geological structure, in making these cuttings, was exceedingly useful, not only in preventing slips, but in reducing the cost of work. For instance, when the dip was in a certain direction, a slip was more probable, and, making canals, the engineer would constantly have to cut across springs, and through some strata which allowed water to percolate, and through others which actually produced water. In going across a district where there was much leakage, it was necessary to have a perfect knowledge of the nature of those strata, which held the water bound in springs; and of those strata and substances which were impermeable. On such circumstances depended many practical difficulties in the construction of canals. It was a remarkable fact, that Mr. William Smith, who founded about a century ago the science of geological study, in the English geology, was himself a mining engineer, and first observed the geological structure of the country, as it affected the formation of canals. His life, lately published by Professor Phillips, his (the lecturer's) predecessor at King's College, would be found very useful and interesting, as it regarded the practical application of so much of geological science as was known at that day. In the life of Smith would be found some account of the construction of canals in his day, then as important as railways now are. They would see how he brought his knowledge to bear upon the problems at hand, and in that way they might themselves learn how to apply a great deal of that knowledge of geology which they might possess.

Supply of Water.—The Professor next treated of the supply of water as an engineering subject, apart from the supply obtained from land springs, or small Artesian wells, considered hitherto on a comparatively small scale, and rather with relation to agricultural purposes than engineering. The subject of drainage and water supply was, perhaps, connected as much with architecture as engineering; but, when he had discussed its relations to the one, it would most easily be seen how the two might be combined.

With respect to the supply of water, the Professor thought he could not do better than give them a short outline of what had been done lately with regard to the large and most important town of Liverpool, which, he noted, for some time, as a proof of how rapidly the supply of water, and had been more remarkable than any other town in England, for the prevalence of fever, the more than average illness of its inhabitants, and the short duration of life in the major part of it. The members of the corporation thought they were very anxious to remedy the evil, and they certainly one source of those evils—namely, the deficiency in the supply of water. Accordingly, they resolved to obtain an Act of Parliament, empowering them to adopt some measure, which should give the town a largerquantity of that important element. The town was situated on a new
sandstone, and had hitherto been supplied from wells sunk into that stratum, which consisted of a red sand rock, sometimes very soft, sometimes rather hard, and consisting of alternations of a fine red sand and clay, and continuous veins, often filled up with clay, and many of them completely impermeable. The new red sandstone rested upon coal measures, and certainly contained a great deal of water, which was absorbed from the immediate strata above it and from the water in the main channel of the river, which portion was in all probability the main source of the water in the district, which actual limits were ascertainable, since they knew how much fell from the clouds, and how much was evaporated; and they could calculate how much was lost by drainage into the river. The supply thus obtained was found to be sufficient for their wants, or, at least, it would appear to be so, but after close examination it was found that the quantity could not be materially increased from this source. This point, however, had to be decided upon by reference to the structure of the district, and by calculating whether they got all the available water. The total yield of water was then applied to, and after close examination and full consideration, he came to the conclusion that a sufficient supply could not be obtained from the new red sandstone formation, he being of opinion although a somewhat larger quantity might be had of the water which fell on the red sandstone, yet that would not be nearly enough for the requirements present and prospective of a town like Liverpool. What was next to be done? Then came in that admissibility of engineering with geological science, and necessity indeed to every engineer, who wished to do his work satisfactorily, and with the consciousness that most men, from the meagre means had been adopted which the circumstances of the case would allow. The engineers looked about the neighbourhood far and near, their object being to discover where the necessary supply was to be found. One scheme, which met with considerable favour at first, was to tap the water from the Bala Lake, in North Wales, and convey it to Liverpool, a distance of 60 miles, by closed canals. Great natural obstacles, however, intervened, and it was found that this plan involved an enormous expense, with the chance of insuperable difficulties. Another was to dig one or more deep wells; the quantity of water out of the limestones found none the obstacles, which could not be well estimated until the work was attempted. This scheme, after exciting much discussion, was at length abandoned, and the engineers began to look nearer home. After again considering the supply from the red sandstone, it was found that they could not be utilized, and they still had to find a new watercourse, and to fix upon some new and sufficient reservoir. The model on the table, which was an accurate representation of the district, would show that all those points were readily attainable. The drainage was regulated by the shape of the country, and it might be seen either by the Ordnance Map, a contour map, or a model. In this case, he was able to exhibit a model, which was the best; but the Ordnance Map was the guide originally used. Having then found the area, the question whether it would yield a sufficient quantity of water to supply the demand of Liverpool was next to be considered; it involved a considerable amount of knowledge of geological structure. It was easy to tell how many inches of rain descended from the sky on a certain space and in a given time; and they had only to multiply that by the whole area intended; but it was not so easy to determine what was the nature of the surface on which the water alighted; for it would lie in them and evaporate. These and other geological considerations had all to be well considered; but geological science showed that the district, being composed of the bed of hard sandstone, called millstone grit, partially covered over with shallow beds belonging to the coal measures, the sandstone rock, and a certain amount of clay, was capable of a sufficient supply. The sandstone rock, sometimes very soft, was here very hard, a good deal faulted but not open—so that it would allow almost the whole of the water to run off the surface. The consequence was, that almost all the rain that fell ran off the surface, and did not return to the water-table. Outside the city they were in nearly a clay—additional indication that a considerable quantity of fresh water had at some period been there. By means of two or three embankments, these lower districts would thus accumulate that water, which the upper would be allowed to run off. The whole of the rain, which falls upon an area of 47 square miles would thus be collected, producing a supply of 20,000,000 gallons per day, sufficient for the town of Liverpool, and also for the supply of a more useful and permanent water of the Liverpool Navigation and other works in the neighbourhood. Here advantage was taken of the peculiar natural circumstances of the district, to make the minimum quantity of surface produce the maximum amount of water; but which could never have been accomplished, but for the presence of the hard sandstone rock which separated the two, and the clay beneath, which prevents the passage of water through the more sandy bed. Clay was thus found in the shape of subsoil, chiefly used for agricultural purposes. In this case it consisted, not only of silt and loam, but also of sand, which when mixed with water, it might be employed for washing. A good clay brick should consist solely of those materials, without lime or pozzolana, and the free sand was not in sufficient abundance; it must be well mixed with water in the finest powder, and, after burning, and generally speaking, the purest, in the common sense of the word, was the best for making bricks. The clay derived from the decomposition of some of the old rocks was particularly valuable, and that derived from the disintegration of slate is generally most pure, and used in the manufacture of fire-bricks. The purest was the best, and contained the purest, without either alkaline or saline, either of which it makes the brick, in the green stage, not so durable. The brick was then subjected to similar treatment, and burnt to a uniform texture of clay for fire-bricks. Clay—either as a class, was used in the manufacture of the tougher kinds of earthenware. This was a most useful material, and did not require to be so carefully selected as that used for fine pottery and stoneware, and they were charged with it and it was used for the manufacture of materials of past use, but it was not well suited for the making of fire-bricks, though it possessed many separate portions that were so. The mischievous ingredients might indeed be separated, but generally it was not worth the trouble and expense, as there was no great difficulty in obtaining the pure. This clay thus for fire-bricks.
to vary in different localities. Pipe-clay was obtained from beds situated in the midst of other clays, and they appeared to form a band of finer material associated with the others. They were found in a small deposit of flint found at Paris, where it was called argile plasique. The lower beds of the London clay were also described as plastic clay; but they consisted, for the most part, of gravel or pebble beds, for which that was not at all a proper name. Still, some of this material.

Puller's earth was another and a finer kind of clay, used in the filling of cloths, on account of its power of absorbing grease readily from woollens. It contained an unusually large quantity of silice, as compared with the ordinary pipe-clay, the latter being 43 per cent., and 40 per cent. of aluminas; while that of the former was—slica, 53; aluminas, 10; the other parts being made up of iron (about 98 per cent.), magnesia (1 per cent.), and water (24 per cent.). Puller's earth was derived from the Weald clay at Nutfield, in the neighbourhood of Reigate, and from the lower part of the oolite rocks in Wiltshire. In each case there was a considerable variation in the colour, occasioned by the condition of the oxide of iron; but the texture was the same, and the colour was a matter of very little consequence.

Porcelain clay was another important material. This was derived from decomposed felspar, obtained generally from gneiss, or granite. It was the purest of all the clay rocks, being a pure silicate of aluminas, consisting of 60 per cent. of silice, and 40 per cent. of aluminas. A large quantity (8,000 tons annually) of the finer kinds was obtained in Cornwall by artificial washing. Besides this, upwards of 25,000 tons of the coarser kinds was obtained from beds formed by the natural washing of the rains. The decomposed felspar was mixed with water in the artificial process, and moved along at a certain velocity, when the whole was gradually evolving the shape of porcelain from the coarsest. The coarser parts were deposited first, when the mass moved most rapidly; next, the finer parts, as the mass moved slower; and, lastly, the finest of all.

There were other clays worthy of notice, as, for instance, the ochres, red and yellow, the colour being decided by the condition of the oxide of iron, which was present in considerable quantities. These, however, were not important as materials.

From some clays, the substance called shem was derived; but that, like the ochres, was not an important material, geologically speaking, although interesting from the chemical process by which it was obtained. The talented lecturer concluded by briefly describing this process.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

Nov. 29.—A. Poynter, Esq., V.P., in the Chair.

The Secretary read the Report of the Committee appointed to examine the design submitted by the Cavalier Nicolo Matas for the completion of the western front of the Cathedral at Florence. The report expressed in general terms an approval of the design; and stated that the architect has shown judgment in adopting the style of the other parts of the exterior; thus seeking to complete the noble edifice in one congruous character, in harmony with the Campanile and the Baptistery. By this unity of sentiment, the design for the western front appears a consistent and integral part of the structure of the Cathedral. The report said that the design submitted by the architect was worthy of notice, and that the Committee recommended the design for further consideration.

A paper was read by J. Gwilt, Esq., entitled, "Some Discourse on Painted Architecture, in relation to its Symmetry and Stability."

The essay was of considerable length, and traced in a general way the origin of Gothic architecture. Mr. Gwilt stated that of a great number of writers on that subject whom he had consulted, he found that twenty were of opinion that it originated in Germany, fourteen that it was of Eastern or Saracenic origin, six that it arose from the hint suggested by the intersection of Norman arches, four that it was the invention of the Goths, and three that it arose in Italy. Mr. Gwilt was of opinion, with M. Michelet ("Histoire de France"), that when the power of the Church diminished about the year 1200 under Innocent III. the arts, particularly architecture, fell into lay hands to a considerable extent; that the impetus thus given changed its character; and that the hands of the Lodgers which then arose Gothic architecture and all its developments were originated and taught. By this means of drawings and diagrams the gradual growth of the fine forms of Gothic architecture were developed and its principles explained; the latter were to be considered the most material. The principle of the arch and pointed arches in the polygonal apsidal of the cathedrals was the governing number for all the parts of the plan and the place of the details. Many curious instances of these analogies were given. Mr. Gwilt batted the "esthetic" theory, as well as the vagaries, as he called them, of the symbolists.

A communication was read from R. Panson, relative to some mural paintings discovered by him in the church of Longford, in Surrey. These paintings, for the production of which he exhibited by him, represented trapped figures, about three feet in height, on a diaper groundwork, and appeared to have been executed in distemper. They had at some period been covered over with whitewash; on which the Commandments and scriptural texts had been inscribed.

DEC. 13.—S. Angell, Esq., V.P., in the Chair.

A paper was read "On the Principles and Practice of Building Sewers," by E. Panson, jun., Fellow.

The intention of the author was to show that sewers might be effectually constructed with a moderate fall; that no one form of section is applicable under all circumstances, but that no form should materially depart from that of the semicircle; and that a piece of sufficient altitude to allow a man to pass through; that no impendiment should be offered to the continuous flow by cross streams or accumulating deposits; and that cleaning by flushing is an efficient means of removing the silt and other matters in the sewers. Mr. Panson particularly alluded to the necessity of all sewers being of sufficient, but not of more than sufficient, sectional area to contain the greatest quantity of water that may at one time have to pass off—or that, as in the case of districts below the level of high water, they might pass at one time to contain. In reference to the idea of constructing sewers of small size and removing the contents by compressed air, Mr. Panson remarked that, as the pumping power should be at all times equal not only to discharge the average quantity of water, but also that of the greatest quantity which may at any time be required to be passed off, it was obvious that there would be an enormous continued waste of power at a cost more than commensurate to the saving effected by constructing the sewers of smaller size.

SOCIETY OF ARTS, LONDON.

Nov. 10.—Thomas Webster, Esq., F.R.S., in the Chair.

The Secretary read an address on the opening of this the 94th Session of the Society.

Mr. J. Constable read a paper "On Ornamental Art as applied to Ancient and Modern Bookbinding."

The author commenced by stating that the earliest records of bookbinding prove that the art has been practised for nearly 3,000 years; previous to which time, books were written on scrolls of parchment. Some inventive genius, to whom the invention is usually ascribed, was said by the author to have conceived the idea of covering the edges of the pages of manuscripts with gold and silver, boards for the use of the Greek and Roman churches, were covered in gold and silver, and some were also enamelled and enriched with precious stones and pearl of great value. In the 15th century, when art was universal, such men as Albert Durer, Baffafale, and Guille Romano, decorated books. The use of gold and silver in binding books has been continued to this day, and is a separate branch of the arts of printing, and there are many printed books bound in calf with oaken boards about the 15th and beginning of the sixteenth centuries; these are mostly stamped with gold and blud tools: the earliest of these tools generally represent such as Christ, St. George, and the Virgin Mary, and the names of the contents of the book. In the reign of Henry VIII., about 1535, Grafton, the printer, undertook to print the Great Bible, for which purpose he went to Paris, there not being sufficient men or types in England; he had not, however, proceeded far when he was stopped in the progress of this "he- retical book," upon which he returned to England, bringing with him presses, type, printers, and bookbinders, and finished the work in 1539. Henry VIII. had many books bound in velvet, with gold bosses and ornaments; and in his reign the stamping of tools in gold appears to have been introduced. In the reign of Elizabeth, some exquisite bindings were done by embroidery, the queen herself working the covers with gold and silver thread, spangles, &c. Count Grolier seems to have been a great patron of the art on the continent, however, all his books were bound in smooth moire or calf ornamented with gold. The style of the books of Malloil was very similar to that of Grolier, or those of Diana of Poitiers, the specimens done for her being among the finest ever produced, and were without design by Petit Bouchard. The design of Faine was the first Englishman who produced a really good binding, and some of his best works, such as French romances, were powdered with the fleur-de-lis. His books on chivalry had suitable ornaments; on poetical works he used a simple line, and carried the emblematical style of the time, as emblems or devices. He used the same style of binding a work is a curiosity, and shows how moderately he charged:—

"Vaneria produm Rusticum, Parisiensis, Modulxv.

"Bound in the very best manner in the finest green moro-
rocco, the back lined with red morocco. Fine drawing-
paper, coasters, and borders of gold. A few leaves stain at the foredge, which is washed and cleaned.......

0 0 6.
The subject of the book being "Railways," I have ventured to put the Vine Wreath on it, I hope I have not bound it in too rich a manner for the book. It takes up a great deal of time to do these Vine wreaths; I guess within time I am certain of measuring and working the different and various small tools required to fill up the Vine wreath, that it takes very near 3 days time. The next side only of the present communication was by Mr. F. Brothers, "On the Plan for forming a Communication between the Passengers, Guards, and Drivers of a Railway Train."

Mr. Brothers proposes, by means of a fly-wheel, to be worked by the rapid current of air passing through it, to set in motion a multiplying power for the carriage, as the universal joint similar in form and construction with which two whistles shall be fixed; one of these the passengers are to be capable of sounding, by allowing the compressed air to escape. The second whistle is to be of a different size and sound, and entirely under the control of the guard, and only to be used when it is necessary to stop the train.

The first paper was by Mr. F. Brothers on his means of effecting a similar communication. Mr. Allen proposes to make use of electricity as a means of sounding the steam whistles. Galvanised wires are to be carried along each of the carriages of a train, and the electric circuit is to be completed by the use of galvanised coupling chains, which, so long as the circuit is complete, magnetise a piece of soft iron and holds a detent attached to the steam-sock; but whatever the circuit is broken, the iron is denaturated, and the detent is forced to go free upon which the steam escapes, and the whistle thereby sounded.

The fourth paper was by Messrs. Brett and Little, on their method of forming a similar communication. In this plan, in Mr. Allen's, it is proposed to use an electric current, the circuit of which is to be completed by means of wires and chains, but is to act only when the circuit is complete, when a bell is rung.

Mr. Hall offered some remarks on the history of stained glass, and exhibited several specimens of modern manufacture.

Mr. S. Moult has exhibited a model of an "Iron Truss Railway Bridge," the invention of Mr. Bish, of New York. The peculiarities of this bridge are its simplicity, lightness, and strength. The directors of the New York and New Jersey Railroad adopted this principle, the span being 70 feet, and having a double track or runway upon it; the entire weight of metal used in its construction was 13 tons, while its cost was under £500.

A paper was read by Mr. Archer, "On Engraving with reference to Monumental Brasses and Inscribed Stones."

The author commenced, referring to the very early period at which the art of engraving appeared and practised by the lapidary and goldsmith, and the probability that those to whom the art was known were subject to a precise code of laws and connected with the priestly office, these laws having the effect of regulating the productions according to a given standard best up abstractions, and were scarcely swept out of the churches with an unparanoid—few (comparatively) having escaped de-
attribution: some of these, however, the author produced rubbings; and, having traced the history down to the 15th century, and referred to the latest period (prior to those produced under his own direction), he proceeded to urge the desirability of possessing as a nation a complete collection of the rubbings of the brasses of this country, as illustrative of the costume and history of bygone times, and the propriety of such a collection being kept in the British Museum. The former a paper by calling attention to the cartoons of several monuments recently executed by himself, by a new process of working on brass, and which he proposed to communicate to the Society at an early period.

Dec. 8—T. Holroyd, Esq., in the Chair.

Mr. H. C. Cook made some remarks in reference to Mr. Archer's paper on sepulchral brasses, and said that the practice of making brasses for church memorials had become so common, that it was necessary to have a regulation to which must be submitted all the columns of the inscription, so that the inscriptions might be kept in a systematic arrangement. He further stated that his paper was a work in progress, and that he was hoping to have it published in the near future. He also mentioned that he had been engaged in the work of reproducing the inscriptions from the brasses of the old church, and that he had made some progress in this work, which he hoped to complete in the near future.

ROYAL SCOTTISH SOCIETY OF ARTS.

Nov. 8, 1847—David Maclean, M.D., F.R.S.E., President, in the Chair.

The following communications were made:

1. On the first principles of Symmetrical Beauty, as developed in the Geometric Harmony of the Human Head and Countenance. By D. H. Hay, Esq.

Mr. Hay commenced his paper with a quotation from Dr. Reid's "Intellectual Powers of Man," showing that it was the opinion of that great philosopher, that, as taste might be true or false according as it was founded on true or false judgment, it must have first principles. He then observed, that by truth being properly investigated in the natural sciences, real philosophy had arrived at its present advanced state, and its application in the useful arts had consequently produced the happiest results. But that in our search after truth in the science of aesthetics, a very different course has been followed, and that its ideas have been clothed in mystery, and that we have not been able to reproduce the forms of the various branches of knowledge in a great measure upon chance. This he attributed to the practice of service copying in our schools of art, instead of studying the first principles or teachable laws of beauty; for short, that we study and imitate results without inquiring into their causes. He asserted that the first principles of a practical nature, by which the external form of the head and countenance must be determined, and by which the proportionate and relative positions of the features may be arranged upon the facial surface so as to give the most pleasing effect upon the eye. These principles were identical with those which produce beauty in architecture and ornamental design. This he demonstrated by combining in a diagram the Platonic triangles and the curvilinear figures that belong to them, showing, at the same time, that the features of the head were the result of the most symmetrical beauty and harmony in geometry. He showed that this diagram corresponded in all its parts to the anatomy of the human head, and that the countenance thereby produced possessed the "beau ideal" beauty of the finest Greek sculptures. Mr. Hay stated that he believed the principles he explained were known to the ancient Greeks, and were introduced by Pythagoras, and taught by Plato in connection with mathematics, and by Pampilius as connected with art. The drawings by which Mr. Hay exemplified his principle were larger than life, and very numerous, and we understand it is his intention to publish them on a small scale.

2. The Report of the Prize Committee, awarding the Prizes for 1846-7, was read.

Nov. 22—G. Buchanan, Esq., President, in the Chair.

The following communications were made:

1. Suggestions for preventing Accidents on Railways. By J. Stewart, Hume, Esq., of Colquhoun, on the injudicious practice of casting light with heavy carriages in different parts of the train, and to the injudicious applications of the break, and the order in which it is applied; and propose the classification of the light and heavy carriages, and the working of the break from the rear to the front of the train. They have also reference to the permanent works of most railways as originally constructed, being too light and insufficient for the heavier loads and high velocities which are now used; and propose to give increased stability to the rail by a well laid pavement of heavy blocks of stone, and the outside of each rail. They have also reference to what is called "jumping," which is often the case of carriages running off the line—unequal subsidence of the roadway, and proposes Telford's plan for forming the embankments in concave layers, or that the earthworks should be allowed ample space to swell and sink, and to make it impossible for the carriage to get off the track. The suggestions also include the explosions of the buffers, and "riding" on each other; and propose to make vertical movement, the overhang of the buffer, the height of the buffer, and the distance of the lower frame of the carriage, and the upper part, each set connected with a horizontal bar of wood, and the whole covered with boarding. Mr. H. holds that this arrangement would prevent the carriage from turning up and rolling over each other when the cars end to end.

2. Description of a Model of a Maleable Iron Railway Chair. By Mr. Ross, Haddington. The advantages are stated to be greater strength, and thus giving additional security in passing sharp curves; the rails will fit much better from the chairs being all the same and will always be true to the rails; the superior manner in which the wooden keys will fit, and with less rigidity. Mr. Robb thinks they can be made cheaper than cast-iron chairs, and that they would be stronger, although one-half lighter, whereas a saving in cost of carriage would be effected in an extent of 50 per cent.

Nov. 22—G. Buchanan, Esq., President, in the Chair.

The following communications were made:

1. Suggestions for preventing Accidents on Railways. By J. Stewart, Hume, Esq., of Colquhoun, on the injudicious practice of casting light with heavy carriages in different parts of the train, and to the injudicious applications of the break, and the order in which it is applied; and propose the classification of the light and heavy carriages, and the working of the break from the rear to the front of the train. The suggestions also include the explosions of the buffers, and "riding" on each other; and propose to make vertical movement, the overhang of the buffer, the height of the buffer, and the distance of the lower frame of the carriage, and the upper part, each set connected with a horizontal bar of wood, and the whole covered with boarding. Mr. H. holds that this arrangement would prevent the carriage from turning up and rolling over each other when the cars end to end.

2. Description of a Model of a Maleable Iron Railway Chair. By Mr. Ross, Haddington. The advantages are stated to be greater strength, and thus giving additional security in passing sharp curves; the rails will fit much better from the chairs being all the same and will always be true to the rails; the superior manner in which the wooden keys will fit, and with less rigidity. Mr. Robb thinks they can be made cheaper than cast-iron chairs, and that they would be stronger, although one-half lighter, whereas a saving in cost of carriage would be effected in an extent of 50 per cent.
3. Description of a proposed Improvement in Railway Switches. By Mr. Nicoll. Arrows are placed on the signaloods or rails, and a rope is passed through the arrows and a rope as to form a loop, when the motion of the switch is prevented by its getting jammed with dust or rubbish; and the chairs, from their peculiar form, pull aside the dust and clear a way for the switch. Mr. Nicoll also gives a description of the apparatus for opening and closing the switch, so as to prevent accidents by the motion of them by unauthorised persons.

4. A Railway Alarm Communicator. By Mr. Mottay. A device for announcing the arrival of a train to the driver, fixed near the engine. A passenger wishing to receive a signal, pulls the knob by which the bell is rung. This device is also used as a speaking-trumpet, mouth-pieces being inserted in each compartment, and the same to the guards and drivers—so that a passenger having rung the bell, communicates to the guard and driver, &c., his reason for so doing.

5. Description and Drawing of an Aerostat for Railway Trains. By Mr. McColl. The air is enclosed in a whistling valve, and extends along the whole train on the locked side; so that any person, by pulling the air, opens the whistle, and informs the driver that something is wrong.

Dec. 13.—G. Buchanan, Esq., F.R.S.E., President, in the Chair.

The following communications were made:

1. Description of the Overarch Suspension Bridge. By Mr. Milne. This bridge is so constructed that the roadway runs under the arch, and is supported by suspending rods, which are disposed in a portion of the arch, which portion forms a small portion of the bridge proper. Each portion of the bridge bear a concentration of weight at any point. The main rods of the arch lean against each other at the centre (where the key-stone of a stone bridge is situated), giving mutual support, which is continued towards each end of the arch by circular extenders, enlarging as they approach the pier. The pressure of the main rods against each other is thus turned to the utmost advantage, and gives the greatest stability possible; and from this construction the les-side will resist the force of the wind with the full power of the arch. The model is twenty inches in length, on the scale of ten feet to an inch. The entire weight of iron is six ounces, and it safely bears a load of 56lb.—nearly 150 times its own weight.

2. Supplementary Explanations on an Improved Railway Break. By J. Straw. Improved method of forming a break by the inventor to the Society last session. It consisted of a rubber block of wood attached to railway carriages by a moveable frame-work; and applied, not to the wheel, like the common break, but to the rail, by a gradual pressure capable of being increased to such a degree, on an emergency of danger, as to raise the hind wheels from the rails.

3. Improvements in Railways. By Mr. John Crake. The first improvement is for locomotive engines to ascend or descend steep inclines. It consists in laying along the incline a toothed rail, outside of the common rail, and keying on additional wheels with teeth on the shaft of the driving wheels of the engine, outside of the bearing rails, and working in the toothed rails, and the teeth of which are to work in the teeth of the rail; thus, the engine is capable of ascending or descending on a gradient of 1 in 100. The second improvement consists in laying the rails on double flanges, one on the outside of the rails, as well as the usual one within them. Thus the wheels would be less liable to go off the rails. The third improvement consists in laying the rails on longitudinal sleepers, connected together by cross-sleeper, and forming a series of an iron ring square frames. The fourth improvement is for a break. Instead of pressing against the wheels, and thereby retarding them by friction, and eventually locking them, the break falls down once between the wheel and the rail, inserting itself between them like a wedge, and thereby locks the wheels, and, at the same time, rams upon the rail. Four wedges are required for ordinary carriages, one pair at each end; each pair of wedges is connected by a bar of wrought-iron, in the centre of which a chain is fastened, which can be raised by the guard, and fastened by passing one of the links over a hook. When the chain is detached from the hook or button, the break, by its own weight, and guided by a rod attached to the carriage, falls under the wheels and prevents them revolving. The guiding rod has to have its centre of motion eccentric to that of the wheel, and that centre to be pin fixed on the axle frame of the carriage, a little above it, so that the wedges when raised may be clear of the wheels.

NOTES OF THE MONTH.

Railway Precautions. Mr. Wyndham Harding, in a letter to the Institution of Mechanical Engineers, recommends, as the most simple and best method of forming a communication between the guards and engine-drivers, that the guards should have the means of readily getting along every train, whether a passenger or a good train, to the engineer's office. This (he observes) was the original idea in narrow-gauge trains, for the men were always kept from the engine, and has been perfectly carried out, inasmuch as a horse-box or a luggage van afford no facilities for getting past them. Nothing is easier than to remedy this by holdfasts and a narrow foothold. In the case of flat trucks with sufficient space for passengers, a rope was let down from one upright to the other, would afford a hold for the guard, and would also, at the same time, tend to steady the load. In the vehicles which travel in passenger trains even such an addition as this would not be practicable.

On the 6th ult., the Great Western Railway, there is generally no facility afforded for getting along the train, but such facilities can with equal ease be afforded in broad-gauge trains as on narrow by trifling additions to the vehicles. Mr. R. D. Steel, I.Mech.E., the Chief Engineer to the Birmingham, Shrewsbury and Chester division, has authorized the addition of small pole-carriages to the broad-gauge carriages on the Birriol and Gloucester Railway when he had the control of that line.

Commissions of Seers.—The old commissions for Westminster, Holborn, and Soho, &c., are now superseded, and a new commission, consisting of the following, were nominated for all the districts, on the 6th ult. :—Lord Ebrington, Lord Ashley, Dr. Buckland, Mr. Hume, M.P., Hon. F. Amherst, Sir A. S. Meymott, Lady G. Back, Dr. J. Clark, W. Stone, Mr. H. De La Boche, Mr. J. Bidwell, Mr. J. Buller, Mr. W. J. Broderip, Mr. R. L. Jones, Mr. J. Leslie, and Mr. E. Chadwick.—Mr. C. H. Heriot, Clerk of the Westminster division, and Mr. Staples, Clerk of the Holborn and Finsbury division, were appointed clerks of those districts provisionally; and Messrs. Phillips, and Roe were appointed surveyors provisionally, and Mr. Austin consulting-surveyor.

Brussels Laces.—M. Blanchet gave an account of the serious consequences resulting from the process of whitening Brussels lace to the persons employed in it. In this process the carbone du levain is used; and a large portion of it is carried into the atmosphere, where it is inhaled by the lungs, and also the membranes of the intestines. It is also very injurious to the sight and to the hearing.

LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM NOVEMBER 30, TO DECEMBER 22, 1847.

Six Months allowed for Enrolment, unless otherwise expressly.

William Betts and George William Jacob, of Wharf-road, City-road, for "Improvements in the manufacture of capacitors, and in the application of certain descriptions of surfaces."—Sealed Nov. 30.

William Eaton, of Camberwell, engineer, for "Improvements in machinery for twisting cotton or other fibres, and apparatus for the same."—Sealed Dec. 7.

Gustave Moreck, of Wellington-street, Strand, D.L.L., for "certain Improvements in clocks and time-keepers."—Dec. 7.

Thomas Chandler, of Stockton, Wiltshire, for "Improvements in machinery for applying liquid manure."—Dec. 1.

Frederick William Movray, of Leicester, paper dealer, for "Improvements in machinery for the manufacture of looped fabrics."—Dec. 1.

Samuel Newtoning, of Frank, Sussex, M.D., for "Improvements in dibbling or sowing seeds."—Sealed Dec. 7.

John Brookes, of Upper Holloway, M.B., for "Improvements in the manufacture and reeling of sugar."—Dec. 7.

John Britton, of Birmingham, machinist, for "certain Improvements in apparatus for cooking, preparing, and containing human food and drinks, and in opening and closing doors, parts of which improvements are applicable to other similar purposes."—Dec. 7.

James Smith Torpore, of Edinburgh, newspaper-proprietor, for "Improved machinery for supplying signs."—Dec. 7.

William Dakin, of 1, St. Paul's Church-yard, for "Improvements in cleansing and cleaning, coffee, in the apparatus and machinery to be used therein, and also in the apparatus for making infusions and decoctions of coffee." (Communication.)—Dec. 7.

James Sweetman Elfe, Esq., of 40, Lombard-street, City, for "Improvements in the manufacture of astronomical instruments, with the spectacles and telescopes."—Dec. 7.

John Hackett, of Leicester, for "Improvements in the manufacture of pill-booses."—Dec. 7.

Charles William Siemens, of Manchester, engineer, for "Improvements in engines to be worked by steam and other fluids."—Dec. 7.
ARCHED TIMBER VIADUCTS.

(With Engravings, Plates III. and IV.)

In the formation of the numerous railways which have been completed within the last few years, it has been found that the greatest exertion of skill, judgment, and varied ingenuity, is the construction of the bridges and viaducts, whether of stone, brick, iron, or timber. The excavation of a quantity of earth, or cutting through a hill to fill up an adjacent hollow to the required level, is in most cases a work of little more than manual labour, unless some unforeseen extraordinary difficulties occur in the strata, which may require energy and promptitude in adopting such measures as will overcome them in the most effectual and least expensive manner. But when rivers are to be spanned and ravines to be crossed, where there exist uncertain and variable beds, and, in many instances, in the vicinity of towns and populous districts, where houses, manufactories, and other buildings are on the immediate spot, the space required for filling up such ravines with a mound, (the base extending far on each side, beyond what is required for the width of the railway) would, by the consequent destruction of property, often involve such serious expenses, as to render the adoption of that method impracticable. Recourse must then be had to other and more scientific means, in the erection of bridges or viaducts, with piers occupying a small superficial area, but having the necessary superstructure, and adapted to the locality in which they are placed. Various considerations are involved in fixing on a certain plan: yet the cost is that of the utmost importance, and invariably presents itself first in all great works of the kind. It will not be denied, therefore, that the great desideratum for the engineer, is the adoption of such means as will fully answer the purposes with which he is charged, and render this without a waste of any kind of material; for every thing that is not fairly and usefully employed in adding to the stability and strength of an erection, can only be considered as superfluous and injurious matter; and fitness and a skilful disposition of parts, combined with correctness of design, may be said to form the great merit of all structures.

The cost of the construction of viaducts and bridges for railways generally forms so important an item in the gross amount of the cost of a railway, that the engineer is led to devise new means of combining his works in such a manner, as to possess stability and durability, without plunging his employers into unnecessary expenses.

Stone has been generally applied as the best material for bridges; in many cases, however, it cannot be used throughout, and in large arches, where the weights are too low for the spans, cast-iron is frequently adopted. It is light, includes various kinds, when the under side as well as the upper side of the platform is required to be horizontal, or nearly so, as in the case of a railway and turnpike-road crossing each other, and only leaving space enough between the surface of each to allow of the free passage of carriages; but the cost and weight of these bridges is generally equal to that of stone. A wood superstructure, however, effects much in this respect; provided a durable mode of construction is adopted; for the cheapness and strength of the material itself being so great, in proportion to its bulk and weight, the piers of a bridge or viaduct can be considerably lightened, and much less material be used in their formation than when the superstructure is to be of stone or iron.

Almost all the wooden bridges that have heretofore been executed in this country are constructed with straight timbers, trussed and fastened by ordinary flat roofing. The process of shrinking, from the number of joints, and the weight of the stock itself, the roadway sinks, and the framing generally becomes bent or crippled, often to an alarming extent; besides, such a system could never be carried beyond a certain extent, as the spans of such framings, framed and joined in wood in roofing.

A new system of building timber bridges, composed of layers of deals 3 inches in thickness, turned over a centre, into the form of arched ribs, has been introduced and applied extensively, in Northumberland and Durham, and in Scotland, by Messrs. John and Benjamin Green, of Newcastle-upon-Tyne.

This mode of constructing the laminated deal arch suggested itself to Mr. Green in 1827-8, when he was engaged in designing the bridge for crossing the river Tyne, at Scotwood: where the depth of water, its rapidity during floods, and the uncertainty of the foundations, would have rendered it improbable to construct a number of piers, in the current, a very expensive operation, and Mr. Green was therefore induced to recommend to the company the chain bridge which is now thrown across the Tyne at that place, as being the cheapest durable structure, and possessing advantages over every other kind in such a case.

The subject of wooden arches continued to engage Mr. Green's attention, and for his own satisfaction, he had a model made of an arch 120 feet span, at a scale of one-twelfth of the real size, which so satisfied him as to the advantages and safety of that mode of construction, that in 1834, when the Newcastle and Carlisle Railway was offered the best plan of a railway bridge, for crossing the river Tyne, above Scotwood, Mr. Green submitted his model and design in competition, when they were approved of and selected by the directors, and obtained the premium.

This bridge was to consist of five segmental wood arches, each having two ribs of 120 feet span, which were to be erected upon timber piers of piles and framings, with stone abutments. The line of railway could not allow a greater elevation than 21 feet above high-water level, and the platform was consequently suspended with iron rods between the springing of the wood arch and the piers; the roadway was therefore partly suspended from and partly supported by the ribs.

In 1835 Messrs. Green were concerned in projecting a railway from Newcastle to North Shields; and afterwards being employed by the Company for the bridges on that line, where, from the magnitude of two of them and the number that occur, the cost was a very important consideration, they were induced to recommend this plan of the laminated timber arch. Having made designs and carefully studied the details, these bridges were commenced in 1837; one at the Ouse Burn in the eastern suburb of Newcastle, and the other at Wilmington, about four miles further on the railway.

The Ouse Burn Viaduct is 918 feet in length, and 108 feet in height from the bed of the burn; it has five timber arches of three ribs each; three of the arches are 115 feet span, and two 114 feet span; there are two stone arches of 40 feet span at both ends of the bridge, which were introduced to give length to the abutments, so as to prevent the mounds endangering them, by coming too close upon the steep banks of the ravine. There are five piers built of drafted and broached ashlar masonry, from the foundations to the full height, with spaces in the middle, leaving an average thickness of 3 feet of ashlar work; all the spaces are filled with rubble masonry, and covered by coping. On the sides of each pier are buttresses projecting 2 feet 11 inches, and diminishing with offsets up to the roadway.

The greatest thickness of the piers at the springing is 15 feet; that of the highest pier at the foundation is 50 feet 3 inches, and at the top, immediately underneath the platform, 15 feet 8 inches; the wall below the springing is 9 feet 11 inches above the footings, and 26 feet across the last or highest off-set underneath the roadway.

The springing for the arched ribs is 40 feet down the piers, where large off-sets are formed with the inner spays or slopes, radiating from the centre. On these springing stones, cast-iron flanged plates or sockets, each weighing 15 cwt. for each rib, are bedded with oakum, into spaces which are cut 2 inches deep in the masonry, and secured with wrought-iron bolts run with lead, fastened down with nuts and screws on the outer surface; the bolts are 1/2 inch diameter, and 1 foot 6 inches long. The ends of the ribs are inserted into these iron sockets as a springing and are well caulked.

The two middle piers are built upon piles driven into the clay, to an average depth of 35 feet below the surface, and the foundations generally required great attention, for it was found that all excavations made for pit workings had been made around and immediately under the line of the bridge. From the extreme eastern pier, a coal seam had been worked out, extending beyond the east abutment; and in digging for the west pier, a pit shaft was discovered in the centre of the area of the foundation. It was found that it was not so near as to endanger the stability of the pier, and that the construction had not proceeded without its being observed. This shaft had been worked to a depth of 70 feet, and in order to render the structure secure, both it and the seam on the other side of the ravinie were built up with well grouted rubble masonry. All the timber used in the carpentry was of the best.
quality from the Baltic, and the whole of it was subjected to the process of Kyan's patent.

The arched ribs are shown in Plate III., figs. 1 and 2; and in detail, figs. 3 to 12. The spans of 116 feet, have a versed sine of 33 feet, the radius being 68 feet. The ribs are constructed of Dantzick deck deals, 11 inches wide by 3 inches thick, dressed and cut to lengths of from 90 feet to 46 feet. The first course of the rib is two deals in width, bent over the centre, and the next is one whole and two half deals, and so on alternately until the whole rib is formed. The whole deals of the ribs in the workshop, are double tenoned into proper mortices cut to receive them, in the timbers and ribs. A spandril beam 12½ inches square, (figs. 3, 4, 8, and 9, Plate III.,) is placed about the middle of the spandril, inclining upwards to the crown of the arch, and butting against a horizontal piece of the same dimensions. All the struts are double tenoned into proper mortices cut to receive them, in the timbers and ribs. The two main struts, between this beam and spandril, and those above are perpendicular to the roadway. One of the radiating struts in each spandril, called in the drawings the spandril strut, (figs. 5 and 6, Plate III.,) is continued from the rib up to the longitudinal beams, and is firmly connected by iron straps and bolts to them and the spandril beams, and the former are then secured down to the masonry with iron bolts, which run 8 feet into the ashlar work. In considering this geometrical arrangement of strutting in the spandrils, it will be evident how much rigidity is produced: a weight coming upon one haunch of the arch is resisted by the horizontal spandril beam, especially by the main strut, connected as it is with the weight of masonry laid hold of by the bolts, from the main longitudinal beam.

The longitudinal beams, 12½ inches square, are fixed and laid the full length of the structure, to the gradient of the railway, above which they are cut by 6 inches, are laid 4 feet apart, from centre to centre, and spiked down upon them. The ends of all the joists are rounded, and project about 2 feet 6 inches over the longitudinal beams, fig. 10, and the whole are then covered with planking, 11 inches by 3 inches, laid longitudinally, and properly spiked and fixed. The foundation is then extended; this is the foundation, which is laid on the bottom of the foundation, which is laid on the ground, to which it is fixed by the weight of the rails and timbers, which is mixed with gravel whilst it is being laid on; thus forming a coating completely impervious to the wet. At the meeting of the longitudinal beam and the crown piece, an iron strap is bound over them and the longitudinal beam, and it is then run through the rib, and screwed up underneath it. Another strap is put round the rib and the spandril beam, about 12 feet further down on each side, and another at each of the spandril struts. An open rai\l, 3 feet high, is fixed alongside each side of the bridge, the upright struts are 8 feet apart, fixed to every alternate joist, and five horizontal rails, halved and spiked to them, run the full length.

The total width of the Ouse Burn Viaduct, measuring within the rai\l\, is 26 feet, from which a footpath is taken, 5 feet wide, separated from the railway by a line of rai\l\, on the south side, as shown in fig. 2.

In constructing both the masonry and timber work of this viaduct, the scaffolding and the centering were very light and simple. For the former, a temporary railway, 33 feet high, raised upon upright bearers, struts, &c., was laid the full length, on each side of the intended structure, and was afterwards raised, as the building proceeded, to within a few feet of the height of the finished platform. On a temporary rai\l\, parallel to the line of the finished rai\l\, the temporary cranes were placed, spanning from one rai\l\, to the other, connected at the top with beams of timber, and fitted up with proper winches, blocks, chains, &c. &c.; these cranes were generally worked by four men. The centering for turning the ribs and building all the timber work was exceedingly light; it was composed merely of three ribs, weighing about 18 cwt. each, or 2 tons 14 cwt. for each rib. A whole centre could be removed in a day from one arch, and fixed in its place for another arch, by about twenty men, employing the travelling cranes.

The Willington Viaduct is precisely the same in construction and design as that at the Ouse Burn; but differs in its dimensions, and though it is not so high, it is longer, and has two more timber arches of greater span. The total length is 1050 feet, and the height is 82 feet.

There are seven spandril arches and six stone piers, with two stone abutments; five of the arches are 120 feet span each, and two 115 feet span each; the width between the rai\l\, on each side is 21 feet, being just sufficient for the double line of railway, as there is no footpath upon this viaduct. Two of the piers are built upon piles 36 feet long, at a depth of about 50 feet below the surface, as there is a great extent of alluvial deposit immediately on the site, which is frequently covered, during high tides or floods, by the river Tyne flowing up at the small burn.

Both these viaducts span over numerous houses and manufactories.

The method of building the viaduct as Willington was somewhat different from that adopted at the Ouse Burn, and perhaps not so unique; inasmuch as there were not travelling cranes or temporary railway, and the removal of the centres was attended with greater labour, for while at the Ouse Burn the removal of a centre occupied twenty men, with the cranes, only one day, the same work occupied twenty men for ten days at Willington. The masonry of each pier was set with a fixed or jib crane, of a sufficient height to hoist all the stones, having the usual counterbalance at the opposite end of the horizontal beam.

In this system of timber bridge building, the straight trussing in the main principle of support, is dispensed with, for the spandril frames are not to be looked upon as a separate or independent factor; it is merely a continuation of the wood-work, to convey the weight coming upon the roadway, on to the simple curved rib, and all timbers in a state of tension are avoided, for when a weight comes upon the roadway, the whole of the structure undergoes compression.

It is not meant to advocate timber bridges on this or any principle in preference to stone, or other more durable material; but it will not be denied, that the great saving of capital in the first instance is a very important argument in favour of their adoption.

The actual cost of the Ouse Burn Viaduct, including all contingencies and extras, was:—for masonry, 17,833; for carpentry, 7,261; making together, 24,500.

The total cost of the Willington Viaduct, was:—masonry, 15,159; carpentry, 10,349; together, 25,509.

The piers, Mr. Green observes, are stronger than necessary for the weight of the superstructure, for the directors of the Newburn and North Shields Railway, in the first instance, attached the greatest importance to the safety of this novel mode of construction, but having a desire to finish all the bridges on the line with stone arches, wished the masonry to be made of such solidity and bulk as to bear stone arches if required, and the piers and abutments were, therefore, built accordingly. The additional cost for building stone arches, however, on a fair calculation, was found to amount to 9,000/. for the Ouse Burn Viaduct, which would have made a total of 33,500. The centering would have cost at least 3,000/ for each viaduct, so that at a moderate calculation the actual saving of capital is upwards of 10,000/.

Messrs. Green have just completed a large viaduct, on precisely the same principle as those of the Ouse Burn and Willington Dean, for his grace the Duke of Buccleuch, across the South Esk at Dalkeith, in connexion with the Edinburgh and Dalkeith Railway, and the extraction of coal from the collieries of his grace in that neighbourhood; it has only a single line of railway and a footpath. The total length of this work is 830 feet, the height is 87 feet to the platform, and the width across the rai\l\, is 14 feet. It has seven arches, five of 120 feet, and two of 110 feet span each, with a spandril beam 30 feet 8 inches apart, in each arch, and of a deal and a half (1 foot 4 inches) in width, and ten deals (2 feet 7 inches) in depth. The longitudinal beams are half balks of timber, 13½ inches by 62 inches. There are two stone abutments, each 40 feet long, and five stone piers. The height of the pillar is 91 feet, 4 inches, and the width 10 feet 8 inches. The total cost was:—masonry, 3,511; carpentry, 3,356; together, 6,867, which is a very small amount for a work of such magnitude.
The great height and length of this bridge, and the extreme lightness of its construction, render it an imposing object, spanning a beautiful and thickly wooded ravine near Dalkeith Palace, with the river Esk streaming through it, and appearing as a mere line of water in passing under the centre arch, which is the largest and highest.

The system of arching with planks, may be carried to almost any extent, and in Mease's Green's design for the proposed bridge across the Tyne, to connect the towns of Newcastle and Gateshead, at a high level, the largest arch over the middle part of the river was intended to have been 280 feet span, with a versed sine of 70 feet, the total length of the bridge as designed was 1,220 feet, and the height 110 feet.

Fig. 1.

The annexed wood engravings show an oblique bridge on the Newcastle and North Shields Railway, crossing the Shields road, at Walker. The angle of the skew is 25°, and the span is 71 feet. Fig. 1 is an external elevation of one of the ribs and the piers, and

fig. 2, a plan of the joisting and piers. The joists of the platform rest upon the longitudinal beams, which are suspended by queen posts and iron straps, from two arched ribs, one on each side of the railway, and stiffened by struts and braces. The ribs are formed of deals 11 inches by 3 inches, dressed one deal and a half for the width of the rib, and nine deals in depth, as shown in figs. 3 and 4.

They spring from cast-iron sockets, bolted to the ends of the longitudinal beams, on which they abut. An iron strap is also keyed over each foot of the ribs, for additional security. The width for

the railway on the bridge is 91 feet 6 inches. In the centre, at intervals of about 7 feet, the platform is strengthened by trusses, which are marked b, fig. 2, and constructed in the manner shown in fig. 4, with wrought-iron bars keyed at the ends of the beams, and coming underneath, having three iron bearers for the full length. The cost of this bridge was about 1,300£.

Fig. 4.

The DINTING VALE VIADUCT, on the line of the Sheffield and Manchester Railways. By ALFRED STANLEY JEE, M. Inst. C.E

(With an Engraving, Plate IV.)

This viaduct consists of sixteen arches, five of which are of timber and eleven of brick, faced with stone quoins. The whole of the large piers, wings, outside spandrils and parapets, are of ashlar stone, of excellent quality, from the quarries in the neighbourhood. The foundations of some of the piers are laid upon the hard shale, and of others upon a bed of wet sand of considerable depth; in the latter cases masses of concrete were formed to receive the masonry. Several of the smaller piers are founded upon the marl; also with beds of concrete beneath them. The piers for the large arches are built solid, up to the surface of the ground, and above that level they are hollow, nearly up to the impost; the hollow portion having an inverted arch at the bottom, and being also arched over at the top. The portion above the impost in the large piers is solid to the top. (see fig. 3.) The smaller piers are cased with ashlar on the outside, and are filled in solid with good flat-bedded rubble, well grouted, and with through stones at intervals of 6 feet horizontally in each course.

The smaller semicircular arches of brick, at each end of the viaduct, are 80 feet in the span and 3 feet in thickness, with stone quoins, and are built in a curve of 40 chains radius. The face of each pier is parallel to that of the next, the piers themselves being wedge-shaped, on account of the curve. The abutments between the large and the small arches are hollow and are arched over in the interior to carry the roadway. The abutments and wings at each end of the viaduct, are also hollow, being composed of longitudinal and cross walls, flagged over on the top. They are surrounded on the outside by the slope of the embankment, the material of which being clay, is kept out by a wall at the ends.

The five large arches are each 126 feet span and 28 feet versed sine, of the best Memel timber, the whole of which has been immersed in a solution of the sulphate of copper, according to Dr. Margary's patent, for the prevention of decay. There are four main ribs in each arch, composed of planking 3 inches thick, laid longitudinally, with a layer of brown paper and tar between the planks, which are fastened together with oak treenails at intervals of 4 feet. These ribs are 5 feet 6 inches deep, and 18 inches wide, and are firmly stayed by diagonal and cross braces, screwed up tight, by means of wrought-iron rods, 2 inches in diameter, passing through and secured by nuts on the outsides and diagonals in the spandrils are also stayed by iron rods, and are morticed into the longitudinal beams which carry the cross joisting. These longitudinal beams are fastened down upon the piers by iron bolts, let 19 feet into the solid stonework, to resist any tendency of the arch to rise in the haunches, when the weight of a train comes upon the centre. The cross joists are placed 5 feet apart, from centre to centre, and are bolted to the longitudinal beams underneath. Upon them is placed longitudinally a half-balk of timber, to which the rails and chairs are fastened, and also a guard rail to prevent the carriages getting off the road. The whole is covered over with planking 3 inches thick, and is coated with a mixture of lime, ashes, and sharp sand, which has set hard and does not crack.

The centering used for turning of the arches is of iron, of light construction, and is shown in fig. 1.

The total length of the viaduct is 684 yards, and its greatest
height from the brook-course to the rails, is about 122 feet. The
roadway is level throughout. It was commenced early in 1843, and
was opened for traffic on the 8th of August, 1844. Messrs.
Buxton and Clarke, of Sheffield, were the contractors, and great
credit is due to them for the very excellent manner in which they
have completed the work.

The area of the section of the valley crossed, between the level
of the rails and the ground, is 13,068 square yards, which gives an
average cost of about 2d. 14½ per superficial yard, and as the viaduct
is 8 yards wide, the cost per cubic yard is 6s. 8d.

The following is a detailed account of the cost of construction of the
Dinting Vale Viaduct, on the line of the Sheffield and Man-
chester Railway.

THE RIVAL PALACES,
OR, BLORÉ'S AND VANVITELLI'S.

By candid.

Neither Mr. Sharp himself nor any one else will be at all sur-
priised at my taking some notice of the oversight imputed to
him by those who have the care of Buckingham Palace, for not discover-
ing that it is "only a reduced copy of the Palace at Caserta." 
Willing as I am to accept the compliment of "lynx-eyed," I think
that in this instance it rather belongs to him, though at the same
time I fancy his sharp-sightedness has overshoot the mark, and
made that kind of discovery which is called finding out a mare's
nest. What appears to Mr. Sharp to be such perfect similarity of
design between the two buildings, that all the faults or merits of
Mr. Bloré's fairly belong to Vanvitelli, completely vanishes upon a
critical examination and estimate of them, nothing remaining but
that general or generic resemblance of forms and features which
they possess in common with many other buildings in the same
style. Those who talk merely at random might perhaps liken
Buckingham Palace to that at Caserta, for much stranger resem-
bances have been fancied ere now,—one traveller having likened
the palace of Charles V. in the Alhambra, to Jones's Whitehall,
and another, the great temple at Balbec to St. Paul's, Covent-
garden! But that an architect should be more struck by the
resemblance, such as it is, than by the prodigious difference be-
tween the two buildings in question, is quite astonishing.

Let us inquire to what the resemblance amounts,—to nothing
more than the general disposition of parts, both vertically and
horizontally, which surely is not sufficient to constitute such simi-
larity of design or character as to justify our calling the one a
copy at all, much less "only" a reduced copy of the other. If it
does, we should be warranted in setting down all the porticoes ever
erected as only so many verbatim transcriptions of one original; or
we might call—as perhaps Mr. Sharp does—the two terraces at
Carlton-gardens a copy of the Garde-meuble in the Place de la
Concorde. In fact, it requires Flueellen's ingenuity in arguing
to convict Mr. Bloré of being, I will not say Vanvitelli's ape, but his
"There is a river in Macedon," says the Verhahan, and
"and there is also moreover a river at Monmout;—and there is
salmons in both." Even were Mr. Bloré's elevation a mere re-
duced draught of the other, as far as what actual resemblance
there is between them extends, as a copy it could be received only
as an exceedingly maimed and imperfect one, some of the most
striking parts of the original being altogether omitted. One ex-
ceedingly important accompaniment to the edifice at Caserta, and
which gives it an air of completeness and consistently-kept-up
stateliness in regard to emplacement, greatly surpassing that of any
other royal palace in Europe, is the spacious oval park in front of
it on its south side, where it forms an expanding amphitheatrical
area, somewhat after the manner of the piazza before St.
Peter's at Rome. Many other royal residences, on the contrary,
are so disadvantageously located, as to have an air of meanness
about them in spite of their own grandeur.

One point, then, of the resemblance contended for is utterly
wanting, since Mr. Bloré's building has no architectural precint
or properly defined enclosure before it, but is made to stand imme-
diately in the Park, and moreover stands out very awkwardly and
abruptly from Nash's building behind, from which it appears quite
inconspicuous. Certainly it is not a fact that it is prettier than the
other, or that the imitation is after all superior. By making the
entire mass look larger than before, it causes it to have a singular-
ly confused and huddled-up appearance. Even taking the mere
erection of the front alone, there is a prodigious difference as to
outline, the angles of the building at Caserta having carried up
higher than those at the Park, the addition of the second storey, by
the addition of a separate second order, comprising two stories, and
making the entire height there not less than one hundred and ninety
English feet. My calculation is from the scale given in the large work
containing plans, &c., of the palace, entitled "Dizionario dei Decorati del Regno
di Sicilia, e di Caserta," &c., and which, strange to say, is not mentioned
by either Millizia or Quatremère de Quincy. In the "Conversations-
Lexionor für Bildende Kunst," which professes to give account of
individual buildings of note, the Palace of Caserta obtains only
three lines out of which it is to tell us that there is architecture by
Mengs in the chapel.—With regard to Mr. Sharp's statement as
to the length, there seems to be some miscalculation or else mis-
print, since 918 palms (taking the palm at 10½ inches) give only
790 feet.

Now that so much fault has been found with his building, and no
merit whatever discerned in it, Mr. Bloré may possibly be disposed to
acquiesce in the charge of plagiarism brought against him, in
order to transfer all blame from himself to Vanvitelli. If he has
copied or borrowed, he has at least, it may be said, gone to a noble
model, which is a thousand times better than what was seen by him
in his "Encyclopedia of Architecture," as the most complete example of
a royal Palace. So far, however, from reconciling us to Mr.
Bloré's work, by what may be thought to afford sufficient precedent
for one or two objectionable points, Caserta,—any comparison with
which will not only make the present building appear coarse and
meaner than ever. By diminishing the scale so very greatly, Mr.
Bloré has exaggerated the defects and entirely missed all the meris
of his supposed original, transmuting grandiosity into insignificance
and triviality. In the mere design of Caserta, there is little to
evoke particular admiration; it is one of those things of which a
"reduced copy," however accurate, can no more convey the actual
impression it makes than a life-sized copy of it can that of an
enormous colossal figure.

Caserta is especially distinguished by a union of qualities that
render it peculiar of its race, and especially by the emphatic vastness of mass and uniformity of design throughout.

Its mass is such, that were the several ranges of building which compose its exterior, together with those that separate the inner
courts, placed beside each other on a single line, similar to the plan of
the Tuileries, they would form a façade full three times the length of that of the last-mentioned palace, or considerably
more than three thousand feet in extent. What enhances astonishment,
although it adds nothing to the merit of the structure, is the ex-
traordinary energy with which the works were carried on, the
workmen not being idle about half a century; whereas many others,
of far less magnitude, have either grown up piecemeal, or have occupied a long series of years; so as not to
have been begun and terminated by the same architect.

From the way in which Mr. Sharp has expressed himself, it
seems to be his opinion that,—the similarity of design which he
insists upon being admitted,—Bloré's façade so fairly represents
Vanvitelli’s (i.e. one of them), as to exhibit all its merits, notwithstanding that it exhibits qualities precisely the reverse. Yet, surely littleness and magnitude are very different in effect; or shall we say, that if he be similarly shaped and proportioned, a dwarf can give us a very satisfactory idea of a giant? Those who hold such doctrine, ought to show their consistency by taking a sixpence, or any representative of, and equivalent to, a shilling. Hardly can I bring myself to believe that Mr. Blore had any idea of palming upon us a Tom Thumb Caserta, because, leaving plagiarism out of the question—and in architecture plagiarism has ceased to be any demerit or disgrace—he must have been perfectly aware that he must fall so greatly short of Vanvitelli’s standard, that likeness in other respects would, if detected, only produce ridicule. No, what kind of likeness there is between the two designs is merely a coincidence, and for Mr. Blore rather an unfortunate one. Had it been intentional and “with malice prepense”—had Mr. Blore really fancied that he could reproduce Caserta, he would no doubt have avowed the imitation, have made it a merit, and have crushed criticism in the bud, by proclaiming that he was about to give Buckingham Palace a façade “after” that of the noblest residence in Europe.”—In such cases, be it observed, the after generally means a long way behind the prototype; and the following are the respective measurements of some of the parts of the two buildings which will show that Vanvitelli’s afforded no precedent for the mezzanine of Mr. Blore’s.

**Caserta.**

| Basement or ground floor, messanine | 47 | n. in. |
| Gateway through ditto | 16 | 6 wide; 36 2 high |
| Principal floor windows | 6 | 10 wide; 14 0 high |
| Columns | 48 | 0 high |

**Buckingham Palace.**

| Basement | 26 | 9 high |
| Gateway: centre one, lesser ones | 13 | 6 wide; 21 0 high |
| Principal floor windows | 4 | 6 wide; 11 0 high |
| Pilasters | 34 | 0 high |

After all, its elevation has been so much better, Mr. Blore’s building would still have been open to some of the strongest objections brought against it now, viz., that it seems to encroach upon the Park in such a very awkward manner, as to appear a more lumpish mass than it otherwise might do, and that blocking up all the rest of that side of the Palace, so far from improving the main edifice, it has frustrated that opportunity of improvement which previously existed, and which, since alteration to such extent was determined upon, ought to have been made the most of. As a range of building the new façade is scarcely more effective than the neighbouring barracks in the Birdcage Walk, to which it may in fact be likened quite as correct as to Caserta; nor would that comparison be, though less flattering, quite so injurious as the other, inasmuch as it must then be admitted that, instead of there being any falling off, the model had been refined upon.

One defect in regard to position, now rendered very prominent by the building being brought so much forward into the Park, is that the Palace is not in the axis of the Park itself, but only of the Mall; whereas, were Mr. Blore’s structure planted at the other extremity of the enclosure, on the site of the Horse Guards, it would there show infinitely better in every respect, and, with some slight corrections, might pass for a handsome piece of architecture. As it is, it is altogether out of place, out of character, and the reverse of satisfactory in effect; nor can I agree with Mr. Sharp that were Mr. Blore “to give the Palace a staircase resembling that at Caserta, the world would forgive him all the faults of his front,” because while those faults would be just as evident as ever, the public would have no opportunity of admiring the staircase. Besides which, it would require the architect to be the Bottle-Conjurer to get such a staircase into Buckingham Palace; and even could it be effected, it would reduce all the rest of the interior to utter inutility. One other remark, and I have done: for what will perhaps be considered lengthiness and loquacity I have no precedent in what Mr. Sharp’s companion, Woods, says in his “Letters” of Caserta, for he dismisses it with little more than a bare mention of it,—with a degree of chilling indifference that does not say much for him either as an architect or a critic.

*Quotemece de Guicci says of Caserta: “Una più grande concezione de palacie n’estre posta in Europa.”*

---

**ON THE LAP AND LEAD OF THE SLIDE VALVE.**

(Concluded from page 17.)

**THE LAP AND LEAD.**

Having separately investigated the two cases of a slide having Lead without Lap, and Lap without Lead, we now proceed to consider the effect of both in combination, together with that of lap on the exhaustion side.

**Demonstration.**

**Case 4.—When a Slide has Lap on Both the Steam and Exhaustion sides, together with Lead.**

Let $a b$, and $a c$, diagram 5, represent the double lap on the steam side; $a f_1$ and $a g$, the same on the exhaustion side; $b e$, and $cd$,

![Diagram](image)

the steam ports; and the lines $e d$ both the travel of the slide and stroke of the piston. Then, supposing $c h$ to represent the lead of the slide, $a e$ will be the position of the eccentric when that of the crank is $a e$; the slide occupying the position shown in fig. 10, and the piston being at the top of its downward stroke.

---

*Fig. 10.* *Fig. 11.* *Fig. 12.* *Fig. 13.* *Fig. 14.*

When the eccentric reaches the point $k$, the port $c d$ will be fully closed (as shown in fig. 11), and the piston will have descended to $l$, the arc $e m$ being equal to the arc $i k$. Again,—when the eccentric arrives at $n$, the slide being then brought into the position fig. 12, exhaustion commences from above the piston, which has descended to $o$; the arc $e m p$ being equal to the arc $i k n$.

When
the eccentric arrives at $r$, the port $e$ begins to open for the admission of steam beneath the piston (see fig. 13), which has then descended to $r$; the arc $e ms$ being equal to the arc $k q$. When the eccentric has reached the point $l'$, opposite to $l$, the port $e$ will be open to the extent of the lead $h_i$, equal to $c h$, and the piston will have completed its descent.

Steam continues to enter the port $e$ during the ascent of the piston, until the eccentric reaches the point $k'$, when the port $e$ will be closed (fig. 13), the direction of the slide's motion being downward, and the piston having ascended to $l'$. Exhaustion ceases from above the piston when the eccentric reaches the point $l'$, the piston being then at $u$, and the slide again in the position of fig. 12. When the eccentric reaches the point $n'$, opposite to $n$, exhaustion commences below the piston, the slide being then in the position fig. 14, and the piston at $s'$. Finally,—when the eccentric reaches the point $q'$, and the crank the point $s'$, opposite to $s$, steam begins to enter the port $c d$ for the return stroke, at the commencement of which the port $c d$ will be open to the extent of the lead $e c h$. The crank and eccentric occupying their original positions, $a c$ and $a t$.

It is here shown that four distinct circumstances result from the use of a slide having lap on both sides of the port, with lead, during a single stroke of the piston. These are:

**First**: The cutting off, for the purpose of expansion. **Second**: The cessation of expansion, and the exhaustion side. **Third**: The commencement of exhaustion on the steam side. **Fourth**: The re-admission of steam for the return stroke.

With regard to the first of these results, we found the steam port $c d$ closed, when the crank and eccentric had described the equal arcs $e m, i d q$, and $i d k$. Now, $c d$, the steam port, is the versed sine of $d k$; and $h d$, the steam port minus the lead, is the versed sine of $i d$. Hence, RULE V.—To find the point of the stroke at which steam will be cut off:

Divide the width of the steam port, and also that width minus the lead, by half the slide's travel, and call the quotients versed sines. Find their corresponding arcs, and call them the first, and arc the second, respectively. Then, if the sum of these arcs be less than 90 degrees, multiply the versed sine of their sum by half the stroke, in inches, and the product will be the distance of the piston from the commencement of its stroke, when the steam is cut off.

If the sum of arcs the first and second exceed 90 degrees, subtract it from 180 degrees; and the versed sine of the difference, multiplied by half the stroke, equals the distance of the piston from the end of its stroke, when the steam is cut off.

**Example 8.**—The stroke of a piston is 60 inches; the width of steam port 3 inches; and the slide's travel is 4 inches. Required the point of the stroke at which steam will be cut off.

Here $3 + 2.5 = 5.5 = \text{versed sine of } 58.5\text{'}$ (arc the first);

and $3 - 2.5 = 0.5 = \text{versed sine of } 58.5\text{'}$ (arc the second).

Then $60 \times 58.5\text{'} = 3510\text{'}$ (arc of versed sine); $5019\text{'} = 30 \times 165\text{'}$ inches = distance of the piston from the end of its stroke when the steam is cut off.

Exhaustion was shown to cease, during the ascent of the piston, when the eccentric had reached the point $t$, and the crank the point $r$; the crank having described the arc $k x, r$ equal to $e t$, described by the eccentric.

Now $e t$ is equal to the arc the second (Rule V.); and $e t$ is equal to 90 degrees minus $t r$, or the arc of versed sine $e f$; and $f$ is half the slide's travel minus the lap on the exhaust side. Hence, **To find the point of the stroke at which exhaustion ceases**:—Divide half the slide's travel, minus the exhaustion lap, by half the travel, call the quotient versed sine, and add its corresponding arc, called the third, to the arc the second, and find the difference between their sum and 180 degrees, multiplied by half the stroke, equals the distance of the piston from the end of its stroke when exhaustion ceases.

**Example 9.**—The several proportions being as in the preceding example,

Here $3 + 2.5 = 5.5 = \text{versed sine of } 58.5\text{'}$ (arc the first);

and $5.5 - 2.5 = 3 = \text{versed sine of } 92.5\text{'} = \text{arc the third}.$

Then $88.5\text{' - }56.5\text{'} = 32\text{'} = \text{arc of versed sine, } 145\text{'}.$ $145\text{' \times }30 = 4350\text{ inches } = \text{the distance of the piston from the end of its stroke when exhaustion ceases.}$

Exhaustion was shown to commence from above the piston when the crank and eccentric had described the equal arcs $k' i$, and $i d n$. Now $i d n$ is equal to 180 degrees minus $n' i$; $n' i$ is equal to $n$; and $n' d$ is equal to the third. Hence, **To find the distance of the piston from the end of its stroke when exhaustion commences**:—Subtract arc the second from arc the third, and multiply the versed sine of their difference by half the stroke. The product will be the distance required.

**Example 10.**—The proportions being as in the two preceding examples.

Here $88.5\text{' - }56.5\text{'} = 32\text{'} = \text{arc of versed sine, } 145\text{'}.$ and $145\text{' \times }30 = 4350\text{ inches } = \text{the distance required.}$

Steam was found to be re-admitted for the return stroke, when the piston had reached the point $r$ in its descent, the crank and eccentric having described the equal arcs $k' s$, and $i d q$.

Now, $i d q$ is equal to 180 degrees minus $q' i$; $q' i$ being diametrically opposed to $i$. And $q' i$ is equal to $i g'$, the distance between arcs the first and second. Hence, **To find the distance of the piston from the end of its stroke when steam is re-admitted for the return stroke**:—Multiply the versed sine of the difference between arcs the first and second by half the stroke, and the product will be the distance required.

**Example 11.**—The proportions being as before.

Here $62.5\text{' - }56.5\text{'} = 6.4\text{'} = \text{arc of versed sine, } 0055.$ Then $0055 \times 30 = 15165\text{ inches } = \text{the distance required.}$

**Rule VI.**—To find the proportions of the steam lap and lead; the points of the stroke where steam is cut off, and re-admitted for the return stroke, being known:

When the steam is cut off before half-stroke, divide the portion of the stroke performed by the piston, by half the stroke, and call the quotient versed sine. Likewise, divide the distance of the piston from the end of its stroke when steam is re-admitted for the return stroke, by half the stroke, and call that quotient versed sine. Then find the difference between the last two quotients, and divide by half the travel of the slide, and call the quotient versed sine, the lap.

When the steam is to be cut off after half-stroke, divide the distance of the piston from the end of its stroke by half the stroke; call the quotient versed sine, and subtract its corresponding arc from 180 degrees. Divide the distance the piston has to move when the steam is admitted for the return stroke, by half the stroke; call the quotient versed sine, and find its corresponding arc. Then proceed with the two arcs thus found, as in the former case.

**Example 12.**—The stroke of a piston is 60 inches; the width of steam port 3 inches; and the distance of the piston from the end of its stroke when steam is cut off 15036 inches; and when steam is admitted for the return stroke 165 inches: required the lap and lead.

Here $15036 \div 30 = 5019\text{'} = \text{versed sine of arc } 60\text{'} 5\text{'}$; and $180 - 60\text{'} 5\text{'} = 119\text{'} 55\text{'}.$

Then $165 \div 30 = 0055\text{'} = \text{versed sine of } 6.4\text{'}.$ $119.55 + 6.4\text{' = }126.55\text{'}.$ $119.55 - 6.4\text{' = }113.54\text{'}.$

$126.56\text{' - }2 = 126.54\text{ = arcc of versed sine } 3454.$ $119.54\text{' - }2 = 56.5\text{ = arcc of versed sine } 3454.$

$3 \div 5454 = 5.5\text{ inches } = \text{half the slide's travel};$ and $5.5 - 3 = 2.5\text{ = lap.}$

$5454 - 3454 = 0090; \text{ and } 0090 \times 5.5 = 5\text{ inches = lead.}$

**To find the Lap and Lead by Construction.**

The stroke of the piston; width of steam port; and distances of the piston from the end of its stroke when the steam is cut off, and when it is re-admitted for the return stroke, being known:
Let the circle (diagram 6) represent the crank's orbit, and its diameter $a b$ the stroke of the piston, to some known scale. Make $a c$ equal to the part of the stroke performed before the steam is cut off; and $b d$ equal to the distance of the piston from the end of its stroke when steam is re-admitted for the return stroke. Draw $d e$ and $c f$ at right angles to $a b$, and mark the point $g$ at the distance $b e$ from $f$. Bisect the arc $a g$, and from the point of bissection, $b$, draw the diameter $h i$. Make $i k$ equal to $b e$; draw $i m$ and $k i$ at right angles to $a b$; and draw $i l$ and $i b$ indefinitely. From the point $m$, set $o f$ $m n$ equal to the width of steam port, full size; from $n$ draw $n p$ parallel to $i m$, and meeting $i b$, and also $o p$ parallel to $a b$, and meeting $h i$: then will $s p$ equal the lap, and $a r$ the lead.

In all the foregoing cases, we have taken the versed sine of the arc described from the crank, from either extremity of the stroke, as the portion of the stroke performed by the piston; but, as has been already observed, the relative positions of the piston and crank depend upon the length of the connecting-rod, which will be seen by reference to diagram 7, where $A B$ represents the stroke of the piston, $C D$ the connecting-rod, and $D O$ the crank. Now, by supposing $a d$ to be the arc described by the crank when the piston has performed one-fourth of its stroke, and from the length of that arc, calculating the amount of lap required to cut off the steam at that part of the stroke, we appear to be in error—for, from the oblique action of the connecting-rod, the piston would have descended only to the point $c$. But the engine being double-acting, we have to take into consideration the position of the crank when the piston has performed one-fourth of its stroke in the opposite direction from the point $B$: and here we find, that by supposing the crank to have described the arc $a b c$ (equal to $a d$), instead of the true arc $b E$, we cause the steam to be cut off when the piston has reached the point $f$; and the distance $B f$ being precisely as much more than $B F$ as $A c$ is less than $A C$, the seeming error is self-corrective.

A Table of Multipliers to find the Lap and Lead, when the Steam is to be cut off at 1/4 to 1/2 of the Stroke.

Example of its application.—Stroke 36 inches; width of port 2 inches; steam to be cut off at half-stroke; distance of the piston from the end of its stroke when steam is re-admitted for the return stroke, 1 5 inches.

Then $2 \times 1 91 = 2 42$ inches $= the\ lap.$

And $2 \times 638 = 1 276$ inches $= the\ lead.$

R. B. C.

HEALTH OF TOWNS COMMISSION.

We may seem to be rather late in noticing the first report of the Metropolitan Sanitary Commissioners, but the first number of our new volume was so filled with other matter, that we were unable to do more than to call attention to the unfair way in which the profession has been treated by the commissioners and the government. Since then we have been uneasy as to the manner in which employing military engineers in making the survey of London is persisted in, and that at a time when numbers of experienced and well qualified surveyors in the metropolis are without employment.

The first part of the Report is devoted to the consideration of the means necessary to resist the cholera. After a careful investigation, they come to the conclusion, which appears to us to be well founded, that cholera is not contagious, and that the great means of lessening its ravages are to be found in improved sanitary arrangements, particularly in connexion with the sewages.

The second part of the Report is devoted to the consideration of the means necessary for preventing the cholera. After a careful investigation, they come to the conclusion, which appears to us to be well founded, that cholera is not contagious, and that the great means of lessening its ravages are to be found in improved sanitary arrangements, particularly in connexion with the sewages.

To improve the sewages is their first step, and they have recommended and obtained the revocation of the old commissions of sewers. This is a measure to which we have already given our strongest advocacy, but we do not think that the commissioners have gone far enough. The Regent-street and Regent's-park district remains a narrow slip, running up from the Thames across the drainage of the Westminster and Holborn districts, and having a grand and deep sewer of nearly the capacity of the Fleet, which being employed as an outfall, would as we have before pointed out be immediately available in improving the drainage of a very large district. It is true that this lies under the virtual jurisdiction of the Commissioners of Woods and Forests, but the commission ought to be at once revoked, and the jurisdiction transferred to the new metropolitan commissioners. The maintenance of this commission by the government is a reason which will not be used for the maintenance of the City of London Commission, which is likewise left untouched, because, as the commissioners say, they have not had time to look into the case, but because, as we presume, Mr. Lambert Jones prevented it, and because the commissioners did
not choose to put themselves involved in a contest with the corporation of London.

The City Commission of Sewers has certainly been among the best managed, and this, perhaps, for the reason that they have always had a regular corps of officers; but still there is no reason why the city should not derive the benefit of an amalgamation with the suburban districts, and thereby receive the advantage of the cooperation, and they will get a share of the influence, control, and patronage, as well as of the economy attendant on the new commission. If they do not accede at once they will not be able to secure the few dinners which they receive, while they will lose the power and patronage. At present the entire business of the city is imperfect and unfinished, the gratings and gully-holes untrapped, the courts and alleys undrained, the footways and foot-pavements not cleansed, the house drains and cesspools in a dangerous condition, while the sewers convey miasma into most of the houses. The statistics of the city in the latter respect are most unfavourable, and show a fearsome influence on the public health.

The commissioners have given such evidence as to the necessity of consolidating the districts, that on the strength of that evidence we call upon them to complete their measure of amalgamation. They say—

"Taking the works of cleansing as they now are, the preventive measure to which those works may be immediately applied with the greatest advantage is that of flushing. But to the general and effectual application of this most important operation, the state and condition of several district offices, and several districts, presents itself as an insuperable obstacle; and, in fact, the operation of cleaning out the sewers by flushing them with water is in systematic use in only one of the upper districts, the Holborn and Finsbury district."

Flushing its sewers, but the operation will be at many points only a removal of a portion at least of the refuse into the sewers of the adjacent districts, unless the operation be continued through the intermediate districts to the outfall. The lower districts complain of being encumbered by the flushing operations in the upper districts.

"In the lower districts, which are flat, there are generally accumulations of refuse, and if in an upper district, which is under a separate jurisdiction, a part of the line of sewer is flushed to keep it free from deposit, the effect upon the lower district in which the flushing is likely to be effective in the offensive emanations, for a time, by disturbing and adding to the deposit there, without removing it. Whilst the sewers of one district are left unflushed, or uncleansed, the emanations are driven by the wind into other districts, particularly from the deposits at the mouth of the sewers. The lower district is thus subjected to the offensive emanations, when the sewers in the Holborn and Finsbury division have been clean flushed, it is stated that the inhabitants of that district, even up to the New River Head, have been annoyed by the currents of offensive gases up the sewers from the accumulations in the lower district. To obviate this evil, and to clean flush the sewers on the 9th of the present month, the Board of Health has ordered the 4-inch lead pipes from the kitchen sinks, and yet they are often made as much as 60 times the capacity of the pipes in the smaller houses. In these, square brick drains are put in, costing from 6d. to 11d. per foot run, exclusive of digging, while in the larger houses brick drains are put in, costing 1d. or 1½d. per foot run. As a general result it may be stated that the rates of discharge through earthenware pipes are very much increased, sometimes as much as one-third. In the application of water for flushing, this is an important consideration, as by the use of the improved drains, a great saving of water will be effected."

In Mr. Roe's experiments he ascertained the rate of flow of water, through the common brick drains for houses, as well as through earthenware drains of the same capacity, and with the same run of water. As a general result it may be stated that the rates of discharge through earthenware pipes are very much increased, sometimes as much as one-third. In the application of water for flushing, this is an important consideration, as by the use of the improved drains, a great saving of water will be effected.

"Works to effect town drainage must be constructed for the removal of surplus or waste water from two sources; the natural rain-fall on the town area, together with water from the springs derived from sources beyond the area which may often require separate arrangements; and the pipe-water, brought into the town, and any refuse matter which it may have received in suspension or chemical combination. Setting aside for the present the consideration of the house drainage, and taking in the first instance, the secondary sewers, we give the following cross section, fig. 1, of a sewer draining two or three streets comprehending between one and two hundred houses. The depths of the ordinary run of sewer-water when there is no rain, is only about three inches, and the depth of the run of water on the occasions of the greatest storms, just covered the invert."

"The cross section, fig. 2, is a section of a main line of sewer in the Westminster district, draining about 50 acres of town area. The ordinary run of sewer-water does not cover the invert, and on the highest ground, where there is any record of the metropolis, namely, that on the 1st of August, 1846, the flow of water was only 2 ft. 3 in. deep."

"In general the flow of water in the collateral sewers of branch lines of street, even where all the houses drain into them, are mere
Mr. Roe proposes to reduce the expense of sewage for one side of a sewer for a house of 17 feet frontage, which lately with upright-sided sewers was £6 6s. 3d., and now is with egg-shaped sewers £6 0s. 3d.—this he proposes to reduce to £2 19s. 2d. for first-class houses, and £1 14s. for sixth-class houses. In these latter charges is included the supply of water. The bottom portions of the larger sewers Mr. Roe proposes should be of well-graded clay, moulded feet long, and well burnt; the upper portions to be formed of radiated bricks, laid in blue lias mortar. The smaller sewers are to be likewise egg-shaped, but to be made entirely of brown stone-ware glazed. Mr. Roe’s first-class largest sewer is 3 ft. 9 in. by 2 ft. 3 in., with an area of 6-6 feet, and costing 17s. per foot run; his seventh-class, or smallest, sewer, is 15 in. by 9 in., with an area of 9 inches, and costing 3s. per foot run.

The greater part of the duties of the officers, Mr. Roe states, is taken up by attending to complaints of the stoppage of drains and sewers, and in superintending the removal of the soil; when, with a proper system of seewage and house drainage, nearly the whole of the duties in that respect may cease. We agree with him that it is far better that a staff of officers should be constantly engaged in making examinations, in order to prevent filth from depositing and accumulating, than in waiting for it to collect and annoy the public with its noxious emanations, perhaps for weeks and months before complaint is made and steps are taken to remove the evil.

We think a great deal may be done by Mr. Guthrie’s plan, mentioned in the Health of Towns Magazine. In this he proposes to separate house drainage from surface drainage. The house drainage being conveyed in tubes, as stated by Mr. Roe, would, under the pressure of water, be carried to the outfall, without gully holes or other communications with the external atmosphere. The surface drainage in the secondary streets could be conveyed in the gullies, and in the main streets be received by the large sewers.

The commissioners come to no decision, as to the use of chimney shafts, with currents of air created by heat, for ventillating the sewers and carrying off the noxious emanations, though they express their approval of the principle.

In conclusion, we must again urge upon the commissioners the necessity of coming to some immediate decision respecting the use by the public of all sewers which have been built at the expense of the commissioners, and at once abandon the extortionate demand of 10s. per foot run on the frontage of a house, which, if it happen to be a corner house, may amount to the sum of £300, besides £5 more for making the drain, for a fourth-rate building that cost only £800. Every facility and encouragement ought to be given to the owners of house property to make drains into the public sewers, and so to abandon the pest of cesspools.

CANDIDUS’S NOTE-BOOK
FASCICULUS LXXVIII

"I must have liberty
Withal, as large a charter as the winds,
To blow on whom I please."
soon be reduced, from mere barrenness, to the necessity of copying himself."—Unvaried uniformity of ideas is not so much a sign of consistency as of limited power of conception and expression, and, moreover, not only would it be more to the bestow greater care upon lesser ones?" Well was it that the remark was put interrogatively instead of affirmatively, for in the latter case it ought to have been, not "How many," but "How few." Were Percier's excellent advice to be followed by country architects—and for the matter of that, by town ones also—did they invariably express the same thing? If the occasion offered them, however inconsiderable it may be in itself, there would be far less of slovenly or else downright trumpery design than there unfortunately is now. The "making the most" of the occasion must not be misinterpreted; it is not to be understood as recommending or consisting in ambitious aim and pretentiousness of design, and in mimicking larger things, as is frequently very absurdly done now, but on the contrary, in attempting no more than can be thoroughly accomplished, and so well accomplished that for intrinsic merit of design and captivating effect the work may not only attract, but succeed to the advantage of others. Note in ordinary estimation—chiefly, perhaps, because their size alone renders them conspicuous and imposing objects. Were this to be duly considered and acted upon, we should have less of vulgar architectural Swaggering, and far more of real study of design, than we find now is too often the case. It is so little the latter, and because architects do not know how to impart to small or comparatively small buildings such character as shall be both striking and appropriate, that we have so much random copying, and injudicious imitation, which serves only to remind us of merits belonging to the grand buildings. In the case of smaller structures it is more room for feeling and also for saying that, taken in general, our smaller provincial buildings show, if not ignorance of design, very great negligence of it—sometimes to a degree almost incredible, if we may believe what profess to be portraits of them. The Mercers' Hall, the Haymarket, and the Ipswich Museum, to say nothing far from bearing out what Mr. Sharp says, as rather to prove that architectural taste must be at the very lowest ebb in those places, if not in any other parts of the country. Such doings in the provinces are, it must be confessed, kept in countenance by similar Pecksniffian achievements here in town, one of the most egregious of them being the College of Agricultural Chemistry in Oxford-street, which, small as it is, is anything but an architectural minia- ture, for it has neither the delicacy nor refinement of one, but is no better than a vulgar and coarse architectural daub. Exceptions there may be to the rule of some of them, with the point of the edifice at Dover House; or, to take a quite recent one, there is Mr. Hodgkinson's newly-erected house in Park-lane, which affords striking evidence of what may be done within a very limited space—how much beauty of composition and elegance of detail may be displayed when a new frontage.

II. Music has, perhaps, been far more fortunate than Architecture, having escaped from the surveillance and trammels of archaeological pedantry, in consequence of no musical compositions of the ancients remaining. No doubt they were altogether different in style from anything in modern European music; therefore, had they been preserved and followed as wholesome precedents, would have checked rather than at all advanced the progress of the art in later times. To say that had the architecture of the Greeks and Romans perished as well as their music, it would have been all the better for the former art, as it would incure far less reproach of ultra-reprobate, and would, besides, be doing violence to my own feelings. Yet it is sincerely to be wished that its examples were studied more, and aped less,—studied rationally and aesthetically; and then it would be perceived that admirable as they are in them- selves, and with reference to the purposes for which they were erected, they are either ill-adapted to, or furnish but very little towards, such an enlarged and complex architectural system as we now require. For actual practice, they afford us little more than a few variations of column and entablature, arches, pediments, and such like, in regard to which we are ourselves wholly adhering to the authority of some one particular antique example, although the structure to which they are applied is in its composition and physiognomy the very reverse of antique. As I have said, I believe, more than once before, modern architects have more patterns from which they have only to choose, without being put to the trouble of shaping out a single idea of their own. So that as far as the orders are concerned, they neither are nor are called upon to act as artists at all; and as to the merit of truthful copying, that belongs rather to the operative stonemason than to themselves. There are many ancient examples which are not so much greater or less exact, and in a variety of ways, without losing sight of the character of the type so followed. Nay, some might be considerably improved upon, and more consistently finished up than they appear to have been, unless they have been greatly mutilated. Take, for instance, the Ionic column of the Erechtheum at Athens. The more severe cornice accords very well indeed with such luxuriant rich capitals, which seem to demand a corresponding florid character in what is the corresponding division of the entablature, and the crowning to the entire order. Together with want of keeping as to character, there is a falling off of effect where it ought, if any thing, to be increased rather than at all diminished. Obvious as this appears to myself, not one of those who have taken that example have ventured to depart from the exact letter of it, by supplying such a cornice as would complete and perfect it. Of the two, even an exaggerated cornice is a more pardonable fault than a staving one. The reproach of heaviness is preferable to that of poverty and meaness.

AIR-TIGHT GRANARIES.

Three conditions are essential to the process of putrefaction of grain, viz.: heat, moisture, and still air. With wind, moisture is carried off; with cold, the decomposing process is checked, as may be seen by the carcases of animals that lie through the winter in snowy mountains, and dry up to glue. Without air, everything is lost; while cold remains; as it may be buried for ages in blocks of stone or ancient trees, and then resumed its vital functions, unchanged by time. In direct opposition to these principles are the granaries of Great Britain and other countries constructed. Their site is generally the bank of a river, or the sea side. They are built of many floors, at a vast expense. Men are continually employed to turn the grain over, to ventilate it, and clear out the vermin; and the weevil is naturalised in every crevice, as surely as bugs in neglected London beds, or cockroaches in West Indian sugar ships. It is the admission of air that permits this evil, that promotes germination, that permits the existence of rats and mice. In the exclusion of air is to be found the remedy. Granaries might be constructed under ground as well as above ground; in many cases, better. They might be constructed of cast-iron, like gasometer tanks; or of brick and cement; or of brick and asphalte, like underground water-tanks. It is only required that they should be air-tight, and consequently water-tight. A single man-hole at the top is all the opening required, with an air-tight cover. Now, if we suppose a large cast-iron or brick cylinder sunk in the earth, the bottom being conical, and the top cylindrical, with an air-screw at the top, or with an Archemedean screw to discharge the grain, we have the whole apparatus complete. If we provide for wet grain, a water-pump may be added, as to a leaky ship. Suppose, now, a cargo of grain, partly germinating, and containing rats, mice, and weevils, to be shot into this reservoir, the cover put on and luted, and the air-pump at work; the germination would instantly cease, and the animal functions would be suspended. If it be contended that the reservoir may be leaky, we answer, so may a ship; and if so, the air-pump must be set to work just as is the case with a water-pump in a leaky ship. One obvious cheapness of this improved granary over those existing is, that the whole cubic contents may be filled, whereas, in the existing mode, not above one-fourth of the cubic contents can be rendered available. But many existing structures might be rendered eligible. For example: the reservoirs of the improved counties, the Reservoir, and the Greenwich. Reservoirs might be erected in farm yards, or in-asmuch as it is a certain thing that all farms must ultimately communicate with railways, by means of cheap horse-trains, or steam sidings, in order to work to profit, it would be desirable that the granary should be placed at the entrance to the station, where a steam mill would do the work of exhausting the air, discharging the grain by Archemedean screw when required, and grinding it into meal. No better purpose could be found to which to apply the atmospheric engines and stations of the Croydon Railway, than their built of many floors, at a vast expense. Cows grazing with all the southern wheat-growing counties of England, and also with the Thames, no spot could be more eligible as a central depot.—Westminster Review.
ON WING WALLS OF BRIDGES.

By R. G. Clark, C.E.

As the drawing of wing walls to railway bridges offers some difficulty when the embankments or cuttings are very high, to obviate this the object of the present paper, which relates to the investigation of some simple formula to determine the angle made by the exterior lines of wing walls with the face of a bridge; the plane of projection being taken on a level with the rails or road, when the latter is level.

There are two cases to be considered,—1st. When the coping of the wing wall makes a given angle with the face of the bridge, or is parallel to the abutment, as in the case of a skew bridge,—nearly when the coping is perpendicular to the face of the bridge.

1st. Let BH be the line of the face of the bridge on H B E D, the plane of projection being as before mentioned; CD the exterior top line of wall; C the given batter, perpendicular to BD. The angle HCD being given, or DC drawn parallel to BD, as in the case of a skew bridge, draw ED parallel to BH; and BE, CF, respectively, perpendicular to ED. For the sake of simplicity, we will first determine the angle CDB.

Let the slope of embankment or cutting be as m to n, and the batter of wing wall as C to n.

\[ \tan \theta = \frac{m}{n} \]

Also, base of slope CF = m; and batter

\[ \tan \theta = \frac{m}{n} \]

Then, by the right-angle triangle CFD, we have

\[ \sin \theta = \frac{m}{n} \]

Also, by triangle CED, right-angled at E, we have

\[ \cos \theta = \frac{1}{n} \]

Example. Given the angle of obliquity H C D = 20°, slope 1 to 1, and batter 1 in 3, to determine the angle of wall H B D:

\[ \tan \theta = \frac{2 \times 33892}{15} = 0.4500 \]

Therefore, \( \theta = 17°23'20" \) required.

2ndly. When the coping is perpendicular to the face of the bridge.

Then \( \theta = 1° \)

Consequently, \( \sin \theta = \cos \theta = \frac{1}{n} \)

Hence, \( \cos \theta = \frac{1}{n} \)

Examples.

When the slope is 1 to 1, and batter 1 in 3.

Then \( \cos \theta = \frac{1}{3} \)

When the slope is 1 to 1, and batter 1 in 5.

Then \( \cos \theta = \frac{1}{5} \)

When the slope is 2 to 1, and batter 1 in 5.

Then \( \cos \theta = \frac{1}{15} \)

From the above it appears, that the actual height of the slope, and the batter in feet, &c., have no occasion to be taken into consideration; but only their respective ratios, as above given.

RAILWAY AND STEAM NAVIGATION DEFENCES.

The course which the Duke of Wellington has thought fit to take is, in furtherance of the measure of increasing the army under his command, has given a general strength to every part. We say, advisedly, that the Duke's letter to Sir John Barlow, may be taken as the statement of an advocate, using every means to make out a case; for there is evidence enough in that letter to show the impracticability of an invasion, if it were consistent to suppose that a commander so experienced could ever countenance a scheme, which the youngest staff-officer knows is in no way feasible. In considering the subject, we do not think it necessary to analyse the Duke's letter, because we do not look upon him as a magistrate in the invasion scheme; but we shall take up the questions upon its merits, which are certainly small enough, compared with the clamour which has been made by so many parties, and of which the Commander-in-Chief has so skilfully availed himself, to further the views of his own department.

It is one of the consequences of thirty-two years of peace, that the present generation know little of the art or science of war; and it is therefore open to ignorant or restless officers to pose upon their statements, which do not meet with the countenance of men well informed in their own profession, and which are not consistent with historical proof. With the public an officer is taken as an authority in virtue of his epaulettes; but, nevertheless, he is as an officer no more an authority on this question of invasion than the most ignorant civilian. It is one of the misfortunes of the English army, that there is no guarantee for the qualifications of its officers; and, notwithstanding the growing desire of improvement among military men, it cannot be denied that it is not easier to find a man well acquainted with his profession than otherwise, for there is no security, and it may be said no encouragement, for procuring. In the navy, and in the artillery, an examination must be passed by; but, under the present system by which the army is officered, except the few college cadets, a man may be put in command of an army, whose only qualification is that he can manoeuvre a battalion on parade. Neither is the service of the English army calculated to qualify an officer for European warfare, for the staff arrangements even of an Indian campaign will give no schooling for a war in the old battle-field of Flanders. One of the statesmen we most want is a good staff of officers, and money cannot be better laid out than in enlisting the military colleges, and encouraging the studies of officers. In the meanwhile, we hope the public will not allow themselves to be frightened out of their wits by men who know no more of the organization of an army of fifty thousand men than a drummer-boy does; and, at any rate, to accept with caution any statements which have not the support of common sense and historical evidence.

It is very easy to start with the hypothesis of 50,000 Frenchmen on the Sussex coast, and to talk of the capitals of France, Austria, Russia, and Prussia having fallen into the hands of an enemy; but it is so difficult to conceive how a French army of 50,000 men, or of any other force, could be brought to London, that any general being offered the command of such an expedition, would give it up in despair. In order that a French army may land upon the English shore, there must be no political disorganization in France, and there must be political disorganization in England. Our great guarantee hitherto against invasion from France, has been the political disorganization of that country by the League, the Protestants, the Camisards, the Girondists, or the Chouans, by the irritation of Prussians, Spaniards, or Savoyards. Napoleon never hoped to be able to make an effectual invasion of this country, unless he could make a political division, by securing the neutrality of parties in opposition to the government. How futile was that dependence is well known; and though some may, in the present time of calm, believe that political factions might hereafter be brought to sympathize with an invader, yet such coalition would become impossible when war shall break out, and the old feelings of bitter hatred be awakened. This is the disturbing influence which cannot be readily overcome. There is nothing more difficult than to overcome a people in their own country, with whatever force, if united in resistance. France will give the example. It, in 1814 and 1815, the allies were able to make their way to Paris in the then political disorganization of that country, yet, in the early part of the war, under the Duke of Brunswick, though France was unprepared, the invaders were driven back with loss.

The circumstances under which an invasion of England will be practicable are—the union of the French, High Dutch, and Russians, the destruction of the naval power of England, our political disorganization, and the agreement of a large part of the people.

*
to welcome the invader. This country has not yet had an enemy on its shores, and it is not to be judged like France, Flanders, Holland, Italy, Germany, and Spain.

Before coming to our telegraphic view of the question, we have a few observations to make upon the military and naval part. The hypothesis of an invasion must be under these forms:—of an army of 200,000 men, or of an army of 50,000; of an army with cavalry, artillery, pontoons, provisions, and train, or of an army with a mere cavalry. Confining ourselves to an army and 50,000 under either of the latter two conditions: such an army, with 10,000 horses for cavalry, 400 or 500 pieces of artillery, horses and carriages for artillery, ammunition, provisions, and train, would require greater steam accommodation, and take greater time in landing than a force of 50,000 men, which is the time for the muster of forces against it. On the other hand, a mere incursive force of 30,000 men, would be defeated by want of means to overcome the usual obstacles of delay. It would want cavalry to drive off the swarms of local mounted skirmishers, and to make its reconnaissances; it would want means of crossing rivers; and when its brigades before concentration were brought in front of a regular force in position, it would want heavy cavalry and artillery.

If the wounded men were picked up they would encumber the march, and if left behind they would be massacred by the populace. For a week or two they would soon become demoralised. Three days' stay in a wasted country would leave such an army, even if concentrated, without provisions or ammunition, with its ranks thinned and dispirited by death and fatigue. If it attempted to fight, every man would be hostile to a worse fate than death. In a word, it is not to be expected that we should have the command of a brigade in an army of invasion of England.

Persons who are ignorant or ill-advised, may say that we have no regular force and no military spirit in the country; but those who take the trouble to calculate know that this country has at all times had great military resources, and at no time so much as at the present. Turn back the pages of the history of England, and watch the progress of preparation. The regulars in England are increased by scores of thousands at a time; sixty thousand militia are embodied and used as regulars; an army of reserve is called out; local militia are brought into the ranks of the regular army; three, four, and five hundred thousand volunteers are enrolled in 1806 for example, seven hundred thousand men are in arms in the islands, besides a vast fleet patrolling around. Since then, the population has doubled, and that seven hundred thousand men will become a million and a half, with the levy en masse to back them. England, without allies, can never be lost, if only true to herself, though the nations of Europe should be poured on her shores. No enterprise could be more dangerous than to land troops in a thickly-peopled country, among a brave and warlike population, strengthend with all the resources of knowledge and wealth. For it is not to be attempted. To take the coast and fill the shores of the Atlantic, and the waters of the deep, with a fierce people, who, as the Hollanders once threatened to do, would take to their ships and seek a new country, whence they could turn upon their oppressors.

It should be noted that it is an old regulation, always renewed in time of war, that in case of invasion, all corn, cattle, and people, within twenty miles of the shore, must be driven up the country, and the district wasted, and efficient means are provided for effecting this. England in time of war, and England in time of peace, are different countries, and it is certainly not matter of blame that the government, in the thirty-second year of peace, do not harass the country with the troubles of war-time. Why are martello towers, shot furnaces, and batteries to decay upon the coast, heavy artillery to rust, and men to be taken from their shops and homes to the drill ground, when all that is wanted in this way can be obtained in peace?

As to sudden invasion at this moment, it is a bugbear; but we are always ready to urge that a consistent system of preparation for war shall be carried on; but then in our opinion the means are simpler than those usually put forward, and are not to be sought in the local skirmishers hanging about the borders, but more in what are commonly called the engineering operations of the country. We do not advocate an increase of the standing army; we have no faith in the fortification of Portsmouth, Plymouth, and other towns, as strong places; we do not think it necessary to lay down the coast, with its whole length, with heavy artillery; still less do we advocate the calling out of the militia. We may observe, that the government of this country have always wisely shown an indisposition to put arms into the hands of the people in time of peace, because they are not under the bond of a feeling of hostile invasion, which in time of war prevents a misapplication of arms to interference in the civil government.

We consider that a due attention to railways, steam navigation, and telegraphs, makes some provision for the defence. The issue is whether we have not the means to prevent the invasion of the country. We have a large growth of steam navigation threatened military and naval men with a new instrument, of aggression, against which they had no means of resistance. We have been in confusion for peace, and that is still the case. We have been in confusion for war. We have been in confusion for the alarm, had war broken out; but since then, the development of the railway system has provided an adequate power of resistance; while, more recently, the establishment of electric telegraphs has thrown the scale of proportions in favour of the defensive resources. It can be longer be in doubt in what direction we are to apply our means and make provision. We must avail ourselves of those three great branches of national enterprise which we have already named. Do not let any think us over-professional in making this view of the matter, for this is the main thing. Which the Duke of Wellington looks at it. He takes his case on a steam navigation, invasion, on this new development of scientific resources; and the fair way to meet it is to consider what resources of such kind are available for the purposes of defence. Engineers and manufacturers have created the means of invasion, and they must provide us, to some extent, with the means of defence.

Considered in reference to the defence of the nation, nothing can be more unwise than that legislative interference which has restricted railway enterprise. Even were it true that there was an undue competition for railways, and that capital was diverted into unnecessary directions, it is not to be wished for. It is better to have the command of a railway system in the hands of the nation than in those of foreign contractors. It is desirable that as many railways as possible should be made. If we are asked whence the capital comes for railway construction, we can have an answer which springs from the very matter now under discussion. In time of war, we keep a couple of hundred thousand regulars and militia, giving no productive return. In time of peace, we can employ two hundred thousand navigators, or, in reference to our present means, four hundred thousand navigators, in making railway works. At present, out of an income of fifty-five millions, thirty millions are a mere transfer of capital, in the shape of interest on debt; the other twenty-five millions are an effective drain upon the energies of the country; and every addition of twenty thousand men to the military forces is a deduction of so many men, and of one million yearly, of so much productive labour and capital rendered unproductive. We can carry on such great railway works while other countries cannot, because France, for instance, keeps three hundred thousand, or four hundred thousand, men under arms,—doing no good, but, on the contrary, weakening its resources.

The less interference with railway legislation and management the better, for it results only in public disaster. Had it not been for this interference, we should now have had coast lines all round the island, and been provided with sufficient converging lines from the great seats of population. As we stand now, the southern coast line is incomplete, the line to the west coast is incomplete, the eastern line is incomplete, and the communications are left in such a state, that in time of war they will require to be completed at the national expense. If erroneous views of policy had not prevented it, we should have had at present the following lines available for the south coast defence:—
A line along the south bank of the Thames, to Dover, to Hastings, to Brighton, to Shoreham, to Fareham, to Portsmouth, and to Southampton, giving the means for pouring down troops most rapidly; whereas, through the fear of competition, we are left with the present inadequate accommodation. If the plan of traffic investigation of the last parliament had not undertaken the futile inquiry whether a line would pay or no, we should have had lines enough made by those who are the best judges how to invest their money. It is, however, the consequence of the meddling policy, that it always reacts to produce serious inconvenience to the country, without doing the slightest good.

Now that railway enterprise has been suppressed and knocked down, it becomes the duty of the government to aid the companies in carrying out the necessary works. Among them are the bridge over the Thames to join the new trunk lines with the others; the branch of the Brighton railway from Croydon to Wandsworth; the union of the Portsmouth and Gosport lines; and the extension of the Brighton and Hastings line through Rye to Ashford. London is the seat of a population which will afford four hundred thousand able-bodied men for military service, to be poured down to any point of the coast between Dorchester and Harwich; and it is therefore necessary to provide accommodation.
for bringing this great reserve to bear upon any point attacked. The metropolis also is the reserve for defending the whole of the northern and west coasts, in case of insufficiency of local force.

Every stream and each highway that could be made useful to the enemy should be obstructed. Every road near the coast, every road by which troops could be brought to bear upon the enemy's works, must be destroyed. Every tree near the roads be cut down for an abattis; barriers would be formed at the hamlets and villages, and guns mounted in the churchyards, mills, and on the hill-tops. In the face of such obstacles the enemy would have to advance, each man carrying sixty pounds of ammunition and three days' provision. Tiraillers would have to be thrown out around the column of the moving brigade, and, after two or three miles' advance, more must be kept in the rear, as the skirmishers would get behind, in order to slay the wounded, for it is well understood in such affairs that no quarter is given. The bridges landed at various points along the course would have their communications interrupted by the deep and wide mouths of the rivers, and their progress impeded by gorges and steep pases in the chalk range, which would admit of a stand being made by the local forces. The bridges would not know whether their whole army had made good its landing, and would not in many cases know the fate of the bridges on their flanks; while, at the points named for the concentration of the divisions, many bridges would not be able to get up, and movements would be necessary in flank and rear to extricate brigades which were cut off and surrounded. Every hour lost by the invaders would be thousands of men added to the protecting force, and if divisions could be got together for an advance, they would then have to carry entrenched camps and fortified positions, against a superior force well provided with cavalry and artillery, and knew the way the battle would be carried on. The brigades landed at various points along the coast road would be detached for picquets and outposts, of which the sentries would be picked off on their guards, while the outposts would be driven in by night attacks. The next morning would offer the choice of a surrender, a retreat, or an attack from a superior force; and this without any more than twenty miles from the coast.

The steam navigation resources of the country must be cultivated by a prudent legislation. On this head, as on railways and telegraphs, private enterprise is ready enough to work without requiring any great expenditure on the part of the state; but, unhappily, legislation has generally been unfavourable to private enterprise, or so tardy, that private resources have been exhausted before public aid was afforded. The Great Western Steam Navigation Company was allowed to drop, when slight—demoralization of the invading force within twenty-four hours would be certain. A very hard day's work would have to be done; nothing would be known as to the fate of other portions of the force; many of the men would have become the victims of the infuriated skirmishers; and a night would be nothing but whistling. From the total dependence of the invading force on the rail and steam roads, it would be impossible to hold ground, for piquets and outposts, of which the sentries would be picked off on their guards, while the outposts would be driven in by night attacks. The next morning would offer the choice of a surrender, a retreat, or an attack from a superior force; and this without having got more than twenty miles from the coast. This is rather a different picture from that drawn by Lord Ellesmere, of the guards marching out of London; but then it is the true one, which those pictures who have had experience in such matters will recognize.

REGISTER OF NEW PATENTS.

PNEUMATIC SPRING.

Moore Poole, of the Patent Office, London, gentleman, for "Improvements in the construction of pneumatic springs."—Granted May 22; Enrolled November 22, 1847. (A communication from a foreigner.)

The mode of connecting two vessels being applicable without the air to other purposes, such as hydrostatic presses, &c., by forcing the water into or between the two vessels.

This mode of connecting two vessels being applicable without the air to other purposes, such as hydrostatic presses, &c., by forcing the water into or between the two vessels.
is represented in the accompanying drawings, in which fig. 1, is a metallic conical vessel, with a convex plate or disc at bottom. The upper edge of this vessel is bevelled inwards around its circumference to receive the edge of the belts $f$ and $g$, the inner edges of which are there secured by a plate $e$, depressed or sunk in the centre, which has a bevelled and grooved flanch, so that when the plate $c$, is drawn towards the bottom plate by four or more screw-bolts $h$, the belts are gripped and firmly held between the grooved edge of the vessel and the bevelled or grooved flanch. The outer edges of the belts $f$ and $g$, are connected with and held by the cylindrical vessel $a$, which surrounds the vessel $b$, having space enough between the two for the working of the belts, which by the pressure of the contained air are alternately pressed against and sustained by the inner periphery of the conical vessel. The belts are secured in vessel $a$, by making its cylindrical part in two portions. The edges of these two parts, where they come together, are bevelled or grooved to receive the outer edge of the belts, which are there gripped and firmly held by drawing the two parts $a$ and $a'$ together by means of screw-bolts $i$, that pass through the head of the vessel $a$, and a flanch in the part $a'$.

The connecting-belts $f$ and $g$, are flexible hoops of India-rubber or other flexible substance impermeable to air, and the edges being firmly held, the space $j$ between them is filled with alcohol or other liquid, which not only prevents all possibility of air passing through, but brings an equal pressure on all parts to prevent rupture.

The connexion of the two vessels $a$ and $b$, by means of the belt, divides the apparatus into two parts or chambers $a'$ and $b'$, the plate or diaphragm $e$ being the division, the inner and depressed circumference of which is perforated with holes to break the passage of the air, as the chamber $a'$ is enlarged or contracted by the movement of the two vessels on each other; this perforated plate is, therefore, termed a respirator, as it permits the passage of the air from one chamber to the other, and at the same time checks its too sudden passage, and therefore avoids to a certain extent all sudden jars in cars or other bodies having such springs interposed.

The motion of the two vessels on each other is guided by a rod $k$, attached to the head of the vessel $a$, which passes into a tube $l$, which tube arises from the bottom and centre of the vessel $b$, extending through the centre of the respirator or plate $e$; or guide-rods may be applied outside. The vessel $b$, instead of being conical, may be cylindrical, but the two vessels should be so formed as to present alternately a supporting surface to the belt, which in consequence of the pressure of the air in the chamber $a'$, rolls gradually from one surface to the other, and is therefore at all times supported by either one or the other, or both of these surfaces.

Instead of one respirator or perforated diaphragm two or more may be employed, the more effectually to ease off the passage of the air as it is compressed or expanded, and this respirator may be of any desired form, and may be located in any part of the two chambers.

Instead of the double belt above described connected together at the edges, it is contemplated to place two or more single belts separated from each other, presented at fig. 2, with the liquid in the space $t$; the holes $h$, being made through the outer casing for the introduction of the liquid and closed by a screw-plug. When this apparatus is used as a hydrostatic press, the water is forced into the cylinders and piston press, except that the friction of the moving part is avoided. Air is to be forced into the chambers when the apparatus is used as a spring.

### MANUFACTURE OF IRON.

REGINALD JAMES BLEWIST, of Llantarnam Abbey, Newport, Esq., M.P., for "Improvements in the manufacture of malleable iron."

- Granted May 57; Enrolled November 29, 1847.

The usual mode of preparing pig or cast-iron for malleable iron is by melting such iron, or by mixing together and melting different qualities of pig or cast-iron with coke, in furnaces called refiners, and keeping it there in a state of fusion, at a great heat, with a strong blast; and the produce, run into moulds, is called refined iron, or metal plate. The patentee uses this, either alone, or mixed with different qualities of pig or cast-iron, in the puddling-furnace, and subject it to the after process of puddling, by which it is brought into the first state of malleability. He states, he has discovered that a better quality of refined iron, or metal, may be obtained from an air-furnace—such as is commonly used for casting, or foundry purposes—than from the refiners, by which there is less waste of metal, and less expense of fuel, in the manufacture. He lights and heats an air-furnace in the usual manner. For each charge about four tons of pig or cast-iron is put in of such qualities as the manufacturer may think most desirable to produce the required quality of malleable iron, as has hitherto been the practice in using refiners furnaces; and the charge, when fully melted and mingled together at the bottom of the furnace, is run into sand, or iron moulds, of any convenient size, and then subjected to the after process of puddling, which is conducted as if using refined metal produced from ordinary refiner furnaces. The fuel employed for heating the air-furnace is a white-ash, semi-bituminous coal of excellent quality, which may be added, with good effect, 1 or 2 cwt. of charcoal to each charge.

### RAILWAY CARRIAGE AXLES.

This invention relates to a mode of connecting the axle-boxes of railway axles with the framing of the carriage, whereby the axles will have a slight horizontal play, sufficient for them (when travelling over curves) to take a line parallel to the radius of the curve over which they may be passing. This is effected by connecting the axles to the carriages in the manner shown in the annexed engravings. For four-wheel carriages the apparatus is shown in fig. 1, 2, 3, and 4. A, A, is one of the two main side-beams of the framing of the carriage; and as side case of the carriage is similarly furnished for the support of the axles, a description of the parts pertaining to one end only of an axle will suffice to explain the nature of the invention.

$4$, are four arms of the use of the belt, two on each side, to the beam $A$; and at their lower ends they are coupled together, in pairs, by a bolt or pin $b$. These pins each carry two links, $c$, $c$; and through their ends a coupling-pin is passed, and secured in its place by rivet-heads or otherwise. $d$, $d$, are two rods or bars, provided at each end with eyes, for the purpose of being connected respectively at their outer ends by the coupling-pins of the links $c$, $c$, and at their inner ends, of being joined together by the coupling-pins $e$, $e$, and intervening links $f$, $f$. These coupling-pins $e$, $e$,...
which are secured in their places by screw-nuts, also pass through the eyes of pendant-links $h, h$, which pass through the step or axle-box $k$, and hold it in suspension. $I$ is the bearing-spring, composed of layers of steel plates, piled one above the other, and embraced by the links $c, c$, which, when screwed tight to the axle-box by the nuts (shown in the drawing), cause the horizontal links $f$ to bind tightly upon the middle of the steel plates, and hold them securely together. It will now be understood, that when it is desirable for the axle to take a position other than a right angle with the side of its carriage, such movement will be permitted by the links $c, c$, being free to oscillate. In order, however, to check an undue horizontal movement of the axle, and allow of its adjustment only to a line parallel with the radius of the curve over which the carriage is passing, elastic stop or check-pieces $m, m$, are provided, as shown at fig. 1; and placed in such a manner, as to allow of a free motion of about a $\frac{1}{2}$ to $\frac{3}{4}$ inch; so that, whenever the axle may have a tendency to sway too much, either forward or backward, the links $c, c$, will come in contact with the pieces $m$, and be prevented from moving further. This horizontal movement of the axle will only occur when the railway deviates from a straight line; but when the carriage again pursues a straight course, the axle will regain its position at right angles to the length of the carriage.

Another modification of the invention, applicable to a six-wheel carriage, is also described in the specification, fig. 5 being a side elevation; to allow the axles to move laterally, as well as in a forward and backward direction, in order that, in a carriage having three or four pairs of wheels, the hind wheels may follow the front pair, not always in a straight line, as they are now obliged to do (whereby a continuous abrasion of the flanges against the rails is caused when passing curves), but that they may take a position on the rail suitable for compensating for the difference in radius of the two sides of the curve of a railway, and permit the cone peripheries to work efficiently for that purpose. In this modification, the same or analogous parts are marked with similar letters of reference. Instead of the four arms $a, a$, fig. 1, forked arms $a$, are made to embrace the beam $z$; and at the junction of the joggles, joggles are provided, and cross-rods are also employed, to insure the rigidity required for the arms $a$. The lower ends of the arms $a$ are hook-shaped, and are intended to receive respectively the shackles or links $c, c$, which, together with the coupling-hooks $d$, pendant from the bars $d$, perform the same office as the links $c, c$, in fig. 1. From the peculiar construction of this coupling, it will be seen that a lateral play or movement is allowed to the axle, entirely independent of the carriage-frame (no fixed point of vibration being employed, as at fig. 1); and, consequently, the object desired, viz., giving a lateral as well as a backward and forward motion to the axle, will be obtained. In order to limit the horizontal motion of the axle, the space for oscillation is contracted at $x$, (fig. 5); to guard against the danger which would result from the breakage of either of the shackles $c$, a block of wood is attached beneath the framing, which, in falling, will be caught by a block resting on the coupling-links of the bars $d$. $g$ is a shield for preventing the step or axle-box $k$, from getting displaced, in the event of such an accident as above alluded to.

The patentee claims the modes, herein described, of connecting the steps or axle-boxes to the framing of railway carriages, whereby the axles of such carriages are enabled to shift their positions, with respect to the frames of the carriages, for the purposes above set forth.

---

**MANUFACTURE OF IRON.**

**William Vickers**, of Sheffield, for, "Improvements in the manufacture of iron."—Granted June 19; Enrolled December 19, 1847.

The improvements consist in melting pig-iron with wrought-iron, and running the melted mixture (when divided into streams) into water; and then converting the product into malleable or wrought iron, in the following manner:—Pig-iron is to be melted with scrap of wrought-iron or turnings, in any suitable furnace, (a cupola furnace is recommended); and the proportions of wrought-iron with pig-iron may vary greatly, but that a very small addition of wrought-iron to pig-iron, run into water, will be found to produce a great improvement in the quality of iron manufactured therefrom. Sometimes the following proportions are employed:—To 30 parts of wrought-iron are added 70 parts of pig-iron, by weight; and, although this may not be found to answer for some purposes, it has been found to answer well. If, however, the iron should be intended to be made into steel, it will be necessary to increase the proportion of wrought-iron, by mixing with the pig-iron about 40 per cent. of wrought-iron. In the manufacture of iron intended for general purposes, there may be used, with advantage, a mixture of 30 per cent. of scrap of wrought-iron, or turnings, with pig-iron; and such mixture, when melted, may be divided into small streams, and run into water, in any convenient manner. For this purpose, the patentee has used the following arrangement:—He takes a cast-iron tray, perforated with holes of half-an-inch in diameter, and this is lined about half-an-inch thick, with sand or composition, such as is used for stopping cupola furnaces with; which is punctured with holes about a quarter of an inch in diameter—such punctures being immediately over the holes in the tray, and then the tray is placed about 15 feet above the level of the water in the tank (employed for solidifying the iron), which is 2 feet deep, and about 4 feet deep; and the melted metal passing from the furnace, through the perforated tray, into the water in the said tank, will be found therein in a divided state. This product is used in the manufacture of wrought-iron, and is treated the same as in the manufacture of wrought-iron from pig, or refined iron. The patentee adds, that he has used, with advantage, in the melting of pig-iron with wrought-iron, from 3 to 5 per cent. of black oxide of manganese, which he believes will be found to be advantageous. This may be added from time to time, by placing small pieces in the tuyere holes—the blast dividing it in the furnace as the mixture becomes melted. The patentee does not claim the melting of wrought-iron with pig, or cast-iron, nor the running of melted cast-iron into water, when separately considered; neither does he claim the precise mode set forth, so long as the peculiar character of his invention be retained; but what he claims, is melting pig-iron with wrought-iron scrap, or turnings, and then running it into water, and using the product in the manufacture of wrought, or malleable iron.

---

**STEERING VESSELS.**

**William Henwood**, of Portsmouth, naval architect, for "Improvements in propelling vessels, and in steering vessels."—Granted May 1; Enrolled November 4, 1847.

The first improvement in propelling and steering relates to screw-propelled ships or vessels, and consists in placing the screw-propeller at the after-side of the sternpost, where the rudder is in vessels generally, and in applying the rudder on the fore-side of the screw-propeller, in the lower part of the sternpost, and below the propeller-shaft, the rudder being such as to form the same part of the run of the vessel, as shown in fig 1. The lower end of the sternpost meets the keelson, or timber running under the keel, at about the height of the centre of the shaft; and the one may be united very securely to the other by a flange or flanges on the shaft cylinder, let into and bolted to the sternpost and keelson. This keelson, or timber, should be large in section, because of the hole through it for the rudder-head to pass through; and must have a rebate to receive the bottom plank.

The propeller is connected with the stern-post and vessel very firmly by a metal-coupling-box $a$, which has a metal-frame $b$, attached to it for raising and lowering the propeller; the coupling-box and hoisting-frame being formed with tongues, to slide in metal-faced grooves in the sides of the sternpost $s$, and the coupling-box having an interior collar of the utmost requisite strength, fitted against a corresponding exterior collar round the propeller.

The union of the propeller to the ship is thus made abundantly strong for pressing the shaft into the propeller, and "backing
A large and very strongly formed rudder-band is fitted at the upper part of the rudder, with a large hole through it, of a square, hexagonal, or other form, into which the rudder-head is fitted for turning the rudder; the lower rudder-bands might also be formed similarly, and the braces fitted with an internal ring, that the rudder-head being extended downward as a substitute for the rudder-pins, may revolve in the bands, whilst it is fixed in the rudder-bands for turning the rudder. The rudder-head above the upper rudder-band is cylindrical, and passes through a metal cylinder with a stuffing-box. It then surrounds the propeller-shaft so that the rudder may turn sufficiently in steering; and it extends to any convenient height to receive the tiller. Should the rudder be carried away a temporary rudder could be applied, by taking up the propeller, using sails only, and having the temporary rudder prepared with braces to slide down the sternpost grooves; by which it would be held securely to the ship, its lower end being secured with guys.

The advantages to be obtained from this improvement are, the maximum effect of the screw-propeller in propelling; the avoidance of risk of serious damage from a vessel's grounding, and the preservation of the strength and the form, and the displacement of the after-part of a vessel.

The claim is for the right of applying a screw-propeller and a rudder conjointly to a ship or vessel in the positions above-mentioned, and as shown in the engraving. The improvement in steering vessels consists also in applying a similar rudder to a ship or vessel not propelled by a screw.

Such a rudder could be either shipped or unshipped afloat; by attaching a water-tight hose or cylinder to the rudder-head cylinder, so that the rudder-head, with the rudder-pin or pin attached to it, may be drawn up in unshipping the rudder, or replaced in shipping it. The keel may extend under the rudder, as shown in the engraving, to protect it in grounding.

The advantages of such a rudder are, much less first cost, indefinite durability, through being always under water, being below the impulses of waves, so that the steering would be uniformly steady, and without hazard to the helmsman, both when a ship is laden, and when she is light; and it is quite below the reach of shot.

The other improvement in propelling vessels consists in making that part of the immersed volume, which is abaft the vertical and transverse plane in which the centre of gravity of the vessel is, of such a form, that the longitudinal stability of the after-end of the vessel may be practically equal to that of the fore-end;—in order that the pitching motion, so far as it may be caused by the form of the immersed volume, may be prevented; and that there may be the least possible resistance of the water to the propelling power. This is of especial importance in screw-propelled vessels, because pitching raises the screw above the water's surface.

The equal stability of the fore and the after-ends of a ship, is obtained by making the area of the load-water section abaft the above-mentioned vertical and transverse plane, equal to the area of the remaining part of the same water section, on the fore-side of the same plane; and the moments of those areas, from the same vertical and transverse plane also equal to the moments of the lower horizontal sections or water-lines in a similar manner; so that the cubic contents of the immersed volumes, on each side of the same vertical and transverse plane, and the moments of the same immersed volumes from the same plane, shall likewise be equal, the one respectively to the other. A vessel of remarkably beautiful form may thus be produced. As the propelling power of the wind on the sails always depresses the fore-end of a ship, when it impels her onward, just as it depresses the lee-side, when the wind acts obliquely, it appears contrary to the dictates of reason and of science, that ships should have, in such manner, that the weight of the vessel and the machinery be borne equally by each pair of driving-wheels. By this arrangement, the adhesion of the wheels upon the rails will be more uniform. The two pairs of driving-wheels are to be connected separately to the driving-cylinder, or in any other convenient manner. The mode preferred by the patentee is shown in the seventh improvement. If it be desirable to construct the engine with six or more wheels, the patentee proposes to place them between the two pairs of driving-wheels, but recommends that they should bear but little of the weight, by the employment of light elastic springs.

The second improvement is in the construction of the fireboxes, for the reception of the axles of the driving-wheels, the driving-wheels of the locomotive engine being placed more forward than the back of the firebox. The fireboxes are to be used a recess is to be formed transversely in the upper part of the firebox for the axle; and for smaller wheels, a recess is to be formed in the lower part of the firebox: this latter arrangement divides the fire-bars into two parts. By either arrangement, the heating surface in the interior of the firebox is increased, and the evaporative power of the boiler augmented.

The third and fourth improvements consist in such arrangement of the various parts of the locomotive, that the axle of the fore or leading wheels may have outside bearings, and the axle of the driving or after-wheels behind the fire-box, inside bearings.

The fifth improvement consists in placing the eccentrics for working the valves on the outside of the driving-wheels, by elongating the axle some distance through the boss of the driving-wheels; the crank-pin, instead of being fixed to the boss of the driving-wheel, is fixed to a separate crank, fastened to the end of the elongated part of the axle, leaving sufficient space between
the crank and the boss of the wheel for the reception of the eccentric upon the axle.

The sixth improvement is for transmitting the power from the steam cylinders to the driving-wheels, by introducing a vibratory shaft in the centre between the driving-wheels, as shown in the annexed figure. The steam cylinders are fixed to the under-

side of the boiler, with short connecting-rods, which act on cranks or levers keyed on to the central shaft; and on the ends of the latter are two arms or levers, which, through the two connecting-rods, cause the two driving-wheels to revolve.

LIGHTING BY ELECTRICITY.

William Edwards Tate, of Lombard-street, gentleman, for "certain Improvements in lighting, and in the apparatus or apparatuses connected therewith."—Granted July 3, 1847; Enrolled January 3, 1848. [Reported in the Mechanics' Magazine.]

This invention relates to a method of lighting by electricity, as shown in the annexed engravings. Fig. 1, an external elevation of the apparatus; fig. 2, a sectional elevation on the line $Wx$ (fig. 3); and fig. 3, a horizontal plan on the line $yz$ (fig. 1). The patentee describes his apparatus as follows:—

M, and N, are two cylinders of carbon, prepared as is afterwards described, which are used as the electrodes, that is to say, the current of electricity is passed from one to the other as they stand end to end, their ends being separated by an interval of from less than one-twentieth to about half an inch, according to the power of the electric current used. The upper electrode, N, is passed vertically through a hole in the summit of the metallic support, or tripod, K, and fixed by binding screws. The lower ends of the legs of the tripod are passed through holes in the circular main-plate, A, of the apparatus, and secured in their positions by collars and nuts, but are carefully prevented from coming into metallic contact with the plate A, by means of washers, a, of some dry, hard, non-conducting wood. The legs terminate at bottom in set screws, LL, which connect them with a conducting wire, which passes round through the extremities of all the legs, and is connected with one end of the coil of the regulator R. The other end of this coil is led to a clamp B, with a set screw fixed at one side of the square wooden basement B, on which the whole of the apparatus is built, and which is mounted on four short supports, b b b, at its corners, to allow room for some parts of the apparatus which project below the basement. The main-plate A is firmly attached to the basement B, by four pillars, c c c c. C, and D, are cones which spring from opposite sides of the apparatus, their common axis passing, at right angles through the centre of the main-plate, A, which is bored out for the purpose. The apices of these cones are perforated, to admit the perpendicular central shaft, O, which
has a socket for receiving and holding the lower electrode M, at its upper end; and this socket is furnished with set screws for securing the electrode in an upright position in its centre, even though the electrode should happen to be of smaller size than the socket. At the bottom the socket is made of wood, in order to keep the lower end of the electrode steady and concentric, so that it may be properly adjusted by the set screws, d, d. This shaft O has a smooth straight part, below its socket, for a length equal to the distance between the apices of the fixed cones, C and D, which is equal to the amount of rise which the shaft admits of, to compensate for the wear or shortening of one of the electrodes, while the light is in action; this smooth part of the shaft moving freely through the hole in the apex of the upper cone. Below this smooth part of the shaft is an equal length, screwed; the threads of the screw giving about one-twelfth of an inch of rise for every turn. This screwed part works through a nut a, which is set tight in the apex of the under cone D, and passes down the centre of a hollow cylinder or tube P, which is slotted internally (as shown at f f in figs. 2 and 3). A little cross piece of metal, Q, is set tight on the bottom of the shaft O, by being screwed fast into its end, and this cross-piece Q (which is afterwards more particularly described) fits across the tube P, taking into the slots or grooves on each side, so that it can slide up or down in them. When, therefore, the tube P is made to revolve, it carries the shaft O round with it, by means of the sliding cross-piece Q, and makes it to rise or sink by its screw working in the fixed nut a, so that the shaft Q, carrying the electrode M in its socket, has a rotary motion combined with its vertical motion, for the purpose of equalizing the wear of the electrodes on all sides. The tube P turns on a pivot g, which works in the bottom of a circular box of metal H, which is screwed into a hole of sufficient size in the bottom of the brass-plate G, which is fixed to the upper surface of the wooden base B. The touching surfaces at the pivot g are coated with silver, as that metal presents a surface peculiarly fitted for receiving the current of electricity. The upper end of the tube P receives the outer part of the fixed nut e, on which the tube turns, and is steadied as an axis. On the upper part of the tube P, a worm-wheel S, carrying forty teeth, is attached, which is made to revolve by a horizontal double-thread tangent-screw T, the pitch radius of which is one-tenth of an inch. To one end of the screw is attached a crown-wheel U, carrying forty teeth, which is actuated by pinions V and W, on an upright spindle X. The pinions are at a somewhat greater distance apart than the diameter of the crown-wheel U, and are driven into it from opposite sides, so that when the spindle X is raised a little, the lower pinion V (having eight teeth), is geared into the lower side of the crown-wheel; but when the spindle is sunk, the lower pinion is thrown out of gear, and the upper pinion W gears into the upper side of the crown-wheel, the ends of the spindle continuing to revolve in the same direction as before, imparting a reversed rotation to the crown-wheel. When the spindle is kept at a medium degree of elevation, neither of the pinions is in gear with the crown-wheel, so that it remains quiescent. This spindle X is kept in its position by working through the middle plate, F, of the apparatus, which plate is attached firmly to three of the pillars c. The upper end of the spindle works through a hole in the centre of the bottom of a circular brass box I, which is fixed to the side of the under cone D, and the under end of the main-plate A. The box contains a centrifugal regulator Y, which consists of a bit of watch-spring bent into the form of the letter S, carrying two little weights H H at its ends, and fixed horizontally across the top of the spindle by the middle part of the spring, which fits into a clevis in the top of the spindle, and is screwed on a small nut. When the spindle is made to revolve too fast, the weights at the end of the spring fly outwards by their centrifugal force, and begin to touch and rub against the sides of the circular box I, which friction checks the motion. This description of governor preserves the motion more uniformly than the ordinary sort of fly, which acts by the resistance of the air. Just below this centrifugal governor there is a cross-piece i, inserted through a transverse hole in the spindle X, so that when the spindle is at its medium degree of elevation, that is to say, when its two pinions V and W are neither of them in gear with the spindle, and is impelled by the ends of the cross-piece i meet a stop k, which may project from any fixed part of the apparatus, such as the cone D, and so stop the revolutions of the spindle; while, as soon as the spindle is raised or lowered, the cross-piece i no longer meets the stop k, but passes over or under it, and allows the spindle to commence its revolutions just before one of the pinions gears into the crown-wheel. The spindle X is actuated and kept with a constant tendency to revolve in one direction by a toothed wheel Z, keyed on to it just below the middle plate F, and this wheel is driven by a train of wheelwork W, supported between the middle and bottom plates F and G, similar to ordinary clockwork, and which is driven by a spring in a barrel l, acting upon a fusee m, driven by a cord or chain; or the wheelwork may have any other contrivance as its prime mover, as, for instance, a common barrel with a cord and weight. The wheel Z is of such thickness that the motion up and down, which the spindle X admits of, will not unger it from the next wheel in the driving train.

The mode in which the spindle X and its pinions are raised or lowered, so as to vary the motion of the crown-wheel U, and thereby of the electrode M, according to the exigencies of the light, is as follows:—The bottom of the spindle X terminates just below the driving-wheel Z, and rests on a plate of ivory n, which is supported on a short upright stem of brass q, which has its lower end screwed into a hole in the top of a solid cylinder of soft iron, p. This iron core moves freely up and down in the central hole of a reel q, round which a quantity of insulated copper wire is wound; one end of this wire is led to the binding screw B, as before mentioned, which connects it with the positive wire of the galvanic regenerators, and the other end to the wire which passes through the binding screws L. The reel of the regulator is fixed firmly to the wooden basement B, and a cap r of soft iron fits over it; but the iron of the cap does not extend quite to the centre of the hole in it
(through which the brass stem p passes), the central part of the top of the cap being of brass soldered to the iron, of one-half of the time in the cap is the same as the diameter of the main plate B, in the coil of the regulator R causes the iron core p to rise or fall, according to the quantity of electricity passing, and so doing, the spindle X, which rests on it, to rise or fall with it. There is a little eye attached to the bottom of the iron core, to which the binding screw M is inserted. The whole spring of the condenser (of which the terepois being kept for use), of such weight as to allow the iron core to be just in equilibrium, or just ready to rise, when the distance between the electrodes is such as to allow the electric current to flow freely enough to produce a steady and certain light. There is also a little ledge a, around the lower end of the iron core, on which rests a disc t, of brass, of about the size indicated in the drawing, fig. 2; which, when the iron core falls below the neutral point) becomes supported around its outer edge by a circle of brass u, and is left behind on it, when the iron core continues to descend, thus relieving the weight, while on the other hand, if the iron core is disposed to rise above the neutral point, it has to lift the whole weight of the brass disc t. This arrangement gives the iron core a tendency to remain stationary at the neutral point, which is that point at which the elevation of the spindle X enables the cross-arm to touch with its stop k, and arrest the rotation, and so prevent unnecessary working of the machinery, until the electric current has varied so much as to render desirable an adjustment of the distance between the electrodes; which the iron core effects, as before described, by rising or falling in thickness.

The neutral position at which the iron core p should remain, is when the top of the iron core is as far below the top of the regulator reel as is represented in fig. 2.

The brass ring u, which supports the equilibrium weight, is tied to a thread running in a groove made in a collar height by being attached to a sufficiently stiff strip of brass w, of a certain length, and which is fixed by its other end to the other side of the wooden basement B. The brass ring u can be adjusted to the requisite height exactly, after the apparatus is made, by a milled-headed screw passing through the brass plate u, and running down on the supporting brass strip (not far from u), so as to depress it to the right position.

The sliding cross-piece Q, before adverted to, is constructed in the manner separately represented in fig. 4. A spring Q (of thin hard brass, for instance,) is attached to one side of the cross part by a small screw, so that when the cross-piece is placed in the slots of the tube P, the spring always remains in close though not forcible contact against the sides of the slots, so as to insure a good conduction to the electric current, which has to pass over the shaft, and enter the inner end into the slotted tube.

The tangent-screw T is made not quite horizontal, but inclined at an angle of one in twenty, because the lower pinion V is smaller than the upper one; and therefore it is necessary that the lower edge of the cross-wheel U should be well shown on the side of the spindle. The lower pinion is made smaller, in order that it may be better wind the main shaft O, after it has screwed itself up, until the ends of the electrodes come into firm contact, lest it should stick in that position.

The screw No. 1, when it is the stand 3 of the tangent-screw to the middle plate F, passes through a hole 4, enlarged sideways in the stand; so that by only loosening the screw 1, the stand may turn on the other screw 2, as a centre, so as to allow of the tangent-screw T being adjusted to the right distance from the centre of the wheel S, in order that when it may work properly into its teeth, or, when required, to throw the tangent-screw out of gear with it altogether.

The thread of the screw of the main shaft O, should be of a square form, so that it shall work with as little friction as may be, when supporting the weight of the shaft and electrodes. A cone of white glass or porcelain, E, is made to slip over the upper cone C of the main plate, and is turned up at the edges (as shown in figs. 1 and 2), to reflect the light better, and to catch any dust and ash which may be thrown off from the electrodes.

The glass may be made into sugar or wax, or any other desired, fits over the electrodes, M and N, and the stand K, and is screwed down to the main plate A, by the brass circle E, into which its lower edge is cemented, whereby the electrodes are enclosed entirely from the outer air. As soon as they have exhausted the oxygen which is within the glass shade, they no longer so rapidly consumed. When the electrodes, however, are composed of some inferior sorts of carbonaceous preparations they give light more steadily if a very small quantity of atmospheric air is continually allowed to enter; that is to say, just sufficient to burn away the button of carbon which sometimes forms on the end of that electrode which is not undergoing decomposition by the electric current, as is the case in the use of a small quantity of atmospheric air, two light valves may be inserted in the main plate A, one opening inwards and the other outwards, which would provide for the varying pressure of the air when the temperature is altered by the presence or absence of the light used in transmitting the current. Two circular brass weights, a, a, fit over the other around the ivory top ns, which carries the pivot of the spindle X; their use is to enable an easier and more precise adjustment of the weight on the iron core than can be effected by altering the large weight F, which is hung at the bottom of the iron core.

When it is intended to use small currents of electricity, the spindle X, and all its appurtenances, should be made very light, and the iron core may for the same object be made hollow with advantage; its sides, however, should not be less than one-twelfth of such in thickness.

The electric current may be obtained from a galvanic apparatus of any of the known sorts, or from any other convenient source; and it may be used of various intensities and quantities. A good degree of intensity to use, is such as would be afforded by one electrode of a sort employed in galvanic apparatuses, and the quantity of the current may vary from that evolved by the consumption of less than one-and-a-half grains of zinc per minute in each cell, to that evolved by the consumption of more than fifteen grains of zinc per minute.

The positive pole of the galvanic apparatus, is clamped with the binding screw at B, which serves as the conductor through the regulator coil, and then up to the upper electrode N. The wire from the other, or negative pole of the galvanic apparatus, is to be clamped with the other binding screw at B, which is connected by a slip of metal (copper) to the bottom plate G of the apparatus, so that the current passing from the lower end of the upper electrode N to the top of the lower electrode M, then traverses the central shaft O, passes through the cross-piece Q, at its lower end, into the slotted tube P, and thence through its pivot at bottom of the metallic box or cavity H, which is metallic connection with the bottom plate G, leads the current to that plate and thence by the slip of copper to the other clamp, from which it passes in return circuit through the apparatus. Now first, the current is applied with the electrodes in contact, flows freely, and that causes the regulator (being properly weighted) to raise the spindle X, and thus put the apparatus into gear for screwing the centre shaft O downwards, and gradually separating the electrodes, whereupon the light begins to appear between them.

The patentee then describes the method of preparing the carbon for his electrodes:—About equal quantities are taken of coal of a medium quality, and of the prepared coke, known as "Church's Patent Coke," and both reduced to a state of fine powder and intimately mixed together. The mixture is then placed in close wrought-iron moulds, which may be made either to give the mixture the form of a block, to be afterwards cut into pieces of the required shape, or to give at once to the mixture the form of the intended electrode. In all cases it is preferred to make the moulded pieces have a temperature of more than 3 or 4 inches in its least diameter, for when it is liable to have fissures, and not to be of such uniform density. The mixture being placed in these moulds, is subjected to heat and heavy pressure until it becomes consolidated into a very dense and firm mass. And when the mass is in a heated state of from 200 to 300 degrees, or for a time to keep hot (not by heat of any liquid,) and kept therein for a short period. It is then taken out and allowed to become cold, when it is placed amongst pieces of charcoal in a close vessel, which is gradually heated until it attains a full red heat, after which the temperature is increased to an intense white heat; at which it should be kept for many hours, or even two or three days, according to the hardness and compactness desired. Or the mass may be a second time immersed in the melted sugar while hot, and the remainder of the process be again repeated as before.
By coating the mass in this way with melted sugar, any pores that may be in it (on its external surface at least), are filled up with carbonaceous matter, and any subsequent drying rendered unnecessary.

The following the patentee states to be the best dimensions for the electrodes:—The lower electrode should be as long as can be conveniently manufactured (8 inches for instance,) when used for ordinary purposes, and it should be of a cylindrical form. The smaller the diameter is, the better the light; but the larger the electrode is (in cross section), the longer it will last with a given current of electricity. The upper electrode need not be of any great length; it is well, however, to have it about one-third as long as the lower, and of half the diameter.

The patentee concludes his specification with the following account of a method of employing currents of electricity to actuate apparatus for effecting the speedy lighting up and extinction or obscuration of signal lamps in which oil, camphine, or other like inflammable fluid is the illuminating substance employed:—Suppose, for example, there are three such lamps with different coloured glasses, say white, green, and red, which are required to be sometimes lighted, and at other times extinguished or obscured, as is usual on railways, and not all at once, but in a particular order of sequence, or each under particular circumstances only, I effect this in the following manner. The three coloured signal lamps are placed side by side, or they may be placed one above the other. A sectional elevation of one of these is given in fig. 5. A' is a bar of metal, having a drop bar B', attached to it. These bars are for the purpose of working three extinguishers, one to each lamp. The figure shows one of these extinguishers as applied to a lamp; the dotted lines in the figure indicate the position, which it assumes when raised up. The drop bar B' is attached to a clockwork escapement, the detent of which is alternately retained and liberated by the passage of electric current, and by its mechanical force raises up the bar B', and causes the light, in whichever lamp it may be, to be put out. The three extinguishers are made to move together, to save the necessity of each being provided with a separate extinguishing mechanism. In the centre of the burner of each lamp is a ring a, of fine platinum wire, which is so contrived as to touch the wick of the lamp, and the current of electricity being made to pass through this platinum ring, it becomes intensely heated, and thereby ignites the wick of the lamp. I do not restrict myself, however, to the employment of platinum wire, as carbon for this purpose may be used, or any other difficulty-fusible material; neither do I limit myself to the employment of a ring of any particular form. The wick may, for instance, be a flat wick, and in that case a straight piece of wire would be suitable for the arrangement.

**ARTIFICIAL FUEL.**

Bondy Arulay, of Roberthite, Surrey, printer, and Abraham Solomon, of London, merchant, for "Improvements in the manufacture of charcoal and other fuel."— Granted June 10; Enrolled Dec. 10, 1847.

This invention relates, first, to the manufacture of charcoal, to avoid waste caused by breaking it. This is effected by reducing the waste to powder, and then compressing it, by an hydraulic press or other apparatus, in moulds, until the mass is reduced to from one-fifth to one-eighth of its original bulk.

The second invention relates to making fuel of small coal, breeze, coke, and cinders, with or without charcoal, by pulverizing the whole, and then compressing the powder into blocks.

The third invention relates to making a fuel for lighting fires, by mixing charcoal powder, small coal, breeze, coke, and cinders (all or any of them), with tar, pitch, resin, or other suitable inflammable substance, and compressing the mixture in moulds; and when taken from the mould, the block is dipped in the tar, &c., and covered with saw-dust and wrapped in waste paper: a block so prepared will readily ignite on the application of a lighted match.

**WATER GAUGE.**

Alfred Vincent Newton, of 66, Chancery-Lane, Middlesex, mechanical draughtsman, for "Improved apparatus to be applied to steam-boilers."—Granted April 15; Enrolled Oct. 15, 1847. (A communication.)

The principle upon which the apparatus is constructed is that of a percussive horizontal action of a flat surface upon a portion of the water to be gauged. One form of apparatus on this principle is shown in the annexed engravings, figs. 1 and 2, being an external view and section. a, the steam-boiler; b, a small cylinder communicating therewith by two tubes c, d, the upper one with the steam, and the lower with the water; e, a piston, moving freely in the cylinder b, and connected by a rod f, to a vibrating lever g, enclosed in a quadrant-shaped chamber. The pivot of the lever g passes through a stuffing-box h, made at the small end of the quadrant, and carries externally another lever h, furnished with an index for indicating, on a graduated scale, the height of water in the boiler. A rod i is suspended from the lever h, for enabling the attendant to raise the piston in the cylinder, and bring it down with percussive force on to the surface of the water, in order to ascertain its exact height. It will be at once understood that the same pressure of steam and water must exist in the cylinder and its quadrant case as in the boiler, and that the working of the apparatus cannot be affected thereby.
ON THE IMPROVEMENT OF INLAND NAVIGATION.

BY HON. & REV. A. P. PERCEVAL, B.C.L.,
CHAPLAIN TO THE QUEEN.

CHAPTER I.—On the Comparative Prospective Value of Railways and Canals.

In the month of December, 1844, while a party of travellers and traders were waiting at the Crewe Station the arrival of the up-train, and eagerly discussing railway matters, that mania being then at its height, they were startled from their propriety, by hearing an individual in the room address them thus: "Well, gentlemen, I will back the canals against the railways now; I intend to invest wholly in them, and I advise you all to do the same." If a pistol had been discharged in the midst of the company, it could hardly have produced a more striking effect. All stared; and most, by movement or ejaculation, gave token of extreme surprise. Some looked with pity upon the speaker, a clergyman, as though the saying, "Ne euror ultra crepudam," was passing in their minds, and they contemplated one about to ruin himself and his family by meddling in matters out of his sphere. But when he proceeded to propound, for the consideration of the company, his grounds for the opinion which he had expressed, none were found ready to gainsay the reasonableness of them. They were these:

I. That the wear and tear on canals is so considerably less than on railways, that the former, if properly conducted, must be able to undersell the latter.

II. That while lines of railway may be multiplied ad libitum, occasioning unlimited competition, and consequently unlimited reduction of profits, such multiplication of lines of water conveyance is next to impossible; consequently, that canals must always retain a comparative monopoly.

III. "Remember, gentlemen," he said, "that human talent and ingenuity have been taxed to the utmost to bring all the appliances that science can afford, to promote locomotion on railways; while, as yet, nothing, or next to nothing, of the sort has been attempted on canals."

Three years have elapsed since these opinions were expressed at Crewe; let us see what light can be thrown upon the soundness of them, by comparing, 1st. The present state of railways with its condition at that time; 2ndly. The respective condition and prospects of railways and canals, then and at the present time.

I. To take three old and well-established lines for illustration:

The value of the under-mentioned was, in Dec. '44; is, in Dec. '47.

London and Birmingham ..... 928 130
Great Western ..... 137 90
London and South-Western ..... 77 50

II. Let us take for illustration the Birmingham Railway and the Birmingham Canal:

In December, 1844, the Birmingham Railway furnished to the proprietors, not merely in actual dividends, the 10 per cent. (to which it had been sought by Act of Parliament to restrict the profits on railway enterprise), but advantages in new shares, &c., in general estimation certainly not less than another 10 per cent.

We have now before us the Report of this company for the half-year ending Midsummer 1847; announcing in the plainest terms, that the second of the causes alleged at Crewe as a reason for regarding railways as offering doubtful security for investment, namely, the liability to unlimited competition, has begun to tell with fearful effect against the prosperity of this most prosperous of railway undertakings, which is no longer able to pay even the legal 10 per cent. The Chairman is stated to have said: "He hoped that before Parliament sanctioned any further extension of the principle of competition, or of reduced fares, they would hear in much of the inevitable results which must follow from pursuing such a course. They saw its effect upon their receipts now... Competition might go on in consequence of rivalry and contention between different companies; but what would be the effect? The proprietors would interfere and force the directors to reduce the rate of engines, the earnings of the company to the lowest possible point; trains would be taken off, servants would be discharged, the whole machinery of the company would be deteriorated, and what would become of the public safety? This would be the result of those doctrines of competition which had been taken up by the legisla-
ture."—Here, then, we have the confession of the most intelligent of railway chairmen, at the head of the most influential of railway companies, avowing in the face of Europe that railways afford so insecure an investment for capital, that they cannot possibly be relied upon, unless in their behalf the doctrine of Free Trade, to which all mankind, to speak generally, have given in their adhesion, be repudiated; and an artificial protection be afforded to the system which has been so often the ruin of the inland navigation, but even to the agriculture of the country!

Meanwhile, how has the Birmingham Canal been faring? In December, 1844, in consequence of the railway mania, it had so fallen in public estimation, and apprehensive value, that projects for draining of the water, and converting the channels into railway beds, were seriously discussed.

We have also before us the Report of this Company for the half-year ending Midsummer 1847: from which it appears, that notwithstanding its operations have been impeded by a very questionable set of prudent measures which it has contrived with the Birmingham Railway, whereby it has placed itself, to a certain extent, under the control of the latter, on condition of receiving from it a guarantee, in perpetuity, of the customary dividend of £4 per share (a guarantee which it is doubtful whether the railway company will be able to afford, the canals ever being so reduced as to demand the fulfilment of it), and notwithstanding a "considerable pressure on the mercantile world," to which in common with the railway, it has been subjected, its affairs are in a state of unexampled prosperity. The account for the last half-year, "the Report," states, that the increase of revenue, the amount for the six months ending 30th of June last, including rents, being £86,423 7s. 3d. [being an increase of £91,192 above the corresponding half-year in 1846]. The balance of the accounts, after providing for the payment of the half-year's interest and the usual reduction for bad debts, on which the committee now recommend to be paid free from the income-tax, shows a surplus of upwards of £20,000.

In other cases, where the canal companies have not tied their hands from competing with rival railways, as the Birmingham Canal Company have done with the Birmingham Railway, the truth of the first of the reasons alleged at Crewe has had opportunity of being tested: and the result has been, to speak generally, to confirm and establish its truth; and Lord Ellesmere on his waters, and the Birmingham and Lancaster Company on the latter, has no other interest in the world than to cease to dread any evil effects from railway competition, through fear of which the former received (according to report) from £50,000 to £100,000, by way of compensation; and the latter unprofitably expended several millions in an abortive rival speculation.

It remains to be seen whether the third of the reasons alleged at Crewe in 1844, for preferring canals to railways for investment—namely, "that while human ingenuity has been taxed to the utmost to facilitate locomotion on railways, little or no attention has been bestowed upon the improvement of inland navigation"—is as sound as the others (apparently) have proved to be: in other words, "whether inland navigation is not capable of very great improvement." This shall be the subject of the next chapter: before entering upon which, let it be well-considered, by way of encouragement to turn attention to the subject of inland navigation and canals, to bring upon the canals the whole or almost the whole of what forms the chief source of revenue on many railways—namely, the conveyance of live stock. No grazier, or butcher, it is believed, will be found to affirm otherwise than that, if the choice were offered to him, he would choose rather to convey the stock that he has to sell, or kill, by water than by rail.

CHAPTER II.—On the Improvement of Inland Navigation.

When the mind has once been directed to devise means of rendering our lines of inland navigation more active than at present they are found to be for the commerce of the country, the small degree of attention which has as yet been bestowed upon them is apparent at every turn. Of the matters calling for amendment, some are obvious to every passer-by; others require consideration to be noted; others again require argument and proof. Again, some are in the power of the parties trading upon the waters; others in that of the proprietors or trustees of the waters; others again require either extension, combination, or the interference of the legislature. Let those matters in which the want of amendment is manifest to all be first considered. Of such let these be named:—1st. The style and condition of the animals usually employed in the traffic. Generally speaking, these are the worst of their kind, disabled, low in condition, ill-groomed, ill-fed,—a striking contrast to those admired in lands not so closely pressed. The steers of the takeaway. Natural earth, mud, water, deep sand, slippery chalk. Contrast these with the roads and ways employed in land traffic. By the sides of other roads care is taken to keep the cattle from trespass.
null
navigation from London to the Channel would be completed; and by continuing the navigation of the Test or Auton to Whitchurch or Ash, with a cut of five miles to the Basingstoke canal, a third line would be completed: and Langston, Arundel or Littlehampton, and Langstone would become the ports of London.

On the other side of the Irish Channel, conveyance companies between Dublin and Waterford (by the Barrow navigation, as thriving a water concern as any in the kingdom, and the receipts on which last year were greater than ever); and between Dublin and Limerick (by the Grand Canal, one of the finest in the kingdom, and the Shannon), obviously present themselves. A cut of three miles, or thereabouts, connecting the Slaney with the Barrow, would bring Wexford within inland navigation of Dublin. A cut of about the same length from the Grand Canal at Ballinamore, into one of the small rivers that run into Galway Bay, would connect, in the shortest line, the Atlantic with the Irish Sea.

It is believed by the writer that every one of the twelve or fifteen lines here enumerated will be admitted by all practical men to present, if properly conducted, as safe openings for capital and industry as any in the kingdom.

---

REVIEWS.

Mr. Hosking's book may be taken as one of the signs of the times, and therefore we give our attention to it, and recommend it to our readers. The outcry for sanitary reform can no longer be unheeded; it has led to a practical movement, which must go on. The architects, engineers, and medical men, who created this movement, and have fostered it—and we rejoice that our publication has been found among the earliest advocates—may feel justly gratified that their proceedings have received the patronage of the legislature.

Those, however, who have held back, or thought that the agitation had no practical authority, and was merely a noise about trifles, must now bestir themselves, or they will be left behind by their more enlightened competitors. Obstinate adherence to old prejudices has already brought public ridicule on some men of standing; and reputations which have cost scores of years to build up are at once knocked down, when it is found that the parties have for scores of years been wasting the public money, in the despite of every warning. The public are now awakened, and they require at the hands of architects and builders a degree of knowledge as to structural arrangements, which formerly was never thought of. For all the better class of buildings it is no longer enough to run up a set of walls and to line them, but the buildings must be made habitable otherwise than by having mere shelters against rain. They must have proper provision for lighting, warming, ventilation, and sewage; matters about which employers and builders thought very little some years ago. The reports of the Sanitary Commissioners, the labours of Mees, Bee and Phillips, the work of Mr. Hosking, are landmarks, whereby professional men may understand the present, and observe the disposition of the authorities to carry out to the full what was used to be laughed at as the theories of sanitary reform. Mr. Hosking, of course, disclaims any official character for his book; but his station as one of the first architects in the kingdom gives him, in the public, an official character to his book in defence of himself; and most of what he says is so reasonable, that it will work its way with the legislature, the public, and the profession, all of whom his book interests.

Although it is perfectly true that the present mode of such structural arrangements has arisen mostly from the labours of architects and engineers, yet it has not been fostered so generally among the profession as is desirable. Indeed, the public at this moment are ahead of architects and builders—a state of affairs which cannot long continue with comfort to the latter. This arises we fear, from a want of appreciation of the value of professional literature, and therefore the want of a laudable spirit of investigation and information. If it be remembered that until our Journal was established, no architectural periodical had been able to maintain itself, the case of our readers formerly was; but though the number of years which this Journal has existed is a proof that we have effected a change for the better, we cannot but be sensible that architects are not so much alive as they ought to be to the cultivation of professional learning. To advert, as an instance, to our own publication, we feel well assured that a great number of our readers or earlier remarks on sanitary and structural arrangements were passed over as being of no interest, or of being of no immediate importance; the reader did not take the trouble to investigate and search out for himself the truth or justice of our arguments. The consequence has been that many, instead of being gradually led and prepared to a practical appreciation of the subject, wake up as it were, suddenly to a consciousness that they have got to work, and to deal immediately with some trouble, which they might have learned slowly and easily. We have sometimes met with remonstrances because we have given attention to questions which were thought the whims of the day, but which we now recognise by all, though it should be remembered, that a periodical like our's is a link between the public and professional men, for those of the public who feel an interest in professional pursuits, or seek for information, naturally apply themselves to such a recognised source. Hence we have been enabled on many occasions to forward professional interests, and to awaken attention among the public, so as to ensure cooperation in carrying out measures which were desirable. In particular, it is incumbent on professional men to apply themselves, or otherwise to make the publication and their own interests, to forward themselves to secure, if they can, some greater share than fairly belongs to them in the new arrangements.

Mr. Hosking's book must be read by the architect and builder, because it is just the kind of book which will be read by the employer. The Committee desire, the gentleman who wants a comfortable mansion, the merchant who requires a safe warehouse, the board of guardians who advertise for a healthy workhouse, are likely to look into the work before us, as a guide to the best modes of securing the health, comfort, and safety of a building. Perhaps it might be put in favour of timber and against iron, and in favour of brick and against stone; but we hardly like to say this, for there is so much candour in stating the case, and so much practical knowledge displayed throughout, that we believe Mr. Hosking is about as fair a guide as can be had. There is very little of his book which is new, and it is hardly likely that there should be; but what there is new, is the careful and close consideration of what is the best and most practical mode of reaching any given end: and this may be called new, for we fear it is too general to run up buildings without the least consideration of their fitness for the purposes to which they are applied. It may be said shortly that the houses of the metropolis are made dangerous to life from their combustibility, and to health from their want of ventilation; while the sewers are so made, as to form an electric machine for the destruction of the infant, for cutting off the infant in its cradle, and taking years away from the life of every inhabitant of this immense and thickly-peopled city.

We have said that Mr. Hosking is unfavourable to the use of iron under some circumstances, and it will be useful to lay before him the following lines:

"There is no kind of economical structure that resists the action of fire so perfectly as brickwork does, and any structure wholly of bricks, set in and combined with proper mortar, may be deemed for all economical purposes a fire-proof structure. But doors and roofs, or roof coverings, cannot be formed in brickwork alone, without a sacrifice of space and materials, so large an extent as to render such a mode of structure inconsistent with a due regard to economy in those important particulars. Means are to be sought, therefore, by which brickwork may be rendered available, to the greatest extent possible, consistently with economical structure. In this may be seen the spirit of Mr. Hosking, who presents itself as a substance wholly incombustible, and capable, in the form of beams and girders, of bearing over space horizontally, and so as to leave, for economical purposes, a large proportion of extent in height, which brick vaulting would not afford; and so that for their lateral abutments, iron, employed as a means of vertical support, in columns or story-posts, will give the requisite strength to that effect in far less space within an enclosure than brickwork requires in piers or pilasters to give the same effect. But iron, being a little more heavy than brick, is not so flexible, and, although incombustible, is liable under the action of intense heat, and is, in its more economical condition, fragile if suddenly cooled when hot; without reference to its generally brittle character, or to the probable effect which attends it under such condition. Beams, girders, and columns or story-posts, of wrought-iron, if such things could be produced in wrought-iron economically, would bend when exposed to a high degree of heat, and let down any structure that had been made dependent upon them; whilst beams or girders of cast-iron break when dashed with water; and columns of the same substance are liable to
Mr. Hosking goes on to suggest the mode in which iron can be safely used for floors and ceilings; but he adheres to the opinion that if pillars must be used, they should be of brickwork.

We ourselves have witnessed the danger of using cast-iron in exposed situations in buildings. We recollect, within the last four or five years, the fire at Fentons's wharf, London Bridge, where the warehouses were ascended upon cast-iron bressummers, the whole of which was through being heated by the fire, and the cold water of the engines falling upon them, were cracked, and in consequence the superstructure was obliged to be taken down. In other situations, we have seen the fronts of houses erected on timber bressummers which have gone in consequence of the external wall being heated, to an inch in depth of the timber being only injured by the flames.

The preservation of life from fire is an object in which Mr. Hosking deservingly takes great interest, and he has brought to bear the results of his remarks on buildings at Paris, which we wish could be of some length to our own pages. After recommending that party-walls shall be reduced to one-brick thick, on condition of cross-walls or partitions being built throughout the house of one-brick thick, and after stating the danger of the hollow quartering partition generally used, he describes the system he observed in Paris.

"The plan referred to is, to frame and brace with timber quarterings much in the manner practised in England, except that the timber used in Paris is commonly oak, and is very generally seasoned before it is applied in building in the manner referred to; and that, as before remarked, the carpenter's work, or carpentering, of the French is not so good as that of the English. The framed structure being complete, strong oak batten-laths, from two to three inches wide, are nailed up to the quarterings horizontally, at four, six, or even eight inches apart, according to the character of the work, through-out and through the ends of the columns; and the quarterings, and behind the laths, are loosely built up with rough stone rubble, which the laths, recurring often enough for that purpose, hold up, or prevent from falling out until the next process has been effected. This is to appear mainly that the partition is completely covered, which it is well to know under the name of plaster of Paris, but of excellent quality, laid on from or upon both sides at the same time, and pressed through from the opposite sides so that the mortar meets and incorporates, imbedding the stone rubble by filling up every interspace, and with so much body on the surfaces as to cover over and imbed also the timber and the laths;—in such manner, indeed, as to render the concretion of stone and plaster, when thoroughly set, an independent body, and giving strength to, rather than receiving support from, the timber."

The same plan is applied in Paris to the stairs, and Mr. Hosking recommends it as the best solution of the French mode of making ceilings and floors.

"But the French render their floors also so nearly fire-proof as to leave but little to desire in that respect, and in a manner attainable with single joists, as well, at the least, as with joists framed into girders. According to their practice, the wooden floor, or solid board, is laid upon the surface of the floor, as inasmuch as the ceiling is formed from above, instead of from below.—The carpenters' work being complete, strong batten-laths are nailed up to the undersides of the joists, as laths are with us; but they are much thicker and stronger, and not only are they held down by being mortised into the bosses, but the staves, or the bars, as they are called, placed upon the surface of the ceilings, are laid in such a manner and fashion that they must be soundly nailed, as they have a heavy weight to carry—a platform, made of rough boards, is struttled up from below parallel to the floor, and upon this the laths are laid, and at about an inch below the platform, and is then laid in from stairs, and over the platforms or laths, to a thickness of from two inches and a half to three inches, and is forced in, under the laths, and under the joists and girders. The mortar being gauged, as our plasterers term it, or, rather, in great part composed of plaster of Paris, it soon sets sufficiently to allow the platform—which, it will be readily un-derstood, has performed the same office to the mortar which centering performs to the parts of an arch or vault—to be removed onwards to another compartment, until the whole ceiling of any room or story of a building is formed. The plaster ceiling thus formed, is, in fact, a strong slab or table, in the body of which the batten-laths which hold it up safely in the air are incorporated, and in the back of which the joists, from which the mass is suspended, are imbedded. By the process, the under side of the plaster table has taken from the rough boards of the platform the roughness requisite to the formation of the finishing coat of plastering, which is of course, laid on from below.

Whether the eventual surface is to be a boarded floor or not, however, the flooring joists are covered by a table of plaster above, as completely as will be necessary, through battens, generally split and in short lengths, looking like ends of oak planks. But even so, when laid from joist to joist, the weight of a man without bending, are laid with ends shutting upon every joist, and as close together as they will lie without rubbing between the edges, so as to joint them. Upon a rough loose floor thus formed, mortar of nearly similar consistence to that used for ceilings, but not necessarily of the same good quality, is spread to a thickness of about three inches; and as it is made to fill in the voids at the ends and sides of the floor-laths upon the joists the laths become bedded upon the joists, whilst they are to some extent also incorporated with the plaster, and the result is a firm floor, upon which, in ordinary buildings, and in the public and commoner apartments of almost all buildings, paving tiles are laid, bedded and joined in a tenacious cement to form the working floor.

It may be added in explanation of the statement, that in Paris the practice of forming a table of plaster over the joists when tiles are to be used as the flooring surface, is employed also when a boarded floor is to be superfine,—the floors of the public schools, for example, are made up in this manner, the plaster table, a base is formed for the boards of what English carpenters would call stout fillets of wood about 23 inches square, ranged as joists, and strutted apart to keep them in their places, over the mortar table, to which they are sometimes fixed, so as to be fixed, and not so as to be fixed, and not at all connected with the structure of the floor, but is formed upon its upper coat of plaster. The wooden floor thus becomes a mere fitting in an apartment, and not existing beyond the floor-room over the passages and landings to which the floor in any case might burn without communicating fire to the stairs, which, in their turn, if they could burn, could hardly endanger the immediate safety of any inmate of the building, because of the complete separation which the tiled and plastered floor of the landings effects between the wooden stairs and the several apartments."

The author remarks that a similar floor is used at Nottingham, where the houses are said never to be burnt, and are free from damp and vermin.

Mr. Hosking objects to timber being laid bedwise in walls, or joists being let into them, but recommends that the rafters be in and properly secured against fire.

We may observe, upon a note of Mr. Hosking's as to Flemish bond, that he says he never saw Flemish bond in Flanders, at Rotterdam and the Hague, Antwerp, Brussels, Liege, Cologne, Ments, and Frankfort. Now there is only one of these towns in Flanders where this is to be found, and that is to be found at Ghent, Bruges, Courtrai, Ostend, Ypres, Dunkirk, Lille, or other towns in Flanders.

Of French carpentry, Mr. Hosking says that it is much behind our's, so that in framing the floors no important bearing is, or indeed may be, trusted to the framed joint, dognailed stitup-strap of iron being always brought in aid. He says, however, that their boarded floors are always tongued in the joints, and almost always parquetted, and so resolved into compartments of various figures, and being tongued and edge-nailed, no nail or bradhead appears upon the surface to detract from its appearance. The French being for such being for the most part of wainscot, are far more stylishly, and better executed beddenned floor with us.

With regard to Parisian masonry our author says,

"It is by means of the girders bearing upon the solids of the wall, though with bad carpenters' work, or carpentering rather, that the French are able to build thinly. When one sees a wall such as a London builder, and that would certainly be unsafe if the walls were seasoned with wooden plates, and shaken by floors of single joists. The author, being at Paris in 1846, measured the thickness in the ground-floor story of a three-storied house—the Dame de La Bouclos (the Grember Street of Paris), and found it to be exactly 18 English inches in that part, whilst the total height of the wall was not less than 85 feet. The wall ran up of that same thickness through six stories, a height of not less than 12 stories. One story was a gallery of from 12 to 15 feet high, of the same kind of structure; and there was besides a vaulted basement story, throughout which the wall might have been 20 inches thick, as other similar walls then in progress to neighbour buildings proved to be. And it is by means of the solidity given to the floors by the girders, and the solid bearers which the girders obtain, that the floors are able to carry the dead
Among Mr. Hoaking's objections is that to the use of concrete as a mere footing for walls, from the notion that a Midland cast concrete floor is thus rendered strong by depth: whereas he advocates the use of a thinner layer of concrete over the whole foundation, so as to gain strength by an increase of base.

Another objection he entertains is to the wooden skirting-board, which contains the fire, and is often kept wet against fire: and if any of our readers do, we recommend to them the following justification:

"It appears from an estimate appended to a Report by Mr. Fairhain on the Construction of Fireproof Buildings, with Introductory Remarks by Mr. Samuel Holmes, published at Liverpool in 1844, that the insurance-offices paid for losses by fire in Liverpool alone, in the ten years ending December 1842, the sum of 1,121,427l. This sum does not, of course, include the losses of, and other injuries to, the poor who do not insure, but who are always great sufferers in cases of fire; and some of the fires which occasioned the losses were extensive conflagrations, in which lives were lost in the attempts made to subdue the fire; nor does it include a probably large amount of property not sufficiently insured to cover the losses.

Urged by successive calamities by fire, and by the high rates of premium which the insurance-offices were compelled to exact to enable them to meet the losses, the people of Liverpool, in 1843, formed an Association at large, and, by Act of 1843, an Act to compel themselves to abide by certain wholesome regulations, as it regarded the security of buildings from fire. The effect of this Act, 6 & 7 Vict. c. 109, and the provision of a supply of water available in case of fire, has been to reduce the rates of insurance considerably; but the protective measures are estimated to have cost from 200,000l. to 300,000l., which being added to the losses above stated, with a trifling addition for the losses not included in the estimate, will show an annihilation of property in one town alone, and within ten short years, to the enormous amount of a million and a half of money."

The author is not quite clear upon the subject of ventilation—but then it is in its infancy: still his remarks are well worthy of perusal.

In conclusion, we may observe that Mr. Hoaking has rendered a great service to the profession by the publication of this book, as a useful work of reference, and as a vindication of the practical claims of the architectural profession to their proper share in structural arrangements.

These are two large volumes with a profusion of plates, forming the third and fourth of the series of railway practice. They are translations from the Portefeuille de Chemins de Fer, by Messrs. Perdonnet and Bree, but derived from English materials. It is a curious thing that we should be indebted to the French for the description of our own railway works, and that there should be a want either of enterprise or zeal to publish an original account. So it is however that we are particularly deficient in accounts of our great engineering works, and this from three causes: that our great engineers have no time to write, that our young engineers have no ability to write, and that engineers generally do not buy nor read works when published. Thus we are often served at second-hand with accounts of our own works by Frenchmen, Americans, Germans, or Russians, when we have made abroad, we get confidence enough to make a trial here. We are, perhaps, the more indebted under such circumstances to those who, like Mr. Bree, take the trouble and the risk of making us acquainted with foreign works. In the present instance, we have from Mr. Bree two volumes, which will be found invaluable as records of the best practical examples of railway engineering. If we have any fault to find it is that he has not sufficiently reduced the French measurements, a labour which if performed by him or his assistant, would have added to his readers.

The third volume is devoted to earthworks, permanent way, blocks and sleepers, rails and chairs, with turn-tables, sidings, and switches. The fourth volume describes stations, carriages, trucks, water cranes, and station plants.

When we say that there are more plates than text, we think we offer a very strong recommendation of the work to the practical man. These plates too are filled with details, so that nothing is wanted to give a correct idea of everything described.

Among the plates are:—The forms of every kind of rail in use in England and elsewhere; machinery used for making rails; navigators and platemakers' tools; switches on various plans by Robert Stephenson and others; turntables of the London and South Western railways; locomotive turntable; weigh-bridge; level crossings and gates; culverts; and single hoist bridges; crossings for temporary works; earthworks of the London and North Western and Great Western; Mr. Jee's Barton station on the Manchester and Sheffield; bridges over the Mer, Clyde, and Meuse; viaducts on the Manchester and Sheffield, and Manchester and Leeds; culverts on the London and North Western. Among the carriages are those of the London and North Western, Birmingham and G洛ster, Great Western, of French, German, and Belgian railways, with details of the wheels, axles, frames, buffers, springs, and other parts. These plates of carriages include passenger and mail carriages, horse-boxes, trucks, and goods wagons. This part is of particular value at a time when the influence of the carrying stock on the structure and working of a line is the point which most affects the engineer. As the plant increases, and the necessity for economy in the working becomes greater, the attention of the engineer is well bestowed on a knowledge of the best construction of carriages, and the most efficient means of improving them. Hitherto very much attention has been given to the locomotive, and to systems of atmospheric traction, but a more immediate reference to the load to be carried is the point to which the engineer will for some time to come direct himself. The establishment of lighter engines and smaller trains will call for a great deal of ingenuity to provide plant suitable to such a different system of traction.

Mr. Bree gives many details of stations and their details. Among them are the South Western at Nine Elms, the Euston-square terminus, the Birmingham terminus, the Nordbahn station at Vienna, the Brunnen station on the latter line, stations at Versailles and Pest, the terminus of the Versailles line at Paris, the Dublin and Kingstown terminus, and the Leeds station. Besides these leading termini and stations at the principal, intermediate stations, as Tring, Watford, Wolverhampton, Newton, and Coventry, on the London and North Western; Thames Ditton, on the South Western; Reading and Slough, on the Great Western, and numerous places on the Great Western, as well as on other lines, are the work of English engineers, and it is gratifying to perceive that many details introduced by them have served as an example to their foreign brethren. The study of the foreign plans by English engineers will enable them to return the compliment, because the experience and ingenuity of the many men of ability employed abroad cannot fail to be productive of many valuable improvements.

In conclusion, we can only repeat what we have said in the beginning, that Mr. Bree's work will be found most useful to the engineer. It is a reperpetuous every engineer who is connected with railway works, and it has the advantage of presenting copious examples under every head of reference. With these words we commit the work to the hands of our readers, being fully satisfied that it is well worthy of their support.

Next to churches, schools are perhaps the class of buildings most in request, owing to the necessity that is felt for providing education for the poorer and humbler ranks of society. Numerous examples of the kind have been found and erected of late years, yet very few are so satisfactory in point of design as they might have been rendered, at the same, or very nearly the same cost, merely by the application of a little study and judicious taste. Or if it be deemed of no moment of what kind the taste shown in such cases be, it at least well more economic to attempt nothing more than what utility absolutely demands. We agree with Mr. Kendall when he says, "although some of the national schools lately erected are very creditable to their respective architects, the general result of the great movement apparent in the building of churches, schools &c., redounds rather to the honour of resuscitated zeal than to that of architectural talent. So great is the tameness, and so apparent the mediocrity of conception, both in arrangement and style, in many of them, that were it not for the good they effect, we should regret their very existence. Frequently shown in things of the kind, blame rests as much with the employers as with the employed, since it is the ignorance of
HISTORY OF ARCHITECTURE.

We have received the following communications in reference to Mr. Elmes's papers, and which we lay before our readers:

Sir,—In your Journal for November last, page 338, there is a statement which, I fear, may lead some of your readers into error. In the life of Stuart it is said, "Preparations for his works were made in such a manner that they were presented to the public under the title of 'The Antiquities of Athens,' &c., 4 vols. folio, 1768." Now, the First Volume was published, as my two original copies show, by Haberkorn, in 1769, and nothing is said in the title-page of four volumes (although in the body of the work two more volumes are referred to, and two only); it is distinctly marked Vol. the First. Vol. II. was published by Nicholls in 1787; Vol. III. also by Nicholls, in 1794; and Vol. IV. by Taylor, in 1816—that is, not till 48 years after the time above referred to.

In page 340, in the life of Sir Robert Taylor, is one of those commonplace and sweeping attacks so constantly directed against the late Building Act, and in which I never did, and do not now join. That it had some defects, as well as some omissions, I am free to own, as well as that in these respects it required alteration—perhaps in no respect more than in its provision for the payment of expenses of party-walls by the owner of the improved rent, a term which the result proved to be quite unequal to the cost of such work. But that it was infinitely better as a whole than its successor, I believe, now almost universally admitted, and I could wish those who so lavishly condemn the late Act in the bulk, would confess to explain more fully those particular parts of it against which their attacks are directed, or to which they object.

A CONSTANT READER.

Sir,—The series of articles entitled "History of Architecture in Great Britain," contains some opinions and remarks that appear to have been uttered rather hastily. I hope, therefore, you will allow me to state, on what ought not, for the interest of art, to be suffered to pass uncontradicted.

To begin by correcting some of the mistakes:—The design of the India-House is attributed to Jupp, the Company's surveyor, who was only employed to execute the works, the design itself being by Holland, as is explicitly stated in the biographical article on the latter in the Supplement to the "Penny Cyclopædia." Jupp certainly does not appear to have been of any note at all in his profession, therefore it is not very likely that he was the real author of the edifice; or, if at any rate, if such claim was to be substantiated, that it would be to his name, that his work being not overlooked but formally set aside. In speaking of the College of Surgeons, Mr. Elmes describes in the present tense the original front, or rather the portico as it originally existed previously to the front being extended and re-modelled by Mr. Barry, who, he says, added two columns to the porch, one each side. In the case of the University of Miss Martin, a lady distinguished during her residence in that beautiful village for her benevolence and extended charities.

All the designs may be designated Old English in style, although it is not that of one and the same period; nor do they all show the same mode of construction, some of them being in imitation of the "half-timbered" houses, others of red brick with stone dressings and quoins. The Elizabethan style has been applied very happily in what strikes us as being the best design of all—namely, the school buildings at Battle, in which, while the character of the style itself is not very well kept up but expressed with gusto, the character of the particular kind of building is most unmistakably pronounced. Although perfectly regular, both in the arrangement of its masses and the features of its elevation, the whole composition, as shown in the perspective view, is pleasingly varied and high picturesqueness, yet sufficiently sober in colour. The last subject, design No. 5, shows a rather extensive and complex group of buildings in the Tudor style, and in perspective makes a very picturesque composition. Independently of the interest and merit of the designs themselves, the artistic skill displayed in the picturesque representations of them cannot fail to excite admiration. They are very superior productions of their kind,—studies of trees and figures as well as of buildings. Owing to which, to the subject itself, and to the tasteful manner in which the work is got up in every respect, we may anticipate for it a highly-favourable reception even among those who hardly make any pretensions to amateurship in architecture.

The Civil Engineer and Architect's Journal, [February
rather strongly with the evident disposition to touch as gently as possible upon the delinquencies of many other architects: Though the general estimate of the abilities and taste of Wilkins may be acquiesced in by many, there is not much reason to think that he was more of the school of the ornamental architect than the architect—far more of the "bookish student" than the artist—is not to be denied. As to Wilkins' pedantry, that charge against him is, no doubt, founded mainly upon his having written and published so much as he did; whereas, had he never taken up the pen at all, he might have been equally pedantic in practice, without incurring the reproach of pedantry. Downing and Haileybury colleges may be abandoned to censure, as equally rigid and tasteless in point of design; but an exception from the general sweeping condemnation undoubtedly is the chapel, in favour of the London University College, which exhibits both classical and artistic character, and very effective play of outline. Undeniable it is that it has, in its present imperfect state, obtained the meed of almost unqualified—not to say exaggerated—a merited applause from Wightwick and other professional men. Even Mr. Elmes himself did not always entertain so mean an opinion of that work of Wilkins as at present; or if he did, he thought proper to keep it to himself, for speaking of it about the time it was erected, he says: "The council obtained designs from several architects, and at last adopted that of William Wilkins, Esq., R.A., a selection in which their own judgment coincided with that of almost every proprietor who inspected the drawings." This goes far to prove that, at all events, the choice was not a hastily, inconsiderate one, or managed with suspicious secrecy. Nor is there a single instance of the writer in the slightest degree of dissatisfaction with it. Yet he now speaks not a little contemptuously of the building, without condescending to specify other objections than what is meant to be so overwhelming as one to outweigh all beauties and merits, namely, that "the portico is, in itself, too large and too high," and as it is stuck up for the admiration of gazing cabmen and hackney-coachmen, whilst loitering on their stand. With what sort of reason is the loggia at the south-west angle of the Bank so highly extolled immediately after Wilkins' portico being decreed? Is being nothing more and less than a little play of light and shade, which does not even carry with it any semblance of usefulness.

Of Wilkins' style it is said that it was "the very mummy of the art;" yet, if it was, he unbundaged it when he designed the building in Gower-street, for even in its present imperfect state it displays no ordinary merit in regard to grouping and the fine focus produced by the central mass. As an example of a decastyle, the portico is unique among those in the metropolis,—a circumstance which an impartial and unprejudiced critic would at least have noticed. It acquires additional expression and splendour from being elevated on a series of steps leading up to it, which are very picturesquely disposed. In this latter respect, too, the composition may be said to be unique—certainly is very striking and artistic. As to the dome, it is of the most elegant and decided description, and it is a feature unknown to pure Greek architecture, the objection is a proof that those who make such futile objection are still more straitlaced and pedantic in their notions than Wilkins himself. The value of it in the composition is such that were it removed the whole would become comparatively tame and spiritless. The portico in the east front of St. George's Hospital affords another proof that the "mummy" was occasionally unbundaged. That square-pillered tetraestyle partakes more of architectural heresy than pedantry. Still the heresy, if such it be, is a welcome one, and it has been allowed by being adopted in the façade of the new Law Courts at Liverpool, where the culmination is carried on, on each side of the central portico, in square pillars; therefore producing contrast and variety, at the same time that continuity of design is kept up.

It begins to time to bring to a close this long letter, therefore I will be somewhat brief in regard to what is said of Soane. As criticism, it is far more indulgent than discriminating, or in some respects even intelligible. At any rate, it is somewhat puzzling to make out what is meant by his buildings at Chelsea Hospital, and the National Gallery, that exhibit a certain amount of originality, and exhibit only very unequal and fitful attempts at it. His building at the Treasury, the Royal entrance to the House of Lords, and "some others of his minor works"—though the two last mentioned were barely noticed, he said: "some of them were very complimentary, for his fancy was in reality exceedingly limited. It exercised itself only on one or two piecemeal ideas, which he dragged into all his designs, without making any thing more of them at last than he had done at first. Soane had no consistency of style,—did not even attend to keeping, but often jumbled together the most finical ornaments and the plainest features. In his building at the Treasury, the windows were as ordinary, bare, and frigid in design as the order was rich. There was not a single touch of Corinthianism in them.

In speaking of the Lothbury Court at the Bank, Mr. Elmes again falls into inaccuracy, describing it not as it is, but as it was intended, for instead of being two loggias there is only one, what was meant for the west one being left unfinished—mere open screen of columns, if that can be called a screen which exposes to view most unsightly naked brick walls and mean, ugly windows. Even the opposite finished side of the court is very much altered. The windows are quite different from what was meant itself, by no means corresponding to the sober richness and dignity of the order. As to the Rotunda, it is most vilely disfigured by the equally barbarous and nonsensical wavy lines around the arches of the recesses, which seem to have been made by a stick upon some soft material while it was moist. It is admitted that the central square of the Bank is "by no means the happiest of Soane's designs," and that is treating it far more tenderly than it deserves, for it is a decided failure and abortion that it ought to be subjected to the same process of rifacimento as his Treasury building has been.

ZERO.

DISSERTATION ON TORRENTS.—By GUGLIELMINI.

Translated by E. CARY, Esq., in his Evidence before the Metropolitan Sanitary Commissioners.

I come now to the propositions of Guglielmini, in which he pretend that a body descending an inclined plane, will not acquire a velocity greater than it would have acquired by descending perpendicularly the height of the inclined plane.

This is most true as respects solids. The elements of a solid body, placed on an inclined plane, will in less time come to rest if their velocity, which is perpendicular to the plane on which they rest is likewise single, as is also the direction; one velocity, one energy, and one action being common to all the parts. On the other hand, a fluid is a mass composed of lesser solid elements, but free and not bound together by any ties, each of which can, so to speak, move in different directions and with varying velocities, press upon each other and oscillate freely. Whence the highest parts press upon the lower, oscillate, and are easily displaced when there is no impediment. When solids descend by a plane, their individual gravity alone operates; which being less than their absolute gravity, generates, at each instant, a velocity less than that which their absolute gravity would have generated, wherefore solids require a longer time to descend by the inclined plane than by the perpendicular, the length of time being regular in the action of the individual gravity, and compensates for the defect of the velocity. Wherefore a solid descending by an inclined plane, has a velocity equal to what it would have, falling the same height directly. Hence the product of the action of the individual gravity, by the time of the descent by the inclined plane, being equal to the product of the absolute gravity, by the time of the fall along a perpendicular, their velocities must necessarily be equal. But in fluids the case is different. Besides the properties which they possess in common with solids, they have another, to wit, the pressure exercised by the upper on the lower part of the fluid, which being added to the impact, increases the motion also, and hence generates a greater effect than a solid would. Neither is it absurd to suppose that the gravity of a fluid generates a greater velocity on a plane, than when acting perpendicularly, since the generation of gravity which in a solid which falls remains, so to speak, idle, but, in the case of a fluid, becomes active. John Bernouilli, in his works, gives a problem to find the velocity generated by a body sliding on the hypotenuse of a triangle, whose base is sustained by a plane, and generating a certain rate of velocity; the descending body being moved in the direction of the base. He decomposed the force pressing the hypotenuse, or inclined plane, into two parts, one of which is employed in giving motion to the triangle, and sliding it forward; whilst the body descends on the plane, advances the triangle, and communicates there to a certain rate of velocity; the descending body thus requires a velocity equal to that which it would have in falling perpendicularly, and the triangle has another force generated by that which presses it, whence it results that the
sum of the two motions is greater than that which a body would acquire by its simple descent. Wherefore, since the aforesaid force by pressing, generates velocity and motion distinct from that which a body, in descending, generates; in like manner it is applicable to water pressing on the lower films, and by pressing, communicating additional motion to the water, there are reasons corroborative of this truth, among which is the fact, that it is necessary to spread the accelerated velocity of water passing from a larger to a narrower section over a mean of pressure.

Galileo says, I have been carefully considering and going through various proofs, and have found that the water having to pass through a narrower channel, also whether it has the same declivity in both." The greater number of authors solve the point by increasing the height of the water, and hence the pressure, thus generating a greater velocity. Eustace Manfredi has expressed the same opinion in the same sense through a greater section, wherefore it is forced to pass with a greater velocity, precisely as will be the case in a vase in which the surface of the water may be at a certain height above the summit of the aperture. Guglielmini, to the same effect:—The upper parts press little lower, and oblige them to receive a force, which being compelled to act, produces the same degree of velocity which the descent would have given them. We might quote other authors, who accounted for the increased velocity in narrower sections because of the increased pressure generated by the height of the upper parts; that they are sufficient to attain so great a velocity it be necessary that the upper water should increase in height till it becomes stationary; not being able to believe that the upper water which is in the act of running is capable of producing a new increase of velocity in the lower. But experience teaches us that if the breadth of the channel has diminished one-half, the water will not rise that half, as would appear necessary; if the velocity does not increase, it increases at least very little, either in section or at the base, where the reduction of sections is of the same breadth, since the water retained by the narrowing of the vessel is not the same, but a slightly raised. Wherefore it is necessary that the velocity increase without paying regard to any new inclination, which is always the same, but only by an increase of height, which causes a pressure on the lower water in the act of running; whence I deduce the argument to strengthen my opinion of the increase of the velocity arising from the inclination, is equal or greater than that which might have been generated by the pressure. Let us take two cases, one which allows the same measure of water to pass through one section, parts press little lower, and oblige them to receive a force, which being compelled to act, produces the same degree of velocity which the descent would have given them. We might quote other authors, who accounted for the increased velocity in narrower sections because of the increased pressure generated by the height of the upper parts; that they are sufficient to attain so great a velocity it be necessary that the upper water should increase in height till it becomes stationary; not being able to believe that the upper water which is in the act of running is capable of producing a new increase of velocity in the lower. But experience teaches us that if the breadth of the channel has diminished one-half, the water will not rise that half, as would appear necessary; if the velocity does not increase, it increases at least very little, either in section or at the base, where the reduction of sections is of the same breadth, since the water retained by the narrowing of the vessel is not the same, but a slightly raised. Wherefore it is necessary that the velocity increase without paying regard to any new inclination, which is always the same, but only by an increase of height, which causes a pressure on the lower water in the act of running; whence I deduce the argument to strengthen my opinion of the increase of the velocity arising from the inclination, is equal or greater than that which might have been generated by the pressure. Let us take two cases, one which allows the same measure of water to pass through one section, parts press little lower, and oblige them to receive a force, which being compelled to act, produces the same degree of velocity which the descent would have given them. We might quote other authors, who accounted for the increased velocity in narrower sections because of the increased pressure generated by the height of the upper parts; that they are sufficient to attain so great a velocity it be necessary that the upper water should increase in height till it becomes stationary; not being able to believe that the upper water which is in the act of running is capable of producing a new increase of velocity in the lower. But experience teaches us that if the breadth of the channel has diminished one-half, the water will not rise that half, as would appear necessary; if the velocity does not increase, it increases at least very little, either in section or at the base, where the reduction of sections is of the same breadth, since the water retained by the narrowing of the vessel is not the same, but a slightly raised. Wherefore it is necessary that the velocity increase without paying regard to any new inclination, which is always the same, but only by an increase of height, which causes a pressure on the lower water in the act of running; whence I deduce the argument to strengthen my opinion of the increase of the velocity arising from the inclination, is equal or greater than that which might have been generated by the pressure. Let us take two cases, one which allows the same measure of water to pass through one section, parts press little lower, and oblige them to receive a force, which being compelled to act, produces the same degree of velocity which the descent would have given them. We might quote other authors, who accounted for the increased velocity in narrower sections because of the increased pressure generated by the height of the upper parts; that they are sufficient to attain so great a velocity it be necessary that the upper water should increase in height till it becomes stationary; not being able to believe that the upper water which is in the act of running is capable of producing a new increase of velocity in the lower. But experience teaches us that if the breadth of the channel has diminished one-half, the water will not rise that half, as would appear necessary; if the velocity does not increase, it increases at least very little, either in section or at the base, where the reduction of sections is of the same breadth, since the water retained by the narrowing of the vessel is not the same, but a slightly raised.
Mr. T. Price, in correction of a statement at a former meeting, said the new sewers at Hampshire were not oval, but egg-shaped.

Mr. Poynter read a paper on "Leather Hangings," illustrated by a number of specimens and Published Pictures. The first stage in the process of leather embossing among the Egyptians, and in the middle ages, and also of its extensive use in the sixteenth and seventeenth centuries, after its revival. The leather was fine, and was either embossed or simply painted. It was chiefly brought into this country from Flanders and France, and there did not seem to have been any manufactories of it here. Some thought that the process had been first revived either at Venice or in Spain, but this is still matter of doubt, though at Venice embossed leather hangings were in general use in the eighteenth century. The first stage in the process was to join the skins, and then to silver the whole surface. Paris to have the appearance of gold were varnished with coloured varnish. After silvering, the leather was stamped with cut blocks under a press. The borders and more delicate parts were executed with metal tools, like those of book-binders. What is called the Titian Gallery, at Blenheim, has paintings on leather, but they are not by Titian. Mr. Poynter exhibited some fine examples, one being Antony and Cleopatra, from a series formerly belonging to the great Lord Clarendon. He recommended such specimens as suitable for museums of medieval antiquities.

Mr. Crace stated that plaster moulds are used at Paris to emboss the leather, and that much floss is worked up to ornament the face.

The Chairman brought to the notice of the meeting the use they had observed in Italy in the making of tiles. Mr. Rained got a machine toulk think for completion. A number of the Institute was the first whom he should name, one whom they all knew and respected, and who had taken an active part in the establishment of the Institute. Mr. Lomond's Elma was not a member of the Institute, but a masonic looking at a school reflects a great credit upon him. A slight fall in getting out of a carriage was the more immediate cause of death, but he was suffering from disease which would otherwise have carried him off.

INSTITUTION OF CIVIL ENGINEERS.

Jan. 11.—Sir J. Rennie, President, in the Chair.

The first meeting of the session was held this evening, when the following papers were read:

Mr. Frederick Ransome's "Process for Making Artificial Stone."

The medium operandi appeared to be very simple. Broken pieces of silica (common flint) being subjected to a force of 2000 pounds per square inch. It was then immediately mixed with 2000 pounds of sand, and a portion of the mixture heated at a high temperature. This production was then heated at a high temperature, and caused to make a comprehensive range of objects for decorative art, and for architectural purposes; busts, vases, flooring tiles, steps, balustrades, moulings, capitals, shafts, and bases of columns, &c., even grinding stones and whetstones for scythes, etc., and, in fact, from the beauty and variety of the specimens exhibited, there would appear to be a vast field opening for such a production. It was stated to be already extensively manufactured at Ipswich, and it was allowed to admit of extensive application where elaborately carved stones would be too expensive.

Mr. Richmond, of Bow, exhibited and explained "An Engine Counter," manufactured by him on an improved principle. The counters in ordinary use were described as either somewhat inefficient machines, liable to error, or of too expensive construction to be generally employed. This differed from others chiefly in its simplicity and its accuracy, whilst, at the same time, its low price of 7l. brought it within the reach of every one. With this machine the number of strokes made by the engine or other machine could be read off at one view without calculation. The leading or unit hand traversed the entire circumference of the large dial, and those of the three small dials revolved in the same direction. The first motion was described as being given by a sliding bar and fixed spring, instead of by a double plate, so that the first wheel could not be thrown out by one tooth by one stroke of the engine. The hands were all moved by a train of wheels and pinions, without skip-wheels, so that the motion was regular and progressive. These were admitted to be advantages, and in the discussion upon the machine its merits appeared to be shown very decidedly.

Jan. 18.—Sir J. Rennie, President, in the Chair.

The annual general meeting of the Institution was held this evening, when the following gentlemen were elected to form the council for the ensuing year:

President—Joshua Field.

Members of Council—J. Churchward, H. V. Wyat.

The report of the council continued to be very encouraging, and shows that the progress of the society is steadily good.

Telford medals were presented to Messrs. Jackson, Richardson, Murray, Gwyn, and Frodsham, and to the two former gentlemen council premiums. Books were added. Telford medals were presented to Messrs. Elliot, Heppell, Shears, and Masters, for the communications made during the past year.

Memoirs were given of the deceased members and associates. Messrs. Thorns, Giles, Lukin, Musher, Reynolds, Holtzapfel, Evans, Watkinson, and Bell. The career of several of these gentlemen had been so varied, and possessed such points of interest, that the memoirs were necessarily extended beyond their usual length. The report noticed the increased attendance of members and visitors as evidence of its advancing career, and of the interest felt for the science of civil engineering. A pressing appeal was made to members of all classes to contribute papers, to induce animated discussions, which are the distinctive feature of the meetings of the society. The principal events of the past session were touched upon, and several private matters relative to the internal management of the Institution were fully discussed. The council then explained the changed form of the balloting papers, necessitated by the new bye-laws, and the retirement of Sir John Rennie from the post of president, which he had filled with such credit to himself and benefit to the society for the last three years. In conclusion, the report said, "Let the civil engineers remember that 'union is strength,' and that, if they are true to each other, and use the Institution as the common centre and bond of united effort, they may set at nought the cries of the detractors of civil engineering in England from the proud eminence where their talents, their practical skill, and their probity have placed them."

Before leaving the chair, Sir J. Rennie, president, addressed the meeting on the claims of the profession in the interests of the claims of Sir Field; not only as one of the founders of the Institution, and who had filled for many years all positions in the society, nor because he was universally respected and esteemed as an upright, honourable, kind-hearted man, but chiefly on account of his acknowledged celebrity as a mechanical engineer, particularly in that most important department—steam navigation; and, because his election would unite more firmly the two branches of the profession, which, it was hoped, would help in the Institution, in truth, to make it appear otherwise. He then reviewed the position of the Institution during his presidency, offering his thanks to the vice-presidents and the members of council, and to the secretary, for the support and assistance afforded him; and then examined, with much candour, the relative positions of the civil engineers, and of the government boards and commissions, which had appeared to clash more than was desirable. This he showed not from any of the acts of the civil engineers, who had ever been ready to afford their best assistance to the government in any capacity; and further, that it would be the interest of the government to take advantage of the talent, energy, and practical skill of the civil engineers, by whom they had ever been well served, rather than incur the hazard and the expense of forming a corps that would require more time to be made perfect than could be afforded in these active times, when even hesitation was pernicious.

This address was responded to very warmly by the meeting; and a vote of thanks to Sir John Rennie was received with cheers. Thanks were also voted to the council and the secretary of the Institution for their services.

SOCIETY OF ARTS, LONDON.

Dec. 15.—P. Le Nove Foster, Esq., in the Chair.

The Secretary read a paper by Mr. A. G. Findlay, M.R.G.S., "On the various descriptions of Lighthouses, Beacons, and Light-vessels; their Construction, and the methods of Illumination employed therein."

Mr. Findlay commenced his paper by alluding to the vast importance of a correct and uniform system, like England, of the most economical mode of constructing and illuminating lighthouses, light-vessels, &c., and proceeded to point out the general uses of lighthouses. The oldest structure upon record is the celebrated Pharos of Alexandria, which served as a guide to sailors for a period of nearly 1,000 years. Pliny says, "It was square, of white stone, and consisting of many stories, and diminished upwards till it attained the height of 547 feet." The most ancient structure known to exist in this country is the Roman pharos at Dover castle, and this pharos still answers its intended purposes, though in modern structures.

The celebrated Cordouan Tower, in the Bay of Biscay, is another instance of stability, having been built in 1611. The Eddystone lighthouse has attracted more of the attention of the public than perhaps any other. The first structure was washed away, and in 1706 was sanctioned for being rebuilt, which was succeeded by the present, and, finally by the present, in 1755. The present tower, one of the artificial wonders of England, and built by Smeston, is 100 feet high, and has given good proof of its capability of resisting the force of the waves. The Bell Rock lighthouse is a
similar structure to the Eddystone; it was built by Stevenson at a cost of £60,000. The most recent erection of this description is on the Skerryvore rock, which cost £90,700.

This is due to the difficulty of constructing permanent light-houses in exposed situations, and the advantages of them over floating lights, as well as the much smaller annual expenditure required to maintain an efficient light. The first floating light was the well-known Nore light-vessel, moored off the coast of Essex in 1724. In order to obviate the difficulty in a lighthouse, Mr. Fiddler stated that it is necessary that the structure should be capable of affording resistance to a pressure of not less than 6,000 lb. to each square foot of surface exposed to the action of waves. This assertion was founded on experiments made by Mr. Alan Stevenson, who estimated it to be between the force of the waves at the Skerryvore rock, on March 25th, 1845, during a westerly gale, when it was found to be 6003 lb. per square foot; this, the greatest force hitherto registered, was cited with many others. He next proceeded to show that the insipidity of the light on the Nore light-vessel was absolutely due to the exposure of the tower to the weather, and that, owing to the shallowness of the sand, which could not afford any support to piles, and to the violence of the sea, which would, in a single tide either wholly break it up or render it leaky. The cofferdam adopted being portable, was moved from one compartment of the cutting, when finished, to another. It consisted of two double frames of timber, each complete in itself, being bound together with iron rods, forming a dam about 10 feet by 3 and 3 feet high. One of these double frames (being somewhat less than the other) was placed with its large side towards the sea, and the inlets between them. In this way the piles could, from the depth of the frames, be driven perfectly straight, and were also quite independent of support from the sand. As each compartment of the excavation was completed, where the dam was removed, one row of piles was driven down to the bottom of the pit and left standing, so as to be a guide for again superimposing the frames over them, and in this way it was impossible for any of the rock to escape being removed. The peculiar advantages of its portability—its ready adaptation to an irregular or to a new construction—cofferdams are not, however, to be looked upon as the only means of eroding rock in general, and particularly with the certainty with which the partitions between each section of the rock were removed, and the double-framed waling that supported and directed the driving of the piles. Whenever excavations require to be made in a rock being covered by a stratum of sand, however shallow, this form of dam may be used, as there is no kind of lateral supports such as shore wanted, the structure containing within itself the elements necessary for its stability. It possesses, indeed, the properties of a caisson, with the additional advantage of an accommodation of workmen in the interior. In the fixtures, the cast-iron beam is fixed in the bridge, and as it is necessary to receive the cast-iron brackets which are keyed into them; these braces, 10 in number, stretch across the bridge at right angles to the ribs; there are also 8 wrought-iron tie-rods, 2 inches in diameter, placed parallel to the line of the abutments, to connect the whole structure together. The ribs and abutments are keyed into massive iron bed-plates sunk into the stone-work of the abutments. The roadway is supported by transverse timber beams 12 inches by 10 inches, bolted to the top of the spandrels at intervals of 3 feet from centre to centre; the planking is laid on these beams and nailed to them, and is crossed by diagonal beams, and spiked to them with 6-inch spikes; and over the planking a coating of asphalt is to be laid. The outside ribs are surmounted by a cast-iron curlicue to correspond with the masonry, and having a cast-iron railing on the top. The estimated waste of the cast-iron in the bridge is 603 tons 4 cwt., and the expense of fitting up the iron and timber work has been contracted for at 8,595. !

3. Observations on the means by which Time may be communicated by Signal Bells from one Station to another. By John Adie, Esq., F.R.S.E. The author of this paper remarked, that the distance of the Nelson Monument from Leith, and more than the distance from Leith to Dublin, would allow a time-ball placed on the Monument to be distinctly seen only in very clear weather, which is confined to a limited number of days, rendering it of little use to the navigators on the coast of Leith. He referred to the question of the method by which the ball on the Monument could be made to be distinctly visible at Leith, might be dropped at the same second of time, by a person in charge at the Royal Observatory, Calton Hill. This he proposed to do by making use of the great force induced on artificial iron magnets, the wires surrounding these magnets being brought into contact with the poles of a galvanic battery placed in the Observatory, and em-
playing this force to draw bolts or catches to free the balls and allow them to drop; a number of magnets in communication will develop their forces at a distant station, and allow balls at several stations to indicate the same second.

4. Description of a Safety Wheel Ring-Revolver, to prevent Wheels of Carriages from flying off the Axles. By Rev. Graham Mitchell, A.M.

The object of this invention is in prevent disasters, by rendering it impossible for the wheel to be sent off the axle, and which is designed to act as a preventative against a wheel ever flying off, whatever be the velocity of motion.

INSTITUTION OF CIVIL ENGINEERS OF IRELAND.

Dec. 14.—Col. H. D. Jones, President, in the Chair.

The following papers were read:

"Description of a Clock with a Registering Machine attached." By Mr. Sharp.—An ordinary clock was exhibited, with the addition of a certain number of projecting pins on the dial; the interval between every two pins expressed a certain portion of time, being that which elapsed while the hour hand of the clock, in its ordinary motion, passed from one pin to another; a lever was attached to the back of the dial, by means of which the hour hand could be pushed in at any time against the face of the dial, and, by coming in contact with one of the projecting pins immediately under it, push it in, and the pin so pushed in would register, in a certain number of minutes, the exact time the hand was brought in contact with the dial. Mr. Sharp explained how, by means of a sufficient number of pins on the dial, very small intervals of time might be registered. This invention he conceived might be useful for many purposes, as in the case of a barometer, to note the pressure of the air; or, in the case of a thermometer, to register the temperature, and in fact to make use of means of an additional mechanical contrivance, be made to register the times of the arrival and departure of the trains, by means of the trains themselves. He also explained how the movement of the clock was not in the least impeded by this addition, and that the means of registering might be also applied to clocks already constructed.

"A short account of the Foul, during a violent storm, of part of a Roof in progress of erection over the Dublin terminus of the Midland Great Western Railway." By Mr. Heams.—The total length of the roof of this building is four hundred feet; divided into spans of sixty feet each, the roof resting on walls at either side, and on columns in the centre. The centre columns are 62 ft. 6 in. apart, and are connected by flat arches and gutter-plates. The whole structure, with the exception of the columns, gutter-plates, tie-washers, and sockets, is composed of rolled iron. The principal, which are only the rafters, are 38 in number to each half-roof, and are 12 ft. 6 in. apart. They are formed of what are called "deck beams." The cover of the roof is of corrugated galvanised iron, and connected by bolted and riveted. A similar establishment has been put in on either side of the walls, which are of proportionate thickness, being three feet at the level of the ground story. The execution of the works in connection with the drainage of Lough Neagh, rendered the removal of this mill necessary, and the use of gates, and was much considered as a most economical manner of affording this object, but the contiguity of the mill to several houses by the roadside rendered it necessary to guard against accident, by limiting the charge of powder. A detailed account was given of the quantity of powder used, the number of charges, and the efficient manner in which the object was satisfactorily proved, the economy of the measure. This work was conducted under the superintendence of Mr. C. S. Ottley, the district engineer for Lough Neagh drainage.—The President stated that he had used gunpowder with much advantage, both as regarded effect and economy, in the removal of large buildings, but especially in the removal of a large storehouse at Plasmas.

Mr. M'beam stated the great advantage of adopting the plan which had been used in the present instance, and that the principal which are only the rafters, are 38 in number to each half-roof, and are 12 ft. 6 in. apart. They are formed of what are called "deck beams." The cover of the roof is of corrugated galvanised iron, and connected by bolted and riveted. A similar establishment has been put in on either side of the walls, which are of proportionate thickness, being three feet at the level of the ground story. The execution of the works in connection with the drainage of Lough Neagh, rendered the removal of this mill necessary, and the use of gates, and was much considered as a most economical manner of affording this object, but the contiguity of the mill to several houses by the roadside rendered it necessary to guard against accident, by limiting the charge of powder. A detailed account was given of the quantity of powder used, the number of charges, and the efficient manner in which the object was satisfactorily proved, the economy of the measure. This work was conducted under the superintendence of Mr. C. S. Ottley, the district engineer for Lough Neagh drainage.—The President stated that he had used gunpowder with much advantage, both as regarded effect and economy, in the removal of large buildings, but especially in the removal of a large storehouse at Plasmas.

Mr. Clarendon described the mode by which the high dock wall had been removed at the site of the Dublin and Drogheda railway terminus in Amiens-street, which had been effected expeditiously and economically, and ministered the use of gunpowder.

Mr. D. N. L. M. G. D. was called to the attention of the Institution to the inefficient state of the sewerage of Dublin.

HINTS TO PLANTERS.

A correspondent of the Gardener's Chronicle says, "In rambling through the New Forest, I have been much struck by observing how much the beauty of natural woods depends upon the open glades; or intervals bare of trees, which so frequently occur, and have often wondered why the landscape gardener so seldom imitates nature in this respect. In the disposition of the open areas, in the wood-sotts, it may be observed that the more common plants fill up the valleys with wood, and leaves most of the brows and eminences bare, and in an undulating country, nothing is more pleasing to the eye than to see the woods creeping up the hollows and gradually feathering off, and disappearing as they approach the summits of the hills, which rise bare of trees above them. The landscape gardener almost invariably does the reverse. He commonly plants all the eminences (probably from the notion of making a more conspicuous show at a distance), leaving vacant spaces in the valleys and lower grounds. By this means (putting appearance out of the question) he subjects his trees to the double disadvantage of a more exposed situation, and a shallower soil; consequently his trees grow incomparably slower than they would do in the deeper soil and more sheltered situation. The advantage of the lower grounds is that the situation is more suitable to the different kinds, that it is of the utmost consequence to the planter that the one should be adapted to the other; if planters could be induced to look after these things themselves, instead of entrusting them to the nurseries, one would often see, and the valuable trees that can be planted, were it not unfortunately subject to that peculiar disease, called the heart-rot, which, I believe, is not known to affect any other kind of tree. After growing vigorously for twenty or more years, the heart of the tree up to this period, and even when it is high in age, has but little external decay. The cause of this singular disease is as yet unknown. I am myself inclined to believe that it usually arises from too great dryness in the soil. In Switzerland the native habitat of the larch is in situations abundantly watered by the springs, or in the bottom of the valleys and plantations in which, in this kingdom, it seems to flourish best, are in similar situations in Scotland and Wales. In England it has principally been planted on dry sandy heaths—a situation which affords the greatest contrast to its native habitat, and which the prevalence of the heart-rot shows to be uncongenial to its nature. In point of beauty little can be said in favour of the larch; it never forms a handsome mass of foliage; and the spiky outline even of the oldest larches always has a poor, unpleasing effect. It must, however, be acknowledged that a single tree of larch often has an elegant and graceful appearance. The Scotch fir is of so hardy a nature that it will flourish in almost any soil or situation. It is in very bad repute as a timber tree when grown in England, which is a very singular fact, as it is well known that the same species of pine, when grown in the north of Europe and the highlands of Scotland, where the winters are harder and longer, produces timber of so much finer quality. The cause of this extraordinary difference in the timber grown in England and grown abroad. Some persons suppose that the home and foreign grown firs are different varieties of the same species, one of which is a better sort than the other. Others consider that age alone is wanting to render the timber good, and that if we were to allow English grown fir to attain the age of one or two centuries, as is the case with the Baltic grown, our timber would be equally valuable. That English fir timber does improve as the trees grow older, is a well-recognized fact; to this end it is usual to reduce the roof of the house in which I am now writing, which was framed of English fir, for very large scantlings, about forty years ago, and which to all appearance is now as sound as the day it was put up. It must also be observed that the timber is the same age, and for the same reason that the Scotch fir is more desirable; it would be to institute experiments on this point. It is stated, on what appears to be good authority, that both in Norway and the rest of the north of Europe firs are trees always felled in summer. In Switzerland, as in the Baltic countries, it is the custom to felled them in spring. As an ornamental tree the Scotch fir is gone much out of fashion, yet when allowed to attain a sufficient age its rounded top and red-coloured bark and contorted
OBITUARY.

MR. HARVEY LONSDALE ELMES.

It is scarcely surprising that the death of Mr. Harvey Lonsdale Elmes should have produced such a strong feeling of regret, as has been manifested at Liverpool by so many of its leading men, for the death of a man of genius in the early prime of life is well calculated to awaken sympathy, and most invidious and distressing to the families and friends of those in whose hands he hastened the progress of disease and death. Our readers will think that such an artist deserves at our hands a more lengthened notice than has he yet received, for there is always a sentiment of personal interest, which attaches itself to the death of one so young, so full of life, and so much before us.

Mr. Elmes was born in 1813, we believe in London, and was the son of James Elmes, Esq., the surveyor of the Port of London, and himself distinguished as a large contributor to architectural literature. With him he was brought up, and the natural abilities he early showed for the study of art led him to the study of architecture.

The death of Mr. Elmes's hands by a friend, as being worthy of his notice, and he took to the late Haydon, one of the earliest friends of his youth, to ask his advice whether he should compose, as Haydon knew many persons at Liverpool, having been employed for pictures for the Picturesque Societies of various institutions. "By all means, my dear boy," said Haydon; "they are noble fellows at Liverpool. Send in a design, and mind, let it combine grandeur with simplicity. None of your broken-up and fittered abortions, but something grand." Following this exhortation Mr. Elmes set to work, and when he had made his first sketch, took it to a friend's house, where a trifling accident gave him the agony of success, for a little boy looking at the drawing very gravely, threw it down, saying emphatically, "Very good, very good; it's worth five hundred pounds." When the designs were sent in, it was successful against eighty-five competitors, and Mr. Elmes received the premium of five hundred pounds. Afterwards he carried off in other competitions the premiums for the Asaizc Courts at Liverpool, and for the Collegiate Institution there. He was likewise the winner in a competition for the Asaizc Courts and St. George's Hall combined. These several victories gave Mr. Elmes the prestige of a reputation, which his own attainments were calculated to support. Entered upon a new career, he now devoted himself zealously to carry out in detail the several designs on which he was engaged, and his professional business greatly increased. He obtained the prize for the County Lunatic Asylum, at West Derby, in Lancashire, and was employed in erecting mansions for Mr. George Hall Law- rencer, late Mayor of Liverpool, for Mr. Hardman Bette, and Mr. Hugh Horton.

These labour, borne by a weak frame, at length brought their own end. In the early part of last summer Mr. Elmes showed such strong symptoms of consumption that change of air was desired, and on the 24th August he left for Italy, where he spent the remainder of his short life, and died in the monastery of Monte Cassino, on the 30th September, a few days after reaching that place. His remains were conveyed to London, and were deposited in the crypt of St. Paul's Cathedral, where a monument was erected to his memory.}

LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM DECEMBER 30, TO JANUARY 20, 1848.

Six Months allowed for Enrolment, unless otherwise expressed.

Thomas Hancock, of Stoke Newington, Middlesex, and Reeves Phillips, of Islington, Middlesex, chemist, for "Improvements in the treatment or manufacture of gutta percha, or any of the varieties of caoutchouc."—Deed December 30.

Edward Pratt, of Manchester, manufacturer, for "Improvements in manufacturing articles composed of nitrocellulose or china."—Dec. 31.

Mary Jenkins, of Aston, Warwick, widow, for "Improvements in the manufacture of pins, hooks, eyes, and other fastenings."—Dec. 31.

Edward Humphrys, of Holland-street, Surrey, engineer, for "certain improvements in machinery for manufacturing copper and iron pipes."—Jan. 4.

William Pudle, of Dartington, Devon, civil-engineer, for "Improvements in the manufacture of iron and steel articles."—Jan. 5.

Thomas Wilson, of Sheffield, manufacturer, for "Improvements in the manufacture of iron and steel."—Jan. 5.

William Holiday, of Huddersfield, manufacturing chemist, for "Improvements in lamps."—Jan. 6.

Charles F. King, of Uttoxeter, Staffordshire, engineer, for "Improvements in carriages used on railways."—Jan. 5.

Alexander Chalmers, of Addington, Surrey, for certain "Improvements in manufacturing articles composed of nitrocellulose or china."—Jan. 5.

George Lambert, of Two-Mile Hill, St. George's, near Bristol, pen-maker, for "certain improvements in manufacturing negro goods for men, women, and children."—Jan. 5.

Joseph Fergus, of Davidson-street, Blackfriars-road, for "Improvements in cock or taps for drawing of liquors and gases."—Jan. 5.

George Bell, of the city and county of Dublin, for "Improvements in the arrangement of wheels and axles for steam and other carriages, which facilitate travelling on railways and common roads, parts of which improvements are applicable to other machinery."—Jan. 6.

James Montgomery, of Saffron-street, Middlesex, for "certain improvements in pianofortes and other similar finger-keyed instruments."—Jan. 6.

Alfred Augustus de Regnault, of No. 11, Cannon-row, Westminster, and Joseph Emett Norton, of St. Mary-le-bland place, Kent-road, Surrey, mercantile, for "certain improvements in bottling or vats or vessels for containing liquids, and in the mode of cleaning and stopping the same."—Jan. 7.

Thos. Beesley, of the city and county of Dublin, for "Improvements in the conversion of coal, and in the storage or conveying of the products thereof into the houses and institutions."—Jan. 7.

William Thorold, of Norwich, engineer, for "Improvements in turn-tables."—Jan. 13.

Robert Wilson, M.A., Greenock, for "Improvements in certain kinds of rotary engines, invented on principles of steam or other engines, and applicable to rotary engines worked by water, or by the wind, also, an improvement in safety-valves for steam boilers."—Jan. 13.

Charles Edwards Moore, of Angel-place, Gray's-inn-road, for "Improvements in the manufacture of plates or surfaces for printing or embossing."—Jan. 13.

Stephan Mitchell, of Huntington-town, farmer, for "Improvements in the manufac- ture of mowers."—Jan. 15.

Robert Heath, of Heathfield, Manchester, gentlemen, for "certain improvements in the method of applying and working friction brakes to engines and carriages used upon railways."—Jan. 18.

Job Cutler, of Sparkbrook, Birmingham, civil engineer, for "certain improvements in welling iron pipes or tubes to be used as the flues of boiler engines."—Jan. 18.

John Gilmore, Lieutenant in the Royal Navy, for "certain improvements in ventilating ships and other vessels."—Jan. 17.

John Cryes, of Stratford, Middlesex, manufacturer, chemist, and James Thoma., for the same place, analytical chemist, for "Improvements in the manufacture of certain articles of food and drink, and new apparatus applicable to the said improvements."—Jan. 18. Four months.

Samuel Caslicas, of Manchester, for the parish of Bradford, esq., for "Improvements in stopping railway bridges and other carriages, and generally where a lifting power or pressure is required."—Jan. 18.

John Hickman, of Birkenhead, for "Improvements in the means of constructing and connecting parts of bettors' and other tobacco articles of furniture" to which such improvements may be applicable, and also in the means of attaching knobs or handles to drums, and other parts, doors, and other parts, and other new articles of furniture, to which such improvements may be applicable.—Jan. 18.

William Newton, of 65, Chancery-lane, Middlesex, civil engineer, for "Improvements in the manufacture of sugar from the cane." (Being a continuation.)—Jan. 18.

John Frederick Bannister, of Manchester, for "certain improvements in vats or vats for the passage of water or other fluids."—Jan. 18.

Thomas Robert Sewell, of Carrington, in the parish of Stafford, Nottingham, chemist, for "Improvements in preparing spirits."—Jan. 18.

Joseph Clinton Robertson, of 166, Fleet-street, London, civil engineer, for "certain improvements in the manufactory of textile fabrics, stuffs, and tissues, and of certain new products obtained by the aid of said improvements." (A communication.)—Jan. 19.

John Dennan, of Brentwood, Essex, gentleman, for "certain improvements in tanning of hides."—Jan. 20.
Candidus's Note-Book

Fasciculus LXXIX.

"I have a great liberty
Withal, as large a charter as the wind,
To blow on whom I please."

I. There is reason for concluding that the peripteral temples of the Greeks were so planned rather for the sake of architectural dignity and effect than, as is generally supposed, for that of any particular convenience or advantage. The cella itself being narrow, colonnades along its sides served to give greater importance to the edifice by enlarging its entire bulk, its ends or fronts being increased from tetrastyle to hexastyle, or from hexastyle to octastyle, if the lateral colonnades consisted of only a single range of pillars; the colonnades at the ends of a circular temple, by increasing the width of the fronts by four more columns beneath their pediments: thus, a cella, with a tetrastyle in front of it, would acquire an octastyle portico, by having dipter colonnades erected along its sides. This last-mentioned mode (the dipteral) certainly does provide a greater sheltered-in space on the sides of the edifice; still, hardly sufficient for any real use of it as an ambulatory—at least, not for a number of persons. Such purpose was far better accomplished by the pseudo-dipteral plan, in which the middle row of columns, or those between the external ones and the walls of the cella, nearly constituted the entire open space, which was obtained equal to the width of two intercolumns and one column. Yet, if much was thereby gained in point of convenience, not a little was lost in respect to effect and richness of character; and the body of the temple showed as a comparatively diminutive structure, standing as an ornamented colonnaded inclosure. As to the single peripteral, its colonnades must have been more for show than for real service, since they were very ill calculated for accommodating a multitude of persons. Even in the Parthenon, the clear space between the external columns and the walls was never wider than five feet, and this, even, in a mere passage, rather than either an ambulatory or a shelter for a large concourse of people.

II. With regard to the Parthenon, a most extraordinary error occurs in the English edition of Gallabaud's "Ancient and Modern Architecture," where it is said that the temple, measured on the top of the steps, is 114 ft., its width 41 ft.; according to which, the area of the building is not above one-fourth of what all other accounts make it, for they make it both twice as long and twice as wide! To puzzle us the more, there is a foot-note calling particular attention to those measurements, from which it would seem that pains had been taken to insure more than usual accuracy, they being there said to be upon the authority of a "recent"—and therefore, it is to be presumed, a more correct—measurement by Mr. Travers. Yet, no notice is taken of the enormous discrepancy between what are six feet and a fraction, yet thirty-four feet four inches high, which would make their height between eleven and twelve diameters! and how such extraordinary proportions could have escaped notice when the proof was read over is incomprehensible. Neither does error terminate here, since, besides the palpable with the apsidal, the height measured to the columns, the latter measurement and that of the entablature (10'-10") renders the entire height of the order 45 feet; which, though in itself it may be correct, is altogether irreconcilable with the width of the front being only 41 feet; and therefore, etc. But there is still another, not of an octastyle but a tetrasyle, and such as it is impossible to give to the former. Here, then, we have a pretty complication of blunders, and those of the most serious kind, in a publication which ought to be scrupulously accurate in regard to the measurements which it gives of buildings. There is what looks like sufficient pledge for editorial responsibility and carefulness, the title-page assuring us that "the translations are revised by F. Arundale and T. L. Donaldson, Prof. Arch., Univ. Coll., London," therefore, to those gentlemen may be left the task of accounting for or explaining away the egregious mistakes here pointed out, and which, inasmuch as the credit is here attached to them, such degree as to demand correction—if in no other way, by cancelling the pages where they occur. Not the least awkward part of the matter is, a detection of the kind naturally excites mistrust as to other articles, where mistakes either of a similar or different kind may have crept in through the same cause. In that very article on the Parthenon, one paragraph that ought to have been omitted, was unluckily suffered to remain—namely, that which says: "We give with this notice a splendid specimen of polychromatic architecture of the Parthenon, being a perspective view of the entablature, made with Travers's plan, from traces which he discovered in the monument itself." There is, however, no such plate in the work—at least, not in the English edition, although it would have been particularly acceptable, and far more valuable than all those of such unarchitectural subjects as Cromlechs and Celtic monuments, put together. Of these, two or three specimens at the utmost would have sufficed: still better would it have been had they been excluded altogether from a work which, were it to be extended to a hundred volumes, could not possibly illustrate all that is worthy of notice in "Ancient and Modern Architecture.""

III. It is not only with regard to the notion of Blore's façade to the Palace being a copy of that of Caserta, that Mr. Sharp and myself differ materially, my opinion of Elmes's "History of Architecture in Great Britain" being so very dissimilar from his, that I think it only fair to have very great reason to give up the carelessy-executed and inaccurate performance being passed off upon him under the responsibility of Mr. Elmes's name. While there is a great deal of mere garrulous filling-up anecdote, quite out of place in an historic outline, and out of all proportion to the brevity and rapidity with which the record itself, there are no few things, and some of them truly unimportant, for which also, both Kent and his patron, the Earl of Burlington, may be said to be passed over in silence, since they obtain no further notice than the complimentary mention of their names as "two accomplished architects of the ancient school, with a syllable dropped in their works,—either the 'Holkham' of the one, or the 'Chiswick' of the other. The name of 'Holkham,' indeed—and it is the name only—occurs elsewhere, but wrongly, for the credit of that palatial mansion is taken from Kent, and assigned to Brequingkin, who merely published the designs of it, with his own name on the title-page. It would seem, then, that "accomplished architects as they were, Kent and Burlington are not entitled to figure at all in a history which brings forward such a mere nobody as John Yenn. Neither is any mention made of Carr, of York, although he has considered the repute in that day, as one of the most important mansions and the most stately structures in the northern counties. Harrison, of Chester, too, is similarly passed over without being so much as named; and to him may, among others, be added Porden. Besides omissions of that kind, there is, with just here and there an exception, the general and pervading omission of all attempt at satisfactory critical estimate of the architects and buildings that are recorded. So little real substance is there in it, that Mr. Elmes's "History" amounts to very little more than a dry catalogue of names. What is worse, it is not trust-worthy: one is thrown into confusion, especially towards the general mistrust, for nothing is to be depended upon which the reader cannot verify for himself. The Royal Exchange at Dublin, which "everybody" knows to be by Cooley, whose talent and taste are very happily displayed in it, is erroneously attributed to Chambers. Gandon is mistook, for he called himself instead of Jones—a mistake, perhaps, of no very great moment, but which, coming along with so many others, o'vinces the writer's habitual carelessness. It would, too, have been as well to have stated, that a "Life of Gandon—such as it is,—was published about a twelvemonth ago," or the same with the same. To this, too, it should be added, for after he had been spoken of as editing the two last editions of the volumes of the "Vitruvius Britannicus" (viz., the 4th and 5th), we are told that "Colin Campbell published his useful work, the 'Vitruvius Britannicus,' in four consecutive volumes, between the years 1718 and 1746, in London, for about ten years after his death—to which, Woolf and Gandon respectively added supplementary volumes of equal skill and correctness." This is so ambiguously worded, that it seems to say, each of the two latter editors separately added more than a volume to the original work,
instead of bringing out conjointly two other volumes to accompany the third that has been published already. When he was mentioning that collection of designs, Mr. Elmes at first must have observed, that it is by no means so complete as it ought to have been; for while it is made to contain several very dull and uninteresting subjects, others are omitted which are either of considerable celebrity themselves, such as Lord Burlington’s Casino, at Chiswick (since altered by Wyatt), and St. George’s, Bloomsbury.

IV. In speaking of Wyatt’s Pantheon—which, if greatly, it is not extravagantly, admired structure, it is equally matter of surprise and regret that no engravings were given, either in Gandon’s last volume of the “Vitruvius,” or in the subsequent work by Richardson. Mr. Elmes sadly neglects his proper duty as an architectural historian, to gossip very provokingly about Lunardi’s balloon, instead of entering into any description of the edifice itself, which he merely calls a “case without particularising any of its beauties and merits. The only part of it on which he makes any remarks, is that which least of all required notice—namely, the front; it still remaining pretty nearly what it was at first. He speaks, however, of the portico as having been of the Ionic order; and if so, the Doric one, which existed before the building was converted into a bazaar, cannot have been that which Mr. Elmes alludes to, although he does not say as much. In what is said of that front, the term “wings” is not very correctly applied, the whole of it forming only a single general mass, without such subdivision into distinct portions as properly answer to the denomination of “wings,” which Mr. Elmes appears, as when noticing the “Trinity House,” and the “Society of Arts” in the Adelphi. Another instance of his indefiniteness in what ought to be explicit technical phraseology, is his very untechnical mode of describing a recessed portico or loggia, calling it sometimes an “incurved” portico, sometimes a “canopy,” one, or by some other more fantastical than intelligible epithet.

V. The admiration professed for what is Soane’s happiest piece of composition has not extended itself beyond words. We may say of it expressus est aedificati, since no one has testified its estimation of it in any other way, than by throwing an idea from it. It may also be noted, that a striking effect and picturesque expression might be obtained without falling into direct imitation. Nay, Mr. Elmes would make out Soane himself to have been there only an imitator,—at least, to have had in his mind the semicircular porticoes of the transepts and St. Paul’s, as if, without them, the idea would not have emanated, as no doubt it immediately did, from his studies of the Temple at Tivoli, whose order—an equally beautiful and peculiar example of the Corinthian, that had previously been ignored by all modern architects and all the systematisers of the Fifth Order, as not extended by him, and by him only, to a new and novel, with unapproachable classical authority for it. Still, though he adopted it, even Soane himself does not appear to have comprehended its character, for it is only at that angle of the Bank that it is exhibited entire, having in the other parts of the building employed the columns of the entablature which belongs to them, not only in conformity with the original example, but in conformity with the laws of aesthetic design. By suppressing—as if such change was of no moment at all—the rich embossed frieze, which is absolutely necessary for keeping up harmony and perfect agreement in the ensemble of the order, he converted the entablature altogether into one which contrasts rather than at all agrees with the columns themselves. Their fluted shafts become too rich, and their capitals look too heavy, in comparison with the emaciated entablature. The energy of expression, as we said, at the death of a design, is insomuch for the columns, stops short with them, instead of being carried on consistently, and extended to the horizontal division of the order, where, if anything, increase rather than diminution of decoration is requisite, since otherwise, a most disagreeable falling-off to take place: _amphora capitis instat, arceus eft_. If decoration is to be moderated at all, it should at least be done consistently, and so not to throw one part out of keeping with another; the going which—and it is by no means uncommon—betrays either downright ignorance, or willful and most unpardonable disregard of both precedent and principle. What we have said is, that those who are gifted with such very microscopic vision asto be struck by the profile of a mere moulding in a cornice, or some equally minute detail, take no notice of such wholesale omissions as the kissing columns of only a frieze of the order. In some instances of the Bank this frieze is, indeed, left entirely blank, it being ornamented with a Vitruvian fret; which, however, has a tame and insipid look in comparison with the boldness of the capitals. If deviation from the original there was to be at all, it would not have been amiss, perhaps, to increase the cornice, and also give it something of richness; whereby rendering the entablature equivalent in force to the architecture.

VI. With regard to that particular feature in the architecture of the Bank which has given rise to the preceding remarks, it has obtained more of professional admiration for its striking effect than of inquiry into the cause of that effect. For such inquiry, however, is by no means unimportant. Every eye at all for the picturesque in architecture, can be at a loss to determine in what the peculiar piqunacy of that composition consists. Still, it is necessary that its merits, in that respect, should be distinctly pointed out, if only in order to force such earnest attention to them as might lead to similar happy results in composition. Precisely the same columns are used in other parts of the buildings, yet nowhere with anything at all approaching the same effect; and why? because here the composition is such as to be unusually productive of those accidents which give life and picture architecture—namely, vigorous chiaroscuro, play of perspective, and richness of combination. There is not merely light and shade in a greater than ordinary degree, but variety of it—deepening shadows and brilliantly-toucht lights when the sun begins to strike upon that angle of the building. Of perspective appearance, also, there is great variety, owing to the apparent changes of position between the external columns and the inner ones, and also to the contrasted disposition of them, the former being upon a curved line, the latter on a straight one. There is also another point of contrast between them which is equally judicious and picturesque, the former columns being irregular. This circumstance, while it adds to the variety of the composition, prevents confusion; and such is the value of the two inner columns, that without them the whole would be many degrees less admirable. They are, besides, both motived by and serve to warrant the mode in which the others are disposed, the loggia being as much an exceptionable thing as the door, or rather the appearance of door, when there can be no entrance from without, and where therefore a window or window-door—even had that also been only in appearance—would have been less of an impropriety. But a statue of some sort, perhaps in a niche, was not an interesting object of itself, but have done away with all necessity for appearance of access into the loggia, since the latter would in such case have had an ostensible purpose as a piece of decoration.

VII. We get architectural criticism—as far as we do get any of it all—merely by a mouthful of it at a time. What professes to be such is seldom more than a single condensed opinion expressed in the jump, wrapped up perhaps in a mass of cumbrous verbiage, ore associated in a sort of oracular decisiveness, intended to awe into silence and stifle inarticulate Horace Walpole’s critical verdicts, albeit they were sometimes turned epigrammatically enough, were both flimsy and unjust, shallow and superfluous. What he says of the campanile of St. George’s, he says to sounded effect, and convicts him withal of being quite obtuse to picturesque expression, and other architectural merits. As to Gothic architecture, Horace disqualified himself for setting up as a judge of that by his own precious Strawberry Hill, which would have absolutely horrified him if he had possessed the slightest feeling whatever for that style. Yet, even as it is, it is, Strawberry Hill has been deliberately praised by another discerning critic and writer on architecture, who says that the connoisseur would there find “all that is fascinating in the Gothic style.” All that is fascinating with a vengeance! Was it possible to conceive that Dallaway was there merely joking, we should account for such vagaries as being one form of declamatory irony; but he seems to have been quite serious, and must accordingly have been exceedingly stupid also. In what its fascinations consist he does not say, although if any such merits there were, it believed a critic to point them out, and to do so in such manner as so fix attention upon them. The comfort is, we lose very little by Dallaway’s confusing himself to only very hurried and superfluous remarks on modern English buildings and architects, since what he does say, indicates but very mediocre taste and talent, and tastes of an architectural critic Allan Cunningham was,—how well qualified to take the title of "Lives of British Architects,"—may be judged from the censure he passes upon the large open arches and loggias above them in the river façade of Somerset Place,—the most striking features, or other points of the strangest character, in that composition. In a fit of hypercriticism, Allan affects to be shocked at the irregularities of the parts of the structure, as being quite contrary to all architectural principle and propriety, he asserting that the columns over the void of the arch produce "an appearance of insecurity that is al-
together intolerable;" which is as much as to say, that instead of suggesting the idea of strength and perfect security, the arch looks unequal to the due support of the columns. Nevertheless, it is certain that those arches are capable of safely bearing the weight of the columns, and can also safely bear the weight of what is much heavier still—namely, Allan’s own leading criticism.

VIII. Very great pity it is that St. Martin’s Church stands just where it does, because it was in consequence allowed to interfere very injuriously both with the National Gallery and Trafalgar Square. Owing to its being obstinately insisted upon as a sine qua non, that the portico of the church should be exposed to view from Pall-Mall-East, the front of the Gallery was obliged to be set further back than it otherwise needed to be, and the site of the building—at best a very cramped-up one in its rear—considerably reduced in depth; in some parts, to little more than half. Hence, the interior of the structure does not at all realise the promise made by its extent of façade. Admitted it must be, that the architect did not economise what space he had so well as he might have done; still, that does not excuse those whose capricious whims thrust difficulties upon him where, without such addition of them, there were many to contend with.—On the other hand, as regards the "Square," its symmetry and rectangularity have been sacrificed for the sake of keeping its east side in a line with the portico of St. Martin’s, which would still have shown itself, even had it not been made to come actually into that corner of it. After all, does the church display itself to such advantage, as to reconcile us to the inconveniences and deformities which it has been allowed to give rise to? The reply will be: "Hardly." Thrown open to view from such a distance as it now is, that portico is not so impressively striking as it formerly was. As it stood originally, the situation seemed altogether unworthy of it, owing to its being much too confined, and to the meaness of the buildings huddled round the church—a species of contrast more picturesque than becoming or agreeable. Nevertheless, as it was then seen, the portico showed imposingly; and all the more so, because the view was confined nearly to that—the steeple not being seen unless it was directly looked up to; whereas now, as seen from a distance, the entire structure, that is, both portico and steeple—the latter of them anything but a graceful and well-composed object of its kind—are seen together; owing to which, the portico loses considerably, and the classical character that would else stamp it, when beheld at such a distance that only its exterior or columns are visible, is greatly interfered with, if not altogether forfeited, by the uncouth appendage which rises up immediately behind it. By no means is the view of the portico from Pall-Mall-East a prepossessing one.—Trafalgar Square itself falls very far short of what was hoped for it. Exaggeration of judgment, bungling, and disregard of architectural disposition have been allowed to manifest themselves in it. Although the area itself seems to have been expressly planned for the reception of the Nelson monument, the column is, after all, not placed within it, but is pushed out of it. The only assignable reason for such downright preposterousness is, that it had been erected in the centre of the area prepared for it, so lofty an object put just there would have had an unfavourable effect upon the front of the Gallery. Very true; but then that consideration ought to have been a raison de plus, and an all-sufficient reason in itself, for not adopting a column, more especially as there was another thing of the same kind just by. There were many other designs which, besides being sufficiently well adapted to the situation, were far more original and artistic. It was, therefore, to be presumed that the second competition was for the purpose of enabling the committee to retrieve the error of their first choice; when lo! to the amazement of every one, the result was just the same as before,—which was only making matters worse than before. Far better—far more honest and honourable would it have been to have abided by their decision, than to make such show of intending to retract it. The least they could in decency have done, would have been to justify by some show of reason for it, a choice so strangely persisted in, and so strangely acquiesced in by those who had been tried with. The best that can be said of the humdrum Nelson monument is that it serves to render the façade of the National Gallery perfectly satisfactory in comparison with it.

### RAILWAY SECTIONS IN SIDELONG GROUND.

**On Tables for Setting out the Width of Cuttings and Embankments on Sidelong Ground; and also Formula for Computing the Area of Vertical Section.**

**By R. G. Clark, C.E.**

The object of this paper is to investigate some simple formulæ, and from thence to construct some tables, to enable the assistant engineer or contractor to set out the widths of cuttings and embankments on sidelong ground; and also to calculate the solid content of any portion of the ground. The subject may be received in the following proposition:

Given the angle of inclination of ground, the depth (from field-book, &c.) of ground to the centre of balance or formation level, and the ratio of the slopes; to determine where they will meet the ground at surface.

Let $HAFBD$ (fig. 1) be a vertical section of the ground; $AB$ the formation line, represented by $2b$; the given angle of inclination of ground $HD$ with the horizon by $\theta$; the given depth $OF$ from the stake $O$ perpendicular to centre of formation level denoted by $a$.

![Fig. 1](image_url)

1. We will proceed first to determine a formula for $OD$. Let it be $x$; draw $DK$ perpendicular to $AB$ produced; $OF$ parallel to $AB$. Let $DB$ be the given slope $m$ base to $1$ perpendicular; draw the vertical $BC$.

Let $DF = y$; then $OC = FB = b$; $EF = my$; also by similar triangles, $CE = ma$. $OF = b + ma + my$. 

Now, by triangle $OFC$, right-angled at $F$, we have

$$1 : x :: \cos \theta :: y : y = x \cdot \sin \theta.$$

Again, $1 : x :: \cos \theta : b + ma + my$. 

Eliminating $y$, then $x \frac{\cos \theta - m \sin \theta}{\cos \theta - m \sin \theta} = b + ma$; 

therefore, $x = \frac{b + ma}{\cos \theta - m \sin \theta}$. (1)

From the factor, $\cos \theta - m \sin \theta$ of the above formula, the Table No. 1, is computed from $5^\circ$ to $90^\circ$.

2. To find an expression for $OH$ measured from $O$ on the descent.

Draw $HM$ (fig. 2) perpendicular to $AB$ produced. Let $HA$ be the given slope, ratio as before. Let $HM = y'$; then will $AM = my'$. Therefore, $HG = NF = b + my'$; also $OG = a - y'$. 

By the triangle $HGO$ we have $1 : x' :: \sin \theta :: a - y'$; 

therefore, $a - y' = x' \cdot \sin \theta$; and $y' = a - x' \cdot \sin \theta$.

Again, $1 : x' :: \cos \theta :: b + my'$. 

Eliminating $y'$, we have $x' \frac{\cos \theta + m \sin \theta}{\cos \theta + m \sin \theta} = b + ma$; 

therefore, $x' = \frac{b + ma}{\cos \theta + m \sin \theta}$. (2)

From this expression, Table No. II, is calculated by the factor $1$

$$\cos \theta + m \sin \theta$$
3. We shall now investigate an expression for the area of the vertical section; the inclination of ground, depth, breadth of formation level, and lengths \( x, x' \), and also the ratio of slope, being all given.

Through centre \( O \) (fig. 3), draw \( PE \) parallel to \( AB \); then \( PO = 5 + ma \). . . . area of trapezoid \( PABE = \frac{(2b + ma)}{2} \.

and area of triangle \( POH = \frac{\sin \theta}{2} (b + ma) \).

Consequently, the whole area of trapezium or vertical section =
area \( PABE + \) area triangle \( DOE = \frac{1}{2} \sin \theta (b + ma) \).

The first column of the table gives the angle of inclination of the ground, and the adjoining column the sines to three places of decimals, to facilitate working out the area, as in equation (3).

We shall now commence with the following Rules.

I. To find the two lengths \( OD \) and \( OH \).—Rule. Add the half-breadth of formation level to the product of the slope and given depth; then multiply this sum by the corresponding tabular number, then will each product be equal to each length required.

II. To find the area of section \( HABD \).—Rule. 1st. Add the formation level to the product of the ratio and depth, and multiply this sum by the depth. 2ndly. Add half the formation level to the product of ratio and depth; multiply this sum by the difference of the two lengths, and again by sin of angle. Add these two products, and their sum will be the area.

Example 1.—Given the angle of inclination of ground 18°; slope, 1 to 1; depth, 44 feet; and breadth of formation level, 30 feet. To find distances of centre stake, area of section, and cubic content, when 100 feet in length.

Here \( b + a \) = 15 + 45 = 60; \( m = 1 \); \( \theta = 18^\circ \); its sin = \( \sin 18^\circ \).

By formula (3) we have \( (30 + 45) \times 60 = 2100 = O \). By formula (4) we have \( b + a \) = 60.

Now, \( 30 \times 60 = 1800 = \frac{2100}{2} = O \). By formula (4) we have \( b + a \) = 60.

Cubic content \( = 499530 \).

Example 2.—Given angle of inclination of ground, 20°; slope, 1 to 1; depth, 50 feet; and breadth of formation level, 30 feet. To determine distances and also area.

Here \( b + a = 50; b = 15; m = 1 = 1; \theta = 20^\circ \); its sin = \( \sin 20^\circ \).

Now, \( 30 \times 50 = 1500 = O \). By formula (3) for area we have \( b + a = 150 \). By formula (4) we have \( b + a = 2100 \).

Example 3.—Given the inclination of ground, 15°; slope to be 2 to 1; depth from field-book, 90 feet; breadth of formation level, 30 feet. To find area and distances.

Here \( b + a = 20; b = 15; m = 2 \). \( b + a = 55 \). \( 55 \times 100 = 5500 = O \). By formula (3) we have \( 30 + 40 \times 90 = 2500 \).

Remark.—If the ground should ascend and descend, as in the adjoining diagram (fig. 4), then Table No. II. is to be used to find the distances. Table No. II. will in like manner be required for ground descending from centre, as in fig. 5.

The Tables will likewise do for embankments.—No. I. for the ascent from centre stake, and No. II. for the descent.

We shall now discuss the equations (1) and (2). Put them respectively under the following forms. \( T, T', \) being tabular numbers, \( A = b + ma \).

\[ X = T \cdot A \quad \text{and} \quad X' = T' \cdot A \]

Divide by \( T, T' \), respectively; then \( X = X' \), \( A \) being eliminated.

Therefore the two distances, \( x \) and \( x' \), are to each other as their respective tabular numbers; consequently, the distances can be proved by a second operation. The Tables might have been carried up to 45°, but then they would require a greater number of places of decimals to insure greater accuracy.

In taking the angle of inclination, the clinometer or common theodolite might be used; but if the spirit-level should be used, then we have only to measure from \( O \) downwards any distance, \( ON \), (fig. 6), and then take the height with instrument; and then will the sine of angle of inclination \( \frac{OD}{\text{angle}} = \frac{OD}{2} \) the height.

Erratum.—The diagrams, figs. 2 and 6, in the above article, are transposed, for which oversight the printers are accountable; but beyond such transposition the error does not extend.

REVIEW.

Birkenhead has been a wonder, and has had its nine days, and many many are quite ready to believe that we have had enough of it. The announcement of such a town springing up in England was calculated to create as much astonishment as that of Aladdin's palace fresh painted by his wonderful lamp. It is not so easy to create great wonders in an old and settled country like this: cities of whitewash and timber-framing, metropolitan centres of slambrook and log-hut, we leave to the far west of the States, or the sand-dunes of Australia; and we should be no more surprised by the flourishing account of a Babylonian capital newly handed in California, than by the sight of the three last joints of the serpent's tail, or the repudiation of a fresh batch of Pennsylvania bonds. Towns grow in the virgin soils of the new world; they are a natural production—or at any rate they can be planted as easily as cotton, or what the Americans dignify with the name of corn. We can reconcile ourselves to such creations as Fleetwood, or Kingston-upon-Railway, Wolverton, or Swindon,—the resuscita-
tion of Folkestone is a piece of the legitimate drama; but the public were truly struck with wonder to hear of the production on the shores of the Mersey of a great town, of the most solid construction and of the most magnificent proportions, provided with all the requisites of a perfect sanitary condition, with its labourers of the most meekly submissive temper and with a pure city of stone and Roman cement, but provided with such vast apparatus for commerce, that the envy of the London merchants was excited, and Liverpool gave signs how much she feared so great a rival near her throne. This, certainly, was a new phénomé-

e in England, for though we are at a distance to know there are cities of the same size to the one we have been speaking of, with a population equal to New York, or enlarge Liverpool with an addition as big as Albany, yet we do not throw our strength into new civic creations.

So Birkenhead burst so suddenly on the public gaze the novelty has been acknowledged, and still more, from fortuitous circum-

stances, its glories have been dimmed, and its growth has been cramped; so that the interest it has excited has much worn off, and we shall be suspected of parading before our readers a stale subje-

ct, when we mention Birkenhead; but as we are not going to describe Mopthorpe Buildings, nor to investigate the statistics of the trade of the Mersey, nor to recommend the Liverpool merchants to give up and settle at Birkenhead, we may, perhaps, meet with a little attention, for Mr. Webster’s book on Birkenhead gives us the spoils of the烦恼ing of the channel, and we will confine ourselves to its features. Though Birkenhead may be a great town, and the docks a great speculation, yet there are scientific considerations involved in the harbour plan, which must render it a matter of permanent interest to professional men. If Birkenhead itself bears experiment, the walling of Wallasey is one of not less im-

portance.

To make a dock is, in the hands of some engineers, a very simple operation; they scoop out a certain space on the shore, they run it under a water- way, or take in so much of the strand, that they are satisfied, though for anything they know there is a care, that the mouth of the new dock is in the right place, and that the water at the entrance of the harbour is lessened, and a dock made for ships drawing eighteen feet will not take in those of fifteen. They have a great idea of dredging and shuffling power; and besides make a dock of harbour which fails in the main by the tides; all the settlements, they hope, will be established for getting rid of the silt which they have let in, and the sand-banks they have created, for it is surprising what very stupid and very careless people can do without knowing it. Mr. Rendel, when he was called in to make a dock for the pool, thought it his duty to survey the whole water-way of the Mersey, and to make himself acquainted with the action of the currents and tides, so that in laying down a deep-water dock at Birkenhead, he might not be scuttling the outer gate to seaward—the Victoria Channel. No affront was affixed; no annoyance fell upon him. He was even employed to examine and complain, and complain with justice, that in consequence of new engineering works in some harbours, the depth of the water in the channel has been reduced, some dangerous shoal extended, some fixed bank made into a quicksand, or a bar which was troublesome was placed. A harbour plan was proposed, and if there be any up-navigation, that is sure to suffer when the point of discharge into the sea is injured, and the lighterman complains that the channels are choked, that the tide does not run up so high, or that he has less tide to carry him up; and the wharfinger finds that his frontage is stopped with siltage, and the dock is more bungling under the name of hydraulic engineering than perhaps in any branch of the profession. It is the opprobrium of engineering, that after hundreds of thousands have been spent on hydraulic works, it is a complete failure; harbours are choked, piers are made out of the quay for single ships, and the sea-walls are made with the most solid masonry and with the smallest modulus of expense or capacity, so that they topple down before the walls are well set. So little is this branch of engineering appreciated by the public, that large tracts of available land—two new shires in fact—are left uncursed on the east and west coasts of England, when they ought long since to have been embanked. There is scarcely a river or water-way in the country which is not kept in a state disgraceful to the engineering science of England. Let any one leave the metropolis, and look at the river Stour and Medway, and so many others, or the Thames, and he will see the marsh of tides and marshy fields flooded and drained, or not drained at all; river walls made so steep that they are yearly cut into or undermined; and stones put year after year to be washed away, because they are put where they never ought to have been.

We do not know whether the government ought to take it in hand, as in Holland, the care of our water-ways, for we place no confidence in what the government does. The constitution of the Tidal Harbour Commission is not such as to inspire any great hopes from government interference, for while that commission is ornamented with a military engineer in due course, there is not one civil engineer upon it. The one great remedy is by the formation of a hydraulic and civil engineering department, the improvement of the state of hydraulic engineering, and particularly to execute carefully whatever duties they undertake. This, we think, Mr. Rendel has done; and though we differ from him in some points, we have no doubt that he has carefully, conscientiously, and labo-
rously executed himself in this instance for Birkenhead.

It is tolerably well known that Liverpool is one of the worst harbours in the country, with long and tortuous channels, among dangerous rocks, and all the doubts and uncertainties of a har-

bour, so that its very continuance as a harbour is precarious, and has before this been considered by the public as a bad harbour, it is a bad harbour on a large scale; and those resources of science which are available for the improvement of small har-

bours can do very little on miles of sea-channel and acres of sand-

bank;—still they can do a little, and it becomes of great import-

ance, that in any operation within the estuary, all cares shall be taken to prevent injury to the outer channels. Mr Rendel has tried to improve them.

The form of the Liverpool estuary is peculiar. It is wide above and below, and comparatively narrow, so that it has been compared to a bottle with the neck seaward. It is, however, a bottle big enough, so that the sea-channels and banks are stretched out. Perhaps we may improve upon the bottle simile, by calling the estuary a curved powder-flask. Liverpool lies on the neck, the concave side and Birkenhead opposite, on the convex side. The wide part of the neck is named to Runcheon, Liverpool formerly had an inlet called the Liverpool Pool. This has been dammed up, and built upon; by which so much has been taken from the breakwater. The whole of the docks of Liverpool have likewise been taken from the break-

water, being constructed upon the strand. Thus the neck of the bottle has been cut off, and the bottle is reduced to a short and stubby form. Just above Liverpool a bank and shelf, called Pluckington Bank and Shelf, have been formed, which are not very advantageous to the docks before which they lie.

The pool is untouched. It has a large inlet running up, named Wallasey Pool, and this has shown a tendency of late years to silt up. Indeed, considering Wallasey Pool, Pluckington Bank, and the general evidence, we should say that there is a decided action unfavourable to the good condition of the harbours.

The deepest water lies on the Birkenhead shore, so that it has a depth below the lowest dock-sills on the Liverpool side. It will be seen, that whatever works are undertaken at Birkenhead, they may act upon the upper part of the flank, upon the neck of the bottle, and upon the Victoria Bar and Channel. Whether this action was to be for good or evil very much depended upon Mr. Rendel; and he might have done as others have done—made his docks, and cared no more about it; but he has wisely taken a wider view, and tried to improve the whole of the Liverpool harbour. This was done wisely, because the continuance of Birkenhead de-

pends upon the good condition of the Victoria Channel; and if vessels cannot get over the bar outside, they will never be able to get into docks either on the Liverpool or Birkenhead side. Mr. Rendel’s plan was to improve the Birkenhead docks, but for improving the harbours of Liverpool.

Wallasey Pool has a wide mouth, and runs, narrowing as it goes, about two miles inland, taking the drainage of a small district. This Pool is mostly dry at low water. The opening of this Pool is perhaps four miles wide.

This Pool may be taken as two parts, the mouth or funnel, and the upper part. Mr. Rendel’s plan is to take advantage of a ledge of rock which runs across the neck, and shut off the upper part by a great dam with lock-gates, and having a line of sluices as here-

after described.

The upper part constitutes a float of 150 acres, kept up at high-
water mark, and on the sides of which docks, wharfs, warehouses, and building-yards may be formed. Around this float a river-wall is to be built as frontage to the wharfs.

Original of this plan was that the Pool, except that part of 37 acres open to the Mersey, is to be embanked, except a low-water basin of 37 acres open to the Mersey.

The sluices in the dam are to be so arranged as to be near the bottom line of the outer low-water basin, so that on being run out the water flows out of the bottom of it. This they do to partake of a part of the tide only, so as to concentrate the action, to keep the basin and its mouth free from silt, and to send the water down to
the Victoria Bar at the best time for action on it. By the construction of the sluices, the water, instead of being poured down to tear up the bottom of the basin, will be sent along in a sheet, so as to prevent the silt from depositing itself. This sheet will be sent below the water in the basin, and Mr. Rendel thinks it will act to sweep the silt 2,000 feet.

It will be seen that by blocking up the Pool and inclosing the greater part of the strand, a considerable body of tidal water is displaced.

Mr. Rendel expects by straightening the shore on the Birkenhead side that the access of the tide to the upper Mersey will be improved, and that the scour being increased Pluckington Bank, on the Liverpoolside, will be reduced, a better entrance will be made to Wallasey Pool, and a more favourable action will be exerted on the Victoria Bar.

The plan seems open to the objection that injury must ensue from the tidal displacement at Birkenhead, particularly as by the construction of new docks on the Liverpool side a further displacement takes place there.

Mr. Rendel says that this is of no importance in the case of the Mersey. If the river were of a funnel shape an obstruction below would impede the passage of the tide up, and diminish the quantity of water available for scour. He allows that injury will ensue if an obstruction takes place in the Liverpool Mersey, because there will be less room for the water to accumulate; and before there will be a less body to scour down on its ebb. He contends, however, that the displacement on the neck of the flasks is of less importance, as the water there is of less power for the scour. He claims that the current from the upper Mersey. The tide will always have time and power to force its way up the neck to supply the reservoir in the upper Mersey; and the state of the channels in the neck is determined by the state of the upper Mersey, and not of the neck. He contends on the ground of the improving state of the Victoria Channel, and, notwithstanding the displacement by the docks at Liverpool, that on the left side the neck cannot injure the Victoria Channel. Pluckington Bank, he affirms, is formed by the set of the current on the irregularly-shaped shore of Birkenhead. By straightening the Birkenhead shore, as he has been in the Liverpool shore, the neck will be made more efficient, the tidal body passing up will deepen it, and Pluckington Bank will be worn down, though he does not say it will sweep it away altogether.

This is really a summary of the harbour question; and we believe we have put it with sufficient succinctness and clearness to enable our readers to exercise their judgments upon it.

The arguments and researches of Mr. Rendel in support of his case are well worthy of perusal, for they exhibit very able treatment and high powers of mind. It is in the preservation of these that the practical value of Mr. Webster's book consists; and it is fortunate for the partnership of the Mersey Board, because it is as it is chiefly an abstract of the evidence, a mere lawyer would have got rid of the practical points, and the book would not have been of the least service to engineers,—whereas it is one which will be usefully added to the library of every member of the profession.

The formation of a harbour at Birkenhead is not new to engineers, for, in 1828, Telford, Stevenson, and Nimm were employed on a plan by Mr. Laird, sen., and Sir John Tobin, and recommended the formation of a canal from Wallasey Pool to the Dee at Hilbre Island, near its mouth, so as to get another access to the sea. This is a resource which Birkenhead still has, and which with its progress it will avail itself, but which will not checkmate Liverpool. Liverpool has, by the plan proposed for an out-harbour at Penny Black, a cheap means of providing more efficiently for all that could be done on new seaboards. Formby Harbour could be made cheaply; while two short cuts to the Leeds and Liverpool Canal, and to the Liverpool and Southport Railway, would allow of goods being carried cheaply and quickly by Liverpool docks and by the Penine steam traffic. Formby Harbour would beat the Hilbre Island. Mr. Rendel's plan may be considered as novel in its whole arrangements and treatment. Mr. Telford in looking at the Mersey is reported to have said: "They have built Liverpool on the wrong side of the river."

We shall now take some stray gleanings from Mr. Webster's book. B.N. says that Pluckington Bank is isolated by two opposing tides or eddies from Wallasey Pool meeting and causing the silt held in suspension to deposit itself. The straightening of the Birkenhead shore would remedy this.

Birkenhead, we may note, besides being the deep-water side, has the advantage of being the weather-side; while the docks on the Liverpool side, most exposed to the waves breaking over the sand-banks, are the most liable to silt up.

The area of the flat at a high tide is 208 acres, the frontage 4½ miles. For the dam, Mr. Rendel proposes tide-gates of 70 feet opening, the level of their sills being the same as that of the Prince's dock, at Liverpool. This flat would allow steam-tugs to enter, which is not the case at Liverpool. Mr. Rendel calculates on the movement of the steamers likewise in keeping his channels clear. Besides the tide-gates of the present float, Mr. Rendel proposes a lock of 50 feet wide and 200 feet long, which could be worked during ten hours out of every twelve, in a spring tide, for vessels drawing 17 feet water.

We shall give in Mr. Rendel's own words his plan of sluicing—:

"It is proposed to run down daily any quantity of water between the levels of the tide of the day and the water which may be considered best as the permanent level of the water: so that the supposed high-water is maintained as a permanent level of thirteen feet above the old dock datum, the average high-water of spring tides being 18 ft. 5 in. above that level, there would be the difference between the permanent level and the tide of the day. The running off the water is a very important feature in the plan; the idea is to make sluices, or apertures, under the great gates and the tide-gates, passing out near the level of the bottom of the great basin, and consequently under the whole of the gates. The openings for the discharge of the water near the bottom of the basin and the level of the sills of the tide-gates and of the locks, as low as we can conveniently get them; say for argument sake, ten feet below the level of low water of average spring tides. The sluices will be so formed as to be five feet square at the top on the water, and they will be so constructed as to produce a kind of sheet of water within two feet of the bottom of the great basin, and inasmuch as the separating piers of these apertures will only be at the point of outfall about two feet thick, the effect will be to produce a kind of sheet of water within two feet of the bottom of the basin, and inasmuch as this presupposes a mean depth of water which we know to be a working depth, it is probable that we shall be able to operate upon the bottom of the basin, and stop the usual way of a large bore of water tearing up everything before it, but a sheet of water which we can regulate to any degree of force which we like, by the sluices on the Narrows. I should also say further, that we have the sluices there, because they will operate most efficiently upon the straight part of the basin; we propose to have the same kind of sluices between the little dock which we have called the Bridge End Dock, and the Harbour, and the sluices to be so arranged that we can have a kind of sluicing or sluicing, which is that, that we shall be able to use at any time, and which will not be so great as it is now. I wish it to be distinctly understood, that we do not propose to run those sluices in the ordinary way of sluicing. I want to give the water, which is to be discharged out of this great basin, more the effect of a river passing through with a gentle current, than a great body of rushing water, and if I arrange the sluices with this view. It is also manifest that a basin of such capacity as this basin, will have lying in it a number of vessels, say of from six to ten feet draught of water; those very vessels will be the means, with a gentle current, of keeping the basin clear with the daily operations we shall employ in running off this water.

If the basin were unoccupied the effect would not be so great as it will be the basin being occupied. If the basin were at the level of low water, if the sluices were not of the sluicing would not be so great as it will be from the fact that vessels are floating in the basin, whereas in large quantities, or small, if the quantity of vessels is small, I would then give the water a greater current; if it is large, I would then give the water a greater current; and we can command that kind of current passing through the vessels from their being shut, which will keep the bottom clear of the daily accretions.

Also we can run off the water at those periods that experience will dictate to be the best. We are not bound to run it off at low water, or any particular period of the tide; that would be regulated by a regard to all the circumstances of the cases.

I know from considerable experience, that many harbours are kept open entirely by the vessels lying in those harbours; the river is forced to pass through their bottoms, and in that way the water is kept at a proper depth. I believe that is notorious."

There will be the power of running off 1,600,000 cubic yards of water at spring tides, which will be available for scouring. The most available water for scouring now passing out of Wallasey Pool is 1,800,000 cubic yards; that is to say, the water passing off after half-tide.

Mr. Rendel's estimate is, for cofferdams and other temporary works, £15,393; excavations, £20,470; masonry, £198,513; gates and sluices, £21,228; draining, £22,572; land and contingencies, £33,378. Total, £381,982.
were very minute; but to be fully understood require the explanatory maps and sections accompanying Mr. Webster’s book. We shall, however, attempt to give an abstract of Mr. Rendel’s evidence in this case.

"The estuary of the Dee, and the estuary of the Mersey, and the character of the two rivers are manifestly wholly different—their forms are different. They are different in this respect; the Dee is for the whole extent of it a shallow estuary; the Mersey, from the contraction at its mouth, has an exceedingly deep channel. Unlike an enormous river, but immediately that it widens out in the same form as the Dee, it loses its depth and becomes a shallow estuary; therefore, suppose the tide to come upon is, as I describe it with reference to the large chart, as at present—and not descend into the estuarial part of the Dee, and you are in the gorge—it comes up in a large body, presenting to all intents and purposes, the head of a wedge, and it gradually tapers out, losing its solid and compact form as it advances up the estuary. It is manifest that if we can make that description, the Dee is a much more perfect the efficiency of the channel after these works are made; the part outside Seacombe is perfectly untouched; we do nothing to that. Then, in order to ascertain precisely the whole economy of this tidal action in the estuary, and to satisfy my own mind, and in order to give evidence before your Lordships, I had tidal observations taken at Formby, which is, in fact, the headland on the Lancashire shore; observations were simultaneously taken at Prince’s dock, which is the narrow part of the gorge of the estuary; also at Netherton, Fiddler’s Ferry, and Warrington Bridge; and also I have been able to trace the relative heights and the relative times of high water of the same tides at those points, and I have done at spring and at neap tides. The results will I give from the diagrams I have before me.

The width of the river at Egremont—the point which corresponds with the north end of the Liverpool docks—at high water, is 4,030 feet; the sectional area of the channel at that point at high water spring tides is 256.449 square feet. At Seacombe, only 3,000 feet within that point, the width is reduced to 2,000 feet, and the sectional area to 164.62; it is altogether a gorge at that point; it is completely the gorge of the estuary, which has been defined by the works of the dock trustees on the one side and the natural rock of Seacombe on the other. At Wallasey Pool the width is 660 feet, and it is reduced to 330 feet at the head of the wall to the other sections, namely, to 3,350 feet. At Woodside pier, the width is 3,500 feet, therefore the effect of the wall is to make the shores parallel, and consequently to take off this great width which Wallasey Pool occasions. That wall is one of the most important parts of the channel, the character of the river; it will directly accomplish that object, and one immediate result likely to follow is the taking away of Pluckington Bank formed by the tide setting into Wallasey Pool and occupying an eddy. The consequent good effect will be, that the quantity of water at the least, if not more, which now goes into Wallasey Pool, would go up into the estuary, and by going up into the estuary it must necessarily be of greatly more value to the maintenance of the estuary and the scouring power of the river than passing into the pool. These will be nearly 330 feet greater than all the others, and I have been able to trace the relative heights and the relative times of high water of the same tides at those points, and I have done at spring and at neap tides. The results will I give from the diagrams I have before me.

The object of these tidal sections is to show how the tides flowed on the day of the observation. At the first place, at the point where the tide is quite at the mouth of the estuary. At the same time, if you carry your eye to the Prince’s dock you find that the tide is hesitating, actually rising up, at Prince’s dock. Then if you go on to Ellesmere Pool you find that the tide was actually rising on the day in question it has fallen at sea; and so, all the way to Runcorn and Fiddler’s Ferry; and you get the profile at all the points by the different lines laid down here, which in words is this: that insomuch as the tide had flowing into the estuary attained a velocity in passing through these narrows at Liverpool, its own acquired speed or momentum it carried it forward, and helped up the estuary according to all these lines, for it would be impossible if that were not the case to account for the fact, that the tide does so. If it had only gone on just this—I tell you, if it had not acquired a given velocity, we know perfectly well in mechanics that unless some force interposes to stop the velocity of the body it will be carried on; and it is precisely so in this case, the water flows on by the impulsion which the tide received at the mouth of the gorge, and the tide is carried on that level. If the elevation were due only to nothing more than the fall of the tide, which is necessarily the pressure of the head without the velocity, it would terminate its course, for there is no law of nature to make it go further. What would be the state of things in an estuary like the Dee, would be determined by the form of the shore and other questions, but here you have the peculiarly so strongly marked, that you cannot mistake the cause. The effect there would be, that as the mouth of the Dee is wider than its head, it would receive a larger wave than would be due to the upper part of the Dee, and, therefore, if it had acquired sufficient velocity, the water would accumulate up the Dee to a certain extent; but insomuch as the extent to which it would accumulate is due to the velocity of the stream, it could not attain the same head in the upper part of the Dee as it does in the Mersey; it is due to the velocity. If I explain, the diagram of the profile represented is that which is due to the stational pressure (which is nothing more than head without force or velocity); all that is above that must be due to impetus; for we see here in the Mersey what we see in every river, and what we see in the Dee; instead of the narrow part being at the top, the narrow part in the Mersey is at the mouth; therefore, so far as is due to momentum, if you could make the Mersey and the Dee at all agree, it would follow, that you would in the Dee have an enormous heaping up of water, which when you begin to cause it to pass, the capability gave to the water entering the Dee the same velocity as the water entering the Mersey, keeping the section the same, it would heap up here quite in the same way as it does in the Severn; but it cannot have that velocity, because there is not the same cause to excite it, namely, the contraction.

For determining how much the tide has risen up the estuary above its level at the gorge, I take the level at Prince’s Basin, which is in the gorge. I take the tide on the 1st of June, which was a spring tide. Suppose we start with the tide at high water at Prince’s dock, which is in the gorge
at Liverpool, it would be 1 ft. 1 in. higher at high water at Ellesmere Port, and fifteen minutes later in arriving at that point; 1 ft. 10 in. higher at Runcorn, and would be thirty-five minutes later than at Liverpool; it would be 1 ft. 9 in. higher at Fiddler’s Ferry, one hour after it was high water at Liverpool; it would be 2 ft. 3 in. higher at Warrington bridge, 1 hour 25 minutes after it was high water at Liverpool. Without going through the details of the observations, it may be said that at Liverpool, 1 ft. 6 in. higher at Ellesmere, 1 ft. 10 in. at Runcorn, 1 ft. 8 in. at Fiddler’s Ferry, 2 ft. 3 in. at Warrington.

On the mean of the three neap tides, of the 8th, 9th, and 10th of June, there was still an elevation, but it was reduced on account of the streams running so strong at the gorge, to 5 inches at Ellesmere Port, 11 inches at Runcorn, 10 inches at Fiddler’s Ferry, and only 9 inches at Warrington; these differences are due to the differences of the neap and spring tides, or in other words, the differences of the velocities through the gorges are as 8 to 5 to 11. At 11 inches at Runcorn, 6 ft. 11 in. at Fiddler’s Ferry, 1 ft. 6 in. at Warrington; and it follows, that anything that would strengthen the velocity through the gorge at neaps, would necessarily tend to make the approximation nearer between the elevations at those different places at neap tides, as compared with springs.

The difference in the quantity of water which passes up the estuary at springs and neaps, I have taken from Captain Denham’s survey; and if you could get the water at neap tides to stand at all those different points with the same differences above the Prince’s dock as it does at springs, you would get an increased quantity of water (18,000,000 or 20,000,000 of yards) up the estuary; any increase of the momentum in the ginge would tend to increase the quantity going up. The observations led me to that conclusion, and I gained the confidence of that at all events, I am convinced that all the water that now passes into Wallasey Pool, would go up into the estuary. It is a mathematical question which I am not going to touch, whether more would go up; but philosophers have endeavoured to show, that a bodies of water (all other things being equal) would have the same velocity of water being discharged as would be discharged in the same time if the pipe were parallel, and this is a similar case, but I am not going into that question.”

This is a timely warning against the bill of the Railway Commissioners, particularly addressed to the engineering profession. It is so clear and practical, that we hope it will not be without its proper effect; at any rate, Mr. Doull deserves the warmest thanks for this exposure of the mischievous measures of the commissioners.

After showing the inconsistencies of the standing orders, and explaining the process adopted in preparing a line of railways for parliamentary examination, Mr. Doull goes on to analyse the amended bill. The chief amendment is the lowering the deposit by way of security from £500 to £500; but which for a line of 200 miles, would still leave the enormous sum of £40,000 in the hands of the Commissioners for the formation of the line, in the manner as they may think fit,—but which, at all events, is a serious impediment in the way of all new lines of railway. Mr. Doull very well observes, that the commissioners are quite ready enough to do work for the money,—indeed, the way in which they make work wait to their profit, by holding up the railways, if it is not so objectionable from its decidedly mischievous tendency.

As is well known, a preliminary survey, often extending over miles in breadth, is necessary to select the line which is to be surveyed in detail. No provision, however, seems to be made for this, or the bill is inconsistent with its performance. Most probably, Colonel Brandreth and Sir Edward Ryan are unaware how the survey of a railway is carried out. The fourth clause of the bill requires that “the promoters of any proposed railway shall apply to the commissioners for authority to make the surveys necessary, to enable them to adopt the level of the line, &c.; but the fifth clause requires that “ten clear days at the least before making such application, the said promoters shall give notice by advertisements, each in the same words and form, in the London Gazette and in some newspaper published or circulating in each county the making of which the promoters are to be held parson to pass, such intended application specifying the course of the line of such railway.” &c.

Of course this cannot be done without a preliminary survey, and how is this to be effected ten clear days before the engineer can apply to the commissioners for leave to go over the ground?

Again, if this notice and this permission be as a protection to the occupiers, it is difficult to conceive how a notice is to be framed to cover the wide extent of country over which it is necessary for the engineer to go, if he is to choose the best line of railway. It is practical that a very large expense must be incurred for advertising voluminous notices (drawn up by lawyers) in the London Gazette and a number of country newspapers.

It will be worth the while of the enterprising proprietor of the Survey Times to publish it all the year round, instead of bringing forth now and then, as the present number of intended applications to parliament for railway bills.

Mr. Doull thinks from the sixth clause that the permission to survey only extends to the very lands through which the proposed line of railway is to pass. If so, a large sum of money has to be given away, much time has been spent, and a cumbersome process to be gone through, for a permission which is worth very little.

The tenth clause, regulating the return of any remaining portion of the £200, provides that one month after the bill for giving power to make the railway, in respect of which such deposit was made, shall have passed or been thrown out or withdrawn by leave of the commissioners or a draft or cheque signed by two of the commissioners order the balance standing to their (the depositors) account, in respect of such deposit, to be paid to the promoters by whom the deposit was made.

—Mr. Doull observes, that the framers of the bill do not appear to have contemplated the return of any portion of the deposit to those promoters who may not advance so far as the threshold of the legislature. We may add, that there is an opening for litigation, in case of any dispute among the promoters of a new company, such as has happened before, and such as may happen again, as cases of Mr. Hume and others. If the Stockman should give notice to the commissioners not to return the remaining deposit to the committee of the railway company, the commissioners may be very well disposed to act upon the hint, and wait for the direction of a court of law.

The thirteenth clause provides that before the said promoters, or any of the companies offered for the survey of the same, or to mark out the line of their proposed railway, as hereinafter mentioned, they shall give to the occupying tenant thereof not less than two nor more than seven days’ notice in writing of their intention to enter and survey the lands. The object of giving not less than two days’ notice explains itself, but the restriction as to not giving more than seven days’ notice must often be most inconvenient to surveyors and engineers, for within seven days many circumstances may occur to delay the survey, while no inconvenience can accrue to the occupying tenant from any length of notice. In this case, it is far better to serve a fresh notice, the first seven days’ notice having expired.

Mr. Doull contends, and with justice, that the number of occupiers who would require to be noticed previously to commencing the survey or levels, would be considerably more than the number at present necessarily included in a railway book of reference, even supposing the survey to extend only to the usual breadth of 30 or 30 chains. It would therefore be necessary to get up a reference-book before commencing the survey; and this would be attended with very great expense, besides the risk of some occupier being left without a reference.

The fourteenth clause is in keeping with the rest. It enacts that “the said promoters shall mark out the line of the proposed railway by means of stakes fixed in the ground not more than thirty yards apart, and in such manner as clearly to point out the proposed line of such railway; and they shall put up posts along the line, so marked out at convenient distances for the purpose of showing the level of such line, and also mark on such posts in legible characters the number of feet and inches at which the rails are proposed to be laid above or below the surface of the ground.”

Our readers will agree with Mr. Doull, that staking out a line of railway, and exhibiting the levels in feet and inches along the line, is a very difficult and complex operation. He estimates that it would double the expense of preparing parliamentary plans and sections. A higher class of surveyors would have to be employed, a great number of devices of devices resorted to, and superior instruments used to take out curves of given radius with accuracy, in the face of the numerous obstacles to be encountered, and of the variety of circumstances to be met with, on an extended survey.

As more damage must be done by staking out the line than by an ordinary survey, another charge will be imposed on the companies, and further claims for compensation be given to the landowners and occupiers.

A new set of parties must be employed in painting the level-pots.

As little good is to be got from stating, in “inches,” a level which will differ whether the land be ploughed or uncleared, whether it be trenched or in grass, we do not profess to see. It can only cause a serious expense without answering any useful purpose.

At present, staking out is delayed to the period when it can be
undeptaken for a purpose of practical utility, and when it can be conveniently performed.

As the extensive and occupiers can now refer to the plans without having the line staked out, and as engineers can check the levels of the line from those plans, going over the ground with the plans in their hands, it does seem very hard upon the companies that they should incur such expense for the officers of Royal Engineers. The work is to be performed on the assumption that the parties cannot go over the ground without having the line staked out, they must be utterly incompetent for the discharge of the duties properly belonging to their own profession, and to the performance of which it is desirable they should be restricted. It will be open to a gratuitous opposition to call about every one of the parties; and the military engineers and the whole party may be employed in ascertaining that the post is wrong by two inches above or below the line.

Clause 21 provides that the plans are to be deposited and inspected. The inspector, who knows as much about civil engineering, is to hold courts along the line of the proposed railway for the purpose of receiving information or suggestions from anyone who may propose such railway, either as the promoters or as the owners of land on or near to such line or otherwise. A very cheap way of so doing is by paying the companies and putting them to expense, will be by the landowners and farmers attending the inspector's court, and occupying the time of the staff by raising all kinds of objections.

The twenty-fourth clause is an ambiguous one, giving the commission power to allow the promoters to amend their plans after inspection.

Clause 25 provides that a second deposit is to be made, and this is followed by another ambiguous and inconsistent clause.

Mr. Doull thinks that Clause 26 contemplates a second inspection of the plans in the hand.

It behoves engineers to be on their guard against this most tyrannical, mischievous, and vexatious measure, which will place them under the inspection of their inferiors, the military engineers, in every operation of a survey; and they are to be subjected to the judgments of these men, whether a level be rightly taken or a curve properly laid out.

It will be seen that this bill subjects railway projectors to the following new act of unprofitable expenditure:

The depositing of £200 per mile with the Railway Commissioners.

The advertising of the intention to survey.

The preparing a reference book for the survey, and the serving of the notices on the occupiers.

Staking out the line, marking the levels in feet and "inches," and setting out the curves.

Making two deposits of the plans.

Preparing amended plans.

Attending the inspector in his inspection of the line as staked out; and fighting for the accuracy of the line, and again the objection to the plans.

After all this has been done, the old preparations for encountering the ordeal of standing orders have to be made; for the new regulation of the Commons, providing for notices being sent through the post is quite inoperative, as service has to be proved, and the Lords require the old mode of service.

Our readers will agree that any system of legislation more disgraceful to a country than that by which railway companies are harassed, was never attempted or perpetrated.

It is stated that the object of this work is to present, in a popular form, a brief sketch of ancient and modern art; and to avoid the faults of other publications, which are of no use to the ordinary reader. By way of correction to this idea, the pages are filled with long passages from the French and Italian, and snatches of Greek and Latin, which are not likely to be very well understood by the public, which are not needful in themselves, and which do not move the learning of the author. As to the execution of the work, without being original, it is loose and unsatisfactory; there is a hash of the opinions of foreign writers on art, and the only novelty is the criticism of the author on English writers and reviewers. It especially falls in giving a clear idea of some or others, and a reader taken from the public would acquire the smallest amount of definite information from its pages. It is a very difficult task to give an abridged view of an extensive subject, so as to communicate exact ideas; indeed, an abridgment requires as high a degree of ability as the original work. It is not surprising that Mr. Cleghorn should utterly fail in this attempt. As from some petty provincial feeling, there is more space devoted to the buildings, sculpture, painting, and painters of Edinburgh than of any other place—indeed, a large part of the work is occupied with the monuments of the nineteenth century. But it is not quite inexcusable, for the quantity with the quality. The work has such small merits, that we should not feel called upon to notice it, if we were not that it is likely to be taken for a popular work, as being a second edition emanating from publishers of reputation. A popular manual of art has yet to be written and is much wanted; but it must convey definite information and descriptions suited to practical men, and less general criticism of artists and works unknown to the public and not particularly known. Mr. Cleg-
used, or the sense addressed, that they differ. We are now agitating for the catholicity of the three arts of design—painting, sculpture, and architecture; but we are not so well developed in the fine arts as music, the drama, and poetry—be likewise cultivated. The attempt to sever single arts, which has failed, is a ground for want of confidence in any system which steps short of completeness. In what do all our complainers fail? to our looking for art, art, art. In a conviction of the low mental condition of the professors of art. When the painter has once taken his brush in hand, the sculptor his chisel, and the architect his compasses, he bids farewell to education and enlightenment, he gives himself up to what he knows, and not to what he must. That was the conviction that when it should be free in its expansion. Precisely for the reason that the artist has no education, the scholar has no knowledge of art; and art is kept back from this state of affairs, and not from the want of manual capacity in our artists, or of adequate encouragement from the public. There have been opportunities enough lately, but they bring forth only Buckingham Palace or Traflagar Square, art-union pictures or pictorial monstrosities. The schoolmaster has been sent abroad; but till our artists are better educated men, and more on a level with those of Greece and Italy, art can have little hope. We do not want academies of art so much as we want schools, liberal training, and the power of reasoning justly.

Among the six fine or imitative arts, there are marked distinctions. Painting or design, sculpture, and architecture are material production; poetry, the drama, and immaterial, and the latter two in their performance are transient or fleeting. The three latter have, however, the power of reproduction of the model work to such a degree as materially to extend their social influence. Painting by the means of engraving, and the means of casting or of etching, presents to him in a less or more modified degree, but the progress of science promises to give these arts greater resources; and although some look unfavourably on the machinery of copying and piracy, we cannot but believe that the artist will gain by being brought into communication with the market. For all that, the public must work together, they must feel for each other, they must join to produce the wished effect. Shakespeare working for the public of his day, and Dickens for the public of this, are under a stimulus which the artist at the present time too rarely feels. The incentive to immortality, the conscientious discharge of a patriotic duty, the inspiring influence of the goodwill and fellow feeling of applauding millions ought to operate on the artist as they do on the statesman, the general, or the poet, and ought to produce greater results than the grovelling selfishness which yields up the secret of the stadium and allotted price, careless of anything but the money reward and the personal gratification.

Architecture has for its province the execution of single and isolated monuments. It is not easy to reproduce the Parthenon or St. Paul's with anything like the mass of the public. The artist and the public must work together, they must feel for each other, they must join to produce the wished effect. Shakespeare working for the public of his day, and Dickens for the public of this, are under a stimulus which the artist at the present time too rarely feels. The incentive to immortality, the conscientious discharge of a patriotic duty, the inspiring influence of the goodwill and fellow feeling of applauding millions ought to operate on the artist as they do on the statesman, the general, or the poet, and ought to produce greater results than the grovelling selfishness which yields up the secret of the stadium and allotted price, careless of anything but the money reward and the personal gratification.

We regret to perceive that Mr. P. Barlow has permitted this book to be dedicated to him, for we are sure that he was ignorant of Mr. Baker's meaning. A chapter has been added by him by the unscrupulous author. There need not be the slightest delicacy or hesitation in affirming that the whole performance is a collection of gross plagiarisms. The formula for the super-elevation of the outer rail of a railway curve is taken from De Pambour. Methods which have long been avowed for settling out curves, the author claims as his own, on the plea that they were privately communicated to his pupil, and that some years ago he sent to the "Gentleman's Diary" a paper on the subject, which was rejected.

The "General Table for the Calculation of Earthwork on Railways, &c." is a direct copy from the "General Table for facilitating the Calculation of Earthworks for Railways, Canals, &c." by Mr. Bashforth. There is not even a colourable variation from the original in the copy,—it is an exact reprint, line for line and figure for figure; with a few additions, but not a single omission. Every one of Mr Bashforth's tabular numbers re-appears in Mr. Baker's. We had intended, in order to render the plagiarism palpable, to print a column from one table by the side of the corresponding one in the other table; but after getting half way through the labour of copying the figures, we found that there was not a single iteration or omission, and therefore abandoned the task as useless.

A general reader, not familiar with the character of earthwork tables, might deem the similarity accidental or inevitable—just as if two persons published different tables of common logarithms or square roots, the tabular figures must coincide both are correct. The slightest consideration, however, will show that the present is not an analogous case. A great number of earthwork tables has been published, but none except Mr. Baker's has the same figures as Mr. Bashforth's; and for this plain reason,—that other methods, or, Sir John Macneill's, are applied by methods, and for purposes, entirely different. Sir John Macneill's, for instance, are not general, but have the results for particular slopes and bases, worked out ready to the engineer's hand. Mr. Bidder's table, on the contrary, is general, and considers the prismoid in three separate portions. Mr. Bashforth's is also general, but considers the prismoid in two portions; one of which has no real existence, but being merely assumed for facility of calculation, is ultimately subtracted. Now considering the perfect independence of these methods, it is clear that the tables, when founded on them, though entirely different from each other, may lead to identical results. But the only person who has adopted Mr. Bashforth's very original plan of considering the slopes to be hypothetically continued till they meet in an apex, is Mr. Baker. He therefore is the only person who could use the same figures.
vated by the attempt made in the work under review to throw dust in the eyes of the reader, by abusing the author whose tables are copied. The attacks commence in the preface, and are continued at intervals to the end of the book, with all the skill of which italics and capitals can give them. For example, speaking generally of other previous tables, our author allows that "none of them are accompanied with directions for finding the contents from the sectional areas, which is the most important part of such tables, except Mr. Bashforth's; but his method of applying them is erroneous." Now, the assertion, which we have given in the author's own italics, is not only untrue, but it would not be uncharitable to assert that it is put forth to disguise the real relation of his own method to Mr. Bashforth's. The supposed error refers to the calculation for side-long ground (or cutting embankments on the side of a hill, where the height of the slopes is unequal), and is established by taking a perverse and preposterous example—that of two sections, 4 chains apart, of the area 10,324 feet and 400 feet, respectively. As if in a length of 4 chains, no intermediate sections would be taken where the first section was more than twenty-five times the last!

Setting aside the extravagant nature of the case supposed, Mr. Bashforth's method, even if so applied, is just as likely to give a true result as that which Mr. Baker would substitute. We are told, that by neglecting triangles in the area of the triangle, the former method gives a result $\frac{3}{4}$ per cent. too small; but it is just as likely that the substituted method gives the result as much too great; for the ground may undulate so much, that the error may be either in excess or diminution. In a case like the present, where the ground falls so much in the direction of length, that the heights of one end-section are only one-fifth those of the other end-section, great irregularities of surface must be supposed to intervene. For instance, suppose a valley or deep hollow occurred somewhere in this length of four chains of cutting, Mr. Baker would tell the contractor to remove all the contents of the valley, which, in reality, nature had already excavated for him. There is no guarding against such errors, except by the precaution which every reasonable engineer adopts where the ground varies considerably—which, in the present case, would be practically inevitable and which Mr. Bashforth's method supposes—that of taking frequent sections.

Our worthy author has not borrowed his predecessor's table of Proportional Parts—which, as we explained in a former review, is printed on card, with a movable index of wood sliding in a groove. It is estimated that by this ingenious contrivance, the table is made to contain all the calculations which, extended, would occupy a surface 42,250,000 times its present area. To have adopted this table also, would have been too palpable a plagiarism; Mr. Baker, therefore, contents himself with copying, "Square for 4 chains", the first twenty-one lines of Table No. 1, which he institutes as "Table No. 2," and the reader is informed (p. 48), that in cases which this "Table No. 2" does not include, he must work out the calculations for himself.

It is not to be expected that every practical person who calculates quantities for contractors, should understand the mathematical principles on which the particular tables which he uses are based. But it is within the simplest comprehension, that the two methods under comparison—and they alone—proceed on the assumption that the slopes are hypothetically continued to their intersection. It is also not a matter of reasoning at all, but one of mere eye-sight, that Mr. Baker has re-printed Mr. Bashforth's calculations identically. The only differences are these—Mr. Baker's table is printed in a less distinct manner; to Mr. Bashforth's table of 63 heights (reprinted without a single omission), seven more heights are added: firstly, of the Table of Proportional Parts, the first twenty-one lines are reprinted, and as to the 42 millions and odd remaining calculations, which the sliding index ingeniously effects—why, the reader is left to calculate them for himself.

The Steam Navy. Mr. Edward Whitely Baker has been appointed by the government to go out with James Brooke, the Rajah of Sarawak. Mr. Baker is attached as engineer to the Benkong (ferry), and is to have charge of a steam launch, to be used in getting up the small rivers and creeks for surveys and in search of pirates, and is to be at the service of the Rajah in Sarawak and Labuan as mechanical engineer. We are glad to see from this appointment that the Admiralty are really desirous to improve the engineering service of the navy, by employing efficient practical men like Mr. Baker.

---

Register of New Patents.

Balance Bridge.

John Harvey Badker, of Holbeck, Leeds, iron merchant, for "Improvements in constructing bridges, aqueducts, and similar structures."— Granted July 7, 1847; Enrolled January 7, 1848.

This invention relates to the construction of cast-iron girders for continuous bridges, viaducts, or aqueducts, and other improvements relating to railways. Fig. 1, is a side view made according to this invention of cast-iron girders c, strongly jointed and bolted together at a, standing upon piers of stone or brick b b b, each girder c, being cast from one and the same pattern, or where no very great length is required, two parts c c', may be cast as one piece c; in either case from the points d, will constitute one girder, which is from centre to centre of two arches, and the two parts on either side of a bar b, will balance each other, consequently, there is no weight or sway comparatively speaking, in the centre of each arch. It will be seen that each girder is loose and at liberty at the centre of each arch d d, and though strongly jointed together by means of plates on each side, they will allow for any contraction or expansion required by change of the atmosphere; and fig. 2, is a transverse section of this joint, showing how the toothed-plates fit into similar teeth at the ends of each girder where they meet at the centre. Fig. 3, is a plan of the cast-iron flooring for bridges, &c., consisting of plates of cast-iron. Fig. 4, shows these plates upon an enlarged scale, the underside uppermost and not closed together, the better to explain how strength may be given to these plates to bear the rails and any weight required to pass over them; and fig. 5, is a transverse section, showing how these plates are fastened together, and bolted to the girders by the brackets f. The covering or flooring-plates e and A, are shown to be a foot in width, and of the length from girder to girder corresponding to the width required for the railway.
The plate upon which the chairs are securely bolted is seen to have three ribs or flanges cast upon the underside in order to give the requisite strength, and also holes cast through it for bolting and securely fixing the chairs for holding the rails. There are studs about an inch square cast upon the sides of each plate, and each plate has holes cast of a size exactly to fit and receive these studs; (see A, fig. 5, which is a side view of these plates,) it will therefore easily be understood that if these plates were shut or closed together, these studs would enter into the holes cast in each for that purpose, clearly showing that the whole covering or flooring will be so united and securely fastened, so as to form one general mass of support to the rails and the weight passing over them.

LOCOMOTIVE ENGINES AND BREAKS.

George Taylor, of Holbeck, near Leeds, Yorkshire, mechanic, for "Improvements in the construction of engines and carriages to be used on railways."—Granted June 3; Enrolled December 3, 1847.

This invention relates, firstly, to improved arrangements of the cylinders of locomotive engines, and the parts which communicate the reciprocating motion to the driving-wheels, for the purpose of concentrating the driving power of the actuated pistons, so as to communicate an even rotating motion to the axles of the driving-wheels, and also to distribute the weight more (without first concentrating it) to one, two, or more pairs of driving-wheels in a uniform manner. Secondly, this invention refers to an improved break, for stopping the progress of carriages along the line of railway; such apparatus being also capable of sustaining its carriage on the rails in case of the breaking of an axle. Thirdly, this invention relates to an improved arrangement of tender. Fourthly, to certain improvements in mounting the wheels of railway carriages.

The improved arrangements are shown in the annexed engravings. Fig. 1 is a side elevation, and fig. 2 a plan, in which the

motive power, communicated to the pistons of the working cylinders, is concentrated in a line drawn longitudinally through the centre of the plane of the engine. a, a, are a pair of cylinders, placed over the end of the boiler b, nearest to the smoke-box; c, are the piston-rods, with cross-heads, which slide in guides fixed to the outside casing of the boiler; d, d, are rods for connecting the piston-rods to the cranks e, which cranks are attached one to either side of a central wheel f. The periphery of this wheel is provided with coges, for gearing into or driving a wheel g, keyed to the axle of the driving-wheels h. In order to insure the proper gearing together of the wheels f and g, and allow of the play of the bearing-spring, the guides, in which the axle-boxes or journals of the driving-wheels a slide, are made at an angle, as shown at i, fig. 1. By referring to the figures, it will be seen that the axles are placed above the boiler, and, therefore, wheels of large diameter (say from 10 to 15 feet) may, if required, be employed with safety; the oscillation of the engine being, in great part, avoided, by the central and uniform driving of the axle of the wheels a, and the weight of the engine being near the ground. When it is desired to make all the wheels driving-wheels, their shafts may be connected together by rods and crank-pins, as now generally employed.

The specification describes two other arrangements of mecha-
SANITARY IMPROVEMENTS IN THE SEWAGE.

(With Engravings, Plate V.)

The importance of the sanitary question increases every day, and the large extent of works which will dividendy be carried out to obtain a perfect system of sewage make it of great consequence to engineers to be well informed of the most approved modes of construction. For this reason we have given copious extracts from the Evidence of Mr. Austin and Mr. Phillips, before the Metropolitan Sanitary Commission, and to which we beg leave to direct the particular attention of the profession.

H. AUSTIN, Esq., C.E., at the request of the commissioners made a survey of the Surrey and Kent district of sewers, and gave the following evidence relative to the flat district of Lambeth, the Borough of Lambeth, as shown in the plan, fig. 1, Plate V.

"There is little doubt that much good might be effected in the present system of sewage, but it could only be carried out at vast expense; and to extend this system over the whole district, so as to render it general and complete, even under such improved arrangements, would not only be ruinous in cost, but the great evils after all would only be lessened, not removed. With a district so situated, nearly flat, and for the most part several feet under high-water mark, all attempts at providing an adequate natural drainage, direct into the river, must end in failure. Do what you will, it must be a cesspool system still. A small additional current of two or three feet would certainly be obtained in the rainfall by lowering the outfalls to low-water mark, but the advantage of this, carried over a distance of two miles or more, would scarcely be appreciable, and could be carried out only at immense expense. It appears to be absolute that this artificial state of things should be treated as a temporary expedient, with a view to give as a lift and discharge the refuse constantly as it is produced. Interim drainage is somewhat more barbarous than intermittent water supply. It does seem extraordinary, that with the steam-engine applied in almost every useful relation of life, its adaptation to this great purpose of the system of drainage of these districts could not have been previously established. A refuse and water system should never have been attempted. It was very satisfactory to me to find, on proposing the system to Mr. Chadwick, that the idea of its practicability had already been impressed on his own mind, from observation as to the efficiency and small expense in the purposes of artificial agricultural drainage. We have ample experience as to the facility with which refuse may be pumped, in its application, in several instances, to agricultural purposes. It only remains a question as to the best arrangement of the drainage to realise the object in the most efficient and economical manner.

The district to be drained should be apportioned into convenient sections or divisions, the drainage of which would be totally independent and distinct, converging to the centre of each division with any desired current, and from these centres the liquid would be raised by steam-engines, placed at convenient points of junction with them by pipes. The skeleton plan (fig. I, Plate V.) of the populous part of the Surrey and Kent district will best explain my meaning, it being understood that the divisions of the district there represented, the position of the centre points, and the situation of the engine power, are only assumed for the purpose of illustration, without at all presuming that they would be the most desirable to adopt. These are matters, the correct determination of which would demand much consideration and study of local circumstances and arrangement. Beyond the consideration of these circumstances, the extent of each division would be limited only by the amount of fall that it would be necessary to preserve to allow of a certain maximum size of drain, and the depth of digging that might be thought desirable.

The most important consideration appears to be the size and material of the drains, and I have founded my calculations on the basis that the maximum size of the main outfall drains should not exceed a dimension that would be conveniently manufactured in pottery clay, so as to allow of the establishment, throughout, of a complete system of pipe drainage rather than of brick sewers. I therefore fix 3 feet as the maximum diameter of the largest drain and 2 feet in the next, being a practicable size to manufacture. Taking then a perfectly flat area—which is the worst case for calculation—assuming a total fall of 15 feet from the extreme points to the centre, upon an area of half a square mile or quarter of an acre to give a current of 1 in 300 as a maximum, and a 2-feet drain, with that fall, will be more than sufficient to discharge the whole refuse of the densest population upon that extent of surface, with an improved constant supply of water of 100 gallons per day per house. With such arrangements, there would have to be discharged from each division of half a square mile nearly one million gallons per day; but as by far the largest quantity is used in the busy time, from nine to one o'clock, I calculate a capacity sufficient to discharge the whole quantity in that time.

It would be essential that these drains should be capable of removing also the whole external refuse of the streets and houses. I think therefore, that an arrangement would be efficacious in accommodating a fall of rain equal to an inch and a-half in 12 hours, a good soaking quantity that would soon cleanse the whole surface of the streets and houses, and convey away the refuse. This amount being added to the house supply of water, the total quantity used at such times in each division would be 200,000 cubic feet per hour.

The only question for consideration as to fall, would be to fix a safe limit for the total inclination of those continuous lines of the drainage that would have to convey the water from the extreme points to the centre. Having decided upon that, the rate of inclination should be graduated from one end to the other; because the accelerated velocity of the stream, as it would approach the centre outfall, would admit of considerably less inclination of the drainage than at the commencement; or, on the other hand, would admit of a great reduction in the size of the pipes. All the collateral or intermediate branch-drains, it will be seen, would have so considerable an amount of fall, as to afford the opportunity of putting them all in of a very small size.

The engines may be fixed in any spot most convenient and available, and there need be only one pumping establishment for the whole district (as shown in the skeleton plan, fig. 1), to which all the various pipes would lead from the several centre wells, precisely as would be practised in raising so much water from a well at a distance. From the engines, one or more discharge-pipes, to convey the whole refuse, would lead to the most convenient outlet in the river, as shown by the double dotted line. The arrangement here submitted would offer this great advantage, that the pollution of the whole southern bank of the river would at once be avoided, as the liquid refuse could, with equal facility, be discharged at any spot lower down the river, where no inconvenience would arise from it. In the end, by, with the public mind is brought to appreciate the value of this material, and to apply it to its legitimate purpose, instead of throwing it away, there would be nothing more required than to lay down the distributing-pipes from the engines in the direction of the demand. The discharge pipe would then serve its proper purpose of a waste-pipe into the river, when the deposit in the reservoirs. I calculate that it would be necessary to provide four times the amount of steam power for the removal of the refuse during wet weather, which would be necessary only on dry days, and this is the very amount that would probably be necessary to raise the refuse to the additional height required for its application to agriculture. Thus, in wet weather, when there would be no demand for the sewage manure, the whole power of the engines would be employed in raising the great quantity of liquid refuse from the houses, and no further amount for its discharge from the district; and in dry weather the full power would be engaged in raising the smaller quantity of the additional height necessary for its intended application to agriculture. The system would so work together very satisfactorily as a perfect whole.

The cost of this improved system of drainage will not amount to more than one-fourth of the system now pursued in the Surrey and Kent district. This commission has recently given notice of the intended execution of works, involving an outlay of £100,000, to be expended in a few main lines of drainage, which, for the real and essential purposes of drainage—the liquid refuse from the houses—will be of no earthly benefit to the inhabitants, but will serve only to obstruct future improvement; whereas the outlay of this amount on the plan proposed would actually suffice for the construction of the entire street drainage, incurring every court and gutter, of the most populous part of the district comprised within an area of four square miles immediately south of the river. The perfect drainage of the most crowded district on this system would cost on the average £2 per house, with an annual charge of 5s. per house, for the entire disposal of engine power, and the interest of the whole cost of the public or street drainage, together with complete private or house drainage, with stone-cure water-closet basin, and including the above annual charge for engine power, would involve a rate of £1 per annum, or about a third of the present cost of emptying a cesspool, where at all decently kept.
Mr. Phillips, C.E., gave the following evidence as to the system of sewage adopted by him:

"Solidity of constitution in construction, economy of materials and labour, combined with strength to bear the lateral and vertical pressures of the ground, and efficiency in affording the best channel for conducting to the best sewageage, and the essential cost of a sewer. The arch is a most capacious area of all plane figures having the same circumference, and conversely its circumference is less than any other figure of the same capacity. It, therefore, supplies the greatest capacity for receiving the water to be conveyed in the smallest area, and therefore at the least cost of materials. As regards strength: when the pressure from the ground around a circle is the same, it is equally distributed throughout the entire thickness composing the arch; for, as the extradosal length is greater than the intradosal length, the arch is most powerful in the centre of the circle; hence the circular form prevents the earth outside of it from forcing it in, and from disturbing it, provided the pressure be equal, while upright walls in the same circumstances would most probably be unable to withstand the pressure.

The removal of sewage and prevention of deposit of matter in sewers are entirely dependent on the quantity and velocity of the water running through them. In order therefore to keep them well washed out and cleansed, the utmost scouring force should be imparted to the streams. A semicircular, or still narrower and deeper-curved channel of a semi-elliptical or catenarian form, combined together, gives a flow on a smaller scale of friction, heat, and turbulence, so increases its velocity, and makes it more powerful in lifting, holding in suspension, and carrying away all matters which may find their way into the sewers, than a wide and flat channel. A sewer, therefore, having an arched crown, curved side walls, and a narrowing and descending bottom, which, combined together, give the shape of an egg with the small end placed downwards, is, in my opinion, the best and most efficient form for all branch sewers. It would appear however from what has been stated, that the circle, from having a more capacious area and less rubbing surface than any other figure, is the best form for all sewers. But this is not the case; for although the surface of contact of the egg-shaped sewer is somewhat greater than a circle of the same area, yet by contracting the channel and so raising the height of the stream, the ratio of velocity and consequent power to scour is increased thereby, as will be evident on experiment being made. It is the progressive of the egg-shaped sewer, therefore, to combine in its form, capacity, economy, strength, and efficiency.

For the short collateral branches of the sewers in streets, courts, &c., the smaller they are, (provided they be large enough to receive storm waters in addition to the ordinary run), the less chance will there be for the same to choke up than there is of my experience I have examined hundreds of drains, and I have always found small drains and sewers which had a moderate fall, and anything like a good supply of water, quite clean and perfect in all respects. It is my confident opinion, that with a combination of the water supply and a tubular system of sewerage and house-drainage, the whole of the annoyance now experienced by the public from defective drains and sewers may be made to cease.

If constant currents of water be carried through the drains and sewers, though the currents may be small, yet provided they be constant and concentrated on very narrow and smooth bottoms, they will keep the sewers clean. Where the supply is intermittent, the matter discharged from the house-drains, meeting with no current, accumulates. In order to prevent deposit in drains and sewers, there must be a certain degree of velocity and force given to each current, so as to produce agitation equal to, or rather greater than the 

The chance of any sewer keeping itself clean is dependent on four things,—namely, its capacity, its form, its fall, and the quantity and force of the water running through it. It is only from observation and experience, and the application of rules deduced therefrom, to the proportioning the capacity, the form, and the fall, as also the quantity and force of water required to prevent deposit, that we can hope to arrive at perfection in sewerage. From observation and experiment, I find that it requires a constant velocity of current to be running through the sewers equal to about 12 feet per second, or 1.2 mile per hour, to prevent the soil from depositing within them.

There is less water running in the sewers on Sundays than on other days of the week; and most on Saturdays. The height of the flow every day goes on increasing from an early hour in the morning until about noon, when it is highest; it then gradually subsides to its lowest level. The period of the greatest flow every day is between 11 a.m. and 1 p.m.

The fall of the sewer being proportioned to the quantity of water that is to pass through them. For, with the same fall, the greater the body of water the greater will be the velocity and scour; and conversely, the less the body of water the less will be the velocity and scour. Again, a large body of water will, with a little run off with the same velocity as a small quantity will with a great fall. Hence the recipient of many branch sewers may have less fall than the branches themselves. A fall of a quarter of an inch in 10 feet has been considered the least fall that should be given to branch and summit-sewers; but this is far from being enough. Not only, in my opinion, have not less fall than half an inch in 10 feet. In some districts it is found impossible to get even so much fall as a quarter of an inch in 10 feet. In districts where proper fall cannot be obtained, it is necessary to resort to flushing to keep the sewers free of deposit and clear.

When a main stream receives a branch stream, the united body of water causes the height of the main stream to increase, consequently the surface rises somewhat higher than the surface of the branch stream. Thus, by introducing deposits of heavy substances about the junctions, which deposits draw back and impede the flow of the two streams. Now, in order to remedy this evil, the bottom of the main sewer, immediately below the junctions should be made some inches deeper than the branch. After a while, forming the bottoms, the surface of the main and branch streams will have a uniform inclination, and the acceleration of this fall will prevent regurgitation and deposit, and the united streams will flow onwards with increased speed.

In order to determine the depth below the junctions, it is necessary to calculate what height the body of water falling from the branches will increase the stream in the main. The capacity of the united stream is very much less than the sum of the capacities of the divided streams, and the velocity in the former is consequently greater. The ratio of increase of velocity follows the ratio of decrease of capacity. It follows, therefore, that a gradually accelerating velocity takes place immediately below the confluence of the sewers throughout the ramified system from their sources to their outfalls, and such I have found to be the case.

Egg-shaped sewers, varying in capacity according to the area, the number of houses to be drained, and the quantity of water to be discharged, from 9 inches wide by 1 ft. 3 in. high, to 1 ft. 6 in. wide by 9 ft. 6 in. high, would suffice for sewers on summit levels, and 2 ft. 6 in. high, would suffice for sewer on branch levels, to receive the drainage of from one to twelve or more ordinary-sized streets. Of course the secondary mains which would have to carry off the water from these branch or collateral sewers, as well as the principal main lines into which the secondary ones would discharge themselves, must be proportioned to a proper arrangement, fewer principal lines would be required.

Instead of discharging a large body of water uselessely, as to any power of sweep, I would, under the system of constant and concentrated supplies and smaller sewers, economise the water by using each separate sewer for its own division instead of one large one. For this reason I would prefer having more outlets, or at least more catch-water sewers, instead of discharging all the drainage by one large main sewer throughout, although at or near the outlet, I might probably be obliged to lead the whole of the water into one main line; I would introduce it into a main line until I had made it serviceable in sweeping as many sewers as possible. As the keeping of all sewers thoroughly washed out is necessarily dependent upon an abundant supply of water, the principle which I have thought best to follow for that purpose is to tie and connect all the sewers together upon a uniform system of levels so as to use the water running along sewers on high levels for washing out those on low levels. For this purpose, as will be seen by the plans, (Plate V., figs. 3, 5, and 4), I would connect the heads of adjoining sewers below with the superior quantity and then arrange the connections so that, as the currents of water running along the latter sewers arrive opposite the connections, they may divide and subdivide themselves by the ridges or groynes formed by the meeting of the inverts. By this means the water would traverse from one sewer to another, and so keep up a perpetual flow throughout the entire system. There can be no doubt that with much smaller sewers than those now in
use, and a more regular and abundant supply of water, the sewers would, by this system of arranging them and economising the currents, keep their pressure thoroughly uniform.

All head sewers, from want of backwater, have a tendency to choke up, and their ventilation is also very bad, consequently there should be as few of them as possible.

The general surface of the metropolis, on the north side of the Thames, is most admirably situated for being efficiently drained, as the ground contains a declivity of less than 1 in 500, and the declivity of the river from the hills some miles to the northward. The surface is divided into several natural areas, each of which has its main outfall sewer running through the lowest level of the valley, and discharging into the Thames, and into these main or valley sewers the whole of the sewers of the several districts discharges. This mode of drainage is a very objectionable one, and should never be resorted to if it be possible to avoid it. The declivities of all natural areas are generally in two directions, namely, transversely towards the valley line, and longitudinally towards the outfall. Now, if attention be paid to the levels, and the sewers on the sides of the declivities be judiciously arranged, a perpetual circulation of water may be kept flowing throughout the whole of them from the sewer on the summit at the head of the natural area to the outfall in the river; that is to say, a system of collateral or sub-sewers be thrown above the valley line to the ridge or water-shed line of the district; each collateral sewer skirting the entire area, and discharging itself into the river by a separate outlet, or in the manner previously referred to. It will be seen that, when the sewers running transversely are connected at their upper and lower ends on the same levels with those running longitudinally, a facility is afforded for the drainage to circulate from the highest sewer to the one immediately below, from this to the one next lowest, and so on throughout.

Mr. Phillips proposes fourteen graduated forms of branch secondary and principal main lines of sewers of the egg-shape for the drainage of a district in which the sewers and the water supply are under one and the same authority. Fig. 13, Plate V., shows the form of one of the sewers together with the radii of the several curves.

Much caution is required in the building of sewers in a clayey soil; otherwise, from the treacherous character of this ground—its liability to expand and slip—the sewers may be forced in. The thickness of a sewer should be proportioned to the nature of the ground and the pressure it has to bear; but its stability is very much dependent on the goodness of the workmanship. A half-brick sewer, under ordinary circumstances, will, if executed well and soundly, the joints made thick, and the sewer worked true to the curve, be quite strong enough, and would be found to answer every required purpose. The thicknesses depend upon the material and strata. The equilibration may be altogether destroyed by a want of uniformity in the working of the curve. The greatest pressure of the ground acts laterally from the sides downwards. Much of this pressure may be prevented by leaving in the trench from the surface downwards short lengths of earth, say of 10 to 50 feet, and about 80 to 90 feet apart, to be tunnelled through for the sewer to pass. These benchings, as they are termed, will keep the sides of the trench from sinking and slipping, and so from producing any disturbance.

The smoother the surface the less will be the friction, and consequently the greater will be the velocity and discharge; and the friction in a glazed pipe must be considerably less than in a brick drain, as commonly built. I am not prepared to say that the friction would be diminished so much as one-third; I think not so much. The smoothest glass pipes have lost off transverse motions, which greatly impede the flow. There is a difference in the flow of pure clean water and of sewage water; the latter moves more sluggishly. This is caused by its being thicker and more viscid, from having matter chemically combined and mechanically suspended in it.

As the velocity increases, so does the transverse section of the area occupied by the stream decrease. This is a natural law observable in all moving streams, for we see that in a moving mass of water the discharge is the same, whatever form and size the channel may assume, the velocity may be greater or less, the channel being narrow and deep, and less where it is wide, flat, and regular; but the exact ratio of decrease of area, from decrease of friction and increase of flow, can only be determined by actual experiment and by taking into account all the attendant circumstances which influence and govern the motion of the stream.

Have you at all considered the capacities of sewers necessary for draining different areas of ground?—Yes, I have given the subject much attention. The consideration of the sizes of sewers was confined solely to the carrying off the water supplied by the several water companies, then I apprehend that pipes somewhat larger in size could be supplied. As large as any provision has to be made for receiving and conveying away the waters of heavy rains. In London continuous heavy falls of rain are not of long duration, lasting seldom more than from one to four hours. About one-fifth of the quantity that falls is absorbed partly by the drains in the surface, and again re-enters into the atmosphere as vapour. There is also a small quantity that enters into the combustion of animal actions, and that is lost from the earth. But the resistance the flow experiences from the friction of the entire surface, being accelerated or detained in proportion as the surface is more or less inclined. To provide for the discharge of a fall of rain of two inches in depth has been considered by Mr. Hawkesley, C.E., that is, in order to provide such facilities as are necessary in town sewers generally. Now I believe that, practically, the sizes in his table, although they may appear theoretically correct, are (excepting for the smallest sizes) too large for sewers in London. It is extremely violent rains alone that produce a depth of two inches in four or five hours. So much of the surface of the earth is covered with buildings, that an inconsiderable fraction of the rain will pass off by the surface, and the receiving capacity of the subterranean drains, no such inconvenience is felt as would justify the construction of enormously large sewers, or the expenditure of large sums of money to provide against it. In August 1840, a most extraordinary fall of rain occurred in London. The storm lasted nearly two hours, aud from the best information I have obtained, the depth of rain amounted to about four inches. Much damage resulted therefrom, by the water in the principal main lines situate in the valleys flowing up the drains and branch sewers, and inundating the rooms and cellars below its level by the influence of its pressure. The inundation of lands and the submerging of property in the valleys could not happen if there were parallel catch-water lines of sewers on the sides of the declivities to convey the drainage into the river by separate outlets. The average fall of rain in London is about 22 inches in a year, or about 2 inches in depth per thousand hours. Now after observing and calculating the depths of different falls of rain in London, it appears to me that if the sewers were of sufficient capacity to receive and discharge, as fast as it falls, a quantity of water equal to the produce of a fall of rain of one inch in depth per hour, they would be found large enough, and that more particularly if they were built upon the intercepting or catch-water principle, and so as to communicate with each other, and all be filled with running water at the same time. The steps to be taken to proportion the capacities of sewers to receive and convey away the waters of heavy rains should, I think, be as follows:

To ascertain the number of superficial yards or acres to be drained by each sewer separately; progressing in a uniform gradation from the entire natural area to be drained by the largest outfall sewer, to the small tract of land to be drained by the least sewer on the surface. Taking the knowledge of the area in square feet at one inch in depth, we must provide for the discharge of a quantity of water (\(\text{cubic feet per hour} \times \text{per acre per second}\)) = 3630 cubic feet per hour, or one cubic foot nearly per acre per second. Then taking into account the loss...
from absorption, the detention from friction, and otherwise, that quantity might be reduced to four-fifths of a cubic foot, but as the carrying off the waste water of the entire of London must be provided for some time, one must consider as the datum upon which to calculate the capacities of sewers sufficient for conveying away that quantity of water per second multiplied by the number of acres to be drained. The quantity of raw water draining from an acre of ground in one second of time may be determined by first ascertaining the exact area of surface drained by some large main sewer; and, secondly, during the time of the storm, the quantity of water passing through the sewer in one second; then the number of cubic feet of water discharged, divided by the number of acres drained, will give the number of cubic feet of rain draining from the surface of each acre per second.

The area of surface that a sewer will drain, and the quantity of water that it will discharge in a given time, will be greater or less in proportion as the channel is inclined from a horizontal to a vertical position. The ordinary or common run of water in each sewer, due from house drainage alone, and irrespective of rain, should have sufficient velocity to prevent the usual matter discharged into the sewer from depositing. For this purpose it is necessary, as I have previously observed, that there should be in each sewer a constant velocity of current equal to 21 feet per second, or 13 mile per hour. The inclinations of all rivulets, brooks, streams, and rivers gradually and proportionally diminish as they progress from their sources to their outfalls. In proportion as the inclinations diminish so does the quantity of water increased. The inclinations throughout the velocity of the united stream at each confluence would increase in nearly the same ratio as its quantity, or equal to the sum of the previous velocities of the recipient and the feeder, and thus would the velocity ultimately become so very impetuous as to tear up and sweep away all the solids of its bed, and cause destruction along the course. If the force of the waters of the river Rhone were not absorbed by the operation of some constant retardation in its course, the stream would have shot into the Bay of Marseilles with the tremendous velocity of 400 feet in a second, or 164 miles every hour; and even if the stream had not been formed in a system of terrains as in the course, the stream would have rushed into the sea with a velocity of 80 feet per second, or 344 miles in an hour. The result, however, of the operations of nature is a compensation for the increased body of water by a diminution of the inclination of the bed, and so an economising of the force of the gradually accumulating current. The inclinations of the sewers of a natural district should be made to diminish from their heads to their outfalls in a corresponding ratio of progression, so that as the body of water is increased at each confluence, one and the same velocity and force of current may be maintained up through the whole of them.

In some situations I would build side entrances to a tubular system of sewers; but I believe their use, in some degree, might be superseded. Means of access to the sewers, so as to be able to get at and remove accidental obstructions, would readily suggest itself. A shaft, having a strong movable grating on it, could be built over the sewer, with ladder-irons built in the angles, to admit a man to go down and up, with a recess at the bottom on one side to give room. This shaft may be also made to serve as a ventilator.

**Gully Drains.**—I have constructed gully drains with terro-metallic and glazed stone-ware pipes of 6 inches and 9 inches diameter, as shown in figs. 7, 8, 9, 10, and 11. I was led to recommend the adoption of this mode of construction from the following causes:—

1. In passing through the sewers I found lying open a large number of the gully drains heaps of stones, and all kinds of streets refuse, which it was utterly impossible for the water to remove. The dams thus formed caused the sewage to accumulate behind them, and the noxious effluvia evolved from the decomposing mass, if the inclinations were the same gullies, and much of the annoyance felt by passengers. The best remedy for this evil appeared to me to be to prevent the stones and street refuse from passing into the sewers, build the drains so that they would not choke up, and to prevent the emission of foul air from the same. We have accomplished these things most perfectly, by reducing the width of the spaces to 1 inch between the bars of the gully grates, by constructing the drains of the form shown by the section from the gully to the sewer, and by fixing at the vent an air-tight cast-iron valve or flap, hinged at the back, as shown in figs. 11 and 12. A grating of trellis-work or cullender is placed under the top grating, at the bottom of the box, for the purpose of catching small stones and rubbish that may pass between the bars of the grate above, and so to prevent them from falling into and choking up the sewers.

I have not, as yet, made use of the lower grating, but probably I should be induced to do so in connection with a tubular system of sewers. It is important to keep large and heavy substances and refuse out of the drains and sewers. I may state that as a proof of the efficacy of the foregoing mode of constructing the gully-drains with the improved grate, the labour and expense of cleaning, not only of the gully-drains, but of the sewers as well, is now, comparatively, nothing compared to what they used to be, and I confidently entertain an opinion that the labour and expense will be still less and less.

Mr. Phillips has just produced his report on the improvement of the drainage of Westminster, and which has been printed. This document of great utility, and we are pleased to see that most of our suggestions on this subject have been adopted, particularly with reference to turning part of the drainage into the Regent Street Commissioners' Sewers. Mr. Phillips proposes to divert the high level streams to a station at the end of Duncannon-street in the Strand, to bring the Westminster drainage to the same station, and to apply the natural power thus to be obtained to work two water-wheels of the most approved construction, with revolving buckets and plunger-pumps attached, to lift the drainage from the well or receiving reservoir below, and discharge the same into channels communicating with the upper stream on a level with high water, beyond the tail of the wheels. The sewage will then be carried under the side-bed of the river into low-water stream.

Below we give a summary of Mr. Phillips' estimates, which make a total of £23,747 1s. 6d.

</table>
ON THE MOTION OF WATER.—By Guido Grandi.

Translated by E. Casy, Esq., in his Evidence before the Metropolitan Sanitary Commissioners.

Our author has taken considerable pains to construct a parabolic table, given in his work (Book 2, cap. 5); by a reference to which much labour will be saved by those who desire to make similar investigations; he thus describes it:

"This table is divided into three columns. The first containing a natural series of numbers from 1 to 1800, representing equal parts, as inches or other measures. These numbers are the heights from which the water falls. The second column contains the roots of the opposite numbers in the first, and expresses the velocity of the water, corresponding to the height in the first column, in integers and decimals: when the root is somewhat greater than the truth, the sign + is prefixed, and when less —. The third column contains the product of the first and second, and must be read off after the solution of the question, according as the sign + or — is prefixed to its second factor.

It is clear that if the numbers of the first column express the height of a parabola, the numbers in the second will be its ordinates when its latus rectum, or parameter, is 1; or at least, they will be proportional to the ordinates in subduplicate ratio of unity to the latus rectum of a given parabola, and the numbers in the third column will be the rectangles circumscribing the parabola which has unity for its latus rectum, and will be moreover proportional to the area of the parabola, which is always # of the circumscribing rectangle.

If the parabola has 1/4 for its latus rectum in terms of the first column, all its ordinates are to the ordinates of the parabola of the same height, having 1 for its latus rectum, in subduplicate ratio of 1/4 to 1, that is, as 1/4 to 1, or as the circumscribed rectangle to the parabola. It is clear that the parabola whose latus rectum is 1/2 will be equal to the rectangle which circumscribes the parabola whose latus rectum is unity; but such a rectangle is equal to the product of the base by the height, which is the number opposite to the third column; therefore the numbers in the third column express the area of a parabola whose latus rectum is 1/2, and is proportional thereto when the latus rectum is any other quantity.

Moreover, since the first column expresses the height of water standing in a vessel, or the distance of each particle of running water above its base, and the numbers in the second column represent the velocity caused by such a height, the numbers in the third column express the quantity of water which will issue through such a width in a given time, through a hole or section whose height would be equal to the whole distance between the water and base of the vessel in the first column, and the base of such a section as the number in the first column.

The difference of numbers of the third column will be the quantity of water which escapes in an equal time through a hole or section of equal breadth, and of a height equal to the difference of the corresponding numbers of the first column; and in the aggregate of such numbers, or the nearest truth, in the third column will correspond to that number in the first, which indicates a height capable of comprising the channels united, as will be better understood by the following examples:

Ex. Given two streams, the breadth of the first of which is L = 750 feet. The velocity of the surface B E corresponding to the fall A B of 1 foot (which, according to Guglielmini’s table is equivalent to the third column of our table opposite 31 feet, will be found 7175.88, from which subtracting the parabola A E B, which is found in our third column to be 41.52, the parabolic trapezium B E will be 7134.36, and this will be the scale of the velocity of the section B C, which multiplied by the breadth L gives a quantity of water = 542211360.

The second stream having a width M = 136 feet, its superficial velocity will be G K, depending on the height F E G, 8 inches (which gives, by Guglielmini’s table, a velocity of 1 foot in a minute, rather less than 3 feet in a second, and 2 miles 56 perches in an hour). The height of its surface G H is 11 feet, and consequently H I 11 feet 8 inches, corresponding in our third column to the value of 1656-50 for the parabola F K H, from which subtracting the opposite numbers in the first column, 8 inches as 22.64, there remains the trapezium G K H I 1653.86, which is the scale of the velocity of the second stream, which, multiplied by the width M, gives the quantity of water passing in a given time through this river = 2427064.94; whence the two quantities carried by both rivers, which be 542211364, Supposing they fly together, without increase of velocity, B E = O R; and let the height O P, at which the united water runs, be the unknown quantity, then since O N = B A through R, and with the axis N P, describe the parabola N R O Q P, the truncazed parabola O Q P, which is the whole quantity of water from the river which is multiplied by L = the sum of the two quantities = 5649178.44, which divided by L gives a quotient 7438.13 = the parabolic trapezium O R Q P, and adding the parabola N R O = 41.92, we shall have the parabola N R Q P = 7479.52, which is the nearest to which in our third column, 7464.58, corresponding to a height of 31 feet 10 inches. This number sought being rather more than the tabular value, it will be found by proportional parts that ¾ must be added. Therefore N P = 31 feet 10 ⅛ inches and O P = 30 feet 10 ⅛ inches; therefore the union of the streams raises the height O C 10 ⅛ inches.

But if, at the confl uence of the rivers, the velocity B E augments, becoming O R, so that the height N O depending on it exceeds A B by 1 inch, the parabola N O R, corresponding to a height of 15 inches, will equal 46.93, which, added to the velocity of the river O Q P, which previously to be united with the other had the total parabola N R Q P = 7480.06, the nearest number to which, 7464.28, corresponding to 31 feet 10 inches; but since this is rather too little, we must add ¼ for the proportional part of the difference, whence N P = 31 feet 10 ¼ inches, and O P = 30 feet 10 ¾ inches; then, when N P be 54167.44, corresponding to a height of 31 feet 10 inches. This number sought being rather more than the tabular value, it will be found by proportional parts that ¾ must be added. Therefore N P = 31 feet 10 ⅛ inches and O P = 30 feet 10 ⅛ inches, making the total increase in this case 94.94 inches.

But if we suppose with Guglielmini, and which is not improbable according to actual observation, that the scale of a velocity in a given water is increased by the increase of the wave, the velocity, as in the case of vessels depending only on pressure, whence the surface alone acquires velocity when it is communicated by the lower water which transports it, the calculation will then be more quickly effected. Wherefore A C = 30 feet, the height of the first river; and F H = 15 feet, the height of the second. The parabola A E D C = 6829.20, in our table, which, multiplied by the width L 760 feet, gives for the quantity of water 5190192.00, and the parabola F I H = 1516.68, which multiplied by the width M = 135 feet = 210819.20, whence the sum = 5401010.20, which divided by the width L, when the velocity of the surface is not increased, the parabola N Q P = 7108.46, corresponding to a height of 30 feet 10 inches, corresponding in the table to the number 7118.80, which is rather more than the preceding; wherefore the rise will be 10 inches.

Then if the velocity of the two rivers increases at their influence, the height will be reduced in the reciprocal ratio of that velocity; so that if the velocity be increased ⅔, the height will be reduced to 304 feet, that is, the increase will only be about 6 inches; if the velocity increases ⅛, the height will be 29 feet 8 inches; so that the height in place of increasing, will actually be reduced about 4 inches by the union of the two streams; likewise the height 30 feet, will remain precisely the same when the velocity is increased by ⅔ since 37 : 36 : : 30 feet 10 inches : 30 feet 10 ⅛ inches.

Example 2.—The influence C B D R in a given point of its bed has the height O H, having a free influx into the recipient R M, when it is low, and its superficial velocity in H is what would correspond to a height A H of 4 feet. Then, raising the level N S of the recipient, regurgitation follows through the level of the influence. It is required to find the increase in the height O H = 7 feet? Suppose it to increase as far as Q, draw the parabola A K R, with its ordinates H Y, Q R; let O S, cut off by the prolongation of the level of the recipient, = 3 feet; then the whole height A O will

...
be 11 feet, and by the table the parabola A O R = 151688; the other, A H Y, 4 feet high, will be 339"64; whence the trapezium H Y R O will be the scale of the velocity, and the quantity of water passing in a given time through the section H O = 1184'04. If the parabola S P O be 3 feet high, its value in the table = 216'00; then the parabolic trapezium Q K Y H, being equal to the aforesaid parabola S P O, will be 216'00, which substituted from the total value of A H Y, there remains the parabola A Q K = 116'64.

This number not being precisely to be found in our table, find the next highest, = 117'60, which corresponds to a height of 2 feet; whence we arrive at the conclusion that the regurgitation at the point O has raised the water 2 feet more than the first, supposed to be 4 feet.

To facilitate the practical application of the principles contained in Grandi's proposition, the following rules will be found convenient:

The height and width of the section of both the influent and the recipient being given in each case and their velocity being equal:

1. When the velocity of the united streams is the same with that of each separately, to find the increased height of the united section.

Find in the table the parabolic value in the third column corresponding to the given height of the recipient in the first. Multiply this value by the given width. Perform the same operation for the influent, and then have obtained the quantity of water brought down by each. Add these two quantities together. Divide their sum by the width of their united section, which may be either that of the influent, or of the recipient, or greater or less than either. Find the quotient obtained by such division in the third column of the table, opposite to it in the first will be found the height of the united sections.

2. When the velocity of the united streams is increased, to find the height of their united section.

Divide the height found by the preceding rule by the number of times by which the velocity is increased, the quotient is the height of the united sections.

3. When the velocity of the united streams is diminished, to find the height of their united section.

Multiply the height found by our first rule by the number of times by which the velocity is diminished, the product gives the required height.

4. When the height of the united streams remains the same, to find their increased velocity.

Divide the height as found by the first rule by the original height, the quotient will give the increased velocity.

5. When the height of the united streams is increased, to find their velocity.

Divide the height found by the first rule by the increased height, the quotient is the diminished velocity.

6. When the height of the united streams is diminished, to find their increased velocity.

Divide the height found by the first rule by the diminished height, the quotient will be the increased velocity.

To exemplify these rules a small table is subjoined, constructed from Grandi's data, that is, supposing a stream 760 feet wide and 30 feet high to receive successively 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, similar influents; the first column contains the number of influents; the second, the height caused by the addition of these successive streams as calculated by our first rule, that is, supposing the velocity to remain the same; the third column shows the increased height found by Genneté, the original height, 30 feet, being here increased by the addition of 136, 90, &c., &c. The fifth column shows the increased velocity requisite to produce the height shown in the seventh column; thus supposing the stream 760 feet wide and 30 feet high to receive two other similar streams, the increased height, according to Genneté, will be 30 feet 7'6 inches, and to produce such a height the required velocity will be 1'97233. Either of these numbers is deducible from the other by one of the preceding rules; thus, supposing the height 30 feet 7'6 inches to be given, and the velocity to be required, by Rule 5, dividing 62 feet 4'6 inches by 30 feet 7'6 inches we obtain a quotient of 1'97233. Supposing, on the other hand, the velocity 1'97233 to be given, we obtain the height by Rule 4, since 62 feet 4'6 inches ÷ 1'97233 = 30 feet 7'6 inches. The fourth column shows the increased velocity required to maintain a constant height of 30 feet, and is found by Rule 4.

</tbody>
</table>

It is found that the several increments of either height or velocity are as the ordinates of a parabola whose axis is divided into the same number of parts as there are required velocities. Hence an elegant method of finding the intermediate heights or velocities when the two extremes are given. Suppose, for example, we require to find the several heights indicated in our first column. Find the height required for twelve streams by our Rule 1. Draw A B, and from a scale of equal parts set off 157 feet 3 inches from A to C, at A erect a perpendicular A D to A B, and set off twelve equal parts thereon, and draw through the points 1, 2, 3, &c., lines parallel to A B, on the parallel I E, set off the first height 30 feet from the same scale as A C. Then by Rule 1 find the height of any one of the intermediate streams, as A, and set it off from 2 to F, then through the points E, F, C, describe a parabola, the portion cut off on each ordinate by the curve will be the several numbers given in the table as measured by the scale from which I E, 6 F, and A C were taken; the abscissae 1, 2, 3, &c., may be set off by any scale, providing they are equidistant, and according as they are wider or narrower, will the parabola increase or diminish its curvature. It is evident that in the case of 100 additional streams the labour of calculation will be materially shortened, as no more than three values need ever be found arithmetically.

In like manner either of the other values shown in our table may be represented parabolically. Column 5, for example, by setting off 1'34023 on I E, 4'33792 on A B, 3'94897 on 6 F, and describing a parabola through those points.
BLACKWALL RAILWAY MACHINERY.

Description of the Machinery erected by Messrs. Maudslay, Sons, and Field, at the Minories Station, for working the London and Blackwall Railway. By Andrew John Robertson. (Read at the Institution of Civil Engineers).

The London and Blackwall Railway is about 34 miles in length, and is worked by six engines of the estimated force of 440 H. P. and 280 H. P., at the London and Blackwall termini respectively: the carriages being attached by straps to a rope, which is wound off and on to large drums situated at each extremity of the line. The greater power is required at the London station, in consequence of there being a total rise of 100 feet, with the direction, of between 60 and 70 feet (average 68 feet); the steepest inclination being 1 in 100. There are seven intermediate stations on this line; the Poplar, West India Docks, Limehouse, Stepney, and Shadwell stations, communicate with the Fenchurch-street terminus; whilst those of the Minories, Cannon-street, Shawcliff, and Stepney, communicate with the Blackwall terminus. This arrangement is effected by appropriating a separate carriage from the termini for each intermediate station, communicating with the same; these are detachable whilst the trains are moving, and by means of breaks they are stopped at their respective destinations; as soon, however, as the terminal train arrives at either end of the line, and the rope ceases its motion, these intermediate carriages are attached to the rope, whilst it is in a state of rest; so that when the engines are again started, the carriages are also simultaneously in motion. In this way, the traffic is carried on in the same order and at intervals corresponding with the position of the places from which they started; as they arrive they are released from the rope, though in motion, by the sudden withdrawal of the grip iron, and their momentum carries them forward to their proper place in the service. It will be seen that the intermediate traffic is by this means provided for, without causing any detention to the through trade.

The peculiar mode of working the line, and the circumstance of so many carriages being attached to the rope at different places, renders it absolutely necessary to employ some system of signals between the termini and the intermediate stations. These objects being deemed attainable by means of the electric telegraph, that system was adopted, although it was of greater extent than any which had been previously tried, and it was executed by Mr. Cooke, one of the patentees. The telegraphic wires are inclosed, for security, within welded iron pipes, with screwed joints like gas pipes; there is a duplicate set of such wires and pipes, in case of one set being accidentally fractured. One pipe runs along each side of the railway throughout its length.

The London engine house, to which the London end of the drum is situated, is located at the Minories station. The carriages in coming towards London are disconnected from the rope, a little before they arrive at the Minories, and they perform the rest of the journey to the terminus in Fenchurch-street by their momentum. The upward inclination is sufficient, in this place, to counterbalance the fall of the rope.

When the down-train leaves the terminus in Fenchurch-street, it descends the incline to the Minories by its gravity, where it is stopped by the breaks, to allow of the passengers being received at that station, and to permit the attachment of the rope; there the train remains for a short time, until signals have been received by the electric telegraph, from each of the intermediate stations, that the carriages are ready for starting, and are properly attached to the rope, in the manner already described. It being thus known at the Minories that all is ready, the signal for starting is sent from thence to Blackwall; the engines are then put in motion, and begin to draw the rope with all the carriages towards Blackwall.

At the same time that the down-train leaves the Minories, the up-train leaves Blackwall, the arrangements being similar to those above described. The train runs by gravity from the Blackwall station to beyond the engine-house, where it is stopped by the breaks, in order to attach it to the rope, and as soon as signals have been received at Blackwall, from each of the intermediate stations, that all is ready, the signal for starting is sent from Blackwall, and the train is put in motion, and begins to draw the rope and all the carriages towards London. The machinery at the Blackwall end is situated a little way along the line from the terminal station; the distance from thence to the place where the carriages going to Blackwall are disconnected from the rope, being somewhat farther from the station than the engine house, and the carriages run that distance by momentum, in the same manner as at the London end; the rise towards the Blackwall station being the same as 1 in 100. The down-train is worked from half-past eight o'clock in the morning until nine at night; and in the summer, from eight o'clock in the morning until ten at night. A train leaves each end every quarter of an hour (giving in winter 31 trains, and during the summer 37 trains per day). The engines are occupied in passing between the termini is thirteen minutes; but the engines are at work only from eight to nine minutes. The engine-house at the Minories is situated beneath the railway. It is 48 feet long by 72 feet wide, and the extreme length, into the recess in front of the drums is 69 feet. The rails are carried over the machinery by runners, which are supported at two intermediate points by cast-iron pillars. The flooring over the engine-house is carried in like manner upon girders.

Beneath each line of railway there is a large drum for the rope, and on the axes of each drum is a mortice spur-wheel, which is driven by another iron spur-wheel of larger proportions. This is a prolongation of the axis of the cranks of the steam engines; the prolongation forming a line of shafting which extends all across the engine-room, with a pair of engines at each of its extremities. Only one pair of engines is worked at a time, the other pair being disengaged from the crank-axle of the cranks, one pair is worked for about six weeks, and then the other pair for a similar period; the object being to secure the traffic from interruption, by having a duplicate pair of engines always ready to be connected at all emergencies and in case of any accident happening to the engines, as well as to enable the engines being taken off for cleaning and repairing of that pair of engines which is not at the time in use. When one pair of engines is connected to the axis of the two larger spur-wheels, the other part must be disconnected from it. This is done by removing the pin of the crank on the extreme side of said axis, and the said pin, by which pin is connected with the pin of the engine-crank, on the other part, and联动 the pin, the attaching rod is jointed. The rope on one line must be wound round up the drum, whilst that on the other line is allowed to unwind from off its drum, so that the two drums will work in contrary directions. The rope winding on and winding off the drums is alternately backwards and forwards on the same line of rails, instead of one line of rails being always travelled over in one direction and the other line in the contrary direction, as is the case on other railways. For instance, if the first train in the morning goes down from London to Blackwall along the north line, the second train down in the same direction will go along the south line, and the third train down along the north line, and so on. One end of each rope is wound round one of the drums at the Minories, and the other end of the same rope around the drum at Blackwall; and whenever the drums are turned round by its engines for winding up that end of the rope, the drum at the other end of the same rope must be disconnected, and let free to turn round as the rope is pulled off it. This requires some readiness in disengaging either of the drums, and this is done by withdrawing the pair of spur-wheels from each other until their teeth become disengaged. The plunger-blocks, in which the two ends of the axes of each of the drums revolve, are mounted on rollers, and are capable of being moved horizontally by screws, until the spur-wheels are out of gear. The two screws, nuts, and plunger-blocks of the same drum, are moved simultaneously by gearing, worked by a handle on the platform in the recess in front of the drums; so that a man by turning that handle, either connects or disconnects the gearing, as may be required.

The main axis upon which the two large spur-wheels are mounted, may be considered as a single axis, but is, in fact, two lengths of shaft, connected together by cranks and drag-links at the mid-length of the prolonged axes, which two lengths can be disconnected at pleasure, by removing the ordinary links and crank-pins. Hence there are two sets of machinery exactly similar, and capable of being connected and disconnected in such manner, as to admit of either of the two drums being worked by either of the two pairs of engines, whilst the other drum is wholly disconnected; each line can thus be worked by either pair of engines independently of the other line of engines. The engines always revolve in the same direction, causing the drums to wind up the ropes around them; but when the drums turn round in a contrary direction for unwinding the ropes, they are disconnected from the engines. A wheel is attached to each train for the purpose of being acted upon by a break, not only for stopping the motion of the drum, after the arrival and stopping of the down-train at

---

*The nominal power of these engines is, 124 horse-power for each pair at the Minories; and 160 horse-power for each pair at Blackwall. There are duplicate engines at each station, making 440 horse-power at the Minories, and 280 horse-power at Blackwall.
the Blackwall end of the line, but also for maintaining a suitable degree of tension on the part of the rope behind the train, in the manner of which it is in the constant object of six or seven minutes to make sure that the rope is not carried away from the drum faster than the train proceeds, and to secure the rope against the risk of breakage, to which it would be liable, if it were allowed to become slack and then to be suddenly tightened, by the acceleration which takes place at the moment that it has ascended the descent of a steeper gradient than that on which it was previously travelling.

The engines being only worked for eight or nine minutes out of every quarter of an hour, the vacuum in the condensers might during the remaining six or seven minutes become insufficient for leakage, or from air contained in the injection water; in which case the setting of the engines would be difficult, except by previously blowing steam through the condenser, to displace the air,—for the greatest power is required at starting, when the machinery, the drums, and the train, have all to be set in motion from a state of rest, and there must be a good vacuum in the condenser to enable the engines to start promptly. For this object an engine of 26 horse-power is provided, and constantly works two auxiliary air-pumps, which maintain the vacuum in the condensers of the large engines, independently of the action of their own air-pumps.

In the arches upon which the railway is carried to pass over the engine-house, eight water-tanks are placed, all connected together by pipes. The overflow of water from the hot cisterns of the engine-house passes through these pipes, and is conveyed to the most distant of the eight tanks. From that tank the water passes into the next, and then to the next, and so on to the last of the eight tanks, in which it is mixed with fresh cold water, and the mingled water is then conveyed into the engine-room, for supplying the steam-jet for each of the engines. The surface of the water in the eight tanks is exposed to the atmosphere, and the hot water thus becomes cooled in passing through them. At first there were only three tanks, in which, as they exposed a large surface to the air, it was expected the cooling of the water would proceed with sufficient rapidity to render the jet of injection water in which it arrived at the third tank, and being there mixed with fresh cold water; but, as it was found that there was not a sufficient cooling effect, five more tanks were added, and the eight tanks now in use are scarcely sufficient for cooling the water to the extent required. The supply of cold water, for mixing with the water in the tanks, is pumped by the 12 horse-power engine from a well in the adjoining part of the building, and, in addition to this supply, a small pipe is laid on from the main of the New River Company. The temperature of the injection water in summer is about 80°, and often higher, and the vacuum that is produced by a jet of 24 feet cord, in such a well, there is no difficulty as to the temperature of the water, and the mercury stands at 27 inches to 28 inches. Each of the tanks is 264 feet square and 3 feet deep, so that the capacity is 3,600 cubic feet, and the surface of water exposed is 600 square feet in each tank.

The steam-pipe from the boilers passes through the wall, and is carried inside the engine-room to the right and left to each pair of engines, with a valve-box, from which two branches proceed to supply the steam. The valve in the box is opened and shut by a screw, worked from below by a handle, by which the engineman regulates the speed of the engines.

The governor is placed beyond the outer frame of the pair of engines, and the number of its revolutions is to the number of strokes made by the engines as 3 to 2. It is worked from the crank of the engine by a pair of wheels on a small axis passing through the outer frame. The governor acts upon a throttle-valve placed in the steam-pipe, immediately beyond the shut-off valve. The resistance the engines have to overcome varies, is a subject of which the governor was found not to be capable by itself of regulating the speed, and therefore it was assisted by the man closing the shut-off valve by its screw handle; but latterly the governor has been disconnected, and is not now used.

To avoid snatching the rope, by which it might be broken, great care is taken to stow the engines as gradually as possible, in order that all the slack of the rope may be wound up, and then the train be started slowly, and gradually accelerated to the full speed. The valve is therefore only partially opened at first, and is afterwards opened fully by degrees; as the engines acquire speed, the valve is closed again gradually, to restrain the speed, as the carriages arrive one after another, and the resistance diminishes.

The Boilers.—The boiler-house is beneath the railway, the five boilers being placed under the arches on which the continuation of the railway is carried beyond the engines. Two of them are double marine-boilers, with the ordinary internal furnaces and rectangular flues; the other three boilers are constructed on the Cornish system, being circular, with two internal tubes through their entire length, and the furnaces in the front ends. The two marine-boilers, which are equal in power to the three Cornwall steam engines.

The two marine-boilers, or the three Cornwall boilers, are worked together as a set, the two sets being used alternately in the same manner as the engines, but for about three months at a time. The chimney is situated between the two sets of boilers. The flues are separated boiler, enters into a main flue, which extends along the back of each set to the base of the chimney; each is provided with a separate damper, and there is another damper at the end of each main flue, where it joins to the base of the chimney.

The top of the steam-chest of each boiler is a shut-off valve box, joined by a branch to the main steam-pipe, which leads to the engines. By these valves, any boiler may be shut off from the rest, in case it is required to be cleaned whilst the others are at work. At the mid-length of the steam-pipe are two safety-valve-boxes, each having an aperture of 12 inches diameter; they communicate with each other, and from one of them a discharge-pipe proceeds into the chimney; one of these safety-valves is out of the control of the men, but the other may be lifted by means of a lever worked from below, in order to discharge the steam at the end of the day's work.

The feeding of the boilers is effected from a tank situated above the arches, at the side of the chimney, at such a height as to give the column of water entering the boiler a greater pressure than that of the steam. This feeding-tank is 10 feet in diameter, by 6 feet 6 inches high, and is capable of holding 471 cubic feet of water. The water is raised into this tank by the pumps of the engines, and feed-pipes proceed from the tank to the feed-cocks in the pipes, at the front of the several boilers. During the time the engines are at work, no water is admitted to the boilers, but as soon as they stop, the feed-cocks are opened, and the water is allowed to flow in until the proper level is restored. At the same time a fresh supply of coals is thrown on the fires, to raise the steam for starting. This is so managed as to waste very little steam by blowing away at the safety-valve.

The chimney is 6 feet 6 inches in diameter at the base, and 4 ft. 3 in. diameter at the top, and 164 feet high from the foundation. The draught is exceedingly good. The spaces opposite to the row of furnaces of the five boilers are stores for coal. Beneath the centre of the passage, in front of the row of furnaces, is the drain for carrying off the waste water.

The steam-engines of 112 horse-power (nominal power) are on the marine construction, with side levers, the same as Messrs. Maudslay, Sons, and Field made for steam-vessels a few years ago. That construction was adopted, as it was requisite that the centre of gravity should be low. Each of the cylinders is 56 inches; the length of stroke is 5 feet; and the average number of strokes 94 per minute. The motion of the piston is therefore 220 feet per minute. The plunger feed-pump is 64 inches diameter, and 2 ft. 6 in. stroke; only one pump is worked at a time. The cranks are all of cast-iron, with axes of wrought-iron, 12 inches diameter in the bearings.

The large spur-wheel on the main axis is 17 feet in diameter at the pitch line, with 120 teeth; the pitch of the teeth is 64 inches, and their breadth is 23 inches. The centre boss of this wheel consists of 108 iron bolts, bored to other ends, including, between them, and closing over the roots of the arms, which are eight in number, cast separately, and bolted to one another, and to the boss. The rim is in eight segments, each having 15 teeth, and the junctions of the segments are made at the ends of the arms. The weight of the wheel is 164 tons; that of the rim by itself being 8 tons 13 cwt. The drum is 92 feet in diameter outside, and 144 feet in diameter at the bottom of the V-shaped groove, wherein the rope is coiled. The width of this part, at the bottom, is 1 ft. 6 in., and at the top 3 ft. 6 in.; when all the rope is wound on it, the diameter of the outside coil of the rope is 30 feet.

The break-wheel at the side of the drum is 14 feet in diameter, and 1 foot broad.

The mortice spur-wheel, on the axis of the drum, and at the same side as the break, is 11 ft. 9 inches in circumference, and at the pitch line: it has 78 cogs, which are also 23 inches broad.

Although the drum, the break-wheel, and the mortice-wheel, have hitherto been mentioned as separate, they are in fact all framed together so as to form one combination. The total weight
is 30 tons. The axis of the drum is of wrought-iron, 18 inches diameter in the bearings. The cogs of the mortice-wheel are made of hornbeam.

The break is formed of two straps of wrought-iron, side by side, each 6 inches wide, to which are riveted plates of copper in lengths of 12 feet, 12 feet in diameter, which extends over the lower half of the circumference of the break-wheel. One of the extremities of the break is suspended by rods from the girder above, and the other end is connected to the hoop around an eccentric-wheel, the axis of which is mounted in a frame fixed to the girder. On the axis of this eccentric-wheel is a spur-wheel, into which a pinion works, and on the axis of the pinion is a ratchet-wheel, to be worked by a lever-handle and click, by a man standing on the platform over the engine-room. The handle passes up through the platform. The length of the lever-handle is 6 feet; the diameter of the pinion is 114 inches, and that of the wheel is 16 inches; the eccentricity of the eccentric-wheel is 52 inches. Hence the force of the man's arm applied at the upper end of the lever-handle is multiplied about 36 times

\[ \frac{72 \times 11}{2\pi \times 11 + 3} = 36.9 \]  

when the leverage is the least—namely, when the eccentric-wheel has made a quarter of a revolution; but for obtaining a greater power on the break, a piston is fitted to the end of the piston in the air-cylinder, which is fixed under the girder; one end of the cylinder is open to the atmosphere, and the other is closed, but communicates by a pipe with the condenser of the steam-engine below. In this pipe is a cock, which can be opened by the breakman when necessary; a chain connected to the rod of the piston in the air-cylinder carries round the spur-wheel and fastened to it. If the breakman opens the cock to establish a communication with the condenser, the air is exhausted from the air-cylinder, and the pressure of the atmosphere on the area of the piston acts by the chain on the circumference of the wheel, to this end the circumference of the wheel is 37 inches of mercury, this pressure is 1,060 lb, equivalent to about 100 lb. applied to the upper end of the lever-handle.

Each of the moving plunger-blocks, in which the drum-shaft revolves, is mounted on six rollers; three on each side. Beneath the plummer-block is attached a handle, between the rollers, is a long nut in which a screw 3 inches in diameter works; the pitch of this screw is such as to move the nut and the plummer-block 3 inches by seven revolutions. The axis of the screw is prolonged by a shaft to reach the platform, and this prolongation has on its end a bevel-wheel 2 feet in diameter, into which works a bevel-pinion 6 inches in diameter; the cross-axis of this pinion extends across the breadth of the drum, parallel to its axis, and carries another such bevel-pinion of 6 inches diameter, which acts on another small bevel-wheel, the prolongation of the axis of another screw beneath the plummer-block, for the other end of the axis of the drum. By this connection both screws are turned round simultaneously and act on both plummer-blocks alike. On the cross axes of the two bevel pinions is a coupled 2 feet in diameter, into which the pinion 16 inches diameter, on the axis of which is a winch-handle, so that to produce one revolution of the screw, the winch-handle must make six revolutions. The thread of the screw making seven turns in 3 inches, and the winch being 10 inches long, the pressure applied to it is multiplied 660 times. The winch is worked by one man, and the time occupied in disconnecting one drum and connecting the other is, little more than a minute.

The rollers on which each plummer-block moves, are made of wrought-iron, case hardened, 2½ inches in diameter, and 24 inches broad. They are hardened with the waste, so as to be part of the frame and of the plummer-block; but after having been at work two or three years, the pressure had caused so much indentation into the two faces of cast-iron, as to render it difficult for a man to connect and disconnect the large spur-wheels. To remedy this, it was decided to let into the frame and another into the underside of the plummer-block for the rollers to act against, and no inconvenience has been since found. The weight upon each of the rollers is about 5 tons. The weight of the drum, break-wheel, and mortice-wheel being 30 tons, and of the axes 3 tons 7 cwt., the complete weight on the drum was unwound 1 ton, and the additional weight of rope when the whole is wound on, 23½ tons, makes a total weight of 57½, or 58 tons, to be sustained on the twelve rollers beneath the two plummer-blocks; and, therefore, suppose each set to bear the same weight, each roller has, therefore, nearly 5 tons; each end of the axis of the drum being 12 inches diameter in its bearing, the break must sustain 59 or 60 tons.

Power.—When all the train is in motion, the engines making 22 strokes per minute, the pressure of the steam on entering the cylinder being 24 lb. above that of the atmosphere, and the mean pressure 9 93 lb. per square inch, the power for the engines, rope, and train, is 323 7/4 horse-power.

When the rope, without any carriages attached to it, is drawn by the engines making 24 revolutions per minute, the pressure of the steam being 6 lb. above the atmosphere, and the mean pressure 7 1/2 lb. per square inch, the power expended on the rope and carriage is 220 7/10 horse-power.

When the drum is disconnected from the engines, and they are allowed to make 28 strokes, the pressure being 13 3/5 above the atmosphere, and the mean pressure 8 lb. per square inch, the power expended on the friction of the engines unloaded, is 26 9/10 horse-power.

Since the power expended on the engines, rope, and train, is 323 7/4 horse-power, and on the engines and rope, 220 7/10 horse-power, the difference, namely, 72 9/10 or 73 horse-power is due to the drum alone.

The number of revolutions made by the engine-shaft per minute being 22, the number made by the drum in the same time is 33 8/10. The circumference of the drum when the rope is off, is 52 feet; when all the rope is wound on, it is 83 feet, the velocity of the rope will therefore vary from 104 feet per minute, to 1,129 feet, that is, from 20 miles to 24 miles per hour.

The Rope.—When the railway was first opened, the rope employed was of hemp, 5 inches in circumference, or 1/2 inches in diameter. After it had been in use for a very short time it broke, and continued to do so frequently; in consequence of which, a wire rope was adopted. This rope, of 1 inch in circumference, or 1 inch in diameter, is formed of six strands, each composed of six wires, or thirty-six wires in the rope. It is covered over with small hemp rope or tarred yarn. The breakages of this rope are much less frequent than with the hemp rope, but still they do occur occasionally. In order to make the rope wind evenly on the drum, it is guided by two levers mounted on one centre pin, and crossing one another in the form of a pair of scissors, the levers having rollers on their inner side. These levers are worked by a man, standing on the platform below, and he guides the rope by pressing them one directly against the other side as his eye directs, so as to wind the rope evenly around the drum. The weight of the hemp rope was 8 lb. per yard, and the weight of the wire rope is 6 lb. per yard; therefore, the weight of the rope lying on the railway was, in the former case, 194 tons, and in the latter, 164 tons. Swivels are introduced at intervals in the length of the rope, to allow it to twist and untwist itself in working. The weight of the rope is sustained by bearing-sheaves, disposed at intervals along the line, in the middle of the space between the rails, some of them being laid at angles to suit the curves of the road.

The auxiliary engine.—The cylinder of the 12 horse-power engine is 20 inches in diameter, the piston makes a stroke of 3 feet, and 34 strokes per minute. The two air-pumps which are worked by it are 13 inches in diameter, with a stroke of 10½ inches, and are placed one on each side of the centre of the main levers.

The air-pumps of the large engine are 31 inches in diameter, with a length of stroke of 2½ ft. 6 in.; so that the capacity of the stroke of each pump is 13½ cubic feet, or 26½ cubic feet for the pumps of a pair of engines; therefore, the capacity per minute, is 13½ × 22 strokes = 303 cubic feet. In like manner, the capacity of the small pumps, per minute, is 35 cubic feet, or nearly ½ of that of the large pumps in the same time.

The well from which cold water is obtained is 10 feet diameter inside, and is steamed partly with brick and partly with iron. In this well are two sets of three-barrelled pumps, but only one set is worked at a time. The barrels are each 7 inches in diameter, the stroke is 18 inches, and they make twenty strokes per minute; so that the quantity of water raised by one set, per minute, is 150 gallons. These pumps are worked constantly throughout the day.

The marine-boilers are 10 ft. 3 in. wide, 10 ft. 8 in. high, and 24 feet long; the steam-chests are 5 feet in diameter and 4 ft. 10½ in. high; each boiler is contained in a chimney 5½ ft. high.

The marine boilers are each 7 ft. 6 in. in diameter, by 24 feet long; the two circular flues, through their whole length are 2 ft. 6 in. diameter. The steam chests are 3 ft. 9 in. in diameter, and 4 feet, 5 feet, and 6 feet high respectively. The average consumption of fuel, is, per day, for the two marine-boilers together, 70 tons, and for the three circular-boilers together, 8 tons. In these quantities is included what is required for getting up the steam in the morning.
The time of working, corresponding to this average is 13 hours. The weight on the safety-valve is 4½ lb. per square inch.

The engines and machinery at Blackwall are similarly arranged, but on a smaller scale. The railway runs past the side of the engine-house on the ground, and therefore the ropes are passed upon the lowest part of the circumference of the drums, instead of at the highest part, as at the Minories, where the railway passes over the engine-house. The engines, constructed by Mr. Barnes, are of the marine side-lever form, of the nominal horse-power of 100. Each engine is 6 ft. 6 in. in diameter, and has 4½ in. foot wheels, and their average speed is 25 strokes per minute. The large spur-wheels are 17 inches to the pitch, line, with 120 teeth, 3½ inches pitch, and 14 inches broad, working into mortise spur-wheels on the axes of the drums, 10 ft. 10 in. in diameter. The diameters of the ropes are 1½ inches when empty, and 2½ feet diameter outside. The small steam-engine for working the air-pumps is 8 horse-power; it was constructed by Messrs. Miller and Ravenhill.

Remarks made at the Meeting after the reading of the above Paper.

Mr. Fear stated that the wire rope consisted of six strands, each of six wires, each wire consisting of 12 plaited sub-strands. The first rope was 9 in. in circumference, with a lay of 44 inches; this was soon diminished to 3 inches, and it broke continually. It was replaced by a rope from which the tar had been expelled by pressure; that was soon worn out, and the fibre appeared completely destroyed. Three ropes of various kinds were then tried; and at last, by the introduction of swivels, and recently by an improved construction of them, the bad effects of the twisting were obviated, although it still took place. In spite of the rapid destruction of the hemp rope, he was of opinion, that as a mere question of cost, it would be found cheaper than wire rope; as, when partially destroyed, the former had still a certain value, but the latter was comparatively valueless.

Mr. R. Stephenson stated that he was unable to account satisfactorily for the twisting of the rope. He imagined that it might be caused, in some degree, by its being wound over the drum at the Minories. The wires were laid round one centre core of hemp. Wherever the wires were in actual contact with the core, corrosion appeared to take place, which of course augmented the rapidity of the destruction of the rope. It was, however, now more a question of expense, as to the adoption of a new breakage seldom occurred. He thought that the old hemp rope had frequently been broken by the undue strain which was suddenly brought upon it, by its slipping on the drum. He imagined that a modification of the method used in cotton spinning for regulating the coiling of the lamaments might be adopted with advantage, instead of as at present coiling it by hand.

Mr. Birdes said he had noticed the peculiar tendency of the hemp rope to twist, and that for many years the first rope was not twisted. The second rope had been 9 in. in circumference, with a lay of 44 inches; this was soon diminished to 3 inches, and it broke continually. It was replaced by a rope from which the tar had been expelled by pressure; that was soon worn out, and the fibre appeared completely destroyed. Three ropes of various kinds were then tried; and at last, by the introduction of swivels, and recently by an improved construction of them, the bad effects of the twisting were obviated, although it still took place. In spite of the rapid destruction of the hemp rope, he was of opinion, that as a mere question of cost, it would be found cheaper than wire rope; as, when partially destroyed, the former had still a certain value, but the latter was comparatively valueless.

FOSSIL FOOTMARKS IN THE COAL FORMATION.

Mr. Lyell delivered a lecture at the Royal Institution, on February 4th, on the Fossil Footmarks of a Reptile in the Coal Formation of the Alleghany Mountains.

Mr. Lyell began by observing that, notwithstanding the numerous remains of land plants in the carboniferous strata and the evidence they afford of the existence of large land animals, such as the reptiles and the invertebrates, no satisfactory footprints of reptiles (which is often indicated by seams of coal and buried forests), no monuments of any air-breathing creatures had been detected in rocks of such high antiquity until Dr. King, in 1844, published his account of the foot-prints of a reptile occurring in the coal measures of Saxon and in Warwickshire and Cheshire, always in the upper part of the new red sandstone or trachy. In the European hand-shaped foot-marks, from the form of which the animal was called by Kaup, ichthochaos, both the hind and fore feet have each five toes, and the size of the hind foot is about five times as large as the fore foot. In the American fossil the posterior foot-print is not twice as large as the anterior, and the number of toes is unequal, being five in the hinder and four in the anterior foot; as in the European ichthochoas the fifth toe is much the smallest, being nearly as wide as the first and second, and somewhat resembles the human thumb. On the external side of the Pennsylvania tracks, both the larger and smaller, there is a protuberance like the rudiment of another toe. The average length of the hind foot is 5 inches, and of the fore foot 4½ inches. The hind feet being in pairs follow each other very closely, there being an interval of 4½ inches between them. Between each pair the distance is six to eight inches, and between the two parallel lines of tracks there is about the same distance. In the case of the English and German ichthochoas, the hind and fore feet occur also in pairs, but they form only one row, in consequence of the animal having put
its feet to the ground nearly under the middle of its body, and the thumblike toes are seen to turn to the right and to the left in the alternate pairs; while in the American tracks, which form two parallel rows, all the thumblike toes are crowded to the right side, or to the left, as the case may be. Dr. Lyell infers, therefore, that the American cheirotherium belongs to a new genus of reptilian quadrupeds, wholly distinct from that from which characterizes the triassic strata of Europe; and such a generic diversity, he observes, might have been expected from reptiles of such different fossiliferous geological position of the sandstone of Greensburg is perfectly clear, being situated in the midst of the Appalachian coal-field, having the main bed of coal, called the Pittsburg seam, a hundred feet above it worked in the neighbor- hood of several seams of coal and iron. Levels or beds of limonite, lepidolodendron, sirillaria, stigmata, and other carboniferous plants, are found both above and below the level of the reptilian footstepes. Mr. Lyell then adverted to some spurious fossil footprints of dogs, hoofed quadru- peda, birds, and lizards found on the surface of some of the red quartzose sandstones in the neighborhood of Greensburg, which had been confounded with the fossil ones. He pointed out the proofs that these had been made by the ancient inhabitants of America, whose graves are seen in the vicinity; and that thestatement made by Mr. D. D. Owen, of Indiana.

To determine the mode of interpreting fossil footprints in geology, Mr. Lyell gave a sketch of the discovery of three distinct species of cheirotheria in Europe,—and explained how, after it had been conjectured by Link that they might belong to gigantic herbivora, Mr. Owen found, by exa-
imining the teeth and bones of reptiles of triassic age, that three different species of birds, and one of the reptiles of the biarmos, labyrinthodon, had existed, both in Germany and England, at that time; their fossil bones indicating that they were air-breathers, and there being as great a disparity in size between the bones of their anterior and posterior extremities as between the fore and hind footprints of the several cheirotheria. To account for the sharpness of the casts of cheirotherium on the surface of slates or sandstone, Mr. Lyell referred to the manner in which he had seen, on the sea-beach, near Savannah in Georgia, a crowd of sea-birds, being driven by the wind filling up the foot-prints of recent generations of the living, or fossil, birds. The presence of the casts on the surface of the rocks connected with the Bed of the Fundy, in Nova Scotia. These consist both of impressions on the upper surfaces and of casts in relief on the under sides of successive layers of red mud (see Lyell’s “Travels in North America,” vol. ii. p. 185),—of which he has preserved a specimen to the British Mu-

The ancient foot-prints of more than thirty species of birds found fossil in the new red sandstone or tris of the valley of the Connecticut river, in Massachusetts, were stated to be analogous to these modern bird-tracks; and the size of the largest, although they indicate a biped more huge than the ostrich, is exceeded in magnitude by the gigantic deinornis of New Zealand,—of which nearly the entire skeleton has been fossilised by Mr. Walter Mantell. The absence hitherto of the bones of birds in the ancient strata of the triassic period appears to the present generation of palaeontologists entirely intelligible; for the circumstances which combine to cause foot-prints of sandpipers in the recent mud of the Bay of Fundy, repeated throughout many superimposed layers, have no tendency to preserve any bones of the same birds, but only leaves and other organic impressions preserved through the red mud, where it has been laid dry by artificial embankments and drained. In all the cases of foot-prints, both fossil and recent, and whether made by quadrupeds or bipeds, the bird at least have been subjected to uncontrolled pressure so deep and distinct. The same conclusion is borne out by the evidence derived from the casts of tracks produced in the same strata, by slates, and so generally accom-

•

The principle of this jack is the same as that of the hydraulic press, but not having been applied to a lifting jack, it is thought that the present application of it will be useful for a variety of purposes. Its advantages are, the ease and neatness with which a great weight can be raised on one person; the facility with which the lowering of the weight can be regulated without labour, and from there being no circular motion of the handle, there can be no tendency in the jack to twist from the position in which it is placed, also by the use of strong wrought-iron tubes for the cylinder and ram, the weight of the jack is less than others now known. This jack can be used in all cases where others are available, and in some where others are not so, for the motion of the lever being vertical instead of lateral, it can be used wherever there is sufficient width to place it. With a jack of the size shown, and the maximum main lift from 15 to 20 tons weight. Mr. Thornton said although the jack was not new in principle, one of its great advantages was found in the additional power which it gave to one man to raise so great a weight.

The Chairman said he presumed they all understood the description given by Mr. Thornton. The jack displayed itself by its own appearance and the drawing. So far as the trial he had had with it, he had every reason to be satisfied. It was very simple, acted very nicely, and he thought it was a very ingenious improvement.

Mr. CRAMPTON wished to know if it had ever tumbled down?

Mr. MIDDLETON said all persons acquainted with such things must be fully aware that they could not get a jack boxed up. Until, however, an alteration could be made in the handle, it could not be considered a good thing practically.

Mr. SLATE observed that though a jack might not be practically good when placed in a tumbling position, it might be good in other cases. A jack
like the one now before them might be useful in lifting a great weight, where the ordinary one would not be sufficient. Mr. Bucklin thought that the jack was an exceedingly useful instrument. An ordinary jack would be much more liable to be out of order than the one before them; besides, it presented greater facilities for lowering weights.

Mr. Milner was of opinion that as it was not generally used as a lifting jack, it would be a great advantage from this. He thought it was a most important machine, and its endeavors should be to prevent it, if possible, from capsizing.

The Chairman said Mr. Thornton's object in introducing it was to have the benefit of their experience.

Another member said he should give the preference to Healey's jack. Lifting jacks when laid aside, like fire-engines in a country town, not being generally required, get out of order, and he was afraid that the one before them would be much more liable to injuries of that kind than the ordinary jack.

The Chairman said, it appeared that it was objected against the jack, that it was liable to get out of order, and that it had not the advantages of Healey's jack in lifting from below, but from the top; at the same time it would be admitted that it was steady in action, and that in lowering weight it was necessary to have power and command, so as to do it slowly and easily. There was one important point in which it had not the advantage, and that was in price. In articles of that kind, the price was a consideration.

Mr. Hindmarsh thought that the jack possessed advantages where there was a great weight to lift, and only one man to work it. Another advantage was its steady action. The great objection against it was the liability to get out of order. If they wanted a jack to raise 20 tons, he was not aware that they could get any other to do it with the same degree of steadiness.

**CYLINDER-BORING MACHINE.**

"On the Fitting-up of Cylinders for Locomotive Engines, and a Description of a Machine for Boring Them." By Mr. C. Bryson.

The desirability of having all the cylinders of every class of locomotive engines exactly the same size, is well known; but the difficulty of accomplishing this with the tools hitherto employed, will be known to most who are engaged in this branch of the business. These considerations, and the defect of cylinders, the author, from time to time, found necessary to have rectified before passing them to be used, induced him, in 1843, to direct his attention to the boring-machine.

The conditions which a good cylinder-boring machine should fulfill, may be stated as follows: 1. It should be steady in its action; 2. That the cylinder should be perfectly concentric or parallel with the outside of the barrel. 3. That the projections beyond the flanges, if there be any, should be truly parallel to the axis of the bore. 4. That every strain or pressure upon the barrel of the cylinder whilst boring should be avoided. The boring-machine hereafter to be described has been found, during several years' practice, to have answered these conditions.

Brothers & Co. cast their cylinders from wood patterns in green sand, and commence the process of fitting-up by describing or gauging off a circle upon the cylinder, concentric to the barrel, and having formed this circle the ends are bevelled inwards by chipping to an angle corresponding to that of the plates of the cone mandrel. The cylinder being fastened to the mandrel is put into a two-foot slide lathe, with facing motion, and has its ends faced to a gauge, and its projections turned to a gauge, and cut to a length of gauge. There are further two notches cut out on the concave sides, and then applying an internal gauge for the out-and-out length of the cylinder. Thus prepared by turning, it is removed to the boring-machine, inserted between two plates, the faces of which are placed, and the holes for receiving them bored from the boring-bar in their places; it is at once perfectly concentric with setting, and needs nothing but clamping to the plates by headed bolts or clamps by its flanges to be ready for commencing boring. For placing the tops of the steam-chests and valve faces the turned ends are again made use of for setting, by placing upon the boring-machine table brackets placed on their faces and bored out to the same gauge; the cylinder is turned to, in order to insure the parallelism of these parts with the axis, as for similar reasons the inside of the cylinder could not be otherwise than concentric with the outside of the barrel. The author prefers this plan, as it is separate from outside the cylinders rather than economise by making one do for many, and risk the chance of mistakes; and he believes that the plan here described, to work always from the same point, is most likely to insure accuracy, as the faults made by neglect of the workmen are not multiplied by subsequent operations.

The boring-machine bores by two cylinders at the same time, and is arranged to bore cylinders of 6" strokes and from 10 to 20 inches diameter. The bed is that of a common slide lathe, sufficiently long to carry a double set of driving gear, and admits of a sufficient traverse of the boring-carriage. The boring-bar is supported by the bearings, the former of which is stationary and firmly fixed to the bed to resist the end and pressure of the work when boring; the latter are fixed upon the carriage and travel with it along the boring-bar, and serve for securing the cylinder during boring, as will be shewn hereafter. To cause the boring-carriage to move towards, from a long distance to a short distance, the machine to give motion to the shaft, and is transferred by means of a feather worm to the worm-wheel and pinion, both of which move above the first stud of the carriage. This same stud serves as a fulcrum for the lever, carrying upon it a pinion, which engages in the intermediate pinions, which gear trains the said pinions. It will be clear, therefore, that by setting the lever in such a position to bring one pinion into gear with another pinion fast on the rack-pinion shaft, motion will be given to the boring carriage in one direction; or, by moving the lever in an opposite or contrary direction by moving the lever so as to bring the pinions to gear with each other; and this carriage will be stationary or independent of the driving carriage altogether, by keeping the lever in its middle position. The rack pinion shaft is extended towards the front of the machine, to work the carriage backwards.

A provision is also made in the train of wheels for varying the traverse of the carriage by changing the pinion.

To hold the cylinder while boring, the top of the carriage is formed into a kind of square frame, by means of two plates, placed on the inside and fastened to the sides of the bearings or standards and two cross stretchers. These latter are also placed upon their inner faces and are secured to the sides and top of the boring-carriage, and have holes bored in them when screwed on; these faces, which rest on the boring-bar, correspond in diameter to the turned projecting ends of the cylinder to be bored. It will be seen, therefore, that if the figure of the cylinder to be bored be turned to the same gauges as the holes are bored to, it needs only inserting and applying the necessary cutting tools, without anything further by setting its pan whatever. One of the cross stretchers is a fixture, whilst the other is removed every time a new cylinder is to be fixed. The boring head is a fixture upon the bar, and has only one plain square tire for boring, ground out at each end. The boring-bar fits into a plain recess made slightly dovetailed, and is held fast by a set screw adjustable to any diameter by another of these machines. We employ three of these machines—two double ones and a single one, and one man attends to these and the lathe for facing and turning the ends of the rough castings of the cylinders. The boring machines are capable of cutting out the cylinders with the best cutting tools we can make, and we find it more advisable to complete the boring in three cuts; the first is often as much as ¾ inch in depth, the second we leave about ¾ inch, and the third can hardly be called cutting, but is merely clearing up or finishing. The advance, or traverse, we rarely change, and is set to ¾ of an inch for each revolution of the boring-bar; or is, for quickest speed of the bar, 3 revolutions per minute; in the second, 1½ revolutions per minute; in the third, or lowest speed, 1½ revolutions per minute, or cut at 7 feet per minute; for boring, 3 revolutions per minute, or cut at 1½ feet per minute; and for finishing, 1½ revolutions per minute, or cut at 9½ feet per minute.

Mr. Fothergill said, that in doing very great injustice to the very valuable paper they had heard read were they to discuss it at that late hour, and he should propose that the further consideration of it should be adjourned till the next meeting. The suggestion was adopted and the meeting terminated.

**JACQUARD PERFORATING MACHINE.**

"Description of a Perforating Machine," made for Mr. Evans, the contractor for the iron tubular bridge which is to carry the Chester and Holyhead Railway over the river Conway. By Mr. Fothergill.

This machine is employed to perforate the plates for the above-named bridge, and is at present adapted to punch such pitches only as that work required, viz.: 36 holes per inch, 12 holes per inch, and for the advantage of preparing for the different sizes of holes, the number of punchers may be put out of action at pleasure; and by means of a blank card at the end of the series, the machine is put out of action at a point where no obstacle is presented to the taking out of the perforated plate and putting in another sheet of cylinders. The plates weighing six or seven hundredweight each, is performed by half a dozen men in less than one minute, and whilst one plate is being punched, these men get another ready to put into the machine. As these machines take card plates (similar to the underused in the Icart loom), 1½ inch pitch a 12 feet plate may be punched in less than four minutes, and consequently that (allowing one minute for changing) it may perforate twelve such plates per hour. Many of the plates in the bridge are 12 feet long, 2 ft. 8 in. wide, and ½ inch thick, and thus three of these machines would be required for this work. As there are but few engineering concerns where such a perforating machine as that at Conway would be employed more than an hour or two per day, it appears to be very desirable that ironmasters should have them, and that
they should also have machines for straightening and bending plates; by which means they would be enabled to supply their customers with plates in a fit state for being rivetted together. Were this system brought into practice, engineers would turn their attention to their work to the capabilities of the materials, and thus great perfection in both the form and use of the work, and the economy of construction would be the result. A drawing represented a machine (similar in principle to that already described) adapted to perforating paper and thin sheet metal, such as weaves and window-blinds are made of, in which the perforations, arranged in squares, may be made by a single row of punches; and perforations, arranged quincuncially, may also be made by a single row of punches, by giving to the plate a lateral alternating motion; but a double row of punches, arranged immediately to each other, is preferable. Each range arrangement of holes forms a great variety of fancy patterns by the application of the Jacquard principle. A large class of patterns may be produced by punches of various forms and sizes, which shall be so grouped together as to give to the work a columnar effect; and the range of the plate may be extended to any requisite number of perforations, making any requisite number of perforations, and throws itself out of action when the plate is completed. Those who are aware of the force necessary to perforate an iron plate of moderate thickness, even with a single punch of small size, may form some judgment of the enormous power required to impel punches, each of which is in diameter, through plates three-quarters of an inch thick; and it is a little singular to see this enormous power regulated in its operation by the identical means employed in producing figures in the most delicate fabrics. The machine is calculated to make, when necessary, the requisite number of perforations, making any requisite number of punches, as distances of three or four inches from each other. The speed with which the work is performed may be understood from the fact, that it regularly completes the perforation of one plate of the size here described,—namely, 12 feet long and 5 ft. 4 in. wide,—in four minutes; and if the plates were so quickly supplied as to prevent any loss of time, which might easily be done, it would complete them regularly at that rate. As it is, fifty have been completed in four hours, and the facility and dispatch resulting from the use of the machine are not, perhaps, its greatest merit, but at least as the construction of tubular bridges and beams are concerned. In such cases, the strength of the fabric depends in a great degree upon the whole of the rivets completely filling the perforations, retaining a regular cylindrical form, continuing perfectly straight, and being, throughout their length, exactly at right angles with the faces of the plates. As each of the perforations represented in the diagram is intended to correspond with a similar perforation, either in another plate, or in an angle or T iron, it must be obvious that deviations in opposite directions of a sixteenth of an inch in each, would prevent them lying exactly one on the other; and whatever might be done by enlarging one or both of the holes, to bring them a little nearer each other, the value and strength of the work must be impaired by the slightest deviation of the rivets from right angles, instead of being exactly at right angles with the plate; whilst, in the work performed by the machine, the perforations are set out with such accuracy that they always correspond precisely, and the rivets retain their proper form and direction.

The Dinner.—In the evening the members and friends, amounting to about 100, dined together at the Queen's Hotel.—Mr. M'C函ell presiding.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

Jan. 24.—Mr. Charles Fowler, V.P., in the Chair.

The donations included a number of works by the celebrated architect, M. de Caumont, of Caen, a corresponding member of the Institute. Mr. Wallen sent a portion of the mosaic pavement found nine feet below the present level, while digging the foundations for the new warehouses of Messrs. Morley, at the corner of Gresham-street and Wood-street. Mr. Wallen thought a Roman temple formerly stood on the spot.

Professor Donaldson read a paper on "Caen, its Churches and Buildings, with a few words on Arras." This paper we have paper in full in another part of the Journal.

Some very high compliments were paid to Mr. Donaldson on this valuable paper.

Feb. 7.—Mr. Angell, V.P., in the Chair.

Among the donations reported were Canina's work on Etruria, sent in the name of the Queen of Tuscany; Mr. Sharpe's "Architectural Parallels;" and eleven volumes of the "Bau Zeitung," the architectural journal of Vienna, sent by Mr. Foster; and parts of Billings' "Antiquities of Scotland.

Mr. Wright sent a set of drawings illustrative of the ceiling at Carpenters' Hall, London-wall.

Mr. G. L. Taylor read a paper in reference to the New Western Gas Company, entitled "Some observations on Gas-works, and the details of the Construction of an Iron Gas Cyan with a view of showing that it is capable of being rendered Pure as to be introduced beneficially throughout House, Manufactory, and Public Buildings,"

Mr. Bean observed that formerly he resided at Edinburgh; that he had twice as many burners as he now has in London, and paid at a much higher rate, but 12 or 1,100 cubic feet of gas for a quarter. He observed, however only one half of the London gross charge, arising from the superior illuminating qualities of the Edinburgh gas. It is true, the latter is made from Cannel coal; but there is an unfortunate temptation to gas companies to fortify the quality of gas, in consequence of the charge being made on the quantity. He further observed, that though the Edinburgh gas is superior in illuminating power, it is not free from impurities; in proof of which he said all the book-binding and leather furniture of a new club-house at Edinburgh had been destroyed by the gas, as the book-binding of the histamin club-house, in London, has likewise been injured.

Mr. Palmer dwelt upon the importance of the purification of gas, and said that the new plan showed its practicability.

The Western Gas Company have their works in a building at Kennington, 160 feet in diameter. The purpose is to use Cannel coal, and supply gas at 6d. per thousand feet, which they say is as cheap as common gas at 4d. per thousand.
INSTITUTION OF CIVIL ENGINEERS.

Feb. 1.—JOSHUA FIELD, Esq., President, in the Chair.

The President, in taking the Chair for the first time since his election, addressed the members at considerable length, dwelling chiefly on the intimate connection between the civil and mechanical engineers, their dependence upon each other, and the importance of maintaining the two branches of the profession that had ever been one of the main objects of the Institution. He showed, that originally engineering was confined to the constructive or mechanical branches; raising heavy weights, building bridges, making roads, etc., but that in the primitive arts by degrees, as civilisation extended, the exigencies of the world became greater; luxuries required, that could only be supplied by greater exercise of talent and skill; manufactories were multiplied, manual labour could not supply, and the steam-engine generally employed, and the consequence of this increase of production was, that the roads required to be amended, rivers and canals to be cut, for carrying this abundance of merchandise and passengers, whilst docks and harbours required extending, for the reception of the shipping for the increasing export trade. These were called inland navigations or canals, with great machines and engines, combined more than ordinary theoretical knowledge and business habits, to enable them to combine and use the powers of all other classes. These men were termed civil engineers, in contradistinction to mechanical engineers, whose education and experience fitted them solely for the art of war; and by these men, Great Britain had been placed first in the list of the civilizers of mankind. Mr. Field, as the first president elected from among the mechanical engineers, dilated, at length, upon the immense strides made within the last century in the production of the mechanic arts and in public works, under the combined efforts of the two classes alluded to. He then entered more minutely upon the subject of steam navigation, to which he had principally devoted his personal attention, and gave most interesting details of the subject, and the improvements which had been made during the whole period. By saying, that he must be permitted to feel more than ordinary pride in being elected the president, when he looked around him, and saw that the association of six young engineers, who, in 1818, met occasionally to chat over mechanical subjects, was now in the course of twenty-two years, into a society consisting of upwards of 600 members, and comprising within it almost all the engineers of eminence in Great Britain. The address was vehemently applauded, and the president was requested to allow it to be printed in the minutes of proceedings.

The paper then renewed upon Mr. Rawson's paper, "On the Manufacture of Artificial Stone."

The Dean of Westminster, Sir Henry De la Beche, Mr. John Phillips, Dr. Garrod, Mr. Barry, and other visitors, took part in the discussion with the principal members of the Institution. The remarks turned chiefly upon the chemical and physical properties of the material, and the cost of its production in the moulded form as compared to that of carved stone. In its chemical properties it was shown to be at least equal in purity to the production of Nature; for, on the statements of the eminent chemists who had subjected it to severe tests, it was proved to be totally insoluble in boiling water, however long immersed, and also to be capable of resisting the action of mineral acids. In this respect it differed from glass, which always yielded a portion of its alkali to the action of water. It was further stated, that it had perfectly resisted the action of fire, and that the action of cold water had been repeatedly frozen without their sustaining any injury. Satisfactory statements were adduced as to its strength and other physical properties, and some very interesting remarks were made on the subject, comparing the substructure of ancient architecture with that of the modern, which, by the action of compression and heat, had attained a degree of firmness equal to quarts. The experiments of Hall and Watten on the production of artificial stones were also adduced to as bearing upon the question. Experiments made on the strength of the artificial stone proved it to be superior to those natural stones with which it had been tested at Bath, York, or Portland stone. Numerous specimens were exhibited to the meeting, showing its universal applicability to constructive and decorative purposes; fractured pieces were shown of every variety of texture, from the porous and absorbent to the most compact, and the color of the material was stated to be such as to render it available for all useful and ornamental purposes.

Feb. 8.—JOSHUA FIELD, Esq., President, in the Chair.

The paper read was "An account of the recent Improvements in the Drainage and Sewage of Bristol." By Mr. James Green.

The paper read appears, that the great work of water and sewerage had been requisite in the town of Bristol, and more especially in the localities adjacent to the course of the River Fromme, whose channel had become a large cesspool, spreading miasma and disease all around. This river formerly emptied itself into the River Avon, in the city, and the river Avon into the sea, the latter in each instance by the tide; but, when to form the floating harbour, the old course of the Avon was dammed across by lock-gates, and a new cut was made for carrying off the contents of the sewers emptying themselves into the Fromme, a nuisance and unhealthy condition of things. All these mischiefs became permanently affected. Mr. Mykle, some years since, constructed a lateral culvert from the embouchure of the Fromme, deobouching in the new cut; this did partial good; but still the general state of the river remained unimproved; and, in deference to the universal demand for sanitary reform, the authorities of Bristol employed Mr. Green to devise and execute plans for the improvement of the sewage of the part of the city most demanding it. The proceedings were laid out of the estimate of the works, the most exceeded the funds at the disposal of the council; so he modified them, and the result had proved most successful. The proceedings were to bring the channel of the river into an uniform width, by building side walls, with gutters in the upper slope, conveying the sewage into the stream, obliterating the abut, and thereby confining the best of the abut; removing the obstructions caused by the pier of the Castle Mill-bridge; lowering the height, and extending the length of the Wear at the castle most, with new flood-gates, &c.; deepening the bed of the upper part of the Wear, and thus raising the estimate of the works, so that they were skillfully combated, and the result has been most complete success; and it is to be hoped, that the further ameliorations of which the general sewage of the city is susceptible, may be equally successful under the control of Mr. Green, who has so ably conducted them upon a modified scale. For, as the actual expenditure was not more than £4,537, as stated in the paper, and such beneficial effects have been obtained, there can be no reason why any proper measure of sanitary reform should not be carried into effect.

In the discussion that took part, bearing testimony to the satisfactory nature of the improvements made by Mr. Green at Bristol. The conversation then turned upon the employment of the contents of sewers for agricultural purposes. The system proposed by Mr. Green was that the contents of the sewers, which had been rendered fertile by the application of liquid manure, near Edinburgh, and near Mansfield, were quoted as examples of the efficacy of the system; but, on the other hand, it was shown that these were not fair examples, as the localities were peculiar; the cost of the establishment would be by no means cheap, if the distribution of the contents of the sewers was to be made by pipes and pumping, the returns would never repay the outlay.

Feb. 15.—The discussion upon Mr. Green's paper was renewed, and continued throughout the evening, to the exclusion of all other business. The main object of the paper appeared, unfortunately, to be lost sight of by the speakers, in their anxiety to bring forward, or to defend, the positions assumed by various companies, which had been formed at different periods for the formation of the sewers and the management of the works, in the former part of the discussion, had been somewhat impugned upon commercial grounds. The statements made at this meeting were only repetitions of what had been repeatedly printed in reports, and in evidence before the sanitary commissions; and the whole evening may have been said to have been wasted, in spite of the attempts of some of the members to bring the discussion to the real question of the best modes of laying out a system of sewage for large towns, the forms of the sewers, based upon the laws governing the conveyance of fluids—which it had been stated took part, in the "blue books," were not understood by civil engineers, a statement which was shown by some of the speakers to be not consonant with facts; for, that, if the selected, rather than collected, evidence given before the Health of Towns Commission, the experts on this subject might be wrong, the experience of the older writers on hydraulics had been received and adopted, rather than the formulæ of modern writers, or the actual practice of civil engineers of eminence, whose experience on such subjects was necessarily greater. It was true, that hitherto, in consequence of the laws, eminent engineers had not devolved themselves to the subject of sewage to the extent they might have done; but, when the time arrived for their doing so advantageously, or the exercise of their skill was demanded by the government, or by private enterprise, they would be found quite prepared to devote themselves to the work.

SOCIETY OF ARTS, LONDON.

Jan. 19.—WILLIAM FOTHERGILL COOKE, Esq., in the Chair.

The Secretary read a paper by Dr. Harding, "On some ancient Greek Vases excavated by him from Tombs near Hexamili, in the Isthmus of Corinth."

"In the autumn of 1840, having obtained by private influence, an order from the prime minister, permitting me to excavate for antiquities, I proceeded (observes Dr. Harding) to Corinth, and hearing that the peasants frequently found ancient tombs, containing vases, under the village of Hexamili, I proceeded thither with a party of labourers. Hexamili lies between Corinth and its ancient port of Chioare, within three miles of the spot where the Isthmus games were celebrated. The ground about these ruins is barren and rocky, the largest stones hewn for the purpose of building the ancient town of Corinth having been preserved. I was enabled to gather a number of vases, both vases of a wine jar and those of a cooking jar, as well as some vases of a different style. The objects which I collected were all ancient and of the most interesting kind."

The secretary then tendered the stone vase to the society, and read the accompanying letter.
1846.

THE CIVIL ENGINEER AND ARCHITECT'S JOURNAL.

manner in which graves are dug in England; and as soon as sufficient of the covering earth has been removed, a stone is placed over the opening; and with this a hole is made in the lid or covering to the tomb. A hand is then carefully inserted, and human bones, vases, &c., are generally extracted. The greatest number of vases I found in any one tomb was fourteen, and children's tombs had proportionally small vases. Having examined the bones of these vases, and come to the conclusion that they were the remains of objects which are not likely to be produced to be of Etruscan produce. The factile art had been supposed to be confined almost exclusively to Italy, although numerous excavations had been made at Athens, and a few at Corinthus, which had produced specimens similar to those exhibited, and which he divided into classes. The most ancient vases (and which are distinguished from all others by the material of which they are composed) are of a light yellow clay, and have figures and animals painted on them in a maroon color. Their date is supposed to be about 616 years before Christ. In the second period the facile art is reported to have been introduced among the Etruscans by the Greeks. The second class of vases are of a pale red clay, and the figures, instead of being of a maroon color, are traced in black, in order to show the details more distinctly. This style appears to date from the fifth to the middle of the fourth century before Christ. The maroon color was laid on by means of a reed. But perhaps the highest style, and one which is peculiar to the vases found at Athens, is that in which the outline, &c., is traced in white paint, or a sort of carbonate of lime. The vases exhibited by the last artist were not limited to the vases found in Athens. Italy may be considered to be the manufacture of Greek vases settled in Italy, and not imported from Greece into that country.

Dr. HARDING stated that the tombs at Halicarnassus seem to have been scattered in the woods, but he does not think they have been very extensive, measuring nearly half a mile in each direction. No inscriptions or marks whatever are visible on the stones of the tombs, nor is there any other apparent difference externally than that of size. The houses in them were tolerably well built and the buildings were of heavy stuff, apparently part of a large bronze needle or badkin. Generally, the contents of the tombs were in a wonderful state of preservation, considering that they were, in all probability, at least 2,000 years old.

Jan. 26.—George Moore, Esq., P.R.S., in the Chair.

The Secretary read a letter from Mr. DWYER, in which he states, as the Society is to meet for the purpose of investigating the forms of Ancient Pottery, he begged to present for its acceptance a series of sketches, believing that they might prove of some utility in assisting its researches. He says that having observed that ancient art generally originates through the imitation of natural objects, he was led to infer as highly probable that the beautiful geometrical designs found on vases from Etruria, which he had contributed to point out the exquisite forms of leaves and fruits, suggesting the probable manner in which they had been used to give character and beauty of outline to those manufactures.

The second communication was from W.T. GRIFFITHS, and accompanied a copy of his work "On the Natural System of Architecture."

The communication alluded to the work as pointing out the geometrical proportions of the temples of Greece, and calling attention to the applicability of geometrical design to domestic architecture, and as also affording a ready means of obtaining beautiful patterns for oil cloths, carpets, &c. The author then proceeded to point out the improbability of the ancient Greek vases being constructed on any other than pure geometrical principles, as is proved by analysis; and concluded by alluding to the mistaken but very prevalent notion that to produce a beautiful building, it is necessary to overload it with meretricious ornament,—instead of feeling that the more simple is often the more beautiful design.

Mr. Valere made some remarks in reference to Mr. Dwyer's communication, and added that our ancestors were many artists of highly-cultivated taste, still they have not the necessary knowledge to enable them to produce good art. In reference to a leaf having given rise to the forms of the Greek vases, he would observe that a leaf itself is in a pendant body, and as such is very beautiful; but a single leaf would in all probability give rise to some pendant fruits, such as the apple,—which might be said to have a base, and some vases might be compared to it; but he did not think that they gave rise to the forms of the Greek vases, although he must admit that they are derived from them. In the same manner that certain rules, Mr. Varley said, which Nature suggests, and which we find the Greeks used; and he proceeded to point out the following method which might be used for producing agreeable forms, such as the bodies of the vases exhibited at the late international exhibition held by the Government, according to the outline desired; and by rotating it on its axis at any given angle, it would be made to produce the figure desired. Similar simple methods for obtaining the necks and stands for vases were also described.

The Secretary made some remarks on the forms of vases, and stated that if beauty consisted in the imitation of Nature, as suggested by Mr. Dwyer, a man would have nothing to do but to take the first leaf of a tree as a form for a vase. But the leaves, he goes on seeking and seeking, till at last he finds one which pleases him, because it comes up to the ideas in his own mind, and which he had preconceived as the standard of beauty.

Mr. Wyndham HARDING considered that the effect of vases and other decorative objects on society. He thought that the architecture of everyday life, should produce upon the eye an effect equally pleasing with music on the ear; and that, as in order to obtain harmony in music it is necessary that the cords or strings should each vibrate a proportionate number of times, so should the proportion of various parts of all Gothic buildings; and these geometric and harmonic relations must be known to the Greeks in the formation of their works.

Mr. SMITH stated that he did not consider that geometry was used by the ancient architects, but generally attributed to them, but that their works were the result of a practised eye and hand, guided by a highly-cultivated taste.

Feb. 9.—Baron Goldsmid, V.P., in the Chair.

The Secretary introduced the business of the evening by some remarks on "Polymer Decorations," as follows:

The discussion on the construction of ancient Greek vases, which had lately occupied the meetings of the Society, had occasioned several treaties to be written and a great amount of attention to be paid to the subject. It is continually alleged as a fault of the art in our day, that instead of boldly trampling on nature, and trusting to the artist's judgment and skill in according to what we consider the enlightened principles which we have struck out for ourselves, we are contented to take for granted that the ancients were artists truly unapproachable, and such we can never hope to equal, much less to excel; and, in deciding the question as to whether we should abandon altogether originality, and give ourselves up to the study and copying of the antique forms. The Secretary then pointed out the effect of a design upon the mind and senses in the case of polygonal art, and called attention to the effect of such a combination of forms and sizes as shall produce upon the mind the effect of a design standing out from the wall or pavement, but which, if felt by the hand or foot, is perfectly flat. He next proceeded to point out the forms of the tesserae and geometric figures which had been so much used in construction design, and pointed out the beauty and variety of design which might be obtained by the combination of a form of tessera, which, although not new, had not up to this time been used as the base of a pattern. The figure which was pointed out as most applicable to mosaic decorations was the triangle of Plato, any number of which might be arranged round a point and made to cover an entire surface, forming bands either horizontally, diagonally, or any variety of diamond figures, as the sides of the triangle bear a peculiar ratio, namely, 30, 60, and 90 degrees; whereas, where figures of inharmonious ratios are used, the variety cannot be obtained. Having thus pointed out the applicability of geometric figures to the production of beautiful forms, the Secretary gave several extracts from a paper on the "Beau Ideal Head," by Mr. D. R. Hay; from Mr. Blomp's paper on the "Construction of Picture;" Mr. Dyce's paper on "The Geometrical Proportions of the Human Figure;' and Mr. Digby Wyatt's paper on "Ancient Tesserae;" also a letter from Mr. J. Jopling, as to the improbability of ancient vases having been constructed on any other than purely geometrical principles. The play is one in which a young man is represented as jeering an abandoned old woman, and is saying:

"But you old wretch, I greatly dread your lover."

"Who?"

"With those hairs that:"}

"He who for dead men paints the Lyceth."

Another quotation as pointing out the use of these vessels, is as follows:—

"After alluding to the probable purposes to which the several other specimens of vases were applied, Mr. Harding stated that what had been said by Mr. Birch at a former meeting (as to the manufacture of vases having been introduced into Italy by Eucher and Eugraphus, artists who had fled from Greece and went into a myth, and could not be received. Corinth, he observed, has been celebrated at all times, according to Strabo, for its politicians and for the promotion of the useful arts, both graphic and plastic, and for every species of useful application of them; also for some beautiful, but not numerous, specimens of objects connected with sepulchral rites.

ROYAL SCOTTISH SOCIETY OF ARTS.

Jan. 24.—George Buchanan, Esq., P.R.S.E., President, in the Chair.

The following communications were made:—

1. Description of a Marine Hydrometer, adapted for ascertaining the contents of Saltiness and Painsness of Sea and River Waters. By George Buchanan, Esq., President.
NEW PALACE OF WESTMINSTER.

RETURN (dated December 20, 1847) of the Aggregate Amount already paid, or agreed to be paid, to Contractors and other Persons for the Purchase of Land and Houses for the Erection of the Palace of Westminster (or Houses of Parliament).

1. The cost of the purchase of the lands and heredita-

2. The cost of the wharfing, terrace, and foundations for the building.

3. The cost of the carriage or ship already executed (exclusive of alterations as under).

4. The cost of the principal alterations made from time to time.

5. The amount of commission and other charges paid, or to be paid, to the architect on account of works and services already executed.

6. The amount paid to surveyors, valuers, clerks of the works, and all other persons who have been employed, and not included in the architect's or builder's charge.

7. Amount of the commission to be paid to the architect.

8. Amount to be paid to surveyors, valuers, clerks of works, and others, not included in the architect's or builder's charge.

Total Cost: £2,141,036

Note: This includes (besides the professional remuneration to the architect on account of works executed to the general building), the commission upon works to the engineer, architect, and foreman, for a total estimated in accordance with the approved design.

The total cost of works executed, and estimated cost of the works to be executed to finish the New Palace of Westminster, is thus £2,141,036; but which is exclusive of extra finishing, works of decoration, fittings in libraries and refreshment rooms, &c.; fixtures, furniture, and upholstery; &c.

1 This amount includes the professional remuneration to the architect on account of works executed to the general building, the commission upon works to the engineer, architect, and foreman, for a total estimated in accordance with the approved design.

2 The estimate for the works is subject to alteration, and the sum allowed for buildings has not yet been ascertained.

3 The estimate for the works is subject to alteration, and the sum allowed for buildings has not yet been ascertained.
warning, ventilating, and lighting, &c., except so far as such works are already executed in the finished portions of the building; also, of the restoration of St. Stephen's crypt as a chapel, if it should be so determined; the formation of luneti-places towards the river, the paving of the several courts, &c., of the building, the raising of the levels, and the re-paving as well as lighting of the streets in the locality, &c., &c. The cost of which must depend on the nature and extent of the works ordered.

In this amount there is a sum of £24,099 6s. for charges upon the purchase of houses and locations, the cost of the river wall and embank-ment, the warning and ventilating arrangements, and the continuous fireproof construction of the building throughout; the additional residences and other accommodation ordered from time to time to be incorporated in the building, the increased depth of the foundations of the entire building, the main sewers for the drainage of the building and its locality, the various modifications of plan suggested and recommended by committees of parliam-ent and other authorities, and for miscellaneous works; all of which formed so part of the original design and estimate.

Miscellaneous Expenditure connected with the building of the New Palace of Westminster, not being for Purchases made or Work done at the New House of Parliament, or included in the Architect's Estimate for the same, but defrayed out of Grants voted by Parliament for that service.

ON CAEN STONE.

From a paper read at the Royal Institution of British Architects,

Being about to employ a large quantity of Caen stone in a work
which is on the point of commencing, I was anxious to make
myself fully acquainted with its properties and varieties, and the
quantity of well-seasoned blocks that might be available in the
market. I therefore determined to go to Caen itself, and visit
the quarries. A few hours carries one over to Havre from South-
ampton, and a steam-boat conveys passengers from Havre to Caen
in four hours. The last hour is occupied in mounting the river
Orne, which, in its course from the sea to some distance above
Caen, is one of the finest canals in France, and the only, on the
right, generally a lofty bank, at times immediately overhanging
the stream, at others receding from it, but again joining it. Not
far from the mouth of the Orne, at a place called Ranville,
quarries are worked in the face of this bank. It is a harder
and coarser variety of the same stone as that near Caen, and
of more open texture, with a more crystalline character, hence
more adapted for hydraulic works than for buildings. I am
informed by our friend, Mr. H. C. Smith, that these coarse varieties,
which doubtless are very durable, resemble in several particulars
the stone from Weldon, in Northamptonshire, of which the oldest
buildings at Cambridge are constructed.

The material generally known to us under the appellation of
Caen stone is of the olitic formation, presenting a close analogy
in its general, and even in some of its minor divisions, with the
rocks of a similar kind in the south of England. The quarries,
whence it is derived are situated at Allemagne, a parish and village
on the right bank of the river, at the distance of about a mile
and a half, or two miles, above the city. The quarries heretofore
worked occupy a superficial area of about four square miles.
Some time recently, which now adjoins, upon the left side of the
quarries under ground, branching off on all sides in long galleries,
or multiplied by chambers, which are about 18 feet wide, and
the ceiling-bed upheld by massive rude piers, which are left 9 feet
square and 18 feet apart, the height being about 15 or 20 feet.
These quarries, which are immediately on the bank of the river—
here abruptly rising from the water—have an access from the side
of the bank, and are approached by inclined roads, leading from
the summit of the bank above and from the water's edge below.
The openings to these dark and gloomy caverns have a very pic-
turesque effect, and a continued series of them present themselves
one after the other. The galleries penetrate to a considerable
distance. The extraction of the stone is done by contract or task
work, at so much per cube, the quarriers removing the blocks
and dressing them, and another set of men contracting for their
carrage from the quarry to the quay at Caen.

Immediately under the soil there are some thin courses of hard
coarse stone and rubble, but the immediate ceiling-bed is called
the banc cloutier, and is about 6 ft. 6 in. thick. It is a hard
clayey material, not applicable for building purposes; it contains
a great quantity of pebbles, which offer great difficulties in the
sawing and working. There are about six beds of good building
stone, the five uppermost ones calculated for outside work, the
lowermost adapted only for inside work, as it has soft portions,
and is not well seasonable. A description of the river Orne is used
in the interior of the new Parliament buildings. The aggregate height
of these six beds is from 22 to 23 feet. It is to be observed that
all these beds are not to be found in every quarry, one or other of
them disappearing and reappearing in the same manner as in the
quarries at Weldon, and the names of the beds are not always obtained
in all parts of the district; and some of them have various designa-
tions given to them by the quarriers. The uppermost bed is
called the banc pourri, about 3 feet thick, which is a very good
quality of stone; but occasionally it has in some portions the hard
pebbles, previously alluded to, as prevailing to so great a degree
in the banc cloutier, and therefore it is not so much esteemed for
finer building purposes as the lower beds. The gros banc is the
next bed, and has an average depth of 5 feet, but as it is inconve-
nient to work to that large size, it is generally split into two, in
heights of 3 feet and 2 feet; and the smaller one is called the
banqueret of the gros banc. La pierre franche bed comes next, about
3 feet thick, which is of a harder quality, and well adapted for
cornices, sills, coping, and the like exposed positions in a building.
Next to this is the banc de quatre pieds, a very fine bed, which has
the same combination of depth and length as the former quarries, as
also the next bed, called la pierre de trente pouces, being 30 inches
depth, a good hard bed of stone, and forming the lowest of those
fit for outside purposes and exposure to the weather. The sixth
and lowermost bed of the building-stone is termed the banc de
trois pieds, a total depth of 6 feet 2 inches, but this being,
like that of the gros banc, an inconvenient depth, it is di-
vided into a lower thickness of 3 feet, and an upper banqueret of
20 or 24 inches deep. The whole of the stone of these beds is soft
and tender in the quarries, and the blocks are extracted with great
care. They are produced of regular size and shape. When taken
outside, and exposed to the atmosphere, they gradually part
with much of their humidity, and harden; and, if exposed on
the quays during the winter, they are covered over to protect
them from the frost. They saw freely with a common peg-toothed
saw, without either sand or water, and are easily worked for
building purposes; and, being of a compact fine grain, they pro-
duce very sharp arrises, and receive a very smooth surface on the
face.

During the winter little work is done in the quarries in regard
to the stones; but they occupy themselves in sawing and squaring slabs about 12 or 15 inches square, and from an inch to an inch and a half, or more, thick, which are used for paving halls, galleries, and even some rooms inside their buildings.

But the most extraordinary use to which I have seen these square
slabs applied, was in the church of the Trinity of the Abbey aux
Dames. Two of the openings between the nave and the transept
were closed up, for the purpose of some repairs going on. I passed
through a door in the partition or inclosure, both of which appeared
to me of the same thickness. My surprise was great, and I examined
the edge of the opening, and found it of stone, and discovered,
upon close inspection, that the opening, about 10 feet high, was inclosed by these square thin slabs, about an inch and a half thick, placed on edge, put to gether with plaster, suffi-
ciently stable to allow a door to work in its aperture. I subse-
quently was told, upon inquiry, that the inside partition in rooms,
10 feet high, are formed of this material, and covered by occasion-
al upright studds, 10 feet apart. These partitions are admi-
rable, for they are very light, occupy little space, and form an ex-
cellent ground to receive the plastering on the surface.

The general character given of the Caen stone is, that all the
beds are of the same quality, and all equally adapted for building
purposes; but evidently from the information which I collected
on the spot, and subsequently in London, from Messrs. Luard, there
are modifications in each bed, as may be reasonably supposed, and
as experience teaches us in the quarries of other olitic stones in
Bath and Portland. Various veins traverse the beds in all direc-
tions, and have a white appearance; this white substance is equally
hard with the stone itself, and if a stone be laid with its bed
parallel with the direction of these veins, it is of little consequence,
but they, of course, indicate a certain unsoundness or division in
the stone.
that part; and if the stone be laid with this vein in a vertical direction, the block will run the chance of being fractured by a weight, or, if near the surface, it probably may admit the wet. These veins are not like those in the Bath stone, for the veins were hard, consisting of a series of fine crystals, rather like a marble; running always in a vertical or inclined direction, and not liable to separation. In general it is considered that the blocks of Caen stone may be placed in construction in any direction, except when the wide veins are perceptible. It is said that the most expert concrete work can hardly detect the different qualities of the stone in the block, when once they have been removed from the quarry, as the action of the quarryman's tool on the surface hardly offers any indication; and there is no appreciable difference in the appearance of the granular formation.

There are in the vicinity of Caen, even to a considerable distance, many beautiful varieties of this formation. At Falaise, about 30 miles off, higher up the Orne, is a fine compact stone, much harder than the Allemagne. Its texture is beautifully equal, and fine grained. Its price is one-third more than that of Caen stone, and, of course, the labour upon it is considerably increased. It is well adapted for exposed situations, and is used, I believe, in the quays and dock basins now constructing at Caen.

I was, of course, anxious to ascertain whether the magnificent and ancient buildings in the city could be relied upon as proofs of the quality of the stone in the Allemagne quarries, of which there is a traditional report handed down from one generation to another, that they are constructed. And, certainly, the lofty pinnacles and spires, and the solid high square towers, which rise up in clouds, defy the fury of the elements, for many years exposed to storms, and which are not more than a few feet thick in some points, have endured the violent alternations of heat and cold, wet and dry, present a sharpness of aris and smoothness of surface, as seen from below, that prove a considerable degree of hardness in the stone of which they are constructed. Less reliance can be placed upon the indications on the parts within reach, as there is every reason to believe the wantonness of the revolutionary phrenzy of destruction, and the Calvanesian zeal of misguided religious feelings, where there are many of the lowest parts broken away and considerably worn. But the attenuated and refined details of some "renaissance" finals, pinnacles, excepting buttresses, in the lady-chapels and apsidal aiters of the churches of St. Pierre and St. Sauveur, and St. Sauveur-le-Marché of the beginning of the sixteenth century, more minutely enriched and elaborately carved and subdivided than even the most refined details of the flamboyant parts near them, are as fresh and sharp as if executed within the last fifty years. Time and weather have not had, on the monuments of Caen, the same corroding hideous influence as on the edifices of Chester, Coventry, or Oxford. The graceful spire of St. Pierre, the summit of which is 220 feet above the market-place, and itself more than 100 feet high, does not appear less than six inches thick. It is in the lower part, and is reduced to 3 inches thick at top. The immense weight and exposed situation do not seem to have affected it in the least degree; and it may be quoted, if not for size, at all events for its grace, daring construction, and state of preservation, after 300 years trial, with its sister spire of our own Salisbury, erected at the same time.

At the same time, I am not prepared to assert whether the stone employed was all taken from the Allemagne, or from some other superior quarries; but the appearance of the stone justifies the tradition of its origin, and I know not how to question it.

CONWAY TUBULAR BRIDGE.

Experiments on the Completed Structure.

We are glad to be able to quote from a contemporary account of the experiments on the tubular bridge just completed, as given by Mr. Fairbairn, in a letter in the "London Patriot."  "We have solved an important problem in practical science; and, despite the prognostication of some eminent mathematicians, the whole of my experiments at Millwall have been more than realised. On Wednesday last, the tube was suspended upon temporary piers, 400 feet space; and with its own weight of 2,200 tons, its deflection was not more than 8 inches. With 300 tons of loaded trucks, the deflection was increased to 11 inches—being, as near as possible, in the ratio of 1 inch to 100 tons of load. The computed breaking weight of the tube is 2,200 tons equally distributed, excepting, of course, the height of its top, 80 feet. The deflection at 300 tons was under 1 inch, and, therefore, I am of opinion that it would sustain 3,000 tons before fracture took place.

It appears from this account, that the deflection under a load of 300 tons, is less than one foot—an amount which Mr. Fairbairn considers so small as to demonstrate the successful issue of the undertaking in which Mr. Stephenson, with the able co-operation of himself and Mr. Hodgkinson, is engaged. Certainly, when we consider the length of the structure, the multiplicity and complexity of the component parts, and the number of joints and rivets, we cannot but look to the accuracy of adjustment, and the extreme nicety of workmanship which effect the result stated, must appear wonderful; and the superintendents of this great work, who have concerned themselves with its minute details, and have felt the full force of its difficulties, must naturally estimate this amount of success more highly than comparatively uninterested persons can do. But iron, even of the best quality, is not perfectly elastic; bolts and rivets, though ever so carefully formed, are not mathematically true; and, therefore, it may reasonably be asked, if the structure sink one foot now, how much will it sink when the bolts have been worn, the bolt-holes enlarged, and the plates strained by the wear and tear of six months' railway traffic?

It is to be remembered, also, that the dynamical effect on the structure of the load in motion, is as much more than the statical effect of a load at rest. In the case of a jointed structure, of which the elasticity is imperfect, the dynamical strain and deflection would be certainly double the corresponding statical effect.

These remarks are not intended as forebodings as to the ultimate success of this magnificent undertaking. All that we wish to do is to point out how much the problem is solved, and how much remains in doubt. Considering the question abstractedly, we cannot deny the possibility of making the structure strong enough to bear its load. Theoretically, a tubular bridge may be made strong enough to bear any assignable load whatever—to be admitted to be admitted to be admissible. The question of strength would be obtained. For as each ton of metal would be disposed so as to bear something more than its own weight, we should, by continuing the process of increasing the thickness of the plates, arrive ultimately at a point where the strength was sufficiently in excess to sustain the loads of the bridge. But the question is, not whether the bridge may be made strong enough, but whether it may be made so at the least expense of material. It is to this point our doubts refer. Mr. Fairbairn says, that his experimental results contradict the conclusions of some eminent mathematicians; and the labourers who have applied the悬ension rods to the bridge: only let it be by rectilinear rigid diagonal bars—not by flexible or catenary chains. Comparing equal quantities of metal disposed—first, in increasing the thickness of the tube; secondly, in diagonal bars, acting either in the tube itself or on the hanging struts which support it; he has mathematically demonstrated that the efficiency of the metal may be trebled by the second method. Were it not dangerous to prophesy on a subject so novel and so difficult, we should be inclined to predict that this second method, in one or other of its forms, of diagonal trusses or diagonal struts, will be found necessary after the structure has been some time in use.

NOTES OF THE MONTH.

The Tabernacle.—Among the interesting exhibitions now open is that of the Tabernacle of Israel, at 58, Pall-Mall. The Rev. R. W. Hartaugh, a clergyman of the University of Dublin, feeling an interest as to the form and structure of the Tabernacle, has had a model made, with all the details elaborately executed, as gold and silver candlesticks, brass sacrificial instruments and emblazoned curtains. The models are two in number, and are executed in strict conformity with the texts in the bible, which describe the arrangement of the original Tabernacle of the Jews. The form of these models represents the Jews encamped in the plain of Moab, with the tribe of Levi seated in the Tabernacle in the midst of the encampment. The tent of the Israelites are in the distance, and afar off the Dead Sea and the mountain range. This is a most interesting tableau. The other model is devoted to the illustration of the court of the Tabernacle in greater detail. Here are shown the sixty priests, the boards of burnt offering, the table of the shew-bread, and all the requisite. The water-vessels are copied from authorities in the British Museum; the pillars are gilt, the candlesticks and vessels are of gold and silver, and the model of a high priest stands at the
LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM JANUARY 23, TO FEBRUARY 25, 1842.

Six Months allowed for Publication, unless otherwise expressed.

Henry Haywood, of Blackburn, Lancashire, for "certain Improvements in looms for weaving."—Filed January 22.

William Hudson, of Wigan, Lancashire, machine-maker, and John Dodgson, of Burnley, same county, overlooker, for "certain Improvements in looms for weaving."—Filed January 22.

Joseph Howarth, late of Derbyshire, commercial merchant, Middleton, but now of Devon's-lane, Bromley, engineer, for "certain Improvements in machinery for executing motive power, and for raising and working mills."—Filed January 22.

Thomas Toppham, of Ripley, Derbyshire, manufacturer, for "Improvements in the manufacture of thin-plates."—Filed January 22.

George Ferguson Wilson, of Berwick, Vanhall, gentleman, for "Improvements in steam engines and steam machinery, especially in the manufacture of candles and night-lights."—Filed January 22.

Henry Highton, of Heavitree, and Edward Highton, of Regent's Park, Middlesex, for "Improvements in electric telegraphs."—Filed January 22.

James Burr Mitchell, M.D., and Thomas Bent Woolwich, chemist, for "Improvements in the manufacture of soap and in treating products obtained in such manufacture."—Filed January 22.

John Collins, of Leominster, in the county of Hereford, architect, for "certain Improvements in furnaces, stoves, grates, and fire-places, and in stoves and other apparatus for preparing vegetables and other substances, and the generation and application of heat."—Filed January 22.

Thomas Robinson, of Coventry, ribbon manufacturer, for "Improvements in looms for weaving ribbons and other fabrics."—Filed January 22.

T. M'Grady, of Petworth, S. London, BANKS, Upham, Shankhouse, Durham, chemical manufacturer, for "Improvements in the manufacture of sulphur."—Filed January 22.

William Henry Barlow, of Derby, civil engineer, for "Improvements in the manufacture of railway bridges."—Filed January 22.

William Russell, of Lydbrook, in the county of Gloucester, iron master, for "an Improvement in the preparation of such bar-iron as is used in the manufacture of certain kinds of iron-work."—Filed January 22.

Alfred Vincent Newton, of Chancery-lane, mechanical draughtsman, for "Improved machinery for manufacturing shot and other balls." (A communication.)—January 31.

James Blackwell, of Winster, in the county of Stafford, sail proprietor, for "certain Improvements in evaporating furnaces."—February 2.

Robert Powle, of North Shields, Northumberland, gentleman, for "certain Improvements in the propelling of vessels."—February 2.

James Bird, of the Crown Arches, Works, Tulsehill, Glamorganside, gentleman, for "certain Improvements in propelling."—February 2.

Godfrey Anthony Emery, of Manchester, cotton spinner, for "certain Improvements in machinery or apparatus for twisting cotton and other fibres substances."—February 2.

Richard Clarke Burleigh, of Featherstone-buildings, Middlesex, gentleman, for "Improvements in busses for conveying or producing light and heat, and in apparatus to be used therewith."—February 2.

Jabez Brett, of Hanover-square, Middlesex, gentleman, for "Improvements in electric printing and other telegraphic apparatus."—February 2.

William Heywood, glorer, of Stone Bridge, Chester, chemist, for "Improvements in the manufacture of oil from balsam."—February 2.

William Bungay, of Beagle-street, Middlesex, for "Improvements in umbrellas and parasols."—February 2.

Jaspine Sevren, of Greenwich, Kent, captain in the French navy, for "Improvements in the propulsion in ships and other vessels."—February 2.

Luke Herbert, of Ryde, Isle of Wight, civil engineer, for "Improved mechanisms for reducing, grinding, and sifting bars, sugar, coffee, seeds, and other substances."—February 2.

William Peter Piggots, of Oxford-street, Middlesex, and Wardrobe-place, Doctors' Commons, city, for "certain Improvements in nautical instruments, and in the manufacture of cases for containing them."—February 2.

Jean Marie Magnin, of Ville Grasse, (Rhône), France, avocet, for "Improvements in machinery for sawing, embroidery, and for making corset and plait."—February 9.

Gustave Adolph Burdach, of Middlesex, gentleman, for "Improvements in obtaining motive power."—February 9.

Felix Douche, merchant, of Rosen, France, for "certain means, processes, and apparatus for conveying or producing light and heat, and in general, in many useful purposes." (A communication.)—February 9.

William Jerry Cannon, of Cambridge, solicitor, for "Improvements in the constructions of carriages for the conveyance of sheep and other animals on railways."—February 11.

The Right Hon. Thomas, Earl of Dundonald, Vice-Admiral of the White squadron of His Majesty's Kett, Knight Grand Cross of the Most Hon. Order of the Bath, for "Improvements in marine steam boilers and apparatus connected therewith."—February 11.

Horatio Black, of the town and county of Nottingham, lace-maker, for "Improvements in evaporation."—February 11.

John Watson, merchant, and Edward Carter, gentleman, both of Hull, for "Improvements in the manufacture of gauze."—February 11.

James James, of Chancery-lane, Middlesex, gentleman, for "Improvements in furnaces, and in the manufacture of glass."—February 11.

William Toddle, of Crosby-square, London, merchant, for "Improvements in distilling." (A communication.)—February 11.

John Weston, of Portland-town, Middlesex, merchant, for "certain Improvements in obtaining and applying motive power."—February 16.

Joseph Darby, of Great Bridge, Hants, for "Improvements in making communications between the guards, engineers, and other servants in charge of railway carriages, and also between the passengers and guards in the carriages, on damp and slippery surfaces where speed and certain communications are required."—February 16.

Edward Massey, of Middleton-square, Middlesex, watchmaker, for "Improvements in use and stoppage of sockets, and other instruments for cutting or carving wood or other materials."—February 16.

Edward Duncombe Lines, of Chelsea, and Samuel, Luis Freestone, of Low-lane, City gentleman, for "Improvements in the manufacture of colours, oils, and varnishes, and in the manufacture of brushes and other substances for getting vegetable substances for, and in the obtaining extractive matters therefrom."—February 18.

William Irving, of Tibgrove, Kennington, labourer, for "Improved apparatus for cutting or carving wood or other materials."—February 18.

James Nasmyth and Holbrook Gascoy, both of Manchester, engineers, for "certain improvements in machines and apparatus for forging, stamping, and cutting iron and other substances."—February 18.

[End of Document]
CANDIUS'S NOTE-BOOK,
FASCICULUS LXX

"I must have liberty
Withal, as large a charter at the winds,
To blow on whom I please."

1. Caryatides completely contradict Vitruvius's conceit, as to Ionio
and Corinthian columns being proportioned respectively after Gre-
cian masses and misses, for the real feminine or lady-like pillars
are far more bulky and robust than even the most masculine ex-
amples of the Doric order,—to such degree, in fact, that they would
be positively clumsy were they mere pillars, whereas variety of
form and play of outline entirely dissipate the heaviness which
would attend simple masses of stone of the same bulk. Of the
effect and value of Caryatides in architectural composition scarcely
anything is said by architectural writers, although it is that which
chiefly demands their consideration and remark; for as to the
origin or first introduction of such figures to perform the office of
columns, that in reality matters not a rush, notwithstanding it is
what exclusively occupies the attention of those who speak of them.
The current legend respecting the adoption of them into Greek
architecture, may be true or may be false; but at all events it is
not necessary in order to account for pillars being shaped to re-
semble human figures, such figures being frequent in the Egyptian
style,—of course with very wide differences as to taste and de-
signs, as columns could not have been employed in the same
Far more to the purpose is it to consider the aesthetic effect of
such statue-columns, and their value in architectural composition.
That while they greatly extend the resources of the latter, there is
direct classical authority for them, and that in an example fraught
with the full force of taste and sculpture, is at least sufficient to
prove the propriety of the taste so displayed has been called in
question, or rather has been peremptorily condemned. It is contended
that such figures both suggest painful ideas, and partake of the
preposterous. With regard to the first of these objections, it is difficult
to understand and therefore statutes of pillars should excite any idea of
pain if they themselves express no such feeling—which of course they ought not to do—but stand calm,
immoveable, and indicate perfect ease and tranquillity. As to the
preposterousness of employing human forms for office which living
human beings could not perform, if there be absurdity in that,
it is of a species which extends itself—or I might say, incor-
porates itself—with a very great deal of both architectural decora-
tion and ornamental design generally. It has been said that what-
ever is contrary to common-sense is contrary alike to good taste.
The validity of such dictum depends very much upon the latitude
allowed to the term "common-sense." If we are to understand by
it merely the knowledge based upon actual experience, a very great
deal that has hitherto been regarded as manifesting refined taste,
must be, on the contrary, said altogether, and pronounced to be in very false
taste. If Caryatides are to be set aside altogether, and pronounced to be in very false
taste, because they represent the human form contrary to
what we know by common-sense it is capable of, the same author-
ity of common-sense must pronounce statues employed as pin-
acles and acroteria on pediments or eaves as being equally repug-
nant to good taste. If a building is found to remain uncompleted
for a considerable time, where real persons—if they could stand there at all—could remain for only a
few minutes, and that at the peril of their necks and limbs.
Again, how can we reconcile with plain common-sense such
classical monstrosities as arabesques or human and animal
figures terminating in foliage? Nay, is there anything of common-
sense—that is, of plain, honest, matter-of-fact common-sense—in
the cramming a crowd of figures into a pediment, where half of
them are, perforce, crouching down? Or what shall we say to
such columns as those, or any others, or any method; as to stave
up the moulings of the head of an arch, in such manner that some of
them are nearly in a horizontal position? If common-sense is not
startled by them, it may surely excuse what are less at variance
with it—namely, Caryatides, which last are at once so picturesque
and astonishing that their very absurdity is the more likely to
excite our wonder. Their being frequently employed is not to be
looked for, on account of their expensiveness as compared with other
pillars of the same dimensions; still what prevents their becom-
ing too common by being applied on ordinary occasions, should
operate as a strong reason for introducing them where magnificence
is affected, and cost becomes a secondary consideration.

II. From what Mr. Gwilt says on the subject, in his Encyclopa-
dia, it would seem that Caryatid figures are by no means uncom-
mon features in architectural composition, for he tells us that "the
variety in quest of which the eye is always in search, and the pic-
turesque effect which may be produced by the employment of Cary-
atides, leads often to their necessary employment."

He reconciles the effect "necessary," with the opinion uttered by him just before, viz., that the purpose of support can be not only as well
but even better accomplished by a small order,—must be left to himself
to explain, which it would, perhaps, puzzle him to do; and puzzle
him also it would to justify the expression "often," by exhibiting
examples. In the contrast, or something less extreme, in this country
more especially, for I can call to mind only one in-
stance of the kind in the metropolis, namely, that afforded by the
church of St. Pancras. Yet, though he evidently entertains no par-
tiality for Caryatides, Mr. Gwilt appears to regard with favour
Inigo Jones's idea for the circular door in the palace of Whitehall,
which was intended to have two orders of colossal figures, answer-
ing to two entire stories of the edifice, which enlargement of scale
for figures of the kind is certainly no improvement upon the taste-
ful Athenian example.

III. It would be well were we to ask ourselves what is likely to
be the result of the present system of architectural copyism and
mere reproduction. The works so formed and fashioned will, by
and by, come to be looked upon, at the best, only as so many clever
counterfeits and imitations of what were previously living styles
of the art, fraught with vitality and with the actual impress of
the period when they respectively flourished. Just now, while we
are imitating, our imitations may interest ourselves, but they will be
of no interest or value to those who come after us. Historic inter-
est, then, we have no reason to see in such mechanical mimicry, and our utter want of inventive and creative
power. Do what we will, imitation of something done before there
always must be in architecture; yet, if that were not sufficient,
we affect and pique ourselves upon direct and express imitation. We
must be always doing something after somebody, or after something
else. And this of itself constitutes a prodigious difference between
the art at the present day and in former periods, our own being little
better than a blank with regard to original ideas. So that
with all our reverence—real or pretended—for precedent, we refuse to
admit the artistic liberty to which we are indebted for those
styles and examples of them which we now copy up as patterns of
excellence.

IV. The free exercise of invention in design is not to be con-
founded with mere arbitrary innovation. The inventive power for
which such freedom is claimed must, however, be of an organic
kind,—that is, be directed by sound principles of art. With them
and a cultivated taste for his guidance, he who has the spirit of an
artist in him may safely be trusted to his own impulses and ideas;
whereas he who has no insight into artistic principles, who has
never been taught to do himself to be more than what is possible
beyond the limits of the most ordinary common-place and jog-trot
design, for if there be a possibility of blundering he is sure to do
so. No matter in what style he attempts to disguise himself, his
vulgarity is certain to betray him, and his irrepressible Fecksnism
breaks through the outward varnish in which he has trusted in
his power to guard against it, for the simple reason that it is his
nature, and he has no idea of what he ought to guard against.
Daily experience confirms the truth of this: how many atrociously
vile and vulgar copies—or rather parodies and caricatures, although
intended for copies—we see of styles and modes of design and
composition that happen to have been brought into vogue—as, for
instance, the satylic "Palazzo" fashion introduced by Barry, which
has in many cases been either positively vulgarized, or else treated
in the most prosaic manner,—as if the intention were to prove
that miserable taste may be displayed in things that affect to
conform to precedent and to be perfectly free from caprice.

V. As to caprice, that term is frequently applied very unmean-
ingfully. It is very common for people to set down at once for
caprice whatever deviates from general rules and usual method;
thereby perplexing that ordinary and petty criticism which has no
other standard of judging than established routine precepts, in-
terpreting them, moreover, to the very letter. Such criticism is
unable to discriminate between what is mere caprice and what is
nothing else but a happy thought. If the latter is permissible,
that for which no satisfactory reason can be assigned by the author
of it; but, however contrary it may be to usual practice, that is
caprice which is done with deliberate intention and well-
studied aim at effects previously untried. And if to do well
merely according to precedent be meritorious, much more so must
be to do so and at the same time beyond actual precedent, creating
what in its turn will be recognised as valid precedent and authority.
It is proper enough to be perfectly well acquainted with precedent,
but to be tied down to it—to be made a slave to it, is ill. Those
who are incapable of thinking for themselves, take refuge in prece-
dent, and make it their stronghold, since it enables them to as-
sume a tone of authority, and to decide dogmatically without any
trouble of thinking.

VI. The adherence of rules will enable any one to avoid
positive faults; but between them and positive merits there is an
immensurate distance—one which defies calculation. In art, it is
very possible to be at once faultless and valueless—without any
specific fault, but also without any interest or any charm,—in a
word, to be altogether humdrum. Perhaps it is rather unim-
portant than not for architecture, that a great deal of humdrum is
of necessity tolerated in it: however worthless or unworthy they
can be as productions of architecture, buildings may as buildings
completely answer the purpose for which they are erected. Besides
which, it must be once erected, remains intact, subject to no
discredit of the art and the corruption of public taste. Humdrum
poetry becomes serviceable as waste-paper; humdrum pictures find
their way into lumber-rooms and garrets; but buildings of the
same or even worse quality cannot be so got rid of, or put out of
sight; otherwise a good many that might be mentioned would now
disappear.

VII. There is something startling, perhaps diverting also, in
the decidedly opposite opinions entertained by two of our architec-
tural professors with regard to Vitruvius. While Professor Hosking
speaks of Vitruvius as an architect of the highest order, and terms
his principles of architecture un Sofian, Professor Cockrell venerate
him;—as to vindicating him, that is quite a different matter, and what
he does not even so much as attempt, but leaves altogether un-
noticed the highly depreciatory remarks thrown out against his
principles by one of his most ardent admirers. The three volumes of
"Discourses," both in that publication and elsewhere. The ignor-
ing them may be prudent enough, but assuredly does not show much
of either courage or ingenuousness, keeping quite out of sight as it
does the fact that Vitruvius has of late years been violently im-
pugned—indeed reviled—by modern writers and architects. It was
declared valueless to the architectural student;—nay, not only
valueless, but in some degree mischievous also, by filling him with
absurd and idle notions, and affording him no insight whatever into
his art;—as also Vitruvius has been unjustly suspected and
vilified, it is only just to Professor Cockrell to say—though he
would be the first to reverence him—if he could;

instead of which, in his closing lecture this season at the
Royal Academy, he gave his hearers reason to suppose that the chief
accusation brought against him has but been by his German editor,
Scheiner, on the score of his Latinity. Schneider, it seems, was
merely a mere philologist, and honestly avowed his ignorance of the subject-
matter of Vitruvius's writings, which I take to have been rather in
favour of his author than the contrary, because, had he been capa-
ble of judging of the value of the matter also, hardly would he
have written so much, if the book of his was anything at all, and
his chief point in it was to show that Vitruvius was, undoubtedly,
one of the great traditional fames—one sanctified by invariable prejudice, partly or even principally be-
cause his books De Architectura represent to modern times all
that remains of similar writings by the ancients. That mere ac-
counting of his work may be the sequel, but then the words
being no one to share it with him; and it has been too lightly
taken for granted, that, writing in classical times, he must him-
self have been a competent judge and expounder of classical archi-
tecture. He shows himself, however, to have been at the
best of a very prudling turn of mind—notwithstanding his pompous
and priggish pompos, and to have been what would now be called a
mere "practical man," acquainted only with matters of routine and
the technicalities of his craft. While there is a very great deal in
his work which is utterly irrelevant, it being only in the remotest
distance to the purpose proper to it, while every other part of his
work may be taken to show exactly what he was; nothing whatever that gives evidence of the artist or the aesthetic
critic. There is not so much as any attempt to lay down and ex-
plain principles of correct taste in architecture. There is neither
argumentative criticism, nor reasoning, nor remark; but every-
thing is reduced to mind and memory. How it is possible for the most
part very obscurely also. What is to us his obscurity may partly
be laid to the charge of our own ignorance,—our not being better
informed as to various matters that were sufficiently well under-
stood by those to whom he addressed himself, but which, after all
attempts to explain them, can now only be guessed at. The
question then, as of what value is Vitruvius to us, especially at the
present day, when by means of various ancient buildings and
examples that have been from time to time discovered, explored,
and delineated, we have obtained a far clearer insight into the
principles and practice of the architects of antiquity than can possibly be derived from the writings of Vitruvius? In some
instances, obscurities in his text have been explained by what has
been observed in extant monuments; yet that only proves that the
latter are infinitely more intelligible instructors than Vitruvius, and
that accordingly he may now be dismissed by us, for any real advan-
tage to be derived from the study of him. Such study will, indeed,
not be found so altogether unprofitable; but it will not help in the least towards making him an artist; rather
will it be apt to render him a pedant, and obstruct the advance he
might else make in his capacity of artist, by withdrawing his at-
tention from what is his proper study as such; as has too fre-
quently been the case. Many would have been far greater pro-
claims in their art, if, instead of poring—perhaps stipulating them-
theselves also—over Vitruvius, they had thrown him entirely aside,
and exercised their own powers freely in composition and design.

VIII. The subject of the invisible—perhaps altogether imaginary
—curves in the lines of the Parthenon has been brought before the
Institute, but it was thought we should hear now more of it. Matters far greater immediate importance
than such vague difficulties and refined subtleties and speculations,
claim our attention, ere we advance so far as to be able to appre-
ciate such matters. In the invisibilities of architectural optics as those attri-
buted to the Greeks. Little less than ludicrous is it for us to pre-
tend to interest ourselves with them, when we complacently toler-
ate the most crude and spiritless school-boy imitations of classical
architecture, which chiefly show how very tall the pretended origi-
nals were superior to the latter. It is a tolerable subject to the
glaring barbarisms in taste, and the harsh contradictions with
regard to style, that are allowed to manifest themselves in copies
of that class, it is in vain to expect that we shall ever open them
wide enough to discover such philosophically-studied minutiae as
are visible to the eye. It is as much as was suspected till very recently, notwithstanding the diligence with which the Parthenon has been examined, not only by Stuart, but
by many others since his time. It has been ascertained beyond
contradiction, that Polychromes was—to use the term of the
architects and legitimate mode of architecture, embellishment, both for the Parthenon and other Greek structures;
and yet even that discovery has been altogether useless to us in
practice, inasmuch as we have not attempted to avail ourselves of it
in any occasion; and if we were to trace the decorum that would
be found in Vitruvius, it might be supposed that we shall ever think of making any new use of refinements in optical
effect that would not be perceptible to one person in ten thousand.
Let us provide the shirt before we think of the ruffles for it: when
we attempt to think how that we are capable of fully entering into the charac-
ter of classical architecture with genuine artistic sentiment for it,
it will be time enough to think of those exquisitely subtle and deli-
cate touches which are now imparted to the Parthenon. For us,
who show ourselves so obtuse as we do to many even tolerably pal-
itable qualities, in case it is less than exactly like Greek work,
which in point of imperceptible workings, is nothing less than absurd. Besides
which, Greek architecture has of late fallen into discredit with
us, we having at last found out that, as our buildings are neces-
rarily constituted, it is nearly altogether inapplicable by us in actual
practice. As a result, many, who like any other nations, are
deeply disturbed, are found to be—except in very particular cases indeed—anything like the genuine Greek physiognomy; so that the degree of resemblance aimed at and
obtained, only serves to render the departure from the original
style the more evident, particularly if the order be the Doric,
since that refuses to accommodate itself to any other purpose than a
simple colonnade.

IX. So very far are we from studiously calculating optical
effects with mathematical precision, that we do not seem to under-
stand—at least, not to be able to foresee—that difference of appear-
cances which, under the precise lights, white or black as it may,
every part shows itself equally distinctly to the eye, and the building
executed from it, in which last it is perhaps afterwards discovered
that much of the detail does not tell at all. Seldom is any calcu-
lation made with reference to the actual locality, and the distance
from which the structure will be generally viewed. Hence, when
erected, it is sometimes discovered that a building can be
seen only so far off that its lesser features are scarcely distinguish-
able at all, or else only from so close a point of view, that all the
upper part of it becomes so greatly foreshortened as to become
quite distorted, and altogether a different object from what the
geometrical design promised. It is not uncommon, again, to find
that while those parts which can be but imperfectly seen—or at
the best seen only in their general forms—are elaborately decorated,
those which being almost close to the eye show themselves dis-
tinctly, but in a way that the spectator had not been prepared for;
—and so they may be with regard to the design as seen upon
paper, but not as it is seen in the building itself. In many cases, the
merest indication of detail and finish would answer the purpose just as well as that degree of the latter which is now deemed indispensable, although the parts to which it is applied may be out of sight, or even so. Therefore, I cannot take the risk of the new Palace of Westminster to be a very great mistake, and a very costly one also. However exquisite may be its beauties of detail, they are valueless if, as really is the case, they are invisible, and cannot be enjoyed by being admired.

X VICTOR CALLIAT And it is there to be difficult to say, when we find among the examples referred to under that designation, in the index to Cressy's translation of Milizia's Lives, not only Barber's Hall, the Horse Guards, Heriot's Hospital, and other buildings which do not seem to belong at all to that class, but also the Monument on Fish Street Hill! We may therefore congratulate ourselves on having besides that, two more palaces which we have not reckoned before—namely, the Nelson and the York Palaces. A most agreeable surprise must it be to Mr. Raillont, to find that he has erected an entire palace when he attempted only to stick up a single column.

THE HOTEL DE VILLE, PARIS.

Hotel de Ville de Paris, Meur, Dessin, Grav, et Publ, par

VICTOR CALLIAT, sculpteur; avec une histoire de ce monument, par Le ROUX DE LENCY. Grand folio. Paris, 1844.

As the seat of the Provisional Government of the new French Republic, this edifice has recently acquired a degree of interest even with those who would be wholly indifferent to it as a work of architecture. Of course, it is as the latter alone that we notice it, and had the same means of doing so been afforded us, should have done so before. Still, late as we are in our notice of the splendid architectural publication whose title heads this article, we are not at all behind others, for we are, we believe, the very first to make mention of it in this country. It may sound odd to say that we detected—events and circumstances account of it, no otherwise such as the case, because anxious to speak of it without further delay, just at the moment when circumstances give the building an incidental importance, distinct from that which it possesses as an architectural subject, we are at present prepared for reporting only of the graphic part of the work, having no time to examine the literary one. The latter is, in fact, so exceedingly copious, and contains such a vast mass of historical matter, as to require very patient study, more especially as the form in which it is given is a highly inconvenient one for either perusal or reference. In our opinion, it would have been greatly better to publish the dates by themselves, or with only so much letter-press as was requisite for explaining them, and describing the present edifice architecturally; the history being made to form a separate octavo volume, either as a distinct work or not, as might be deemed expedient. Had that been the case, the order of the work would have been a very different one, and the divisions of the octavo of text, would have answered their respective purposes much better than is now accomplished. The former would not have been so inconveniently bulky; the other would have been a readable volume, whereas now, however readable the matter itself may be, hardly can it be said to be in a readable shape; whence the probability is, that very few will encounter the fatigue of reading it at all. The perusing the text continuously in its present shape would, to ourselves at least, be a formidable task; yet, fortunately, we are not particularly solicitous about matters of mere historical record... The whole edifice and its situation, which show no other relation to the edifice itself than what is derived from the latter having been the locality where they occurred.

Leaving M. Le Roux de Lency's portion of the work, we shall confine ourselves to M. Victor Calliat's department of it, who, we should observe, holds, or lately did hold, the office of Inspecteur de l'Inscription du building, and who employed five years in carefully measuring and delineating the various parts of the structure, having, besides, free access to the designs of MM. Godde and Lesueur, the architects employed for the new work. Until the recent amplification and alteration made by the Government of the three monuments of the French capital even in its present greatly improved and embellished state, the Hotel de Ville was of little architectural note, except as a souvenir of old Paris. The style of it had been voted "Gothique" and obsolete; and the actual design showed a system of decorative motifs which, according to Mr. Woods says of it in his "Letters," when speaking of the buildings of Paris, is: "It has a certain richness of appearance, although it is not in a style of architecture capable of great merit (?!) and even not one of the best examples of the sort. It is, however, as good as our Guildhall." As good as our Guildhall—as well might he have called it at once intellectually bad.

The initial edifice that formed the nucleus of the present greatly extended mass, was commenced in the reign of Francis I. viz., in 1533, after the designs of Domenico Boccadoro, or Boccadoro, otherwise called Domenico di Cortona, assisted by Maître Jehan Astelin, and the façade and the Cour d'Honneur, "now the middle one," in 1545, after the designs of Pierre Largilière, Mignard, Vanloo, and other masters,—or if not actually destroyed, removed, nor is it now possible to ascertain what has become of them.

During the Empire and the Restoration, the edifice underwent some partial alterations; but it was not until 1836 that it was determined to undertake improvement upon a comprehensive scale; and great as it was, the scheme has been carried out so successfully that the Hotel de Ville may be placed foremost among the architectural monuments that mark the reign of Louis Philippe.

If not particularly remarkable in itself, relative to the new construction, the edifice, which, in some degree at least, similar in purpose, is also contemporaneous with our own new Palace of Westminster, except that it is already completed, while the completion of the other cannot at present be predicted. Further, being in the Renaissance style, it shows what might be done with a few of our own building at Westminster, had the stipulated—for Elisabethan or Anglo-Renaissance style been adhered to, but at the same time treated with the same freedom and refinement as are shown in the parts of the Duchess of Kent's Palace, or their refacimento and enlargement of the Parian Hotel de Ville.

The improvements which the structure has received from them, not one of the least is that whereas it before showed only a single front—that towards the Place de la Grève—it now forms an entirely insulated mass, except to its three regular façades, the original or west one (now greatly extended) towards the Grève, the corresponding or east one towards the Rue Loubau, and of the two shorter ones, that facing the north towards the Rue Tixerandie, and that on the south facing the Quai de la Grève. So far, if in no other respect, it has greatly the advantage over the Palace of Westminster, one side of which, and that which according to the design is the principal façade, is altogether inaccessible, so that its elaborate decoration, requiring as it does the closest inspection, is completely away from view.

The façade, if it be not the front, but the one towards the Place—which was all of the edifice that then showed itself externally—was not quite 200 feet, but is now extended to upwards of twice that length, by the addition of two more lofty pavilions, similar in character, but somewhat varied in design, from the original ones. Hence, the general appearance of the edifice, which line of no other relation to the edifice itself than what is derived from the latter having been the locality where they occurred.

At the time when the inscription was in its present state, the edifice consisted of the three monuments of the French capital even in its present greatly improved and embellished state, the Hotel de Ville was of little architectural note, except as a souvenir of old Paris. The style of it had been voted "Gothique" and obsolete; and the actual design showed a system of decorative motifs which, according to Mr. Woods says of it in his "Letters," when speaking of the buildings of Paris, is: "It has a certain richness of appearance, although it is not in a style of architecture capable of great merit (?!) and even

---

* Pepys's representation of the building is exceedingly poor as to be scarcely intelligible, all the features being so very rudely expressed, that it is impossible to make out what the building is. We give general directions for the several parts here copied, as also to be guarded against. That so able an architectural artist as Mr. Allom is, should have given only a single exterior, and not so much as one inside view of so important a public monument, is to be regretted. Perhaps he himself, or his publishers, might have cast our circumstances have given a particular interest to that particular building. Let us hope then, that in the next edition of the French Classic, where is the "Third Edition," since he may there find many subjects for his pencil which he had passed over—among others, the Church of St. Vincent de Paul, and the Hotel des Beaux Arts, both of which would require to be illustrated by more than one drawing.

14*
movement, a confused, crowded-up look, and shows not a few disagreeable inequalities of taste. The new façades, on the contrary, exhibit a sober simplicity that is very becoming to the style. There is infinitely more of homogeneity of character, the character itself of the style adopted being purged from its little-nesses of manner and other defects. The architects—or perhaps we should say M. Godde,* for the other appears to have been only his assistant in the execution of the design—have given us the ideal of Renaissance—that is, French Renaissance, modified so as to be applicable at the present day.

Previously to its assuming its present shape and greatly extended dimensions, the Hotel de Ville had only a single inner court—a trapezium in plan, whose eastern side, or that facing the entrance, is considerably wider than the latter. Besides this, which is denominated the “Cour d’Honneur,” there are now two other spacious ones, that on the south side being the “Cour du Préfet,” and on the north the “Cour des Bureaux.” Yet, in the letter-press account, it hardly can be called—of the building, in Alom’s “France,” no notice is taken of this very material enlargement of the plan, but we are left to understand that there is only a single court,—a spacious (?) quadrangle, entered through the lofty arches in the principal front; whereas those entrances lead into the two separate new courts. The letter-press writer, the Rev. G. N. Wright, M.A.—don’t let us forget the M.A., though it does not mean Master of Architecture,—is one of those ready writers who pay more attention to quantity than quality; for he gives the credit of the present structure to Molinos, an architect who was only employed in additions at the time of Napoleon, which have since been entirely swept away. He also assures us that all the additions have been made “in the most exact and complete harmony with the original façade, which, as far as it means anything at all, means that they are little more than a skin covering.”

Although not very spacious, the inner courts are not the least beautiful parts of the structure; it is, however, easier to judge of their design than their effect, for they are shown only sectionally, whereas subjects of that kind require to be represented perspectively. The façades of the three courts are entirely new, and little more than a single general plane of facade, without advancing or receding parts—a geometrical elevation may be sufficient; but where several façades or sides—be they those of a room or of a court—are seen in combination with each other, the aid of perspective becomes requisite in order to convey an idea of the actual appearance. There ought, in fact, to have been a perspective view also of at least one of the façades, and it should have been of that facing the Rue Loubat, it being the finest of them all, and moreover distinguished from the others by a circumstance that is not likely to escape notice. For instance, there is a magnificent cupola surmounting the main entrance, especially one merely in outline, where there are no shadows to express the various degrees of relief;—the distinction we allude to is that in front, instead of being engaged ones, the columns of both orders are completely detached from the wall behind, at least sixty feet high, and of gigantic proportions. If, therefore, we come to fifteen arched intercolumnations in its length, and having a large and highly-enriched lucerne over each alternate intercolumnation.

From the exterior alone, a very imperfect idea is to be obtained of the magnificence of this noble pile of building, which may be one reason for its not having obtained the notice, or anything like the notice, which it may justly claim. Truly palatial in outward appearance, it is equally so within, containing, as it does, besides a very great number of various offices and other mere business rooms, no inconsiderable number of state apartments for municipal use. The ground floor, like the ground floor of all French public buildings, he made plain, elevations, and sections of various churches at Paris, amounting in all to about three hundred drawings; yet whether they were ever published it is not stated.

* From what is said of him in Nagler’s *Kunstler Lexikon,* we find that this architect (who was born at Toul on July 28, 1841) was employed, among other works, on the restorations of the Cathedral of Chartres, the Abbaye de St. Denis, the Eglise de St. Sulpice, and the antique *vieux Puits de Salon,* he made plans, elevations, and sections of various churches at Paris, amounting in all to about three hundred drawings; yet whether they were ever published it is not stated.

† It is mentioned chiefly for the purpose of informing us that it was from the central window of the west front that the people of the Ligue of Louis-Philippe afterwards addressed them, when Lafayette told them, that in him they had the true representative of the people, and that in this picture the present Revolution and the new Republic will probably react most disastrously.

bined architectural beauties, that taken altogether has not its equal in any royal palace of Europe.*

The most striking thing is something like an adequate idea of this part of the interior—from the lower vestibule is seen extending to the right and left (or north and south) a magnificent staircase, consisting of two wide successive flights of steps, carried in a straightforward direction, between arches supported his his own design, the marble columns of the second gallery or open corridors along its sides. On ascending to the upper landing, a highly enriched dome, though one of moderate dimensions, presents itself; and through this, and these ornamental compartments over the stairs,† the staircase is lighted. On looking back, that it is landing a most striking architectural coup de d’ail presents itself—an exceedingly rich perspective vista through an open saloon (the “Salle des Caristides,” over the vestibule below), into the other staircase.‡ It is, therefore, not without just reason that the staircase is spoken of in the text as a chief-courage of its kind. Even admitting that either of the staircases, in some respects, and among others in spaciousness as to width, yields the palm to the one in the Bibliothèque at Munich, the ensemble produced by the two greatly surpasses it; for as here managed, it is far more striking than it would have been, had the entire space been thrown open from end to end. In one respect, these staircases have a decided advantage over that at Munich, they being lighted from above, in the manner described,—consequently more picturesquely. Besides which, the Munich one leads architecturally speaking, to nothing, there being merely a number of small rooms and book-rooms, after all the extraordinary parade of approach to them.

Such highly-disappointing falling-off, both with regard to purpose and effect, is most assuredly not experienced in the Hotel de Ville, when on passing from either staircase through a noble hall, then to the Galerie* of the first floor, with its Corinthian columns, profusely enriched pendentives and plafond, and other elaborate decorations, expands itself in all its magnificence. This apartment, which comes in the centre of the Rue Loubat front, is 160 feet by 48, and 40 feet high, with thirteen intercolumnions on each side of entrance, and one at the right angle. The ceiling is divided into a series of arched and round lights, the former with balusters and lunettes; of which last, the thirteen on the side facing the windows are open, so as to form a gallery or series of tribunes for spectators, who, through open arches, have a view down into the “Galerie” from the floor or roof above the staircases, which run down the whole of the wall, and having pillars along its sides, is thus ingeniously turned to account, and made to produce much novel effect. A similar view is there obtained into the “Salle des Caristides,” through similar openings and the gallery carried around the upper part of that room, to which they afford access. The room just mentioned is on the front, and here the staircase is left, so as to stand on its own plafond—comes in between the “Galerie des Fêtes” and the “Salle du Conseil Municipal,” as well as between the two staircases; so that from this point—a most happy “episode” in the plan—one can already see, whether we look towards the “Salle du Conseil” with the “Cour d’Honneur” beyond it, or towards the “Galerie,” or towards either of the staircases. In fact, this part of the plan is eminently replete with piquant complexity—or what seems to be complexity—and variety of effect; and it is all the more striking, because it unexpectedly opens a vista branching out from one side of the “Galerie,” and which, therefore, breaks up that excessive sameness of arrangement which, so dull and unartistic in itself, is so prevalent—we might say so uniformly a defect in continental buildings, not of a single city, but of a whole nation.

There is, besides, a more than usual degree of variety and play in other parts of the plan; for instance, in the several saloons in connection with the “Galerie” at either end of it. One of these bears the name of the “Salon Louis-Philippe”—an appellation, which, now doubtful, will be reformed; another that of the “Salon Napoleon.” Then there is the “Salle des Banquets,” respecting which, however, no information is afforded, nor does it show itself.

* After all, such omission on the part of the letter-press was perhaps judicious, because to have spoken of those parts of the interior as they deserved to be, would have been accusing the artist of culpable omission on his part, in not describing any of them more fully, and more especially of interior designs, in which his peculiar talent, more especially on interior work, would have more than ordinarily shone.

† From the perspective view of the staircase, it appears that these compartments in the angle are somewhat new, and as they are at each end. The case is divided in two stories, and the staircase is lighted by three windows, the lower one of which is a large rectangular area in one side of the staircase, the next smaller, and the last almost square, in the other. The whole is nothing but an arrangement of windows or doors, with respect to which we are left to conjecture.

‡ With regard to more general disposition of plan, these staircases are somewhat similar to those in our National Gallery, but other resemblance there is none. In all other respects the difference is amazingly great, nor need we say which side the me. med. superiority lies.
in any of the sections; and a grand saloon of reception on the south side of the building, which forms altogether a space of 80 feet by 60, where the presence of three rooms thrown open to each other by means of three large arches on two opposite sides of the central one. This saloon and the “Galerie” form the subjects of two most exquisitely-elaborate perspective views, replete with a multiplicity of the richest and most delicate line, all the grandeur and precision true marvellous. The other perspectives are, a view of one of the new staircases looking from the upper landing towards the “Salle des Cariatides,” and one of the old Staircase as seen from below. There is also a detailed elevation on end of one of the “Salle du Trone,” showing one of its chimney-pieces and the large casement which is placed the spacious mirror over it. Unfortunately, we are left to desiderate a perspective of the “Salle des Cariatides,” which would have been highly welcome, because, although it comes into two several sections, it is on such a scale, that little more than its general aspect can descript, as made out, and the effect which is of a peculiar kind—is left to the imagination. Many of the plates are occupied by details and ornaments of both the old and new portion of the edifice, and show how elaborately it is finished up.

One important apartment and architectural feature in the building, which we have not yet mentioned, is the “Salle des Elections.” This is on the ground-floor, immediately beneath the “Galerie des Freres,” and of the same dimensions, except that it is somewhat shorter, and, as may be supposed, considerably less lofty. The columns here are of the Doric order, and are brought forward to a greater distance from the walls than in the upper “Galerie.” We will now conclude this account—after all, but an imperfect one—by saying, that not only is the edifice itself a most noble and tasteful monumental work, but M. Victor Calliau’s publication illustrates it—if not exhaustively, yet sufficiently to enable the visitor to understand the value and admiration of each detail of the building.

It is not long since the Archiit of the New Dublin Museum stated that he had undertaken to act as patron and to supervise the construction of a new church, which should be a memorial of the martyrs of the Reformation. The scheme has now been carried out, and the result is a building of great beauty and dignity. It is a most excellent example of the Gothic style of architecture, and is worthy of the attention of all who are interested in the history of Ireland.

ARTS MANUFACTURE EXHIBITION,
AT THE SOCIETY OF ARTS’ ROOMS, ADELPHI.

The Exhibition at the Rooms of the Society of Arts deserves particular notice, because it shows that the workmen of this country are as capable of producing artistic works as are those of any other country. The Exhibition is well arranged, and the objects on show are of great variety and excellence. There are paintings, sculptures, bronzes, and paper-hangings,—to the Prussians for iron castings and embroidery patterns,—and to the Italians for objects of art, that we began to set up schools for giving our workmen knowledge of design. The tax we pay to foreigners for our lack of knowledge is so great that it would hardly be believed; we spend millions yearly for goods that we ought to be able to make as well; nor does the evil end here, for as we cannot make for ourselves, so neither can we meet the foreigner in the market abroad. This loss falls, too, upon those who have no need of a knowledge of design. Because the French can bring out silks, satins, muslins, cottons, and shawls with better patterns, the English spinner and weaver of plain goods, the machinist, the drysalter, and the merchant, lose a very large share of employment.

It is good that it should be so, that there should be a tie by which all are bound to work, for otherwise there would be no getting any change, for many would give no help to bring it about. Nothing is easier than to show that the machinist, who deals with hard and stiff forms, and who thinks taste is as much beyond as beneath his care,—nothing is easier than to show that even he, the man who is enabled largely for the use of which has a share in the welfare of art. If more silks and cottons, fancy and stained papers, carpets, shawls, furniture, and glass can be sent abroad, more machinery must be provided for their production. Mr. Fairbairn and his brethren at Manchester, the machinists at Glasgow, and the rest of our manufacturers, are so full of zeal and ought to know that they have a fellow-feeling in the right growth of the arts of design. If a School of Design be good for anything, it ought to be good for making the trade of the town in which it is greater: it ought not only to better the goods now made, but new ones should be evolved which are not manufactured by the foreigner, or such as we cannot now send abroad. Therefore, we say this has as much to do with the machinist as with any one; but we say that art has to do with all.

Pleased as we were with the Exhibition now open, we cannot but see that what has been done as yet has not carried art down among the people. The works in the Adelphi are either for the higher or middling classes, those who are already cared for—and not for the people. We have always held, from the first time that we undertook to write about it, that art must not only bring forth good works, but cheap works; that it could be that which would bring the dwelling of the working-man, as well as in the drawing-room of the rich. The earthenware, the glass, the paper-hangings, the furniture in the smallest cot may be as well made as those in the abode of a king,—while taste shown in them will do much more good than the most ornamental work, as it is a matter of something else; and we cannot have a people powerful in the art, unless they be well taught. The Society of Arts have the chance of leading in this path,—indeed they have given a few prizes; but we call out again, that more ought to be done. Many working men and women and their children will, no doubt, see this Exhibition, but they will go away with the thought that such things are not for them, and that the rich only are happy in being able to gratify their eyes with such sights. Thus, the great teaching of the Exhibition will be thrown away; for we hold that working-men will be a greater feeling for what has been done; the art will bring a charm to their own dwelling, than as a mere means of livelihood at the will of the rich.

Felix Summerly has taken upon himself a task which is truly work. He has written these days, he wants a Felix Summerly for the kitchen as well as the drawing-room: and he hopes he will take this further task upon him, that some one else will. Mr. Cole, as Felix Summerly, by choosing this path in art, has made himself a good name, as Mr. Hay has by choosing house-painting; and Mr. Scallon that other men who have taste and skill would follow, and take each some branch in which he has artistic knowledge useful. Sir Walter Scott spoke most wisely when he led Mr. Hay to follow house-painting instead of high art; for although Mr. Hay’s powers of mind cannot be doubted, we could much better have an Edward Lear or a Wiltshire, the one who by his works and his writings has done good to a whole trade, and has taught hundreds of workmen that they may use theirs hands and eyes as well as their heads.

In the late free-trade speeches in the House of Commons, we
were much struck by what Mr. Wilson said, that the only goods sent out in 1847, on which there was no falling off, but which were more worth, were silks sent to France, a trade which has grown very much, and which some few years ago would hardly have been believed. If we try we can push the French home, but then we must set about it in the right way, not narrow-mindedly as we have hitherto done, but boldly and skilfully. The workman must be as well taught in France as in this country; he shall do no good.

Mr. L. must not have him kept back for fear he should turn out a master, and come in the way of some Royal Academician hereafter; but we must have him as well taught as the Royal Academician. The ground-work of art is one and the same, whether for a paper-maker, or a jeweller, a Landseer or a Gibson; and I believe that often, more taste is shown in some glass, porcelain, and japanned furniture than in the many landscape and Art-Unions paintings which deck the walls of the Royal Academy. So sorely has the School of Design been managed by the Board of Trade, that we are still no better off, though we have been eight years ago, because there are not a better and fairer feeling for the arts of design than now.

Since Somerset House lost the spur of the Society for Promoting Practical Design, in Leiceste-square, it has gone on but slowly, and it has done nothing for spreading a knowledge of the arts of design among the people.

The Board of Education is as much behind-hand. Though drawing is as useful to the child of a working-man as reading and writing, and though Mr. Wyse has for years brought before them, masters and mistresses in National and British and Foreign Schools, they have not signified the least desire that the schools should teach it. The few who do, teach drawing only to a small number of the elder boys, however willing the younger ones or their fathers are that they should learn.

Little or nothing too has been done to teach drawing to girls, so as to teach them to earn a livelihood in many trades. There is a great deal of drawing that is done which is of great use, both in the trade of flower-making, which is a new one, and in which in 1841 there were a thousand women at work, has now grown very much; but still, many thousand pounds' worth of these flowers, which are better made, are brought over from France.

It is hardly fair to say anything about the Exhibition without speaking of the Catalogue, which will do as much good as the Exhibition itself. It not only tells us what the Society of Arts did last year, and what is shown this year, but it lays down a plan for spreading wider the good the Society is now doing. This plan is followed up in three ways. First, by sending to the country Schools of Design objects shown in London each year, and thereby to bring it to bear upon the scholars and workmen throughout the country; and second, to have a great show every three or four years, to be held in a building raised at Charing-cross. Altogether, there is much encouragement in this, and we wish to add that we are thankful to the Society for the work they have done, and we hope they will have the help of the Board of Trade, and of the Board of Works, in carrying out the two plans. Indeed, the former Board have already made known their good-will towards it.

There are so many things worthy of being named, that we are almost kept back from saying anything, because we cannot speak of all.

The bronze and iron castings show that we have made way; but we must not hold till we have got beyond the Prussians and the French, as a few of our best are to the country Schools of Design. Stewart and Smith, and Mr. Messager, are very good; and the last has sent some good bronzes, as Mr. Hatfield has likewise done.

Messrs Leighton, the book-binders, have sent a few designs by Luke Limber (John Leighton), and some book-covers in paper-maché, which are very ably done, and show that their trade is not behind-hand. Indeed it is perhaps doing more than others to spread taste among the people.

The carvings in wood by Mr. Jordan's machinery are truly wonderful. They are as good as those of Grinling Gibbons, or of any of his school, and free from them which shows the hand of a master, rather than of a machine.

Mr. Drayton, it will be seen, has brought forward his new way of silvering glass, by which he can now silver the inside of cups and bowls, plain or carved.

The improvements by Mr. W. B. Simpson are sure to strike the looker-on, for there is a power in them beyond what has been seen in decorations. The cartoon of "Loyalty," from Mr. Redgrave's fresco in Westminster Hall, is so good, that it seems the handiwork of a skilful painter; and we can hardly believe that it is not so, for it is so unlike what we see in the generation of decorators.

We think this new process very likely to spread a knowledge of art among the people. There are many places where it can be used, and many joint-stock undertakings which will give it their help. For first-class waiting-rooms in railway stations, for board-rooms, offices, banks, assurance companies, and docks, it might be well applied. There are places where we are sure, willingly lay out a little money in what would please the public, and do credit to themselves. A set of likenesses of engineers would fit a waiting-room well. We would name Watt, Trevithick, the two Stephensons, Bunsen, and Locke. Many paintings bearing on trade might be shown, as Mr. Lee finding out the stockling room; Queen Elizabeth giving a charter to the East India Company; Drake teaching ship-building to Prince Henry in the Tower; the Marquis of Worcester likewise in the Tower making our cam-engine; King William's show chart to the Bank; the Duke of Bridgewater and Brindley overlooking the works of the Bridgewater canal; Arkwright and the spinning jenny; Watt and Dr. Robison making experiments on the steam-engine; Don Ricardo Trevithick directing the putting together of a steam-engine in Peru; Peel, Huskisson, and George Stephenson witnessing the starting of a locomotive on the Liverpool and Manchester railway.

Some of these have been already painted, and there are many other subjects shown in Westminster Hall which might be chosen by Mr. Simpson, as an early English trial by jury, Alfred manning his ship, and first sign of the discovery of America. The inland work from Messrs. Holland and Sons shows that in this branch the French and Belgians are not before us, and give hopes that we shall in time drive them out of the furniture trade to America. The taking the duty off foreign woods now allows our works; what can be done with English oak, mahogany, and ash and deal, Mr. Heathcote shows in his designs.

The only fault we find is with the centres of some of the tables, which in Nos. 7 and 8 are very ugly.

The copy of an antique shield (No. 10) is a favourable specimen of iron casting.

Nos. 11 and 12 are a very good application of papier-maché to picture frames, by Mr. Biesfeild.

The papier-maché cheval screen by Jennens and Bettridge has been got up with great labour. It is called in the Alhambra style and decorated with Arabic inscriptions, but we neither like the style nor the composition. We think the labour was misapplied. The colouring of the frame, gold upon a warmish white, looks tame without being rich.

Most of the encaustic tiles by Minton and Co. are dull in colour, which arises from the attempt to apply all colours, instead of being the true encaustic, or white body, with a Lisbon or Spanish glazed tiles. We cannot but wish that the old Flemish glazed chimney-tiles, or something like them, were brought out again. An old chimney-corner, with its set of bibie tiles or Flemish landscapes is a story book in itself, and pleasing to old and young. If we wish to bring the artistic way of the old churchwardens, with maps, would be welcome in schools and many other buildings.

Mr. Copeland seems a worthy follower of Wedgewood. His works in earthenware are amongst some of the best in the Exhibition. The taste and care shown in them cannot be gainsaid, and they keep up our fame in this trade, which is worth so much to us. The English earthenware is now the best in the world, and much of it is sent abroad. Indeed, it is a great staple, and worth the more to us as the work and the ware are all our own, only some of the colours being brought from abroad. By the care given to the higher end, we have the power to be able to put down foreigners in that branch of the trade likewise.

There are so many good works of Mr. Copeland's that we can name very few. An earthenware wash-stand (No. 37) is a very good design. It has a blue ground and white borders tastefully drawn. There are many other jugs and bowls well worthy of praise. The wash-stand No. 86 we do not like so well; its effect would depend wholly on the hangings which might be used in the room. The enamelled porcelain cups and saucers, Nos. 139 and 140, show the resources of the establishment in decoration.

The produce of Mr. J. W. C. Whiting has been made in the application of porcelain and painting for this purpose. The lock-furniture and bell-lever, likewise in porcelain (No. 170), are richly ornamented with gold. Porcelain is now being much used by builders, as is likewise glass for ornamental purposes.

The large collection of Chinese porcelain shows Mr. Copeland's power in what may be considered a more purely artistic department. This material has been employed by the Art-Unions for prizes, and promises to be very useful in spread-
ing a knowledge of the works of our best sculptors, for in effect it comes near marble, and in cheapness near plaster. It takes a middle place between marble and plaster, and being more lasting than the latter, is likely to be very much used by the middle classes. We fear, however, that it will give us in sculpture a school of statuettes, as we have had in cabinet pictures, and so far draw away the public mind from high art. Still, we welcome the statutesque porcelain and the Parian as a good beginning, and we can take the evil when they come with the less remorse, as now sculpture is far from being in the most palmy state. This kind of copy porcelains, like the later cardboard to the artist, for marble is a material costly in itself and hard to work, and therefore the sculptor gets few orders for a good study, and few are fond of casts. Now, a small gallery of groups can be had for a very small sum, and no one need be ashamed of having such works in his drawing-room. Illustrations to this we could notice the Narcissus, after Gibson (No. 209); Innocence, after J. N. Foley (No. 210); Paul and Virginia, after Cumberworth (No. 211); the Return from the Vintage (No. 212); Apollo, after Wyatt (No. 214); Cupid chained (No. 216); and Ondine, after Pradier (No. 218). The busts do not tell so well.

The Cupids holding a Tazza (No. 182) is a very good design for a flower-stand, in statuesque porcelain. Mr. Copeland is very successful in the Portland Jug (No. 209), and the same may be said of Mr. Henley.

Another work of his we shall name is the Armada battle (No. 217). We are likewise pleased with this vase after Cellini (No. 223).

Mr. Chamberlain, of Worcester, have sent some very gorgeous statuettes, as well as painted, and enamelled. Mr. Magnus, of the Pitilico Slate Works, has sent slate chimney-slabs, likewise table tops, which are worthy of notice by builders. Mr. Pratt's Anglo-Etruscan vase, in the Great Room, is very pleasingly worked.

The large candelabrum must be the work of an architectural student, and have been chosen for the prize by an architect. He is what some architects call classical, and what other people call tame, stiff, and bald. We think the prize is thrown away, and we should have been more pleased with a copy of one of the chandeliers in the Metropolitan Museum.

The prize lamps are not much better. They may catch some eyes, being in silver, but are poor and common-place. We wish there had been more designs for silver-plate. One very good is No. 348, an adaptation of the trumpet lid for a dessert-stand.

The papier-maché productions to our mind show much more splendour than taste. They are too much in the gawgaw and Vanxhall way.

The "Repose" arm-chair (No. 242), is very unluckily named, for there is no repose in its composition, and there can be none with it. Its arms, Mr. J. C. Horsey is the inventor, but his skill is quite thrown away, for the reliefs have no effect. The terminal figures, in whatever material they may be finished, will be indistinct.

Mr. Nicholson has shown a very elaborate shell camel (No. 249), but the subject is too complicated, and therefore indigestible. M. A. Nicholson has the same defect in his camel cutting is worthy of care, for in Paris it goes to work to many hundred men.

The glass works (Class XI.) are so very good that we hope they are an earnest of our making a great trade in glass, and becoming free from the Bohemians and Germans.

The Decorative Art Society is doing so much good, that we look forward to see some other society raised which shall take in a larger class of workmen. There is room for a great deal to be done, and we feel very strong hope from what we call the small exhibition of the Society of Arts—small because we are sure we shall soon have much larger exhibitions held under its care.

INDIAN RAILWAYS.

Indian Railways and their Probable Results, with Maps and an Appendix containing Statistical of Internal and External Commerce of India. By an Old East Postman. The Editor, London: Newby, 1848.

We are now in 1848, and Indian railways remain where they were, though the East India Railway Company has got a guarantee and leave to begin. This is a hard lesson, but one which is of no good so long continued, and it will, we fear, find its little better in the future. Governments are not ready scholars, even in the matter of revolutions. We have always upheld the freedom of joint-stock undertakings, as the best safeguard against speculation and the want of it. The East India government were fearful in 1843 of the gambling madness of the times. Scheme after scheme was brought before them, money was held out freely, but many a back-frightened soul set themselves down in what they held to be a quiet and orderly way, to lay down rules on which railways should be carried on and shareholders should pay their money. Following in the path of the Board of Trade here, they sent out to India a railway board, with Mr. Simms at its head. He has done as well as he could, he could not have done some long blue-books, from which, however, we are sorry to say, we have learned no more than we knew before, so that they have in no way put railways forward one inch. Everything has to be tried still; Mr. Simms has given us no answer as to embankments in the hills. Germany has changed, long before it will. We must learn to observe for sleepers, how works are to be carried on, nor one single point in engineering has he settled,—and from no fault of his, because experience is the only guide and judge. Therefore, three years have been lost on this head, and instead of beginning with or four years' experience, we are as far behind-hand as we were before. It is during the first three or four years that the greatest changes are made, because it is the time of experiments; every day shows something, and instead of trying to settle the engineering of India before-hand, a wise man would wait for practice to guide him in many things.

India has needlessly lost so many years of railway transit; by this time the traffic of the Ganges would have had some small help from railway works. Perhaps a couple of hundred miles of railway would have been open; and if only so much, or even less, still would have been the great, because the saving of a railway is the saving of a day in the communication with the upland. The opening of a railway would have been felt by the steamboats, and more of them would have been put on the river, while branch roads would have been laid down to reach the railway. The making of a railway is, as is well known, only a small part of the good which is to arise. The railway will be the trunk towards which steamboats will run, and roads be made. The traffic will be always growing, so that at each step food for new railways will be found. The steamboats have shown this, though not so much. At first six small steamboats were run, sometime after six more, and latterly six large steamboats have been put on, and there is a call for more. All are paying well, though there is more than four times the power that was in the first instance held needful. We have heard of railway carriages, carrying their own rails with them, but it may be said of Indian railways that they will carry their own traffic with them.

When we come to the money part of the question, and say that three years have been lost, we do not give a right idea of the evil which has been done. Time in the share-market cannot be trifled with. When Louis Philippe's death or fall has been long hanging over us; it was known that it must happen, and that when it did the share-market would be utterly upset. Never was it so needful to make hay while the sun shone, or be very careful in timing in sight, and there was no time to be lost. In the years 1843 and 1846, any money could have been raised; in the years 1847 and 1848, no money can be raised,—and who dares look forward with hope?

If the share-market were as law-makers wish it, and as they have tried to make it, it would be very well; but unhappily it is not so. It does not work so smoothly as they think it may; it has its ebbs and its floods; sometimes setting in with a full tide, whirling and eddying round, the waters rising to the top of the flood, and then being set out with powerful suction and leaving all bare. People were wonder-stricken that there should be gambling in 1843, as if there never were before; and though they were quite ready to say that a heavy fall would follow, they did none the more wisely. Time has shown that while share-gambling is going on, railway-making is going on; and when share-gambling is at an end, money cannot be raised even for the most useful undertakings. There is a cloud hangs over all, the good and the bad; and though those who have helped to make the storm worse may wish it otherwise, the good feel it as much as the bad.

While the share-market flourished, and the East India govern- ment was thought to give an example, the railway was begun, they stopped short, as if they had time in their own hands, and could wait as long as they pleased. They have so often set up kings in the east and put them down—they so often send out their word, and a mighty kingdom springs up or is cast down, that they thought they had only to speak, and railways would be made whenever they liked. Had they then, as they were told, given the
of late years has laid the way for railways. The steamboat has shown the Hindoo that speed can be got, that goods can be brought up quickly, and they are ready to believe that railways will do for them what it has been held out they can do. India waits only for railways, for the locomotives to come and spread as many arms over the land as they have in England or America.

In Southern India the companies are still less ready to begin work, so much have they been weakened by the loitering of the standstill government, but as railways are fully as needful there as in the north, we must see that the steps are taken to bring them forward. The growth of cotton in Bombay and Madras is kept back by the want of railways, and a little help only will enable the merchants and people of those two presidencies to make their own railways. They have come forward most warmly and although their late losses have lessened their means, they will be found ready to follow up the lead of the government.

Railways in India must be made, and they must be carried out as joint-stock undertakings; for whatever may be the want of power of these latter now, the government in India are no strangers, and always find it hard to raise money. Let us hope, as so much blame belongs to them for the hindrances they have hitherto thrown in the way of railways, that they will see good to make a change, and do all they can to make up for lost time. If they do not do it of themselves, the British government must do it for them; for if the cotton-growers of India cannot be heard, they will be heard here, and the cotton-weavers of Manchester have already spoken out. We cannot be left in the power of America for the cotton, on which our great staple manufacture depends, and whereby so many Englishmen live luxuriously in price.

The third edition of the book before us is on the same plan as those that went before it. It is enlarged by some new extracts, which are put together without any great regard to order, and the staple is still from the works of Mr. Macdonald Stephenson. The right title would be "Indian cotton, from the works of Mr. Macdonald Stephenson, with other matter by an Old Indian Postmaster." Except Mr. Stephenson's materials, the best thing in the book is a map of the lines of railway in Northern India.

THE WICKSTEED ENGINE.

Mr. Wicksteed was the first to introduce the Cornish engine into the metropolis, and he deserves great credit for his exertions. The first engine was put up about four years ago, when a description of it was published in this Journal. The second, which is larger, is named the Wicksteed engine, and is erected at the East London Water Works. It was started to supply water to that company's district in June 1847, and is the largest engine hitherto erected in London; the invention was by Mr. Wicksteed, who is engineer to the company, and was erected under his superintendence. It was manufactured by Messrs. Sandys, Carne, and Vivian, of the Copperhouse Foundry, Hayle, Cornwall. The diameter of the cylinder is 90 inches, the diameter of the pump 44 inches, length of stroke 11 feet, and it pumps 90 imperial barrels at each stroke. When working at the rate of eight strokes per minute, it raises 5,792 gallons per minute, or 8,340,480 gallons per diem, 84,563,200 imperial barrels per annum. The power when working at this speed is 200 horse-power. The main beam is 39 feet long, weighs 33 tons—it rests on a cast-iron main gudgeon 16 inches diameter, and the whole is supported by four columns and an entablature of cast-iron, designed in the Grecian-Doric style. The plunger with its appendages weighs 43 tons, which mass of matter is raised 11 feet high at each stroke of the engine. The pump-work is supported by two casters weighing each 10 tons, and is strongly bolted down to a mass of masonry in the foundations. The boilers, four in number, are cylindrical, 34 feet long, 8 ft., 8 in. diameter, with an internal fire-tube four feet in diameter. The diameter of the steam-pipe is 16 inches. The total weight of the engine pump work, in casters is 14 tons, and the whole cost was £10,000, or £50 per horse-power, or about £24 per ton.

The quantity of coal consumed by this engine, if working at full power, is about 1,500 tons per annum, and the quantity of coal that would be consumed by the best of the ordinary non-expansive engines in doing the same work would be 6,400 tons; showing a saving in favour of the Cornish engine of 2,500 tons, which at 1s. per ton is £1,250 per annum, and 1½ per cent. upon the cost of the engine for coal only.

COAL DROPS, AND MIDDLESBROUGH DOCK.

(With Engravings, Plate VI.)

Account of the Drops used for the shipment of Coals at Middlesbro'-on-Tees, with a description of the Middlesbro' Dock. By George Turnbull, M. Inst. C. E.---(From a paper read at the Institution of Civil Engineers.)

The dock was commenced in the spring of 1840, and was opened for trade on the 19th May, 1842. The general form of the dock and its position with respect to the river Tees will best be understood by reference to the annexed engraving. It possesses an area of 9 acres at the water surface; the approach is by an entrance channel, more than a quarter of a mile in length, cut through the sand banks of the river, kept open by means of occasional sluicing from the lock-gates, and also through culverts built in the lock walls for that purpose. Some apprehensions were entertained of the practicability of keeping open the entrance channel by these means, as there is much shifting sand in the bed of the river Tees, and every interference with the current of the river produces marked alterations in the form and position of the shoals or sand banks. Due to deliberation, the scheme was at length carried into execution, under the sanction of the Tees Navigation Company, and the result has been marked with the complete success which was anticipated by the projectors; the channel was dredged out to its full depth, the slopes and banks were covered with a paving of rough chalk and stone, and after a trial of nearly three years the channel is now in a better state than when it was first made, and is kept up at a very trifling cost.

The entrance lock is built principally on a foundation of hard sand, and on account of the quantity of water found in it, an unusually large proportion of piling and wooden platforms were required in the foundations. The lock is built of stone, chiefly from the Byker quarries, on the river Tyne; it is 132 feet long and 30 feet wide; the depth of water in 13 feet at neap tides and 19 feet at spring tides: the bottom of the dock was excavated to the depth of 3 feet under the level of the lock cills.

In connection with the dock, a branch line was laid down, diverging from the Stockton and Darlington Railway and terminating in ten double lines, leading to the ten drops (1 to 10) situated on the west side of the dock. The raised platform of a triangular shape, covered by these diverging lines of railway, comprises an area of 15 acres, and affords spare room for 1,200 loaded wagons, or more than 3,000 tons of coal, besides means of egress for the locomotives with their trains of empty wagons. This great amount of standing room forms a principal feature in the arrangement of these works, as in the district, of which this is the shipping port, there are numerous descriptions of coal, several of which come down the railway in the same train; a separation is made on the platform, and each colliery having its own drop assigned to it, the wagons, with the proper description of coal, accumulate in one branch, and descending along the railway, which is so inclined as to permit the wagons to move by their own gravity, the shipment is carried on with much facility. An inclination in the contrary direction is given to the empty line, sufficient to allow the unloaded wagons to move of themselves, by which means some saving of horse labour is effected.

The cost of all the works connected with the dock, including the branch railway, raised platform, permanent rails, dock work, entrance lock and channel, and breastworks along the shore of the river Tees, with the ten coal drops, amounted to the sum of £192,000.

These works were designed by Mr. W. Cubitt, V. P., and the author was the acting or resident engineer.

The coal drops are peculiar in their construction and are probably not much known beyond the district in which they are used; they are distinguished from the drops in common use on the Tyne, by the coal wagons being lowered perpendicularly to the ships' decks, whereas in the latter the wagons are lowered by means of a cradle and vibrating frame, which describes the arc of a circle in its descent. In places where the wagons have to be lowered from a height of 80 feet and upwards to the ships' decks, which is a common circumstance in the Tyne and the Wear, the vibrating frame (originally invented by the late William Chapman of Newcastle) are found well adapted for the purpose; but where the height is limited, or where the railway is so low that the wagons are just clear of the taffrail of the light ships, the perpendicular drop becomes more convenient. This ingenious contrivance was first suggested to the Clarence Railway Company by Mr. George Leather, of Leeds (M. Inst. C. E.), and was carried into effect at
Port Clarence on the river Tees, where several of them have been in use for some years, and are very effective.

The machinery of the Middlebench Dock are almost similar, in every respect, to those at Port Clarence. The principle of their construction and mode of operation will be readily understood by a reference to the engravings, Plate VII.

Fig. 1 shows a front elevation, and fig. 2 a side elevation of the vessel machinery; fig. 3 shows the machinery, as seen from the top, the cradle and wagon drawn to a larger scale; the same letters refer to the same parts in the different drawings.

The wagon A, weighing about 30 cwt., and containing one chaldron or 53 cwt. of coal, is shown standing on the moveable stage or cradle B, which is suspended by means of chains passing over the sheaves C, C; the ends of the chains are attached to the large sheaves F, F, the latter being cast with grooves of unequal depth, to accommodate the two chains, which it will be seen are of unequal length, and require a corresponding inequality in the sheaves, to preserve the cradle in a horizontal position. These sheaves are fixed on a strong iron shaft H, on the extremities of which are two other sheaves or pulleys K, K, to take the chains which sustain the counterbalance weights M, M. The break machinery for lowering the wagons consists of the toothed wheel W, 7 feet diameter, fixed on the same axle H; the pinion-wheel Q, 9 feet diameter; and the bevel-wheel R, 6 feet diameter, having a break over its whole circumference, worked by a strong lever-handle, which controls the descent of the loaded wagon, and its ascent when empty.

When the machinery is at work, the loaded wagon is run on to the cradle, or stage, B, and is stopped by wooden chocks in its proper position, directly over the hatchway of the vessel to be loaded (T, T, fig. 1). The breakmen then release the break-wheel, when the cradle and wagon descend perpendicularly, the suspending chain winding off the sheaves Y, Y; the cradle and counterbalance weights rise, the break-wheel is turned on to the shear, or pulleys K, K. The cradle, with the wagon upon it, still maintaining its horizontal position, having nearly reached the ship's deck, the contents are discharged by a man who descends with it for that purpose; the counterbalance weights rise to the position reversed, by the weights descending and the empty wagon and cradle rising to their original position. The whole is so guided and controlled by the breakmen, and the counterpoise weight so adjusted, that the wagon can be made to descend and ascend quickly or slowly, as stopped in ease in any position, either ascending or descending.

The drops at Middlebench Dock are constructed of strong wooden framework fixed on Memel fir piles, and the cost of the ten drops was £7,300, or £730 each, including all the timber, iron-work, machinery, etc., and the labour in fixing.

Each of these drops can ship a wagon load of 55 cwt. in a minute, or about 150 tons in an hour; but as the coal cannot be trimmed off so quickly in the ship's hold, about thirty wagons an hour may be taken as the ordinary rate of working. Forty wagons containing 2,200 tons, which are 660 tons or 106 tons an hour, may be considered the limit of working.

In the year ending 1st July, 1845, 505,486 tons were shipped by means of the ten drops here described. The shipment in the six months ending 31st December, 1845, amounted to 264,180 tons.

ON THE RESISTANCE TO BODIES IN FLUIDS.

On the relation between the Velocity and the Resistance encountered by bodies moving in Fluids. By John Mortimer Heppler, Grad. Inst. C.E.—(Read at the Institution of Civil Engineers.)

The determination of the relation between the velocity and the resistance encountered by bodies moving in fluids, has always been an interesting topic of inquiry, as well as the speculative philosopher as to the practical mechanic, and perhaps on no portion of physical science have more pains been spent; whether looking to the sagacity with which experiments have been devised, the liberality with which they have been carried out, or the mathematical acumen with which their results have been interpreted under general laws. To enumerate the names only of the men, illustrious by their science, who have brought their energies to bear on this subject, would fill a larger space than these few remarks are intended to occupy. It is sufficient to mention Newton, who in this, as in so many other departments of science, shed the light of his brilliant genius on the former obscurity;—after him the scarcely less celebrated Daniel Bernouilli, and in

latter times Bossut and De Buust, whose patience and accurate research opened such fruitful fields of observation to the contemplative mind of the theorist. Again, the valuable experiments of the French Academicians; the indefatigable labours of the late Colonel Beaufoy, so liberally made available for the objects of science by his son; and lastly, though not among the least, must be mentioned the excellent experiments of Mr. Palmer and Mr. Macneill, given in the Transactions of the Institution (vol. i. pp. 165-237). After such a retrospect it may appear presumptuous in a young and unknown individual, attempting to add anything to a subject already enriched by such contributors; as his remarks, however, are brought in a humble and modest spirit, and the views of the author are of the same simplicity and simplicity unadorned by any pretence of authority. He has been the subject of a change, and the author is as good as his words, for the change, as well as the author, is not an invention by any premeditated design, but the result of the study of a subject to which he is entirely devoted.
where they are arranged so as to be disconnected, being included in the determined resistance; and in these cases, this would have to be allowed for and be deducted. As however the resistance to flat surfaces has been so fully investigated, this would occasion little difficulty. An example perhaps will serve better to render the foregoing proposition clear. Suppose a vessel to be going through the water with a velocity of 15 feet per second, and on the stopping of the engines, the speed be observed in one second to sink 14 feet per second, the velocity destroyed in one second of time would be equal to 6 inches; this is 4/5th part of the velocity which would have been destroyed, in the same time, by a force equal to the weight of the vessel, and the force which destroyed it is therefore equal to 5/4th part of that weight. Now suppose this, as ascertainment from the displacement, to be 1,000 tons, then the mean force of resistance between the velocities of 15 feet and 14 feet per second is 666 tons, and the power expended in overcoming this resistance, at the mean between the two velocities, or 14 feet per second, is

\[
1000 \times 9240 \times \frac{6}{4} \times \frac{X}{550} = 6335 \text{ m.p.}
\]

Having thus described the mode in which the observation should be conducted, it may not be uninteresting briefly to notice the advantages which might result from a well-arranged set of experiments on this plan.

In the first place, it would offer an infallible means of testing the qualities of any particular vessel, apart from those of her machinery; since the action of the engines being stopped during the observation, has clearly no influence whatever on the rate of diminution of the velocity. The observer would thus, in case of any deficiency of speed, be enabled to fix the fault with certainty upon the vessel, or the engines, as the case might be. Indeed, if all vessels were submitted to the observation here described, there seems to be no reason why their resistance should not be as precise and definite a quantity, and as capable of accurate expression for any particular draught, as their displacement; and it might be confidently asserted, that the vessel which in this way showed the least resistance, ought to bear all others ceteris paribus, and if she were not found to do so, that the fault was either in the engines, or in the propelling apparatus, and certainly not in the ship.

This however, though one advantage, would not be the only one, as a series of observations made upon the same vessel, at various velocities, could hardly fail to demonstrate some expression or law of relation, between the observed velocities and the resistances, which if found to be uniform within the limits of the experiment, might fairly be presumed to extend to some distance beyond them, so that there would be a strong ground for predicting, with confidence, the increase of speed which might be expected to result from any proposed increase of power.

Again, as these results were repeated for various draughts of water, in the same vessel, the means would be furnished of knowing, a priori, the precise amount of power which should be necessary for maintaining a given speed, with any required load. Or if the power remained constant, what would be the speeds which should correspond to various draughts, and as before, if the performance of the vessel should fall short of what had been so determined, the fault would be in the machinery.

It may be mentioned, that although hitherto no opportunity has been afforded for testing the correctness of the views here professed, by a practical application of them to the point in question, yet the author has on several occasions adopted a method, similar in principle, in determining the resistance of shafting and machinery, by observing the rate of diminution of the velocity, on shutting off the steam from the engine, and having had good grounds for believing the results, in those cases, to have been tolerably accurate, in spite of the difficulty of correctly estimating the aggregate momentum of so many bodies revolving at various velocities, he is encouraged to suppose, that in the case of a floating body, whose momentum is so easily and precisely ascertainable, the result would be more exact and unquestionable.

The method adopted by M. de Pambour, for ascertaining the amount of resistance to the motion of railway trains, by the circumstances attending their descent and stoppage upon two consecutive inclined planes, is based upon precisely the same principle as that here advanced.

It remains only to consider, by what means the variable velocity of the vessel can be measured, so as to ascertain it, at any instant, with the necessary precision. In the absence of a better, the following arrangement might perhaps be adopted with advantage:

To the bowspirt of the vessel ('Fig. 1'), sufficiently high to be beyond the disturbed water, should be screwed a small iron bracket, carrying a pin, which should pass through a hole in a slender rod, hanging down below the surface of the water, and prolonged a few inches upwards above the water. Upon this rod, a metal sphere should be fitted, so as to be fixed at any required distance from the point of suspension; from the upper extremity of the rod, a small cord or wire should be brought, passing to some convenient spot on the fore-part of the deck, where it should be attached to one arm of a rectangular lever, whose other arm or index should move along an arc of a metal.

It will be clear, that when the vessel is at rest in the water, the rod, with the sphere attached, will hang vertically, and the cord being properly adjusted, the index of the bent lever will be horizontal, at which position the zero of the graduated arc should be commenced. If the vessel moves through the water, the resistance on the sphere will throw the rod out of the perpendicular, as indicated by the dotted line, and the angle which it makes with its former position, will be shown by the new position of the index on the metal arc. It is obvious, therefore, that the same degree of deflection will always be produced by the same resistance, and the same resistance by the same velocity. So that if the arc has once been carefully graduated, by moving with known velocities, which would have to be done once for all, it would always afterwards furnish a correct indication of the velocity with which the sphere, and consequently the vessel, was moving through the water, at the instant of observation. A slight consideration of the nature of this apparatus in action, will make it apparent that the position of the ball, or sphere, on the rod is indifferent, and that the same angular deflection will always correspond to the same resistance. This would contribute to render the arrangement convenient as being applicable to vessels of various kinds.

The mode of using this apparatus is obvious; an observer, with a second watch, would note the positions of the index on the arc, at such intervals of time as should be determined, when the diminution of velocity and consequently the retarding forces would become known, as before described.

Mathematical expressions have in the course of this paper been expressly abstained from, as being unnecessary to a general view of the method proposed. It may however not be out of place to remark, that perhaps the best way of treating the observations when obtained, would be to endeavour to discover an expression, representing accurately the velocity in terms of the time, in which case, its differential co-efficient would be accurately proportional to the resistance.

Remarks made at the Meeting after the reading of the above Paper.

Mr. Scott Russell said he could not venture, without more careful consideration of the subject than was permitted by merely hearing the paper read, to draw any conclusions between the results stated by the author and those which he had arrived at from the extensive series of experiments he had made; but his first impression was, that the method proposed was not the most direct, and that it was liable to several objections. He should, however, of course, be able to judge whether there was any advantage of the resistance of flat bodies moving through fluids, to enable the portion of resistance due to the floats of the paddle-wheels, in a state of rest, to be separated, in the general result, from the resistance due to the body of the vessel. Assuming such to be the case, he must content, that unless some means existed of
raising the paddle-wheels out of the water, simulataneously with stopping the engine, an accurate result could not be arrived at. The screw propeller offered considerably more difficulties than the paddle-wheels, and it was necessary to have a separate condenser for each. The paddle wheels were not loaded with the full force of the water, but the full force of the screw propeller was applied to the water, and the paddle wheels were in a much better position to get it out of the water. He was of opinion also, that unless the experiments were tried in perfectly smooth water, they could not give accurate results, on account of the dipping of the paddle wheels, and the consequent oscillation of the suspended sphere and revolving platform.

These were practical objections, which were raised in his mind, by the difficulties he had experienced, in determining the method of conducting his own experiments, which were all fixed upon vessels of considerable bulk and tonnage. The difficulty of keeping them in any degree of uniformity of both light and loaded. First taking all the float boards off the paddle-wheels, and by means of a steam-tug, of about 250 h.p., drawing the vessel through the water, ascertain the resistance at different velocities by means of a dynamometer; then, by replacing the float-boards, varying the weights of the vessel accordingly, and observing the results, he found an extraordinary uniformity in the amount of resistance by similar forms at equal speeds. At first he conceived, that it would have been necessary to reduce all the oscillations of the dynamometer, but he found the motion was so uniform, that any ordinary instrument would suffice for the purpose. He used an instrument, called Pitot's tube, for measuring the velocity, and he had found it very valuable; he might say almost unerring. It consisted of a vertical glass tube placed in the centre of the vessel, through the bottom of which a bowl of about half an inch diameter was bored, to pass a metal tube, continuing for a distance horizontally beside the keel, and terminating in a funnel-shaped mouth. When the vessel was at rest, the water outside, and the column within the tube, stood at the same level; but the velocity of the vessel increased the height of water in the tube rose; and by graduating the tube in accordance with observed heights for given speeds, the results might be read off with great facility and accuracy. Any undue amount of oscillation was prevented, by connecting the metal tube to one spot, by a stopcock, and the tube was only opened when taking observations. He thought the method he had described, combined with the use of Pitot's tube, was preferable to that proposed by Mr. Heppel.

Mr. Rennie concurred with Mr. Russell in his opinion of the proposed method of experimenting. No subject was more difficult than the resistance of fluids. It had occupied the attention of the most learned philosophers, yet nevertheless the present state of knowledge of the subject was still very imperfect. The true theory had never been discovered. Newton to whom, after Galilei, the credit of the experiments was given, the first of the two theories, of which the least imperfect supposed the body to be directly struck by each of the molecules in motion. The subsequent experiments of Bernoulli, Euler, Robins, Borda, Bosaut, De Boust, and others, had shed considerable light on the subject, and on that of the breaking up of objects, but no exact and satisfactory theories were formed until the present century, until the invention was taken up by Colonel Beaufoy, who, in 1791 established "a Society for the Improvement of Naval Architecture," under whose auspices be made, in the Greenland Dock, the elaborate experiments, the first portion of which had been so manifestly productive of the best results, by the scientists, the society, however sunk for want of funds, and the experiments were eventually conducted and brought to a conclusion, entirely at the expense of Colonel Beaufoy. A short notice of them in Thompson's "Annals of Philosophy" induced the communication of the results of the experiments made at the Royal Institution, by Sorels, Foresles, and Kallinentius for the Society of Ironmasters of Stockholm, at the Fablin mine, between 1811 and 1815. Owing to the combined circumstances of the Swedish language being little cultivated in England, and a want of mathematical attainings in those who did understand the language, the Swedish experiments remained untranslated, until after Colonel Beaufoy's decease. Mr. Henry Beaufoy then committed the book to the Rev. Elijah Smith, of Sidney College, Cambridge, who learned Swedish and compiled, as far as the history, the work of the Swedish "Recherches sur les Bateus & Vapeor," in a single volume of 100 pages. A translation was made by Mr. Bousaut, made by Mr. Bousaut, of the "Memoires de la Societe des Sciences," Journal des Sciences, March 1813.

3rdly. That the increasing the length of a solid, of almost any form, by the addition of a cylinder in the middle, diminished the resistance with which it moved, provided the weight in the water remained the same.

4thly. That the greatest breadth of the moving body should be placed at the distance of two-fifths of the whole length, from the bow, when applied to the circular forms in naval architecture.

5thly. That the bottom of a floating solid should be made triangular; as in that case it would meet with the least resistance when moving in the direction of its longest axis, and with the greatest resistance when moving with the broadside form of the stern.

Such was a short summary of the labours of Colonel Beaufoy, to whom the scientific world was deeply indebted. Mr. Rennie thought, however, that errors had been fallen into, by not sufficiently considering the question of the shape of the bow. They try to find on the sides of the broadside forms used in the experiments. They were moreover tried upon masses of too small dimensions.

The papers on the same subject in the archives of the Institution of Civil Engineers, presented by Bidder, Carlseun, Telford, Palmer, and Macneill, and those of Fairbairn and W. F. Page, 4 treated of experiments upon larger vessels, and produced more practical results.

The great difficulty of separating the resistance from the friction, arose out of the imperfect apparatus hitherto adopted. The balance of Colcombe, and the pendulum, had been tried with doubtful success. Profiting by the problem of the cylinder revolving in the vortex, in the Principia of Newton, Mr. Rennie undertook a series of experiments in the year 1830, which were published in the Transactions of the Royal Society. "On the Resistances of certain Bodies in Air and Water." 5 The apparatus consisted of an upright spindle of wrought iron, made to slide up and down in a frame, so as to be plunged to any convenient depth in the water, or to revolve in air only, as required.

2ndly. That the resistance of fans and discs with equal areas, was to the squares of the velocities up to 8 miles per hour.

3rdly. That the resistance of fans or discs with equal areas, was to the squares of the velocities up to 2 to 1.

4thly. That the resistance of fans or discs to the squares equal in area in water, was to the squares of the velocities.

5thly. That the mean resistance was—

Of Circulors in water

Square disc in water

Wooden discs in water

Of Circulors in air

of Circular fans in air

Wooden discs in air.

were to each other as the numbers 23 to 3,

16 to 2, and 4 to 2.

were to each other as the numbers 25 to 18,

22 to 1, and 10 to 2.

Mr. Bromax doubted whether the question of resistance, or friction, could be fairly tested by a cylinder revolving in a fluid, insomuch as a rotary motion was imparted to a portion of the water, in the same direction as the revolution of the cylinder.

The subject was one of great interest, and to which he had devoted much attention. Some years since he assisted Mr. Walker in a series of experiments in the East India Dockyard, and he came to the conclusion, that it was not possible to arrive at one law suitable for all cases. There were in reality three cases to be considered—

First. The resistance due to displacement.

Secondly. The resistance due to non-pressures.

Thirdly. The resistance due to non-pressure and non-dissipation.

As regarded the first case; the resistance due to displacement included that of the area of resistance of the water heaped up against the bows, which augmented as the velocity increased. In such case he found, that the increase of resistance was in a more rapid ratio than the square of the velocity.

In the second case; that of non-pressure, occasioned by the filling up of the channel in the wake, vacated in the passage of the vessel through the water. In this case he found the resistance increased in a less ratio than the square of the velocity. In Mr. Walker's experiments, boats were used with bluff prows and with acute prows; it was found that at a slight immersion, and when drawn at a low velocity with the bluff prow foremost, there was no increase of resistance; that when deeply immersed, all other conditions remaining the same, there was the greatest amount of resistance.

As to the third position. The formula of Du Bost with regard to friction was found applicable; as there was no distinction whether the vessel was moving through the fluid, or whether the fluid was running over the bottom of a river. In this case the resistance due to friction was as the square of the velocity.

Bousaut tried a variety of experiments upon the angles of resistance, by achittic rectangular parallelogram various shaped prows, at angles varying from 160° to 12°, with the view of ascertaining the law of resistance due to the angle of the plane meeting the water; but he overlooked the constant deduction necessary for the non-pressure due to the rectangular form of the stern, which formed the largest portion of the resistance, and consequently invalidated the deductions from the experiments.

5 Vide "Phil. Trans.," 1831, p. 422.
The view Mr. Bidder took of the mode in which the subject should be considered, was not with reference to the reflection of the particles due to the angle of incidence, but with reference to the absolute velocity imparted to the particles of water the vessel would have to displace. For instance, if the angle of the vessel was such, that the speed was one-half the radius, then the resistance was double, but only one-quarter of the pressure, and hence the resistance would be reduced to one-fourth; subject to the previous explanation of the heaping of the water against the bows.

With reference to a plane disc dragged through a fluid; it formed for itself a sort of dead water which was drawn forward with it; but the form of this prow varied with the velocity, the massing current along, and hence the anomalies which had been observed in all experiments on the subject.

He could not agree with the infallibility of the Pitot tube; for he thought, that in proportion as the vertical tube was moved from the stem, an error must arise from the lifting of the stem and the dropping of the stern as the velocity increased.

Palmer's experiments gave anomalous results. The resistances came out as the tubes rather than the squares of the velocities. This Mr. Bidder thought must be attributed, in a great degree, to the friction arising from the small area of the channel, as compared to the surface of the body of the boat, and that of the sheet of pent-up water between the flat bottom of the boat and the bottom of the shallow channel.

In trying experiments upon large vessels, he conceived, that a tug boat could scarcely get up sufficient speed to obtain satisfactory results, and that it was necessary for the vessel to be floating in perfectly still water, in calm weather; or else the circumstances being changed the results must be modified accordingly.

As regarded the resistance offered by the paddle floats, when they were dragged through the water, as alluded to by Mr. Peppel, when it was remembered that the absolute velocity of the paddles impinging upon the water did not exceed 4 miles per hour, to propel a vessel at a rate of 12 to 15 miles per hour, it would follow, that as soon as the engines were stopped, unless the paddles were disengaged simultaneously, they would be dragged through the water at the same velocity at which the vessel was proceeding; and that the resistance offered by the paddles would be so enormously disproportionate to that offered by the body of the vessel, as to render the results entirely nugatory.

Mr. Walker confirmed Mr. Bidder's statement of the results of the experiments tried in the East India deck, which were communicated to the Royal Society in 1827. The machinery employed for those experiments was very simple. It consisted of a crash-winch with a barrel 3 feet in diameter, and handles of a sufficient length for the necessary number of men to work at it. The line, 8 inch diameter, was attached at one end to the barrel, and at the other end to the davits, of the hoist of a boat, 19 ft. 6 in. long, by 6 feet broad, with a depth of immersion of 2 feet; the greatest immersed cross section was 9 feet. The experiments were tried in the Import Dock, where there was a space of 1,410 feet in length, 560 feet in width, and 24 feet in depth; so that there was no resistance from the sides or bottom of the dock. The velocities were calculated from the time of passing through 176 yards, or one-tenth of a mile; thus length being marked off in the middle of the distance traversed by the boat. The speed was attained by a given number of men working at the winch, and was regulated by the vibration of a pendulum.

The results obtained were, that in almost every instance the resistance showed an increase, amounting to the square of the velocity for the distance traversed; but where the velocity was considerable the resistance followed a still higher law in the channel. These results would have been considerably greater. The excess beyond the square, must, be conceived, he attributed, in a great degree, to the raising, or heaping, of the water against the bows at high velocities, and to the simultaneous depression of the stern.

In those experiments the weight, or power, required, was of course, as least, in the ratio of the cube. For instance, if one man at the winch produced a velocity 1, eight men were required to produce a velocity 2; but as the same time double the space was passed over, the exertion of power over the same space was the half of 6, or 4; but the velocity being doubled, it required twice the force; or eight men while they were at work; the distance was, however, traversed in half the time, so the expense of power by doubling the velocity was only as 4 to 1.

The results showed by dragging the bluff prow or the sharp prow foremost, at various velocities, showed clearly, that very different figures should be taken for vessels intended for carrying cargo, from those intended for great speed.

Mr. Bidder said, that Mr. Barlow, in his deductions from Mr. Palmer's experiments, had considered only the heaping of the water, and still more the variation in a higher ratio, viz.: as the cube of the velocity very nearly, if not exactly, and from the experiments he had computed the power of traction on a canal, thus:

At 4 miles per hour 1 lb. would draw 200 lb.
At 2 miles 1 lb. 1000 lb.

The rule adopted by some of the principal marine engine makers (as

Mr. Boult, Watt, and Co.), for ascertaining the sailing qualities of the vessel, viz.: multiplying the sectional area by the cube of the power, and dividing the product by the velocity, had, he believed, been found a true test; and if when the power in the same vessel had been increased, the quotient had been found uniform, which he had also reason to believe was the case, it would have accorded with the correctness of the theory, of the resistance being as the square of the velocity.

Mr. Spiller thought the results of Mr. Palmer's experiments were to have been anticipated, from their being tried in a narrow and shallow channel, and the friction of the water against the sides and the bottom, a mass of water which could not be dragged along with the boat, and not having space to expand, react against the boat, unduly increasing the resistance, particularly at high velocities. Under ordinary circumstances the resistance would be as the square of the velocity, and a vessel going at a given velocity would be roughly eight times the power.

Mr. Scott Russell thought the incongruities in the results of the experiments arose from want of due attention in noting all the circumstances attending them. The forms of the vessels were not particularly registered, nor were the various forms and sizes used, under similar circumstances. Now, as the law of resistance must vary with every difference of form, although a general rule might be given, it could not be relied upon in practice, and it became essential to analyse every experiment carefully before any deduction was made. One point to be particularly noticed, was the resistance of different forms of the bows of vessels, and of the quarters, as the law would vary as they were changed. Any experiment made in a channel of contracted dimensions, perhaps only three or four times that of the area of the ship section, could not be added; the law of resistance would vary with the form and dimensions of the channel, and great error might be made for lateral friction. In short, as a practical man, and speaking upon the authority of nearly ten thousand experiments, made upon large vessels in open spaces, under every variety of circumstances, he must still think the true mode of trying experiments, by means of the indicator attached to the engine. He was of opinion, that method would be found preferable to any other, if the vessel was tried at various rates of immersion, different speeds, and under circumstances that enabled deductions to be drawn.

Mr. Bidder replied, that in practising such a mode of experimenting, it would be first necessary to ascertain with accuracy the slip of the paddles, and the allowance to be made for the angles of impact and the depth of immersion, all which difficult problems were as yet little treated of and but imperfectly understood.

He was not satisfied with the accuracy of the Pitot tube, even as a measure of velocity, as the statistical pressure must be affected by the varying velocity, and false results would be indicated.

Mr. Scott Russell said, it was true that if the tube and the funnel mouth...

9 Extract from a letter from J. Brown, Esq., dated January 29, 1889. — "Mr. Boult, 1819 and 1829, Mr. Bidder, and Mr. Boulton with his vessel, the 'Caledonia,' to ascertain her velocity under different circumstances, and amongst the rest, the effect with one engine disengaged from the other. Each was nominally 14 hp., and the operation of uncoupling one occupied about five minutes, so that the trials in both instances were precisely under the same circumstances as to tide and wind."

12 Mr. Bidder, in his deductions from Mr. Palmer's experiments, had considered only the heaping of the water, and still more the variation in a higher ratio, viz.: as the cube of the velocity very nearly, if not exactly, and from the experiments he had computed the power of traction on a canal, thus:

Mr. Bidder said, that Mr. Barlow, in his deductions from Mr. Palmer's experiments, had considered only the heaping of the water, and still more the variation in a higher ratio, viz.: as the cube of the velocity very nearly, if not exactly, and from the experiments he had computed the power of traction on a canal, thus:

4 Miles. With both engines as work, eight experiments gave average ... 801
5 With one engine ditto, eight experiments gave average ... 17
6 In the above were repeated with the same six foot diameter, ... 845
7 Both engines working during eight experiments, gave an average of ... 829
8 One engine ditto " eight-seen ditto ... 87
9 One ditto " eighteen ditto ... 824
10 Similar trials were made with the 'Magnet' in 1822, Two engines of 60 hp. — with
11 Both engines as work during four experiments, the average speed was ... 7-42
12 One engine ditto four ditto ... 82
13 You will see that the velocity with one engine in all these experiments, something under what should arise, but is accounted for from the circumstance, that the number of strokes per minute, was reduced below the maximum, from the excess of load.

The results are however sufficiently near to establish the fact, that the power required in this case, another variation of the 'Caledonia,' estimated in 1818, with one engine, should have given 8.30 miles, instead of 6.17 miles; and in 1819, 6.29 miles, instead of 6.16 miles, and 6.39 miles, and 6.46 miles respectively.

In none of these experiments was the indicator applied to the engines; in actual practice carried by each was, therefore, not ascertained, but the nominal power was taken. "A most mischievous affair!" is the expression of Mr. Scott Russell about this attempt of Mr. Bidder's to ascertain the actual power, when both engines were at work, to be equal 227 b.h.p., the steam velocity, with the same velocity, which is within the limits of decimals of what should be, say 247 b.h.p. [
were large and the orifice was near the surface of the water, the effect apprehended by Mr. Bidder would be produced; but with a small tube and a proportionate orifice, with a proper arrangement of the apparatus, having the orifice immersed from 10 feet to 15 feet beneath the surface, the statical pressure was so uniform at all velocities, that no sensible variation could be observed, and he must record his conviction, if he properly graduated, and conveniently arranged, no instrument he had hitherto seen possessed the same amount of advantages for trying experiments.

ON REACTION WATER-WHEELS.

Communicated to the Franklin Institute, United States, by Z. Parker, of Philadelphia.

On the subject of Barker’s wheel, which, with but few exceptions, appears to be the only reaction wheel noticed in the elementary books till recently, I have seen no notice of any variation in the discharge, caused by variations in the velocity of the wheel; from which I infer that the writers regarded them as uniform in their discharge under all velocities. In practice, however, it has been observed that, when the wheel runs without resistance to its free motion, the orifice moves with a velocity considerably greater than that due to a pressure of the head of water, and that the discharge is greater than the theoretic discharge. So far as I am informed, no experiments have been recorded, or rules given for determining the ratio of discharge under different velocities of such wheels.

The following rule, I think, will be found to hold good for all wheels of the reaction kind which discharge the water at their verge, and into which it enters without circular motion, or in which a circular motion of the water is caused by the wheel itself— the supply being full:

“To the head of water actually pressing at the orifice, add such a head as will, by its pressure, produce a velocity equal to the circular motion of the orifice; the velocity through the moving orifice will be the same that it would be if stationary, and under the pressure of the sum of the heads.” For example:

Suppose such a wheel to have an issue of 36 square inches, under a head of 9 feet, and that the orifice move at the rate of 16 feet per second; the discharge will be the same that it would be if the wheel were standing under a head of 13 feet. Consequently such discharge would be the same as if standing under 18 feet head; in each case, the discharge should be 144 cubic feet per second.

It is obvious that, in applying this rule in practice, such deductions must be made (as in other cases) as may be due to the form of the orifice, the angles in the passages, and the friction on surfaces.

The following experiments were made with a centre discharge reaction wheel of the form and proportions represented in the accompanying sketch. The wheel was 34 inches in diameter at its outer verge; the inner diameter of the annular rim 26 inches. It had 16 issues (8 by 1½ in.) = 230 square inches. It received the water at the verge, from an involute sluice embracing the whole circumference. The water was conducted to the involute through a large conduit; the discharge of which into the involute 24 in. wide by 14 inches deep = 326 square inches. The terminus of the involute was within an inch of the verge of the wheel. The circular motion of the water caused by the involute coincided with the motion of the wheel.

The condition of the works at the time the experiments were made was favourable to the wheel. It had run about two months after being repaired and adjusted, and the proprietor (Mr. A. Parker, of Troy, N.Y.) stated that it was performing as well as it ever had. There was a fault, however, in the construction. The “spout” (so called) conducting the water from the fume had an elbow of nearly a right angle, first descending from the bottom of the fume and then passing horizontally to the involute; the section at the commencement of the horizontal portion being about 16 by 36 = 576 square inches. The opening into the “spout” from the bottom of the fume was about 30 inches square, with sharp angles. All things considered, I am of the opinion that this method of employing the “pressure” of water, with a good structure, in good condition, is capable of giving about 60 per cent. of available power.

A remarkable feature of inward-discharging reaction wheels is found in the smallness of their discharge, and its tendency to uniformity under all velocities of the wheel, obviously arising in this application, from the outward pressure of the circular motion of the water in the involute sluice and wheel.

The theoretic discharge of 230 square inches, under a pressure of 8½ feet, is 2,949 cubic feet per minute. The actual discharge is only 498 of this. Had the discharge been outward, through the same aggregate aperture, and with the same circular motion of water, in the portion of the wheel occupied by the vanes, the discharge (judging from the results of experiments stated in 1844), would have been 884 of theoretic discharge; and had it been outward, and without circular motion, it would have been about 1,289, at the speed of maximum power.

ON THE VELOCITY OF ATMOSPHERIC JETS.

The following table (communicated by Z. Parker to the Franklin Journal) of the velocity of atmospheric jets, under the given pressures, may be useful.

The table is constructed under the assumption that all fluids acquire equal velocities under the pressure of equal heights, without regard to their specific gravities; allowing the superincumbent column to be homogeneous with that portion at the jet. The formula is \( V = \sqrt{gh} \); and for a pressure of 16 lb. per square
STEAM-ENGINES.

By WILLIAM BACON and THOMAS DIXON, of Bury, Lancaster, engineers, for "certain Improvements in steam-engines."—Granted August 19, 1847; Enrolled February 19, 1848. [Reported in the Patent Journal.]

The invention of improvements specified and embodied in this title applies generally to that class of steam-engines usually termed Woolf's engine, or the compound-cylinder engine; that is, an engine having two cylinders, where the steam is admitted into one cylinder, at a high pressure, and entering the piston of that cylinder, it is admitted thence to the larger cylinder, where it again produces a motive power, and usually subject to compression. In one case also, herein specified, it is applicable to single-cylinder engines. The patentee states that in the ordinary arrangement of compound-cylinder engines, the area or content of the passages from the expansive valve for the high-pressure cylinder to the inside of the low-pressure cylinder are so large as to form a large proportion to the cubical content of the high-pressure cylinder; and that this content or space is filled, at the conclusion of each stroke of the engine, whether it be the upward or downward stroke of the low-pressure piston, with steam of a similar density as that produced by its admission into the low-pressure cylinder, which so that by a peculiarity of the steam in its passage from one cylinder to the other, and also to simplify the construction and at the same time to obtain an increased amount of duty from the steam in compound-cylinder engines. To attain the advantageous results just enumerated, the patentee construct's improved engine so that by a peculiar arrangement of the passages, valves, and openings, the exhausting-valves for the high-pressure cylinder, or admission-valves for the low-pressure cylinder, are placed as nearly as possible to the ports or entrances to the low-pressure cylinder. On account of this arrangement of the passages between the steam-valves for either of the ports of the low-pressure cylinder, and the opposite end of the high-pressure cylinder, these passages are constantly filled with steam of the same density as that in the high-pressure cylinder; therefore, the steam admitted to the high-pressure cylinder will have to occupy, and the steam always be in reserve for the commencement of the stroke of the low-pressure piston; consequently the pressure of the steam will be reduced but to a very trifling degree; and, therefore, they argue that a more perfect expansion of the steam in the low-pressure cylinder is obtained, which is attended with a corresponding additional result in the motive-power. These improvements consist:—First, in so arranging the valves, passages, and openings, that one valve-box, one double hollow valve (or two sliding-valves of the cut-away construction) are adapted to serve for both the high and the low-pressure cylinders. The same passage in the valve which admits steam to the top of the low-pressure cylinder from the bottom of the high-pressure cylinder, in a downward stroke of the pistons, also forms the passage from the top of the low-pressure cylinder to the top of the high-pressure cylinder; and the same passages in the valve which admit the steam to the bottom of the low-pressure cylinder from the top of the high-pressure cylinder, in the upward stroke of the pistons, also forms the passage from the bottom of the low-pressure cylinder to the condenser, in the downward stroke of the pistons. The same part of the valve which admits the steam to the high-pressure cylinder forms the exhausting-valve for the opposite end of the high-pressure cylinder. Secondly, these improvements consist in using separate plate or other valves for the admission of the high-pressure cylinder, and using these valves as expansion-valves with which to cut off the steam from the high-pressure cylinder, and so arranging them that the amount of expansion may be varied to any required extent in the high-pressure cylinder without interfering with the ingress or egress of steam to or from the low-pressure cylinder. Thirdly, these improvements consist in arranging conical-valves, Cornish, or other description.

REGISTER OF NEW PATENTS.

SACK HOLDER.

By HENRY GILBERT, of St. Leonard's-on-Sea, surgeon, for "Improvements in apparatus for holding sacks, to facilitate the filling of them with corn or other materials."—Granted May 27; Enrolled November 27, 1847.

Heretofore when filling sacks it has been usual for one person to hold up the sack whilst the other fills the same. In other cases the sack has been hung from hooks or instruments from a wall or post or some other permanent structure. The object of this invention is so to arrange apparatus that it may be carried about with facility, and stand in a field or other place, and uphold a sack in an open state so that the sack may be filled with facility; the invention simply requiring such an arrangement of parts that it may be independent of a fixed or permanent structure, and be capable of being moved from place to place, and yet uphold an empty sack in an open state and allow of a person readily filling the same. The annexed engraving shows a side and back view of the apparatus. a is the main frame, having two legs a'.

The sides a are combined together by the bars b, which are bent to receive the sack as it rests against it; c is a diagonal frame which turns on axes, and d are two studs or projections fixed to the side rails of the frame, by which the legs or feet can be caused to stand at a greater or less distance apart, there being notches in the projections to receive the studs or projections. At the upper part of the apparatus is fixed an elliptical frame f, through which the mouth of the sack is to be drawn. The upper part of the sack is to be folded over the bars f, and the clamping-bars brought down which will clamp the upper parts of the sack surely between the parts f, and g, by which means the sack will be held open at the mouth and supported or suspended from the frame f, and the apparatus may be placed in the position shown in the side view.
of disc-valves for compound-cylinder engines, so as to effect the same result as by the slide-valves above-mentioned, and in arranging each valve to be raised by a separate tapet (or by other mechanical means), so that any one valve can be closed without interfering with any of the others; by reason of which arrangement any amount of expansion or compression of steam in either the

high or low-pressure cylinder can be effected. Fig. 1 represents a vertical section of a low-pressure cylinder, together with the steam-passages, so arranged that by one valve-box, six openings, and two common, single, hollow sliding-valves, they are adapted to serve both the high and low-pressure steam-cylinders; and Fig. 2 is a transverse vertical section of the passages through the line 1, 2, showing also the position of the cylinders. a indicated the admission and exit openings for the top of the high-pressure cylinder; and a': the opening for similar purposes to the bottom of the high-pressure cylinder; and b, and b', the ports for the admission and escape of steam for or from the top and bottom of the low-pressure cylinder; c, and c', the passages to the condenser; d, and d', steam-passages to the high-pressure cylinder; e, and e', the hollow sliding-valves; and f, and f', the lap or covering for the condenser-ports c, and c'. The action of this arrangement is as follows:—Steam being admitted from the boiler to the valve-box a, enters at d (when the valves are in the position shown), and passes thence by the passage g, to the top of the high-pressure cylinder b, where, having performed the downward stroke of the engine, the position of the valves a, a', will be reversed, and the steam will return by the passage g, and the opening d (as well as the port e'), being now covered by the valve a', the steam will be conducted thereby below the piston of the low-pressure cylinder c, and, on a subsequent stroke taking place, it will escape through the valve a', to the port f', and thence by a suitable passage to the condenser. For the upward stroke of the engine, the port d' will be uncovered by the valve a, and steam will enter, passing by the passage g', to the bottom of the high-pressure cylinder, and by the change in the valves it will escape from thence by the passage g', through the valve a, into the top of the low-pressure cylinder c, where, having performed its office, it is exhausted by the condenser through the passage f, which, in its turn, will be covered by the valve a. The ports d, and d', are always covered either by the valves a, and a', or by their projecting-pieces e, and e'. Fig. 3 represents a vertical section of a valve-case, together with the requisite passages, by which arrangement one valve-casing, five openings, and one double hollow slide are made to serve for two high-pressure cylinders and one low-pressure cylinder, these being arranged, in the drawings, one on each side of the low-pressure cylinder, to which the slide-case and slides are attached; the different valves, openings, and passages are lettered severally, as in the last figures, and to which the description thereof will be equally applicable, as the steam is conducted precisely in the same manner as in that case. Fig. 4 is a vertical section of a low-pressure steam-cylinder, with its valves and openings so arranged that by one valve-box, six openings, two plate expansion-valves, and two common, single, hollow slide-valves are adapted to serve one high-pressure steam-cylinder, and one low-pressure steam-cylinder. Fig. 5, a section through the line 3, 4, showing the arrangement of the passages, with the relative position of the two cylinders. A, represents the valve-case; B, the high-pressure cylinder; C, the low-pressure cylinder; a is the opening in the valve-face, which is connected with the top of the high-pressure cylinder by the passage b, which passage also serves to convey the steam from the top of the high-pressure cylinder B, to the bottom of the low-pressure cylinder C. a' is the opening in the valve-face for the admission of steam to the bottom of the cylinder B, the passage b communicating thereto, this passage serves as a communication between the bottom of the high-pressure cylinder B, and the top of the low-pressure cylinder C. These openings a, and a', are covered alternately by two expansive plate-valves c, and c'; which valves are furnished with suitable apparatus for varying the amount of expansion, and are placed on the same rod as the valves d, and d', which are for the purpose of controlling the direction of the steam in its entrance and exit to and from the low-pressure cylinder C. c, and c', are the steam-passages to the cylinder C, and f, and f', the openings in the valve-face to the condenser; g, and g', are the openings in the valve-face to the steam-passages b, and b'; and a, and a', the laps of the slides a, and a', for the purpose of covering the openings f, g, g', and f'. Steam being admitted to the valve-jacket from the boiler, at a high-pressure, it enters at a, to the passage b, which is filled as far as g'; that opening being covered by the lap of the valve d', it is conducted thereby to the top of the high-pressure cylinder B, where, having performed the downward-stroke of the piston, the position of the valves will become changed, the steam in the top of the cylinder B, will escape by the passage
A, through the opening \( g \) in the valve-face, which will now be covered by the valve \( d' \), and by it directed through the passage \( e' \) into the bottom of the low-pressure cylinder; the opening \( a \), to the passage \( a' \), during this part of the stroke, being covered by the expansion-valve \( c \). During the up-stroke, passing through the passage \( h' \), the high-pressure steam in the valve-case will pass in at the opening \( a' \), thence by the passage \( b' \) to the bottom of the high-pressure cylinder, the opening \( g \) to this passage being now covered by the lap of the \( h' \); but the valve \( h' \) being again changed, the steam will rush from the bottom of the cylinder \( B \), through the passage \( b' \), where it passes through the opening \( g \) in the valve-face, and is directed by the valve \( d \) into the top of the cylinder \( C \), by the passage; when the down-stroke takes place, during this part of its course through the passage \( b' \), the opening \( a' \) is covered by the expansion-valve \( c' \), preventing any admission of steam from the valve-case. The steam from the top and bottom of the low-pressure cylinder is exhausted by the condenser through the passages \( f \), and \( f' \), which communicate alternately therewith by the change in the valves, \( d \) and \( d' \); when the opening is covered by the valve \( d \) and the steam directed thereby to the condenser, the opening \( f \) is covered by the lap \( h' \) of the valve \( d \), and when the opening \( f' \) is covered by the valve \( d' \), \( f' \) is in turn covered by the lap \( h \) of the valve \( d \).

The object aimed at in these improvements, besides the simplicity of construction, are, that a more effective pressure is obtained from the admission of the steam immediate on the opening of the steam-valves to the low-pressure cylinder, and, consequently, a more effective result is obtained. Drawings are represented in the specification, showing the application of Cornish or disc-valves adapted to effect the admission of steam to the low-pressure cylinder in a similar manner, and so as to obtain a similar beneficial result, as with the slide-valves already described; but, from the simplicity of the principle of the invention, it will be unnecessary to give any description. In combination with these foregoing improvements, they also specify an improved apparatus for what is technically termed "blowing through" when an engine is to be started, the improvements being for the purpose of preventing the engine starting in the wrong direction. The improvement consists in arranging two passages from the blow-through valve to the low-pressure cylinder, one of these passages being connected from the blow-through valve to the top of the low-pressure cylinder, and the other passage from the blow-through valve to the bottom of the low-pressure cylinder—the openings into these passages being so regulated by a three-way cock or valve, that when the operation of blowing through is performed, the steam enters simultaneously on each side of the piston in the low-pressure cylinder; and that when the said valve is closed, any communication between the passages will be entirely prevented. Having described the nature of their invention, and in what manner the same may be carried into effect, the principal effect of the improvement is not to claim the application of one valve-box to high and low-pressure cylinders, but what they claim as their invention is:—First, the peculiar arrangement of the valves and openings as they are represented in the cuts and hereinbefore described in detail; that is to say, the application of two high-pressure and two low-pressure valves, of the ordinary construction, to effect the necessary communications between the steam-chest, cylinders, and condenser; and the arrangement of ports or openings, whereby the steam is reduced as little as possible in passing from the high-pressure cylinder to the low-pressure cylinder alone. They claim also the application of two high-pressure steam-cylinders to one low-pressure steam-cylinder, and in so arranging the ports or passages that the same number of valve-boxes and openings serve for one high-pressure and one low-pressure steam-cylinder, will also be sufficient for two or more high-pressure cylinders and one low-pressure cylinder. They desire it to be understood that they do not confine themselves, in the application of the improvements, exclusively to compound-cylinder engines with condensation, but also claim the application of their improvements to compound-cylinder engines without condensation, passing the steam from the second or low-pressure cylinder into the atmosphere instead of into the condenser. Thirdly, they claim the application of their improvements in the methods of blowing through for the purpose of starting engines, as applicable to every description of double-acting compound engines, whether with compound or single-cylinder engine. They also claim any combination of the improvements herein specified, whereby similar objects may be accomplished.

CONSUMING SMOKE.

WILLIAM EDWARD KYAN, of Westbourne-park-villas, Paddington, clerk, for "Improvements in consuming the smoke and economising the fuel of steam-engines, breweries, and manufacturies generally."—Granted July 23, 1847; Enrolled January 23, 1848.

This invention consists of a combination of mechanical means, to be applied to the furnaces, ash-vents, flues, fire-doors, doors-frames, and chimneys of steam-engines, boilers, coppers, stills, and panes generally, for consuming the smoke and gas and lessening the expense of fuel.

First, to regulate the draught of the chimneys, whatever may be their altitude, so that their area of cubical capacity shall not exceed the conjoint area of the furnaces, the space above the bridge of the still under the boiler, &c. Secondly, to effect the admission of atmospheric air, at given points, to afford the precise proportion of air needful to effect the perfect combustion of fuel, and its products of gas and smoke.

Fig. 1. is a longitudinal vertical section of a steam-boiler of cylindrical form, with its furnace. \( a \), the furnace-doors; \( b \), the plate; \( c \), the fire-bars; \( d \), the bridge; \( e \), the air-flue; \( f \), the fire-flue under the boiler; \( g \), the lateral or side fire-flues.

Fig. 2. is an enlarged view of the furnace-doors, which are in two heights; the upper one has ventilators with regulating slides to admit the air over the fuel (without lessening the temperature of the furnace which partly opening the door occasions), and is opened to supply fuel; and when that is done, it is closed, and the lower (plain) door is then opened to arrange the position of the fuel on the bars. \( e \) is the air-flue with ventilator to regulate the air admitted. A, A, are the ash-pit doors with their ventilators, by which the needful quantity of air is allowed to enter. There is a second air-flue marked \( k \), which enters the side flue into which the blaze first passes from the boiler, and this has likewise a ventilator marked \( l \).

In addition to the horizontal damper in the machinery to contract and regulate the draught, there is also a vertical damper fixed on one side of the chimney with a counterpoise weight, which damper is raised as occasion may require, to supply that is done, it is reduced as little as possible in passing from the high-pressure cylinder to the low-pressure cylinder alone. They claim also the application of two high-pressure steam-cylinders to one low-pressure steam-cylinder, and in so arranging the ports or passages that the same number of valve-boxes and openings serve for one high-pressure and one low-pressure steam-cylinder, will also be sufficient for two or more high-pressure cylinders and one low-pressure cylinder. They desire it to be understood that they do not confine themselves, in the application of the improvements, exclusively to compound-cylinder engines with condensation, but also claim the application of their improvements to compound-cylinder engines without condensation, passing the steam from the second or low-pressure cylinder into the atmosphere instead of into the condenser. Thirdly, they claim the application of their improvements in the methods of blowing through for the purpose of starting engines, as applicable to every description of double-acting compound engines, whether with compound or single-cylinder engine. They also claim any combination of the improvements herein specified, whereby similar objects may be accomplished.
admission of a large volume of air with undue force at any of these given points above enumerated.

These arrangements are also applicable to boilers of marine steam-engines. Thus, where the boilers are set in brickwork, with flues or fire-bed passing under the boiler, and side flues surrounding the boiler, like those of stationary land-engines, the same method of applying the arrangements as before described will answer the purpose, and where the furnace and ash-pit are within the boiler, the ventilators are to be applied to the ash-pit doors, to the furnace door-frame and upper door, and to a metallic pipe to convey air to the back of the bridge, and should there be a slide-flue, one also to that; the regulating damper to the chimney and a vertical damper enclosed for safety in a case open at the bottom to admit air.

As some of the arrangements herein described are old, or have been in use, such as the horizontal damper, the divided furnace-door, with apertures therein, and the admission of air at the back of the bridge, the patentee does not claim any one of these separately, but claims their application combined with the following improvements (that is to say) the vertical damper marked, the openings in the door-frame, and slides to cover them occasionally, the side air-flue, and ventilator, and that marked, the ventilators in the ash-pit doors, and the tube for conveying the air to the back of the bridge, marked, in the manner set forth, to produce, by their regulated and united action, the effect of more complete combustion, by igniting the gas and smoke, and thereby saving fuel to a considerable extent.

CONDENSER FOR STEAM-ENGINES.

Christian Schiele, of Manchester, mechanic, for "Improvements in machinery or apparatus for condensing steam."—Granted May 27; Enrolled November 27, 1847.

The new condenser consists of a cylinder A, one end of which is divided off, forming a separate chamber B; the two chambers are connected by a valve h, in the partition n, and a tube e, leads from near the bottom of the small chamber into the large one, proceeding along the upper part of the cylinder, and having its lower surface pierced with holes. The cylinder contains water, and on steam being admitted from the engine, through the pipe c, into the large chamber A, it forces the water through the valve h in the partition into the small chamber; but as soon as the steam begins to condense, and the pressure on the surface of the water is released, the compressed air in the small chamber forces the water up the connecting-tube e, and which, flowing along, passes through the orifices f in a shower, and completes the condensation. k is an elbow-pipe, in connection with the steam-pump of the boiler, to carry off the condensed fluid; it is provided with a vertical tubular slide l, to be raised to any suitable elevation by a rod m, to regulate the level of the condensed fluid, and steam space c. q is a valve on the upper part of the chamber.

opening outwards to allow of the escape, at certain periods of the operation, of any steam or air contained in the chamber. p is a glass gauge-ball, in communication with the chamber B, by means of a small pipe, which depends from the top of that chamber to about one-fifth of its depth. This ball p is intended to show the diminution of the air in the chamber B, by the rise of the fluid into it. r is a small pipe with a stop-cock, for supplying air to the chamber when required. A third pipe q is connected with the chamber B, and is intended to furnish a fresh supply of water from an elevated cistern, in order to compensate for the fluid lost by leakage.

GAS BURNERS.

John Hunt, of Birmingham, brass-founder, for "Improvements in the combustion of gas, oil, camphene, and other substances which are or may be burned for the production of light."—Granted July 3, 1847; Enrolled January 3, 1848.

This invention relates to the application of caps or discs, made of perforated metal or wire gauge, to the tops of the chimneys or glasses of gas, oil, or other lamps, as shown in fig. 1.

The second part of the invention relates to the manufacturer of argand burners and the chimney-holders attached thereto. Fig. 2 is a vertical section of a burner and chimney-holder. In the ordinary method of making them, the several pieces are joined by soldering at the parts marked a, a; but the patentee proposes to cast in one piece either the outer cylinder b, and the bottom c, and rim d, of the glass-holder, or the inner cylinder e, and the bottom and rim of the glass-holder; or, instead of casting, it can be made the same by stamping from sheet-metal. The completion of the burner by the addition of the inner or outer cylinder, as the case may be, is effected by the ordinary method of soldering.

RAILWAY BREAK.

Frederick Chaplin, of Bishops Stortford, Hertfordshire, tanner, for "Improvements in wheels of railway carriages."—Granted June 29; Enrolled December 29, 1847.

The improvements consist in applying to the tyres of railway wheels belts of hide, skin, or leather, in such a manner that they will be in contact with the rails while the wheels travel, whereby the driving-wheels of a locomotive engine will be enabled to take a firmer hold of the rails, and the wheels of the railway carriages will travel more slowly and with less noise.

RAILWAY WHEELS.—Patented June 28, 1847, by W. E. Newton, of Chancery-lane, consisting of a peculiar method of casting the iron wheels for locomotive engines and railway carriages, the object being to cool uniformly all parts of the wheel at the same time, and thereby preventing fractures from irregular shrinking. From the time when wheels with a chilled hub and flange were first brought into use, the difficulty of casting them has been known, for the chill sets and cools the metal of the rim before the spokes or parts connecting it with the hub, and these, in cooling, shrink, and either break, or become so weak as to break on the least strain. To obviate this, the hub was for a long time made in sections, to enable it to open and yield to the contraction of the spokes, but this was attended with a diminution of strength, and the necessity of putting on wrought-iron hoops or bands. The patentee avoids these objections, which is effected by casting the whole wheel in a chill, and cooling all the parts at the same time, and without undue strain on any part. For casting a wheel of this kind a circular metal mould is to be constructed in several pieces, as shown in the annexed engraving, which, when put togeth
or separate one portion from another. \( a \) is the circular metal plate, and \( b \) a metal ring, accurately fitted together; \( c \) a conical metal plug forming a core, with a feather \( d \) affixed, to form the recess for the key to fasten the wheel to the axle.

**Silvering Speculum.**—Patented August 3, 1847, by T. Fletcher, of Birmingham. It consists in coating glass, after it is silvered with metal, by the electrolytic process, whereby the quicksilver is protected from injury, and a stronger power of reflecting light given to the speculum. The silvered glass plate is lightly and carefully coated on the back, or silvered side, with a varnish composed of two ounces of shellac, half a pint of highly-rectified spirits of wine, and half an ounce of the best lamp-black; this varnish protects the quicksilver from damp, and from the acid used in the subsequent process. Before the varnish is quite hard, shake over it from a muslin bag, finely-pulverised plumbago, black oxide of manganese, or any other metallic powder, over it with thin metal, so that the whole surface will be covered with a perfect but thin coat of metal; after which it is submitted to the electrolytic process, and by this means a thin coating of copper, or other metal, will be precipitated over the entire back of the plate.

**Direct Application of Steam-Power to Mills.**—Patented July 22, 1847, by J. Haste, of Greenock. It consists in the application of direct action of steam-power to turn mills, by making the axis of the crank of the engine serve also for the axis of the mill—whether the same be vertical or horizontal. The shaft is provided with a fly-wheel, which receives an endless belt for driving flour-milling machines, and on the shaft there is an eccentric for communicating motion to the slide valves. When two pairs of millstones are to be worked by the same engine, it may be effected by causing the piston-rod to pass through both ends of the cylinder, and connecting it at each end with the shafts of the upper mill-stones; and, in case it should be at any time desirable to work only one of the upper stones, the other may be disconnected.

**Waller's Patent Coffee-Pot.**

This invention consists of a vessel divided into two equal parts by a diaphragm \( A \), with the centre depressed and pierced by a hole; around the edge is attached a bent tube connected with a cock \( B \), forming a passage through the strainer \( C \), from the upper to the lower half of the vessel; the strainer is finely perforated with metal. Ascending from within a short space of the bottom of the lower chamber to within nearly the top of the upper one, is a tube \( E \), passing through the centre of the partition and perforated plate, and which tube is surmounted by a valve \( D \). \( F \) is an ordinary spout communicating only with the lower division, and fitted with a ground stopper.

The mode of using the apparatus is this: the stopper being removed from the spout, the water is poured into the upper half of the vessel, the tap is then turned downwards to allow the water to run into the lower half; when it has done running, the ground coffee is put into the top division, the tap again turned horizontally, the coffee is re-inserted, and the vessel placed on the fire. When the rising of the valve, and escape of steam from under the lid have continued a few seconds, the coffee-pot is to be taken quite away from the fire and allowed to stand about two or three minutes; the tap is then turned downwards, when the infusion will rapidly filter into the lower division, and be ready for use in a beautifully bright and boiling condition.

The principle of this apparatus will be readily perceived. When it is placed on the fire, the water in the lower division is forced by the pressure of steam up the central tube, lifting the valve and sending part of it as a uniform stream, at a gradually increasing temperature, upon the coffee; as soon as all the water above the inferior orifice of the central tube has been forced up, then only steam arises; when the vessel is removed from the fire the valve falls into its seat, and prevents the re-entrance of air into the lower chamber, after its total expulsion thence by the steam; during the period of infusion, the steam in the lower chamber is allowed to condense, and thus a partial vacuum is produced, and preserved for any period, and rendered available for effecting rapid filtration whenever desired, by the employment of the tap.

From experience we can state that this little apparatus is one of the most useful domestic articles that can be had. It produces the most brilliant and fragrant coffee in three or four minutes. We should observe that during the process the vessel is quite closed; consequently, not the slightest quantity of the aroma of the coffee is dissipated.

**On the Flow of Water.**

Of the Union and Division of Running Waters, with the Laws of their Increase and Diminution. By Bernardino Zandrini, della Città de Ravena.——(Translated by E. Cressy, Esq., in his Evidence before the Metropolitan Sanitary Commissioners.)

1. A river which unites with another does not cause this latter to rise in proportion to the quantity of water which it brings, as would be the case supposing water to be considered as a solid, but only increases the height by as much as the greater or less velocity of the influent or recipient may permit. On the contrary, if a river in the middle of a canal be diminished by a certain quantity of water, it ought to be lowered proportionally to the velocity of the canal of derivation and the river from which the water is abstracted, and such an alteration ought to be perceived not only at the lower part at the point where the water is added or subtracted, but also in the upper. In which law, however, there is much obscurity; what appears certain is, that both in the case of the union and of the separation that the surface continually adapts itself to the alteration in a regular progression, and although the impregnation rising from such an anomaly does not disturb the whole level of the river if it runs over a long course, it reduces the problem to find the point where the disturbed mixers and unites with the undisturbed surface after following the oscillation of the water, which point in geometric rigour ought to traverse the whole length to the source of the river, since it would describe a regular curve; but the course of the water encounters so many impediments and obstructions, that these laws do not really obtain. And in every river there is, in fact, a point beyond which the regurgitation does not take place. That, however, as much as possible, we shall treat of in another chapter, when speaking of the falls of rivers, of their highest rise and lowest levels.

For the present it will be sufficient to seek the elevation or depression which will be produced in a river by the addition or subtraction of a quantity of water.

II. Suppose \( A B \) to be the height of a recipient previous to the influx of another stream, let \( LM \) be its width in a given section, \( FG \) the height of the influent before the union, \( HI \) its width. Supposing this latter introduced into the recipient, it ought to experience a certain rise. What will that rise be? Since the addition of water ought to continue to the width of the section of the recipient, conceive the height \( FG \) of the influent altered to that of the recipient \( AE \), then the water of the one will have passed into the other, and since this fresh water presses upon the other, that of the recipient will be obliged to lower its surface, and from the point \( B \) will be brought down to \( C \); likewise the point \( E \) will pass to \( D \) and \( ED = AC \), and consequently \( BD \) will be the entire height of the recipient after the addition of the influent water.
Calling \( AB = d, \) \( AE = x = CD, \) \( BD = x, \) \( FG = b, \) \( HI = a, \) \( LM = c. \) The velocity of the recipient before receiving the influent \( u \); its velocity after having received it, but before it could exercise any pressure and reduce it to equilibrium, is the same which it would have if the water of the influent ran in the width of the recipient \( = t, \) the velocity which the recipient has after the union and after the waters have equilibrated in their course = \( q, \) and the velocity which the influent had in its own level before the union = \( r. \) Then since the two masses of water of the influent and recipient in a given and equal time can pass separately in the level of the recipient, they ought to be able to pass together through the aforesaid recipient. Hence the equation \( du + tx = qx \) and \( x = \frac{d + t}{q} \) the first general formula; now since equal masses of water pass in equal times both through the influent separately and through the aforesaid influent when reduced to the width of the recipient, we shall have \( ct \times x = abr, \)

whence \( x = \frac{ab r}{c} \) and \( x = \frac{cd u + ab r}{cq} \) the second general formula expressing the whole height \( BD; \) wherefore \( AD, \) which is the whole increment produced by the influent above the first state of the recipient will be \( \frac{cd u + ab r - cd q}{cq} \).

III. Corollary 1.—If the velocity is a mean proportional to the height, we shall have \( AD = \frac{d^2}{\sqrt{d + x - d\sqrt{x}} - x - d} = x - d, \) which reduces itself to \( x = \sqrt{d^2 + 2dx + d} \times \sqrt{d + x + x} \) and \( A D = \sqrt{(d^3 + 2dx - d - x)} - d, \) in which \( x = \sqrt{a} \), as is obtained by substituting in the formula \( ct \times x = abr, \) the values of \( t \) and \( r, \) which are \( \sqrt{x}, \sqrt{b}, \) which value of \( x \) if substituted for that of \( x, \) will give the value of \( A D. \)

V. Corollary 3.—And consequently if \( u = dm - r = bq = q^2 \) where \( m, n, \phi \) are numbers which may be integers or fractions expressing any power of the height by the velocity, we shall have the general formula \( x = (d^m + 1 + a \times c - 1 \times m + 1) \times d, \) in which \( x \) being already eliminated, it only remains to substitute the values of \( d, a, c, \) taking the aforesaid exponents as fixed, supposing \( u = d \) unknown, the aforesaid formula will give the general equation of the whole curve of the increment of the river by the addition of the other stream, the abscissa of which will be \( x, \) the ordinate \( d, \)

generally making \( u = \delta p, r = b p, q = \phi p, \) we shall have

\[
\begin{align*}
\frac{\phi + p}{p + m} = c d p + a b p + n, \quad \text{and that } x + \phi + p = \\
\left( \frac{c d p + a b p + n}{p^m} \right)^p, \quad \text{and we shall be able to determine the relation of } x \text{ to } d \text{ in the following manner:—}
\end{align*}
\]

\[
\begin{align*}
\frac{p + m}{m} = \text{Let } d = \delta p \times y, \text{now } d^m + m = b^m \times y^p; \text{ we shall have } x + \phi + p = \\
\left( y + \frac{a b}{c} \right)^p \times b^m. \quad \text{Construct the curve } AE \text{ expressed by the equation } d^m + m = b^m \times y^p.
\end{align*}
\]

Take \( B A = a \times b^m - \frac{p^m}{p}, \) and from the point \( B \) describe another curve, which has for its equation \( x + \phi + p = \\
\left( y + \frac{a b}{c} \right)^p \times b^m, \) we shall have \( DE = d, CD = x, \) and the intercepted portion \( CE \) will be the increment required.

VII. Scholium 1.—In the simplest case of the velocity in proportion to the height, using the first formula of the preceding corollary, change this into \( d = x = \frac{a b}{c}, \) the equation of the equilateral hyperbola \( A, \) of which as well the parameter \( b \) as the diameter \( b m = \frac{2}{b} \) and \( c \) have analytically \( d = x = \frac{a b}{c}, \) which is the equation proposed; whence appears the method of describing such a hyperbola, so as to contain every possible case of increment arising from an addition of water. And calculating with the second formula the two parabolas of the preceding corollary, we shall have \( d = b y, B A = \frac{a b}{c} \) and \( x = y + \frac{b a}{c}; \) and if \( b y \) we substitute its equivalent \( d \), we shall have \( x = d + \frac{b a}{c}, \) the equation which is found and constructed above.

VII. Scholium 2.—If the velocity is as the root of the height, the equation resulting from the formula of \( \$ \) will ascend to the sixth dimension of the unknown quantity, and the progression will be \( c x^2 - a b t t \times c = x^2 + a t b - 2 c t^2 - a c t b d^2 + c d^2 = a, \) which does not transcend the limits of a cubic equation; but with the second formula \( m = \frac{n \times p}{p + p} \) we shall have \( x = \left( y + \frac{b a}{c} \right)^p \times b; \) and supposing \( d^2 = b y, A E \) will be the parabola expressing the aforesaid equation, and \( B C \) that of \( y = \left( y + \frac{b a}{c} \right)^p \times b, \) without otherwise embarrassing itself in the resolution of the aforesaid equation, already sufficiently complicated.

VIII. The converse proposition to \( \$ \) deduced from the formula there enunciated, which gives the height of a river from which a quantity of water is deduced, to find the section of a canal, such as shall discharge the same quantity of water, and whose height \( B \) shall descend to \( B C. \) The equation \( c x = a d + ab t \) is then changed into \( a b \times c q - c d u, \) which solves the problem. Let it be required to diminish it by such a quantity of water as may have to the first, before the subtraction, the ratio of \( t \) to \( p, \) whence we shall have the analogy \( c x = c d u; \) \( c d u = \frac{1}{p + m} \times \phi \)

by making \( r = b m, \) and \( u = d w, \) and we have \( b = \frac{\phi}{p + m + 1} \times \phi \)

whence we deduce the height of the canal of deduction \( d = \frac{a}{p + m + 1} \times \phi \)}
and \( u = \frac{a}{s} \), the equation will be reduced to the following:

\[
\frac{p + m}{a + p} = \frac{p + n}{b + p},
\]

in which \( a \) and \( d \) are the unknown quantities, and \( c, f, b, s \), the given quantities; or else, if a certain breadth be given, and the height remains unknown, we shall have:

\[
\frac{\left(\frac{e}{a} + \frac{1}{b + 1} + \frac{1}{d + 1} + \frac{1}{m + 1}\right)}{n + 1} = \frac{c}{a}.
\]

Now in the case of horizontal, or nearly horizontal streams, the canal of derivation being open, whose bottom regulates also the height of the water of the river; that is to say, the portion which acts to produce the greater or lesser quantity which it deducts, the other remaining in order of importance relative to such a canal of derivation, the formula will be:

\[
d = \frac{c}{a} \frac{e + p}{f + c} + \frac{1}{n + 1}.
\]

IX.—Corollary 1. In the second formula of the preceding paragraph let \( m = n + 1 \) we change it to:

\[
d = \frac{\sqrt{1 - \frac{c}{p}}}{\sqrt{1 - \frac{c}{p}}},
\]

if \( l = 4000, p = 3500 \), numbers expressing the quantity of water which passes through a given section of the river both before and after the subtraction of the water, \( b = 10 \) feet, \( a = 200 \) feet, \( c = 300 \) feet, performing the proper operation, the logarithm of \( d = 1.3954534 \) answering to \( 21.125943 \); the value of the first height before the diminution will be \( s = \frac{p + m}{a + p} \), where \( d b \) being known, all the other quantities will be known as well, and is 22.125943 feet.

X.—Corollary 2. Making \( n = k \), which is the case of Torricelli, Mariotti, and others, transmuting the aforesaid second formula into:

\[
d = \frac{\sqrt{a + p p}}{c c} \left(\frac{e}{a} - \frac{f f}{c c}\right),
\]

Substituting the proper quantities and placing the values of the quantities \( p, b, a, c \), as above, the logarithm of \( x = 1.3846588 \), the number to which is 30.125943, from which it appears that if the river be lowered by the water, diminished by the effluent so that the first height shall be to the second after the diminution as 22.125943 to 21.125943, the quantity which passes through a given section below the point of diminution, before the water is subtracted, will be to the quantity which passes through the same section after the water is subtracted as 40 to 38 in the first case, and the height in the second case as 30.125943 to 29.125943.

XI. Corollary 3. Taking the third formula of the preceding paragraph, in which we have supposed \( p, f, b, c \) given, making \( \phi, m = 1 \), by the hypothesis of Castelli, let us seek the width of the canal of derivation. We shall have:

\[
a = \frac{e d d}{c} \frac{e - f f}{b b},
\]

Suppose \( e : f : 9 \) to 8, \( d = 20, b = 18, c = 300 \), the logarithm of \( a = 1.3900926 \), corresponding approximately to the number 98, of so many feet will be the width of the canal of derivation, that the first height may be to the second, after the water is diminished, as 9 to 8; but on the supposition that \( m, n, \phi = 4 \), the formula changed to:

\[
a = \frac{e d d}{c} \frac{e - f f}{b b},
\]

and the logarithm nearest to \( a \) will be 1.3900926, whose nearest number, 78, will be the width required.

XII. Corollary 4. Using the general formula, \( a = \frac{c d u + a b r}{c q} \),

to obtain the residual height of a river, after a certain quantity of water has been subtracted, we shall have:

\[
d = \frac{c q s + a b r}{c q}.
\]

Now by substituting for \( q, r, u \), their respective values \( s, b, a, d \), we shall have:

\[
\left(\frac{e}{a} + \frac{1}{b + 1} + \frac{1}{d + 1} + \frac{1}{m + 1}\right) = \frac{c}{a}.
\]

If then \( \phi, m \) will be equal each to \( \frac{1}{c} \), we shall have the equation:

\[
\phi = \frac{ab}{c^2} s + \frac{ab}{c^2} s^2 + \frac{2a^2 b}{c^2} s^3 + \frac{a^4 b^2}{c^2} s^4 = 0.
\]

Or if, for greater simplicity, we reduce it to the following expression:

\[
d = \frac{b s}{c c} (s^2 - 2 a s + 2 a b x^2) = 0;
\]

and since \( x = \frac{b}{c c}, \phi \) we shall have:

\[
\phi = \frac{ab}{c c} s^2 - 2 a c b + \frac{2 a b}{c c} s^2.
\]

XIII. Corollary 5.—Using the preceding formula, in which we have constructed two parabolas, according to what has there been laid down,

\[
d = \frac{c d}{p + m} d \frac{p + n}{a + p} \frac{p + m}{ab} + \frac{c d}{p + m} \frac{p + n}{a + p} + \frac{c d}{p + m} \frac{p + n}{a + p} \frac{p + m}{ab} + \frac{c d}{p + m} \frac{p + n}{a + p}.
\]

We now have:

\[
d = \frac{p + m}{a + p} \frac{p + n}{a + p} \frac{p + m}{ab} + \frac{c d}{p + m} \frac{p + n}{a + p} \frac{p + m}{ab} + \frac{c d}{p + m} \frac{p + n}{a + p} \frac{p + m}{ab} + \frac{c d}{p + m} \frac{p + n}{a + p}.
\]

We have, making the necessary substitution:

\[
\left(\frac{y + \frac{ab}{c} (p + n) m}{p + m}\right) \times d m.
\]

Now let \( B \) be the curve whose equation is \( x = \frac{a b (p + n) m}{c p + m} \), and from the point

A describe another curve \( A \), expressed by the equation:

\[
\left(\frac{y - \frac{ab}{c} (p + n) m}{p + m}\right) \times d m.
\]

We shall have \( D E = d, C B = s, \) and \( C E \) the required difference of height.

XIV. Scholium 1.—We shall give some examples of the fall of the surface of rivers, produced by derivative canals, as they have been called, and these examples will be taken from the Adige, which, as is known, affords many such, and on which I had cause, at various times, to make several observations for its general regulation. It was found

1st. That the Bova della Badia, in flood time, measures 10.7.4 Venetian feet, or 1592 lines, above the sill; a its breadth is 194 feet, or 1800 lines. The reduced height of the Adige, opposite it, at flood time, was 11.3.1, or 1621 lines, being 409 feet wide, or 57868 lines; now by a preceding rule, § VI., in which we supposed the velocity as the height, having \( x = \frac{b}{c} = 269 \), and consequently \( d = \sqrt{\frac{a b}{c} (p + n) m} \). which being subtracted from the height of the Adige before the diminution, there remains 23 lines, that is 1 inch 11 lines for the required diminution.

2nd. At the outlet or sluice of the Sabbadinas we found that \( x = 18.1.11, \) or 2759 lines; \( b = 9.2.11, \) or 1231 lines; \( a = 27 \) feet, or 3860 lines; \( c = 2980 \) feet, or 30240 lines, whence \( s = 264 \) and \( d = \sqrt{\frac{a b}{c} (p + n) m} \). which, deducted from 2759, the first height, gives 56 lines or 42 inches.
lines, \(a = 60 \text{ feet} = 8640 \text{ lines}, c = 318 \text{ feet} = 45792 \text{ lines}\), and \(x = 306, \text{ and } d = 1441, \text{ giving 29 inches for the diminution of the Adige.}\)

4th. At the Fossa Bellina which is the lowest of the two highest with respect to the sea, it was found that \(x = 10.11.8 = 1580 \text{ lines}, b = 4.45 = 626 \text{ lines}, a = 60 \text{ feet} = 8640 \text{ lines}, c = 298 = 37539 \text{ lines} \), whence \(x = 301\) and \(d = \sqrt{x(x - x)} = 1531\), which subtracted from 1580, leaves 29 lines for the diminution of the Adige, that is 2 inches and 5 lines.

5th. But at Castagnaro, which is the first and farthest from the sea of all, it was found that \(a = 2050 \text{ lines}, b = 1491 \text{ lines}, a = 35064 \text{ lines}, c = 85040 \text{ lines} \); dimensions taken above the two falls on each side of the Cunetta, which remains in the middle, the result of which calculated separately will be \(x = 230 \text{ lines} \), and \(d = 1816 \text{ lines}, a \text{ sum which diminished by 2030 lines, leaves 234 lines for the diminution of the river.}\)

6th. By reason of the diversification, which the two falls are able to produce on each side of the Cunetta. Calculating then the diminution of this, we have \(a = 2050 \text{ lines}, b = 2127 \text{ lines}, a = 3816 \text{ lines}, c = 85040 \text{ lines} \), as above, whence \(d = 8000 \text{ lines} \), which, subtracted from 2050, leaves 30 lines, or 4 inches of water, wherefor we have for the whole diminution of the Castagnaro 11.18, or within 4 lines of 2 feet.

XV. Sciolium 2. The celebrated Abbate Guido Grandi, mathematician of the Grand Duke of Tuscany, in his treatise on the motion of water, professes “that if two horizontal rivers, LG, FG, moved in the same direction, LG, GK be placed in one, and FG, FK in the other, then the velocity and direction will be GH; and, on the other hand, supposing the said trunk HG, has the velocity HG, it ought, with the retrograde motion to divide itself into two branches, LG, GK, they will not regain the velocity, LG, GK equal to the first, unless the angle GFK is 90°, and the right angle, which the being different from what we have before established, we are obliged to examine, according to our power, the foundation on which the aforesaid proposition rests. Grandi resolves the total velocity, GH, which arises from the two, GK, GI, by means of the complement of the parallelogram to which we add the forces, HG, H, of which HE is the perpendicular fall on GK produced; but if conversely, says he, the trunk, HG, he resolved into branches, whose velocity shall not be the same as on entering the trunk, it may be greater or less, and will only be equal in the case when the angle, LGF, is a right one. The direction of the trunk, HG, resulting from the conjunction of the two lateral, GI, GK, is exactly what all statisticians have laid down. To have a clear proof: on the line GH raise the perpendiculars, K, L, and the velocity, GI, which will be obtained, resulting actually from the two GI, GI, of which K, I, nowise contribute to the progressive motion, but only GI, GI, then G + GI are equal to GH, as is more easy to demonstrate; then each quantity denotes really the velocity with which the water moves after receiving the influents, and it is to be noted that the perpendiculars K, L, are equal and perpendicular to the other I will only oblige the branch to lend a little from its course. Wherefore the illustrious author then considers the converse of the proposition, that is, when the trunk passes into the branch to the motion, HG, into two, LG, GK, and says, that in GKF the water will run with the velocity GE, greater by the acute angle than GK, the which will be true, whatever bend and through whatever arm, GE, all the water of the trunk may flow, whilst HG does not express all the velocity, the same quantity not going through G, GE, which, according to the principle of conservation of energy, it results that HG ought to resolve itself in another shape than that which is the case, that is, considering G by the velocity G, and G by the velocity GK, whence the original velocity, G, G, in the two canals respectively, will be precisely restored, as if it moved as different branches, G, G, and, the conversion of the influents into diffusers will not change the velocity; in either case it will be retained, provided it be not changed by any external circumstance.

XVI. Sciolium 3. —I think it would not be superfluous to give an example of the increase of height which a river really acquires from the superposition of another. We will suppose the mean proportional of the height, using the preceding formula \(x = \sqrt{d^2 + 2dx + x^2}\). The average depth of the section of the recipient = 3962 lines = d, its breadth 113900 lines = c. The true section of the recipient is figured, in which as the bank of B to denote the backward action of the water, PF the average depth; the next figure is the section of the influent in which the shoal EH appears much more elevated than the bottom I and BM the surface. The better to adapt it to practice and calculation, I shall divide the section into several parts, reducing them one by one to the section of the recipient, which when added together, gives the amount of increase. In the section of the influent, DE H I L N R T, DE denotes the right bank, R T V the left, E H the bottom of the shoal at the toe of the right bank, L N R the bottom on the left bank, and H I L the dam or weir. The portion B E F must be considered of the mean height 3.04, that is half EF by reason of the triangle B F E or B A E, the base B F is 11 feet, or 1534 lines, wherefor performing the necessary operation, we shall have \(x = 3963 \text{ lines, from which subtracting 3962 lines, the average height of the section}, x = 3963 \text{ lines, from which subtracting 3962 lines, the average height of the section, there remains one line for the increase of that portion B F E. Likewise through the portion F G H E, 17 feet wide, and 6.09 feet high = 973 lines, we shall have \(x = 3968 \text{ lines, from which subtracting 3962 lines, there remains 6 lines for the increase of the recipient in height by reason of the aforesaid ad-

...
FRENCH RAILWAYS AND FRENCH REVOLUTIONS.

At length the time has come when the French are awakened to the truth about their railway undertakings. There were very few who understood the plan of government interference; it was thought quite right that the government should take charge of the railways, and private enterprise was crushed. We say crushed, because it had not free play, and because the concession system was a clog on those lines which were left in the hands of shareholders. France is behind-hand with her railways; private enterprise when most wanted is dead, and the finances have been upset by the wasteful manner of making the government lines. M. Garnier Pagès, the new Minister of Finance, says this plainly, and names among the causes of financial embarrassment those great jobs, the government railways, made for private profit. Thus a demand is now put on France, which she will very much feel, for taxation is at all times burdensome to the people, but always most in their times of greatest need. It was wrong that railways should be made by loans and taxes; but it was still more wrong, when the private enterprise of France was in its childhood, to take away from it the food, as it were, of growth. France has always been backward in such public works, and when there was a fair chance of getting the French to take shares in railways, they ought to have been put forward instead of being kept back. It has not been done, and France is burdened with the government railways, and the springs of private undertakings are broken up and can do nothing, when France wants them most.

If, however, the late government struck a great blow at joint-stock undertakings, the future government holds out no hope, for with the government will go to the people, if need be, what may be their share in anything they may undertake. The working-man comes in now, and asks for his share in the newly-opened lines, and though it may be small at first, it may be very much afterwards, or it may be all. Railway undertakings are not there this plan can be better tried, and the workmen have very much means of making the traffic greater; for when a railway is made, the bulk of the traffic flows upon it, and though it may be nursed, yet, as we have said, the underlings can do but little for it. The shareholder does the most in making the line, and the working does not much want for work, and is seeking a livelihood, not like the Swiss and others who crowd to Paradise Island, spread which Frenchmen might earn; but they have been asked to go there—they have been sought. English skill and English knowledge were wanted for French railways, French power-lawns, and French engine works. There were no Frenchmen to do the work, and Englishmen were brought over to teach them. So far from the English doing as the Swiss—working under the French, taking away their livelihood, or shortening their earnings—the English have been always paid higher than the French, and have followed new callings in which no Frenchmen came in their way, while they have given help to the others by teaching them their trades, which they did not know before. The power-lawns and other weaving and spinning works of the north of France have been set up by the English, and carried on by English foremen; and thus the French have been brought into the market against us. The English foreman is to be found all over Europe, not because he is liked, but as they cannot do without him. This not in France only, but in Flanders, Holland, Germany, Italy, and Spain.

The withdrawal of French engineers and English workmen from France is a blow struck at France, and not at us. Instead of English working as enlightened as the French workmen, as like to their own, and be beaten as they were before. We do not believe that this swarm of Englishmen abroad did us the least good. They mostly laid out in France what they made there—they seldom brought anything back; and if we had not to keep the few thousands they have left here, still better, for they have not out of work at home, who if they had to deal with the French only would have beaten them, for after all the English are far better in all the higher work. We shall have so many men brought home, and we shall have to keep them: it will be most likely by our
HEALTH OF TOWNS BILL!

The promised bill for securing the health of towns is again before the legislature; and we hope with some prospects of success. To the general principles of the measure we are most favourable. We have long been laboriously to obtain a redemption of the very serious evils which so much affect the public health. At the same time, there are many clauses which require great and grave consideration before they become law; and in making some remarks upon them, we do so without any hostility to the bill generally. In clause 35, the householders have the power of putting the act in motion. In large towns, such a number gives the power to an insignificant minority; and in small towns, fifty may be found too many. There ought either to be a proportional number, according to the population of the town. Although the eighth clause speaks of existing local boards, we do not find any provision for their abolition; and we therefore expect that great confusion will arise between the new local boards of health, and the old local boards, for paving, cleansing, highways, sewers, and for other purposes. Great confusion must likewise arise from the election of new officers, who will be brought in conflict with the present clerks and surveyors.

The qualification of elected members of local boards seems too high for small towns. The number of inhabitants rated at thirty pounds a year is so small as to restrict the choice of the voters.

We think the provision for contour lines in clause 27, is useful; but if the lines are taken at every ten feet elevation, it will be quite enough.

By clause 39, the board of health will have the power of carrying the act as far as the law allows. In the words "through or under any lands whatsoever." Surely this will never be allowed to pass; this power will enable any sewer to be carried across a garden, pleasure-ground, or park, without any notice or compensation.

Clause 35 requires that notice of building a house shall be given to the local board of health fourteen days, and that works shall not be begun without leave of the board. Seven days seems to us quite time enough, and the works should proceed unless the board can show some objection to them.

It appears very unlikely that clause 42 will be found practicable. It provides for engine and factory chimney's consuming their own smoke.

Clause 49, although aimed at great evils, is very objectionable; and however effectual it may be in checking tram-houses, it will not touch the evils of overcrowded Irish lodging-houses. It makes all houses, other than public houses, liable to registry and inspection, where persons are lodged for a single night or less than a week. Unless some exception be made for Brighton, Margate, Gravesend, and other watering places, the inconvenience and annoyance will be great; as house-holders are glad to accommodate visitors who run down by steamboat or rail on the Sunday, and return on the Monday.

The clause 54, giving control to the commissioners for regulating the levels and plans of new streets, is arbitrary in its interference with private property, while six weeks is very much too long for any inquiry to be made by a local board or its officers.

In the next clause, 30 feet is too wide for a mews; 24 feet is ample.

The clause 58, for enabling local boards to set up waterworks, however necessary in itself, is likely to do evil by throwing impediments in the way of private enterprise, for the existence of any company to be set up is precarious and dependent on the local board.

After all that has been said about graveyard in towns, it is a pity to see the countenance given to this abuse by clause 67, which allows of graves being made with only thirty inches of soil over them, a shameful and fearful nuisance.

The clause 78 is inconsistent with the general tenor of the act, for after making it compulsory on every house to have the water laid on, the measure of cutting it off for non-payment of rates, is one not favourable to the public health.

REVIEW.

The science of ship building appears to us one of those in which the precise application of mathematics is not to be attempted; but of which, nevertheless, the leading principles should be based on the theoretical laws of mechanics. For ship building, mathematics must formulate the mathematical principles of everything. The former cannot take account of the thousand and one practical requisites of a good ship—the latter leave sufficient margin for the attainment of the needed qualifications; the former impose laws which are not always just, and even where they are just, are too minute and restrictive; but the latter establish a more liberal and lenient code—one more easy to be obeyed and more deserving of obedience. In choosing between a scientific principle and an analytical formula, the ship builder chooses between a friend and a master.

There is, however, a great difference between general principles and vague principles. It is the latter which are now almost exclusively observed in the public docks. Grave official personages have a great horror of matters which they themselves do not understand, and consequently the range of their antipathies is very comprehensive. It includes science. It is a great scandal to assert that in the government docks, the most profound science is not so useful a personal commodity as kinship to one of the Lords of the Admiralty. Let a man prove by rigorous scientific demonstration, that some established rule of ship building is untenable, and he will be the object of his pain.

Will he be thankful for making an advance in science? Will the obligation under which he has laid society to him, be discharged? Quite the contrary. The chances are, that he will be frowned down as a visionary, or rebuked for pretending to know more than his superiors. In the eyes of men in office, to be set right is to suffer low-majesty.

There is one chance, however, that a scientific discovery may be useful, if not to the discoverer, at least to the public;—some one who dines occasionally at the Admiralty, may think it worth while to appropriate it.

Our respect for government science, for the researches of royal commissions, the mathematics of blue-books, and the investigations of official inspectors, is extremely limited. In matters of experimental philosophy, we should lay it down as a general rule, that the less likely they are to find out the truth are—the "properly constituted authorities." What a satisfactory affair the Gauge Commission turned out! How well Sir William Symonds' ships sail! With what universal and unhesitating deference did the railway engineers receive the reports of Sir Charles Pasley! And to still further back, how admirably the Irish Railway Commissioners executed their task! of which the most favourable thing that can be said is—that their report suited the character of the country affected by it. The blunders of admeasurement in the plans and sections were not much more egregious than some which have been detected by the Standing Orders committees: and Mr. Barlow's investigations of the effect of gradients are not very much worse than a mathematical student would write in his first year.

It seems to us quite clear, that for the future advancement of the practical sciences we must trust entirely, or almost entirely, to private efforts. At rare intervals, indeed, a commission will be
THE CIVIL ENGINEER AND ARCHITECT'S JOURNAL.

1848.

competent for the scientific investigation assigned to it: it is rea-
sponsible, for instance, to expect much benefit from commissioners
selected as those appointed to consider the use of cast-iron girders
on railways have been. But on the whole, these cases may be
looked upon as exceptions and happy accidents. In naval matters
the inefficiency of the old, is frequently deplored, and the
cause of the enormous expense which it entails upon the nation.
After all the visits of the Lords of the Admiralty to Portsmouth
—after all the parliamentary returns and parliamentary debates
—after all the enormous cost of ships built on new models, to be
subsequently remodelled and patched over at a prohibitive cost,
—after all the exploits of experimental squadrons—we have
come to the very gratifying conclusion that our most weatherly
vessels were taken from the French in the late war, O, for an
Ecole Polytechnique in England!

The author before us professes no more than to "give some
direct principles for actual building," and to put the reader in possession of just so much information as is requisite for
preventing the "larger and more scientific works on the subject."
But the present treatise, though it does not aim at extreme pro-
fundity, has the higher merit of expressing in simple terms some
very important views respecting the application of hydrostatics
to the theory of ship building. The stability of a vessel is properly
insisted upon, as a perfectly indispensable requisite—one without which
all other merits are valueless. The form of a vessel may enable her
to sail faster than another; but if the motion be excessive, the practical utility of the vessel is proportion-
ably lessened, her security endangered, and her durability diminished
by the constant strains to which she is subject. Sir William Symonds' vessels are, our author remarkes, liable to these
grave objections. He argues, that the stability of a vessel is so in-
times so great, that the stem is inclined to the keel at an angle
of thirty degrees. By thus cutting away, so to speak, a large por-
tion of the force of the waves, it is clear that when the vessel pitches ahead,
there is less immersion or sustaining power to bring her up again,
without making a headway, than there would be if the stem were upright.
The author has, indeed, submitted a similar error with respect to the lateral rolling. The
lateral stability, of course, depends in a great measure on breadth
of beam; but the general form of section amidships must be duly proportioned in reference to it. "Here," says our author, "we
can consider, is the great defect in the surveyor's midship section; it is comparative safety is kept to the warp line;
and, as such, is manifestly deficient in bearing, until its extreme
immersion takes place, which is sudden almost to a jerk;
whereas a rounder line would prevent the great degree of lateral
inclination, and what must take place would be much more easy.
The advantage of this, in comfort upon the deck, efficiency at the
guns, wear and tear of the rigging, and indeed, the safety and com-
fort of the whole, must be apparent."
The conditions of stability, either laterally or longitudinally, are
not after a hydraulica, and are very difficult to ascertain. The problem is prac-
tically a hydrostatics one, and therefore simpler and easier, and
much easier than that of determining the forms best adapted for
speed. If navy surveyors had only a moderate acquaintance with
the properties of the Metacentre—if their appointments de-
depended rather on their knowledge of hydrostatics, than on their
government influence, or aristocratic connections, we should
have to pay for much fewer of those great wooden coffins which
degracce our navy. As far as we may judge from Sir William
Symonds' actual performances, he either does not know the mean-
ing of the word "metacentre," or he cannot have studied its prop-
erties. He may possibly have an idea that the have some in-
fluence on the stability of a vessel—but he certainly cannot know
that they are, not merely important, but all-important—that in the
question of stability, the properties of the metacentre constitute
the question, the whole question, and nothing but the question.

Mr. White's practical directions we will not venture to criticise
at length. The accuracy of his general views, however, and his
long experience in his profession, seem just grounds of dependence
on his authority in matters of detail. The folio plates are care-
fully drawn and admirably executed: and the descriptions which
accompany them, though in their minutiae, and appear well suited to the
purposes of the ship builder. The author concludes with the tend-
count of the methods now in use for measuring tonnage, and with

 marks on the complexity and inefficiency of the new method
 established by law. We conclude with the following brief extracts,
the first selected for its scientific importance, the second for its
curiosity.

"The form of body best adapted for steam vessels, is a primary consi-

deration. It will be found that most of the principles which constitute
a good sailing ship, will also apply to a steamer. We have repeated instances.
in which first-class steam ships that have afterwards proved of superior char-
acter, have been sold at a loss, under jury rig, and with not more than half
the momentum of canvas allotted to sailing ships of equal tonnage, as
they have subsequently gone under the full power of the engines. Many
steamships have been thus abandoned, without compensation,
the cause of the enormous expense which it entails upon the nation.
After all the visits of the Lords of the Admiralty to Portsmouth
—after all the parliamentary returns and parliamentary debates
—after all the enormous cost of ships built on new models, to be
subsequently remodelled and patched over at a prohibitive cost,
—after all the exploits of experimental squadrons—we have
come to the very gratifying conclusion that our most weatherly
vessels were taken from the French in the late war, O, for an
Ecole Polytechnique in England!

An Historical, Practical, and Theoretical Account of the Breakwater
in Plymouth Sound. By Sir John Rennie, F.R.S., F.S.A., F.G.S.,
President of the Institution of Civil Engineers. London: Bohn
and Weale, 1848.

Sir John Rennie could not have more worthily devoted himself
to than to the commemoration of the great work of his father, the
Plymouth Breakwater, and he could not have erected a monument
more munificent than the volume now before us,—one which it
records the merits of his father, and gives proof of his own en-
larged, enlightened, and improved taste; will be of value to the engineering profession of
the Scripture narrative. The break was twice as long, and twice as wide and
deep, as the West-India mail steamers, and consequently would make eight of
them, considered as regular figures."

An Historical, Practical, and Theoretical Account of the Breakwater
in Plymouth Sound. By Sir John Rennie, F.R.S., F.S.A., F.G.S.,
President of the Institution of Civil Engineers. London: Bohn
and Weale, 1848.

Sir John Rennie could not have more worthily devoted himself
to than to the commemoration of the great work of his father, the
Plymouth Breakwater, and he could not have erected a monument
more munificent than the volume now before us,—one which it
records the merits of his father, and gives proof of his own en-
larged, enlightened, and improved taste; will be of value to the engineering profession of
the Scripture narrative. The break was twice as long, and twice as wide and
deep, as the West-India mail steamers, and consequently would make eight of
them, considered as regular figures."

"The arks in Scripture were of these proportions, namely, six times the
breadth for the length, and one-tenth the length for the depth. Other
proportions may in particular circumstances tend to promote stability and
security at sea, the proportions of the ark, destined as she was to en-
dure the greatest commotion of waters the world has ever known, are,
we fearlessly assert, infallible, since the experience of four thousand years
has endorsed them; will be of value to the engineering profession for
many generations. Well may we describe it as a monument more
lasting than brass, while it bears a more noble inscription than was
ever sculptured on marble. Of Sir John Rennie's works we will
not speak, for others can put forward a claim to the production of
works of equal magnitude and merit, but we cannot refrain from
saying that this book is another public service rendered to the
engineering profession. As President of the Institution of Civil
Engineers, Sir John has upheld the social rank of the profession,
and has maintained its public hospitality; by the contribution before
us, he has shown his earnestness in the cause of professional litera-
ture. These are to our mind merits in addition to the material
monuments of his skill, and speak powerfully of his enlarged and
liberal mind, and of his public and disinterested spirit. They
show that his heart and soul are engaged in the career he pursues,
and are a guarantee of his professional independence and integrity.

We speak warmly, because it is rarely we have the opportunity
of speaking of a book from the hands of one of the higher members
of the profession, and therefore it comes more welcome to us. It
is true there are excuses for the silence of those members, and Sir
Rennie is one of the very few who have not had the opportunity
to exempt us from our duties towards him, who stands a brilliant exam-
ple of successful exertion. Sir John Rennie's words merit atten-
don, for they must be the exculpation of our engineers in the eyes
of Europe. He says:

"Continental engineers have generally more time than English
engineers for writing and reflection. The former, confined for the
most part to a single work at one time, have leisure to study and
reflect upon every operation connected with it, and to deduce
general laws from them which may be applicable in similar circum-
stances. The sphere of his knowledge is more limited, and he is not
accustomed to begin with that of English engineers, and they have not the same faculties
of acquiring that readiness of application, that versatility in
inventing remedies to meet every case which occurs in practice,
and which alone can be derived from extensive and greatly-varied
experience in all kinds of works, such as falls to the lot of English
engineers. This defect is necessarily inherent in the continental
system, notwithstanding the numerous able engineers we find there.
The whole of the works, as well as the engineers, being in the
employ and under the control of the government, their energies
are directed towards the purposes of the government, and not
that strongest of all inducements to exertion, viz., competition,
which has been productive of so much benefit in this country. Here,
where engineering, everything has been free and un-
tramelled; thus every member of the profession has been at liberty
to follow out his own ideas, and those best calculated to acquire public favour, and secure his own interest;
and the public, on the other hand, has never found any deficiency
talent to carry out any work as often as the emergency required.
The Young Surveyor's Preceptor. By John Reid, Surveyor, Parts I. and II.

The object of this work is to explain the present system of measuring and estimating builders' work;—for this purpose the author has given the plans of a first-rate building and explains how the measurements are taken, commencing with the digger, and going on with the bricklayer and carpenter. The dimensions are all given in detail as taken off in estimating, and are accompanied with a specification of each trade. Mr. Reid appears to have adopted the practice of the most experienced surveyors, and has produced a work which is likely to be of great benefit to the pupil, in assisting him in his professional pursuits. In saying this, we must caution him not to imagine that he can obtain a sound practical knowledge of the duties of a surveyor or architect, from merely reading or studying this work, or any other book or lecture: it can only be attained by accompanying an experienced surveyor in measuring or making an estimate of the building itself.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

INSTITUTION OF CIVIL ENGINEERS.

Feb. 22.—Joshua Fild, Esq., President, in the Chair.

The paper read was by Mr. A. Mitchell, of Belfast, Assoc. Inst. C., "On Some Improvements Found in Mooring and Moorings." Considering that the entire subject of the various sorts of piling, of solid stone foundations, of cofferdams, of masses of concrete, and the numerous modes adopted by ingenious men for overcoming local difficulties, would occupy too much time, and scarcely possess novelty, the author restricted himself entirely to the description of those objects which could be made by him with the screw-piles, as that had been chiefly employed for supporting structures on loose sand or mud banks, wholly or partially covered by the sea, where it had been previously considered very hazardous, if not impracticable, to erect any permanent edifice. The screw-pile, he scrupulously avoided all connection with other modes of proceeding, even when they had the same object. The origin of the screw-pile was the screw-moorings, which was designed for the purpose of obtaining, for an especial purpose, a greater holding power than was possessed by either the ordinary pile or any of the usual mooring-anchors or blocks, of however large dimensions. It was proved by experiment, that if a screw, with a broad spiral flange, were fixed upon a spindle, and forcibly propelled by rotary motion to a certain depth into the ground, an enormous force would be required to extract it by direct tension; and that the power employed must be sufficient to drag up a mass of earth of the form of the frustrum of a cone reversed—the base being at the surface of the ground, and the section of the apex being equal to the diameter of the screw. The extent of the resisting mass must, of course, depend upon the nature and quality of the soil. Even in this reasoning, it must be evident that a vertical force was calculated upon; but as, practically, that seldom if ever occurred, the angle of tension and the curve of the buoy-cable again gave the moorings greater power. This was found to be correct in practice, the experiment of Mr. Mitchell. The arrangement of the moorings was made with the port of Newcastle-on-Tyne, by which, for the sum of 2,500L, the right of fixing these moorings in the Tyne was given; and Mr. Brooks, the engineer, showed that last year, whilst in the neighbouring port, damage was done to the shipping to the extent of nearly 30,000L, so that the injury was sustained in the Tyne, entirely owing to the sound holding of Mitchell's screw-pile moorings. It naturally occurred to Mr. Mitchell, that the same means of resistance to downward pressure might be used; and he proposed to apply it for the foundations of lighthouses, breakwaters, and other structures, which, for maritime purposes, it might be desirable to place upon sand and mud banks, where hitherto it had been considered impracticable to place any permanent edifice.

We have been apt to adduce as a merit in professional works that they were profusely illustrated, and we believe our readers will agree with us, for such books are thereby of more practical value. In this respect, Sir John Rennie's volume has few to surpass it; and it is undoubtedly one of those great works, which must at once take its place in the standard library of engineering. No expense has been spared, we may say no care has been spared, to make that portion of the work complete which speaks to the eye, illustrating the words of Horace:

"Legum irretint demissa perennis
Quam sunt occulti subjecta Selibus!"

The eye of the practical man seizes at once the construction and proportions in a drawing, while the most copious description fails to convey an impression so complete. Again, it is more easy for those who wish to copy a good example to do so from a drawing than from a description, and when we consider that a work of this kind is to be a text-book for hundreds of engineers, it appears most desirable that it should be, as it is, really and truly useful.

On leaving the presidential chair, Sir John Rennie has not retired from the public service for their interests a word or syllable, but he has well claimed exemption from further contribution. That he has completed this magnificent work gives him an additional title to future fame, as it does to the gratitude of his contemporaries for his maintenance of the dignity of their profession.
A project was started by the East of Courtown, in the year 1847, for adding to the length of the pier at the Harbour of Courtown, on the coast of Waterford, which had proved an entire failure, from the channel between the solid pier being continually choked up with sand. Iron piles, with screws of 2 diameter, to be driven from 11 feet to 15 feet into the sand, and blue clay, were decided to be used, in order to force the channel over the sand country by the pile, and the platform would be used for loading and discharging the shipping. The surf was so heavy on the coast that the usual barge or flat-raft could not be used for putting the piles down—so an ingenious plan was designed by Mr. Mitchell, for projecting a stage of water, and for the anvil being used for the upper part of the piles on the top of the pile, passing an endless rope-band around it, and round a pulley fixed 150 feet back, and then, by a number of men hauling upon the base, a rotary motion was communicated to the pile, which screwed it down very firmly. The vessels thus sunk were of the depth of 3 feet 17 feet long, were built on their founds daily, even in very rough weather. The entire length of the jetty was 260 feet, its breadth 16 feet, with a cross-head 54 feet long, with landing stages at each end, and two lines of railway throughout. The entire cost of this extension was £1,050, or about 47£ 10s. per lineal yard—an extremely small sum compared with the cost of stone piers; but even that which was more than the expense would be now, as the system of work is better understood, and materials are now cheaper. The account of the difficulties incurred in the execution of these works was most interesting, and ample testimony was borne by engineers of eminence, and men whose maritime experience gave weight to their opinion, of the superiority of Mr. Mitchell's screw-piles and moorings over every other system for holding buoys, or for supporting bays, and lifesaving. The system was adopted on the Cohong, the islands, and numerous railway and other works, as well as a multiplicity of applications which had not hitherto been thought of.

Mr. W. A. Brooks gave an account of the method of laying down the moorings at Newcastle-on-Tyne, under his direction. A heavy chain, formed of 12 inch square links of 3 feet 6 inches long, was driven into the bed of the river, in the direction of the current. To this chain, beneath each pile, was attached a 21-inch mooring-chain, fixed to the head of a screw mooring; another screw being also placed beneath each tier, and driven down 6 feet into the coarse gravel below the bottom of the rock. The screws were 4 feet in diameter, and were placed in depths varying from 15 feet to 24 feet at low-water spring tides. They were screwed down to the depth of 15 feet in an hour and a half, and sometimes 21 feet in two hours. The surface upon which the chain was run was entirely cut into the sound holding of the screw moorings. He argued, therefore, that the small amount of 2,500£ paid by the harbour commission of Newcastle for the right to put down these moorings was a very wise expenditure.

Mr. T. Samra, Pilot Master of the Port of Shields, corroborated Mr. Brooks's statement.

Captain Washington, R.N., had, in the course of his surveying duties, seen the screw moorings in almost every position, and had heard them universally eulogised, as being the best and safest moorings hitherto known. He strongly recommended their employment. He had been sent many times to try the screw-piles and boulders, and had every reason to be satisfied with them, as affording a means of placing light-houses and buoys where they were before impracticable, and enabling floating lights to be generally supererogated. The cost, however, was in proportion to the number of chains, that the annual cost of the chain was one-third less annual cost than the former, and certainly more useful to sailors; for, in all the care, attention, and even lavish expenditure of the Trinity Board to moor the lightships securely, they did go astray just at the time when they were most required. He, therefore, advocated fixed lights in every situation where a foundation could be obtained; and he believed that, with the screw-pile, there were scarcely any situations where this could not be accomplished.

Messrs. Walker, Cubitt, Reynolds, Murray, Moorison, Mitchell, Scott Rossel, and others, took part in the discussion, adding instances of the efficiency of the moorings and the piles, and of their applicability to numerous engineering works, for which they expressed their intention of employing them. The high praise hitherto charged for the right of using them had somewhat retarded their general introduction; but it was explained, that Mr. Mitchell had feared to entrust to others the fixing of them, lest a failure might ensue before his system was perfected, which, however, he now thought it was. Now, however, as the right of granting licenses for their use was transferred to the Board of Trade, he had no doubt of their being brought within the reach of every application.

Feb. 29.—The paper read was entitled "Remarks on the Formation of the Entrances to Dockets, situated upon a Tide-stream." By Mr. J. B. Redman, M. Inst. C.S.

After illustrating the subject by the example of the position and direction of all the dockets, and the entrance of the Thames at the port of London—showing that the variation in the opinions and practice of engineers had been very great—the paper detailed the ordinary methods of docking and undocking ships, and the precautions to be taken in constructing entrances, which should be best adapted for facilitating these operations; and, although it was difficult to lay down any positive rules upon the subject, as the engineer must, in every instance, be guided by local circumstances, yet in ordinary cases the following general rules were recommended:—For graving docks, an angle of about 45°, pointing up the stream; for wet docks, an angle of about 80°, in the same direction; and a right angle for the entrance of the Manchester dock. These, it was believed, would generally be found the most available.

March 7.—In the discussion upon Mr. Redman's paper, the merits and defects of several dock entrances in the Thames and in other situations were discussed, and the general result appeared to be, that although the engineer must be guided by local circumstances, yet in ordinary cases the following general rules were recommended:—For graving docks, an angle of about 45°, pointing up the stream; for wet docks, an angle of about 80°, in the same direction; and a right angle for the entrance of the Manchester dock. These, it was believed, would generally be found the most available.

The discussion upon Mr. Redman's paper was continued. Letters were read from Mr. Maclean, describing the Barras and Piët sea embankments; and from Mr. MacDougall Smith, on the importance of using stone of great specific gravity in sea-works.

17
Mr. Bateson stated the necessity of using hard and tough stones, which would resist disintegration by the friction of the shingle moved by the waves.

Mr. Murray corroborated the statements of Mr. Bateson, and recommended groynes as the best means of collecting sand and gravel, to protect exposed coasts, and the foundations of sea-works.

Mr. Rankins replied to some of the remarks which had been made. He remarked on the practical value of the paper as being partly confirmed by his observations. He disapproved of the intention of laying down universal rules for the construction of breakwaters in deep water, from observations on walls built on a flat beach; but, to show how the principle of the paper might be applied, alluded to a breakwater, on which the flaps of some willow boards formed an artificial beach, on which a vertical wall was founded.

The paper read was descriptive of "A Method of Setting out a Railway Line," by J. Beadle.

The object of the paper was to supply a methodical rule for setting out that portion of a branch line of railway included between the rails of the main line. The author observed, that in all ordinary cases the curve of a branch line could not be set out from the main line, which was supposed to be straight, by the ordinary methods of setting out railway curves, since the junction was required to make an offset of 4 to 6 inches on the length of the switch-rail, which was much greater than the offset made from the tangent in the same length by a curve of moderate radius. The object of the paper was to devise a method of making the junction line abrupt at a finite angle with the main line. He, therefore, considered the junction-curve, to be determined by its passing through three given points—a point, the two extremities of the switch-rail, and the furthest point of crossing; and from these lines he had developed the rules for the radius of the circular arc, might be found, as well as the positions and angles of the various crossings.

The council are of opinion that the design marked "Christophorus" possesses, on the whole, the greatest degree of merit, notwithstanding the unsatisfactory state in which it is represented in the drawings of the elevations and sections, and sufficient to justify the bestowal on it the award offered.

The author of the essay marked "Junna," is Mr. Henry Bayley Garvan, and the design marked "Christophorus," Mr. James McLaren, of Edinburgh.

Mr. Pembroke read a paper on "On some of the Geometrical Lines and Optical Corrections of the Greek Architects," which will be given next month.

March 6.—C. Fowler, V.P., in the Chair.

A paper was read, "On the Ancient Buddha Architecture of India," by J. Ferguson, Esq.

Mr. Ferguson commenced by showing that the generally assumed primeval antiquity of Indian buildings was not borne out by facts; as the oldest monuments in the country, whether cut in the rock or structural, belonged to the Buddhists, and the founder of that religion died only 543 B.C.; and that their latest date was too early, as it did not become the religion of the state till after 250 B.C., in the reign of Asoka,—by whom the earliest monuments hitherto found in India had been erected. After showing that there was no real similarity between the architectural styles of Egypt and India, he proceeded to point out, that it was much in use at the present day; nor reservoirs, nor the requisite apparatus for heating the large quantities of water that would be required to supply such extensive warm and tepid baths as are shown in the drawings; neither are chimneys or shafts provided to carry off the smoke, steam, &c., which it would be impracticable, under any circumstances, to consume.

Mr. Ayrton, in the Chair; Mr. Jones, Sunderland, and Mr. Cumber, in the Field, said the council were of opinion that the design marked "Christophorus" possessed, on the whole, the greatest degree of merit, notwithstanding the unsatisfactory state in which it is represented in the drawings of the elevations and sections, and sufficient to justify the bestowal on it the award offered.

The author of the essay marked "Junna," is Mr. Henry Bayley Garvan, and the design marked "Christophorus," Mr. James McLaren, of Edinburgh.

Mr. Pembroke read a paper on "On some of the Geometrical Lines and Optical Corrections of the Greek Architects," which will be given next month.
more modern ones its forms were repeated in the rock. After concluding
the Indian part of his subject, Mr. Ferguson pointed out the striking
similarity that existed between the arrangement of the buildings he had been
describing and those of Stonehenge,—which he had no doubt whatever was
a Buddhist building; and he thought every part of that hitherto mysterious
erection admirably adapted for such a purpose. He concluded by
showing how doors were constructed in India; and pointed out the simi-
larity that existed between the Indian examples and the well-known tomb
at Mylase, in Asia Minor,—and the curious circumstance that the humped
backed Lycaenian flies present a striking parallel to the Indian arrangement
on only in form, but in construction, those Indian buildings which had formed
the subject of the lecture; while the language of the inscriptions on them
was a dialect of the Sanscrit, about as far removed from the mother tongue
as that found on inscriptions in the Indian examples.

March 20.—Mr. Eaton Hodgkinson was elected honorary member, and
Mr. Thomas Read, the following :

The honorary secretary announced the following as the subjects proposed
for the medals :

"Her Majesty having been pleased to grant her gracious permission for the
Royal Medal to be conferred on such distinguished architect or man of
science, of any country, who may have designed or executed any building of
high merit, or produced a work tending to promote or facilitate the know-
ledge of architecture, or the various branches of sciences connected therewith,
the council will, in January, 1849, proceed to award the Royal Gold Medal
to the author of some literary publication connected with architecture.

"The Silwood Medal will be awarded:

"1. To the best essay on the peculiar characteristics of the Palladian school
of architecture, and a comparison and contrast of its elementary principles
and details with those of ancient art.

"2. On the manner of covering the roofs and forming the slates and
quitches of buildings; the nature of the several materials used in various parts of
the country, and the materials that are the best adapted to the various
requirements; the inclination to be given to the different parts, and the other
practical precautions to be adopted to prevent snow and rain penetrating
into the building.

"The Soane Medalion is to be awarded to the best design for a building to serve for
a national repository and museum for the illustration and exhibition of the
productions of the industrial arts.

"The successful competitor for this medal, if he go abroad, will be entitled
to the sum of £50. At the end of one year's absence, on sending satisfactory
evidence of his progress and his studies.

"A specimen has been sent in an essay, on "Cyclopean Walls" (Aegyptischen Baukunst), by Dr. Forchammer; parts of M. D'Alby's "Révue
Générale de l'Architecture," and of Mr. Ferguson's beautiful work on Indian
architecture. The foreign secretary, in commenting on the donations,
paid attention to an article in the Révue Générale, complimentary to the
Institute for not restricting the competition for the Gold Medal to this
kingdom.

Allusion was made to the circumstance that all the impressions of Mr.
Leitch's translation of Müller's "Ancient Art and its Remains" (of which a
copy was presented to the Institute at the last meeting), had been destroyed
by fire.

Amongst the letters read, was one from Herr Lange, of Fulda, acknow-
ledging the honour of his election, and setting forth several subjects on
which he contemplates to write in the future; amongst which, the twelfth
(sixth and seventh century), of his neighbourhood, and a collection of terms
in use amongst the workmen of the middle ages.

Mr. T. H. Wyatt read a paper on the "History, Present Condition, and
Proposed Restoration of Llandaff Cathedral."

ROYAL SCOTTISH SOCIETY OF ARTS.

Feb. 28.—GEORGE BUCHANAN, Esq., F.R.E., President, in the Chair.

ON CAST-IRON.

At the request of the council, an exposition "On the Strength of Mate-
rials, particularly Cast-Iron and Malleable Iron, and their application in
the construction of Railway Bridges (Part I.)," was given. By GEORGE
BUCHANAN, Esq., President.

On this subject, so important at the present time from the extensive use of
these materials in the construction of bridges for railways, and from the new
and extraordinary forms and dimensions which they are now beginning to
assume, the council of the Society had requested their President to make a
communication on the present state of our knowledge and practice, and
this evening he read the first part of this communication, illustrating his subject
by various iron bridges and models, more particularly a large and
beautiful model, with drawings and elevations, of the high level bridge across
the Tyne at Newcastle, which, through the liberality of Mr. Robert Stephen-
son, the engineer of the bridge, he was enabled to exhibit, and to explain
the situation, cost, and construction of this great work in all its details.

Mr. Buchanan began by stating that he did not profess to communicate
anything new or original, but would be happy if he could only draw from
the stores of information which had of late years been accumulating on this
subject, under the hands of very eminent, scientific, and practical men, such
leading facts and maxims as might prove a safe guide for our practise; and
such truths, when they become known and established on the unerring
grounds of experiment and calculation, could not, he thought, be too widely
published. The subject might be reduced to two kinds, according to the material
is either nitered or compressed by any force or
pressure. From these two all others arise, and either consist or are composed
of them. The tensile strain is the simplest of all, depending neither
on expansion nor compression, and is therefore generally spoken of as the
single element, namely, the Section of Fracture. This peculiarity of the
tensile force was explained and illustrated. In regard to cast-iron, the result
of the extensive and interesting experiments by Messrs. Hodgkinson and
Pendlebury, of which a full account will be given in the next Number of
the Journal, had been so uniformly and essentially good, that it showed, in a
moment without distending itself or giving any warning of danger. Malle-
able iron, again, is much superior in tensile strength, and, by its remarkable
ductility, inspires confidence in a still higher degree; bears no less, at an
average stress, ten or twenty times as much stress as cast-iron, on the same
surface, and gives very nearly 50 tons on the square inch—the weakest 26½ tons, and
the strongest 60 tons. It is thus six times stronger in compression than in
displacement, and since it is highly recommended for sustaining any super-
structure, it is obvious that its weight in cast-iron, for the same purpose,
is as 1 to 2½, as to resist the strain arising from the load into a longi-
tudinal compression. This is often in our power by proper arrangements,
chiefly giving a sufficient height and curve to the arch; and in cases,
where, for the want of head-rooms, the arch is unduly fastened, or resolved
into masses of brick or masonry, the load is conveyed directly into the
stone, experiments have been generally made on specimens rather too minute.
Like cast-iron, the crushing strength is superior to the tensile, and hence
its adaptation for buildings, particularly bridges. Creaghleith stone will bear 2½
tons per square inch, or upwards of 10,000 tons in the case of granite 600 tons. In regard to bricks, he had occasion to make experiments
in relation to the great chimney of the Edinburgh Gas Works. It became
matter of consideration whether the ordinary brick could withstand the
weight of a single column, made up of malleable iron and stone, press, not on
small specimens, but on the actual brick. The ordinary stock brick was found to bear 140 tons on the square foot, and the
common fire-brick 157 tons; but the brick of which the chimney is con-
structed, consisting of a mixture of fire-clay and ironstone, bore, a single
brick on its bed, no less than 140 tons, equal to 600 tons on the square foot.

The effect of the transverse strain was then considered and illustrated by
various experiments and models. This strain is a compound of the tensile
strain and the transverse strain; the one expanding and the other nitered,
and the beam itself becoming a lever, and acting often with enormous power against its own strength. Hence it became easy to calculate the strength, this being in every case proportional to the area of the section. In the case of the arch, element modified by the length and depth of the beam, diminishing in exact
proportion to the length, and increasing in proportion to the depth. The
transverse strain acting with such severe advantage over our mate-
rials, as it is well known, the bridges that have been constructed by means
none is more remarkable than the principle of the arch, the effect of
which was illustrated by experiments, and particularly the necessity in flat
arches of having secure abutments to resist the horizontal thrust, and this was
fre-
quently pointed out, where the length of the arch is more than two times the
extremities of the arch by strong malleable iron rods, in the same manner as
in the case of the roof, the feet of the rafters are united and prevented from
spreading by the tie-beams; and this is the principle, the most accurate of all,
on which the great iron bridge at Newcastle, now in progress, is constructed,
the object of which is to cross the river and valley of the Tyne, on the highest
level of the railways on each side, as to unite them in one uninterrupted line from London to Berwick, and unite the termini of the different railways, now separated three quarters of a mile or more, into one great central station, a little to the west of the centre of the city. The termini of the York and Newcastle Railway is 4,937 feet, consisting chiefly of the space occupied by the bed of the river Tyne, and the steep banks on each side, well known to travellers in descending from Gateshead Fell on the south, and Dean Street on the north, both to be now superseded by the smooth and level surface of the road, and the turnpike road running on the same bridge directly under the line of rails. The steep banks on each side are spanned by stone arches of a very substantial character, the river and low banks by six metallic arches, all of the same dimensions and structure, resting on solid piers and lofty columns of masonry. In the bed of the river the piers are laid on very solid foundations of piles and planking, with concrete, many of the piles 40 feet in length, and driven to this depth through hard gravel and sand till they reach the bed of freestone rock. The arches in the Tyne are in full operation here, and with wonderful effect, and has come most opportunely in aid of the work; driving night and day, at the rate of 60 or 70 strokes a minute, the pile heads being often set on fire by the rapidity and violence of the blows of the ram. Piers laid 12 feet below low-water mark, and raised above 100 feet to the springing of the arches. The arches consist each of 4 main ribs of cast-iron, each in 5 segments bolted together, and forming one entire arch 125 feet span, and rising 17 ft. 6 in. in the centre, and the level of the rails on the upper platform 10 ft. above the level of high-water mark of the Tyne. Depth of the river at high springs, and 3 ft. 6 in. at the crown, with a crest 12 inches broad, external ribs 2 inches thickness of metal, internal ribs 3 inches. Total sectional area at the crown 644 square inches, which would bear with safety a load of 5,800 or 6,000 tons, and would form, with proper additional means to hold itself, but for the fullest security, and to prevent the possibility of inconvenience or risk from deflection or vibration, or otherwise, each rib is united at the springing by strong malleable iron bars or ties, 7 inches broad and 1 inch deep, of the best scrap iron, and in all 34 in number are supported on the bottom of the arch, and the roadway suspended from beneath, by hollow cast-iron pillars 10 feet apart, and each 14 inches square, through which are passed strong malleable iron circular bars, binding the whole into one stiff and solid mass. The sectional area of the lower bars is 168 square inches, which would sustain 6,000 tons without breaking, and 1,500 tons with perfect safety, but the whole weight of the bridge will not exceed 700 tons, leaving 800 tons of surplus strength. The railway, which is at the summit level, runs on a level 4 feet above the arch rib, and is supported in the center of the arch, and the roadway suspended from beneath, by hollow cast-iron trough girders resting on the top of the pillars 10 feet apart, and raised by longitudinal timbers laid with strong planking. The roadway runs nearly on a level with the malleable iron ties, leaving a space of about 20 feet beneath.

In the whole of the work the utmost pains has been bestowed on materials and workmanship, and in making everything complete, the surfaces, which abut together, being regularly planed or turned, as in machinery; and, from all the arrangements, the most successful results may be anticipated from this fact. The whole of the iron work and roadway, by the estimates, comes to £112,000, and the contracts for the bridge and viaducts to something above £300,000.

CONWAY BRIDGE, CHESTER AND HOLYHEAD RAILWAY.

We give the following details of floating the tubular bridge at Conway, on account of their highly interesting character. Next month we hope to be able to give full particulars of the raising of the tube and the machinery.

In sight of a large concourse of people, covering the whole space of the suspension-bridge, the towns and walls of the noble old castle, and the fields in the background of the spot on which it was built, the wonderful effect of the sub-bridge, with its magnificent arches, is in full view, and moved from the piers and stays on which it was constructed, and fairly brought into the tide-way of the Conway, while its flood-tide was running at the rate of at least two miles per hour. It appeared to float with the greatest ease, and not immersing the six poutonches on which it rested (three at either end) to within at least 3 feet of their decks. The precautions taken by Capt. Claxton, R.N., to whose sole direction the transporting of this enormous mass was committed, were admirable contrived to prevent the mischief which was suspended at 11 a.m. The moment when the tide appeared to slacken, and the tide was dropped as it was raised, as it were, on a level, the chains and ropes were hove upon, and the first Rubicon—gradually but steadily for it. Mr. Stephenson, with Mr. Edwin Clarke and Mr. Brunel, accompanied Capt. Claxton, who directed the proceedings. He used two figures, of large dimensions, Nos. 1 and 2: when the red side was shown of the tube, the figure of a capital was cut in it and placed under the tube works and was hove upon; when the white side was shown the bearing stopped, and a similar operation with No. 3 governed the operations of a powerful capital (cast by the Admiralty), fixed on the railway on the Chester side, made fast round the round the arch, and the work turned; on the the poutonches three enormous masses of timber, 95 feet long by 25 feet wide, and 8 feet deep, bound together by powerful cranes worked by 44 men, have upon the chains, which had previously been tightened up by a large crane, and by a dozen or more men strained with their utmost efforts at either end on shore, one end of each chain being fixed at the piers of the suspension-bridge, while the other ends were fast to the aforesaid cranes, on the opposite side of the river: on these chains the poutonches appeared to traverse. The western, or Conway end, was pointed first, but did not come quite home afterwards. The eastern, or Chester end, was dropped in after, or while the sbb was making; but before it reached by about a dozen feet the exact berth, it took the mason-work, and now effort could disguise it. No further work was done on the bed sufficiently to be landed and bedded up with timber previously prepared from a lower bed, which had been provided in case the tide should fall before the upper bed could be reached. The most extraordinary efforts were made with screws and tackles, so less than four of which latter were at one time applied, besides the Chester side crab, manned by 60 people, while the tide was falling, to overcome the obstacle; but they appeared to be ineffectual, and Capt. Claxton was heard to give orders for bedding up, which was speedily accomplished. The barges which were temporarily fixed near the noble fabric rested very near the hydraulic presses which are to be used in raising it. Eighty men were in each set of poutonches—one set commanded by Capt. Dunce, R.N., an assistant of Mr. Brunel, and the other set by Lieut. R.N., the engineer. The great difficulty to be overcome was apparent—the small space to play in—for on the Conway side it wants 9 inches, by actual measurement, of being home, or in place; while on the Chester side, it is fairly jammed against the masonry so that in all there were barely 9 inches free in 400 feet. No sooner had the tide fallen sufficiently than the obstacle to the exact fixing in position became apparent to all. The inner poutonche was battling at its end against and partly on a rock. It took the ground which had been blasted away from the solid rock in consequence of having got a little twisted previously to starting, we were assured full 4 feet. On the 11th ult., the tube was again floated by the poutonches, and was finally placed with its two ends resting upon the shelves of masonry constructed to receive it, prior to its being raised to the elevation at which it is placed, about 15 feet or 16 feet above. The lifting of this enormous mass of iron, which weighs about 1,500 tons, is to be effected by two hydraulic presses, with 18-inch rims, and pumps 3 of inch diameter. These pumps are to be worked by steam in the usual way, is equal to 3 to 4 times the pressure on the circular inch, or a total lifting power for each press of 927 tons, which, of course, will be amply sufficient for the purpose. Each press has a lift of 6 feet; and as the ends of the tube rise, the masonry which is intended to support them will be carried up from the shelves on which they now rest.

AUXILIARY STEAM-POWER FOR VESSELS.

Sir,—In consequence of the great extension of railways, and the facility they give for quick transit of goods, they are operating seriously against the shipping interests and coasting trade, and it must be imagined that some mode can be adopted by which coasting vessels can be made to compete with the railways, this trade will be completely destroyed, which will be a serious loss to many harbours, and also the mercantile interests of the country; for we obtain the greatest part of our coal and other goods, but also many of the more bulky articles, in consequence of the want of regular sailing trade.

I think it would be interesting to many of your readers who feel a deep interest in the subject, to ascertain what has been done in many places by employing small steam-power auxiliary to sailing vessels; and as you have the means of doing so, I have taken the liberty of directing your attention to this important subject, which many of your correspondents could easily supply, and answer questions at.

The best system of applying auxiliary steam-power to vessels in the coasting trade, of 150 to 300 tons burden per register?

A description of any such?

Whether wood or coal, or oil as fuel?

The size of engines: have those engines to be placed on deck, or to be placed within, like a paddle?

The draught of water, etc., &c., and any particulars as to the trade and in, and how they are answering?
N.B.—Some time ago, a vessel was tried on the Thames (no notice of which has been taken in the Engineer's Journal," as called the Albion, with a new system of propellers, patented by a Mr. Simpson; which was very favourably spoken of in the journals referred to by me.

—Could you state any particulars connected with it?

—Trusting you may not consider my suggestions as out of place, and that any notice you give in your Journal of such improvements, will be very interesting, and give much information to many of your readers,

I remalce, etc.,

A. B. [\footnote{We were not present at the experiments, and not having much faith in newspaper reports, it is the reason we have not noticed them.—Ed.}]

NOTES OF THE MONTH.

An hydraulic telegraph is now being exhibited in the arches at Eater Change. It is on a very small scale, but works well.

On the Monmouth and Hereford line, a wooden bridge over the Wye is to be erected, at a height of 50 feet above high-water mark. The embankments are now in a forward state, and the frame-work is being prepared at Bristol.

Mr. John Fairfull Smith, secretary of the leading Glasgow railways, has addressed a letter to the Lord Provost, in reference to the late riots, and urges the necessity of having a government despatch given to the railways. He says that 10,000 men, who were supposed to be employed on the railways in the neighbourhood of Glasgow, which are stopped by the state of the money market. The same views are spreading among the railway interest, and the mischief is felt in the repressive measures which were commenced early in the season by the government.

We should not feel the pressure. We always deprecated the government tampering, and the propriety of the cause we have advocated is fully justified by events. We do say the great question is, whether so many thousand important railway workers are to be left in a state of idleness, or whether they shall be employed on public works? They are already maintained by their own savings, by the contributions of their friends, by credit given by the small shop-keepers, or by theft, or in the work-house. The question is not one of finding more food, but of giving work which shall do good to the common stock, and put the men in a happier condition.

We hope the legislation will immediately be amended, the power of using for calls be withdrawn, and the power be given of allowing interest on calls, likewise a further power of raising money on debentures, or on loan notes. As the government have by their measures brought railway works to a stand, or dead lock, temporary and exceptional measures might be allowed, in order to set the machinery of investment again in action.

We would even countenance the issue of railway notes, which should be a legal tender for all railway payments and calls, or the advance by government of exchequer bill loans; though on all ordinary occasions, we have always been opposed to their interference in any shape. The abolition of the Railway Board, founded on wrong principles of legislation, and calculated to prejudice the main bill, was a step preliminary to a healthy course of action on the part of the government to the railways.

The electric telegraph is now taken up by the publicans. A dial is used in a smoking-room, marked with the various articles wanted, and corresponding with a similar number of articles on the opposite side. A Royal Institution of Engineers has been founded at the Hague, which has two hundred members.

On Amalgaing Glass Tubes.—M. Bonetup read a paper at the Industrial Society of Mulhausen, on the causes of the breaking of glass tubes and cylinders. In order that a glass tube be in good condition, it is necessary that the interior surfaces should give way at the same time as the exterior. For this purpose, the tubes—such, for instance, as thermometer, barometer, and pressure-gauge tubes—are placed in a baking or annealing furnace, called the baking furnace, a brick casing of 6 inches diameter, and the length the tubes may require. This furnace is heated at one end to a full red heat, at which the glass is nearly malleable, but not put out of shape; they are then taken in the wheel, and drawn gradually towards the cool end of the furnace, but so slowly, as to traverse the distance in 15 to 24 hours, according to the nature of the glass thus drawn gradually through a diminishing temperature to that of the atmosphere. There is a vast difference between glass baked and that un-baked—the latter is not so homogenous, and possesses the light in passing through it. By applying, therefore, a fragment of a tube to a polarising apparatus, it can be ascertained if the tube has been baked.

A Rare Surprise.—Commander Mackinnon in his "Steam Warfare on the Parana," mentions the following almost incredible instance of a shot passing through both of the paddle-wheels of his vessel, without touching any part of either:—It struck the paddle-box on the enemy's side, 3 feet or 4 feet above the shaft, went clear through the wheel without touching any part of it, and then passed through another paddle-box, not above 18 inches from the shaft, still not touching a single blade, or any portion of the paddles. At the rate the wheels were revolving (about 17 times a minute), it appeared quite impossible to fire a pistol-ball through without striking some part of them; and yet this 18 lb. shot had gone through both wheels, leaving no mark but the hole at entering on one side and departing on the other.

Curious Phenomena of Fire.—At the Royal Institution, on the 17th of February, a temporary furnace was erected for the purpose of making some experiments on glass manufacture by Mr. Pellatt. In consequence of some accident, the lecture-room was nearly set on fire, but by timely aid the flames were extinguished. After a lecture at the Institution on the following Friday, Prof. Barlow paid the attention of the members to two phenomena which had happened during the temporary apprehension of fire. 1. At three different times the water poured on the sides of the temporary furnace, when, on the fire being drawn, they fell on the hearth, became heated by the ignited masses of metal, and hydrogen, driven off by the sudden expansion of steam, etc., having penetrated the hot and porous hearth-stone, found its way to the heated beams and space which were immediately beneath. 2. This gas, though not in the state of flame as it passed through the hearth-stone, was charged with the air below sufficiently hot to enter into combustion, producing three flashes of flame downwards from beneath the hearth; and it was experimentally shown that a temperature so low as barely to sear paper, and in which the hand may be held for seconds without inconvenience, is yet able to ignite a jet of coal or hydrogen gas in air.

Liverpool Waterworks.—The two Companies which supplied the town with water, and the Corporation of Liverpool who were empowered by Act of Parliament to purchase the existing interests for the purpose of taking the water-supply into their own hands, appointed Mr. Robert Stephenson as sole arbitrator to determine the amount of compensation to be paid to each Company. After a patient hearing of all parties, and a minute inquiry into the works, he has made his award, by which the Harrington Water Company are to receive £230,719 13s. 4d. or £235,000. The former Company received £237,500, and the latter £234,000.

Carlton Club Designs.—A correspondent informs us that in a former number of the Journal, we were in error in attributing to Mr. Sidney Smirk the "sole designing" of the Carlton Club, now erecting in Pall Mall, as well as the decoration of Sansovino in the north. He states that the designs were entirely completed and sent in under the arrangement of the late Mr. Basaei and Mr. Sidney Smirk, during the lifetime of the former, and that though Mr. Smirk may possibly make some deviations from their joint arrangement, yet the designs are, in the main, to be executed as agreed between them.

Prevention of Accidents in Coal Mines.—The Staffordshire Mercury describes an invention by Mr. Edward N. Frondrinier, of Cheddleton Mill, a very simple and ingenious, but important contrivance, for preventing the accidents which are constantly resulting from the breakage of the chains or ropes, and drawing the skip over the pulley, or the whirl, or run. The apparatus is now in daily use at one of Mr. Snead's pits, at the Snead, green Colliery, between Hanley and Barston. In one instance the merit of the invention was fully tested by the chain being unintentionally drawn over the pulley; no disastrous consequences, however, resulted, the skip or cage being detached from the chain, and remaining safe on the guides. A heavy load was subsequently lowered about 40 yards down the pit, and the chain cut at about 20 yards above the surface, by which means more than 60 tons of coal having been let down by a rope to ascertain the result, found the machine perfectly secured, and the chain safely coiled on the top of the cage in which the man ascends and descends. The man immediately attached the rope to the cage, which having been drawn up again was let down and fastened to the apparatus. The whole was then safely drawn up, with the man in the skip, the experiment having occupied no more than 20 minutes, and no injury whatever having been sustained either by the machine or the guided. There can be but one opinion, as to the great advantages to be derived from the general adoption of this invaluable invention, and it is to be sincerely hoped that no time will be lost in making this arrangement for the more effective preservation of human life.

On the Electro-Dynamo of Metals.—MM. Brunel, Bassin, and Guain presented to the Académie des Sciences, at Paris, specimens of metals bronzed by electro-chemical means. M. de Molk, in 1941, communicated to the academy a process for brassing metals, by depositing upon them, by the agency of an electric current, a coating of brass or bronze, which having been let down into the water, 500 parts of carbonate of potash; 23 chloride of copper; 40 sulphate of zinc; and 250 nitrate of ammonia. To produce bronze, a salt of tin is substituted for the sulphate of zinc. By means of these solutions of brass or of bronze, a coating can be laid on steel, lead, zinc, or whatever other alloys of these metals, with one another, or with bismuth and antimony, after a previous cleaning according to the nature of the metal. The operation is conducted with a cold solution. The metal to be coated is placed in connection with the negative pole of a battery, and a plate of brass is placed at the positive pole. When the objects have been covered with a coating of the metal desired, and have received their proper colour, they will be found to rival the finest bronzes.
LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM FEBRUARY 29, TO MARCH 22, 1848.

Six Months allowed for Enrolment, unless otherwise expressed.

Elizabeth Wallace, of Lalefield, Cheshunt, Herts, spinner, for "certain Improvements in making, figuring, designing, decorating, planning, and otherwise fitting up houses and buildings, parts of which are applicable to articles of furniture." — Patent 29.

John C. Roberts, of Holywell, Flintshire, surgeon, for "a simplified and improved mode of communicating intelligence, by means of electricity and magnetism, combined, or arranged on rails and wires, for railway purposes, and on the line and the engine or tender, so that the guards and passengers may give notice to the engineer or engine-driver, for the prevention of accidents ensuing on account of the negligence of anyone, and the protection of human life and property from loss or injury; and, also, of communicating intelligence to agents, and conveying together several messages or causes of alarm, and a new mode ofascertaining the passage of electricity, for the above purposes, to be substituted or not for the aid of stations, and of communicating intelligence between distant places on the line." — Patent 32.

Patrick Palmer, of Sutton-street, Clerkenwell, for "Improvements in melting steel, and in the manufacture of candles." — Patent 40.

Francis Whitehead, of Hampstead, Middlesex, civil engineer, for "a certain manufacture of pipes of earthenware, pottery, and glass, and certain applications and arrangements thereof." — Patent 12.

Charles Statham, of Lodge Park, Harborne, for "certain Improvements in threshing machines, and in steam-boilers, engines, and other apparatus for driving the same, which apparatus is applicable to driving other machinery, part of which Improvements is a communication, and a new mode of ascertaining the passage of electricity, for the above purposes, to be substituted or not for the aid of stations, and of communicating intelligence between distant places on the line." — Patent 15.

Theodore Corbett, King of the Order of Redlearnshulde Lenin, of Saint Grainturks, Guernsey, and now of Leicester-square, Middlesex, physician, for "Improvements in the constructions of railway carriages." — Patent 18.

William Beckett Johnson, of Liverpool, engineer, for "certain Improvements which are applicable to the construction of masts for vessels, and for performing other purposes." — Patent 21.

Warren de la Rue, of Roundhill-row, Middlesex, manufacturer, for "certain improvements in machinery used in the manufacture of cardboard and pasteboard." — Patent 27.

John H. Rowland, of Stepney, Middlesex, surgeon, for "Improvements in obtaining motive power by the aid of atmospheric air, and in obtaining combustion." — Patent 28.

Charles Paulson, of Plaistow, Kent, for "certain Improvements in purifying and depositing, cleaning, and grinding iron and steel." — Patent 33.

George Lloyd, of Stepney, Middlesex, iron-founder, for "certain Improvements in furnaces and blowing machines, and improvements in engines and machinery for driving the same, which Improvements are also applicable to other purposes where motive power is required." — Patent 34.

Joseph Mauclere, of the firm of Mauclere, Sons, and Field, of Lambeth, engineer, for "certain Improvements in obtaining and applying motive power, and in the machinery and engines employed therein." — Patent 36.

Alexander Allott, of Lenton Works, in the county of Nottingham, bleacher, for "Improvements in apparatus used in the working of steam-boilers, also apparatus used in cleaning dye-stuffs." — Patent 42.

John Hadfield, of Blackwell, Kent, engineer, for "Improvements in iron, girders, beams, trusses, and supports, and in rendering the floors of buildings fire-proof by the use of iron." — Patent 43.

George Coode, of Haydock-park, Lancashire, for "an improved method or methods of manufacturing, and the use of paper for the manufacture of paper and clothing, and for casting, and certain improved apparatus and machinery employed therein." — Patent 51.

John Ashbury, of Openshaw, near Manchester, for "certain Improvements in the construction of vehicles for use upon railways and common roads, and in the methods of preparing and constructing the tyres used therewith." — Patent 57.

Alexander Allott, of Lenton Works, Nottingham, bleacher, for "Improvements in paper-making and in balances, also in bridges, and in the means of working bridges." — Patent 58.

James Firth, of Edenderry, Lancashire, for "certain Improvements in carding-engines for carding wool and other fibres and substances." — Patent 59.

Frederick William Michael Collins, and Alfred Reynolds, both of Charterhouse-square, Middlesex, engineers and spinners, for "Improvements in the art of ornamenting clothing, earthenware, and glass." — Patent 61.

John Hooper, of New Cross, Surrey, surveyor, for "Improvements in apparatus for sucker pumps for lifting water, from levels at a great distance from each other, and in the manufacture of such apparatus." — Patent 62.

William Dutton, of Charney-le-Poney, Middlesex, for "certain Improvements in or improvements in making compounding joints for pipes, nozzles, and boilers, stills and cylinder heads, and other apparatus." — Patent 64.

Henry Stieben, of the Crescent-road, Middlesex, for "Improvements in steam-engines." — Patent 67.

James Foster, of Edenderry, Lancashire, for "certain Improvements in carding-engines for carding wool and other fibres and substances." — Patent 68.

Henry Stieben, of the Crescent-road, Middlesex, for "Improvements in steam-engines." — Patent 67.
BLOOMSBURY BAPTIST CHAPEL.

John Gibson, Esq., Architect.

(With an Engraving, Plate VII.)

Bloomesbur~street now presents a very unusual, if not altogether unprecedented, assemblage of church architecture, there being three distinct and independent uses of the building—together in a line by the side of each other. With general similarity of purpose, they display great variety, or we might say contrast. That to the north—namely, Bedford Chapel, or what used to be so called, and which was originally of a most dismal "tabernacle" appearance—was merely redecorated about a year or two ago; a circumstance that perhaps excuses many defects and inequalities in the design, the architect being compelled to retain all the former openings, both doors and windows, and it would seem, the former turret and a bit of the gable also, which are being sticking up most awkwardly over the new horizontal line of the front. Were it not for that, and for the meanness of the doors, the front would have been passable.

The second of the three buildings in point of date is the south one,—a French Protestant church, with a small residence for the clergyman attached to it. For this, the style adopted is Gothic; but the design is exceedingly sober and unpretending, there being scarcely anything in it except the large window to give it expression. Even that feature is not made so much as it might have been; for although sufficiently correct as to mere form and composition, it has a tame and spiritless look.

The Baptist Chapel, which comes in immediately between the two other buildings, is by far the most ambitious and conspicuous of the three. It is that which announces itself most distinctly as a church—in fact, much more as a "church" than as a dissenting place of worship, the latter having hitherto generally eschewed, instead of at all affecting, the ecclesiastical orthodoxy of towers, and spires; while here we have not only tower and spire, but a pair of them. And here they produce a most agreeable diversity of outline, not only as regards the structure to which they belong, but the general group of all the three; more especially as the aspect of their fronts is an east one,—wherefore they are invariably in shadow, except early in the morning. Standing out in bold relief against the sky, and catching the light on one of their other sides, the towers serve to produce some play of light and shade, as well as form and outline. They tell very strikingly in the view from New Oxford-street,—perhaps more so just now than they will do some time hence, for at present they occasion something like surprise also, they seeming to have started into existence all at once, as the building was begun only last autumn. Owing to a singularly happy accident—to more accident, and nothing more—one of the towers displays itself very picturesquely from Hart-street—near by St. George's, Bloomsbury,—at the end of a vista, formed by a cross-street that runs obliquely from New Oxford-street, into Bloomesbury-street.

The style of this Baptist Chapel is of exotic character to English eyes, it being mediæval Italian or Lombardic; but whether selected on account of its being unlike our own Anglo-ecclesiastical style of the same period, or whether it is a case of campanilli partakes very much more of English Gothic than of Lombardic physiognomy and mode of composition. As our engraving explains the design itself much more intelligibly than the most accurate description could possibly do, we need not attempt any; accordingly, we shall confine ourselves to a few remarks. While we readily confess that the architect (Mr. John Gibson, whose name was quite unknown to us before) has shown competent knowledge of the style generally, we also desiderate more regard to the spirit of it in some of the details. The uppermost story of the towers, and the large circular window, are satisfactory enough; not so, however, the doorways, which might very properly have been made far more important features; important, we mean, not as regards size, but with regard to design and execution. Such parts of a building being those which are most clearly of all seen,—in fact, those which subject themselves to the closest inspection, they naturally demand more elaborate ornamentation and finish than others which can be seen from, comparatively, only a distance. Such at least seems to have been the principle generally observed by mediæval architects, whose doorways and portals were frequently most profusely adorned, even when all the rest of a façade was either featureless or left quite plain. The bestowing particular attention upon them is indispensably requisite for any adequate characterisation of the Lombardic style; more especially so, unlike the Gothic, it affords very few resources of design for windows (circular ones alone excepted), which were seldom more than mere small single openings, without any of that variety and richness which arise from mullions and intersecting tracery. If not richer in their general design, the doorways of this chapel might very well have been considerably bolder in their details and execution. Were they more deeply recessed, and their mouldings in greater relief, they would make a far better appearance.

The building is of white brick, with ornamental dressings of Caen stone. The spires are constructed of timber, and are covered with ornamental tiles. The width of frontage is 70 feet, and the height to the top of the spires 115 feet.

The interior affords accommodation on the ground floor for about 460 persons in pews, with a vestibule and two vestry rooms. In the towers are staircases leading to the basement and gallery floors, the whole extent of the former being set apart for two schools, for boys and for girls. The galleries occupy three sides of the chapel, with an organ gallery on the fourth—these will accommodate 470 persons in pews, with a separate gallery for 250 children; total accommodation, 1,180.

The span of the roof, clear of supports, is 65 feet. The height from the floor to the ceiling is 39 feet. The whole building is nearly a square, and covers a superficial area of 5,130 feet.

GOTHIC WINDOW.

Su—During the autumn of 1846, in which I stayed some weeks at Boppard, on the Rhine, I met with, in an old church at that place, a Gothic window, of which I made memoranda. From these, a friend has been enabled to send me the inclosed. I now forward it to you, in case you may think it worthy of insertion in your very useful publication.

I am, yours, &c.,

I. J. CHAPMAN.

Athenæum Club, Pall Mall,
March 16, 1848.

No. 128—Vol. XI.—May, 1848.
CANDIDUS'S NOTE-BOOK,  
FASCICULUS LX. 

"I must have liberty  
Withal, as large a charter as the wind,  
To blow on what I please."

1. We are never, it would seem, to have more than one view of the new Palace of Westminster; for though many representations of it—or what call themselves such—have been published in various shapes, they are merely copies of each other; all of them showing only the river front, as taken from the south-east. What sort of fidelity and taste stamps such barefaced piratical manufacture, may be more readily imagined than decently—at least temporarily expressed. Nothing less than nerves of iron—or else a more thorough and unconceived in such an artist, can enable Mr. Barry to endure some of the abominable libels so infested upon him. Schinkel, Klenze, Gartner, and other foreign architects, have been similarly libelled, and perhaps more grievously still; but then there are their own authentic representations of them, as well as their buildings themselves, to shew to those who have no other means of judging of them, what the latter really are; whereas, without such incontrovertible evidence to the contrary, some of them might be supposed to be the most barbarous and miserable things ever erected,—at least, such would be the case were it not that the very vileness of the representation comforts us with the assurance that the structures themselves cannot, by any possibility, be so hideous.

11. That plodding adherence to precedent, which is now made a sine qua non in design by those whose influence and authority—more especially in matters of church-building—amount to dictation to architects, has a tendency to operate injuriously to art, in various ways. For art—in the worthy meaning of the term—is substituted what is or quickly will become mere routine, sufficiently dexterous, perhaps, and clever, but still routine. As far as design is concerned, all, it may be said, that is now required of architects is, that they shall be able to follow the rules of the master, and not be altogether worthless. More, mediocrity is, so far from affording any precedent for, rather opposed to that system of tord impitation which is now regarded by many as the most salutary and efficacious for art. During the middle ages, there was continual change and innovation in architecture, by which time a master would stand them in stead of his own imagination, invention, artistic feeling, contrivance, and much else besides. The architect is in fact degraded from his position as artist, the exercise of the faculties which such character implies being interdicted him, and all that is expected of him being that he shall scrupulously adhere to express patterns for the particular style he is called upon to imitate. Daily experience convinces—at least might convince us that, somehow or other, the spirit of the original is not transfused into the copies, or else the peculiar sentiment and associations connected with the former evaporate altogether. 

IV. If the Dictionary in petto, here alluded to, is to contain articles of architectural criticism and aesthetics, it will have to supply a very great deal indeed merely in that single department of it. In fact, the artistic philosophy of architecture has scarcely been more deeply rooted than the best, and as it were, a soggy, loosely, and drily, where it requires to be fully elucidated by actual instances and examples. Character, Composition, Contrast, Effect, Grandiose, Grotesses, Heaviness, Picturesque, Purity, Richness, Simplicity, and many other terms, might be made to furnish exceedingly interesting and instructive articles—such as would assist very much in popularising the study of architecture. That it greatly needs to be popularised can hardly be disputed. Of very little use is it for its professional followers to call architecture the queen of the fine arts—or rather their so calling it partakes of the ridiculous, while the attempt at the same time is, patently indifferent to it as a fine art; and that such is the case the exhibitions at the Royal Academy strongly testify, where the picture of a "poy-faced girl," or of a damsel painted "in buff," will attract crowds of spectators, while the architectural room is a desert, or used only as a thoroughfare, and in fact to anything much more strong an attraction for the many, that the architectural draughts which are comparatively quite disregarded, or if looked at, are looked at rather as pictures than as designs, and judged of not so much according to the architectural merits and ideas which they display, than according to ability of execution, and the pictorial qualities put into them; which last species of artistic recommendation is quite distinct from architectural, and is what may be imparted by a skillful pencil to very poor, or even wretchedly bad designs.

V. If the notices bestowed upon the Fine Arts by the newspaper press may be taken as a fair criterion by which to judge of the lower in which the former is placed, Architecture can be scarcely above zero according to such thermometer of popularity. Although the class of publications just mentioned professes to be au fait on every subject, architecture is ignored by it; and why?—because it can be done with impunity. Is it to be supposed that such a journal as the Times could, not, if it thought it worth while to do so, command as able and energetic in the department of the Fine Arts generally, and architecture among them, as in any other? Most undoubtedly it could; and would do so, were there, on the part of the public, any demand for such information and improvement. We may therefore fairly conclude that there is none. This seems discouraging enough, but is said not for the purpose of discouraging, but on the contrary, of stimulating architects, and inducing them to make an effort to create greater general interest in behalf of their art. Their vaunting it as the only one of the age is more than so much idle vapouring. It is the public, not they themselves, who will be convinced of its importance and excellence. Yet, what has the
"Institute" done towards promoting and disseminating architectural taste among the public? The answer must be—just nothing at all. The mere idea of anything of the kind does not appear to have even so much as occurred to them. Nay, the "Institute" might be exterminated at all, how much the more the "Institute," nor the public would miss it. Although I do not pretend to be a particular admirer of the "Institute," I am, in one sense, its warmest well-wisher, since most earnestly do I wish that it would signalize itself, by doing, or attempting to do, some real service to architecture, as branch of Fine Art. At present, that body is not only exceedingly drowsy itself, but its torpidity has a benumbing effect which extends beyond its own immediate sphere. Still, I am not for having the "Institute" abolished; but I do wish that it were entirely re-constructed. If I cut it up, it is only for the purpose of its being put together, to be read better, to look better, and to come forth again vigorous and energetic. Or if a fresh and more genial spirit—if greater activity, and greater sympathy with Fine Art, can be infused into it, without resorting to the process of re-construction, the sooner it be done the better. Were I less devoted than I am to architecture, the "Institute" would not be thus reproached by me; and if to be so enthusiastically devoted to that art, as to be quite regardless whom I please or offend while advocating its interests, should subject me to reproach in return, I can endure it with far more of pride than of shame.

VI. The natural death of Ludwig the First of Bavaria would have been many degrees less distressing than is his moral and political one, by which he has terminated his career that forms an epoch in the history of art, as an infatuated old dotard. Scarcely ever before in the world have so profound a feeling of his esthetic establishment of his capital, as has been accomplished by Ludwig for Munich; whose name has in consequence become a familiar household word in the mouths of artists throughout all Europe. What other princes have done for art has been in a great measure out of either interest or passion; but for the dust of his ex-king, it seems to have been all along warmly attached to art for its own sake. It was himself personally that originated the idea of, and sedulously watched through their progress, monumental structures, some of which would of themselves highly sufficed for recording architecture; and to very important purposes; and not, that the reign of Ludwig has been equivalent to the lengthened rule of a dynasty, when we compare Munich with what it was some thirty years ago and now is. And now—why now, the tears shed over his coffin would have been far less painful than the sigh which we give to his folly and his fate.

VII. There is a vast deal of prate and palaver about Proportion, as if all beauty in architecture were referable to them alone, independently of all other qualities that go to make up beauty, and independently of all circumstances. It is so convenient to have the innate interest of the human form kept to a point, and a theory so compact that it may be put into a nutshell, or carried on the tip of one's tongue, ready to dart out the magic word—Proportion. Yet, so far from being on that account a simple one, such theory is an exceedingly complicated and abstruse one. If we ask what are beautiful Proportions, we shall be told—just ones; when, if not satisfied with such elucidation, we return to the charge and inquire what are just Proportions, we shall, perhaps, be further enlightened by being assured that they are those which are harmonious and conducive to beauty. For the human figure and other animal forms, there are standards of Proportion, fixed by nature herself. But in architecture, there is no immutiable standard of Proportion for any one style, much less one applicable to all styles alike. In the Greek orders, we find the very extremes of proportion—such as could not be exceeded either way without falling into deformity and disproportion—to the extent of the Parthenon Doric, and the still more extreme in slender, Corinthian. Yet, utterly dissimilar as they are, all the orders may be said to be admirable proportioned in themselves; which, however, instead of at all simplifying the matter, only renders the subject of Proportion the more abstruse and perplexing. The very best Proportions are studied so very much by degree different, applied with breadth, or height exceeding the usual relative proportion which it bears to width? To attempt to fix variable Proportion by rule is worse than nugatory, since it is positively mischievous, and detracts from the privileges of art; rendering that a merely mechanical process which ought to be determined very differently. After all, it is the eye which judges of Proportions; therefore, surely the eye of the architect—supposing him to be at all worthy of such name—ought to be able to decide what are pleasing Proportions quite as well as that of other people. And so that they be pleasing, it must be for the reason that the eye be attracted by the structure and its rules. Undue stress is laid upon Proportion, because it is generally spoken of as if it were all-sufficient in itself alone, and capable of ensuring excellence; whereas, it is only one element of beauty in design. Besides which, the term itself is usually understood in only a very limited meaning—namely, with reference to that mechanical species of it which concerns itself with merely parts and individual members or features, without that higher artistic one being included in the idea of it, which regulating the whole of a composition, stamps it to the eye at once as a captivating ensemble, all whose parts are in perfect keeping with one another. Proportion is quite beyond the reach of rules. Those who cannot find out for themselves how to produce it, must dispensy with it, trusting that it will never be missed by those who are content with Proportion in pieces and bits,—by hairbreadth measurers of columns and mouldings.

VIII. Oious as the Window-tax may be as a tax, I cannot at all agree with those who consider it, or talk as if they did consider it, to operate injuriously upon architectural design. So far is appearance from being at all benefited by a multiplicity or frequency of windows, that the more windows the worse, at least is its external appearance; for unless sparingly introduced, such openings sadly interfere with breadth and repose. We certainly do not find that in designs produced as specimens of their author's taste, consequently composed without the slightest regard to the Window-tax, as a peculiarly onerous and oppressive one, let it by all means be got rid of; but in the name of common-sense, don't let its effect upon architectural design be urged as a reason for its removal, because if taste is to have any voice in the matter, it might find a very strong plea for the maintenance of this tax, as a powerful deterrent to the intrusion of too many unnecessary windows, or of too many combined, which it exhibits itself. Much also depends upon situation; for the latter may be such as to render the minimum of exposure to our view of it desirable. Again, the sort of cheerfulness derived from window-light is entirely dependent upon the weather; if that be gloomy and cheerless,—triste and dull. In dismal weather—no very great rarity, by the by, in this climate—a blazing fire is far more exhilarating than the mere daylight. Of quantum of window or aperture for light in a room, there may be excess just as well as deficiency. Yet, because light is pleasant, it is thought that there cannot possibly be too much of it.

IX. While some of the studies and qualifications enumerated as requisite for the architect are very remotely connected with either the practice or theory of his art, even if they can be said to be agreed with at all, yet all other arts which are at least passed over in silence. It is difficult to repress a smile when we find History and Biography included among the studies which an architect ought to be conversant with—for why not Geography also—more especially Photograph, or descriptions of cities and monuments? The quantum of History, however, is so far from being formidable, that it dwindles down into a mere homeopathic dose,—no more of it being insisted upon than what relates to architecture. Just the same is it with Biography; for architectural biography is exceedingly scanty indeed, and does not seem to be of much practical importance. Mr. Donaldson points only to one source for it—to Militia albums, with a mention of Tactoma, Quatremer de Quincy, and Cuen-Bermudes. Of biography in general, it may safely be predicated that it is "a most attractive branch of history;" but the same cannot possibly be averred of architectural biography as a particular species of it, since, as it has hitherto been treated, it is particularly drawn a fault that might be forgiven, were it not also particularly jejune. Biography, says Mr. Donaldson, when speaking of its importance to the architect, "teaches us the course by which great men have attained eminence," yet that cannot be said of the species of it, however, to which he must be supposed to have referred. On the contrary, it leaves us wholly ignorant of the studies and mental impulses to which the "eminence" in the profession have been indebted for their ability, and their distinction in the art. Nay, we very rarely learn what were the external matter-of-fact circumstances that shaped out and attended their professional
career. Biographical notices of architects we most undeniably have, yet scarcely anything really deserving the name of architectural biography,—nothing written in extenso and fully developed. Passing over other studies which are strangely claimed for the architect, I will point out what, although overlooked, I myself conceive to be very essential qualifications—I say essential, not indispensable,—because daily experience convinces us that dispensed with they are. Now I should say that talent for invention and Contrivance stands almost foremost among the qualifications for an architect. Without it, he can be little more than a barren copier,—the creature of comme-il-faut routine; a very respectable automaton, but not an artist. If we care only for mechanical skill and excellence, let us boldly say so at once, and desist from that maudlin, namby-pamby prating about architecture as art.—except it be just that brattish grade of the latter, by virtue of which tailoring and cookery claim to be enrolled among the so-called arts. For the display of other talent and merits, the opportunities are comparatively few; but those for the exercise of Contrivance are continually presenting themselves. It is what so far from requiring favourable circumstances, it is of all called into operation by disadvantageous ones, and by difficulties and untoward circumstances which, by a little exercise of it, might be overcome, not only sufficiently well, but even happily, and so as to be productive of both conveniences and beauties that would not have been thought of but for the obstacles which prevent compliance with usual matter-of-course proceeding. A taste for and acquaintance with art generally, as well as his own particular branch of it, is also highly desirable, if not indispensable, for the architect—a taste not so much, perhaps, expressly for painting and sculpture themselves, as for pictorial and sculpture decoration; and as regards an eye for colour, effect, and various combinations of form.

ON THE STABILITY OF ARCHEES.

On the Stability of Arches, with practical methods for determining, according to the Pressures to which they will be subjected, the best form of Section, or variable depth of Vessuer, for any given Intrados or Extrados. By Gwason Swall, Assoc. Inst. C.E.—(From a paper read at the Institution of Civil Engineers.)

The first section of this paper treats of the general conditions of stability in structures composed of many blocks of materials, as walls, arches, &c. The second and third sections discuss the conditions of stability of an arch, the form of which and the pressures sustained by it, as regards position, direction, and amount, are similar on either side of the crown of the arch; such as an arch sustaining its own weight only, or that of a symmetrical superstructure. In the second section the arch is supposed to be formed of blocks of an incompressible material; but in the third section the limited strength of materials is taken into consideration. The fourth section discusses the condition of an arch, acted upon by forces of any amount, applied in any position and direction in the plane of the section, or of an arch whose form is not similar on both sides of the crown.

The effect of the adhesion of the cement is not taken in any case into consideration.

SECTION I.

ART. 1.—A structure built of blocks of stone or other material, as A B C D, diagram 1, may yield under the pressure to which it is subjected; first, by the slipping of certain of its surfaces of contact the yielding of the materials of which the structure is composed, as diagram 4. For the first effect to take place, it is necessary that the resultant P" of the pressure P', on one of the blocks A, should coincide with a perpendicu- lar drawn from the surfaces of contact, at an angle greater than L A R, the "limiting angle of resistance" of those surfaces. For example, if the materials are calcareous oolite, this angle, L A R, is 30° 50'; and if, as in diagram 2, the direction of the resultant is none inclined from the perpendicular, the "limiting angle of failure" will take place, from the one block slipping on the other.

For the second effect to take place, the resultant pressure must act in a direction which passes without the joint, as in diagram 3.

The third effect depends, first, on the strength of the material; secondly, on the amount of resultant pressure; and thirdly, on the position and direction of that pressure. Thus the material may be capable of sustaining the pressure, if it acts through the axis of the stone; the pressure in that case being equally distributed over the whole surface of contact; but if the direction of the pressure approaches very closely to one of the edges, so that one portion of the block sustains a much greater pressure per square inch than another, then the material may yield and failure ensue, as in diagram 4.

If, however, none of the resultant pressures P, P', P", P", diagram 5, fulfill any of the above conditions, that is, if none are inclined from a perpendicular to the surface of contact at an angle greater than the limiting angle of resistance of those surfaces, nor fall without the joint, nor approach so near to the edge as to cause the material to yield, then the structure will withstand the pres- sure. Also, if instead of being acted on by a pressure p, the resultants p, p, p, p, p, do none of them fulfill any of the conditions of failure, it will withstand this pressure. In like manner, an endless variety of pressures, or systems of pressures, may be sustained by the structure, each giving a different series of resultants on the successive joints.

ART. 2.—If any other joints are made in the structure, the position and direction of the resultant pressures on them, also, must be drawn and examined, before the stability of the arch is determined; if, however, a curve such as that in diagram 6 could be traced, the pressure P" on which should be at any point in it the tangent should represent the position and direction of the resultant pressure, as the arrows P, P, P, P, which are tangents to the curve, and which also show the position and direction of the resultants; then if no part of this curve passed without the structure, or so near to the edges of it, as to cause the material to yield, the structure would be stable, however numerous, or in whatever direction the joints might be, provided that the perpendicular from the joint were inclined to the tangent to the curve, at an angle less than the limiting angle of resistance. This curve is known as the "limiting curve." If this were determined for the first time by Professor Moseley, in essays published in the "Cambridge Philosophical Transactions," it can be traced by application of difficult mathematical analysis, as shown in the fourth part of the Mechanical Principles of Civil Engineering and Architecture, p. 171. Here, however, the line of resistance can be traced with sufficient accuracy from joint to joint, by means of a bent whalebone, or a metal spring, or by hand as in diagram 5.

ART. 3. PROBLEM 1.—To find the position, direction, and amount of the resultant pressure on one of the blocks being given in position, direction, and amount, and the specific gravity of the material forming the structure being also known.

Diagram 6 represents a structure of seven blocks of stone, or other material, the weight of the first block being 80 cwt., and its position and direction represented by the arrow; it is required to determine the position, direction, and amount of the resultant pressures on all the other blocks.

Construct a scale of equal parts, each part representing one cwt., or one pound, &c., as may be convenient. In this figure each equal part represents one cwt. Calculate the weight of each stone (in this example, if the first block weighs 15 cwt., the weight of the others are as figured on them in the diagram).

Find the centres of gravity of the blocks; (they are indicated in this and the following diagrams by this mark *)

Then the pressures on the second block are, first, the weight of the first block = 15 cwt., which may be represented by a pressure of 15 cwt. acting vertically downwards through the centre of gravity of the block; draw the line WY, representing the position and direction of this pressure on the first block, which acts in the direction and position indicated by the

If, instead of the pressure on the first block, the pressure on any other block be given, the resultant pressure on all the others may be found in a similar manner. If the pressure on the fourth block is known, the pressure on the fifth, sixth, and seventh will be found in precisely the same manner as above described. Then with regard to the third block, it will be acted on by its own weight, and the pressures from the second and fifth blocks, and the given pressure on the fourth block, is the resultant of these pressures; if, therefore, a vertical line is drawn through the center of gravity of the third block, and another line is drawn in the direction of the given pressure on the fourth block, and from the point of intersection of these two lines there is measured off on the vertical, as many parts of the scale as the given cwt. of the weight of the block, and on the other line, as many parts as the cwrts. in the given pressure on the fourth block; then there have been measured the side $W_3$ of the parallelogram and the diagonal $R_3$, $W_3$, $P_3$, and these two lines determine the parallelogram, the second side of which, from the point of intersection, gives the pressure on the third block. This pressure on the third block being determined, that on the second and that on the first block may be found in the same manner, the lines drawn being the same as those in the example.

Art. 4.—In nearly all cases of arched structures, the pressure on any one of the voussoirs is unknown, and this constitutes the difficulty of the subject: the point of application, the direction, and the amount of the resultant pressure on any of the voussoirs being determined, the conditions of stability of the whole structure are found by the application of the foregoing problem. To determine the stability of the arch with regard to the first condition of failure, diagram 2, that is, supposing failure to take place, by the slipping of one voussoir on another, the direction only of the resultant pressures is required; but to determine whether the arch will fail (as in diagram 3 or 4), by the voussoirs falling on a second voussoir, or by the material failing, not only the direction, but the point of application and the amount of the pressures must be determined. The theories of the arch, which preceded that of Professor Moseley, take into consideration only the first condition of failure (Art. 1, diagram 2), it being supposed that if the arch fails, it would be by one of the voussoirs slipping on another. The experiments of Rennie, Morin, and others, had not then been made, and the resistance of the friction of one stone on another was much underrated, so that it was considered necessary for stability, that the direction of the pressures should always be perpendicular to the joints; of course this could only be the case for one particular system of pressures, and if the weights on the voussoirs and other pressures were so arranged, that the resultant pressure on each joint acted in a direction perpendicular to it, then if any weight were added to it, the system would be in a state of stability. If, however, the positions and directions of the resultant pressures would, of course, vary also, and their directions be no longer perpendicular to the joint. It seems to have been the practice of bridge-builders, to take the weight of the arch-stones and backing for the fixed system of pressures, and this weight being given, the positions and directions of the weights of the wagons, carriages, and people passing over, the effect of the latter was not an important consideration, and the old problems sufficiently answered the purpose. In the case, however, of a light railway bridge, traversed by a heavy train, which, coming upon it suddenly, has twice the effect of a stationary pressure of the same weight, the effect of such traffic must not be omitted from the calculation; but if the arch is designed and the weights on the voussoirs arranged, so that the resultant pressures shall be perpendicular to the joints when the train is on the bridge, then, when the train is removed, or any of the resultant pressures taken new positions and directions, no longer perpendicular to the joints; so that, according to the theories themselves, the arch would fail. These theories are also quite useless in determining the stability of vaults on high walls; there is not, perhaps, a single vaulted roof now standing, that does not prove their fallacy.

Art. 5.—Without taking into consideration the adhesion of the cement in the joints, the limiting angle of resistance for the surfaces of all materials used in arches, is so large, that it would be difficult to design an arch and loading, in which the first condition of failure of the arch would be fulfilled; in the pier or abutment, however, such failure is likely to occur, and must be carefully guarded against.

The second condition of failure, diagram 3, is, strictly speaking, impossible, for no block will turn on its edge upon another, without a third point of support, and in that case it becomes that shown in diagram 4, or the third condition of failure; however, as the failure takes place from the tendency of the pressures to turn the blocks on their edges, it seems that the
subject is best discussed by first supposing that the materials are incompressible, and tracing the conditions of stability on this hypothesis, and then by examining in what respect those conditions are modified by the limited strength of the materials.

Art. 6.—In applying the following methods to analyse the strength of any given structure, the first question to be solved is: Is the structure, when acted on by the given pressure, on the balance between standing and falling? The problem determines if this is the case, and if not, if the tendency is towards stability or instability. If the structure be on the balance between standing and falling, then the slightest alteration in the pressures may cause it to fail, and it would therefore be condemned as unsafe. If the tendency be towards instability, unquestionably the arch will not stand. If, on the other hand, the tendency be towards stability, then another question arises: How great a degree of strength does the structure possess? When it is decided in what terms this strength is to be measured, the problems in the following pages can be applied to answer the question. Thus, the strength may be measured by the weight in different positions and directions, that will be required to produce the state of unstable equilibrium, or the balance between standing and falling. Or, again, the strength of the material may be hypothetically diminished, until this unstable equilibrium is produced, and thus a measure of strength is obtained; as for instance, if the hypothetically diminished strength of the material is one-tenth the actual strength of the material used, then the structure is ten times stronger than is theoretically necessary.

Section II.

Art. 7.—On the conditions of stability of an arch whose voussoirs are incompressible; the form of which, and the pressures sustained by it, as regards position, direction, and amount, being similar on either side of the crown of the arch.

In such an arch, the conditions of failure are, as before stated, the first and second; that is, the voussoirs may slip on one another, or turn over on their edges: the latter condition will first be discussed.

It need not be proved, that if in one part of an arch the voussoirs turn over on their edges at the extrados, causing the joint to open at the intrados, then at some other positions, other voussoirs must turn over on their edges at the intrados and the joints open at the extrados. Also it need hardly be proved, that if the arch is similar in form and similarly loaded on either side of the crown, that if failure takes place, in the manner above described, one of the points of rupture will be at the crown of the arch; this is nearly self-evident, and may be proved by experiments on any model of an arch; it is, however, proved geometrically by application of the problem in Section 4. If the arch fails at the crown, by the voussoirs turning on their edges at the intrados, or at the extrados, as in diagram 7, then at some point in the haunches, the voussoirs will at the same time be turning on their edges at the intrados, in which case the crown will sink and the haunches will spread.

If the arch fails at the crown, by the voussoirs turning on their edges at the intrados, as in diagram 8, then at some point in the haunches, the voussoirs will, at the same time, be turning on their edges at the extrados, in which case the haunches will sink and the crown of the arch will rise.

Art. 8.—When the arch is falling, as shown in diagrams 7 and 8, then the points of application of the resultant pressures at the places of failure are beyond the edge of the voussoir, as shown in diagram 3. But when the arch is in the condition of unstable equilibrium, that is, when it is on the balance between standing and falling, and when the voussoirs are on the point of turning on their edges at A, A, &c., then the point of application of the resultant pressure must be at the extreme edge of the voussoir, and its direction must also be that of the tangent to the intrados, or extrados, at A, A, &c., because if not, the line of resistance passes without the boundary of the voussoir, either on one or other side of the point A, and the structure has already failed, by the turning over of some other voussoir. Therefore, when the arch is in the condition of unstable equilibrium, then, at all the points of rupture, the directions of the resultant pressures are tangents to the intrados, or extrados.

Art. 9. Problem 2.—To find the second point of rupture, in an arch whose voussoirs are incompressible, the form of which and the pressure sustained by it, as regards position, direction, and amount, being similar on either side of the crown of the arch.

Also to find the amount of pressure at the crown and at the second point of rupture.

Take for example an arch with a backing, or superstructure, diagram 9. It is required to find the second point of rupture, that is, that point in the haunches, at which the voussoirs will be about to turn on their edges, when the arch is in the condition of unstable equilibrium.

As the form of the structure leads to the supposition, that, if failure take place, it will be by the sinking of the crown and the spreading of the haunches, let it be first assumed that the arch is about to fail in that manner. Then the point C, in the extrados, at the crown, will be the first point at which the voussoirs are about to turn; and the horizontal line C E, will represent the direction and position of the pressure upon the side of the arch drawn in the figure, caused by the weight of the opposite and similar side; see Art. 8.

Choose some point R, in the intrados, and, for trial, suppose that to be the second point of rupture. Then the voussoirs will be on the point of turning on their edges at R, and the resultant pressure will act through R, in the direction R T, of the tangent to the intrados; see Art. 9. Draw the joint or normal to the intrados R N, and the vertical line N B. Find the centre of gravity of the mass A D R N B; and draw the vertical line G W, and produce it till it intersects C E, at the point I. Then the only pressures acting on the point R, are the pressure of the opposite arch, acting in the direction C E, and the weight of the mass A D R N B, acting in the direction I W; and since the direction of these two pressures intersect in the point I, therefore, by the well-known law of Statics, the direction of their resultant also passes through the point I; but when the arch is about to fail at the point R, R T, is the direction of the resultant, and this does not, if continued, pass through the point I. Therefore, R is not the second point of rupture, and some other point must be tried. If the line R I, be drawn, it will be seen that its direction is less inclined to the vertical than R T; and this leads to the supposition that the point of rupture is lower down, at some point where the tangent to the curve is less inclined to the vertical. Therefore, choose some other point R, and pur-

Diagram 9.
sue a precisely similar method to that described for \( R, \) as shown in the figure.

Then, since the tangent \( R, T, \) produced, does not pass through the point of intersection \( I, \) but is less inclined to the vertical than the line \( R, I, \) the point of rupture is above \( R. \) Also since the line \( R, T, \) more nearly coincides with the line \( R, I, \) than the line \( R, T, I, \) with the line \( R, I, \) the point of rupture is nearer to \( R, \) than to \( R. \)

One more subsequent trial generally suffices to determine the correct point, which, in this example, is the point \( R. \) For the tangent \( R, T, \) produced, passes through the point \( I, \) which is the point of intersection of the direction of the weight of the mass \( A D R, N, B, \) and the pressure of the opposite side of the arch. Therefore, if the arch fails by the sinking of the crown, the second point of rupture is \( R. \)

The second case is now to be considered: Where will be the second point of rupture, if the arch fails by the rising of the crown? Draw the horizontal line \( D L, \) which will, in this case, represent the position and direction of the pressure of the opposite side of the arch. Let the point \( N, \) be tried; then if \( N, \) be the point of rupture, the tangent to the extrados at \( N, N, P, \) will, if produced, pass through the point \( Q, \) which is the point of intersection of the directions of the pressures of the opposite side of the arch, represented by the line \( D L, \) and of the weight of the mass \( A D R, N, B, \) represented by the vertical line \( W, I. \)

But \( N, P, \) intersects the line \( D L, \) far from the point \( Q. \) Also if the point \( N, \) be tried, it will be found that the tangent \( N, P, \) is far distant from the point \( Q, \) of intersection \( Q, \), and in like manner it will be found, that at no other point above \( N, \) will these conditions be fulfilled, except at the point \( C. \) Therefore the arch will not fail by the rising of the crown. Therefore the arch will, if it fails, fail by the sinking of the crown and the spreading of the haunches, and the point \( R, \) is the second point of rupture.

**Art. 16. The second part of the Problem.** It is required to determine the amount of pressure at the crown, and at the second point of rupture.

Construct a scale of equal parts, as in Problem 1, each division representing some unit of pressure, as pounds, hundredweights, or tons. Through the point of their intersection \( I, \) produce the lines \( R, I, \) and \( W, I, \); then on the line \( W, I, \), measured, produce, measure off the distance, \( I, F, \) containing as many equal parts of the scale as these units of weight, in the mass \( A D R, N, B, \), and from the point \( F, \) draw a line parallel to \( C E, \) intersecting the line \( R, I, \) produced at the point \( H. \) Then, by the well-known principle of the parallelogram of pressures, the line \( F H, \) contains as many equal parts of the scale as there are units in the pressure of the opposite side of the arch on the crown at \( C, \) and the diagonal of the parallelogram \( H, I, \), contains as many equal parts as there are units in the pressure on the point \( R. \) Thus in Example 1, if the weight of the mass \( A D R, N, B, \) is 3 tons 3 cwt., then the pressure at the crown will be 1 ton 2 cwt., and the pressure at the point \( R, \) 3 tons 5 cwt.

**Art. 11.** Thus the resultant pressure on one of the blocks of the structure is determined in direction, position, and amount, which is the datum required in Problem 1; and therefore, that problem may be applied and the line of resistance be traced, as in the example in Art. 3, through the whole structure, commencing either from the crown, or from the second point of rupture; and this line will represent the resultant pressures at every part of the structure, when it is on the balance between standing and falling, that is, when it is in the condition of unstable equilibrium.

If the line of resistance, at any point, passes without the boundary of the voussoirs, the structure will unquestionably fail. If it touches the intrados or extrados, at the base, then the structure is in the condition of unstable equilibrium. If the line of resistance passes through the base of the structure, some distance within the mass, then the arch has a certain degree of stability, which may be tested, as described in Art. 6, by the methods given in the following Sections.

The stability of the structure, with regard to the first condition of failure (Art. 1, diagram 2), has to be considered, and is at once determined by inspecting the line of resistance, drawn as described in the foregoing examples. If at any part of the structure a joint is made, in such a direction, that a perpendicular drawn from it shall be inclined from the tangent to the line of resistance, at that point, at an angle greater than the limiting angle of resistance of the surfaces of contact, the structure will fail at that place; if, however, this is not the case at any position in the arch, the structure will not fail by slipping of the blocks one upon the surface of the other, and the first condition of failure will not be fulfilled.
he angle $BPI$ and the angles $Amp, BIP$, are right angles; therefore, the length $Bj$, is equal to the length $Am$, and therefore, the pressure at $A$, is equal to the pressure at $B$, and similarly the pressure on the whole edge $eA$, is equal to the pressure on the whole edge $fA$. Therefore, in both cases, diagrams 10 and 11, the pressure will be sustained in a similar manner, by the base $efgA$. So that if the resultant pressure at $p$, diagram 10, is equal to one ton per square inch of the surface $efgA$, and does not crush the particles in that surface, then, if the resultant at $p$, diagram 11, is equal to one ton per square inch of the surface $efgA$, the particles in that surface will not be crushed.

If in either of the cases, diagrams 10 and 11, the portion $tikg$, be added, it is evident that the pressure on the base $efgA$, will not be increased. And therefore, if a stone, as in diagram 12, be acted on by a pressure, the resultant of which, and the weight of the stone, passes through a point $p$, in the base $efgA$: Draw a line $AC$, through the point $p$, to the edges $eA$, and $ik$; then measure, on the line $pC$, a portion $pB$, equal to the length $pA$, and draw the line $pB$, perpendicular to the line $AC$. Then, if the resultant pressure at the point $p$, divided by the number of square inches in the surface $efpB$, is not greater than the pressure per square inch, that (by the experiment in diagram 10) the material was found unable of bearing, then the stone will not fail when acted upon by the given pressure.

It is of course implied, that no natural fault, or laminated structure, of the stone, should cause it to yield, it being evident that the judgment of the engineer must be called into requisition, to guard against such a catastrophe.

Art. 14.—The method here proposed, for the determination of the proper section, &c., of arches, or for discussing the stability of arches already designed, the limited strength of the material being taken into consideration, is founded on the above-mentioned principle.

Section IV.

On the conditions of stability of an arch, acted upon by forces of any amount, applied in any position and direction in the plane of the section; or of an arch, whose form is not similar on both sides of the crown.

Art. 15.—In an arch under the conditions stated at the head of this section, the first point of rupture is not necessarily at the crown, and it is this which constitutes the difficulty of the question. It may here be remarked, that when the terms first, second, and third points of rupture are used, it is not meant that the failure of an arch commences at the first point, and then spreads to the second point of rupture, and so on; for theoretically speaking, the structure will fail at all those points at the same time; but by the first point of rupture is merely meant the point of rupture first determined, and by the second point of rupture, the point of rupture secondly determined, as by the process detailed in the preceding sections, one point of rupture being already known.

Art. 16. Problem 3.—To find the first point of rupture in an arch acted upon by any given pressures, in any given position, and the arch itself being of any given shape. The method proposed to solve this problem will, it is thought, be more easily shown, by reference to the example of the arched vault in the previous sections, than by a general diagram and demonstration.

Example.—Let the arched vault shown in diagram 13, of 80 feet span, and whose depth of voussoir at the crown is equal to one-ninth of the radius, be acted on by a pressure, equal to the weight of a portion of arch of 200 feet length of intrados, and one foot in length of transverse section, and applied vertically to the extrados, at a distance of 30 feet from the crown. Required the first point of rupture, under these conditions; the materials being incompressible. First, suppose for trial, some point $R$, in the extrados, to be the first point of rupture, say 48° from the crown, as in diagram 13.
left to right is equal to the weight of \(42\frac{1}{2}^\circ\) of the arch, and that from right to left, equal to the weight of \(44^\circ\); so that the pressures are very nearly in equilibrium; therefore, the first point of rupture is very near this trial point; and the pressure of the right side of the arch preponderates; therefore, take for the next trial, a point a few degrees nearer the crown.

Thus the first point of rupture will soon be arrived at, which, in this case, is at the extrados, \(10^\circ\) from the crown, for when the voussoirs are about to turn on their edges, at this point, the pressure from the left equals the pressure from the right; each being equal to the weight of \(41^\circ\) of the arch.

The second point of rupture on the right side is, as at the extrados, \(35^\circ\) from the crown, and the pressure there is equal to the weight of \(71^\circ\) of the arch; then Problem 1 can be applied, to trace the line of resistance through the rest of this side of the structure, and it will be found, that for the arch to be in the condition of unstable equilibrium, about the springing, it is necessary that the voussoirs should be deepened about 12 inches, at 86° 40' from the crown.

The second point of rupture on the left side, is at the intrados \(30^\circ\) from the crown, and the pressure there is equal to the weight of \(90^\circ\) of the arch, and Problem 1 being applied to trace the line of resistance through the rest of the structure, it will be found, that for it to be in the condition of unstable equilibrium, at the springing, the voussoir must be notched at the extrados, to the depth of about 6 inches.

Art. 17. The principles and the method described in Section III. may be applied to the arch sustaining pressures, as described in the heading of this section, and of unsymmetric form; as well as to that arch whose pressures and form are similar on both sides of the crown, as described in Section II.

It is also evident, that the above method will apply to any irregular form of arch, and that the principles and method described in Section III. might also be applied.

**ON A GENERAL THEOREM TO CALCULATE THE AREA OF A CROSS-SECTION OF A RAILWAY ON SIDELONG GROUND.**

By R. G. Clark.

The intention of this paper is to investigate a formula, free from surds or any approximation, to compute the area of a cross-section, without having regard to the side stakes. We have given (fig. 1)

![Fig. 1](image)

the breadth of formation level A B; the depth O F from centre stake; the difference of heights q d, taken by the spirit-level; the corresponding hypothenus length q r; and the ratio of the slopes. On referring to page 68, present volume, article "Railway Sections in Sidelong Ground," to formula (3), which is

\[
\text{(2 b + m a)} \cdot \text{(b + m a)} \cdot \frac{x - y}{x'} \cdot \sin \theta = \text{area};
\]

where \(b = \frac{1}{2} \) formation level; \(a = \text{depth or height from centre stake to crown of formation level} \); \(x \) and \(y \) equal the distances O D, O H; \(\theta = \text{angle of inclination of ground} \); and \(m \) base of slope to one perpendicular. Also let \(h \) = difference of heights by level \(q d \); and \(l = O d \), the hypothenus length on surface.

From (1) and (2), page 67, in the article above referred to, put

\[
T = \cos \theta - m \sin \theta \quad \text{and} \quad T' = \cos \theta + m \sin \theta;
\]

then the above formula becomes, by substituting \(T \) and \(T' \),

\[
(2 b + m a) \cdot (b + m a) \cdot (T - T') \times \frac{\text{sin} \theta}{2} = \text{area}.
\]

But \( (T - T') \times \frac{\text{sin} \theta}{2} = \frac{2 \text{m sin} \theta \text{cos} \theta - m^2 \text{sin}^2 \theta}{2} \cdot \text{sin} \theta = \frac{m^2 \text{sin}^2 \theta - \text{cos}^2 \theta - m^2 \text{sin}^2 \theta}{m \tan \theta} = \text{area}.
\]

Now consider, in the right-angle triangle \(q d r \), the height \(q d = h \) to be a tangent, the horizontal distance \(d r \) the radius; therefore, \(\text{tan} \theta = \frac{h}{d} \). Substitute this value in last expression, and then in (4); we have for the required general formula:

\[
(2 b + m a) \cdot (b + m a) \cdot \frac{m^2 h^2}{m \text{tan} \theta} = \text{area}.
\]

Let the slope be 1 to 1; then \(m = 1; \cdot \cdot \cdot \)

\[
(2 b + a) \cdot (b + a) \cdot \frac{m^2 h^2}{m \text{tan} \theta} = \text{area}.
\]

The general formula is more simple than it appears: when these numbers are large, we shall only require a table of square numbers to work out any question. Two examples are subjoined:

1. Given length on slope of ground = 20 feet; the difference of heights, 6 feet; slope to be \(2 \) to \(1 \); depth of cutting, 20 feet; and breadth of formation level, 30 feet. Find area by the formula (5).

Substitute the above values in (5):

\[
(33 + 40) \cdot 20 \div (16.5 + 40)^2 \cdot \frac{2 \times 36}{200 - 180} = 2304 \times 7., \text{ area required.}
\]

2. Given the length 20 feet on desert of ground; difference of heights by level, 6 feet; intended slopes, 1 to 1; depth of cutting, 45 feet; and breadth of formation level, 33 feet. Find the area.

(See fig. 1; and for embankment, see fig. 2.)

By substituting the above values in (a):

\[
(33 + 45) \cdot 45 \div (16.5 + 45)^2 \cdot 36 \div 200 - 72 = 3923, \text{ area required.}
\]

From the above it may be observed, that when a centre line of railway is ranged and staked out, and the depths known on inclined ground, we can always find most expeditiously the area of any vertical cross-section, by means of the spirit-level, without requiring the distances of the side stakes from the centre. By way of comparison, I have to refer to an article for a similar purpose, page 263, vol. VII. of this Journal.

**SOCIETY FOR THE PUBLICATION OF ARCHITECTURAL KNOWLEDGE.**

From what has been said of it, the main purpose of this Society—which, perhaps, may not mean to call itself exactly by the title for the present assigned to it—seems to be to bring out what shall be a complete Dictionary or Encyclopedia of Architecture—a very meritorious undertaking, and one which, as the want of such a work is felt, might have reasonably enough been expected on the part of the Institute. That the present Dictionaries which we have of the kind are all more or less defective and unsatisfactory, even considered with reference to the time when they were produced, is universally admitted. Even had they no other deficiencies, they have one and all lagged very much behind the actual time when they made their appearance; whereas every work of the kind ought to bring down its information to the latest possible moment. Let us hope this important point will be attended to in the one now promised, and that it will duly notice all those improvements, both in matters of construction and those of embellishment, which
have come up of late years, and to which every year adds something. As the Society in question of course looks to usefulness and reputation, rather than to anything in the shape of pecuniary profit, we may fairly anticipate from it something greatly superior to everything else of the kind. Much will depend upon their most carefully maturing the whole of their plan beforehand,—a work of no small labour in itself, but which would save them innumerable difficulties and perplexities. Let nothing be overlooked: let them not have a natural prejudice for the judiciously considered; without consideration of these, their object might be materially injured. We could not, indeed, scarcely believe, whilst turning over the pages of such a work, that it could not have been written by Mr. Tate turned back; the title-page to verify our belief!

Of Mr. Tate’s other works, without exception, we think very highly. His treatise on “Factorials” bespeaks considerable analytical power; and though rejected by the Royal Society (which we deem to be no criterion of the merit of the work), it contains much that is new, and the whole system is developed with perspicuity and elegance. His “Arithmetic,” again, is just what a treatise on arithmetic should be:—the rules are given clearly, and such reasons or approximations to reasons as could be comprehended by the minds of young students, are attached to the rules. The efficient demonstration of the rules of arithmetic constitutes the basis of algebra; for we hold that algebra is fundamentally only a statement of the rules for arithmetical operation, obtained by induction from the particular instances supplied in actual computation. We have no faith (because we have no proof) in the doctrine of “the permanence of equivalent forms,” as a fundamental principle, apart from the evidence of induction, and of the verification afforded by deductions from it. Again, in the “Exercises on Modern Geometry,” Mr. Tate, by philosophical, consummate skill, by exhibiting very simply and very clearly, the primary laws of mechanical action; and the exercises are admirably chosen from amongst the most familiar combinations of machinery, and the phenomena of daily observation, which tend to elucidate the principles very happily.

Our readers (and even Mr. Tate himself) must, then, be convinced that we are actuated by no hostile or unkind feelings towards that gentleman, when we express our objections, and very grave objections too, to his “Principles of Geometry.” For no other reason, indeed, should we have said so much by the way of preface. Our objection then is—that Mr. Tate has either misconceived or misrepresented the fundamental character of geometrical evidence and of geometrical reasoning. Either of these charges seems almost alike improbable:—the former in consideration of his intellect, his reputation, and his cleverness; the latter, in consideration of his scholastic position and his high character for probity. We have no alternative to the one hypothesis but the other; and we have no hesitation in saying that misconception is the real cause of the objectionable principles of this work. We will state our reasons for thinking so.

Mr. Tate, like nearly all our “analysts,” appears to have never acquired a clear view of the essential principles of geometrical evidence. Analysis (employing the word as synonymous with algebra, after the dictum of D’Alembert) is a system of inductions only—at least, as far as operations and what are called “principles” are concerned. Its most general theorems are wholly dependent upon induction for their evidence—as much so as the parallellogram of forces, or the law of gravitation. In Mr. Tate’s case, on the contrary, the former is the dogma; and the only appeals to experience are the few axioms respecting the visible and tangible properties of figures which are put down at the opening of Euclid’s first book, together with those fundamental conceptions respecting multiples which are prefixed to the first book of Mr. Tate’s. This has been sufficiently established between the essential characters of geometry and of algebra; and he has thereby been led into the discussion of the former subject, the methods which are not only legitimately available in the latter, but in a great degree essential to its development.

There may be an additional reason, dependent on Mr. Tate’s professional position, for his vagueness of conception on this head. The Battersea Training Institution was formed, we believe, for the purpose, not so much of education itself, as for training the humbler order of schoolmasters in the art of teaching. Most certainly the object was a noble one: for probably no one of our social classes stood relatively so low in respect to skill in their particular duties as the general mass of schoolmasters. A good teacher, or even a moderate scholar, was the exception to the rule rather than the rule itself. This has been sufficiently established by the Reports of the “Government Inspectors of Education”—even after all allowance has been made for the over-colourings in those Reports, which in some cases cannot be denied to have been made.

The formation of suitable schoolmasters, especially for the rural districts, required them to be trained ready and popular exposition of their science, as well as of mere methods of computation. Popular rather than technical language is often found to be convenient; and, below a certain grade of mental development, it is essential in such a case. In the devising of such popular modes of exposition, Mr. Tate has been employed for many years; and, as is always the case, his daily routine of duties may be supposed, without any diminution of our respect for his talents, to have destroyed that vividness of conception and rigorous spirit of reasoning which mathematical science naturally produces in respect to the essence of evidence.

Mr. Tate takes every work of thought as an object for which that work is written, and the principles on which the author composed it. A reference to Mr. Tate’s preface, with one or two specimens of his method of proceeding, will, we are sure, convince every reader that we have not formed our unfavourable opinion of his work without adequate reason.

Mr. Tate considers that “it will be instructive to trace the origin of our ideas in geometry, with the view of suggesting to us the means whereby first notions on the subject should be conveyed to the mind of the learner.” Now, the ambiguity involved in the word “our” is the same as that of the first geometrical speculists of our race, or to those who in our time have been trained in the terminology and popular traditions of geometry—is very objectionable. The former would appear, from his subsequent remarks to be his view: but it is not at all clear. Used in the other aspect, however, it means totally different: and, certainly by writers of the highest scientific and philosophical authority, it is always rejected. In truth, the actual order of discovery is almost invariably found to be the most inconvenient for the systematic exhibition and development of scientific truth. The universal history of science is at variance with this conundrum of Mr. Tate’s.

The author’s delineation of that creature of his brain, the primeval geometer, is a sufficiently ludicrous piece of seriousness: but his talk about the vast amount of facts accumulated independently of the formal demonstration, of a rigorous demonstration, actually startles us. It is more like the raving of an illiterate person than the language of an accomplished geometer. Neither can this be called a stray passage accidentally expressed in an offensive form; for the animals are the same throughout the work. For instance, he says a little further on (p. vii.): “In the demonstrations contained in the following treatise, conciseness and simplicity have been preferred to the artificial verbiage of a technical logic; and he has created his primeval and philosophical geometer, without any precise views relative to them. A formal, or a logical, or a logical demonstration would consist in a simple appeal to common-sense, or in such an exposition as might be sufficient to carry conviction to the mind.” This primeval geometer is created, too, as the Battersea-pattern for the formation of Englishmen of science; and Mr. Tate has falsified Euclid’s assertion as respects “a royal road to geometry.”
We wish, however, to ask Mr. Tate a question or two on these subjects. What does he mean by "common-sense" in connection with the acquisition of science? We often hear the phrase used, it is true, by men who call themselves "practical"; but as far as our memory serves us, we never heard it employed by a common-sense person in the way it is here used by Mr. Tate, though very often so by persons destitute of all science. In geometry we can attach no other notion to it than that it is intended to express the inference which we may draw from visual evidence, or from instrumental evidence at the least—in short, the evidence of experiment performed with the ruler and compass, or in some other way with a balance, such as those made by Bate, of the Poultry, Be it so—but do not degrade science by calling this "geometry."

Again, what does Mr. Tate consider to be such an exposition as might be sufficient to arraign conviction to the new teaching? Did he have in mind something like the imbecile facility with which conviction is carried to the minds of the most astoloph pupils? they are most readily "converted" by the bare words of the enunciation, provided they are excused the trouble of understanding it, and still more readily if they can be excused the trouble of proving it. Common-sense people, and people without any sense at all except the five physical ones, are alike adroit learners under these conditions; and it would seem that the founders of the Battersea Normal School knew pretty well what they were about, when they conceived it as a "common-sense" scheme. Our own wonder is, not hat Messrs. Tate and Tait should have found a use for a college for such purposes:—it is, that Mr. Tate should not only have ministered to this extraordinary system of training schoolmasters, but that he should have pushed himself forward into such inavowable notoriety (for a scientific man) as the Cypheus of a non-synthetic school. Let us do the justice to the system that it has given place to the artist (or rather enthymeme) in which Euclid delivers his reasoning, it will surely bear comparison, even for real simplicity, with the vague, unmeaning, slip-shod sentences which Mr. Tate has substituted in its place.

Euclid, it seems, was "ashamed of the lowly origin of his geometry"—viz. the method of superposition. Mr. Tate considers that it "gives a graphic interest to an investigation." Now, it surpasses our power to conceive what sort of interest a "graphic interest" is: but we suppose the author to mean that the mind is enabled to follow the course of the argument by the eye and hand conjointly. Even then we cannot understand on what ground mere superposition can be supposed to give graphic results. Did space allow, we could easily explain the cause of Euclid's sparing use of the principle, without suffocating the cheek or blanching the lip of the geometrical patriarch with "shame." As to the employment of the principle of motion, we have simply to ask, what advantages Mr. Tate thinks he can confer upon accurate geometrical reasoning by the introduction of it into geometry? Nay, more, will he tell us how it would aid demonstration? What use can be made of that so riveting a utilitarian line as in the definition of the circle, which is more or less than Euclid's definition? Can he have forgotten that the cone, sphere, and cylinder are actually defined by their geneses? Can he have forgotten that the favourite method of superposition is not discarded from the subsequent parts of Euclid's Elements, where the principle could be made to facilitate the objects aimed at? We are sorry to come to the conclusion, but we can scarcely avoid the inference, that Mr. Tate has never "read and inwardly digested" the work which is the object of his animadversions—and we can have no scruple in concluding that he has never understood its objects, seized its import, or fully comprehended the system of philosophy of which it is one of the most enduring specimens.

Mr. Tate says that "many of his [Euclid's] problems are solved by methods which are never used in practice"; and he instances a single one. Can he instance another? We can with tolerable confidence assert, upon the authority of the editors of all the technical works, there is not a construction given in the whole range of the "Elements," of a problem which occurs in practical geometry, which we could not point out as being copied into recent, or comparatively recent works intended for the use of practical men. It is a perversion of the meaning of an abuse of a technical term to make such unfounded assertions. That better practical constructions than many of them may be given, we have already said; but that does not affect the present case.

The objection that the doctrine of similar triangles is deferred so long as it is a matter of proportion, that it is not made the first of a series until the fifth book, when it might have been, and may, according to Euclid's treatment of the subject, be made to follow the third proposition of the first book. Would Mr. Tate obtain the doctrine of similar triangles without all consideration of propor-
Such is the substitute propounded by Mr. Tate for the artificial erudition of a "technical logic," and the "tedious erudition of a rigorous demonstration," such as geometers give us! It is very possible that some readers may consider the substitute to be little else our "vulgar and illiterate erudition," worthy only of the scientific charlatan, rather than of Mr. Tate and the Battersea Training College.

Were this book merely thrown on the market for those who may wish to purchase it, our concern would be less than it is about such works, but we have heard that all the schools in England which are under the control of the Government Board of Education, are likely to have it forced upon them, as the condition of their receiving any part of the sums voted by the House of Commons in aid of those schools. The dedication of the work to Dr. Kay Shuttleworth is ominous; and the rumour that the books have reached us since we sat down to write, appear in perfect consistency with such a suspicion. Yet we can scarcely credit the rumour; and we believe that such an adoption of it would create a degree of dissatisfaction with that decision of that Board amongst scientific men and the friends of real education, which would be very disagreeable to the Government, and which might endanger its possession of the patronage which it is the policy of the Government to extend in all directions.

Oh, no! despite the misrepresentations and perversions with which we are met, but we have heard that all the good old Euclid of our earlier days—unnurtured, and in his own venerable costume. The true spirit of geometry will be lost in England as it is elsewhere, if Euclid shall cease to be our text-book for the Elements of Geometry.

A Treatise on Practical Surveying, as particularly applicable to New Zealand and other Colonies, containing an account of the Instruments most useful to the Colonial Surveyor and Engineer, &c. By Arthur Whitehead, late Civil Engineer to the New Zealand Company. London: Longman, Orme, Brown, Green & Longmans, 1848. 8vo. pp. 196, with plates.

The title of this work sufficiently explains its object. The author, acquainted by experience with the particular difficulties and exigencies of colonial surveying, has here recorded a large amount of useful knowledge, which has probably been acquired amid many toils and hardships. To the English surveyor, accustomed to the well-provided country, the task of mapping the untrodden wilds of New Zealand must be a new and formidable undertaking. The greatest difficulties of surveying at home, sink into insignificance in the colonies. Here we have open country, and the use of the instruments is little impeded by obstructions to vision—there the thick forest closes in on every side, impene-

trable to the eye and almost to foot of man. Here there are well-known way-marks and boundaries, of which every particular is already accurately ascertained and delineated—there everything is new and uncertain; the endless, unvaried scene presents nothing but interchanged thickets, without mark or vestige beyond the rare and fading traces of the hatchet of the savage. Here we have high-ways and bye-ways for chariots and horsemen—there the pioneer forces his way through a fence which is as thick as it is long. Or else his journey lies over the treacherous morass. Or he must swim the unbridged, unforderable torrent. Or his path mounts up the steep hill-side, with some 100° of Fahrenheit, and 45° of angular acclivity against him. No cheerful hostelry for him where he may turn in to tarry for the night. He must not ask, with Falstaff, "May I not take mine ease in mine inn?" His inn is his blam. His kitchen is his forest. His kitchen and forest are the basket which accompanies him at every step. To hop on a place where food might be obtained by barter, would be as surprising to him as to meet a po-

lisceman or postman. He pioneers without a road, and thinks himself fortunate if his course be along the mazes and rapidas, the roads and shoals, of an unknown.
played in colonial surveying. For instruments used in the bush, portability is of course rather more important than it would be on the Sussex Downs. There are various risks from rough usage to be guarded against or remedied in the former situation which are comparatively immaterial in the latter; and on all these points our author gives minute instruction. Chapters II. and III. detail the methods of laying out town and country lands, and the particular objects which demand the attention of the explorer are carefully explained. The fourth chapter (on practical astronomy) does not from its nature admit much that is new, but appears to be a useful compendium. There are two other chapters, on marine surveying and colonial roads, and some tables of mean refraction, corrections for the sun's declination, &c. On the whole, we are inclined to think that when the English surveyor packs up for the colonies, he ought to put Mr. Whitehead's treatise in a accessible corner of his portmanteau.

**IMPROVED MODE OF WORKING EXPANSIVE STEAM VALVES.**

*Communicated to the Mining Journal, by Mr. Thomas Chadock, of Birmingham.*

Fig. 1 is an end elevation; and fig. 2 a side elevation. In this design, one eccentric, which is shown at 4, 4, 4, is made to give motion to both the steam and expansive valves. The time at which it is desired to open and close the expansive valve, in relation to the stroke of the piston, will be understood from the following description of the parts:—a is the clip and eccentric rod, which communicates motion from the eccentric 4, 4, 4, to the expansive valve n, through the right angular lever b and d, which moves upon the pin c, which is attached to the small projecting parts s, s, which project from the lever F—the lever d, terminating in a forked end, which takes into the groove of the circular ring e, e, which ring is moved longitudinally by the action of the eccentric through the aforesaid lever b and d; j is another right-angular lever, which communicates motion to the expansive valve n, through the valve-rod v. The part represented at r, r, receives its support from the foundation, or other fixed part, to which the main shaft of the engine is attached, and has a projecting socket, on which the valve-f and ring e work—so that these parts have no direct communication with the main shaft. The ring does not revolve, but only partakes of the longitudinal motion imparted from the eccentric, and from thence through the levers l and n', to the expansive valve. The arc of the part marked i, i, supports the lever f—it being also graduated, indicates the point at which the steam is cut off; as it will be seen that, by moving the lever f, the whole of the parts a, b, d, s, &c., are carried round with it to any desired angle in relation to the main crank of the engine, whereby the same thing is effected as if the eccentric 4, 4, 4, itself were moved round, which governs the time of opening and closing the expansive valve. The part marked A, A, is attached to the lever f, and serves the purpose of steadying the eccentric clip, and also embraces the arc l, so as to keep the lever f firmly attached thereto. At q is seen a small lever, acted upon by a spring, having at the opposite end a pin, which, on passing through the lever f, and arc e, holds the lever f firmly in its vertical position; whereas, on pressing the smaller lever with the hand, the lever f is liberated and moveable: S, S, is the eccentric clip, which is supposed to work the steam valve.

**LLANDAFF CATHEDRAL.**

*The History, Present Condition, and Proposed Restoration of Llandaff Cathedral. By Mr. T. H. Wyatt.—Read at the Royal Institute of British Architects, March 20.*

Upon the history of the cathedral, I shall not detain you at any great length. The first bishop is stated to have been Dubritius, who died in 525, on an island off the Caernarvonshire coast, and whose bones were in 1120 translated to Llandaff by Bishop Urban, the founder of the present cathedral. Urban was consecrated the thirteenth bishop of Llandaff in 1108; and to him all concede the honour of having founded the present cathedral. At his first coming, he found his bishopric in a very poor and miserable condition; and such was the ground, that the King and the Pope in 1119, he procured letters and gathered large sums together; he pulled down the old church, which was but 28 feet long, 15 feet broad, and 20 feet high; and in 1120, according to Leland and Godwin, or in 1129, as stated by Dugdale, he commenced the fabric dedicated to St. Peter and St. Paul. Bishop Godwin (who wrote in 1601) describes this building as "a very elegant one, 300 feet long, 80 feet broad, and adorned at the west end with two stately towers of great height, and a neat chapel of our Lady; a work truly magnificent, and to be remembered with honour by posterity." Urban died in 1133, whilst travelling from Rome. From this period to the beginning of the last century there is no further record of any kind that I can find relating to the cathedral, and here conjecture must commence.

If Bishop Godwin be correct in supposing the church commenced by Urban to have been completed by him with two towers and a Ladye chapel, and to have been 300 feet long, it must have disappeared between the period of his death (1133), and 1180 or 1190, which will, I think, be conceded as the earliest date at which the present Early English structure have been commenced. The extreme length of the present building is only 200 feet, and its breadth 75 feet. Of pure Norman work, such as we may believe Urban to have executed in the beginning of the twelfth century, we only have the large arch between the presbytery and Ladye chapel; the remaining portion of a window on the south side of the presbytery, so curiously stopped up at a later period; portions of a Norman string-course, with a fret ornament, running round the walls of the presbytery (being the string-course of the Norman clerestorey); and a variety of Norman arches carved into the presbytery; and the two doors at the west end of the north and south aisles, which, though later in their detail and finish than the large arch, may fairly be considered as of Urban's time, particularly if he commenced the east end and worked westward to these doors.

The size of the chancel arch, and the importace and decoration of the aisle doors, clearly prove that they could have forced no portion of the early and insignificant church knocked about by the Normans, and eventually demolished by Urban; for although the preservation of doorways with chancel arches of Norman churches, rebuilt in the thirteenth and fourteenth centuries, is of frequent occurrence, yet in this instance I think the says must have originated with Urban and not have been removed or perpetuated by him.

The character and finish of the large arch at the east end of the presbytery, clearly proves that it must have opened into a chancel or Ladye chapel; and thus we may believe Urban so far to have realised Godwin's description as to have completed, "a neat chapel of our Ladye." And the existence of pure Norman work, so far westward as the two aisle doors, may be taken as a presumptive evidence that Urban's church was truly magnificent, and must be remembered with honour by posterity," even if his western towers were fabulous. Certainly these doorways are of rich and beautiful design, and the general character of all the Norman work remaining is of a pure and good period, corresponding with Urban's prelacy. What befell this Norman church, or how it could have been so completely destroyed in the short period between Urban's death and 1180 or 1190, as to have rendered necessary the almost entire rebuilding of the church in a new and distinct style, remains a mystery. However, no traces of that gradual and clearly-marked transition from Norman to Early English, which we find so evidently and so instructively displayed at Canterbury, Norwich, Gloucester, St. David's, and Buildwas Abbey. With the single exception of the western doorway (in which the circular and trefoil arches, and the detail of the shafts and mouldings are Early English), the new work was commenced free from any taint or prejudice of a past style, and stands forth as pure and beautiful an example of Early English compositions and detail as any with which I am acquainted. An able writer in the Ecclesiologist thus speaks...
of it:—"The exquisite Early English work of this part of the church is truly beautiful; not the least idea is obtained by the wretched drawing given in 'Winkle's Cathedrals.' To stand opposite the western front—itself once a marvel of art—and view through the now vacant and ruinous windows the patterned nave and partly decorated tower, with its pinnacles and gables, its carved piers and towers, its clustered chapels, its deeply recessed arches, its beautifully detailed and exquisitely wrought spires, is to feel the most forcible contrast between the speaking graces of the Christian and the burlesque absurdities of the revived pagan style."

Although from the affinity of England to Wales, where our ancestors fought and died for their ennobling conquests, yet as authorised visitors, we may fairly believe architecture to have been almost on a level in point of date, we can have no reason for imagining that theWelch were some 70 or 80 years in advance of the English in the periods of their architecture, or that the character of their cathedrals in this respect, by which we call them"Early Welsh," should more properly have been called "Early Welch." If this is allowed, I am unable to believe that any antiquary can assign an earlier date than 1180 or 1190 to the west front and nave of this cathedral; for though it is perfectly impossible to fix with peremptory certainty the exact date when a particular stage or style of art ended and another commenced, yet we find that when the pointed arch first made its appearance and became blended with the Norman semicircles, years elapsed before the newer style or form had shaken off the influence of its predecessor.

We find in numerous instances, as at Gloucester, Canterbury, the Temple Church, and St. David's Cathedral, that this transitional feeling existed in full force—nay, that the Norman preponderated—although the portions I allude to are well known to date about the end of the twelfth century. You will, I fancy, have heard of this, and the belief is so prevalent that the pure Early English work at Llandaff could have been commenced sixty or seventy years before the Norman arch had elsewhere ceased to prevail. In Buildwas Abbey, which is one of the earliest transition works I know (the date of which is stated as about 1190), the pointed arch forms a very small part of the Early English façade.

In the section of one of the bays of the nave of St. David's Cathedral, built in 1180, you find the only Early English work consists of a small arcade, between two series of clearly-defined Norman arches!—certainly not a thing to make the Early English work in the sister cathedral of South Wales sixty years before this work was commenced.

Henry (prior of Abergavenny) was consecrated bishop of Llandaff in 1191, and died in 1211, at the age of eighty, a life remarkably protracted, and probably much less burdensome than to some antiquarian assertions, he supposed, if not actually to have commenced the erection of his cathedral in the new style of his day, at least to have promoted works, the character and period of which are so evidently coeval with his twenty-seven years of pontificate.

The western part of the north tower, and all the remaining part of the south tower, the nave, and clerestory remaining, are all of the same pure Early English character. In the columns and arches of the nave and choir a slight variety of arrangement occurs without deviating from the style; somewhat more ornament is introduced, and by the time they reached the Ladye church, the gradation of style becomes apparent; and with a view to give increased richness to this more sacred portion of the building, or more the "decorated" fashion of the day, when they arrived at this part of the building, theblacksmiths or joiners, in the execution of the side windows, and in the easternmost window tracery becomes apparent, until it almost assumes the character of a "decorated" window.

In the two bays of the presbytery a fault (as geologists might term it) occurs, which it is difficult to account for. These arches are evidently of a later date, though the form and line are as much of the nave and aisles, in their form and detail are of a later date than the Ladye church. Whether this portion of Urban's work may have remained unijured and undisturbed until after the completion of the Ladye church, when they may have thought it necessary to assimilate the Norman piers and arches more closely to their pointed neighbours, or whether some injury took place to this part of the cathedral, which rendered rebuilding necessary at a later period, I have no means of determining, but it is curious that in this portion of the building we find the Norman style is here altogether wanting. There still exists a Norman string-course in its original bed, with a sort of "embattled fret" carved upon it, running round the three sides of the presbytery; we find pilasters and portions of cylindrical shafts, which may have formed (as at the nave) the piers through which we go beyond it, with its flat panelled roof, its richly filled lancet windows, and all over the screen; the casual remains of a Norman window, so unceremoniously blocked up by the Early English architect who built against it; and in the rough masonry of the walls of this part we find walled-up numerous fragments of a most remarkable and ornamental nature. One might almost say that this portion of Urban's original cathedral to have escaped the early destruction I attribute to the rest of his building, and to have been preserved intact by the Early English architects who rebuilt it. At some later period, for fashion's sake, or from decay, we find this portion of Urban's building in a constant state of dissention, as I believe they did, the Norman clerestory undisturbed. The string-course even now remains; and in the view given of the north front by Godwin, in 1713 (when it was almost perfect), it will be observed that a semicircular and apparently Norman line of windows is shown in the clerestory of this part, as distinguished from the Early

* There is a good reason to believe that the Ladye church was the addition of William de Green, the forty-third bishop, from 1216 to 1227. He was buried close to the size, and his tomb still remains.

English in the nave. Of the history of this alteration or portion of the work, I can find no trace.

The "decorated" altar-screen is stated, in Brown's Willis's, and all the other histories of the cathedral, to have been erected by a Bishop Marshall, who was consecrated in 1478; but as the detail is pure "decorated," it must have been completed, in all probability, 100 years before this time. I have little doubt but that the piers and arches of the presbytery and this screen were erected at the same time, or by the same architect—an opinion which is supported by the fact of the building of the altar-screen being raised considerably above the opposite pier on the north side, and corresponding exactly with the level of the base of screen and the base of the sedile which it immediately adjoins. The decoration and enrichment of this screen, attributed to Bishop Marshall, and the preponderant use of his name, are only the result of the confusion and gilding upon it. "There are eleven niches in the principal level, painted with roses and hyacinths interchangeably. The centres of the roses and flowers of the hyacinths are gilt. The roses are white (which quite identifies the decoration with Bishop Marshall),—the white rose being the device of the city of York, and the hyacinth the badge of Richard IV. Bishop Marshall having been preferred to this diocese by Edward IV., the adoption of his badge was a natural and proper compliment. Under these eleven niches is a row of eight niches, painted in fresco, exactly similar. After the description, as being the only painted in the same manner; within these are two little ones, with a pilaster between the ground-work throughout is interchangeably blue and red, and the ornaments all over the niches are gilt. At each end is a door leading into the vestry." Thus far I conform, from the remains of this screen, the description given by Brown's Willis. He then proceeds to say—"Above the altar-piece are two rows of large niches, in which formerly there have been figures. In both rows the middlemost niche is larger than the rest; and on each side of it are two lesser niches, each containing the images of our Lord and the blessed Virgin, and the other twelve were for the twelve Apostles. Under the two large niches are the ten commandments, written with gold letters, within a frame, and over all is a handsome fretwork." Unfortunately, the destruction of the rest of the portion of the screen has been complete (doubtless the work of puritan or political fanaticism). Nothing remains above this line, but we have found walled into the various portions of the structure fragments of corbels, canopys, and bosses, which evidently, from their size and form of moulding, belonged to this screen.

From the period when Godwin described Urban's church to have been complete, of certain dimensions, and a work truly magnificent," there is no notice of the cathedral until 1719, when Brown's Willis, in antiquity of that day, has placed "collected" various sundry matters, and gone with his work certain draughts of the said church, in order to illustrate the descriptions thereof. These draughts, as you may imagine, are not very clear in their distinctions of style, or in the best possible perspective, but they are valuable as we cannot record it, we have of what the old cathedral was (before lightning, storms, and Wood of Bath played such havoc with it); and, consequently, as being our principal guide and authority in the restoration. It was then falling into a state of decay, though probably it was not as bad then as it was five or six years before, February, 1722, the "roof and floor of the south tower fell in, and destroyed a good deal of the church." The complete ruin of this old structure must have followed very rapidly on Willis's visit; and in 1724 we find the Archbishop of Canterbury interesting himself in its proposed rebuilding (I cannot say reconstruction). He obtained 1,000£, from George I, and, like our bishop of the present day, tried in vain to get anything from the Prince of Wales. Sufficient funds were, however, eventually raised to erect the frightful shell which now enforces the once noble piers and arches.

About 1735, Wood of Bath, commenced the deceleration of this fine old work, and of his own prior fame; for most assuredly a more barbarous or tasteless grafting of unconnected modernism upon an ancient stem was never perpetrated; and never was the sarcasm of the historian Whittaker more pronounced than in the case of this building. That it will appear! for modern architects have an incurable propensity to mix their own absurd and unauthorized fancies with the genuine models of antiquity! They want alike taste to invent, or modesty to copy." All that can be said in explanation of the cause that the cathedral should be altered so much is that the power of which Wood may have been unable to resist; I wish it was in evidence that he had tried to do so. That this fashion approved such barbarism may be inferred from the accompanying letter, which I find copied in the "MSS." in the British Museum. It was by a Rev. Thos. Davies to Brown Willis, who appears still to have taken much interest in the old wreck:

"22d Nov. 1736.—The church on the inside, as far as his ceiling and pillars, is somewhat finely paved, and looks exceedingly fine, and is a very stately and beautiful room. The area of the whole church is to be considerably raised, so that when finished it will (in the judgment of
most people who have seen it) be a very neat and elegant church, unless, indeed, the altar-piece, which looks like a huge portico, spoil the whole effect."

Mr. Cole illustrates his amusing MS. by elevations of the west and south fronts, and a view of the altar-passage, which was feared (not without some reason) might mar the whole effect.

We had no traces of the portico at the west end, nor can I learn that the pigeon-house cupola was ever carried into effect. The altar was removed some few years ago.

The bishop's throne, the pulpit, and stalls consist of an Ionic colonnade, with niches in the back; they still exist in their pristine propriety and beauty, and I can conscientiously recommend them to any architect about to build such a court; the pulpit and throne would form admirable judge's seats, and the stalls a most dignified row of seats for the magistracy.

I do not imagine that much was done to Mr. Wood's structure until 1840, when the plaster ceiling and lead over the nave being in a very bad and unwearthly condition, a considerable sum was expended in repairing and making good as it then existed.

So much for the history of the cathedral. A very few words will describe its condition when the present restorations were commenced.

---

**REGISTRY OF NEW PATENTS.**

**PRESERVING AND COLOURING WOOD.**

François Augustin Renard, of 40, Rue du Rocher, Paris, merchant, for "Improvements in preserving and colouring wood."—Granted August 19, 1847; Enrolled February 19, 1848.

This invention consists in a mode of constructing apparatus in which a vacuum can be produced, after the same has been applied to one end of a log of wood; so that a preserving or colouring liquid, contained in a suitable vessel or receptacle at the other end, will be forced into the atmosphere by the pressure of the vacuum produced in the log in the longitudinal direction of the fibres.

The annexed engraving is a side elevation of the apparatus employed. A is a metal cylinder, provided with a top-piece B, from which is suspended a rod, with a piece of perforated metal or wire gauze attached to its lower end. C is a metal disk, fixed to the cylinder A, having an opening at its centre, communicating with the interior of the cylinder; and between this disk and the end of the log of wood D, a narrow leather washer E, is interposed, so that there will be a small space left between the log and the disc. The position of the log upon the frame F, is to be adjusted by the chain and the screw G; R is a collar, placed around the log of wood, having a chain attached to it, and by which the wood may be moved to and fro, as required, upon the frame F, by means of the screw G; in turning the screw, by means of the lever, the chain will act upon the collar R, either to bring the block nearer or remove it farther away, as may be required. The other end of the log is enclosed in a bag H, of impermeable material, which is connected to the cock of a vessel I, containing the preserving or colouring liquid. Now if a vacuum be produced in the cylinder A, the power of the atmosphere upon the surface of the liquid in the vessel I, will force it through the log. The vacuum may be obtained by any convenient method; but the patentee prefers to produce it by dipping the wire gauge, carried by the rod of the top-piece A, into some inflammable matter (such as alcohol), and introducing it in an ignited state into the cylinder A; the air will then escape through the cock K, which is to be left open for that purpose, and is to be closed as soon as the required vacuum is obtained, as indicated by a small barometer, connected by a tube with the interior of the cylinder A. When the moisture of the wood, or the preserving or colouring liquid, has been forced by the pressure of the atmosphere into the cylinder A, the vacuum will be destroyed, as will be indicated by the barometer K; the cock K being then opened, the liquid will run into a vessel N, beneath; after which, a vacuum is to be produced in the cylinder A, as before.

The passage of the liquid through the log may be accelerated by a force-pump or other suitable means. Although the log is shown in a horizontal position, yet it may be operated upon in a similar manner when in a vertical position by substituting for the bag H, and vessel I, a vessel with a suitable opening in the bottom of it to receive the end of the log. When the log or piece of wood is square, then, instead of the bag H, and vessel I, a trough is used to contain the preserving or colouring liquid, and the whole of the log is immersed therein, excepting the end to which the metal disk is applied.

---

**REFINING SILVER AND LEAD.**

Arthur Harry Johnson, of Gresham street, City, assayer, for "Improvements in refining silver and lead, by effecting a saving in one of the materials used."—Granted September 23, 1847; Enrolled March 23, 1848.

The improvements consist in rendering again available, the phosphaté of lime or bone-ash, whereby the cupel or test used by refiners of silver is composed, and in the process saturated with lead, and a portion of silver. For extracting this lead and silver, the course usually adopted is to return the used cupel to the furnace, by which means the whole of the saturated bone-ash is destroyed; while portions of the lead and silver, combined with the phosphaté of the bone, passed off, and are lost. By the improved method, little or no waste occurs of either the bone-ash, silver, or lead.

To carry out the invention, a solvent of the oxide of lead is used in the following manner:—First reduce the used cupel to a fine powder; then add a sufficient quantity of pyroxyline or acetic acid, varying from 1,009 to 1,048 specific gravity, according to the per-centantage of lead contained, to render it of a thin consistence, that it may be thoroughly stirred in a dolly-tub, or some such convenient machine, or by allowing the acid to percolate through the powdered test. After allowing the powdered cupel and acid to remain together for two days (during which time occasionally stir them well together), the bulk of the lead becomes dissolved. The mixture is next put into cloth or flannel filters, or other percolators, to allow the lead solution to drain off; this done, remove the remaining soluble salt of lead, by washing it with water and by the application of pressure, previous to drying the resulting bone-ash.

After the above process, the silver, and some lead, still remain in the bone-ash, though not sufficient lead to materially interfere with its absorbent powers, on again using, provided it has been properly freed from the solution. If, however, it be wished to extract the lead more perfectly, add a second portion of the acid to the filtered or drained bone-ash, and again thoroughly stir it in this second acid—the washing and pressing, as before described, following this second operation. To bring the lead, contained in the solution, into a marketable form, after due saturation, either simply evaporate it in proper pans to make a sugar of lead or by means of the several re-agents commonly employed, form respectively the carbonate, the sulphate, the sulphur, or other compounds of lead that may be desired.

Instead of pyroxyline acid, a solution of caustic potash may be used, or soda, containing about 20 per cent. of the pure alkali; but this has not been found so useful in practice.

---

**GAS STOVE.**

William Brockedon, of Devonshire-street, Queen-square, Middlesex, for "Improvements in heating rooms or apartments."—Granted September 9, 1847; Enrolled March 9, 1848.

This invention relates to heating rooms with gas. It consists in so constructing stoves or fire-places which are open in front that gas may be burned therein, and the decomposed air and products of combustion pass into chimneys, as from open fire-places or stoves when burning coal. The stove or fire-place may be constructed as nearly as may be like those now used with open fire-bars, and may have a bottom grate similar to that which are used for burning coal, and they may be made to fit the fire-places as at present constructed, or the stoves and fire-places may be greatly varied in design, so long as the stoves or fire-places are capable of consuming gas in an open fire-place communicating with a chimney or flue.

In order to give a gas stove constructed according to this inven-
tion, as much as possible the character of the present open fireplaces used for consuming coal, they are to be made with a front grating or bars, against which is to be placed lumps of pumice-stone or other substances which will allow of being heated by the flame of gas and yet not consume. The front bars should be made nearer to the back of the stove than when for burning coal, and so that there shall be but small space between the back of the stove and the front bars; or such substances may be placed in a wire or other frame suspended near to or amidst the flames of gas where the form of the stove or fire-place is not otherwise adapted to receive such substances; and in some cases the front bars of the stove or grate are made hollow, so as to allow gas to pass from a supply-pipe into them, and thence to pass out through perforations so as to produce numerous small flames which may be partly inward towards the pumice-stone, so as to heat the same, and other flames may be afterwards through between the front bars of the stove or grate, and the front bars in place of being simply across the fire-place may be made into any fanciful form, such as basket work or otherwise, to hold the pumice-stone, or other substances. Or in place of having the front bars or open grating hollow and perforated to produce numerous jets of gas, the jets of gas may be wholly or partially from the bottom or the back or sides of the open fire-place or stove. And it should be understood that it is essential to this invention that the apparatus should be open to view, and also be open to a chimney or flue, so that the gas in burning may give heat to the room or apartment without the decomposed air and products of combustion caused thereby coming into the room or apartment, and at the backs and sides of such stoves or fire-places, bright steel, glass, china, or other reflectors, may, with advantage, be placed. It is not essential to this invention that the open gas fire-place should have a receptacle for the pumice-stone or incrustable substances, as the same may be dispensed with, but it is preferred to have an arrangement for receiving such substances, as thereby the cheerful character of the old English side is retained. And the inventor believes that the most elegant result may be obtained by using jets of gas from front bars or grates combined with jets of gas from bars or apparatus at bottom, so arranged that air may (as is now the case when burning coal) pass up between the bottom, the lower bars in such case supporting the pumice-stone or other substance, for by such means, by a comparative small consumption of gas, the appearance of a large flaming fire may be produced.

JENNINGS'S PATENT INDIA-RUBBER TUBE COCKS.

This improved cock is made by placing a flexible india-rubber tube of any required size within one of metal, as shown in fig. 1;

![Fig. 1](image)

and then by mechanical means to flatten the flexible tube, as shown in fig. 2.

The advantages which the patentee states this cock possesses over any at present in use are—1st. The ease with which it can be at all times opened or shut, and the means used for that purpose being so simple, it cannot be set fast by corrosion or become injured by frequent use. 2nd. When open it is part of the main or pipe, as shown in fig. 1, and presents the same uninterrupted pas-

sage as the pipe itself, and as the means used for closing or stopping the circulation have no communication with the gas or water passage, leakage is impossible. 3rd. It will be seen by fig. 2, if the vulcanised india-rubber tube be properly flattened the cock must be sound. 4th. These cocks are capable of standing any pressure, as the elastic material of which the cock is composed never can become injured by pressure, as long as the metallic casing which surrounds the flexible tube remains perfect.

SEPARATING IRON FROM ORE.

ARTHUR WALL, of India-row, East India-road, Middlesex, for "a new or improved apparatus for a method of separating from their compounds and each other."—Granted October 14, 1847; Enrolled April 14, 1848.

The apparatus is for separating iron from the ores of copper, &c., and consists of two hexagonal drums with an endless chain passing over them, made by connecting with links a number of horseshoe magnets; on the extremities of each of the magnets a number of steel blades are so fixed as to stand out at right angles to the magnets. These drums are made to revolve over a trough in such a position that while the chain of magnets passes immediately above the trough the steel blades reach nearly to the bottom; the bottom of the trough being inclined at each end, so as to correspond with the direction of the blades. The ore (previously roasted and ground) being introduced at one end of this trough the blades, as they pass through it, will take up all the iron contained in it and carry it to the other end; and, indeed, would bring it back again in the next revolution but for the following arrangement. Opposite the point where the blades emerge from the trough, a set of magnets are fixed to a frame with their poles in the reverse order to those forming the chain, so that when the steel blades come opposite these fixed magnets, their magnetism is neutralised, and the iron which they had collected in the trough falls off, and is collected in another trough placed beneath to receive it. The patentee does not confine himself to the permanent magnets, but he claims also the use of electro-magnets, though he prefers to use the former as being more convenient.

PLATE-Glass.—Patented October 7, 1847, by JAMES HARTLEY, of Sunderland. The improvements relate to the manufacture of rough plate-glass immediately prior to the pouring of the melted glass or metal upon the table, and rolling.—Instead of ladling the melted metal into a separate cistern as usual, the patentee ladles it direct from the melting-pot to the pouring-table, where it is immediately poured and rolled. The patentee employs, for the purpose of ladling the melted metal, should the quantity required be large, two or more ladles; and he states, it is not absolutely necessary that the whole should be poured at the same moment upon the table; but the second ladle may commence to be poured at nearly the termination of the pouring of the first ladle. After the manufacture of the rough plates, they are to be piled and annealed in the same kind of furnace and in the same manner as crown or sheet glass, thus dispensing with the more expensive annealing furnaces employed for plate-glass.
PORCELAIN KILN.

ALFRED VINCENT NEWTON, of the Office for Patents, 66, Chancery-lane, Middlesex, mechanical draughtsman, for an invention of an improved kiln for firing objects and other similar ware. (A communication.)—Granted July 29, 1847; Enrolled January 29, 1848. [Reported in Newton's London Journal.]

The inventor, in order to explain more fully the nature of his improvements, has prefixed his specification with the following observations, explanatory of the ordinary mode of firing or baking hard porcelain, and the difficulties and objections incident thereto.

The employment of pit-coal as a fuel for firing or baking hard porcelain hitherto has been thought impossible, or at least subject to almost insuperable difficulties. It was thought that the hardness and infusibility of the clay (kaolin), and the high degree of heat necessary to fuse or melt the glass which is placed to it, made hard porcelain, were insurmountable obstacles. A long and sufficiently large or extensive flame to occupy the whole space of the oven or kiln is indispensable for this kind of manufacture; and the liability of the matters composing the hard porcelain to become discoloured, rendered this superabundance of flame the more necessary, in order that no smoke might be allowed to remain in the kiln or oven. It is requisite, therefore, to cause pit-coal to develop such an amount of flame as would have the same effect, and would act within a given time in the same manner as wood.

The matters of which hard porcelain is composed, are divided into two classes,—first, the paste or clay, which is a principal element; and second, the glazing or enamelled covering. The paste or clay consists essentially of two elements; the one is an infusible argillaceous matter,—this is kaolin, either alone or mixed with plastic clay, or magnesite,—the other, and infusible, is given by felspar or other stony minerals, such as silicious sand, chalk, or gypsum, either separately or mixed together in different combinations. The enamel or glaze consists of quartzite felspar, sometimes alone and sometimes in combination with gypsum, but always with some lead or tin. Hard porcelain must, in fact, be considered as being composed of pottery ware, which is essentially translucent, and ought not to be confounded either with stone-ware, delph-ware, pipe-clay, or even with the ordinary tender English porcelain. The kilns or ovens for firing or baking hard porcelain are generally cylindrical, and divided into two chambers or laboratories. In the lower laboratory, the upper one which is supplied with heat from the flame of the lower laboratory, and serves to warm or heat the articles, which, when taken from thence, are dipped into the glazing composition, and afterwards exposed to the great heat in the lower laboratory, which may be properly said to constitute the kiln. The passage of the flame as above said, requires a very high temperature; and it is in the laboratory where this operation is carried on that the temperature is raised to the highest degree. In both these laboratories the articles must be inclosed in fire-clay vessels or saggars, which should be carefully used, in order to prevent the introduction of deleterious matters. The necessary amount of flame and heat may be obtained by increasing the number of fire-grates and openings for the flame; thus a kiln or oven, six yards in diameter, which, when heated with wood, requires six openings, must have ten when pit-coal is employed. A kiln or oven, five yards in diameter, would require only five fire-grates for wood, but must be furnished with eight for coal. A kiln or oven, four yards in diameter, heated by wood, would require four fire-grates and apertures for wood, but must have six for coal. In order to make the flame sufficiently long and abundant for the requirements of the manufacture, the combustion ought to be supplied with a double draft, or additional currents of air. Thus, besides the supply furnished between the fire-bars from the surrounding atmosphere in the workshop, air obtained from outside is conducted by horizontal channels to the fire; that is to say, beside the ordinary supply of air, an additional quantity, obtained from the external atmosphere, is made to act with energy on the fires in the grates. By this means, the kiln is supplied with a very large and superabundant supply of air, which furnishes the fuel with a much greater quantity of gas to decompose.

The engravings represent a kiln or oven, constructed according to the present improvements; and it should be observed, that it is always easy to obtain the necessary quantity of air, by taking it from the atmosphere of the workshop, either by having an aperture of a sufficient size or by opening openings below the fire-bars in the two side walls of the furnace.

The improved system of firing or baking may be applied to all kilns, whatever may be their form or dimensions; and, by means of a double roof in the upper laboratory, hard and tender porcelain may be fired in the same kiln simultaneously: that is to say, hard porcelain may be baked or fired in the lower laboratory, at the same time that tender porcelain or common earthenware is being fired in the upper laboratory. In manufactories where at present the baking of biscuit-ware and glazed ware is carried on in separate kilns, it will be evident that these kilns may, by the application of a double roof, be more advantageously employed in the following manner:—In the biscuit kiln, herefore employed, delph, or earthenware, or unglazed tender porcelain, may be operated upon in the lower laboratory, while hard porcelain may be dried and heated in the upper laboratory; and in the other kiln, formerly used for glazing, the hard porcelain should, on the contrary, be placed in the lower laboratory, to be baked or fired; and glazed delph, or earthenware, or tender porcelain, may be operated upon in the upper laboratory,—the heat in which will be found sufficient for this kind of ware.

The kilns being furnished with the required quantity of fire-places, the combustion must be kept up, by supplying an excess or superabundance of air, obtained either from the external atmosphere or from the workshop, and supplied in some convenient and suitable manner, depending of course upon the situation of the kilns, their peculiar construction, and other circumstances. The fire should be gradually supplied with fuel, at first at long intervals, then at shorter intervals. The state of the fire-place should be looked to carefully, for it is the rapidity of the combustion of the coal which indicates the quantity of fuel that is required, and the moment when the charges are to be thrown on quickly. The fire-place must be well watched, for the purpose of levelling the fuel, so that the fire-bars may be suitably and evenly covered, and that the air to support combustion may always find a proper passage. It is also necessary to rake the fire frequently, in order to clear out the cinders, and to prevent the fire-bars from getting foul, and to remove clinkers therefrom, which would otherwise stop or diminish the convection. Holes through the mass of fuel should never be allowed to exist, and the flame should always be well watched; and the baking or firing operation always be carried on with a long flame. All these precautions are necessary, in order to obtain very pure and white porcelain, as the defects of the firing operation arise most frequently from the want of proper heating.

Fig. 1 represents a transverse vertical section, taken through the centre of a kiln of the improved construction; and fig. 2 is a horizontal section or plan of the same. a is the outer chimney or flue of the upper second laboratory; b is an upper chamber, which may be used for drying or heating; c is a roof (shown by dotted lines), which will be required if it is intended to bake or fire both tender and hard porcelain in the same kiln; d is the flue of the lower chamber or laboratory; e are passages or openings, of which there are the same number as there are fire-places in each kiln; these passages should be placed between the fire-places, and open a communication from the lower to the upper laboratory. f is the lower laboratory, where the principal firing or baking operation is carried on; g g g, are the fire-places; and h h, openings, to allow the flame to pass therefrom into the interior of the kiln. i i, are the fire-bars; j j, the fire-doors; k, the ash-pit; and l l, passages communicating with the ash-pit from the external atmo-
sphere, to supply air to the fire: this object may, however, be
affected by making an aperture in the front wall of the fire-place,
but immediately below the fire-box and grate-bars. a a is the floor
or hearth of the kiln. a, a, are holes, covered up in any suitable
maner, but communicating with the ash-pit, and intended to allow of
the scoria, cinders, and clinkers being removed. p, p, in fig. 3,
show another means of ventilating the kiln, by making openings
in the side walls of the same. q represents another mode,
by which air is supplied from the atmosphere of the workshop
through a grating communicating with the ash-pit. The inventor
reminds that, whatever may be the mode adopted for supplying the
air to the fire, the same plan should be invariably adopted in
all the fire-places of the same kiln.

The patentee, in conclusion, states that he is aware of coal hav-
ing been used for heating the kilns in which common earthen or
delph-ware, and even tender English porcelain is commonly baked or
fired, and that from the use of the softer kinds of coal or pit-coal for
such purposes as constituting part of the present improvements;
but he claims, First,—the application of coal for heating the kilns or ovens in which hard porcelain is submitted to
the baking or firing; operation; and, Secondly,—the arrangement
or construction of kilns or ovens, as herein shown and described,
or any mere modification thereof, whereby pit-coal may be employed
as the fuel for heating such kilns or ovens for firing or baking hard
porcelain, in the place of wood, which has heretofore been employed for
that purpose.

ON GEOLOGICAL CHEMISTRY.

A lecture on "The Application of Chemical Principles to the Science
of Geology." By Professor Daubeney.—(Delivered at the Royal
Institution, Albermarle-street, March 24th.)

The Professor commenced his lecture with some preliminary ob-
servations, in which he said, he had for the last twelve months
devoted his leisure to the accumulation and study of facts in relation
to volcanic forces; and, having, in this pursuit, travelled a good
deal along the great boundary line dividing the two kingdoms of
geology and chemistry, he had obtained glimpses of truths, which
neither pure chemist nor pure geologist, nor administrator of the
employment of coal for such purposes as constituting part of the present
improvements; but he claims, First,—the application of coal for
heating the kilns or ovens in which hard porcelain is submitted to
the baking or firing operation; and, Secondly,—the arrangement
or construction of kilns or ovens, as herein shown and described,
or any mere modification thereof, whereby pit-coal may be employed
as the fuel for heating such kilns or ovens for firing or baking hard
porcelain, in the place of wood, which has heretofore been employed for
that purpose.

Few metallic deposits occurred in the secondary formations, and
even these only when there was dislocation or metamorphic action
in their neighbourhood; while, on the other hand, metallic veins
were found in the volcanic lavas, or in the pseudomorphs of the
lava that had been erupted in the open air, though several geologists had brought
forward facts to prove a connection between metallic matter and
basaltic or trappean dykes. There were various theories to ac-
count for the formation of mineral veins—the first supposed them
to be the result of infiltration, the water which percolated the
substance of the contiguous rocks carrying with it the several
mineral matters they contained, and afterwards depositing them
upon the walls of fissures caused by the contraction of the sur-
rounding parts; the second supposed the materials of the vein to have
been brought in solution by water deposited in the form, owing to slow electro-chemical action; the third hypothesis
assumed, that the contents of the vein, being separated from the
other materials by sublimation, found their way into fissures,
either in other parts of it, or in the contiguous forma-
tions. No doubt many facts might be alleged in favour of each
hypothesis. In the first place, granting that a given rock con-
tained, disseminated through it, any quantity of an oxidizable
metal, such as iron, copper, lead, or tin, and that these were al-
ready in combination with sulphur, the action of water and air, by
generating sulphuric acid, would gradually give rise to soluble
sulphates, which might find their way into the contiguous fissures,
where, owing to certain electrical or chemical reactions, the metals
would be deposited in an insoluble form. Decomposition could be
brought about by weak electrical currents; and thus the second
hypothesis might be brought to explain the irregularly left un-
affected for the first. But both presupposed the existence of
metallic matter in the rock from which the veinstone was derived,
for it was evident that these several metals could not be present
in the requisite quantity, in strata deposited from water, or all
our mineral springs would contain traces of them, just as they
did the siliceous and other substances of the rock through
which they had been percolated. He could not, therefore, help
supposing, that the mineral matters, which had been confined to
the neighbourhood of plutonic rocks, were, in the first instance,
derived by igneous agency, which constituted the machinery by
which the metallic materials were brought from the very bottom
originally from the depths to the surface of the earth. It was
remarkable, however, that they were not confined to the intrusive
rock itself; but, in many instances, were in the metamorphic strata
contiguous. There was also, evidently a connection between the
metallic matter in the vein and the character of the enveloping
rock, seemingly showing, that the ingredients of the former were
not sublimed directly from the interior of the globe, but had been
introduced from the formation in contact with the vein. Thus
Fournet had stated, that at Andrauburg, in the Hartz, the veins
began in the metagabbro, and then passed to the vein slate
formation into the flinty-slate, and Voltau mentioned a vein in the
Vosges which, in traversing successively different varieties of
gneiss, had its contents modified in each. Thus, in the first va-
riety, which was charged with mica, the vein was small in its di-
ger, and nearly wholly composed of quartz; in the second, which
had more of the character of slate-slate, it swelled out to a width
of 18 inches, and contained silver, combined with antimony,
copper, &c., together with sulphate of barytes; in the third,
which contained hornblende, the former was wanting, but the
last-mentioned ingredient continued, by the fourth, which
was wholly destitute of mica, the silver returned for a certain
distance down, but was afterwards replaced by selenite, galena,
and sulphur, in small quantities. Sir H. de la Beche mentioned
similar cases in Cornwall; and the frequency of their appearance
is also a fact in itself strongly in favour of this view. As, in
many instances at least, dependent upon the character of the
rock which it traversed; so that, supposing them derived origi-
nally from the same igneous source, a process of segregation had
subsequently taken place, by which particular bodies were deter-
mined to certain kinds of rock, to the abandonment of others.

In order to prove the way to a solution of these and other diffi-
culties, he submitted two questions—the first, whether igneous
rocks did not contain, disseminated through their substance, mi-
nute and, probably, infinitesimal quantities of many of those rarer
metals, which are found together in mineral veins;—and the second,
whether all those substances that possess a certain amount of volatility, at temperatures below their freezing
point, and thus become transported from place to place, at periods
long subsequent to that at which they were originally evolved
from the interior of the earth, in a state of admixture with other
more abundant ingredient? In adopting the affirmative, with re-
ference to the former of these questions, it was not necessary to
go so far as to assume, that every basaltic dyke, or even every
great volcanic formation, contained, as an integral part, minute
quantities of the metallic materials, or even that such materials
existed at all; for, considering how infinitely small was the proportion which they bore to the en-
tire bulk of the crystalline igneous rocks, their absence could not
be safely inferred from the fact of their not having been dis-
covered. The facts which inclined him to suspect that they might
exist, were the circumstances—first, that the discovery of phos-
phoric acid, in so large a number of volcanic products, led to the
conclusion, that this body, at least, was derived from volcanic
emanation, and, by analogy, that metals were also so derived; se-
condly, the observation made by Henry Rose, that in every
piece of copper might be detected by the test of sulphurated
hydrogen; and, lastly, the fact, that not only iron, arsenic, and selenium, existed amongst the products of Vesuvius,
but that lead, copper, zinc, tin, and, in a limited extent, probably
were ejected from Mount Etna. Now, according to the presence
of metals, and other bodies of rare occurrence, amongst the matters
evolved from the interior of the earth by igneous processes, the
second hypothesis stated would enable us to account for the diffu-

sion of such matters through the substance of the contiguous strata, as well as for their local accumulation in fissures, or veins; for it was evident, that if these bodies were severally capable of undergoing volatilisation, at temperatures below that of their fusion, the least, with respect to the rock, of the cutting through the formations contiguous for a great distance around, would drive out portions of all these substances, causing them to become disseminated throughout the latter, and, where fissures existed, to enter in, and contribute to fill them. For this purpose, however, the heat must have been applied, and possessed of a certain intensity and hence, whilst metallic veins were frequent in connection with granite, they were entirely absent from sub-aerial lavas, owing to the more rapidly cooling that would take place in the latter, than where the matter was thrown out under the sea, or at great depths beneath the surface. This, according to this theory, is the formation of metallic matter in veins, while they have arisen, not from the latter having been the original receptacles of whatever was disseminated from the interior of the globe—for he agreed with Prof. Basch, in considering that the idea of metallic, or indeed of any description of veins, being injected in a state of fusion from below, as trap and granite dykes were supposed to be, was encumbered with insuperable difficulties—but owing to the subsequent action of the heat upon the erupted matter, by which the metal might have been slowly volatilised, and thus have found its way into the fissures and veins, which, by the principle of chemical affinity, described by Prof. Faraday in his "Memoir of the Limits of Volatilisation," would come into play; and no sooner was a thin layer of metallic, or other body, collected along the walls of a cavity, than the portions subsequently sublimated would be determined to the same point, until the cavity was filled up.

The learned author was more particularly alluded to Tilgman's discoveries with regard to the decomposing influence of steam at high temperatures, which accounted for the decomposition of many rocks, and the formation of combinations between the alkalies and fixed acids. Various facts also proved that a certain fraction of the water at high temperature would favour the separation and the new combination of metallic matter, though that was not essential. To influences of this kind such formations as that of nodules of flint in chalk had been referred, but he thought it more probable that the deposition of silex was the result of the extraction of carbonic acid by the decomposition of animal matter.

He, therefore, suggested the importance of ascertaining by more precise experiments what were the laws which regulated the vaporisation of solids at temperatures below that at which they were fusible. Assuming the truth of this principle, he threw considerable light upon the alterations which contiguous strata underwent from the intrusive rocks—for, supposing a certain degree of mobility to be produced by heat, without actual fusion, would enable us to understand these changes. The learned lecturer then proceeded to discuss the different processes of volcanic eruption, which might be contended for by a reference to the same principles, sided by analogous facts known to chemists, with respect to carbon and other substances. The whole question, however, appeared to be open to further inquiry, both as to the degree of volatility possessed by magnesium, and the combination, its power of penetrating the substance of a calcareous rock, and combining with its ingredients in atomic proportions—neither body being in a state of absolute fluidity—its transmissibility to great distances through an intervening mass of rock, and the circumstances which caused it to accumulate in certain sets of beds, and to pass over others. Experiments should, likewise, be made as to the changes which augitic rocks sustain under the influence of a high temperature, and as to the possible disengagement from them of magnesium under the circumstances supposed; nor was chemical research less called into request, for the purpose of enabling us to explain such results as were caused by igneous eruptions, and the present day, than for the elucidation of processes of higher antiquity. When he reflected upon the assemblage of chemical phenomena which presented themselves during the several phases of volcanic action—the enormous and long-continued evolution of carbonic acid—the inexhaustible supplies of sulphur, arising from the decomposition of sulphuretted hydrogen—the volumes of steam and muriatic acid disengaged by those volatiles which were in a state of activity—the sublimations of common salt, sal-ammoniac, &c., which generally accompanied eruptions of a similar nature, and which could not be accounted for from many thermal springs—when he saw these, and other results of internal chemical action, come so prominently into view in every part of the world where opportunities for studying the operations of internal heat were presented, it did excite his surprise that philosophers of high name should have rested content with a theory which professed to ascribe everything to the mere protrusion of some of the fluid contents of the globe through parts of its crust, without regarding features so important, and apparently so essential, as those to which he had alluded.

It was next learned with respect to volcanoes, by minute chemical examinations of the solid products ejected, with a view of comparing their constitution one with another, and of the gases and vapours evolved before, at the time, and subsequently to, a volcanic crisis. The learned lecturer then referred to Prof. Abich's experiments with regard to felspar and to the recent discoveries at Vezirius, representing the evolution of hydrogen from an active crater, and to the results which might be expected from further discoveries. In the meantime, even with our imperfect knowledge of these mysterious workings, we might obtain glimpses of a utmost importance—of much adaptation of means to an end—which struck the observer all the more, when it was displayed, as in this case, in the midst of those terrible manifestations of irresistible force, which the workings of a volcano, or an earthquake, revealed. This was shown by the useful purposes performed on the surface of the globe by the carbonic acid evolved from its interior, and was also illustrated by the occurrence of metals in veins, and the diffusion of phosphates in minute quantities so generally through the strata. Had not this been the case, the former would not have become known to us, and the latter would not have been available for the nutrition of plants.

Such were a few of the facts to which he had been desirous of directing attention, by way of inducement to his auditory to pursue the science of geology with a frequent reference to chemical principles; and he wished to be understood, not only in the strictest and most particular, the great truth, that all research of chemistry was to be regarded as the grammar to the language of Nature—the key to unlock her most secret mysteries; and that those who were ambitious of following in the footsteps of the great men who had adorned, and still adorn, the noble Institution of physics, must get their primary lessons in physiology—vegetable or animal; in scientific husbandry; or in those cosmical phenomena which presented themselves to the explorer of mountainous regions—chemistry would suggest at once the right principles for interpreting the facts observed, as well as the soundest practical application that admitted of being deduced from them.

THE TIDES OF THE IRISH AND ENGLISH CHANNELS.

Report of Experiments made on the Tides in the Irish Sea; on the similarity of the Tidal Phenomena of the Irish and English Channels; and on the Importance of extending the Experiments round the Land's End and up the English Channel. By Captain F. W. Bercow, R.N. (Read at the Royal Society, March 9 and 16, 1838.)

The author commences by stating, that the set of the tides in the Irish Sea had always been misunderstood, owing to the disposition to associate the turn of the stream with the rise and fall of the water on the shore. This misapprehension, in a channel varying so much in its times of high water, could not fail to produce error; and in order to remove it, he would establish the probability, a large proportion of the wrecks in Carnarvon Bay. The present inquiry has dispelled these errors, and furnished science with new facts. It has shown that, notwithstanding the variety of times of high water, the turn of the stream throughout the north and south currents occurs at the same hour, and that this time happens to coincide with the times of high and low water at Morecombe Bay,—a place remarkable as being the spot where the streams coming round the opposite extremities of Ireland finally unite. These experiments, taken in connection with those of the Demodane made at the suggestion of Professor Airy, show that there are two spots in the Irish Sea, in one of which the stream runs with considerable rapidity without there being any rise or fall of the water, and in the other the water rises and falls without having any perceptible stream; and the same stream makes high and low water in different parts of the channel at the same time; and that during certain portions of the tide, the stream, opposing the wave,
runs up an ascent of one foot in three miles with a velocity of three miles an hour.

The author enters minutely into the course of the stream, shows that the point of union of the streams from the opposite channels takes place in the island of Funchal and in Traunfelsbargh before they reach Isle of Man on to Morecombe Bay; and concludes his remarks on this part of the subject by adverts to the great benefit navigation will derive from the present inquiry. He then notices a chart of lines of equal range of tide, which has been compiled partly from the ranges published by the Royal Society, and partly from observations made on the present occasion; and has annexed a table by the aid of which the seaman will be able to compare his soundings taken at any time of the tide with the depths marked upon the Admiralty charts. Next follows the mention of a feature in the motion of the tide-wave, which Capt. Beechey thinks impossible of escape observation; viz. that the upper portions of the water fall quicker than the lower,—or in other words, that the half-tide level does not coincide with the place of the water at the half-tide interval; that this difference in the Bristol Channel amounts to as much as four feet, and that the law seems to be applicable to all the tides of the Irish Sea.

We are next presented with a table exhibiting the various curves assumed by the tide-wave, and with the durations of the ebb and flow at each place. Having explained these observations in the Irish and English seas, the author proceeds to apply to the tides of the English Channel the law which he found to regulate the stream of the Irish Channel,—availing himself of the observations of Captain M. White and others for this purpose. There was no difficulty in adapting the rule in the upper part of the channel; but below the confluence of the two streams, the author finds that nothing but a reliance on the general accuracy of the observations prevented the inquiry being abandoned. It seemed that the streams are operated upon by two great forces, acting in opposition to each other; viz. that there is a great off-shore stream setting along the coast of the British Isles, and flowing in opposition to the tides of the channel above the contraction, turning the stream with greater or less effect as the site is near or, removed from, the points of influence. By pursuing this idea, it was seen that the observations in the English Channel respond to it; and then applied to the ebb and flow of the Irish Sea, and concluded that the English Channel to comprise within its limits the Bristol Channel, as the English Channel does the Gulf of St. Malo, it was found that the observations there also fully bear out the idea. So that there was afterwards but little difficulty in tracing the course of the water, and bringing into order what before appeared to be all confusion.

The author then traces the great similarity of tidal phenomena of the two channels, and proceeds to describe them. For this purpose he considers the Irish Channel as extending from a line connecting the Land's End with Cape Clear to the end of its tidal stream; the head of the tide at Peal, and the English Channel from a line joining the Land's End and Ushant, to the end of its tidal stream off Dungeness.

With these preliminary lines, he shows that both channels receive their tides from the Atlantic, and that they each flow up until they meet a shore stream, that from the outer limits of the English Channel to the virtual head of its tide is 282 geographical miles—and in the Irish Channel, from its entrance to the virtual head of its tide, it is 263 miles. In both channels there is a contraction about midway by Cape La Hogue in the one, and by St. David's Head in the other, and by St. Malo in the last nearly 5 miles of distance from the entrance. In both cases this contraction is the commencement of the regular stream, the time of the movement of which is regulated by the vertical movement of the water at the virtual head of the channel; situated in both cases 145 miles above the commencement of the parts of the stream above the rise of the tide. Establishment, is the same in both cases. Below the contraction of the strait, in both cases the stream varies its direction according to the preponderance of force exerted over it by the offing stream. In both cases, between the contraction and the southern horn of the channel there is a deep estuary (the Bristol Channel and the Gulf of St. Malo) in which the times of high water are nearly the same, and where, in both, the streams, meeting in the channel, pour their waters into these gulfs, and in both raise the tide to the extraordinary elevation of forty-seven feet. From the Land's End to the head of these streams in case one is seventy-five miles, and in the other is the same.

In one channel, at Courtown, a little way above the contraction, at 150 miles from the entrance, there is little or no rise of the water; and in the other, about Swanage, at the same distance from the entrance, there is but a small rise of tide also (five feet at spring). In both cases these spots are the node or hinge of the tide-wave, on either side of which the times of high water are reversed. And again, near the virtual head of the tide, in both cases, there is an increased elevation of the water on the south-east side of the channel of about one-third of the column—the rise at Littleham is thirty-one feet, and at Cayeux thirty-four feet.

The author traces a further identity in the progress of the tide-wave along the sides of both channels opposite to that of the node. In the first part of the channel the wave in each travels at about fifty miles per hour; in the next, just above the node, this rate is brought down to about thirty miles per hour, and to sixteen miles in the other; it then in both becomes accelerated, and attains to about seventy-six miles per hour. Lastly, the author observes that the node or hinge of the tide, placed by Prof. Whewell (in his papers on the tides) in the North Sea, is situated at the same distance from the head of the tide off Dungeness, as the node near Swanage is on the opposite side of it; and that in the Irish Channel, at the same distance nearly as the node at Courtown is from the head of the tide off Peal, there is a similar spot of no rise recently observed by Capt. Robinson. Capt. Beechey's letter was illustrated by charts and diagrams, showing the identity and singular phenomena of these two great channels.

MR. HAY'S THEORY ON SYMMETRICAL BEAUTY.

On the Production of the Beautiful—an attempt to prove that the Theory of Proportion, in the Works of Vitruvius, in the Society, founded on the development of the Harmonic Ratio, is fallacious. By Mr. Thomas Purdie.—(Read at the Royal Scottish Society of Arts, March 13 and 27).

Part I.

Mr. Purdie commenced his paper by referring to the opinions of those philosophers in the Society, whose names had been used in support of the theory of the under consideration. He endeavoured to show, by quotations from Lord Jeffery's "Essay on Beauty," and from Dr. Reid's works, that these opinions were hostile to all theories of such a nature. He next adverted to Vitruvius, and stated that he propounded a theory of a similar character to that whose futility he had undertaken to prove. One of the diagrams used by Vitruvius in applying his principles to practice was exhibited; the same diagram being used by the author of this theory in explaining the harmonies of the Parthenon. He stated, however, that Vitruvius could not be considered as an authority in regard to the principles on which styles are founded, having been led away by his fondness for metaphysical distinction and refinement, to refer them to sources with which they had no connection. This statement was supported by quotations from the works of Vitruvius himself, from Lord Aberdeen's "Principles of the Beauty of Grecian Architecture," and from the article "Architecture" in the "Encyclopaedia Britannica."

As the second division of his subject, Mr. Purdie referred to the labours of Kepler in proving the harmonies and analogies he supposed to exist throughout on nature—"to prove which, great part of his Mysterium Cosmographicum" and "Harmonices Mundanae" is devoted to the assumption of the twelve and thirty-six degrees of the Zodiac being divided into 360 degrees. It led him into some subtle considerations in relation to the divisions of the musical scale. Mr. Hay investigates the properties of the number 360, and his investigation seems to lead to a conclusion of a similar nature.—(See p. 24 of his book, "Symmetrical Beauty.") A quotation was read from one of Galileo's Dialogues, denouncing the belief prevalent in his time as to the beauty supposed to reside in the harmonic ratios, that being the principle on which the present theory is founded. He quoted a passage from Bacon, tending to show that he considered the ideal beauty of the Greeks, and that formed by geometrical proportion, to be antagonistic. In "De Baco" contrasts Albert Durer, "who would make a figure by geometrical proportions," with Apelles, "who would change it to suit the parts and attributes of the person. Numerous quotations were given from various authors, as to the universal prevalence, in the 15th century, of the "dangerous ideas of the aptitude and congruence of numbers," and of the absurdities to which the style of reasoning from numbers was reduced. By this, it is shown that the existence of Jupiter's satellites. A celebrated musician held that God created the world in six days, and rested the seventh, because there are but seven notes in music; and Kepler, by a similar process, explained the music of the sphere by the proportions of the planets, Mars, the Sun, the tenor, and Venus the counter-tenor, and Mercury the treble.

As the third division of the subject, Mr. Purdie gave a short account of the theory advanced by Alison, advocated by Lord Jeffrey and others, and generally recognised by modern metaphysicians. He did not feel himself qualified to discuss on the subject of Mr. Green's "Alison, and Jeffrey, Payne Knight, and Dugald Stewart. They appeared to be as much of a philological as a metaphysical nature, and did not affect his branch of the subject. He had not had time to make himself acquainted with Sir George McKenzie's refutation of Alison, and could not say what effect it might have.\footnote{[May,}
had in modifying his opinions on the subject. In the meantime, although he could not say this theory accounted satisfactorily for every phenomenon connected with beauty of form, it seemed to him to account for far more of them than he yet met with.

As the fourth branch of the subject, he stated the nature of the theory under consideration, and attempted to show the fallacies contained in it, and in all others of a similar nature which attributed beauty to proportion. The grand principle of this theory—that by which it must stand or fall—was this: Greek art, as it appeared to the ancient philosopher, was not one of geometrical, but of mathematical beauty. But there was in the human mind "an universal inherent mathematical principle of harmony which gives a response to every development of its laws, whether in sound, form, or colour." He devoted some time to the consideration of this faculty. He asserted it was a faculty that, if a faculty existed, it would be nothing else than what is commonly called instinct. To combat this idea, he quoted a motto from Mr. Hay's publication on Form, itself a quotation from Burke:—"Wherever the best taste differs from the worst, it is necessary to harm the understanding, and nothing else." He argued, if the faculty by which we distinguish the musical intervals be that by which we become sensible of the beauty of form, the result is inevitable,—that all animals, such as the mooring bird, which can distinguish these intervals and follow them, must be conscious of the beauty of form also.

He stated that he only advanced in favour of this theory was drawn from analogy, because we find the harmonic ratios are necessary to the primary beauty of a musical chord. These ratios have been applied to form, as being necessary to constitute its beauty also. He argued, if we are to conclude that these ratios are necessary to constitute the beauty of form, simply because we find they are so to the primary beauty of a musical chord, on the same reasoning we are to conclude it is easy to the taste of many of the other senses; but that this would involve the absurdity of attempting, on mathematical principles, for the same man partaking with equal relish of things sour and sweet, salt and fresh; of eating pickled and other food one day and lick a hollow jay the next; for an European lady preferring the scent of aromatic vinegar to asafoetida, while some tribes of savages infinitely prefer the latter. He spoke at some length on what he conceived to be the supernatural nature of such a mode of establishing a theory. A sound is always present, he says, the precise pitch of which can be described with greater certainty, that is, it could be said to be beautiful at all, as there is no point from which all these diaphons could possibly be presented to the eye in their true position. Even standing immediately in front of the building, the diaphons drawn in the right triangles between the nearest columns would necessarily present to the retina a much more acute angle with their base line than those farther removed. Take one step to the right hand or the left, and the angle of one becomes one of 78 or 77, and so changing with every step, till it is seen close together, and every one of those angles becomes a straight line.

Mr. Purdie followed this with some remarks tending to prove the fallacy of all theories which assume proportion as their basis. How could any such a theory account for the beauty we discover in a human figure, or in a horse? This is the beauty in styles of architecture so various that some of them seem to be beautiful from the want of qualities which some of the others possess—as the Moorish, the Grecian, the various kinds of Gothic, and Elizabethan; none of these being a single feature in common, either in their proportions or their details. That these differences are not confined to the different orders, but exist in various examples of the same order,—a drawing was exhibited of four specimens of Corinthian: from the Choragic Monument at Athens—the temples of Jupiter Stator and Penates, in Rome—and of Vesta at Tivoli; all exceedingly beautiful specimens of the order, but without a single feature in common, either in their proportions or details. He adverted to the universal agreement as to the principles of harmony in the modern taste, and the modern artist, would, in ten years, address us in antiquated language, without having the respect due to antiquity. The Grecian statues speak to us in a dead language which changes not, and they speak to us in the language of antiquity, and the cultivation to which that wonderful people had attained, and from whom they are descended to us.

Mr. Purdie concluded his paper by characterising all attempts to establish a theory on such grounds as this, in the words of Lord Jeffrey, as "dogmatically from a few examples, instead of defining any general comprehensible principle, in which all beauty may be supposed essentially to consist."

At an attempt he continued, as reasonable, and of precisely the same nature, as that of a man who, setting out with the premises that every oak tree is a vegetable, attempts therefrom to prove that every vegetable must be an oak tree.

Mr. Purdie then intimated that he would be prepared, in the second part of his paper, to go somewhat more into detail, and to prove the fallacy of the theory from its own inherent defects and self-contradictions; for of these he conceived it contained sufficient for the purpose, although he might have failed in convincing any one on the general question.

PART II.

Mr. Purdie commenced the second part of his paper by recapitulating shortly the contents of the first. He then proceeded to explain the scope of the theory he had undertaken to refute. It was intended to be applied to universal nature. This was sufficiently shown by the "universal symmetry," which he considered, as the "inherent beauty," for the "purpose of giving a response to the laws of the theory. It followed that no object could be beautiful in which those principles were not developed. He quoted two passages from Mr. Hay's book on Symmetrical Beauty as still extending intercaliations are relieved against the sky, while the others are seen against the ground; and this assists in harmonising them.

Mr. Purdie then showed, from Mr. Stuart's plans of the building, that there is an open space of only two feet through the outer intercalations, while nearly four feet can be seen through that next it. This, therefore, instead of assisting the theory out of its dilemma, only increased the difficulty. Besides, a glance at the ground plan would have shown the inconvenience of applying such an arrangement to a building row of columns, which were so close to the building, they could never be seen against the sky at all. He then explained the reason usually assigned for the nature of the intercalation used in Grecian Doric, which is connected with the arrangement of the triglyphs and metopes. He said, Mr. Hay stated that the line of the tympanum formed with its base an angle of 15 deg.; that this was the length of the pediment in Plates 6, 7, and 13 (of Stuart's Athens) all differ," he "adopted that of the latter, as being the most likely to be correct," because the pediment in Plate 15 is by itself, and are the principles of symmetry, beauty, and proportion itself is not in accordance with them. By a calculation made from these measurements it would be found to form an angle of 13 deg. 24 min. There was a statement in the text, noticing the inaccuracy of the elevation. The real elevation there is there given by itself, and is all the combinations of harmony and melody of sounds, are most pleasing. His proportions as assigned to form are most correct and most beautiful. They are not, however, those of the beautiful sounds to which he assigns them.

The Grecian Doric, therefore, was not in accordance with the principles of this theory. Perhaps the attempt might be more successful when tried with
the other orders; but if it failed with the Doric, the proportions of which were comparatively invariable, the Ionic and Corinthian must be still more perfectly adapted to the laws of that which varied the next order. Architecture, in the "Encyclopædia Brittanica." said it was scarcely possible to give any general description of it. If it failed with any of these, there would remain for it but a small chance of success with the Gothic or the Billy.

Mr. Purdie said, it might save the introduction of much irrelevant matter, if it were kept distinctly in recollection that he was not attempting to refute some imaginary theory which might be brought forward in the course of the discussion, but that advocated before the Society by Mr. Hay, and contained in his admirable paper, which has been so well discussed on the table. No doubt, order, proportion, and harmony were all necessary to the beauty of architecture; but it was not by the harmonic ratios these were to be obtained. The "Greek architects allowed themselves to be fettered in their general proportions by the existing general harmonies of the several nations at all. In music, the application of harmonic ratios, while they allowed all latitude as to general proportion, limited beauty to certain fixed points or coincidences, from which when the slightest deviation was made, discord ensued. Thus a difference of a semitone would make as disagreeable a discord as a full tone, and one quite as easily recognised. It mattered not whether too high or too low. The application of the harmonic ratios to forms was intended to produce a similar effect. Thus in the case of a well-proportioned column, six inches added to its height would be as easily obviated as 18, and quite as destructive of its beauty; and were the height diminished by 18 inches instead of being increased, it ought to be no more so, the departure from the harmonic ratio in either direction being equally discordant. The instant the correct proportions were departed from, deformity resulted, but let the alteration be diminished a little farther in the same direction, the deformity would be got rid of—a new chord struck, and beauty and symmetrical proportion again obtained.

Mr. Purdie stated shortly what he conceived to be the source of the beauty of architecture and sculpture, and referred, as the best sources of information with which he was acquainted, to Lord Somers's "Inquiry into the Examples of beauty in Grecian architecture—"Wilton's Preface to Chambers's Works—"the Essays of Alison and Lord Jeffrey, and the lives of Christopher Wren and Michael Angelo Buonarotti, published by the Society for the Diffusion of Useful Knowledge. It was not necessary to seek for any mathematical law. The taste of a nation, and their power of producing and appreciating beauty, depended on their progress in civilisation, education, and the refinement these naturally produce. "The beauty and perfection of the style, the style itself, produced the beauty and perfection of the times, and art was most perfect when Echecly, Sophocles, and Euripides, produced their tragic poems; and Socrates and Plato, and the great Grecian statesmen, by their writings and example, improved the moral and political state of mankind."—(Life of Michael Angelo.) That this tended to prove the general correctness of Lord Jeffrey's definition of taste—"That the power or faculty of taste is nothing more than the habit of tracing those associations by which almost all objects may be connected with interesting emotions.

Mr. Purdie then took notice of some of the methods given for applying the theory to practice, and contended it was equally potent to produce the ugly or the beautiful. According to the method given by Mr. Hay for drawing the human countenance, an oval was first described, and within it a triangle next undercut. At the base of the triangle was placed the eye, and the eye at the two upper angles. But no rule was given for placing the apex of the triangle undermost. One might, if he felt so disposed, reverse both the triangle and oval; it might be some bungling Grecian sculptor who thus reversed as this was invented, the Cyclopian type, with one large eye placed in the forehead, and a mouth extending from ear to ear at its base.

A similar effect would take place with the profile, in drawing which an oval is given for the face and a circle for the back of the head. He said the profile is not an oval, nor is the back of the head a circle. To render the back of the head a circle, a large slice must be taken from "self-esteem," and "philoprogenitiveness" would suffer an amount of reduction which might seriously interfere with the increase of the population. The back of the head was, strictly speaking, no more a circle than a square; and if it were a circle at all, the proportion of it was not harmonious to consistencies with the principles of the theory might have been quite as easily manifested.

Mr. Purdie then proceeded to consider what are styled (p. 51, Symmetrical Beauty) a series of peculiarly symmetrical rectangles, which are evolved by using the diagonal of the square as the base of the first, the diagonal of the first as the base of the second, and so on. Mr. Hay, however, did not adopt these as they naturally arise. They did not accord with nature, and were not adapted to suit.

Mr. Purdie pointed out on a diagram the amount of the alteration. He said Mr. Hay referred to the temperament used in music in its justification. Mr. Purdie explained the nature of musical temperament, and showed the analogy between that and the use of these rectangles. He stated the temperament in music was a modern invention, and seemed somewhat out of place in a treatise which claimed support as elucidating the principles of the ancient Greeks. Were such a principle of argument admitted in architecture, it would be impossible to obtain any results. Such an arbitrary alteration of a series of figures in a science claiming mathematical accuracy, would have been conclusive against it, had it been in other respects unassailable.

Mr. Hay's method of producing it, which might be new to many of the members, was (leaving out the harmonic ratios) the simplest and best method. He said, whatever merit its application to the drawing of vases might possess, it had the merit of novelty, and had long been familiar to every one who had given any attention to the subject. He exhibited in Nicholson's "Architectural Dictionary" several good examples of vases so constructed, along with a variety of methods of producing the figures on which they were based.

Mr. Purdie explained the effect of engraving the harmonic ratios on them, and exhibited a variety of diagrams to test whether any one could point out the discordant from the harmonic. But the method adopted in forming these vases was, he contended, altogether irrespective of the theory.

Four pins are put in at certain fixed points, and a string tied round them, for the purpose of obtaining the form of two harmonic triangles; but, proceeding to the third, the string is pulled out. For this no reason could be assigned but the will of the operator. It did away at once with all idea of harmonic relation. A figure so constructed could bear no mathematical relation to the triangles on which it was based. Extend the radii to infinity, and a circle would be obtained independent of the shape of the triangles: reduce the string to a sufficient tension, and it would become a triangle. A figure so constructed vibrates between the circle and triangle. At no possible point between the two could it bear any harmonic relation to the triangle on which it is based.

In conclusion, Mr. Purdie said, that the origin of the fallacies contained in this theory appeared to be an extravagant fondness for analogy, through which the idea had been conceived of engraving the principles of music on vases, the instead of the phenomena of mind, and deducing the principles of a science from the facts so ascertained. The mental phenomena had been left out of view altogether, and the theory formed on a mathematical basis depending on the harmonic ratios; and that the result had been that in those with whom it had had no influence on the manifold blunders into which it had fallen.

After the reading of the above paper, Mr. Hay made some remarks "on the effects of perspective upon proportion, being the first of a series of short papers upon the Harmony of Form."

Mr. Hay commenced, in 1832, and members of the Society generally, for calling their attention to a fact, with which they believed they were familiar. But that fact had been denied at the previous meeting, in an attempt to prove the fallacy in his system of applying the numerical harmonic ratios to the proportioning of rectangular forms; and its denial seemed to be well received by the younger members. Mr. H. therefore, felt called upon to state the fact, and to demonstrate it. The fact, he stated, was that whatever system of proportion may be applied in arranging the parts in the geometric elevation of a building, will also operate upon the effect of that building, in whatever degree of obliquity it may be viewed. He exhibited five drawings, two of which fully explained his system of applying the numerical harmonic ratios, and the other three, which had been drawn for the purpose of stimulating the members to symmetrical beauty, with the mystical application of particular numbers by the alchemists, and some of the philosophers of the middle ages; and offered to prove that this attempt was also a failure, insomuch as he employed numbers in an intelligible, not a mystical manner.

PECULIARITIES IN THE CONSTRUCTION OF GREEK ARCHITECTURE.

Abstract of a paper: "On the Geometrical Lines and Optical Corrections of the Greek Architects." By F. C. Pembroke, Esq. (Read at the Royal Institute of British Architects, February 21st.)

I will observe, that although the scrupulous accuracy with which the measurements which I shall produce have been recorded may appear almost absurd to some, it will not appear so to those who have been so fortunate as to see the originals, and observe the perfection of the workmanship with which they are put together, and the exceedingly happy preservation of the several parts, and in which measurements are to be taken with precision in those, where in many buildings they could only be a matter of approximation.

I use as my standard of measurement the English foot, and divide it into 100 lines, so that 100 lines shall be exactly a foot. In the beginning of the year 1846 I was at Athens. I had an introduction to M. Riedel, a Bavarian architect, who accompanied me on my first visit to the Acropolis, and pointed out to me the peculiarities of construction of which I am about to speak; it was the first time I had any intimation that there was any departure from ordinary line and rule work in these
buildings, constituting a rumour which I heard from our consul at Trieste, that there was something very curiously discovered in the ancient buildings at Athens.

These peculiarities, which were then pointed out to me, were the convexity of the stylobate on the four sides of the building, and the inclination of the columns to the north and south. It is to say, on the east, the axis of the columns inclines in a westerly direction, and those of the west, easterly. Those on the north and south flanks, south and north respectively. It follows that the angle columns share the two inclinations; for instance, the north column is inclined to the west direction.

This fact has been ascertained some time; it is given with considerable accuracy in that part of the supplement to Stuart which was supplied by Mr. Jenkins. The exact amount, owing to the slight displacements which the building had suffered, is only to be obtained by a diligent survey of the whole building.

The observation of the convexity of the lines of the steps is more recent. I believe that one of our countrymen, Mr. John Pennythorpe, was the first who paid any discriminating attention to these lines. I use this phrase as they cannot but have some measure influence on our earliest investigation, as no one could ever have cast his eye along any portion of the upper members without being sensible of them. The lower lines of the building were, as I understand, quite uncovered with rubbish until the excavations of the last few years. Any measures obtained by boring must have been vitiated, and they have doubtless given many a diligent measurer a vast deal of trouble, and many have been the dimensions which have stood a dismal variance with themselves, and been cast aside without being really to blame.

Mr. Penrose first to see in these an original intention and meaning; he however kept his knowledge a secret, and it was not until the first heard of it through the communication of MM. Hofer and Schwabert, German architects, to the Bauzeitung, in the year 1838.

I was very much struck, as all who have seen the Greek building must be, by the perpendicularity of the columns, and I took each level and dimension as I would with the instruments I had with me, for the purpose of ascertaining the amount and nature of these adjustments. And I arrived at a sufficient degree of exactness to assure myself that it was well worth while to go into the matter more carefully.

In 1842, I was not able to pursue the subject any further, and I returned to England in the autumn of that year, and had the pleasure of reading a paper to this Institute on the observations.

They attracted more sensation than I had any right to expect, and I received a proposal from the Society of Dilettanti, that if I were willing to go out to Athens, and take charge of the observations, they would assist me with a sum of money. This proposal I willingly accepted, and provided myself with the necessary implements, and induced a young architect (son of Mr. E. Wilson, of Lincoln, the well-known archaeologist) to accompany me, and we arrived at Athens towards the end of October last year. I was also so fortunate as to fall in company with Mr. Mayer, associate.

The first thing which we attempted was the measurement of the base line, namely, the length and breadth of the building. This was done with steel tubular measures, compared at the time of measurement with the thermometer, from which also long deal rods were graduated for the measurement of the heights, and for general purposes. The steel rods were carefully compared both before and after my return to England, and the standard, and I gave the results as delivered at Athens. They are still subject to a very minute correction, but not worth troubling you with at present.

As soon as the weather allowed, and the requisite permission obtained from the local authorities, I proceeded to bolt a scaffolding at the east-end, of which I made an entire circuit, beginning with the three columns which are standing on the north side, and ending with the south-west angle columns.

In this examination we plumbed every column, measured every stone of the architrave, the capital, and upper and lower stones of each column, in every direction; took careful measurements of all the cracks which have in any way modified the original form, and obtained levels of all the lines of the entablature at fixed points; and finally examined the entasis of five different columns—taking several sections of each.

We then migrated to the west-end, where I contented myself with making an exact examination only of the two angular columns, which position enabled me to obtain the levels of the upper members of the western part. I also took measures at my disposal up to the eastern part had pointed out to me as necessary to arrive at the exact original state. I then proceeded to examine the upper members of the posticum, and the arrangement of the tympanum, which has some peculiarities worth notice connected with the support of the statues. Then the roofing of the temple, the temple orna of the roof in the cella, and the arrangement of columns within it. This sums up our proceedings at the Parthenon, which occupied nearly five months. The Propylæa occupied a considerable share of attention. I will now proceed to the temple of Theseus to find how far it was analogous to the Parthenon.

Last, but not least, we ascended the temple of Jupiter Olympus, from which we obtained various measurements and drawings.

The measurements of the breadth of the temple on the upper step, at the east and west ends. I found to be respectively 101'341 and 101'361.—The breadth of the south and north, 228'141 and 228'141 respectively. There is therefore a very slight difference in measures which were certainly intended to be equal, points out the limit of error, which can be attributed solely to inaccuracy of measurement in other dimensions, namely, about 1' in 5000. I may mention that I found my wooden measures, notwithstanding they had been previously saturated in oil, subject to a fluctuation in various states of the atmosphere rather greater than this amount. So that, had the eastern front of the Parthenon been set out with deal rods on a dry day, and the building erected a moist day, we should have had as great a difference between them as actually exists.

It follows that all quantities which tend to proportionality must be looked at with great suspicion, in which varieties exist sensibly greater than this small admixture of error.

The breadth of the temple of Theseus is 45'011, and its length is 104'23. The former is almost exactly in proportion of 3thos of the breadth of the Parthenon; this, I think, was intended.

I would now proceed to describe how we measured the breadth of the temple at the upper step. It had been suggested to try the equilateral triangle. That, however, notwithstanding its being near enough the mark to suggest the trial, leaves the quantity = 282 unaccounted for at the end; moreover, I do not find that in the Parthenon there are any affinities whatever to that figure.

I very much prefer to descend from the upper step, and try the proportions on the second. By this addition, the flank becomes 106'63, and the front goes to 107'39.

We now obtain a proportion 9 to 4, differing from exactitude by so small a quantity as to be fairly admissible.

It is somewhat remarkable that the quantity 1'065 is found frequently in the measures of the Erechtheum.

The proportion of solids to voids is 4522 to 1000, nearly 9 to 2.

I have now stated the principal larger proportions; I will state a few others, which are the more important secondary ones. A very happy artifice is the walls of the pronao and posticum being thicker than the cella, and their columns being less.

The height of the columns of the Parthenon is exactly 1'44 length of temple on upper step, the breadth of the aecus of six of the eastern columns is exactly 1'5 breadth of temple; they are not all equal, but I have given the dimensions of those at the eastern end, which always gives the key to the main proportions.

In the temple of Theseus, the columns is exactly 1'56th of length of temple on the lower step, and the aecus 1'5th of the breadth on the upper step.

In both, this member appears to be the unit of measure for all the details.

The whole building is most accurately proportioned in every part, and I think it not unlikely that it will be possible to find a standard which shall express every dimension without any incommensurable fractions.

I now proceed to that part of the subject which is more particularly the object of the present paper, namely, the observations on the curves of the building and on the arrangement of the columns, or Wiston's, or that of an ellipse or paraboloid.

The pavement of the Parthenon is divided by four curved lines, viz., the edges of the upper step on the four sides of the building. The four axes of this curved surface are not precisely level, the south-west angle is about 45 above the north-east and south-east angles. I think that this is simply owing to the lines of the earlier temple, which were also curved, being made use of as far as they would go, and by being produced in one direction, and extended fixed at the same time.

The curve of the west would naturally fall below the fixed point. This is the case on the west front, south and north sides. The extreme points of the upper step of the east front are exceedingly near level. The result of a number of observations gives only a difference of '008, or 49 inches, a quantity which we need not stop to discuss.

If these two points be joined by a straight line, the curve which forms the edge of the step will be found under the middle columns to rise to a height of '006 above the level of these, the curve of these columns would have been '218 in the middle, which is about '343 breadth of front; and the curvature is so regular on the northern half of this front, where the steps rise immediately from the solid unbroken rock, and consequentiy no settlements have been made in any part of that face, that the curve of each column, three agree exactly with a circular arc: the fourth differs only by '003. The curve is so very slight that it might be any regular continuous curve; for instance, in so small an arc no appreciable difference would be discernible between the three points of the circles of the breadth of the column, and I think that the work was set out by means of the latter figure, which might be done very easily; whereas, I need scarcely point out the difficulty,
or rather impossibility, of using the circle, which would require a diameter of about 22 miles.

Let it be required to construct a circle or other arc of uniform curvature, whose length is 100 feet, and the rise at the centre is to be 25 feet, or any other proportions which must be equal to the angle, with any axis a parabola, and set off from the vertex AB = the proposed rise, and draw LM at right angles with AB. Now, LM will represent the 100 feet horizontally, and ordinates drawn to the curve perpendicular to LM will determine the exact rise at as many points as may be required, ful size.

The curve on the upper step north side of the Parthenon, also approximates to a regular curve very closely; its entire rise in the centre above the line of the pediment would not have a very slight curve, between '02 and '08. If we take one point out the directions which those lines had originally, and they were as nearly as possible parallel to the line of the step, excepting that just at the angle columns the step has a little more the declension. The frieze and cornice are exactly parallel with the architrave. In the temple of Theseus, also, the line of the pediment upon which the flanks, jg. g. The lines in the architrave are exactly parallel to the step.

There is one refinement which the temple of Theseus possesses, which the Parthenon is without. In addition to the cornice being raised, the inclined lines of the pediment do not make any slight curve, between '02 and '08. If we take one point out the directions which those lines had originally, and they were as nearly as possible parallel to the line of the step, excepting that just at the angle columns the step has a little more the declension. The frieze and cornice are exactly parallel with the architrave. In the temple of Theseus, also, the line of the pediment upon which the flanks, jg. g. The lines in the architrave are exactly parallel to the step.

Mr. Ferguson has kindly favoured me with an illustration, which I will read to you, from a description of the construction of an iron foundry at Kasipur, near Calcutta, built in the year 1816. The foundry is covered by a single roof, with principal rafters, tie-rods, and suspension bar from the centre. The rise is 5 feet and the span 50 feet, which is exactly the same pitch as the Parthenon and Propylæa. The passage is extended from vol. iv. of the Journal of the Asiatic Society of Bengal, p. 116. "Before closing our short account of the Kasipur roof, we must notice a curious optical deception, for which we are somewhat at a loss for a correct explanation. On entering the room and looking up at the roof, it strikes every beholder that the tie-rods and rafters, and the horizontal tie-rods about half way, lower in the centre than near the walls. We were not convinced that it was a deception until Major Hutchinson, at our request, caused an actual measurement to be made by a perpendicular wooden staff from an azimuthal adjustment on the column of the pediment of the temple, that there did not exist a difference of level even to the tenth of an inch." The conclusion is obvious that a straight tie-rood appeared to be deflected; and I have no hesitation whatever in ascribing the cause to the contrasting lines of the principal rafters. I do not think that it is necessary to have our eyes refined by a southern climate or the political interests of these effects. I suppose that there are very few gentlemen here who have not felt the same disagreeable effect of a flat open roof with horizontal tie-rods, unless, indeed, the latter be very much cambered. That this was the modern the ancients took of the matter I am convinced by these two facts—

That the great temple at Pæstum has the convexity only in its fronds, and not on its flanks; and in the Propylæa at Athens, although the base on which the propylæa is constructed, but in the lower part of the pediment in the east portico—the central columns are actually about '12 higher than those at the angles. The base in this building is cut in two by the ascending cornice, so that there could have been little or no advantage in a convex base line.

It will be well to remember that the temples at Athens were the result of the expense of several centuries in which these refinements were gradually developed. The first step was to construct the cornice under the pediments and entablature, by making the middle columns a little higher than those towards the angles, as I have mentioned in the case of the Propylæa. Still it is likely that to a fastidious eye the straight line of the cornice would appear of the opposite kind to that found in the great temple at Pæstum, in which the fronds have the convexity in their steps, as well as their entablatures, the flanks being composed with horizontal lines. Perhaps a reasonable man should be content with this. I must willingly admit that I was perfectly content with the temple at Pæstum; still nothing short of perfection could satisfy the refinement of vision which the Greeks alone, among all the people of the earth, seem to have been endowed, and perhaps by looking at a temple constructed as the Parthenon and the Athenians would have been the result, with the ornament of a similar ornament to the straight line of that on the flanks, or more likely the comparison of the two different forms of line on the stylobate, suggested the possibility of improvement; at any rate, as early as the time of Pausanias, the Athenians would have been exactly recovered, which also is the perfect construction, as the foundations of the temple of Jupiter Olympos testify, which we know were laid during his reign.

I also refer to his time, the earlier temple of Minerva, which occupied the space of the Propylæa, which also was exactly recovered, which also is a proof that we find that the lines on the four sides of the building were convex. I can bear witness also to convexity on all the four sides of the temple at Nemea, in the Peloponnesus, and Segeste, in Sicily. I could find no trace of convexity in the temple at Segeste, in Sicily.
CAST AND WROUGHT IRON BRIDGES.—(Part II.)

(Continued from page 126.)

At the request of the Council of the Royal Scottish Society of Arts, the second part of a paper, "On the Strength of Materials, and applicable to the construction of Cast or Wrought Iron Bridges, including an account of the Tubular Bridges over the Conway and Menai Straits &c.," was read, April 10th.

By GEORGE BUCHANAN, Esq., President.

In the first part of this paper, Mr. Buchanan described, on a former evening, the form and construction of the cast-iron bridge which is intended to complete the communication by railway between London and Berwick-upon-Tweed. Some inquiry having been then made from the chair regarding the bridge over the Tweed, the only remaining link unconnected between London and Edinburgh, and from various particulars from Mr. Harrison, the resident engineer under Mr. Stephenson:—

"This bridge is to be of stone, and is to consist of 28 semicircular arches, each 61½ feet span, resting on lofty piers, carrying the level of the railway 103 feet above high-water mark, 125 feet above low-water mark, and 125 feet above the deepest part of the bed of the river. The top of the bridge, with abutments and wing-walls, is 2140 feet. The 28 arches are divided into two series by a broad pier, 28 feet in thickness in the middle. The piers of the arches are 6½ feet in thickness at the springing, increasing by quadrants, and the bottom 12½ feet thick on 18 months, but it is intended to have a temporary bridge ready for traffic in the month of July next. This viaduct is a work of great magnitude, and will, when finished, a striking and imposing structure, and one of the most important on the extension of the railway. While on this subject, he would mention two other remarkable works, recently designed and executed by Mr. Miller on the North British and Ayrshire Railways. The one is the viaduct over the Valley of Dunglass, between Dunbar and Berwick, not far from the once-catering Bridge, pierced for the valley and banks by six semicircular arches, each 60 feet span, and then the deep ravine by a single arch, 135 feet span, and rising 105 feet above the bed of the stream. A large and beautiful model of this structure was exhibited by Mr. Miller, at a recent meeting of the Society, and such a bridge as this is also to be shown to the Society. The other viaduct is that of Ballochnie, across the Water of Ayr, on the Cumnock Extension of the Ayrshire Railway, and is similar to that of Dunglass in crossing the valley on three semicircular arches, each 80 feet span on each side, in a field, although not so magnificent. The 28 semicircular arches are 5 ft. 3 in. deep at the springing, and 4 ft. 9 in. at the crown, and the appearance from below of the stupendous arch rising to such a height is singularly grand and striking. The whole arrangements connected with the quarries and raising and driving the tunnel into the bed of the stream are scientifically arranged, and the stone chosen for the work was tested experimentally before adoption. The walling and facing are all of stone, the timbers entire.

The subject of stone bridges opens a wide and interesting field, but extending beyond the limits of this paper. He would, therefore, resume the one more immediately described, namely, the strength of materials, particularly for iron bridges. Some important experiments, performed the previous evening did not permit to be shown, were then made on the tensile strength of stone from Hailes and Craigleith quarries. The Hailes stone bore on the square inch 360 lb., the Craigleith considerably more; and a remarkable effect was observed here after the load had hung for a little while it was suggested by a member to give it a slight tap with a hammer; and, on this being done, it immediately snapped sunder, showing the effect of vibration or concussion when the materials are greatly strained in aiding and completing the fracture, a circumstance which appears to throw light on what may sometimes occur by the rapid and violent actions of the trains on railways. The compressive strength of the Hailes and Craigleith stones was then shown, by experiment, to be much greater than the tensile strength; and if required, indeed, more weight and a more powerful apparatus than could be commanded; these experiments on different stones were deferred to another evening.

The compressive strength on posts or pillars was then considered, and the remarkable effects of the length of the pillar in diminishing its strength. On each side much light has been cast on the subject by the experiments of Messrs. Hodgkinson and Fairburn. Pillars or rods were tried of different lengths, from 3 inches to 5 feet, and of different diameters; rods half an inch diameter, with 28 inches length, bore 11 tons; but when the length was 7 inches it bore 5 tons, when 15 inches only 15 tons, and when 15 inches and 13 cwt. From these experiments, a general rule may be drawn for different lengths. Taking the strength of cast-iron as formerly given at 50 tons per square inch, this will hold good in pillars till the length reaches five times the diameter, and then it begins to diminish. When the length is ten times the diameter, the strength is reduced in the proportion of 15 to 1; with the length at 15 times the diameter, it is reduced as 2 to 1; 20 times as 3 to 1; and 40 times as 6 to 1.

21
Hence the great advantage in cast-iron, of using hollow pillars or tubes in place of solid metal, whereby, with the same area or section of fracture the diameter of the pillar is increased, and with it the resistance to flexure, and an increase of strength in proportion to the length. A solid pillar, for instance, 6 inches in diameter, if extended to 7 feet in length, would be weak enough to break by the first blow, but a tube 10 inches thick, giving the same weight of metal per foot in length, it might then be extended to 12½ feet, and still possess the same strength as the other. In all these cases a remarkable circumstance was observed in regard to the means of strengthening the pillars, for if the proportions of the different parts of the structure appeared to have attained a fair and proper distribution. The strength of the tube, which at first only carried seven times its own weight, was then increased to eleven times, and from these considerations the principle that tubes in general are in proportion to the length, 15 feet wide, 2½ feet high, and weighing no less than 1,200 tons. This is intended for one set of rails, and there is another tube of the same dimensions in preparation to be parallel to it for the other.

The situation of the structure is close to the town wall, and close to the base of the magnificent Castle of Conway, and the effect of spanning the wide estuary of the Conway, with this view, with the nature and construction of the tube or bridge itself, was illustrated by a model which he had himself constructed. The model was composed of only three thicknesses of paper and of one cloth, and the sides were strengthened by slips of wood to represent the angle-iron; it was 5 ft. 6 in. long, 4½ inches deep, and 3¾ broad, and although weighing only 47 lb. it led a weight of 270 lb. for deflection.

The dimensions and structure of the bridge he would now describe, from information for which he was indebted to Mr. Fairbairn of Manchester, and, through Mr. Stephenson, to Mr. Edwin Clarke, the resident engineer under him.

The sides of the tube, which are 25¾ feet deep at the centre, consist of malleable iron plates, only ¾ inch in thickness, riveted together in plates 2 feet broad and from 4 to 8 feet long (as was shown in an enlarged view on the paper), with cross ties, in which cross ties, the plates may break land. At the joints, however, the strength and stiffness of these plates is greatly increased by slips of T or I iron, one of which is laid on the outside of the plate and the other opposite to it on the inside, face to face, and the surfaces strongly riveted together. The tube, again, consists of two separate horizontal plates, running parallel to one another, 1 ft. 9 in. apart, forming together as it were a ceiling to the tube or tunnel and an external flooring on the top. These plates are ¾ inch thick, in iron riveted together, 14 ft. long in plates, in lengths of 6 feet, and between them there runs seven vertical plates longitudinally, from end to end of the bridge, 1 ft. 9 in. high and ¾ inch thick, separating the ceiling from the floor or upper platform, and at the same time uniting them strongly together by rivets and joints, each vertical plate having a rib of angle-iron on each angle, running longitudinally the whole length, by which it is united into one vast cellular mass, consisting of eight separate cells or tubes, 1 ft. 9 in. square. The object of all this strength and distribution of materials is to give the necessary stiffness and strength where the compressive force acts. And on this account the top and bottom plates are merely united by butt joints with covering plates. The whole sectional area of this cellular frame consists of 608 square inches. Lastly, the ribs, or bridge floor inside the tube, must be strengthened, so that the number. The upper plate consists of two layers of plates, each ¾ inch thick, and the under one the same; but as these plates are intended to resist tension, and ought to be formed, if it were possible, like a chain, then they should be laid on the one side to break on the other, and, a covering plate 3 feet long and as thick as the plate is placed over every joint with sufficient rivets, such that the bearing strain is equal to the tensile strength of the plates they connect. The plates are 18 feet long and 3 ft. 4 in. broad, being the whole breadth of the cell. The angle iron in the bottom cells and plates is rendered continuous by covers. The top and bottom are united to the cells by strips of angle-iron running the whole length, inside and out; the interior vertical angle-iron at the centre is removed, by which it increases the strength of attachment, and the sectional area of the bottom frame of cells is 508 square inches.

These are the dimensions in the centre of the tube, but the top plates become thinner towards the ends, where they are only ¾-inch thick, and also the bottom plates, where they are reduced to ¾-inch each. The side plates again get thicker towards the ends, where they are 2½thick. The ends of the tube are finished with cast-iron frames, and there are also castings in the cells for 8 feet at the ends, and the sides are also strengthened at the middle. The tubes are 2½ inches thick on the top 7 inches, and was brought to the straight line by the elasticity of the material as calculated on; showing that with its own weight, 1,300 tons, it only sunk 7 inches. The one end of the tube is to be fast in the stone wall, and the other is free, the other end, which has been found quite viable in different states of the atmosphere. Mr. Clarke says that the tube is a sensitive thermometer. The half-hour's sunshine at one end, or on the top, will move it laterally an inch and a half, and vertically two inches, and this when the tube is loaded with 200 tons in the centre.
Such are the dimensions and structure of this extraordinary work, and in regard to which, he was happy to say, the trials which have been already made appear to promise every success. A load of 100 tons only sunk the engine 4 feet. It is estimated to be capable of delivering 60 horse strength if he was not able to enter on these at present for want of some of the data, but expected to do so on a future occasion.

The thanks of the Society were voted to Mr. Buchanan for his excellent and instructive address, and Mr. Alexander, Mr. Clarke, and Mr. Harrison, civil engineers, for communicating the information relative to the tunnel bridges at Conway and Menai, and viaduct at Berwick; and to Mr. Miller, C.E., for allowing his elegant model of the viaduct at Dangast to be exhibited. Mr. Beazley, in consequence of the same time requested to continue his observations, and lay them before the Society at a future time, which request he kindly promised to comply with.

At the conclusion of the above paper, the following communications were read:

1. "On a New Lubricant for Machinery" By Mr. ALEXANDER BRYSON.
   This paper described a new compound, possessing properties which seem to render it a better lubricant than those in use for large machinery. It is composed of oil, sulphur, and vulcanised causticchile.

2. "On Economizing Fuel in Gas Works." By Mr. WILLIAM KEMP.
   The author states that he has made a valuable discovery in gas works, by which almost all expense of fuel is saved. Where coal tar is burned, it has an injurious effect on the furnace bars and retorts, and from this, it is obvious that the rapid coking up of the furnace bars, to remove which the frames had frequently to be thrown, must have been due to this cause. It was found that the dry bark absorbed tar equal to its production at the works. His method is as follows:—The bark is dried and mixed with the coke of the gas, coal, and base; a pallet of tar is thrown upon it, and the mixture is then placed in a vessel and covered. It was then found that the tar, if the mixture is thrown into a gas retort, is turned into useful fuel.

3. "Description and Drawing of a New Plate-Holder for the Daguerreotype Camera." By Mr. Andrew K. STIRLING.
   Mr. Sparkes's plan is as follows:—A small mahogany box is made rather larger than three times the breadth of the plate, and half an inch on each end deeper; the width is three-eighths of an inch. A hole is cut in wood, so as to cover the center of its pieces. In this box a vessel frame is made with a place for the glass plate, and glass, on a line with each other; this is pulled backward and forward by a piece of wire or string, through a hole made at the center. By this arrangement the plate is protected from bruises or scratches, and will be found admirably adapted for taking moving objects. It is made of iron, to avoid the trouble of shifting the ground glass frame for the plate-holder, and the consequent losing of the camera, so annoying in the old plan. The plate is also exactly the same distance from the lens as the ground glass. For a camera not achromatic, the ground plate of the glass may be placed outwards, so that the plate will be the thickness of the glass nearer the lenses than the image seen on the ground glass, and consequently nearer in the chemical ray.

INSTITUTION OF CIVIL ENGINEERS.

March 28, and April 4.—Joshua Field, Esq., President, in the Chair.

The paper read was "The Engineering of the Rhine and the Moselle." By Mr. G. B. W. JACKSON, Assoc. Inst. C.E.

This communication was written during a short visit made to Holland, for the purpose of inspecting personally the works with which the author had become familiar in the writings of Baudouin, Vander Bergh, Delafoiteinques, Hibbert, Krayenhoff, Ockhov, and Wimenkamp. It commenced with the geographical course of the Rhine from its source on the Boden, in the canton of the Grisons, to its numerous outlets into the sea. It then treated at considerable length of the geographical and geological formation of the country through which the river and its branches thus traversed. The ancient works, as far back as the time of the Romans, were then briefly described; and the general state of the bed of the river, with the comparative rise and fall of the sea, the progress of the modern works, were then laid down in a tabular form, as points of data; and then the capability of the Rhine for forming banks by warping, or depositing the matter held in suspension, was discussed. The remarks of the descent of the drainage, and the descrip-

of blasting the rocks, which latter considerably impeded the course of the stream. Our limits will not permit us to follow the details of these works, which differ so essentially from any in our own country, but the whole writer has endeavored to give the facts with such precision, that the paper, when it is published at length, with the copious details with which it was illustrated, will form a most interesting portion of the minutes of proceedings.

The second part of the paper consisted of considerable extent of a translation of an account of the spare, greyhans, and other works on the Moselle, for restricting the dimensions of the bed of that river, and increasing the depth of water, so as to enable the navigation to be carried on, which was at one time suspended. From the calculations of the channels which he was enabled to make, it was shown, that to effect this, numerous arms of the river had been dammed across, and allowed to silt up; the course had been straightened, embankments had been cut off, and the convex shores, after being filled up by deposit between the gauges, had defended by the formation of new channels, whereby the flood had been established for the inflowing rivulets, so as to carry the gravel to a greater distance down the stream. Rocks also were removed by powder, and general improvements to such an extent were executed, that the river was comparatively under good control.

The account of the Rhine was then resumed, and, after detailing the various plans that had been proposed for ameliorating its course, giving numerous interesting and valuable tables of Blanken's and Bolstra's experiments as to the tides, the inclination of the bed of the various rivers, the duration of the ebb and flow, and average height of the river at the time of new and full moon, the height of various dykes above the extraordinary flood-line, &c., the paper finished with these general views:—"On looking at the various plans that have been proposed, it does not appear singular that frequent stoppages should take place in that country, whilst such occurrences are comparatively rare in Germany; for, as long as the Rhine retains its single course, as at Emmerich, no stoppage will occur. If the same improvements made on the banks of the Rhine were adopted on the Moselle, but, as soon as its divides at the Waal and Pannerden Canals, the evil commences and increases, according to the number of arms and channels lower down. It is generally agreed that a river should have as few outlets as possible. It is also agreed that the tide should be admitted as far as possible, whilst at the same time, the action of the winds should be diminished; again, that the more the surface water of any river is obstructed, the more quickly the sand will accumulate; and also that, if the cut be made, and the ice stoppages to take place below it, so as to raise the water-level above; and it is also agreed, that if a cut be made, as capacious as the river itself, or be permitted to increase to that extent, it will soon get beyond control, whilst the length of the new channel will increase. When the new ice gets into eddies, loses its velocity, and by degrees close up the passage below the opening, so as to raise the water above. The question, therefore, to be solved with regard to Holland and the system followed there, in order to prevent breaches in dykes, and to save the better part of the country (taking into account its weak, marshy soil, and its incapacity to withstand any great force), is whether it be the better plan to relieve the pressure on the dykes, by cuts and new channels, and local flooding, at the tendency of increasing the number of ice stoppages; and at the same time, diminishing the velocity in the main rivers, thereby greatly augmenting its liability to accumulating sand. It is true, as is already stated, that the rivers are at present in such a condition, that it must be very expensive to remove the great mass of ice and snow, and the importance of the port of Rotterdam, and the certainty of the mouth of the Meuse at the Brielee in the course of time closing up like that at Katwyk, if no improvement be attempted, is so clear, that it is very much to be regretted that this country has not been taken into these, and to a great flow of water from passing out by the Hollands diep to Helvoet.

The author directs the attention of the Institution to this subject, and gives the following points for the consideration of the members:—"That the object to be aimed at, in any steps which might be adopted for improving the Meuse at Rotterdam, should be to protect and strengthen the shores and dykes likely to be operated upon by the alterations; to straighten the course of the Leck, so as to lessen chances of ice stoppages; to separate the Waal and Meuse waters as much as possible, and to lead off the former, together with the Leck, into the sea by the Brielee; to narrow the Bresbooch channel (now divided) into one, regulating the quantity of water; to provide the dam of the Noord, and the Scheldt, and, for the purpose of widening the outlet, to join the Island of Rosenberg to the main land at Vlaardingen—thereby causing the ebb water to act upon this island, and with increased velocity and an additional quantity of water, attempting to remove it;—"Observations on the Resistance to Railway Trains at Different Velocities." By Mr. D. GOON, of the Great Western Railway.

For the purpose of performing the experiments, a dynamometer carriage was constructed at Swindon, in which all the results required were registered upon a large scale, on the same roll of paper, thus exhibiting at a glance the resistance of the train, and the force and direction of the wind; the registration of the results was made upon the paper at every sixteenth part of a mile, and the time was registered in correspondence with the distance travelled during every fifth part. The dynamometer was very carefully arranged. It was only necessary to count the number of seconds, or fractions of a second, in one or more of the distance divisions, and the
speed was accurately ascertained. The form and direction of the wind was ascertained by a wind gauge, placed 3 feet above the top of the carriage, with a scale thrown down to pencils which indicated the wind pess at all the results. Indicator cards were also taken simultaneously from the steam cylinders as frequently as was practicable, but not continuously, as it was a service of some danger, the experimenter being obliged to sit on the buffer-beam of the engine at a velocity of 60 miles per hour, and in that wind position to take off four sets of cards in three quarters of a minute.

The spot selected for performing the experiments was one mile of railway perfectly straight and level, and nearly on the surface of the ground; and in the plane the height of the trees, hedges, and every intervening object which could affect the accuracy of the wind was clearly marked. The experimental train consisted of first and second-class carriages, each on six wheels, 4 feet diameter, taken indiscriminately from the working stock, and loaded with iron to represent a fair load of passengers, giving a gross weight for each of 10 tons. The experiments were made in various weather and speeds up to 100 tons and to 62 miles per hour, and the results were clearly arranged in a tabular form, with copious explanatory headings, so as to render reference to them exceedingly easy.

The author first reviewed the deductions of Mr. Wyndham Harding's formula, which was given at the discussion at the Institution in 1846, and gave his reasons for dissenting from that formula. He then examined critically several experiments recorded in the tables, stating candidly all the exceptions that could be taken to them; showing that although there was a difference of 2 miles per hour, the resistance as calculated by Mr. Harding's formula and the experiments made by Mr. Cathcart for the Charterhouse, that difference might be accounted for by the methods employed by Mr. Harding, which were objected to, as calculated to produce erroneous results; viz., allowing the wind to run down the track by their own gravity, using wheels of 3 feet diameter instead of 4 feet, having a much greater length of train for the wind to act upon, &c. He reviewed the great effect of a side wind against a train—driving the flanges of the wheels against the rails; and argued that the length of a train of carriages was much more important than its own weight. The author did not offer any formula that should be applicable for calculating the resistance of all railway trains; but his tables gave examples of almost every case that could occur, and hence data could be supplied for those who wished to carry the investigation further, and make a formula for themselves. He arrived at the conclusion that in practice the friction of the axle-journals was not a constant quantity at all speeds, and thought that the number and diameter of the wheels in a train, in proportion to the weight, should form elements in any general formula. He showed by experiments that atmospheric pressure acted on the wheels, and that wheels weighing 30 tons differed but slightly from that to a train of 100 tons weight, if the carriages were small and the train long in the one case, and the reverse in the other case.

The general result of the diagram of resistance with trains of 100 tons and with 50 tons showed that the resistance calculated by the formula with a 50 ton train, at 62.4 miles per hour, was 37 lb.; with a train of 100 tons, by the same formula, at 61 miles, it was 31 lb. The broad gauge railways showed the same results, at 62.5 miles per hour, being under 23 lb.; and with a train weighing 100 tons, 61.5 miles per hour, was 22 lb. We cannot, of course, give fully the results, except in a comprehensive form, but such were the general results.

The author concluded his paper by saying that it appeared to him necessary, before any general formula for calculating the resistances to railway trains could be made, that the value of the following elements, necessary in such formula, should be determined by experiments—

1. The axle-journal friction, at different velocities and with different weights, per square inch of journal surface.
2. The resistance to the rotation of the wheels and axles per pair at different velocities and with different diameters.
3. The resistance due to the rolling of the wheels upon the rails, with different weights upon them, and with different diameters.
4. The resistance due to the passage of the train through the atmosphere, at different velocities, with different proportions of weight, and length and breadth of train.
5. The resistance due to the oscillation or unsteady motion of the train, at various velocities.

The author considers that all these values might be determined, with a considerable degree of accuracy, by careful experiment.

SOCIETY OF ARTS, LONDON.
April 19.—Sir J. V. Boileau in the Chair.
Mr. Degen Wyatt, architect, read a paper "On the Art of Enamelling, Ancient and Modern."

The paper commenced with some remarks on the necessity of increasing the resources of the designers of metal work, by effecting changes in the process of manufacture; and by that act, producing a novelty which might possess all the charm of freeness, without any of that extrava
gance so constantly resorted to in the attempt to produce variety. The art of enamelling presented this so much wished for desideratum, whereby by engaging the practice of the medieval artists in this material, we might considerably enrich our metals, and furnish us with a superior utilitarian art.

After a hasty description of the composition of pure enamel, and the nature of the pigments usually employed to colour it, Mr. Wyatt proceeded to enumerate the various manufacturers which have been adopted, at various periods in the history of the art, to unite the vitreous paste with its metallic base; endeavouring, as far as possible, to describe each genus by a language of some temporary authority. The first, or Byzantine process, which obtained throughout the Eastern empire, the empire probably from the time of Justinian, down to about the year 1300, was illustrated from the particulars furnished by Theophiles, the celebrated artist monk of the 11th or 12th century; and its chief peculiarity appeared to have been the formation of casemates, or cavities, for the reception of the enamel, by means of gold filigrees.

The second, or early Limoges style, which was so much practised in the city, from probably the 11th century, until the frightful siege and massacre by the Black Prince, was described as a combination of the admirable notices of Mr. Albert Way with those of MM. Petit, Dousieux, Pottier, and the Abbé Texier; and would seem to have substituted for the vigorously compartments of the Byzantine mode, incisions in the thick copper-plate by the graver.

The third, or early Italian mode, practised for probably some 50 years before the days of Ugoalin Verti, the artist who executed the celebrated Enamels at Milan, was carried on by subsequent goldsmiths and enamellers down to the end of the 16th century. It was detailed from descriptions given by Vasari and Benvenuto Cellini; about the middle of that century it appears to have held a midway position between the ancient Limoges style and the new. During the 16th century, what afterwards produced, consisting in engraving silver after the manner of metal enamel, and then finishing it over with variously coloured transparent pastes.

Benvenuto was said to have, if not invented, at least been the first to discover the improvement of the composition of the 16th century, in the art which constituted what Mr. Wyatt called Jeweller's enamel. It consisted in using as a vehicle, with the glass powder employed to cover small gold or silver objects in the round, or in the highest relief, water in which pigs of pears had been steeped. This held the paste in its place until vitrification took place, and was yet so delicate a cement, as in no degree to interfere with the perfect purity of the enamel.

The fifth or late Limoges" variety, was described as having sprung at the close of the 16th century, under the auspices of Francis the First, and differed from its predecessors chiefly in covering the entire surface of the metal with an opaque paste, and then painting on it with transparent colours; regaining the effect of a translucent ground by applying silver leaf in particular situations, fastening it with a glass of colourless enamel, and then tinting over it. These peculiarities, as well as the peinture grisaille, and touching with gold, were illustrated from the interesting manuscripts published by M. Maurice Ardent, of Limoges. This style appears to have dwindled into necessity under the hands of the Noisalleries, a family who lived (they can scarcely be said to have flourished) during the latter part of the 17th century. In connection with the detail of the sixth and last process—the Miniature style—honourable allusion was made to the labours of Sr Theodore de Mayence (whose interesting manuscript we may shortly hope to see published under the auspices of Mr. Heindrie) and his connection with Petitot, the principal and best of the six leading masters who excelled in the style of Limoges in the 17th century, and whose works exhibited in this style would seem to have been a great enrichment of the palette, by the addition of new pigments, the power of multiplying the number of tints, and graduating the succession of tints, their hardness, and fusibility, by the addition of fluxes, &c. Unhappily, the mystery which many self-taught artists have thrown over their modes of procedure, renders them exceedingly difficult to analyse or describe.

Mr. Wyatt then commencing with Egypt, gave a rapid sketch of the history of the art, noting the bizarren enamels existing in the North, probably previous to the Roman conquest; touching on the connection between the Limoges and Byzantine schools; and concluding, though necessarily in a very brief manner, all the art of enamelling, both as a manufacture and as an art, in our own and other countries. He then placed at what had been recently done in the studios of Wagner and Rudolph, at Paris, and the exquisite paintings of Mears. Bone and Essex; and concluded by examining an earnest hope that the knowledge of art possessed by those gentlemen might soon be granted on the soil of our workshops, and that we may ere long adopt, and fully carry out, the old practice of the middle ages, so ably characterized by the Abbé Texier, in his eloquent declaration that, "in those days, our artists were blended and identified; Art gaining by the affinity great practical facility, and Manufacture much original beauty."

Sath Line.—Mears. Newall and Co. have greatly improved their patent copper wire cord, which is now made extremely flexible, and is well adapted for window-blind cord, sliding door, bathhouse, lightning rod, bell-hanging, and many other purposes for which hemp rope has hitherto been used; the advantages being that it is cheaper, much more durable, and one-sixth part the bulk of hemp rope.
COMPOSITION OF COAL GAS.

Extracts from a lecture, by Dr. A. W. Hofmann, delivered at the Royal College of Chemistry, Hanover-square.

The composition of gas evolved in the distillation of coal is by no means constant, as is well known, depending principally on the nature of the coals, the presence or absence of moisture, and the temperature at which the distillation takes place. The chief elements which constitute coal are carbon and hydrogen, with small quantities of nitrogen, hydrogen, oxygen, and sulphur. According to the quality of the coal, a larger or smaller amount of earthy matter. Another frequent ingredient is sulphur. This sulphur occurs almost invariably in combination with iron, in the form of iron pyrites. The quantity in which it exists varies very considerably; many kinds of coal contain so large an amount that they become altogether useless for the purpose of distilling gas. If coal be ignited, and atmospheric air excluded, a portion of its elements are evolved as gas, and the remainder becomes coke. The gases thus evolved contain carbon, hydrogen, oxygen, nitrogen, and sulphur. None, however, of these elements, except nitrogen, are found in an uncombined state among the products of the distillation of coal.

The following tables show the different combinations into which these elements enter during distillation. These combinations are very numerous, and are divided into two groups:—substances which are solids or liquids at the ordinary temperatures, and compounds which present themselves at the common temperature in the form of gas.

COAL GAS MAPPING.

Hydrate of phenyle.... C 12.... H 6.... O 2

Neutral Portion.

Benzol.... C 12.... H 6

Toluol.... C 13.... H 8

Cumol.... C 12.... H 12

Methacetylene.... C 20.... H 10

Permethacetylene.... C 20.... H 12

Pyren.... C 12.... H 5

Benzene.... C 12.... H 4

Basic Portion.

Aniline.... C 12.... H 7.... N 1

Phenol.... C 7.... H 7

Leyocoll.... C 18.... H 8.... N

NOTE.—The letters represent—C, carbon; H, hydrogen; O, oxygen; N, nitrogen, and so on; the figure, the weight of each atom in the compound; thus, one atom of aniline contains 12 atoms of carbon, 7 of hydrogen, and 1 of nitrogen.

The above series of substances are each of them highly interesting to the scientific chemist, whilst several are likely to be of high practical utility. These substances, along with others which are little known, constitute the complex viscid mixture called "tar," and it is rather singular that many of them, in their separate form, are oils, possessing the most delightful odours.

The second table exhibits the different constituents of the gaseous products of the distillation of coal, as follows:

</table>

In this table, the first is hydrogen, one of the constituents of water. From it is obtained a colourless transparent gas, remarkable for its low specific gravity, being one of the lightest substances known. It burns with a pale flame, requiring 4 1/2 volumes of oxygen or 3 volumes of atmospheric air, for its combustion. It is not, however, the luminous principle of coal gas. The next, light carbonised hydrogen, or marsh gas, is a compound, combining a proportion of carbon with two equivalents of hydrogen (C H 2). This gas, along with carbonic acid, is produced by the putrefaction of vegetable substances under water—hence its name of marsh gas. It burns with a pale bluish flame, rather more substantial than that of hydrogen—though it is also evident that it could not be, any more than the other, the illuminating principle of coal gas. The chief constituent of coal gas is olefiant gas—a name derived from its property of producing, when in contact with oxygen in the atmosphere, a peculiar aromatic oil (of which a specimen was exhibited). It very much resembles chloroform, and does not combine with the same gases. Its chief constituent is olefiant gas, three of oxygen, or 16 of atmospheric air. Marsh gas is composed of one atom of carbon, and two of hydrogen; while olefiant gas combines the two in equal quantities. There is, therefore, a large amount of carbon in this gas, which may be proved in a striking manner, by lighting an admixture of one volume of olefiant gas with two volumes of chloroform, which will produce a light of a peculiar blue, which will continue to burn, even when the carbon contained in the gas in a cylinder, in the form of a dense smoke, which renders the gas perfectly opaque.

Volatile hydro-carbons was the next constituent, but with respect to which we have no further data. The first table contains the names of several substances which have been extracted from the liquid products of the distillation of coal, called tar. These substances differed much with regard to their physical properties—some of them boiling only at the temperature of boiling water, while others were volatile at a distance from the boiling point, or even at the temperature of boiling water. It was evident, then, that the gas, generated along with these liquids in the retort, would carry off a certain quantity of these hydro-carbons—varying with the distance from the works at which the gas was examined. The greater number of the quantities of these substances would become obvious if their composition were considered. Benzol, for instance, contained not less than 93 per cent. of carbon, a far greater amount than that of very olefiant gas itself. This was proved by infusing a small quantity of it into water, when a quantity of oxygen for complete combustion; and, in this way, a large portion of the carbon was separated. When mixed with a due amount of oxygen, the combustion of this liquid afforded a splendid light.—[The talented lecturer showed this, by passing a current of atmospheric air through the lighted benzol; and also illustrated the peculiarly rich illuminating power of this vapour, by passing it through the pale and almost invisible flame of hydrogen, which, when thus combined, gave out a volume of light, which gradually and steadily increased in vividness, until the eye could hardly bear its dazzling glare.]

Carbonic oxide was the next constituent. Carbon combined with oxygen in two proportions, forming two compound gases; the one containing the smallest proportion of oxygen was called carbonic oxide; and the other, containing the largest proportion, was called large acid, which is also called carbonic acid. The former of these was called carbonic acid, and the latter sulphide of carbon. Cyanogen was distinguished by its beautiful violet flame—carbonic acid being produced in its combustion, and nitrogen set free. It was also remarkable for its solubility in alkalies—cyanide of sodium was produced, which, with iron salts, yielded Prussian blue. This gas occurred in coal gas in such small quantities, that its presence might, for a long time, have remained unknown, but for the very delicate test chemists possessed for cyanogen, by which the smallest traces could be detected. Sulphur of carbon was also found in coal, and was responsible for the pungent smell, and for producing carbonic and sulphurous acids. These substances had been actually found in coal gas, though they were by no means produced from every kind of coal.

Sulphured hydrogen was the next substance on the list; it was, however, in very small quantity, and that too frequently in considerable quantities. Sulphures of iron, or iron pyrites, which were disseminated through the mass of the coal, was the source of this gas; and its quantity, therefore, depended upon the amount of that mineral in the coal. Sulphured hydrogen was also the offensive principle in the exhalations from putrefying substances containing sulphur. Sulphured hydrogen was a colourless gas, burning with a pale blue flame; it had not only most offensive odour, but produced a most deleterious effect upon health, even when mixed with a large proportion of atmospheric air. He had frequently witnessed, in the laboratory, fainting produced by the inspiration of this gas in canisters. Professor Faraday had proved, that a dog would die in an atmosphere of which 1-800th only was this gas; and that a bird could not exist if the gas formed only 1-150th of its breathing medium. Fortunately there was converted, by combustion, into sulphurous acid, which was very much less dangerous and offensive. It was necessary, however, in making coal gas, to obliterate every trace of sulphured hydrogen, for the sulphurous acid is very strong, though far less injurious to health, attacked very readily every metallic surface. Besides, the small quantity of sulphured hydrogen which would escape unburnt between the burning of the cock and the ignition of the gas at the burner, and by leakage, would have sufficient time to destroy life even in short time. The presence of sulphured hydrogen might easily be detected in gas, by submitting a piece of paper, moistened with the solution of acetate of lead, to the gas uninfused.

Ammonia was another product, largely found in the distillation of coal gas, but not in nearly all the coal gas thus obtained. The nearly all the coal gas thus obtained. The ammonia was a colourless gas, which, of itself, was very difficult to infuse, though, when mixed with other combustible gases, it was entirely consummable. Respecting the products of the combustion of ammonia, accurate
experiments were still wanting. Observing to all known analysts, they were certainly water and nitrogen. Many works have stated that nitric acid 2 was also produced; but he could find no actual grounds for this; and he believed, like many other such statements, it had been copied from work to work, and repeated until it had become received as a well-established fact, without the slightest reference to such a conclusion, and he had never been able to find the smallest trace of nitric acid. Ammonial gas was very soluble in water, more so still in acids. The great avidity with which it was thus absorbed, rendered its separation from coal gas very easy.

Sulphurous acid was the product of the combustion of sulphur in the coal; and hydrochloric acid from the decomposition of some chlorides, when they were present in the coal. 

\[ \text{Sulphurous acid} \]

When by this table, that it was of the greatest importance that the heat in the manufacture of gas should not be carried to too great an extent. In the first hour, 12 parts of olefant gas, and 72 of marsh gas, were evolved—while only eight of hydrogen were generated. At the end of 30 minutes, the only gas separated from the coal gas. Carbonic acid had been considered with carbonic oxide, and that completed the whole of the constituents of coal gas. The illuminating principles of coal gas were olefant gas and the vaporess of volatile hydro-carbons; there were no other gases burning in the coal-gas flame—namely, hydrogen gas, carburetted hydrogen or marsh gas, and carbonic oxide. Besides these, the gas which we actually burn might contain traces of sulphur of carbon and nitrogen—all the rest having been, or ought to have been, perfectly separated in the different processes of purification. During the progress of the foregoing short description, the audience had already become acquainted with the manner in which these constituents singly burnt, but they would best obtain a correct idea of the contribution afforded by each, and the illuminating power of the gas, if they were to observe this experiment. He then lighted the burners attached to the vessels containing the separate constituents, so as to afford a view, at the same moment, of all the various flames.

In the process of purification which coal gas underwent before it was fit for use, the cyanogen compounds, the sulphuretted hydrogen, the ammonia, the sulphurous acid, and the hydro-chloric and carbonic acids, were separated; and he proceeded to illustrate this process by passing coal gas, contaminated with such gases, through a vessel containing sodium carbonate; and after which the liquid, which before was tolerably clear, became quite turbid, and the gas no longer contained the deleterious constituents.

The lecturer then proceeded to devote a few moments to describing the manner in which this distillation was made, if not all? at any rate, a very great amount of it. After this, the lecture concluded with the usual notice of the manufacture of the coal, the gases distilled in iron pots, but now iron vessels of a cylindrical form were used. These were placed horizontally in a furnace—one fire heating five of these retorts. The shape of the cylinders was not unimportant; and, after various changes, ear-shaped cylinders were now generally preferred—the heating surface being greater than that of any other. The front of the retorts, or mouth-piece, as it was technically called, was fixed by screws—iron cement being placed between the flanges to render it air-tight. These arrangements, as well as that by which the gas, when evolved from the retort, was conveyed into the main pipe of the engine, was of great importance. This arrangement, too, was such that the gas was led being fixed, the gas passed through a system of pipes into what was called the hydraulic main—a long, wide, horizontal pipe, half filled with water. Each retort was thus perfectly isolated, and the end of the pipe below the level of the water in the immediately attached cylinder. In this manner, the gas might be opened, in order to charge it afresh, without fear of the gas already generated rushing back through the opening. The temperature of the hydraulic main being comparatively low, a large quantity of tar and ammoniac was collected in this tube, which flowed into cisterns erected for the purpose. From the hydraulic main, the gas passed into a system of refrigerating pipes—the temperature of which was kept low by a constant current of water, whereby another quantity of tar and ammoniac was separated. The gas entered next into the illuminating gas, which should not now enter into the various ingenious contrivances proposed by various clever gas engineers and chemists. It would, perhaps, suffice, if he stated merely, that now the gas was forced through hydrate of lime, merely moistened with water.

In conclusion, he begged to offer some general remarks upon the combustion of coal gas. In enumerating the constituents of coal gas, he had pointed out those compounds which must be considered as impurities, and which must be separated before combustion took place; but, at the same time, he warned his hearers, or nothing to do with the power of the gas, which, when once formed, could not be separated from the gas. These were hydrogen, marsh gas, and carbonic oxide. Were these, then, to be considered also as impurities? If the gas were used for illuminating purposes, or to a certain extent, it might be considered thus, as impurities, because they were burnt, and in their combustion, a large amount of heat was evolved; the products of their combustion impinged the salubrity of the atmosphere in which such a light was burning, and no adrocity but the power of the illuminating power was derived from them. If, then, there were no means of separating these substances when once formed, an effort should be made to prevent their formation. With regard to carbonic oxide, it would be difficult to find a method which secured us against its formation—the entrance of the retort, when being charged, being

**STEAM WORKING EXPONENTIVELY.**

On the Influence of Rapid Motion of the Piston upon the Effect of Steam in Engine working Exponentively: with Experiments upon the subject. By M. FAULFENZER. (Translated for the Journal of the Franklin Institute.)

The researches and numerous experiments which I have made upon the application of motive power to machines, and particularly my experiments upon the effect of springs, have convinced me that in the expansion of steam there is a loss of power: a loss which should have a certain relation to the number of superimposed stratas of steam which occupy the cylinder, from its bottom to the piston.
These strata, moving with the piston, should naturally develop themselves, in order to follow and push it; and it is in this development of strata, one after the other, that the steam must employ a portion of its force, a portion which is certainly lost to the engine. The greater the number of strata, the more rapid is their development; and the more power that is thus absorbed, the less will there remain for the experiments, with engines of greater power, and an exact calculation with regard to the results obtained, can alone establish, with the accuracy desirable, all these relations. I believe, however, that the reasoning upon which my opinion is founded, and the results of the experiments which go to confirm it, are established by the following conclusions:—

1. That the velocity of the piston has a much more remarkable influence upon the useful effect of steam than has been heretofore supposed.

2. That this influence is very greatly increased, and according to a certain ratio, on account of the amount of expansion which is allowed to the steam; the greater the amount of expansion, the greater is the difference of effect.

3. That in order to obtain from steam the greatest amount of useful effect, it is necessary to use cylinders wide and short as may be practically convenient, and that the piston should move at a very low velocity.

It is certainly not unknown that the effect of steam has a relation to the velocity of the piston; but it has not yet, so far as I know, been recognized that the velocity of the piston has a particular and considerable influence upon the effect of the expansion; and I believe myself to be the first who has called attention to this subject, and who has sought to demonstrate the truth by experiment. The numbers in the table show, in effect, very considerable differences, although the velocities of the two pistons appear only in the ratio of 1 to 4. The experiments mentioned have manifested two other phenomena which have attracted my attention, and which I recommend to the notice of scientific persons: the first is, that in the engines which I used, and when they were worked by expansion, the pistons were compelled, in some of the experiments, to complete their stroke while having against them a pressure due to the expansion of the water, or of the air, far greater than the force by which they were impelled. The other phenomenon is relative to the work done by the two engines. In most of the experiments made, the useful effect, as measured by the break, was always, and even considerably, more than the theoretical effect of the motive power. Does this difference of effect depend upon the partial vacuum created in the escape-pipe on account of the rapid passage of the steam, so that the pressure upon the piston has a relatively greater force? May this rarefaction in the escape-pipe also account for the continuance in the stroke of the pistons, and not for the uniform increase of the atmospheric pressure before making a half, or two-thirds, of their stroke?

All these questions, the importance of which will be readily perceived by men of science, have need of study and elucidation, by experiments, perhaps of a different kind. On my own part, I shall do all that I can; but I call for the aid of learned persons who are conversant with such matters.

ROYAL POLYTECHNIC INSTITUTION.

This Institution was re-opened at Easter, although the additional buildings are not quite completed. When this is done, there will be greatly increased accommodation, for the whole building will be doubled in size. The grand theatre will be one of the largest in London, and capable of holding fifteen hundred persons. The screen is like that of the old theatre, and the results will show that a vast picture may be produced in a very short time, and that the theatre may be thrown into a state of microscopic illumination, but a few years back. The old great theatre has been very much improved, and the screen room is now reserved for the exhibition of microscopic art, consisting of porcelain and glass works, of great merit, from the establishments of Alderman Copeland and others. They show, even more effectively than the exhibition at the Society of Arts, the great progress of important arts in London. When the front of the Royal Polytechnic Institution in Regent-Street is finished, it will make one of the finest buildings in the street, and a very great ornament to it.
tions have, it is understood, been made chiefly through the exertions of Mr. Nurse, the chairman of the Institution, who has evidently spared no pains or expense, and has succeeded in giving to the metropolis an establishment of a very high class, equally useful and ornamental. The works are much to do great credit to the skill and taste of Mr. Thomson, the architect.

NOTES OF THE MONTH.

The Art-Union.—The report shows that there has been a falling-off this year of £5,000 in the income. This may be partly attributed to the badness and partly to the threatened government interference, but mainly to the fact that the subscriptions have been on the wane. The engravers have caused disappointment to the subscribers, and brought about the suspension of the committee. Their commercial value has long since been settled, the prices of frames and glass being sold at the picture-dealers for seven and ten shillings. The engravings have not illustrated any subject of legitimate interest, and have wanted the character of high works of art; their utmost merit being that of middling wall-hangings. Upon such taste, thousands of pounds have been spent most wastefully, for any jobbing engraver to be obtained. In practice, the administration of the Art-Union is equally bad, and is very unfavourable to the true interests of art. The plan of prize casts is most ill-taught, for it is little better than desecration to break up a mould for the purpose of preventing more such desecrations. It may be hoped that the Society will be more useful, even if the control of the prize-money should be taken from the prize-holders, and given to the council,—for the latter have shown their incompetency in everything they have undertaken, like most self-elected bodies.

Paper-Hangings prepared by means of Nitrate of Silver and other Substances.—M. Larocque presented a paper to the Académie des Sciences, Paris, explaining a new process for colouring and designing paper-hangings. He observes, in the first place, the volatilisation of potassium nitrate, the introduction of water or saline solutions, and that the nitrate of silver, among other salts, on account of its easy reduction, would furnish a great variety of shades of colour; and by means of reserves made in the paper, any designs in white may be obtained. The following illustration is a picture painted with pure nitric acid, sp. gr. 1-50, two parts; and distilled water, one part. Place the mixture in a porcelain capsule and heat it, throw in about two ounces of silver, and continue to apply heat until the action of the acid on the metal has ceased. The acid will form 500 or 800 sheets of paper, according to the extent of colouring. In this operation but a very small loss of silver will be found, for the residue can be formed into nitrate of silver and sold; or, if calcined at a red heat in a crucible with carbonates of soda, the metallic silver may be obtained and employed as a whole lot of engravings at a much less charge. In order to obtain good designs, it is necessary to operate in a place well lighted and out of currents of air.

Quarrying Machines.—We took occasion (says the Newcastle Chronicle) to examine a new stone-breaking machine, and that it was worked upon some of the quarries in the neighborhood of Newcastle. We can now understand the machinery upon which Mr. A. C. Campbell, of Newcastle, worked, for the purposes mentioned for the stone-mine at that place, where the stones are of a fine grain, but of no large size. This machine was put in motion by four men, and worked for an hour, when they obtained a depth of 9 feet, and a 4-inch gage. The hole was then charged with 15 lb. of gunpowder, and the 2,500 cubic feet of air thus obtained had the demand that it is likely to be very greatly patronised by quarry owners, from the reduction it does to its work.

Chemistry of the Sea.—A lecture was delivered on this subject at the Royal Institution, by Dr. Thomas Williams, of Swansea. In commencing, the lecturer observes that the sea contains abundant oxygen and carbon dioxide, for the purpose of which air was obtained on the French coast and subjected to the atmosphere of the sea, to test the presence of the gases. It was found that there were no traces of these gases in the sea, and this was demonstrated by the fact that the sea was free from all traces of the gases. The lecturer next observed that the condition of the water in the sea is very different from that of the air, and that the organisation of the sea is very different from that of the air. The lecturer then observed that the sea is a most important source of oxygen, and that the sea is the most important source of oxygen. The lecturer then observed that the sea is the most important source of oxygen.

LIST OF NEW PATENTS.

Granted in England from March 27, to April 20, 18

Six Months allowed for Enrolment, unless otherwise expressed.

Benjamin Greys Abington, of George-street, Hanover-square, Middlesex, for "Improvements in the manufacture of metallic pens."—Sealed March 27.

John Coates, of Seedley, Lancashire, callo printer, for "Improvements in the manufacture of apparatus for printing or apparatus for printing,"—April 9.

Michael Joseph John Doolan, of Abbot's Bromley House, Staffordshire, for "Improvements in the manufacture of apparatus for printing,"—April 9.

Joseph John Knowles, of Heaton Tower, near Newcastle, and W. Maitland, Hants, for "Improvements in generating, indicating, and applying April 17.

Joseph Foot of Spital-square, Middlesex, for "Improvements in the manufacture of paper,"—April 8.

Abbot's Paston-square, Haymarket, for "Improvements in the manufacture of paper,"—April 8.

Thomas Gill and John Edgemoor Gill, of Plymouth, manufacturers, for "Improvements in the manufacture of paper,"—April 9.

Thom Potts, of Birmingham, brass tube manufacturer, for "Improvements in the manufacture of paper,"—April 9.

James Pattie, of Rochdale, Middlesex, engineer, for "Improvements in the manufacture of paper,"—April 10.

John Crody, of Rochdale, Lancashire, machine maker, and John Eccles, of a paper mill, for "Improvements in the manufacture of paper,"—April 10.

James Mosecraft, of Liverpool, gentleman, for "Improvements in preventing the formation of paper in the machine,"—April 10.

John Masters, of London, engineer, for "Improvements in the manufacture of paper,"—April 10.

James MacTavish, of the United States of America, for "Improvements in the manufacture of paper,"—April 10.

Henry Henson Henson, of Hampstead, Middlesex, gentleman, for "Improvements in the manufacture of paper,"—April 10.

Thomas E. South, of New North-road, Middlesex, engineer, for "Improvements in the manufacture of paper,"—April 10.

Charles Green and James Newman, manufacturers of Birmingham, for "Improvements in the manufacture of paper,"—April 10.

John Barlow, of London, paper manufacturer, for "Improvements in the manufacture of paper,"—April 10.

Charles Atwood, of Woolwich, engineer, for "Improvements in the manufacture of paper,"—April 10.

John Britton, of Birmingham, manufacturer, for "Improvements in the manufacture of paper,"—April 10.

Matthew Cochrane, of High-street, Paisley, Renfrewshire, for "Improvements in the manufacture of paper,"—April 10.

Samuel Clegg, of Regent's-square, Middlesex, engineer, for "Improvements in the manufacture of paper,"—April 10.

John Bresc, of Lowry-cum-Netherlingworth, Huntingdonshire, farmer, for "Improvements in the manufacture of paper,"—April 10.

Henry Gilliat, of Saint Leonard's-on-Sea, Sussex, for "Improvements in the manufacture of paper,"—April 10.
6 similar girders \( f \) above; and upright cast-iron stanchions \( g \), on each side of the tube, to which are bolted the ends of the girders, top and bottom, and also the cross lifting girders \( A \).

motion to lift the tube another six feet, when the second were removed as before described, and the operation repeated above, until the tube had been lifted the height required, 10 feet to 26 feet.
...minimum of equal heat to the sea bottom was noticed as proving that the heat...knew that...he heat of the dissipated air was rendered sensible as the pressure—i.e., as the depth increased. Dr. Williams concluded by referring to the maximum density of water, the laws governing the solution of air in water, and by explaining the influence of those conditions on the existence and distribution of plants and animals in the sea.

"...an improved mode of fitting certain girdles and straps."—April 20.

Henry Gilbert, of St. Leonard's-on-Sea, Sussex, for "...an improved mode or improved modes of operating in dental surgery, and improved apparatus or instruments to be used therein."—April 20.
THE CONWAY TUBULAR BRIDGE.

(With Engravings, Plate VIII.)

The great engineering event for 1848 is the raising of the Conway Tubular Bridge, and which after so much fear and anxiety has been effected with great success. This work derives its importance not so much from its greatness, as from its opening the way for the adoption of a new system of bridge building, which by the resources of engineering are made greater than those which have been made before, to make a railway longer than those which have yet been opened, or to construct a more powerful locomotive, is a great work; but it is of very much greater importance to execute something entirely new. The engineer who has constructed the greatest lighthouse or the greatest dock in his day, may be overcome by some one else, and then his claim is at an end; whereas the engineer who extends the resources of his art, has a clear and unique claim to distinction. Mr. Robert Stephenson has the merit of carrying out this system of tubular bridge building, and it will be a special event in his career, beyond the many works of constructive skill he has already produced. The success of the Conway bridge is none the less important, because it settles the practicability of that greater undertaking, the Menai Tubular Bridge. Thus progress in any one direction leads most certainly to greater extension; and it is peculiarly necessary to give every encouragement to all attempts, which open a new career for the engineer, and give him greater means of exertion.

We are glad to learn that the trials hitherto made within the tube of the Menai are satisfactory, and that the motives have been successful, though we have not had the opportunity of personally investigating the real progress of the undertaking. We shall, however, watch it with interest and attention, to see how far its continued working justifies the opinion which has been entertained of its success: at the same time, we must express our opinion that the fears which are entertained by some of our mathematical correspondents.

We have this month given engravings of the tube, and the lifting apparatus, and next month we propose to lay before our readers drawings of the ingenious Jacquard machinery invented by Messrs. A. and H. Ward, for launching the proposed pontoon.

The construction when finished is to consist of two tubular bridges, formed of wrought-iron plates, each tube being for one line of rails. We shall now confine ourselves to the description of one of the tubes, which was fixed in its place in March last, and is shown in the accompanying engravings, Plate VIII.

Fig. 1 exhibits a transverse section of one of the tubes and the masonry of the pier, together with the lifting apparatus. Fig. 2 is a side elevation of 19 feet in length of the tube, resting on the masonry, and the lifting apparatus. Fig. 3 is a section through the tube, both of the elevation of wrought-iron parts. Fig. 4 is a plan of the top of the tube to the extent of 20 feet in length, and plan of the hydraulic press. Fig. 5 is a front view of one end of the suspension girders, and fig. 6 a side view.

The tube consists of a shell or external casing, a, a, of wrought-iron plate of 9 ft. 6 in. square, 2 ft. 6 in. thick in the centre, and 3 ft. 6 in. thick towards the end, riveted together to 2-inch-iron ribs, placed on both sides of the joints, and angle-gussets at the feet of the ribs to stiffen them; a ceiling, composed of 8 cellular tubes b, each 20 inches wide, and 21 inches high; and a floor containing 6 cellular tubes c, 27½ inches wide, and 51 inches high. The whole length of the tube is 412 feet, and 22 ft. 34 in. high at the ends, and 25 ft. 6 in. high in the centre, including the cellular tubes at top and bottom, running the whole length, and 14 feet wide to the outside of the side plates. The floor of wrought-iron plates, 2-inch thick in the middle, and 4-inch thick towards the ends of the tube, put together with angle-iron in each angle of the cells; and over the upper joints is riveted a slip of 4-inch iron, 4½ inches wide. The lower cells consist of 3-inch-iron plates for the divisions, and the top and bottom of two thicknesses of plates, each 12 feet long, 3 ft. 4 in. broad, and 4½-inch thick in the centre, and 4-inch thick at the ends, and so arranged as to break joint; and a covering plate of 4-inch iron, 3 feet long, is placed over every joint on the underside of the tube. The external tube is riveted to the side plates and bottom cells by angle-iron, on both the inside and outside of the tubes, as shown in fig. 4.

The ends of the tube, where it rests on the masonry, are strengthened by cast-iron frames d, to the extent of 8 feet of the lower cells; 6 cast-iron transverse 1½-shaped girders e, on the floor; 6 similar cast-iron transverse 1-inch stanchions f, on each side of the tube, to which are bolted the ends of the girders, top and bottom, and also the cross lifting girders g.

In order to allow of the free expansion and contraction of the tube, the ends rest on 8 pairs of iron rollers, connected together by wrought-iron frames, so that the lower plates f, k, 12 feet long by 6 feet wide, and 4½ inches thick. The lower plate is laid on a flooring of 3-inch planks h, bedded on the stonework; and the tube is also suspended to 6 cast-iron beams m, the ends resting on longitudinal bearers n, 12 feet long, with a circular bearing beneath. The whole rests upon an iron bed p, 5 inches diameter, standing upon an iron bed q, and supported on the ends of the cast-iron bearers s. The tubes are suspended to the beam m, by wrought-iron bolts r, and spade-pieces rivetted on to the sides of the tube, as shown in figs. 5 and 6.

The lifting apparatus for raising this enormous pile of weight was entrusted by Mr. Stephenson, to Messrs. Easton and Amos, engineers of the Grove, Southwark, to whom great credit is due for the very successful manner the tube was lifted. The machinery consisted of 2 steam-engines, erected in the recesses B, of the corresponding tube, one on each side of the river; and each engine drives a horizontal cylindrical, 17 inches diameter, and 16 inches stroke, with piston-rods working through stuffing-boxes at each end of the cylinder; each piston-rod has a cross-head, and gives motion by side-rods and cranks to two fly-wheels; and the ends of the two piston-rods work 2 forcing-pumps with plungers, 1½ inch diameter, and 16 inches stroke. These pumps inject the water into the hydraulic press C, shown in the engraving, through the small tube (3).

The press was erected on a stage constructed above the level of the top of the tube, and consisted of two cross-girders of casting-iron, 142 ft. wide by 11 ft. 6 in. high and the upper one 2 ft. 6 in. high; the ends resting upon cast-iron bearers e, imbedded in the masonry of the pier. Upon the cross-girders was fixed the casing F of the ram, which is 5 ft. 6 in. long, by 3 ft. 9 in. wide, cast with ribs; and on the top of the cylinder are fixed two diagonal girders, 5 ft. 6 in. passing upwards through the cross-head of the ram, and a cast-iron girder H, nearly at the top of the tower, and 18 feet above the girders D.

The press consists of a cylinder (1), firmly fixed in the casing, 37½ inches diameter externally, and 20 inches internally; and the ram, 38½ inches long, 15 inches in diameter, with an inch all round, to receive the water injected from the pumps already described, through the tube (3), the orifice of which is 3 inch diameter; this tube is furnished with a lever-valve close to the cylinder, for safety, in case the pipes should burst. In the event of such an accident, by an ingenious contrivance the lever-valve would be instantly closed, and the weight supported by the water in the cylinder.

On the top of the ram is a cross-head (4), of solid cast-iron, 9 ft. 10 in. long, 1 ft. 10 in. deep, and 8 ft. 4 in. thick, with two apertures, 1 ft. 1 in. long, by 1 ft. 1½ in. wide, through which the forces of the two main pistons pass, and the two main pistons are fixed two clipping vices or clamps (5, 5), each consisting of a pair of wrought-iron jaws, 3 feet long, 11 inches deep, and 6 inches thick, and a winch which turns a small pinion (6), that takes into two cog-wheels (7, 7) fixed upon the heads of two horizontal screws (8, 8), 4 ft. 8 in. long, by 9 in. diameter, by which two jaws from the clamps rise and fall. Thus it will be perceived, that as the winch is turned, the jaws are made to open or close, for the purpose of clipping the heads of the lifting chains; below these clamps are two others (9, 9), for clipping the heads of the lower links.

The two lifting chains consist of wrought-iron flat bars, in lengths of 6 feet from centre of bolt-eye to centre, and each bar is 7 inches wide and 1½, 1¼, and 1 inch thick, with heads having shoulders fitted to the jaws of the clamps. Each chain contained nine links of 8 and 9 bars alternately, besides the two lower links, each consisting of 5 and 6 bars; the upper links passed through the upper lifting clamps, fixed on the top of the cross-head of the ram, and there secured by the jaws of the clamps being screwed up taut; the second links passed through the lower clamp, the jaws of which were left open, and the heads of the two lower links were made to but against the underside of the lifting girders, 9, 9. When the pumps were set to work, the ram was lifted 6 feet, its full range; when it had attained this elevation the jaws of the lower clamps (9, 9), were screwed up close and clipped the heads of the third links (11), and there held the chain firm; the jaws of the upper clamps (5, 5) were again brought under the heads of the second links, and screwed up taut, so as firmly to clip the shoulders of the links, the jaws of the lower vice (9, 9) opened, and the ram was then set in motion. When the upper and lower links were removed as before described, and the operation repeated as above, until the tube had been lifted the height required, about 28 feet to 24 feet.
I. Surely there must be something wrong somewhere, when, notwithstanding all the numerous apparatus and aids which Architectural study can boast of, Architecture itself seems so often to have come to a dead stand. In the inability to get a step forwards, a merit is made of what an Irishman would call advancing backwards. To say nothing of the Institute, we have besides that a Royal Academy, which professes to extend its fostering protection to Architecture; also Architectural Societies, Decorative Art Societies, Schools of Design, and lastly, though not least, Professors of Architecture;—yet what is the art the better for them all? Can it do more than hash up again and again the cold remains of the banquet which it used to serve up in by-gone ages? If that “more” be not possible, there is little cause for us to vapour at the rate we do about Architecture as one of the Fine Arts. Either it has now lost, or is no longer permitted to exercise, the powers—to maintain the privileges of one. After studying all extant styles of the art, we are reduced to the mortifying conclusion, that we can do nothing whatever with any of them beyond copying them ourselves wholly unable to catch and preserve the artistic spirit that pervades the best and most characteristic examples of the styles which we propose to ourselves as models. By dint of pains-taking industry, we can follow them tolerably well as far as they go; but where they stop short of what our actual pursuits demand, we stop short too, and break down; and not only do they not go far enough for our present requirements, but they sometimes lead us astray, forcing more or less upon us that which is adopted merely because it is significant of the style, although at the very same time much that is incompatible with the style is tolerated on the score of necessity; so that, after all, it is generally suffered to be seen that there has been conflict between style and purpose. Without such thorough mastery over a style as can bend it, and render it quite plastic and tractable, it is hardly possible to produce more than either direct copies of foreign examples, or a sort of decent patchwork composed out of them. As one of the Fine Arts, Architecture might now very properly take for its motto, Fui:—“I was once, but am no longer.”

II. It would not be amiss were some term introduced to distinguish those whom we now call Architects, from Builders, or else to distinguish the Artist or Fine-Art Architect from him whose practice and abilities do not extend beyond estimates, specifications, the preparing working-drawings, and the superintending the execution of buildings. Why not have the term house-architect, as well as house-painter, understanding by it those who make no pretensions, or who make none but to do what can be done, until the time that the more ambitious name of Architect in the sense of artist. At present, all who come under the somewhat vague denomination of Architects, assume to themselves the rank of artists—followers of what is by common consent and the laxity of language admitted to be a fine art, such as poetry, but take it too little entering enough; but then it carries with it a corresponding degree of responsibility. If it can be adequately supported, it is one of honour; if not, it becomes one of reproach and disgrace. In not being an artist there is no demerit; but the pretending to pass for, or at least rank as such, without possessing the least artistic talent, is surely not very many removes from quackery. If there can be no higher title than that of Architect for those—and they do not seem to be many—who follow their profession in the spirit of artists, a voluptuous designation better be the majority, and would relieve them from the sneers and reproaches to which they now expose themselves.

III. The idea of erecting single colossal columns as monuments and architectural objects, was, no doubt, borrowed by the Romans from the Egyptians. They were of different materials, and wrought upright, or obliquely, until the appearance and objects, exceedingly well calculated to show a considerable distance, the column and obelisk agree; but they also differ as much, and the difference is decidedly in favour of Egyptian taste. Whereas the obelisk is evidently a monument—a pillar erected to commemorate a fact or figure, either in the same way as a statue is fitted by its shape to stand as an insulated, independent monolith, the column plainly expresses itself to be a component member of a fabric; therefore taken by itself alone, meaningless,—in the condition of a verb without a noun, or a noun without a verb. Not only does the column suggest the idea of a superrumpent architecture, for supporting which it is intended,—but detached from it, acquires a topheaviness and unstable look, the very reverse of that attending the pyramids in which the obelisk is made to terminate, and which produces an obtuse apex, instead of the whole being prolonged to a sharp point, like a spire. Except its general proportions of height, there is nothing that recommends it for officiating in lieu of an obelisk. The so employing it manifests very great poverty of invention and barrenness of ideas,—the inability to devise new and more appropriate forms for new purposes. What is characteristic in the column, considered as an architectural member, departs entirely from entablature or an arch springing from its capital, ceases to have propriety or meaning in a pillar erected merely as either an ornamental object or a votive monument. Such monument may still be a pillar, but it should be one expressly adapted to its peculiar purpose. In the present state of the better. In this respect, the Rostral column possesses a decided advantage: it shows itself most plainly to be neither more nor less than a trophy pillar. A column of that kind does not look like a fragment of a building. In a building, such form for the columns would be preposterous. To employ Architectural columns as detached monumental pillars, savours of pedantic and puritanic conceit, akin to that which during the Elizabethan period fashioned chimney shafts into columns, designed, more orthodoxy than taste-fully, according to some one of the regular orders.

IV. It is very possible for a man to have too much scholarship,—or, if not too much, at least too much of it, that he has no room in his head for any ideas of his own, nor any time for exercising his thinking faculties. In Architecture, scholarship is far more likely to prove injurious than at all profitabile. While with the ignorant it may pass for deep study, it is generally respected. It resembles any of the so-called "orders," and is so far from really being study—that is, study to any purpose—that it is rather apt to check the latter, to become the substitute for it, and sometimes to lead astray into fancies as chimerical as they are extravagant. Infinitely better would it have been for Wilkins, if instead of labouring to convince us that the Temple of Solomon was a building of the Grecian-Doric order, he had applied himself to more diligent and real artistic study at his own drawing-board. Pity that Solomon's temple, the tower of Babel, and the Parthenon too, including a great many other things be not left at the same helm of the same man, ambitious of displaying their pedantical erudition, than of contributing to, or in any way promoting artistic study—the very study of all others in which we are most grossly deficient. Did we find that archaeological knowledge tends to enlarge the judgment, and to fertilise both taste and feeling, we should desire to be engrossed in it, and would, however, to have quite a contrary effect—contract instead of at all expanding. Hence is it that copysim, which should be our shame, is made our pride; and much as we vapour about art—mere empty vapouring after all—we show that we have no longer any feeling for art as art. We are as capable of doingught further than it already has done. To revert to a former style, for the purpose of gradually moulding it into one that shall be far more suitable to our present occasions and wants than the original one, is, would be allowable enough. But no:—the work must be done,—such mode of proceeding would be accounted downright heresy. It would be tantamount to admitting, that excellent as former styles were for the times which produced
them, they require considerable modification in order to render them, in the eyes of a general public, generally acceptable at the present day. After all, it may be questioned whether what looks so much like praiseworthy reserve, and scrupulous adherence to authentic models, does not proceed from motives that are not the most laudable. Merely to copy, saves such an infinity of study, thought, and trouble, as to render the copying a valuable art; for, as matters go, if we get one out of a hundred who answers to the latter character, we ought to be grateful. It will be said, perhaps, that the opportunities for showing artistic and original talent are so exceedingly few, that we ought not to judge of the ability in question by the little ability which manifests itself in escu... Opportunities do them, nevertheless, and what is the use we make of them? Why, to pirate, in the most unblushing manner, designs from Sansovino! It is true, Count D'Orsay makes a merit of such doings: what then?—he merely shows himself a prigish cocxomb. His countship's opinion may be very good authority for the cut of a coat, or other question in tailoring, but in Architecture not worth a straw; although it had, it seems, overbearing weight with the "Armoury and Knavey Club." V. Beloved, but most unhappy Architecture, how art thou beset!—by the mere most on one side, and the mereest parrots on the other—creatures who merely repeat by rote what they have either heard from others, or got out of books, without bringing so much as a single idea of their own to incorporate itself with, or work upon it. So long as we merely listen to them in silence, they go on fluently enough, though, but if we turn a good eye upon them, and it is all up with them. Nothing then is left for them but to express astonishment at the ignorance which cannot perceive, or the impudence which presumes to throw doubt upon excellence that has all along been universally admitted. Anything like satisfactory reasons or intelligent reasoning, is not to be expected from people whose ambition is founded upon mere prejudice—upon authority, tradition, and conventionalism. Their criticism consists of nothing better than mere cant and parrot-like rote; and their dogmatism is in proportion to their shallowness. The most innocently-put wry disturb them,—upsets their criticism and their temper too. Albeit, anything but poetical themselves, they firmly maintain with the poet, that "What is, is right;"—in other words, everything is excellent for which due authority can be produced. And would they but be content to stop there, a good deal might be said in their defense. But no; the very same thing they insist upon our believing that whatever is not—i.e. has not been done before, consequently derives no support from direct precedent for it, but must stand upon its own merits,—must of necessity be wrong, even though it should evidently be warranted both by analogy and experience. And, in the end, that is a particle or two of shrewdness in the narrow-minded dulness of such persons: they have just discernment enough to be aware that they themselves depend entirely upon precedent, rote, and routine; and that by insisting upon others abiding by them likewise, they bring them down and keep them down to the level of their own intellect. 

ARCHITECTURE AT THE ROYAL ACADEMY; AND THE ARCHITECTURAL DRAWINGS AT THE EXHIBITION.

Most cheering and encouraging symptoms manifest themselves this year in the Architectural Room,—that is, supposing there be truth in the saying, that when things come to the worst they are sure to mend, for to that comfortable stage of passim are matters now come. Never was there before, within our recollection, so miserably poor an architectural "spread" at the Academy—such a beggarly and ill-arranged set-out. Even before we begin to look round, we perceive that one interesting class of architectural subjects is altogether missing. Either no architectural models were sent, or they were turned away; and incomprehensible as the last may be thought, it is quite as probable as the other case—at least to ourselves, because we happen to have seen some of the rejected designs, designs, too, by those who have been exhibitors for several years past, and who are now among the most productive of the Academy. For this want of commendation, both from ourselves and others. Their productions are now missing from the walls, and their names from the cata

logue, which contains very few names indeed of any note in the architectural world; and what few there are, are not by any means pluralist exhibitors, they having contented themselves with sending no more than what just entitles them to an exhibitor's ticket. Possibly, however, we are here in error, and do them injustice, for though only one subject of theirs is to be found here, several may have been turned away, for which we have to have been in the case in one instance, and in that instance the drawing admitted is precisely the one which its author cared least of all about.

Knowing as much as we do, we cannot help suspecting that a great many more ugly revelations might be made, and a good deal of scandal that would excite the Academy of most preposterous manumissanments in this department of its exhibitions, if nothing were. That architecture is there most uninviting, there can be no doubt. That has been growing more and more evident for several years past. And to the chilling coldness with which its first improvements were treated by men of liberal tastes, may perhaps be attributed the forbearance of their architectural brethren, and the discomfitting, as far as in them lies, the practice of exhibiting architectural drawings at all. In the days of Sir John Soane, it used to be the custom for the Academy's Professor of Architecture—at least it made it such—not only to contribute, but to contribute each season, and to contribute abundantly. The present Professor, on the contrary, chooses to put himself upon the shelf, where he lies wedged in between Colonna, Vitruvius, and a good many other very mumly and musty matters,—and wedged himself so tight that it seemed impossible to expect him to look at and protest against the outrageous doings in the architectural room. Most enviable state of repose! it saves him from being horrified. Mr. Barry has of course other and far better "fish to fry." Sir Robert Smirke has been all along a nonentity in the Academy—that is, its true treasurer, and keeps a keen eye upon its "shillings." We should just as much expect to find a design by one of the porters as by him. Mr. Hardwick and the new associate, Mr. Sydney Smirke, are the only architects connected with the Academy who condescend to let us see anything of theirs in the Exhibitors. Such being the case, we can forgive the editor of the Art-Union for so strongly objecting, as he lately did, to architects being elected into the Academy. Unless they enter it with the intention and full determination of really representing their own art there,—of upholding and promoting its interests, the R.A. so acquired becomes more of a reproach to them than an honour. They only take upon themselves the ungenerous and odious part of the dog-in-the-manger; doing nothing themselves for either the Academy or for architecture, and excluding from the former those who deserve to be in it, because they would prove active and efficient members. There is, however, a very strong reason possible why those few should exert themselves manfully, instead of sitting by most tamely, while architecture is all but actually kicked out. For it to be kicked out altogether would perhaps be less ignominious than to be treated as it is at present. From among the architectural drawings will be thrust aside into the Octagon-room—a hole, never intended, we presume, by Wilkins to form one of the exhibition rooms,—for this season most terrible inroad has been made by the painters upon the space hitherto allotted to such subjects, and to which they might be supposed to have acquired prescriptive right. The whole of the east-end of the room is now given up to oil-paintings,—not that we should at all complain of that, provided they were strictly architectural in subject, instead of being the refuse of the works of their kind in the Exhibition, with such charmingly namby-pamby members. "The Pugilist, the Squire, and the others of the same "misery" and lack-a-daical stamp. Had no architect-Academician courage to protest against such an invasion of the architectural territory on the walls? Was there not in the whole Academical council one single Abel

* Wilkins, during his professorship at the Academy, exhibited only two small drawings, and those showed him of his worst work of all—Downing College, Cambridge: The original drawing, however, was preserved. Many of the critics of any architectural design of his own, he exhibited first what was only a mealy concoction of Sir C. Wren's buildings; and next and lastly, merely a sculptural conception for a pediment in a building erected by another architect.

That there was not even one such seems, for had such one there been, either his remembrances would have had due effect, or he himself would have withdrawn, and reoccupying the management of R.A., would have escaped the ignominy of being crowned with the faithless,—for as matters stand, the being an
architect and Royal Academician is very much like being a traitor. Nor is it to such alone that it is reproach that they should have allowed architecture to be reduced to the degrading position to which it has been brought. When the Institute of British Architects also, who, instead of contributing to the architectural department of the Exhibition, and of coming to its rescue in the hour of its imminent peril, content themselves with standing aloof in sleek dignity, Think of it, the Institute does not show themselves elsewhere to be other than cyphers, is not much matter for wonder,—perhaps even less for regret. But its stars—the luminaries who shine so brightly in Grosvenor-street,—can it be that their talent quite exhausts itself in talking, and concerning what little subject, it is only Exhibits?—can it be that their manifest energy of self-repair? Half the business of the Institute seems to consist in voting thanks to, and complimenting each other; which, for any good that the rest of it does, may pass for the better half of it. In the meanwhile, both the Institute and the Academy seem alike to shut their eyes to some of the consequences of their innocent indolence. Although they are not, it would seem, directly responsible to any one for their doings or non-doings,—for their sins of commission or of omission,—it behoves them to pay some little respect to public opinion,—and to preserve if possible, decency of appearance. After long hovering upon the verge of it, the Academy has at last overstretched that line of discretion and safety. It has this season put the "last feather" upon the camel's back. The time for remonstrance has passed away, since remonstrance has been tried, and has proved fruitless, or worse than fruitless. What has been remonstrance, and what more unpalpable an admonition, will now become unsparing obfuscation. Unless the architects of this country be the meanest-spirited creatures conceivable, they will now break out into open rebellion against the Academy, and then, when prauximus argis defegam, will the Institute be able to utter its charge? There is, indeed, something in its charter which suggests the word of warning; is it not even written upon asbestos? At least, let that Palladium be saved; if only to be deposited in the British Museum, where it may in time come to be looked upon with—veneration.

Those who imagine that we are now writing in mere reckless pate de cagnac, are exceedingly mistaken. It is with feelings of sorrow, mingled with shame and indignation, that we pen what is likely enough to be set down for mere dippance;—with sorrow for the continually cast upon the art we love,—with shame for those who are themselves shameless,—with indignation against those Judaic-like fellows who, for the love of cash, are ready to make use of as a "fire-escape," yet whether it has sagacity enough ever to avail itself of such means is to us very doubtful. The probability is, that it will prefer the fate of a martyr—prefer being roasted alive, to making the least effort that would break the spell of its present evil service. Let us hope then, that, come what may, its charter is written upon asbestos. At least, let that Palladium be saved; if only to be deposited in the British Museum, where it may in time come to be looked upon with—veneration.

Nor is it the "hanging" alone which is to be complained of, similar perverseness in selecting and admitting subjects. There are many things which, though not belonging to it at all, for it very strongly reproaches the Institute of British Architects also, who, instead of contributing to the architectural department of the Exhibition, and of coming to its rescue in the hour of its imminent peril, content themselves with standing aloof in sleek dignity, Think of it, the Institute does not show themselves elsewhere to be other than cyphers, is not much matter for wonder,—perhaps even less for regret. But its stars—the luminaries who shine so brightly in Grosvenor-street,—can it be that their talent quite exhausts itself in talking, and concerning what little subject, it is only Exhibits?—can it be that their manifest energy of self-repair? Half the business of the Institute seems to consist in voting thanks to, and complimenting each other; which, for any good that the rest of it does, may pass for the better half of it. In the meanwhile, both the Institute and the Academy seem alike to shut their eyes to some of the consequences of their innocent indolence. Although they are not, it would seem, directly responsible to any one for their doings or non-doings,—for their sins of commission or of omission,—it behoves them to pay some little respect to public opinion,—and to preserve if possible, decency of appearance. After long hovering upon the verge of it, the Academy has at last overstretched that line of discretion and safety. It has this season put the "last feather" upon the camel's back. Not only Exhibits.
rather have found here something that would have enabled us to judge of the interior. By not doing so, we perhaps miss very little; for from what has been said of it, we may be reasonably sure to find it to be excessively common-place. There are about half a dozen other designs for the same Club-house; therefore, instead of being scattered about on the walls, and some of them put where they are scarcely visible, it would have been better to have collected them into a group. We should have been able, here, to judge of the general tendency for those drawings were not exhibited at Lichfield House, although some of the plans convinced us that the sections belonging to them must have been more than usually interesting. Sections, however, are not at all in favour with the Academy;—are things by far too prosaic to be admitted into their Architectural Room. Isometrical perspectives of prisons are in their opinion more artistic drawings and dignified subjects than sections of even palatial club-houses. Such doggrel mode of drawing as isometrical perspective tolerated on the walls of a Royal Academy!

Designs for Railway Stations are quite as numerous, perhaps even more numerous, than those for the Club-house; and they may be allowed to show a good deal of variety, with a good deal of sameness,—variety, inasmuch as they conform to no generic character, but associate all sorts of masquerade, from the costume of almahouses to that of aristocratic mansions;—and sameness, inasmuch as they nearly all affect to look prodigiously "olden-time-ish"—a very great propriety, no doubt, when we consider how many centuries ago it is since railways were first established. A herald would trace them back to the Conquest, at least, and make out that they came over with the Normans. Sameness, too, there is with respect to any idea of scale, even of invention. If we consider them merely as drawings, showing imitations of the respective styles and classes of buildings, some there are well enough entitled to approbation, but hardly so as designs for a specific and wholly un-presented purpose, and accordingly demanding to be invested with some sort of specific character.

(To be continued.)

ON ARCHITECTURE AND PAINTING,
ESPECIALLY IN RELATION TO THE ERECTION OF PROTESTANT CHURCHES.

Letters written in Italy, by W. M. L. De Wette, D.D., Professor at Baele.—[Abridged from the German.]

If one, who like myself, is merely an amateur of art, and quite a stranger to technic,—ventures to lay down principles and give advice, he may be sure of encountering the prejudices of artists antriaci ne. I, moreover, have got a mind, with a certain independence of judgment, of a mind where tradition and custom away all minds—feeling towards such of the existing prejudices, his giving offence is unavoidable. Still, I shall make the venture, and my ignorance of technic detests me the less, as I have found this science can be studied very often mistake the true scope of art, on account of their predilections. And the more I learn about art of a prejudice, from which I, at least, am free. I may possibly be tampered with other prejudices and with one-sidedness; still, I hope to give some useful hints.

I begin with a few remarks on painting; and, without wishing to enter into a definition of what it is, or ought to be, it is certain that its destination is to convey representations and feelings to the mind. But all representations, be they what they may—either intuitions of the senses, or images of the fancy, or conceptions of the reason, or ideas of the mind,—consist of two elements; one suggested by the sensation, the other by the thought, the activity of the mind: one real-sensual, and one real-spiritual and primordial. In the intuition of senses, the first element preponderates so much, that we may be tempted to consider it the only one; but the more accurate observer will soon perceive that the mind has also its share in it. For, when we see what the mind does in the senses—receiving that which it has viewed, within the pale of his other observations, and converting it into an intuition. The products of imagination may appear to a superficial observer as something produced by the mind, but the substance of it appertains entirely to the experience of senses; imagination having merely decomposed it, and combined it in another shape and way. Even the ideas of the mind (be it in art or otherwise) are no absolute produce of our thinking faculties; being merely deduced from experience.

Undoubtedly, the arts have risen from the imitation of nature, from the representation of the really existing—and even their present process and progress are the same. Thus, while conceding, that in any art-object so much of the real be existing, we may add that the ideal is to be the image of the real. And, if we take the difference between a picture and a daguerreotype, the case will become perfectly clear. In the former, that which occurs to the external eye piecemeal, must be seized by the mind and intellect as a whole—and put forward as a self-existing, indestructible fact. In the latter, we are given the images of anatomy, &c., are used, all which will yield materials on the artist can and may dwell; but imagination will supplant many of these helps, as we see in Raffaello, who, after having devoted nearly his whole talent to painting, became the compieter of the first order of botanists. Thus, the imagination in art will give us Петер—what will lead us to a more detailed inquiry on the art of the builder.

Architecture may be called the most difficult of arts, as it is a fact that its products have experienced the most opposite and most severe criticism. The reason for this might be found in architecture being not sufficiently free—being, as no other branch of art, tied up to a certain scope; and only after this is accomplished, the demands of the beautiful may and can be attended to. On the other hand, the freedom accorded to the architect is something very vague, as he cannot follow any prototypes, but (as in music) has only to be guided by the internal measure of mathematical intuition, or the judgment of proportion and esthetics. This, however, can never afford such certain and stable rules as the other arts have deduced from the observation of nature, &c. Amongst the many styles of Architecture are the Egyptian, the Greek, the Byzantine, the Moorish, and Gothic. Parallel to all these, a contrast of two opposite qualities—beauty can be achieved. In this incertitude of legislation, if we may so call it, the chance of falling into the arbitrary, burlesque, or absurd, is greater than in most other arts.

The surest way is—to start in architecture from the scope given, as the other fine arts start from observation of nature, which with all of them constitutes their store of reality (Boden der Realität), and by which, after all, the character of the architectural style is determined. Because it is easy to conceive, that, for instance, the Greek temple and the medieval church are mostly shaped after the circumstances of climate and the surrounding mountains. To choose a style, not adapted to our wants, is an imitation bare of character,—which, however, is frequently to be met with to-day. A similar tendency of imitation and dallying with the antique and the foreign, and a want of originality, pervades much of modern art, but nowhere more than in architecture, where it seems that all trace of inventiveness has exploded; still, this cannot be the case, as our most modern times must have and have wants of their own. This, most assuredly, is the case with Protestant (evangelical) church architecture, to which the particular character of our worship prescribes special rules, and on which we have been invited to. If we refer the word "Church" to the original Ecclesia, the importance of the sermon becomes with us paramount; far more so than ever had been with the old (Papal) church. Taking the sermon as the chief feature of our worship, the scope and aim of a Protestant church can be determined. For the sermon (like any other speech) be accomplished, the orator must not only be heard, but seen by all. This applies with equal force to the orator himself, as he requires to have all his hearers within the reach of his eye, to enter with them into a living contact, which some may call mesmeric. For this aim, the churches, as they have come down to us from Catholicism, are not appropriate. In a Basilica or Gothic church, with one or two lateral naves and a choir, the pulpit cannot be conveniently placed, nor the orator heard; which is the reason, that in Italy a large cover or carpet is spread over the pulpit. The central position of Jesus in the church of Christianity could not re-model everything at once, and especially in the department of architecture: it adapted itself to the already existing. Roman Basilicas were converted into Christian churches, and retained by custom their mis-appropriate form.

For the sake of making clear what is meant by all this, it is also in accordance with the spirit of a truly evangelical worship—which is, that the congregation be conscious of their communion and community during the time of divine service; and for this aim, not only the preacher, but every one attending ought to see all, for the sake of the connection that they make with a community. The life of community, which existed in such extent among the first Christians, exploded gradually, as priesthood became paramount, until all idea of a congregation (community) degenerated into that of a complete priest-hierarchy. In Catholic churches, such things as congregations, properly speaking, never exist; but one portion attends to the mass, others pray at the several altars,
others come to and fro; and even the preacher has only a portion of the people around him. The priesthood, alone, form a compact, uniform body, which, however, secludes itself in the choir, taken up with particular functions. In this part of Catholic churches, as well as in their whole structure, the want of community is apparent; and if it has been the case to erect new churches, they change a creed, Protestants ought never have used Catholic churches for their worship. Necessity, however, prevailed, and some of these older structures deserved preservation on account of their beauty. Still, it is a dereliction of duty, if new Protestant churches were to adopt the old casas or the old cross form. It is not our province to make any specific proposals for the erection of Protestant churches; still, it is the duty of our architects to see after, and to discover that form—provided all power of invention has not left our age! So much we may say, that, according to our foregoing reasoning, this form ought to approach the ellipse. The most form may possess some disadvantages in an acoustic point of view, but we do not doubt that they can be overcome by study and research.

While the architect attends to the scope of a building, he has, especially in public buildings, also to take care of its character of beauty. All nations have imparted to their sacred edifices, beauty, character, and proportion, but the comprehension of a comprehensive form of religion, cannot neglect the above requisites of sacred buildings. The aim of worship requires an adequate and worthy expansion of space. The sentiments of holy earnest, of pious peace and adoration, will receive much additional strength from a worthy and adorned locality.

It has often been asked, what constitutes the beauty of an edifice? Surely not the costly, glittering materials which Catholicism has squandered on them in Italy, partly from heathenish spoils transferred there. Another—and we say a superior mind reflects from the Gothic churches of the north of Europe. The temples of Pisa, superior to all the ruins of Rome, are of travertine; which coarse material, however, is defined, as it were, by the exquisite form and proportion. It is a form which constitutes beauty—which, after all, is but form perfect. Both appertain to the mind; mind creates form, and then reflects, with estancy, on his own work—the laws of its own being brought to manifestation—beauty.

Certainly, before an intuitive observation, the distinctions of material and form vanish. Certainly, marble is more pleasing to the eye than gristone, on account of its finer component parts and colour, which both are forms. The architect cannot disdain the nobler material on this account, as well as for its greater plasticity and adaptation to elaborate workmanship. The custom to construct public, especially sacred, buildings of noble materials, and to adorn them costly and splendidly, is most ancient, and based on a true sentiment of our mind. Everything rests here on certain proportions: as, for instance, that of the whole of the edifice, and form obeys the same laws. Even a building, or parts thereof, the interior of a church or hall, may become heavy and cumbersome by being overloaded with ornaments, on account of form being here obscured and borne down by material. The latter is the case with the Milan Domo, the outside of which is too rich in ornament, while the inside is grand and sublime.

The beautiful in architecture can be divided into several radii which we shall attempt to enumerate, in accordance with the relation of their usefulness and adaptation. The latter may be raised to beauty, or even sublimity—if the size be far outside the bounds of absolute necessity. The scope of religious assemblages requires but a limited height of space; but the tendency of art soars beyond that, and attempts to expand, conjointly with material space, our feelings and sensations. Another way of achieving beauty is to employ greater dimensions and use of proportions, as absolutely necessary. The building may, for instance, require pillars for its support; but art takes hold of this want, and increases their number to the greatest amount compatible with true proportion. Finally, the scantiness and stern simplicity of the straight line may be increased by lines arced and way. But to all the elements of beauty proceed the words—which, however, may be best termed harmony, concordance, and unity of conception. Size and height—fullness and diversity, the free scope of form, must all combine towards unity; and naught to appear as superfluous, isolated, or preponderant. But the height by abstracting laws therefrom, certain rules of proportion (numerical, geometric, and others) have been arrived at; to which fanciful architects are accustomed to adhere slavishly. But the true laws of construction lie in the impression a building will produce, and which the real artist will know how to anticipate by some sort of internal art-intuition; this inward conception precedes all sketches on paper or parchment.

Let us now endeavour to sketch that impression, which a Protestant (evangelic) house of God has to produce. The usual chancel is the high altar, which is esteem as a starting point. The Grecian temple is conspicuous for its moderate compass, and the rectilinear form of construction. It is altogether the type of the polytheistic mind of their builders, unable to seize the greatness of One-God. Still, it produces the effect of a clean, unmajestical; and further, the Doric may be said to be more stern than the others. It seems to us the fundamental fault of Michael Angelo, and other architects, who have taken the antique for their prototype, to transfer the Grecian-Roman style into Christian churches. The Doric colonnade would have been, no doubt, a better and adapted form for a Roman building; but, so far as we know, that style has been used but rarely; substituting for it the more slender, serene—nay, lascivious Ionian and Corinthian orders, where, at times, colossal dimensions were introduced to palliate the inconvenience thus arising. But already the Byzantine-Romanic style of architecture had changed the Greek into one more appropriate to the Christian mind, by adopting greater height—thereby, expanding the column to gigantic proportions, and substituting the round arch for straight lines. For the external ornament of churches, or even the upper parts of their interior, this is not used; the short arches, over which a decoration of sculptural and masonic ornament is spread. The too stern character of the ensemble is thereby modified, and amenity added to sublimity; just the same as the worship of the true Christian is tempered by mildness and love.

Gothic church architecture achieved the greatest sublimity of religious sentiment, by its pointed vaults; but here, also, a richness of ornamentation unites the serene and lovely Peculiar to this style of architecture, is the mysterious and awe-inspiring, which arises partly in the structural proportions and forms, and partly in the tinted windows, spreading a mystic light over the whole expanse of space. If we assume, in fine, that Protestantism has developed faith and adoration to its greatest height and freedom, there can be no doubt that the character of sublimity,—viz., the pointed arch style, has to be chiefly adopted. It can hardly be doubted, that the adaptation of this style to permit the requisites of Protestant worship, consequent on its very essence and mind—yet, we acknowledge that a sacred edifice thus constructed will be much different from a Gothic cathedral. It may be thought, that the character of the structure might be somewhat modified by a greater clearness and serenity of its plan and conception. Protestantism educates towards self-thought and clear ideas; henceforth, even its external manifestations must seek for clearness and light. As the congregation has to see itself, as bibles and books are to be often referred to than with Catholics—stained windows are not adapted, as they have been caused by us, as a chief ornament for the walls of the interior, would be quite confused and obliterated thereby.

Of these we shall speak in conclusion. In this respect, also, a certain chaste economy, if we may so say, is to be recommended. In Catholic churches, not rarely a sensual profusion of marbles and gold is to be regretted, and at the same time, walls and ceilings are overloaded with paintings. This medley, however, of a motley coloration, makes an especially confusing impression on the beholder. Against the painting of ceilings we must pronounce most strenuously, as even with the best light it is impossible to view them with the requisite quiet and ease: the outward quiet, however, of the beholder being the necessary condition of the inner satisfaction, which is the aim of all art. At times, moreover, the light for such ceiling-paintings is quite a wrong one, as is the case also with the windows, as the meanings have been wasted in ceilings, and how slight has been the result! On ceilings, art should not effect but an adequate and harmonious display of colour; at the utmost, arabesques or facusses are to be used, as is the case in some of the churches of upper Italy. But to all the elements of beauty, in the extreme distance, and in no distorted positions or fore-shortening. If our idea of a communion in Protestant congregations be asssigned to pictures, ought to be used but rarely, and of a simple, but grand character; else they would distract the attention of the people. The historical compositions attract too much attention; but figures or heads of great and pious personages will be much appropriate, besides requiring only a limited space.

If we endeavour to combine the purport of our foregoing observations—we have to repeat, that painting has to receive a real element and substratum; architecture, to manifest the scope of
adaptation; all pervaded by an ideality, which pertains to the subject—an intimate connection (permeation) of the real and ideal.

We have to insist on compositions, clear, free, and well-combined: in fine, the preponderance of the art-scope,—viz., to bring the beautiful and sublime into external existence, and thereby to awaken art-feelings—viz., feelings of serenity, elevation, and contentment. We cannot forego to express our opinion, that great religious buildings can and will never be conceived but by men possessing those feelings in an eminent degree. The complication of estimates and business can hardly be avoided now-a-days; but composition and inspiration can alone produce huge structures, worthy and able to inspire the people—a sentiment they cannot any longer be kept without.

J. L....y.

REGISTER OF NEW PATENTS.

LOCOMOTIVE ENGINES AND CARRIAGES.

JAMES PEARSON, of New North-terrace, Saint David's, Exeter, for "certain improvements in locomotive engines and carriages."—Granted October 7, 1847; Enrolled April 7, 1848.

Fig. 1.

This invention applies to several parts of locomotive-engines and carriages. One part consists in the form of the boiler, which is made with the fire-box in the middle part of the boiler, instead of being at one end. The general outline of the boiler is such as would be formed if two locomotive boilers of the ordinary construction were placed end to end with their two fire-boxes about four or five feet apart, and then the parts of the fire-boxes below the fire-door were joined together by an additional piece of fire-box, so as to connect the two ends together into one large fire-box in the middle of the boiler with a chimney at each end (fig. 1); or the boilers may be entirely separate and distinct, that is to say, having two entirely separate and distinct fire-boxes butting against one another, and having water and steam communications common to both, but which may be shut off from either boiler at pleasure. The axle of the driving-wheels is placed in the middle of the boiler, above part of the fire-box and below the foot-plate, so that any desired amount of steam may be brought upon the driving-wheels, and at the same time the centre of gravity may be kept very low. The axles of the trailing-wheels are placed below the cylindrical part of the boiler, and two pairs of these are placed in one swivel-frame at one end, and two pairs in a similar frame at the other end. The two frames are coupled together by two tension-rods (fig. 2). Near the ends of these rods a, are placed springs a, made of vulcanised india-rubber, and beyond these springs are nuts to confine them. The use of these springs is to allow each swivel-frame to adjust itself to any inequality of the road, and to bring it back to the straight position when the road is even. The swivel-centre-pin r, is fitted into a socket o, which is allowed to slide a little endways in guides p, to allow for expansion and irregularities, and the holes in the links t, are made oblong, for the same reason, and so that the links may pull instead of pushing. The boiler and engines are supported on a long underframe which is attached to the lower swivel-frames by the two centre-pins r, and by the links t, at the end of the engine. The whole forming one compound swivel-frame.

The coke-box s, is placed on the top of the boiler. The water-tank may be on a separate tank, or it may be placed between the coke-box and the boiler, or attached in any other convenient way. The two steam-heads may be connected at such a height as is convenient to leave head-room for the engine-man.

Another part of the invention consists in the application of an exhausting-fan in the smoke-box to draw the heated air through the tubes of the boiler, and to discharge it either up the chimney, as shown in fig. 1, or, if preferred, it may be again returned as hot blast into the furnace. This fan will allow the use of waste steam-pipes of a large size direct from the cylinder into the open air, and so avoid the great pressure on the back of the piston when the ordinary blast-pipes are used. The fan or fans may be driven by bands from pulleys on any of the wheels or axles, or by a small engine fixed on the side of the boiler, which may also if required work the feed pumps. The fans if driven by pulleys must each have two pairs of pulleys and suitable clutches, one pair driven by an open strap, and the other pair by a crossed strap, so as to drive the fans always in the same direction, whichever way the engine may be going. The clutch-gear may be attached to the engine reversing-gear if required.

Another part of the improvements relates to coupled locomotive engines, in which arrangement the compound swivel-frame is adopted. There are other improvements mentioned, but they are merely variations of those already explained. The patentee does not claim the invention of swivel or "bogie" frames generally, but his claims are, the compound swivel-frame, with coupling-rods, provided with elastic springs or cushions, and the various attachments to the upper frame; the form of boiler; the use of exhausting-fans for obtaining strong draught; and the compound swivel-frame, connected by rods with elastic cushions, and provided with guides and end links, as above described.

CHRIMES' PATENT FIRE-COCK.

The accompanying engraving (one-third the full size) of a firecock or valve, is a substitute for the ineffective wood plug, now in use in service mains. When under constant high-pressure, it forms a substitute for fire-engines, as in cases of fire it can be brought into almost instant operation, without loss of time and waste of water which the use of the wood plug involves. It can be also expeditiously, cheaply, and most effectually applied to the watering and thorough cleansing of streets, courts, alleys, public buildings, windows, &c.; and in railway stations, to almost every use for which a free supply of water is required, including supplying engine-tenders, cleansing carriages; and it is also adapted for watering gardens and pleasure-gardens, and by the application of suitable outlets, for syringing fruit-trees. It is especially adapted for high-pressure supplies, as from the circumstance of the valve part of it being closed the pressure is increased, the higher such pressure becomes, the more is the tightness of the valve secured, and effectual safety from leakage insured. One great advantage it has over the ordinary fire-plug is, that the stand-pipe with the hose can be placed on to the valve without the escape of any water, although the mains may be charged with water at a high pressure.

By the present system, unless a cock is attached to the branch of a fire-plug, a great loss of time unavoidably occurs in removing the wood plug, as the water has to be turned off the main pipe.
before the plug can be removed, and to be turned on again after it has been removed, to say nothing of the delay and difficulty which often occurs before it can be removed at all.

**STAND PIPE.**
For opening Fire Cock

**PADDLE-WHEELS.**

_Thomas Hunt Barber_, of King-street, Cheapside, London, gentleman, for "Improvements in machinery for propelling vessels."—Granted October 7, 1847; Enrolled April 7, 1848.

This invention consists of an arrangement or combination of parts into paddle-wheels for propelling vessels. The external case of the wheel is a cylinder, which is fixed to and revolves with the driving-axle; and the floats are so arranged within the cylinder, as to be projected outwards when required to act, and are again withdrawn into the cylinder as they go out of action; such construction of paddle-wheel allowing it to be wholly immersed in the water. To govern the action of the floats, the patentee prefers to use a cranked axis, one end of which enters into the main or driving axle. On to the main-axle is placed a boss, to which arms are attached, for holding firmly the floats. The annexed diagram, which is a side-section of the paddle, will explain the manner in which the floats are intended to act. The cylinder A, A, has as many slits or openings through it as there are floats to the wheel; and within the cylinder are angular hollow vessels f, f, which give buoyancy to the wheel, and also serve for the purpose of offering inclined guiding surfaces to the floats as they are moved outwards. The arms h, h, are attached by pin-joints to the boss or collar on the crank axis; and to the ends of the arms the floats are to be fixed. The floats i, i, i, are represented to be in action, whilst the others are drawn within the cylinder. The patentee says, that although he prefers to use a cranked axis for governing the action of the floats or paddles, it will be evident to an engineer that an eccentric might be substituted and produce a like result; and it will also be evident that in place of having the floats or paddles wherein the arms or spokes governed or controlled by a crank or eccentric axis, the case b, might revolve on and be governed by fixed eccentrics on either side. In such case there would be a fixed axis between the eccentric bearings of the case b. The nave having the arms of the floats or paddles would revolve freely on the fixed axis of fixed eccentrics, and the case b would receive motion by a cog-wheel affixed thereto driven by another cog-wheel actuated by the engine, or in any convenient manner.

What the patentee claims in this invention are, the modes of constructing paddle-wheels whereby floats, or paddles, or arms are combined with a case b, such floats on the case being governed by a crank or eccentrics.
RAILWAY CARRIAGES.

THOMAS DUNN, of Windsor-bridge Iron Works, Manchester, for "Improvements in the suspension, stays, jacks, &c."—Granted November 2, 1847; Enrolled May 2, 1848.

This patent comprises several objects connected with railway locomotion. Mr. Dunn first describes several improvements in the construction of wheels. One of the principal is the easy removal and replacement of the tyre upon the wheel when it has become worn. This he effects in several ways. His first method consists in having the nave, arms, and an inner tyre cast in one piece, upon which the outer tyre is bolted by means of a flange, which projects inwards a few inches beyond the inner surface of the tyre. The joint between these two pieces, out of which the wheel is formed, is packed with gutta percha or some other elastic substance. A second method consists in having the nave of the wheel cast with mortises in it for the reception of wooden or metal keys, and of afterwards fixing the tyre to the nave, by bolts passing down through the middle of the spokes. According to a third method, that part of the wheel which is occupied by the arms is entirely filled in with segments of wood, between which segments there are driven wedges of either wood or iron, so that the wheel is almost entirely solid. The tyre is attached to the nave by bolts, as in the former instance.

The patentee makes his axles of wood and iron, the wood forming an internal solid core, with an outer covering of iron. He also makes a portion of the axles, perhaps by the addition of wrought iron, have a collar attached to them, and driving into them a short axle, or rather part of an axle, which is formed on the outside of the wheel, into the journal or bearing, and on the inside projects only a few inches, leaving sufficient strength of material to pass a cotter through to retain the axle in its place. This was to prevent the axle from becoming loose, and the iron, which have collars formed upon them near to their ends. The portions beyond the collars are passed through holes formed in the naves of the wheels, and have screws upon their outer ends, so that the wheels are, in a measure, devolved of axles—the connection it is to be used for it.

The second portion of Mr. Dunn's improvements relates to the construction of jacks for moving carriages and locomotives on to the line of rails when they have got off. The chief feature of this improvement consists in providing the jacks with four small friction-rollers at the bottom of the pillar, by which the jack, with its load, is easily made to run upon a smooth surface in any direction. A third improvement consists of a means of removing carriages from one line of rails to another, which the patentee effects by means of a low truck, running upon a set of cross rails. A portion of the main lines of rails is made to form an inclined plane at pleasure, by means of cams fixed under the rails, whereby he is enabled to run the carriages on to the low truck.

LUBRICATING COMPOSITION.

THOMAS DUNN, of Bermondsey, Surrey, strap manufacturer, for "Improvements in the manufacture of grease or compositions for atmospheric pipes, and for lubricating the axles and moving parts of machinery."—Granted April 27; Enrolled October 27, 1847. [Reported in Newton's London Journal.]

The improvements consist, first, in preparing a lubricating composition by combining oil, tallow or other grease, with certain light, soft, white, or other fast precipitantes or bodies, insoluble in water (so as to be incapable of being used as detergents), and obtainable in the manner hereafter described; secondly, in preparing a lubricating composition by combining oil, tallow, or other grease, with vegetable black or with lamp-black; and thirdly, in preparing the compositions, prepared according to the first and second improvements, in such proportions as may be desirable, in order to render the same more suitable than when used alone for the lubricating purposes above mentioned.

The mode of carrying out the first improvement is as follows:—The patentee possesses a vessel or tank such a quantity of liquor calcis, or of a saturated or other solution of sulphate of magnesia, or of sulphate of magnesia and ammonia, as he considers will be sufficient for the quantity of composition required to be prepared; he then gradually pours into and mixes with the same a certain proportion of the oil, tallow, &c. so as to form a composition that is not only the most suitable for the purpose, and which have been rendered miscible in water by boiling the same with alkali or caustic liquor; or, instead of the solution just mentioned, he employs a strong solution of either the soft or hard soap of commerce; or he introduces the liquor calcis, or the solution of sulphate of magnesia, or of sulphate of magnesia and ammonia, into the pasty and saponaceous fluid, obtained by boiling either oil, or tallow or other grease, with alkali or caustic ley,—having first drawn the fire and allowed the pasty mass to cool down to 100° Fahrenheit. The mixture is then allowed to stand for some time, so as to allow the precipitate continually to be produced; and then he separates such precipitate from the mother liquor, by filtration through a fine linen sieve,—preserving the mother liquor when it contains, in solution, any valuable salts, so as to make it useful for manufacturing the pasty mass.

For the pasty mass, 112 lb. of the precipitate, obtained as above are to be combined with from 40 lb. to 112 lb. of palm or other oil or grease; the quantity of oil required will vary according to the peculiar character of the oil employed; but about 56 lb. will, in most cases, be sufficient. The apparatus used for effecting this combination is a cylindrical iron vessel, the latter of which is the top containing a revolving agitator, and having two pipes at the bottom, furnished with stop-cocks, for the purpose of discharging any water or other fluid that might accumulate inconveniently during the process. After the precipitate has been introduced into the mill, and the agitator set in motion, the palm or other oil is gradually added; then, as soon as the proper quantity of oil has been used, the mixture will thicken and assume a consistence considerably greater than the oil or other ingredient or ingredients possessed in the first instance; and a chemical combination will so far take place, that the precipitate will be brought out of the mother liquor, and the precipitate will be driven out, and must be drawn off by the pipes above mentioned. A supply of cold water is next allowed to run upon the grease or composition in the mill, so that it may be washed therein, in order to cleanse it from all adhesive impurities of the mother liquor, and so the mixture is allowed to be washed and mixed, and then a few pounds of oil are to be mixed with the composition, to separate any adhering particles of water, and to give it a finer and better appearance. The grease or composition is now ready for use; but if it should not possess sufficient consistence for the purpose to which it is to be applied, from 56 lb. of melted tallow should be mixed with it in the mill; or, when the mixture is to be used, it may be mixed with the composition before the latter is washed with water, as before mentioned.

The second improvement consists in the production of a black grease or composition, which may be exposed to great extremes of heat and cold, and does not readily freeze, by combining 160 lb. of palm, olive, or other oil, or grease, with from 10 to 40 lb. of vegetable black or lamp-black. The oil is first placed in the mill before described, and then the agitator being put in motion, the vegetable black or lamp-black is added in small quantities at a time, until the black and oil are well mixed together. The composition has acquired a sufficient amount of consistence.

The third improvement consists in combining a portion of the black grease or composition with grease or composition made in the manner described under the first improvement, to prevent the same from freezing when exposed to frost or snow, or to protect it from the action of extremes of heat or cold; the combination of the compositions is effected by the use of the mill before described.

BRONZING METAL SURFACES.

CHARLES DE LA SALLE, of Paris, for "Improvements in brassing and bronzing the surfaces of steel, iron, zinc, lead, and tin."—Granted September 30, 1847; Enrolled March 30, 1848.

The improvements relate to coating steel, iron, zinc, lead, and tin, with brass, copper, or brass, by means of a solution containing with briss, a bath is prepared, composed of the following ingredients:—5,000 parts by weight of distilled water, 610 parts of sub-carbonate of potash, 23 parts of chloride of copper, 48 parts of sulphate of zinc, 3,05 parts of azotate of ammonia, and 19 parts of cylindrical potash. The quantity of potash black is dissolved in a small portion (about 120 parts) of the cold distilled water; at the same time, the sub-carbonate of potash, chloride of copper, and sulphate of zinc, are introduced into the remaining portion of distilled water (contained in a separate vessel, and having its temperature raised to 100° Fahrenheit, in order to dissolve these matters); and when they are perfectly dissolved, and the solution has become cool, the azotate of ammonia is added. After the solution has been shaken for a long time, it is
allowed to stand for 24 hours; it is then decanted with a syphon, and the solution of cyanide of potassium (which should be limpid) is added thereto. If the solution thus prepared be submitted for about five hours to the action of a volatile battery with a rapid current (such as Bunsen's, Grove's, or Daniel's battery), and at a mean temperature of 77° Fahrenheit, it will deposit a coat of yellow copper, or brass, on the metal article immersed therein. The process may be performed by means of porcelain, clay, or wood (which may be lined with bitumen, or any isolating resinous matter); and the vessels are preferred to be of a rectangular shape.

If the appliance be to be coated with bronze, 25 parts of chloride of tin are to be substituted for the above-mentioned 48 parts of sulphate of zinc; the proportion of chloride of copper is to be increased from 32 parts to 48; and a plate of bronze is to be used as the electrode: in other respects the bath is prepared with the same ingredients, in the proportions above stated, and the process is conducted in the manner before described.

A bath, for coating articles with brass, is prepared, by dissolving 500 parts of sub-carbonate of potash, 15 parts of chloride of copper, 35 parts of sulphate of zinc, and 50 parts of cyanide of potassium together, in 5,000 parts of cold distilled water. After the bath has been stirred, it is allowed to stand for from 24 to 48 hours; it is then subjected, in a cold state (from 25° to 30° Fahrenheit), to the action of a voltaic battery, during the same time, and in like manner to the preceding baths. When this bath becomes impoverished by use, the salt of zinc, or copper, which has been absorbed, must be replaced, and the bath then refilled to the original quantity. The process may also be used for bronzing, by substituting about 10 parts of chloride of tin for the 35 parts of sulphate of zinc, and employing an electrode of bronze.

In either of the processes above described, instead of the sulphate of zinc, or chloride of tin, any neutral salts of zinc, or tin acids, may be employed, according to whether the article is to be covered with brass, or bronze, so long as the bath is sufficiently rich in potash, that there may be no action upon blue paper of turnsol. The proportions of the salts of tin, zinc, and copper, may be varied according to the colour desired to be given to the metal coating. This invention may also be applied to the coating of alloys.

RAILWAY BARS AND CHAIRS.

Richard Shaw, of Gold's-green, West Bromwich, Stafford, railway-bar finisher, for "Improvements in the manufacture of wrought-iron railway bars and railway chairs."—Granted October 21, 1847; Enrolled April 21, 1848.

The improvements described in this specification relate to the construction of railway bars and railway chairs, as also the arrangement of the material for their construction; and consist, First, in the mode of forming and piling the bars on the railway-bar, for preventing the lamination of the metal. This is effected by placing and piling the bars in the manner shown in the annexed diagram, fig. 1, the lower portion of the bar being piled in the usual manner with flat bars, and the upper portion piled with a broad bar bent into the form shown, the edges abutting upon the surface of the bars beneath, and the interior being filled and piled in the usual manner. When the railway-bar is finished, the grain of the metal is arranged in the form as presented in fig. 2, and thus no lamina occur on the head of the working surface.

The other improvements claimed by the patentee are, Secondly, the mode of manufacturing wrought-iron railway bars with projecting rails or flanges affixed thereto, in such a manner that the ends of the rails or flanges project beyond, and are supported by the heads of the bars. Thirdly, the mode of manufacturing railway-bars with hollow heads or working surfaces in such a manner that the cheeks of the chairs may pass into the holes of these heads or working surfaces for the purposes of support.

Fourthly, the mode of rolling railway-bars with rollers placed three high; and also the mode of rolling by the same means the curved bars used in placing and piling for making his improved railway-bars. Fifthly, the construction of chairs for supporting his improved form of railway-bar.

BORING AND SINKING.

William Gosworth Gard, of Calstock, Cornwall, engineer, for "certain Improvements in machinery and apparatus for boring and sinking."—Granted October 21, 1847; Enrolled April 21, 1848.

The object of this invention is to improve the form of the cutting-tool used in boring so as to remove the debris more easily; and also to work the boring instrument more effectively. It is in the form of the tool; however, that the chief novelty of the invention consists. The cutting edges are made of a concave or inverted cap-like form, divided by a cross into four segments, with apertures leading from these segments into a hollow cylinder or shaft, screwed into a neck of the bit, whereby the bored-out materials are removed out of the way of the cutting edges. Fig. 1 represents a vertical section of the borer or bit, constructed according to this invention; and fig. 2, an under plan view of the same, showing the cutting edges. The shaft or hollow part A, forms the receptacle for the bored-out materials. This hollow shaft has the part A, which forms the cutter, screwed or otherwise fixed thereto, it being made of steel or some other hard metal. The cutting face is of a hollow form, or rather of four distinct hollows, the area being divided by a cross into four sections, d, d, d, d (fig. 2), each separate hollow terminating in a hole e, leading to a main opening m, in the trunk of the borer. The outside diameter of the cutter from the cutting-edge to the point a, is of a cylindrical form, and from the point b, (fig. 1), to where it joins the hollow shaft, it is tapered about half an inch in order to clear the shaft-part b, and allow it to pass freely after the cutter. The cutting edge, forming the circumference, is bevelled only on the inside; consequently, the material, which becomes detached by the force of the tool projected inwards and upwards, leaving the external part free from obstruction in its working. The pieces detached by the cutting edges, forming the cross, are also projected upwards, and by the concave forms of each wedge, driven into the openings e, e, e, to the main channel m. A valve-seat of brass c, (fig. 2), is secured in its place by having the stem b, screwed down on its surface. This valve-seat has its opening in the centre, corresponding with the main channel m, and is fitted with a ball-valve k. The detached materials pass up the main channel m, into the body of the stem b, at each successive stroke of the borer; the quantity of materials detached each time nearly filling the concavities d, d, d, d; but by being conveyed directly into the receptacle, detached freely from impeding the operation of the cutter. The valve k, which is fitted into the body rising too high by a cross-pin in the stem, cuts off any return downwards of the boring. In this manner the operations of boring are continued until the entire capacity of the stem a, is filled, when it is to be withdrawn from the boring, and the contents removed, which may be effected by turning the bit upwards, when they will pass out of the aperture, g; but the patentee prefers, when the detached materials are of a dry description, to keep the tool vertically in its boring position, and by raising up the valve from below, to allow the contents to run out.

The second part of the invention, which relates to the mode of working the boring-tool, needs little description, as it contains nothing that is novel in principle. The patentee adopts the Chinese mode of boring, by fixing the tool to a chain or rope, and producing the effect by continually lifting it up and letting it fall, the height of the full being regulated by the resistance to be overcome. There is a lever attached to the chain at the top, to one end of which weights are suspended, for the purpose of counter-balancing the increased weight of the chain as the depth of the boring increases, so that the working may be rendered as uniform as possible.

MANUFACTURE OF IRON.

Alfred Vincent Newton, of Chancery-lane, Middlesex, for "Improved machinery for blooming iron." (A communication.)—Granted October 14, 1847; Enrolled April 14, 1848.

This invention is for the purpose of more effectually compressing or shilling puddles, balls, or loupes of iron into blooms. The im-
provements are—Firstly, the mode of compressing or shingling by means of a compressor acting in combination with two rollers, and producing therefrom a bloom. Secondly, in the use of cheeks, between which the bloom is formed, having springs at their backs for the purpose of setting and keeping the ends of the blooms square and of proper shape; these cheeks act in combination with the cam-formed compressor and rollers. A third improvement consists of an arrangement of apparatus for feeding the shingling-apparatus with balls to be shingled, and for discharging the bloom when sufficiently compressed and shingled. These combined improvements are represented in the annexed sectional elevation. A, the cast-iron frame of the machine, securely fastened to the bed-plate B; within the upper part of the frame are sliding blocks, C, C, forming bearings for the shaft D, upon which is mounted and properly secured the cam-shaped compressor E, of the peculiar form shown. The periphery of the compressor is eccentric to its centre of motion, for the purpose of squeezing and compressing the ball of iron between the periphery thereof and the rollers F, F; this eccentricity of the periphery of the cam-shaped compressor commences at the point 1, where it begins to impinge upon the ball of iron submitted to its action, and continues round three-fourths of the whole circumference of the compressor to the point 5, in the following manner—namely, from the point 1, of the periphery, to the point 2, thereon, the eccentricity is very abrupt; the periphery recedes from the centre quickly outwards from the centre of motion for the purpose of more quickly and effectually compressing the ball of iron and squeezing out the impurities therefrom; from the point 2, to the point 3, the eccentricity is more gradual; from the point 3, to the point 4, the eccentricity is still less, the point 4, being at the greatest distance from the centre of the motion; from the point 4, to the point 5, the eccentricity of the periphery is reversed, that is, it inclines very slightly inwards towards the centre of motion; the whole space from the point 5, to the point 1, being one-fourth of the whole circumference, is left open and free for the purpose of allowing sufficient time for discharging the bloom produced by the last revolution of the compressor, and for receiving into the machine another ball or lump of iron to be shingled. The periphery of the compressor is also formed with teeth or indentations thereon, for the purpose of more effectually entering into the ball or lump of iron and squeezing out the impurities from it; these teeth or indentations from the point 1, on the periphery of the compressor, to the point 2, are very deep, for the purpose of entering more deeply into the ball at the commencement than at any subsequent period of the process; from the point 2, to the point 3, the teeth gradually become less coarse, being fine at the point at 4; from the point 4, to the point 5, the periphery is nearly or quite plain. Another advantage attending the construction of the periphery of the cam-shaped compressor, is the turning the ball or lump of iron round upon the lower rollers by means of the grip or hold of the teeth or indentations, the lower rollers F, F, are placed in the position shown below the compressor E, at such a distance therefrom as to suit the size of the ball or lump of iron to be shingled and the size of the bloom to be produced; these rollers F, F, revolve in bearings fixed to the main frame A, of the machine; they are placed close together but not in contact; the peripheries of these rollers are provided with projections thereon, for the purpose of effectually turning the ball or lump of iron round while using the operation; and thus subjecting every surface of it to the squeezing action of the compressor. The rollers F, F, are connected by toothed gearing with the cam-shaped compressor E, so that they revolve in different directions, also the peripheries of the rollers and the periphery of the compressor must revolve at nearly equal velocities; there is a mode of adjusting the distance of the compressor E, from the rollers F, F, to suit the quantity of metal in the ball or lump by means of the set screw G, passing through the head of the frame A. For the purpose of setting up the ends of the bloom square and discharging it endways, at the same time that it is compressed by the compressor and the rollers, another patented second improvement—namely, the spring or yielding cheeks; these cheeks H, H, are placed one each side of the compressor E, over the rollers F, F, the compressor in revolving passing between them; to the back of each round the cheeks are secured two rods or studs passing through holes in the main frame, which thereby serve as guides to them. Around the rods, and bearing stiffly against the backs of the cheeks, and the inside of the main frame A, are helical springs, for the purpose of pressing the cheeks H, H, together against each other, and thereby pressing and setting up the ends of the bloom of iron when pressed outwards by the action of the compressor; the outer ends of the rods are provided with washers and pins for the purpose of preventing the springs from pressing the cheeks too near together, and thereby coming in contact with the sides of the compressor E. The front faces of the cheeks (those which are against the grip or hold of the bloomer) are of a convex form, somewhat flattened in the middle. The feeding-apparatus, which constitutes the patentee's next improvement, consists of a trough or frame L, attached to the main frame A, in front of the machine in an inclined position; within this trough or frame is placed the plate or frame M, to which are attached the two bars N', N', one on each side; they move in the guides O, O; upon the bar or frame M, is placed the ball or lump of metal to be fed into the machine; the frame M is kept back by a balance-weight below the foundation of the machine; the end of the bars N', N', is kept open in the hooded plate R, by means of the feeding is this—the ball or lump of metal to be operated upon is thrown upon the bar or frame M, where it remains until the compressor comes into the position shown in the engraving, that is, when the compressing surface of the compressor is out of action with the rollers, and the open or free space of the compressor from 5 to 1, is over the rollers, thereby allowing an opportunity for discharging the last-formed bloom, and receiving another ball or lump to be operated upon; at this moment two pins or studs, projecting from the sides of the compressor, come in contact with the ends N', N', of the bars N, N', which is thereby drawn upwards, and the ball or lump deposited upon the rollers F, F. At the same time also, an arm or crank, fixed upon the compressor-shaft D, outside the main frame, acts upon the bar Q, which is connected by a lever to the discharging-plate R, in such manner that the bloom of iron is discharged from the machine at the back at the same time a fresh ball or lump is fed into it at the front. The discharging-apparatus is retained in its proper position during the shingling process, by means of a spring.

The patentee claims—First, the arrangement of machinery as described, for compressing or shingling puddles, balls, or lumps of iron into blooms. Secondly, the spring or yielding cheeks for setting up the ends of the blooms, as also the cam-shaped compressor and rollers as described. Thirdly, the feeding and discharging apparatus.

A CENTRE-VENT REACTION WATER-WHEEL, Communicated to the Franklin Institute, U. S., by E. Parker, of Philadelphia.

In my notes of the experiments on the centre-vent reaction wheel at Troy, I mentioned the fact of the small amount of water discharged, in proportion to the aperture, and of its disposition to uniformity under all velocities of the wheel. [See Journal, ante p. 110.]

I may have stated that in all cases in which the vanes of the wheel direct the water nearly tangentially to the inner circle of the annular rim of such wheels, the quantity discharged (under circumstances of full supply) appears to be about 50 per cent. of the theoretic discharge; and that this proportion appears to be but
little affected by changes in the velocity of the wheel, from being held stationary, to any velocity it may acquire by the pressure of the water on the vane,—or by any change in the circular motion of the water (as in the verge), either with or contrary to the circular motion of the wheel.

In corroboration of this position, we have the experiments at Troy, in which the discharge (at the maximum) was a trifle less than 50 per cent, owing probably to the unfavourable form of the vane,—and the fourth set of my model improvements (the notes of which you have), where the water passed inwardly through a structure, which, when the wheel was removed, was exactly similar to such a wheel,—the quantity discharged in this instance, being just 50 per cent, of the theoretic discharge.

Among the many 'interesting objects' at the American Institute Fair, of the present season, there was a centre-discharge reaction wheel, in a very neatly constructed model, the wheel, about four inches in diameter, being made of brass and neatly finished. To the under side of a disk, attached to a vertical shaft, were attached plane vanea extending from the verge to a circle about one-half of an inch from the verge. To these vanea was attached the annular rim, in the usual way. The angle of the vanes directed the water somewhat without the direction tangent to the inner diameter of the annular rim, and after passing into the wheel, it fell through the opening of the rim, and bottom of flume some inches, into a basin beneath, where the water passed inwardly through a structure, which, when the wheel was removed, was exactly similar to such a wheel,—the quantity discharged in this instance, being just 50 per cent, of the theoretic discharge.

Suspecting from my former experiments that the discharge of such a wheel must be uniform under all velocities, I took the opportunity of experimenting on this, by applying friction to the shaft (about half an inch in diameter) with my fingers. I could make no sensible variation in the height of surface by any change of velocity, from being held, to running beyond its natural free velocity (by rolling the shaft between the thumb and fingers), nor by turning the wheel backward.

TREATISES ON THE STEAM-ENGINE.

The want of a satisfactory treatise on the steam-engine has long been felt. The existing treatises, notwithstanding their general merits, do not supply the whole of the information which the accountant entering the subject, the looseness of scientific views, the neglect of systematic arrangement, observable in most of them render much of the knowledge imparted either dubious or inaccessible.

We have been frequently called upon to give advice in the choice of a work on this important subject. In answer to correspondents who have made an application of this kind, we replied some time ago, that a complete treatise appeared to be one of the desiderata of engineering literature. Several subsequent letters strongly confirmed the opinion then expressed, that the existing treatises on the theory, construction, and routine management of the masterpiece of mechanical invention are not what they ought to be—accurate, complete, and systematic.

It is no disparagement of the efforts of those who have already written on the subject, to assert that we now know more of it than they did. This branch of knowledge is necessarily progressive. The operations of the steam-engine have been extended in diversity and magnitude, and have attained a universality which to its great inventor himself would have appeared incredible. The new demands of the manufacturer, engineer, navigator, and mechanician, stimulate and suggest new applications of the most powerful and most obedient of the agents of human industry upon machinery so complicated, the fertility of modern invention and the boldness of modern enterprise are incessantly and successfully exerted: while the minute details of the apparatus are constantly receiving fresh improvements, as practical skill becomes more and more developed and refined.

Yet the apparatus itself is in the main unchanged. The steam-engine of Watt is the steam-engine of 1848: the great inventor bequeathed it to us almost perfect in its principal parts, and the small amount we have been able to add to his legacy is a striking and accumulative testimony to its original value.

This consideration greatly simplifies the labour of compiling a perfect exposition of the combination of the mechanism. But though the improvements of practice be here confined to details, in other respects the changes have been fundamental. Experience has effected great alterations in the purposes, the management, and the dimensions of the engine itself; and the accessory parts, of which the boiler and furnace are the principal, have received modifications which have completely changed their character.

The theory of the steam-engine is also fundamentally different to that originally propounded by the inventor; the rationale of its action have been totally falsified by subsequent experience may be unhesitatingly asserted. It is much to be regretted that his authority, deservedly great as it in some respects is, has given weight to opinions which of themselves cannot stand the test of the great body of experience which has been extended. A mistaken partiality to his works should have induced subsequent writers to gloss over his errors, and defend that which is indefensible. When the theory of the Count de Pambour appeared, its obvious truths ought not to have been resisted by absurd prejudice in the name of right—Tredgold and his followers is wrong. This sounds like a very dogmatic assertion: and we intend it to be so, for if the lucid demonstrations of De Pambour fail to convince his opponents, they are either too perverse or too dull to be converted: we are driven as a last resource to the futile cry of caballing against the works of great men. The theory of De Pambour had no sooner appeared, than all scientific writers denounced their previous views, and without reluctance signed their adhesion to his.

Not indeed that all his conclusions are absolutely indisputable. The chief problem to which he addressed himself was this:—Given the dimensions of an engine, to ascertain the resistance it will overcome at a given velocity, or the velocity at which it will overcome a given resistance. Now, the main difficulty of the question, and that which De Pambour has only partially met, is to ascertain the amount of resistance. It is an essential element, and a certainty respecting it affects the whole subject. Without particularising further, we may observe that he has erroneously estimated the resistance to which locomotive engines are subject, and has assumed a law of friction (Coulomb's) which is in this case inapplicable. Another difficulty is in ascertaining the actual efficiency of the boiler. Its apparent evaporation and its effective evaporation are not the same—part of the water being drawn into the cylinders in a liquid state. The amount of priming depends on minute and varied circumstances,—the violence of evaporation,—the fineness or purity of the water,—its level in the boiler,—and the capacity of the steam-pipes. Certainly, no mathematical formula, such as De Pambour has laid down independently of these considerations, can be universally and exactly correct.

The materials for an improved treatise are abundant; and those who would enter on the task of reforming that branch of science and ramass every source of information. Notwithstanding our stricutures on Tredgold, we are disposed to think that his work ought to be the basis of a new treatise. There are many reasons which conduce to this conclusion. In the first place, on comparison, his plan and arrangement seem the most perspicuous hitherto published. In the second place, most engineers are familiar with it. This is a great point: readers do not like to be constantly learning out of new books, and engineers especially have seldom time to spare in familiarising themselves with new systems.

The plan which Mr. Exor De Pambour has pursued in his edition of the "Treatise on Cast-Iron," appears to be the best for the case before us: he has left his author's text as he found it, appending his own corrections and additions. With respect to a treatise on the steam-engine, the authorities to be searched and cited are numerous and valuable. In pure theory, the views of De Pambour should be clearly stated, with the modification above suggested. Some of Professor Morely's most useful practical
results should be also referred to: his researches respecting the
effects of friction of the parts of the engine are too complicated,
and depend on data too uncertain, to be available; but some of his
investigations respecting the fly-wheel, &c., are invaluable, and
have the advantage of lending some theoretical rules.

The geographical authors require to be diligently and
thoroughly examined. It is principally from the French writers,
with Navié at their head, that foreign assistance must be expected;
and the system pursued in France in the education of
engineers, renders some treaty treatises written in that country
on practice of machinery, which is worthy of consideration at least.
The articles contributed to our own cyclopædias, and the recent treaty of Mr.
Hann, also furnish several useful suggestions for rules, which an
intelligent artisan may understand and apply without a knowledge
of mathematics.

The transactions of learned societies contain invaluable records
of the results of experiment and routine experience. Numerous
papers have appeared under the auspices of the British Association
and Institution of Civil Engineers, on what we just now designated
the most difficult part of the problem of the steam-engine—the
resistance to which it is subject; and in reference to the locomotive
engine the labours of Mr. Wyndham Harding may be particularised.
The transactions of the Royal Society also contain some papers
referring to the resistances to marine engines—a subject to which
Mr. Scott Russell has long devoted attention.

The scientific periodicals—The Mechanics' Magazine, the Journal
of the Franklin Institute, &c., ought also to be examined: they are
storehouses of facts of the greatest importance. Of course, discretion
and accurate scientific views are indispensable in selecting
from the vast mass of contradictory and controversial statements,
containing the contemporary ideas of engineering. But even
elegant ideas coming from practical men have some use, if
suggested by experience—they serve at least to put debated
questions in a new light.

The blue-books of Parliamentary and Royal Commissions contain
also that which is valuable, amidst heaps of rubbish. It requires keen
instinct and patient industry to separate the grain from the chaff;
but such a labour must be accomplished, if a perfect work on the
steam-engine is to be written. Commissions such as those upon
the Gauge question and Atmospheric Railways, are convocations of all
the leading men of science in different departments of the subject;
they may be thought of as being inquiries for the benefit of
the public. But even when they are so public, they are not
excluded; for the report of a public inquiry, like the evidence
is a synopsis which could not be obtained in any other
manner.

There are many other sources of information and separate treatises
possessed of great merit, but too numerous to be here recited.
These ought all to be referred to. The labour of reference is great,
but is not the subject worthy of it?—the great marvel of the
civilization—of the wonderful, wonder-working agent upon which the political
constitution of the whole world depends—which, when the human
family has become so numerous that all its labour can scarcely
obtain the barest efficiency of usefulness, is the great struggle for existence. In some sense, our very lives depend on the
steam-engine. Without its aid to convey the emigrant from
over-crowded shores—to inter-change the products of various soils
in climates—to convert those products into clothing and other
necessities of society,—without, in a word, its help in carrying on
the business of the world, the business of the world would become too great to be accomplished.

He who has increased by the least particle the knowledge of
the steam-engine, has therefore conferred on society a benefit of
which it is impossible to foresee the extent. Without hyperbole, a
perfect account of the steam-engine would stand among the
highest of national undertakings. It can scarcely be expected, how-
however, that any treatise now written can be absolutely perfect, for
there are many parts of the subject which it requires the experi-
ence of future years to entirely develop. Still, the present epoch
is particularly favourable for systematizing the knowledge already
acquired. A uniformity of practice and experience has been at
length arrived at, which may indeed be hereafter extended; but
which, in all probability, will never suffer any great fundamental
change. This difficulty is to be considered, not as an obstacle to
knowledge systematic. If it be not digested—if it be not perfectly
consistent with itself—if the whole observe not simple and demonstrable
dependence on definite principles, the failure of the undertakings is inevitable. Simplicity and system are the two keys
to the successful results on practical subjects, and are more earnestly on the necessity of scientific connection and unity
of plan, because experience has shown how far the neglect of those
requisites impairs the utility of a treatise on the steam-engine.

That bearing the appellation of the "Arizonian," will always be
in high repute, for the vast quantity of practical information which it
contains, but this advantage is greatly diminished by the want of plan.
Works which contain the labours of several independent
writers should always be subject to the supervision of some
controlling editor, who should be responsible for the scientific accuracy
of the whole. Many readers of engineering works are necessarily
obliged to receive scientific information on trust—their own previous
education being devoted to practical, and not to theoretical
pursuits. It is all-important that such readers should not be misled.
The slightest error of principle, the neglect of particulars in them-
seems apparently trivial, will frequently lead to the greatest errors.
Of what importance is it then that all mechanical doctrines should
be accurately conceived and strictly expressed?

Lastly, it should be carefully and constantly explained to the
student, that the abstract laws of mechanics are demonstrated—
that respecting them, debate would be as frivolous as respecting the
true value of the dollar. The conclusion of the whole is that mechanics
about mechanics are those who are imperfectly acquainted with
the science. In the applications of mechanics to the steam-engine,
the only questionable topic is the accuracy of data—the methods
of calculating from those data have been long since settled beyond
all possibility of dispute.

* We observe with satisfaction, that a new and improved edition of Two gold on the
steam-engine is proposed. The name of the publisher is a guarantee for the excellence
of the typography and value of the illustrations. If scientific accuracy, which we have
heretofore been accustomed to regard as so important, be also attained, a most valuable
addition to the engineer's library will be produced.

** Reviews. **

Account of the Sherryvore Lighthouse, with notes on the Illumination of Lighthouses.
By Alan Stevenson, LL.B., F.R.S.E., M.I.C.E.,
Engineer to the Northern Lighthouse Board. Edinburgh: Adam
and Charles Black, 1848.

When we lately noticed the praiseworthy labours of Sir John
Rennie, in bringing out his costly work on Plymouth Breakwater,
we hardly hoped to be so lucky as to have brought before us so
stupendous a work as that now before us. The whole amount of the
labour involved in the design and construction of the breakwater
may be thought that we are better satisfied by this, and less ready
to grumble; but we must freely own that it makes us grumble the
more. It is not because Sir John Rennie and Mr. Stevenson have
so well done their duty, that the ground of our complaint is gone.
Our outcry is not against them, but against the other
engineers of high reputation, who, having the same means, have
done nothing for professional literature. We know the answer;
the hackneyed one of want of time. Sir John and Mr. Stevenson have
answered that, and the public are quite willing to make every
allowance for any short-coming on the ground of the want of time;
but it should not be forgotten that the greater share in a professional
book is not in the writing, but in the plates: we may add that the
greater part of the cost is for the plates. Nothing, therefore, can
be more easy for those who have the money, than to put into the engraver's
hands the drawings which they have by them, and then, if
they cannot themselves do all the writing which is required, they
must get some one to help them; and that, too, is only a matter of
money. In any way in which the question can be looked at, it
resolves itself into one of outlay, and of good will; and we
cannot help saying that it is far more creditable to our engi-
ners to be so neglectful of publishing proper records of their
works. We cannot free them from the charge of want of will, for
it is too well known to spirited engineering publishers, to authors,
and to editors of professional works, that it is next to impossible
to get information, either from the leading engineers or their as-
sistants. Thus, what is published is mostly very imperfect; and then the
parties who ought to have given the information are the first
to decry what has been done, and to lay blame for what is wrong,
or is wanting.

We are disposed to rather believe that the wrong lies in this want of will,
than in want of liberality, because many of those open to blame have always
given very freely to professional institutions. Want of means we cannot allow;
for those who can spend money in buying
bouquets, and in getting a seat in parliament, can well give a few
hundred pounds for bringing out a book. If, too, the evil lay in
the want of liberality, we should be hopeless of overcoming it; but
if it be from want of rightly thinking about it, or from want
of the will to set to work, then we have some trust from what we
know of our leading men, that they will not in the end be found
wanting; but, after careful thought, do that which they
find to be right. The matter is, indeed, one of great weight, and mostly as it touches the good name of those concerned; for how can the standing of the profession be kept up, if its members lie open to the charge of mere money-grubbing, and an utter carelessness of doing anything to keep up professional knowledge? The engineer has been taught by others, and he has learned by those who have taught him, he has for his help to teach others. By building the Eddystone Lighthouse, Smeaton laid the groundwork of the greater lighthouse on the Bell-rock; and Mr. Alan Stevenson, following in the footsteps of his father, has outdone him in his great work at Skerryvore. Have we not the first work, we have the last, it would still be wanting; but it is remedied by gathering little and little, that it grows until we can work out those wonders which are the pride of all time. The slight tramway has, by the work of many hands, been brought to such a height that it has become the strong arm of civilization. Time has been overcome by the motion of these wheels, and the weight by the speed of the men, and the mind by the thought of the group. Why, however, do we talk of such things? Why do our great men take their seats at the meetings of the Institutions—why have they anything to do with them, if they do not acknowledge them to the full?

The Institution of Civil Engineers sets out with the purpose of communicating knowledge to its members, and of keeping a record of every new work. Each member is pledged to write something, and to give his mute to the common stock. This is an acknowledgment of the principle, and it would be well if the members of the Institution, in their daily pursuits, in their studies, in the unceasing mind, and only name those of their brethren as president and vice-presidents, who had given their fair share to professional learning. This would be a right acknowledgment to those who, like Sir John Rennie, George Rennie, Sir John Macneill, and Alan Stevenson, have done such thinking, and written such things.

So long as engineers look after money only, and do not care for their good name, on them long will they be without their right weight with the public; and so long will the government be able to tamper with them, and give their emoluments to the military engineers. It is they who have raised great works, the ill-willed will always say, those were done for money, and will be ever ready to take away from the honour which would otherwise be awarded. The thankfulness of the public is not so sure, that any means of earning it can safely be left undone. How many great men are there whose names are almost forgotten, and whose deeds are unknown! Very few, when they see a canal, think of the labours of Brindley, or when they see a locomotive, think of how much we owe to Trevithiok. Those who were careless of their good names in their lifetime, would have little right to complain of the forgetfulness of those who came after them; and our great men of this day can look forward to nothing better. If they have tasted the ill-will of those amongst whom they live, and who see them and their works, they cannot reckon that they will fare better hereafter, when they have done nothing to show that they care for other men's renown for themselves. Stevenson lives in his writings, as much as in his other works; and he has earned for himself a share in the works of those who have followed in his path. Thus, Mr. Stevenson bears witness to Smeaton's good works. Before beginning the Skerryvore light-house, he carefully read what had been written by the great man who went before him. Even to the shape or bearing of a stone, or the setting of a joint, Smeaton had carefully put down what he had done, and Mr. Stevenson was able to come to a sound judgment as to what he himself thought of doing. The knowledge of a hundred years was at once brought to bear, and the engineer has cut from the great man's stock.

Skerryvore will withstand for hundreds of years the storms and blasts which burst upon it, and those who look at it will see, with wonder, its strength and its bulk, and acknowledge its builder has done his work. A rock of stone is raised upon the crags of Skerryvore, but the even seems hide all the work within: each layer buries from sight the cunning handiwork beneath it. The very finish stands as it were in witness against the hardihood of the builder; and there is nothing scarcely to show his skill,—nothing to show the care, the sweat, the peril spent in putting stone on stone, among those who have seen the work as Smeaton and Stevenson. The slender, narrow dwelling of the workmen, ready to dash them into the troubled sea which yawned beneath them. There is greater heroism in fighting against such risks, than in shedding blood in every field of Scinde, or in warring against the bold Highlanders of Cabul. Not one of them claimed to be a master, but the engineer shares them with him. Great as the risks which our seamen have to meet, they are not greater than Mr. Stevenson and his workmen underwent on the rock of Skerryvore. The first shelter they raised was wrecked in a winter's storm, and they dwelt for months in a barrack upon the rock, which they could not but believe was threatened with the same end. Cranes, windlasses, forges, and anvils, were tossed about the rock by the storm, as freely as pebbles, dashing timbers to pieces, and helping the wall to fall. The workman who tool could be left for a day without being lashed to ring-bolts, even then these were sometimes snapped off. The surf dashed in sheets against Mr. Stevenson's window, fifty feet above the sea; and one night, he tells us the barrack reeled so with the shock of the waters, that all the men left from their hammocks with a fearful start, believing that their doom was come, and that they would be swept into the seething waters. Here were sometimes laid up for days, unable to stand upon the slippery rock, or face the sweeping storm; and lying in their hammocks day and night, for shelter against the bitter cold. Sometimes they were left almost without food, for the steamer could not always come; and once their stock was brought down to the wants of one day only. At all times it was hard to land, or to get the stones out of the lighters; and often they were hauled back by the steamer after snipping every warp. The rock was as smooth as glass, and so narrow that the workmen had hardly room to work. In blasting for the foundations, there was no shelter under which the men could lie down; so that Mr. Stevenson had to cover the rock with matting when blasting was going on. On this spot, they worked under the broiling sun while daylight lasted, snatching only hasty meals from the deck, and lying in the unceasing mind, which often made them sea-sick; and afterwards in the barracks, whence the storm might have in one moment hurled them from sleep to death. The few words which Mr. Stevenson gives to these risks he and his helpers endured are all the charm of romance, and may well be put side by side with any tale of the sea. They are most pleasing, however, as a record of true courage, successively exerted in a useful undertaking. Had we not this record, we should know but little of what Mr. Stevenson has done, or how to value at its true worth; indeed, half of his merit would be lost, for there would have been too much of the boast of; and others could match him even in that. The skill, the foresight, the battle with the hardships of every kind, which beset this undertaking, tasked his powers to the utmost; but he answered to the call.

Professional gallantry in meeting danger is, we are happy to say, far from rare. The engineer is ever ready to share with the workmen in every work of risk, and there are few great works which have not some tale of gallantry to tell. The lighthouses of the Eddystone, the Bell-rock, and Skerryvore, were beset with peril; in the one case, under the water, the other, on land. The Rock, Sir Marc Brunel, and Mr. Gravatt, risked themselves; and daily, wherever a new locomotive is tried, a new boiler is set up, a new mine opened, or a new engine built, some engineer puts his life at stake. Courage is not the virtue of a blue coat, or of a red one: the medical man who makes his way in the shreds of the poor, is a greater hero than he who boards another's bulwarks, or who storms a breach; because he has no hope of glory or advancement, and a greater chance of danger.

The reader of Mr. Stevenson's book is sure to be struck by the thought of its value to engineers now and hereafter, but most to those in our far settlements, who have no chance of going to Skerryvore, or to the Eddystone; and who, indeed, if they had, would see the work—but not how it has been done. Mr. Stevenson has been careful fully to explain every step which he took, to account for his course, to give at the close his estimate. He has described every process, however common, or however trifling. He thought that nothing belonging to his work was beneath him; and as he looked into everything, he was enabled even to make improvements in many of the common operations. By recording what he did, he enables others to do likewise, and to follow in his path; and no one thinks that his book is too long,—but rather, each wishes that it were longer, though nothing is left out. Care in such works is highly needful, and is most wanted where there are no bounds to the outlay which may be made. By leaving out such dovetails and such details, as Mr. Stevenson and Thomas the foreman did in their lower layers, Mr. Stevenson saved above four thousand pounds in the cost of dressing the granite, and without any loss of strength or safety. By getting everything ready beforehand, he had no loss of time in running up his building on the rock, but had every stone in its place before he could begin to work. The whole building is as well finished as if it were raised upon the main land, with every help at hand,—whereas, there was hardly room on the rock for blasting, no mooring ground, no pier, no quay, hardly room
for a windlass, and everything was brought from Hynish, twelve miles off.

Whoever reads this book must think highly of the labours of engineers. We look at the vastness of the work which is being spread over this land, we cannot but wish that we had recorded them. The public will name many who are well able to do justice to their own labours, and the fulfilment of the public wish would greatly enrich our libraries. The history of the Liverpool and Manchester Railway, by Mr. Stephen Stephenson, will be a hand-book for all time. Mr. Robert Stephenson, M.P., has in the London and Birmingham Railway a good subject for illustration. Mr. Locke, M.P., can do no better service to the profession than by the publication of an account of the Grand Junction Railway. Mr. Brunel has spent many years upon the perfection of the broad gauge system, and has succeeded to the extent that the Great Western Railway has achieved a success which should not be forgotten. Mr. Cubitt has allowed his assistants to give accounts of the tunnels and blasting operations on the South Eastern Railway, but a full account of the whole line is wanted from his own hands. We hope the time is not far off when we shall see these among other contributions to our professional literature.

We shall now call attention to the rocks on which the Skerryvore lighthouse was raised. They form part of a long reef, 11 miles to the south of Tyree, in the outer range of the Hebrides or Western Islands, so that they are on the sea-way between Scotland and Ireland; and ships from seaward, if they miss the north of Ireland, are often driven on Skerryvore, where many wrecks have happened. In 1814, an act of parliament was obtained for building a lighthouse, but it was not till 1834 that Mr. Alan Stevenson was sent to make the survey. At low tides, Skerryvore measures about 280 feet square; but it is cut up by gullies of unlooked-for depth, so that the solid part is only 160 feet by 70 feet. On this a loaf of rock, about five feet broad, rose to the height of eighteen feet above high-water level, the greatest height being about six feet above that level. The rock Mr. Stevenson calls a syenitic gneiss, consisting of quartz, felspar, hornblende, and mica.

It was not till the summer of 1835 that the survey was finished, and Hynish, in the wretched island of Tyree, was chosen for the workyard. We give the plans of Skerryvore. In 1836 and 1837, quarries were opened in Tyree, and in the latter year the first part of the foundation of the Skerryvore was begun. Mr. Stevenson was now busy in drawing up his plans, and here he came to a weighty question.

"A primary inquiry, in regard to towers in an exposed situation, is the question, whether their stability should depend upon their strength or their weight; or, in other words, on their cohesion, or their inertia? In preferring strength to strength, we more closely follow the course pointed out by the analogy of nature; and this must not be regarded as a mere notional advantage, for the more close the analogy between nature and our works, the less difference we should have in passing from nature to art, and the more directly will our results correspond with the natural. In the case of Skerryvore, we were likely to have a wooden foundation, and this, when the work is of an extent to require the building of a stone or iron tower, would probably require two artificial projects. If, for example, we make a series of observations on the force of the sea, as exerted on masses of rock, and endeavour to draw from these observations some conclusions as to the amount and direction of that force with which we can build such towers, a little thought will show us that the result may be arrived at, not by the examination of two artificial projects, but by the observations in the state of the sea, as exerted on masses of rock."

In fixing the quantity of matter needful to produce stability, in determining the shape of the tower, Mr. Stevenson had to proceed empirically, for there is a want of sufficient experiments. Mr. Stevenson gives, however, a full discussion of the data, which are available. At this point he brings in an interesting comparison of the three lighthouses.

| Height above | Contents of | Diameter. |
| manuscript course | tower | At Base | At Top |
| Feet | Cubic feet | Feet | Feet |
| Eddystone | 66 | 13,343 | 20 | 16 |
| Bell-rock | 100 | 28,530 | 42 | 16 |
| Skerryvore | 138-5 | 58,580 | 42 | 15 |

The first barrack raised was swept away by the sea, so that in 1839 the summer was spent in raising another, and in excavating the foundation of the lighthouse tower. The difficulty of doing this may be appreciated from the following account:

"It was commenced on the 6th of May, and was continued up to the last hour of our remaining on the rock, on the 3rd of September. A more unremittent exertion of one of the lighthouse leaders, and in each instance present at the commencement of our labours, I can scarcely conceive. The vast irregularity of the surface, and the extraordinary hardness and unworkable nature of the material, together with the want of room on the rock, greatly increased all the other difficulties and delays, which could not fail, even under the most favourable circumstances, to exceed the expenditure of a quarter of a century, performed by a convict on a rock at the distance of 12 miles from the land. The rock, as already noticed, is a hard and tough gneiss, and required the expenditure of about four times as much labour and steel for boring as are generally consumed during the Aberdeenshire Auchnagatt.

After a careful survey of the rock, and having fully weighed all the risks of injuring the foundation, I determined at once to enter upon a horizontal cut, so as to lay bare a level floor of extent sufficient to contain the foundation for the tower. The tower was raised and strengthened, and upon this eminence a quarter of a century's work was performed on a rock which might be considered an almost necessary precaution, in order to prevent any misconception as to its real state, for it was traversed by numerous veins and bands inclined at various angles, on the position and extent of which the stability of the foundation might, to a small degree, depend. That operation occupied 30 men for 102 days, and required the firing of no fewer than 246 shots, chiefly horizontal, while the quantity of material removed did not greatly exceed 2,000 tons. It was a work of some hazard; for the small surface of the Rock confined us within 30, and sometimes within a dozen yards of the mines, while its form afforded us no cover from the flying splinters. The only precautions we could adopt were to cover the mines with mats and with coarse nets, which had been made to be moved during the previous winter, of the old tow and 1,000 cubic yards, and taken all the risk of coming into contact.

For the top of the lighthouse, it may be doubted whether there be any instance in modern engineering of an operation of so small an extent occupying so much time, and involving so great risk. The blasting of the rock, however, was not the only difficulty of the lighthouse. We endeavoured to place the pedestal of the rock to the place of the pedestal of the Skerryvore Lighthouse."

The second lighthouse was built on the island of Lingay, and the third on the island of Colonsay. The first quarried materials, amounting to about 2,000 tons, into the deep water round us, to prevent their being thrown by the waves upon the rock, and to endangering the future temporary barrack. That was rather a laborious work, and occasioned two with temporary runs and to the other, during the greater part of the time we spent on the rocks, and all aware that the quantity of materials which I have just mentioned, will be apt to produce a smile from those who have been chiefly conversant with the gigantic but simple operations which generally characterise the great railways of this country; but if it is remembered that we were at the mercy of the winds and waves of the Atlantic, and were every day in the expectation of a sudden call to leave the rock, and betake ourselves to the vessel, and, on several occasions had our cranes and other tools swept into the sea, the slowness and ingenuity with which the operations were performed would, I beleive, weigh the dangers of our daily life, both in our little vessel and on the rock, and who, at the same time, reflects on the many striking proofs which we almost every hour experienced of the care of an Almighty hand, be dis-
posed to withhold their sympathy from the heartfelt expressions of gratitude with which the event unfolded our little circle. In the twilight from the rock to the ship. Isolation from the world, in a situation of common danger, produces amongst most men a free interchange of the feelings of dependence on the Almighty, than is common in the more sheltered recesses of life.

With a view to lessen the dangers of blasting in such a situation, I had provided a galvanic battery on the plan proposed by Mr. Martyn Roberts, but I used it less frequently than I intended. The attachment of the wires was very liable to be broken from various causes, where there were many men congregated in a small space; and as we could not venture to leave the apparatus on the rock, the frequent re-shipping of it in a heavy sea was another cause of the derangement of its parts. I soon, therefore, laid aside, and only had recourse to it when any work was to be done under water. So far as the plan was executed (and it is admirably adapted) was of importance in effecting any special purpose.

When the floor had been roughly levelled I again carefully surveyed the rock, with the view of fixing precisely the site of the foundation-pit, and of taking such measures as would ensure the success of the operation. The largest diameter from the tower of which the rock would admit. In some places I found that parts of the rock, apparently solid, had been undermined by the constant action of the waves, to the distance of 13 feet inward from its face; but none of these parts was conduced to the strength of the mass. So, to and fro, were repeated examinations of all the veins and fissures, I was enabled to mark out a foundation-pit 42 feet in diameter, on one level throughout. That was a point of no small importance; and although it had cost a little extra expense, the work was saved by its adoption, and the subsequent stages of the work. Not only was the labour thereby avoided of cutting the rock into separate terraces, and fitting the blocks to each successive step, as was done by Smeaton at the Eddystone; but the certainty that the foundation to start with was sound enabled us at once to determine the dressing of stones without regard to any irregularities in the surface of the rock; and the building operations, when once commenced, continued unimpeded by the necessity for accommodating the courses to their places in the tower to be built; for the stones rose in the most secure manner from the water, and the growth of them being removed, was removed by the waves before the pressure of the superincumbent building had become great enough to retain them in their places.

The outline of the circular foundation-pit, 42 feet in diameter, having been traced with a trowel on the rock, numerous jumper-holes were bored in various places, having their bottoms all terminating in one level plane, so as to serve as guides for the depth to which the basin was to be excavated. The depth did not exceed 13 inches below the average level, already laid bare: this was cut to the rough horizontal floor which has just been described; and before the close of the season of 1839, about one-third of the area of the circle had been cleared, and was ready for the final pick-dressing which prepared it for the reception of the first course. The excavation of this circular basin was conducted with the greatest caution, so that, if allowed to be freed lest the foundation should in any place be shaken by the action of the gunpowder on any of the natural fissures of the rock. The work was chiefly done by means of what are called pluge and feathers. In some places, the work was very intricate, and the action of the pluge and feathers was to throw up a thin superficial shelf or paring of rock of from 6 to 12 inches in depth, and not more than 2 feet square. By that painful process an area of about 1,400 superficial feet was cleared. The character of the rock, unconnected with that operated on by the pick, a vertical face for the entrance of the Horizontal jumpers or boring rods; and wherever advantage could be taken of natural fissures it was gladly. Another considerable source of labour was the dressing of the vertical edges of the basin, as that implied cutting a square check, 15 inches deep and about 130 feet long, in the hardest gneiss rock; and the labour attending which, can only be fully estimated by a practical stone-cutter who has wrought in such a material. The plan employed was to bore all around the circumference of the circle, 18 inch vertical jumper-holes, 6 inches apart, to the required depth, and to cut out the stone between them. The surface thus left was afterwards carefully dressed, so as to admit vertical and horizontal mounds, representing truly the form of the mass by which the checker was intended. The experience of the work gave me great reason for congratulation on having adopted a foundation on one level, instead of cutting the rock into several terraces, at each of which some of the cutting of angular checkers must necessarily have been encountered. The cutting of the foundation occupied 20 men for 217 days in all, whereas 168 days were in the season of 1839, and the rest in the summer of 1840.

It was not till 1840 that this pit was finished, when Mr. Stevenson says—

"The rock, indeed, was in many places so hard as often to make it seem hopeless that tools could make any impression on it. The time employed in the excavation of this basin is often estimated on it, were very small. The outer parts of the rock, standing alone, was, therefore, used for the whole. Our perseverance was at length amply rewarded by obtaining a foundation on one level, so fair and uniformly throughout the whole area of a circle 42 feet in diameter, and so present to the view the appearance of a gigantic basin of varied depth, and so much pleased were the workmen themselves with the result of their protracted toil, that many of them expressed serious regret that the foundation must soon be covered up, so as (we trusted) to save the town of Glasgow for fencing marks to protect the men's faces. In all our work, nothing was more grudged than the occasional loss of half a day in bailing out the water from the foundation-pit after it had been filled by a heavy sea."

The mortar employed in the building was composed of equal parts of Aberdura lime and Pozzolano earth, being identical with that used by Smeaton.

In 1840, six courses were set, being a mass of masonry equal to the whole of the Eddystone tower. In 1841, 30,300 cubic feet were built, being twice as much as the Eddystone, and more than the whole Bell-rock lighthouse. In 1842, the masonry work was finished.

The general arrangement of the tower is much like that of the Bell-rock lighthouse.

"The ascent to the outside door is by a ladder or trap of gun-metal, 26 feet high. The first apartment on the level of the entrance door, is chiefly appropriated to the reception of iron water-tanks, capable of holding a supply of 1,251 gallons. The next story is set aside for stores, which are stowed in large iron boxes. The third apartment is a workshop; the fourth is the provision store; and the fifth is the kitchen. Above are two stories, each divided into two sleeping apartments, for the four light-keepers. Over the provision room for the visiting officers; then follows the oil store, and lastly comes the light-house, making in all twelve apartments. The nearness of the oil store to the light-house is a great convenience to the keepers, who are thus saved the trouble of carrying the daily supply of oil to the light-house by a long flight of steps. The passage from story to story is by open trap ladders, passing through hatches in each floor and partitioned off from each apartment in order to prevent accidents and to check cold draughts from." The light was exhibited at Skerryvore on the 1st of February, 1844.

The whole cost of erection was £20,836. 19s. 1d., but of this very little was spent directly on the lighthouse. The cost may be subdivided:

- Establishment at Hynish
- Rock barack, No. 1
- No. 2
- Establishment and quarries at North Bay
- Signal tower and lights at Hynish
- Wharf and railway at Skerryvore
- Steamer, tender, and stone lighters
- Moorings
- Boats and freight of hired vessels
- Labourers discharging cargoes
- Travelling expenses
- Coals
- Gunpowder
- Excavating platform
- Dressing light-house blocks
- Tools and machinery
- Cartage
- Mortar
- Lighthouse tower, putting together and fitting
- Light-house
- Salaries
- Light-keepers' houses
- Pier at Hynish
- Dock at Hynish for the tender

From the whole cost, £2,936, is to be taken off for the steamer and materials sold, but each item is given by Mr. Stevenson in detail.

Having thus followed Mr. Stevenson throughout his labours on the tower at Skerryvore, we must keep until next month our remarks on a subject no less interesting—that of lights, to which a great part of his book is devoted.

---

**Electric Telegraph.** London: Bogue, 1848.

This is a shilling volume of scraps for the railway carriage, which contains more information about the Electric Telegraph, and more amusement, than any which has yet been published. There is not an invention in England, the United States, or abroad, which has escaped the author's attention.

This work relates to the great Manchester water controversy, which for the last few years has so much occupied that town. There are at present two canalised waters: the Manchester and Salford Waterworks Company, the Corporation of Manchester, and the Manchester, Salford, and Lincoln Railway Company. Mr. Homersham is the follower of the last-named, and has carried matters so far as he can, though we believe it to be for the most part fair and straightforward.

The Waterworks Company suffer from a short supply and the bad quality of their water, which is got partly from peat-moss, and partly from the drainage of an inhabited district, but sked out by a supply of water from the rail way Company. The supply is clearly neither enough nor good enough for the growing town of Manchester. The town council have therefore got a bill to enable them to get water from Longdendale, gathered into reservoirs from a mossy surface. In the meanwhile they have likewise bought water of the Railway Company.

The Manchester, Salford, and Lincoln Railway Company having bought the Peak Forest Canal, were struck with the profit to be got by the sale of water to the great towns of Manchester and Stockport. Their canal, beginning in the Peak district of Derbyshire, supplies, given them by the proprietors, water required by the millowners; and as there is more than enough water for the trade of the canal, it is a clear gain to sell it in those towns. The Company do not however wish to retain water to the housekeepers, but to sell it wholesale and in bulk to the corporations or water companies. The Manchester and Salford Waterworks Company in July 1844, bought some of this water, and soon after contracted for 120,000,000 gallons yearly, for three years certain, at 9d per 1,000 gallons, or a rental of 1,000, yearly. In 1844, they agreed to take 50,000,000 gallons more. In August 1847, the Corporation of Manchester bought 120,000,000 gallons yearly, at 3d per 1,000 gallons, or a rental of 9,500, yearly. The Railway Company offer to supply the Corporation with seven millions of gallons of filtered water daily, at 14s per 1,000 gallons, or a yearly rental of 14,000/. 15s.

By the terms of the Railway Company, this large supply of good water is secured; and we have no doubt that in many other cases, railway companies might have done great good to the public in the supply of water and gas, if it were not for the prejudices indulged in by the legislature, which shackle railway companies as they do private enterprise generally. Indeed, the whole drift of legislation is to thwart enterprise, even when there is the pretence of consulting the public interests. Thus, what with the sanitary measures, threatening to interfere with the companies, and what with the Standing Orders, they are in a bill before the House of Commons for waterworks. The Board of Trade presses likewise very heavily on small companies, besides the House of Commons fees.

Mr. Homersham thus describes the country around Manchester from which the chief drainage supply is made.

"The town of Manchester is situated at an average height of about 120 feet above the mean level of the sea at Liverpool, and is bordered on the north-west, the north, the east, and the south, by high hills and upland that, in a distance varying from twelve to eighteen miles from the town, rise 1,100 to 1,600 feet above the sea, when they begin to fall in a contrary direction. The highest points in this range of hills are Rivington Pike to the north-west of Manchester, 1,535 feet above the mean level of the sea; Blackstone Edge to the north-east, about 1,600 feet; Holme Moss to the east, about 1,580 feet; Kinder Scout to the south-east, about 1,041 feet; Axe Edge, south-east by south, 1,791 feet; and Bosley Minn, nearly direct south, about 1,260 feet. These hills rise very abruptly, and the numerous valleys and mountain gorges that intersect them in various directions contain channels, called rivers or streams, that drain off the rain which falls upon them. The names of the principal rivers deriving their waters from the sources now pointed out, are the Irwell, the Irk, the Medlock, the Etherow, the Etherow Derit, the Goyt, and the Goyt Derit, which are the waters of the whole of these rivers unite in the river Mersey, and by this channel are discharged into the sea at Liverpool.

The rivers upon which the towns of Manchester and Salford are situated, the Irwell, the Irk, and the Medlock; the two latter streams joining the Irwell within the town. The area of land upon which the rain falls that feeds these streams before entering Manchester is about 15,000 square miles, and the river, as the result of which the waters of about 11,500 drain into the river Medlock; 17,000 into the Irk; and 184,700 into the Irwell; these rivers, like all others having a similar origin, are very irregular as regards the quantity of water which passes down them at different seasons.

Nothing is idle in that busy district—even the water is made to work hard. Mr. Homersham says of the river-gods of Lancashire and Cheshire—"They are made to turn innumerable water-wheels, that give motion to machinery of various kinds; they are used to supply both the means of forming and condensing asphalt, the coal chiefly directed, performs such a prodigy of labour with uneasing and unirritating effort; they are used to scour, bleach, and dye the goods they have helped to spin and weave; and their flood-waters, collected in large valleys or reservoirs, feed with water the canals and rivers that transport both the raw and manufactured material. They supply our houses with water for domestic purposes, and they perform the office of scavenger; removing from our dwellings the excrement and filth, that would otherwise contaminate, and undermine our health, engender fever, and cause premature death."

Of the fall of water two very interesting tables are given, which show that the depth of rain falling at the same place is very unequal in different years, and that it seems to follow no law, but the greatest depth of water falls to the west, which is nearest to the sea.

![Table showing the Depth of Rain fallen for a series of years in different places situated in the upland to the west, north-east, and south of Manchester, and the level above the mean level of the sea.](image)

**Table:** Showing the Depth of Rain fallen per annum for a series of years in different places situated in the upland to the west, north-east, and south of Manchester, and the level above the mean level of the sea.

Note.—The observations for Salford were procured from J. Mawgill, Esq.; and for Stockport from J. Watson, Esq.; from Bury, from J. Norris, Esq., F.R.I.B.A., who, since September 1846, has resided at Heavik House, near Preston; from Rochdale, from J. Scroft, Esq.; from Bredbury, from Mr. H. Matthews, the engineer of the Rochdale Canal; and the rest from observations supplied by J. Meadows, Esq. The whole of the observations, with the single exception of Blackstone Edge, were made with rain gauges fixed very near the ground.

Mr. Homersham charges against the corporation water that is drained from peat land, and is charged with organic matter, which is hurtful to health. He affirms that no filtration can remedy this, as when the water is warm the pest is soluble in it.

Our author, not content with charging his opponents on every side, asserts that his own company is free from all defects, that the water is most abundant, is collected at the best time, and is little tainted by pest, while he contends that it is likewise the cheapest supply that the corporation can obtain. In his seat, he says of the fashions impounded by the Railway Company—"This system of collecting water is very favourable to its purity, as when it flows off the hill-sides during heavy rains (except in a peaty or boggy district) it is much less contaminated than water (percolating slowly from the soil, and reduced in quantity by evaporation) which forms the streams in dry weather; besides, over most large tracts of land, consisting of thousands of acres, there will be found farm-houses and a considerable resident population, and all the excreta and filth created from these sources, with the soluble parts of manures placed on the land, must, of necessity, drain into the streams, and tend to foul them in comparatively dry weather, although, in heavy rains and floods, the water is not perceptibly soiled by these impurities."

We must say this doctrine is new to us, for we always considered
that the freshets should, if the water could be spared, be prevented from entering the reservoirs.

Upon their act of parliament the corporation are to take all the water of Long Island into their reservoirs, and supply a daily quantity to the millowners. This, Mr. Homershaw affirms, will cause a greater expense for reservoirs, and will yield less water to the corporation; and he contrasts it with the system adopted on the Peak Foot Canal, where all the water above a certain gauge goes into the canal reservoirs.

When he says that reservoirs for the millowners have not answered (p. 44), and that therefore money is not laid out by the millowners in that way, leaving the inference that the corporation reservoirs will be filled up, he is wrong, and useless, we consider, his case too much, for there are great difficulties in the case of millowners, as that of getting all the millowners and landowners on the stream to join, and the great expense of getting an act of parliament.

We must notice that there is a great deal of valuable matter incidental to the discussion of the several schemes, which may be usefully read by the engineer feeling an interest in this important branch of practice. Thus, Mr. Homershaw discusses rain-gauges, the fall of rain, the duration of fall, evaporation, absorption, and filtration. We should like to see complete records of the movement of some considerable streams. Mr. Homershaw says below that he has made such, and we wish he had published them.

"The quantity of water flowing down streams fed from rain falling on the sides of hills varies with every passing shower; no one or two observations per day can possibly give anything like an accurate result; a flood will sometimes occur in a short time, but it is unknown for the stream to run high for a month. For the time it is frequently more water will run down the streams than at other times will flow down in as many weeks. I have had occasion to make observations on streams every hour in the day, and every half hour in the winter weather for weeks together, day and night, and at almost every measurement varied.""}

Mr. Homershaw gives an estimate of the cost of the corporation works, which, at five per cent. makes a yearly cost of $20,832.52, while he asserts that the same quantity of water, of better quality, can be had for half the amount. It is followed by the cost of the Ashford and Linen Railway Company for $5,926.15, or a yearly saving of nearly $25 per cent. All this, however, depends on what the real cost of the corporation works may be, and for that purpose we should have the estimate of their engineer, and not of Mr. Homershaw. Indeed, the whole gist of the question lies upon this, which must likewise be the comment on his concluding statement.

"As you are aware, in the spring of last year the corporation could have made arrangements to secure for the use of the inhabitants of Manchester, eight millions of gallons of filtered water per day (as much as will be required in the future use of the Lancashire coal for some time), and have delivered at Marble, 890 feet above the high part of the town, for 1d. per 1,000 gallons: in August last year (after having spent a large sum of money in opposing your scheme), the corporation, in conjunction with the Waterworks Company, have put a large amount of money in order, and again, millions of gallons per annum of the same water unfitted, to be delivered in the Gorton reservoirs, at 3d. per thousand gallons; or at double the prices they might, by adopting a wiser course, a short time previously have secured the same water filtered."

EXPLOSIONS OF STEAM-BOILERS.

The Causes and Effects of Explosions in Steam-Engines Investigated; and their result from an explosive principle different from the force of elastic steam demonstrated; and conclusive evidence adduced that more than four-fifths of the weight and strength of the engine are required to sustain the explosive force: with an easy and certain means of preventing its destructive effects, and greatly lightening and accelerating the immense weight of the engine. By John Wilder, New York. 1847.

The elaborate title of this pamphlet fully explains the views and objects of the writer, who lives in the land of steam-boiler explosions, and seems to have had much experience therein. He commences by adding a number of facts which are valuable in their way, but which are not for us to enter into, and often very fallacious. After mentioning several instances of the explosion of cylindrical boilers, in which the ends were blown off and projected to great distances, he proceeds to make calculations of the strength of the relative parts of such boilers, and concludes, that "it is impossible that a cylindrical boiler should be rent asunder endwise by the force of elastic steam, since half the force requisite thereto would burst it open laterally." The following is a specimen of the calculations on which he found this assumption:

"The diameter of the boiler which exploded at Baltimore, is stated in the Sun at 20 inches; the circumference, therefore, 62.82 inches, one-fourth thereof, 15.706, multiplied by 20, the diameter, gives 314.1 square inches as the area of the end of the boiler; but the whole periphery or ring resists the pressure on the ends, and its cohesive strength is the circumference, 62.82 inches. In like manner the rectangular section of the boiler, made by a plane passing through a portion of the axis one-fourth of the circumference, in length, is 13.55 inches, by 0.337, the amount of metal which resists the pressure on the ends is double the amount of metal which resists an equal lateral pressure; and it appears impossible that they should be rent asunder endwise by the force of elastic steam, which would have been great enough to do the work generated."

The area of a circle is greatest in respect of its circumference, of any figure whatever; much less, therefore, can a boiler not cylindrical be rent asunder endwise by the force of steam. But numerous cases have occurred wherein boilers have been rent asunder endwise, what could only be effected by an almost unlimited explosive power. No trace of such power is found in the history of boilers other than those of steam-engines; nor in these has it been indicated by the safety-valve or steam-gauge, although they show, with sufficient precision, the variations in the strength of steam. Against the force of elastic steam, as generated in a boiler, a properly loaded safety-valve is a complete security, but it has not the least value as against the effects of explosive action."

The "explosive principle," to the action of which Mr. Wilder attributes most of the accidents in steam-engines, appears to be electricity, though it is not so stated distinctly. This force is, he conceives, generated principally in the valve chambers in the following manner:

"It has been proved (?) that explosions in steam-engines are the consequence of the escape of elementary caloric from its combination with water or its vapour, and result directly from the removal, in the valve chamber of engines, of the compressing force which kept up the combination; for when the steam-valve is opened, the steam which passes into the valve chamber has free space to expand and the caloric to escape, but that escape and the further opening of the valve must diminish in a degree the compressing force, and must have space to escape. If the consequence action must depend more or less on the temperature and expansive force of steam within the boiler. The occasional violence of its action is shown by the producings of the beams, cranks, &c., which are frequently broken. From all the considerations, that if the valve chambers be disused, and the steam let directly through the ends of the cylinder, the smallest clearance of the piston from the end, which does not admit its touching, will be the only vacant space for expansion and escape, and this need not be an hundredth part of the space in the valve chamber, and of consequence the explosive action cannot exceed the hundredth part of its present violence."

Though Mr. Wilder considers he has "proved" his position as to the cause of explosions in steam-engines, we confess that his evidence is not sufficient to satisfy us; and his opinions are frequently supported by very inconclusive and often very fallacious. As an illustration to his theory, the explosion of a gun barrel when merely corked at the muzzle, he does not seem fully to comprehend the cause of its exploding under such circumstances; which the explosive force of gunpowder is sufficient to account for, without the supposition that any new force is suddenly brought into action. High-pressure steam is, according to Mr. Wilder, "the most elastic, yielding, and manageable of all prime movers," and only requires to be kept close, so as to prevent the escape of the "elementary caloric," to become an explosive as water power. We might hence indeed infer, though probably Mr. Wilder is not prepared to go so far, that high-pressure steam is dangerous only when it escapes, and that what are usually considered safety-valves ought to be regarded as generators of explosive force.

Carbonic Acid-Gas Engine.—Another attempt to apply carbonic acid gas as a motive power, has been before the notice of the Paris Academy of Sciences, by M. Jagu, C.E., who proves very satisfactorily the power, and, from them it seems inconclusive, and often very fallacious. After mentioning several instances of the explosion of cylindrical boilers, in which the ends were blown off and projected to great distances, he proceeds to make calculations of the strength of the relative parts of such boilers, and concludes, that "it is impossible that a cylindrical boiler should be rent asunder endwise by the force of elastic steam, since half the force requisite thereto would burst it open laterally." The following is a specimen of the calculations on which he found this assumption:

"The diameter of the boiler which exploded at Baltimore, is stated in the
APPARATUS FOR SUPPLYING BOILERS WITH WATER.

Report (by Order of the American Government) on an Apparatus for Supplying the Boilers of Ships with a Continuous Supply of Fresh Water. Invented by Captain John Ericsson.—[From the Franklin Journal.]

In acceptance of your invitation of the 17th ultimo, we, the undersigned, had the honour to meet together in the city of New York, with the view of testing and reporting upon an apparatus invented by Captain John Ericsson, for the purpose of supplying the boilers of marine steam-engines with a continuous supply of fresh water, and applied by him under your direction in the United States Revenue Steamers Legari.

We have now respectfully to report, that on the 23rd ultimo we embarked in the Legari at 12 M., proceeded to sea, and remained on board till the following morning. During this time the boiler was in operation 15 hours, and we had ample opportunity of examining the means employed for supplying it with water and the results produced.

By the ordinary method of condensing steam in marine navigation, boilers are supplied with the water of condensation, composed of the steam that is withdrawn from the boiler and the necessary quantity of salt water required for its condensation. Hence, a boiler in operation is constantly parting with steam (fresh water) and receiving the same in exchange; hence the necessity of a considerable degree of salinity in the water of condensation, which is frequently not sufficient to pass the boilers, and is therefore removed by evaporation and addition of fresh water. In the apparatus here under examination, the water of condensation is restored to the boiler, and the heat thus conveyed is not dissipated in the air, but is retained for the production of steam. The water of condensation is condensed in the boiler, from which it is distilled and conducted to the condenser, through which a current of alcohol is driven, and thus a continuous supply of fresh water is supplied to the boiler.

The Evaporator, as constructed, is a parallel-sided cylinder with a perfectly serrated top and bottom, the lower portion of which is occupied by a number of tubes inserted in a jacket, whereby the condenser is heated, and steam conveyed to the boiler. At the top of the cylinder a tube is placed, through which a current of air is driven, and thus a continuous supply of fresh water is supplied to the boiler.

Upon the experimental trial to which we were pleased to request our attention, all fresh water arrangements for correct observations were entered into; and with a view to acquire full and progressive notes of the operations of the apparatus, the observations of the various points were confided to special committees, which upon the conclusion of the trial, reported full notes for furnishing the following view of the operation:

The boiler was filled with fresh water from the opening of the blow-off cock; below this, salt water had been left, from an impression of its effect being too inconsiderable to authorise its removal.

At the commencement of the operation of the engines, the water in the boiler as indicated by a saline hydrometer, when at a temperature of 150° Fahrenheit, was 32.°

The highest temperature of the feed water observed was 158° Fahrenheit.
The lowest 132°, and the average 150°.
The highest evaporation was from 16 to 18 inches.
The lowest from 11 to 15, and the average was from 12 to 15 inches.
The highest steam pressure was 54 lb. mercurial gauge.
The lowest was 20 lb., and the average was 45.5 lb.
The highest number of revolutions was 47 per minute.
The lowest number was 30, and the average 42.3.
The point of cutting off was at three-eights of the stroke.
The temperature of the sea water was 57°.

Time during which steam was raised, 20 hours.

DIMENSIONS OF ENGINE, &c.

Cylinder.—36 inches in diameter, with a stroke of piston of 32 inches.
Boiler.—1,400 square feet of heating surface.
Condenser.—637 square feet of heating surface.
Evaporator.—100 square feet of heating surface.

Upon coming to, the freshness of the water was again tested, and when at a temperature of 150° by a different thermometer than that used at the first operation (it having been broken in the interim), the hydrometer indicated 32.; whether this difference in the indications is to be attributed to a change in the density of the water or to a difference in the thermometers, they being of different

* 11.892 being the point of saturation of water when at a temperature of 200°.

24.
manufactures, we are unable to decide; fortunately the difference is quite inconsiderable, and is not regarded as deserving of further consideration.

So soon as the temperature of the Condenser was reduced to a degree that rendered an examination of it practicable, one of its heads was removed in our presence, and the tubes, when examined, were entirely free from any deposit or incrustation upon their surfaces, and the opinion is entertained, that at a temperature of feed water commensurate with economy of fuel, any difficulty from the deposit of oleaginous matter in this instrument is not to be apprehended.

Regarding the particular performances of the Condenser and Evaporator, it appeared that Capt. Ericsson had relied too confidently on a general current of the cold water through the former instrument, whereas the current was quite partial, being but directly through its narrowest part, the sides of it: hence, the upper portion of it was almost inoperative—this feature was clearly developed by the application of a hand along the surface—while the effect of it was apparent in the moderate condensation indicated by an attached mercurial gauge.

Of the Evaporator, its capacity was clearly shown, in the facility with which the level of the water in the boiler could be raised through the space between two gauge-cocks, and by a resort to its operation not being necessary for more than one-tenth of the time.

Immediately after the close of this trial, measures were taken to effect a diffused operation of the cold water, and as diaphragms could not be introduced between the tubes to alter the current of the water, without incurring an impracticable delay, the expedient of causing the steam to circulate through the tubes was resorted to, and was effected by the application of diaphragms in the open space at each end of the tubes. Upon the completion of this, a further trial was had on Friday, the 1st inst., when several observations furnished the following:

Pressure of steam, 50 pounds mercurial gauge.
Revolutions, 47 per minute.
Vacuum, 20-5 inches.
Temperature of feed water, 150° Fahrenheit.

Compare, with the ordinary method of condensation, the value of the method observed is determined by an investigation and consideration of the following points, viz: Evaporation, Pressures, Consumption of Fuel, Safety and Duration of the Boiler.

1.—EVAPORATION. Ordinary Method.

Temperature of Feed Water, 100° Fahrenheit.

Temperature of sensible and latent heats of steam, 1192°
Deduct temperature of feed water, 100°

Heat to be added, 1092°

Temperature of Feed Water, 150° Fahrenheit.

Temperature of sensible and latent heats 1192°
Deduct temperature of feed water 150°

Heat to be added 1042°

Then 1092 - 1042 = 50° which represents a gain in the evaporating temperature in the new method of 4-56 per cent.

2.—PRESSURES. Ordinary Method.

Pressure of steam—mercurial gauge 75 lbs.
Vacuum, 20-5 inches 137 lbs.

Cut off at three-fourths of the stroke.
Effective pressure on the piston 63-7 lbs.

New Method.

Pressure of steam 50 lbs.
Vacuum, 20-5 inches 10 lbs.

Effective pressure on the piston 44-5 lbs.

Then 44-5 / 100 which represents a loss of pressure by the new method of 5 per cent.

3.—CONSUMPTION OF FUEL. Ordinary Method.

In the Gulf of Mexico and between the Tropics, it is necessary to blow-off, when a hydrometer constructed in the manner to the one already referred to indicates 2:5 in the Northern Atlantic and Pacific oceans, when 32 indicates 2:5 + 2:5 the average point for blowing-off.

As the average degree of saturation of feed water is 2:5, the quantity of water blown off compared to that fed to a boiler is as 75 to 2-25, which is in the proportion of 1 to 3.

Temperature of the water blown off at the pressure and degree of saturation gives 290°
Deduct temperature of feed water 100°

Temperature lost by blowing-off 190°

As the heat to be added for the purpose of evaporation is 1092°—1092 x 3—1, the proportion of feed water evaporated, 2184°
And 190 x 3—2 the proportion of feed water blown off 190°

The heat absorbed, 2374°
Then 190 = 08° which represents the loss of heat by blowing off in the ordinary method of 8 per cent.

Summary of Results.
Gain by Evaporation 4 56 per cent.
Ditto by Consumption of fuel 8 00

Loss by Pressure 12 56

Total 7 56

Which is a saving in the expenditure of heat, affording a like economy in the consumption of fuel and altogether independent of the loss of heat, by the presence of scale in a boiler, when salt water is used, and from leaks incurred by the oxidizing effects of salt water.

With the Ordinary Method, the level of the water in a boiler is constantly varying from one or both of the following causes, viz: the quantity of the water blown off, or the particular extent of opening of the feed-valve; while the effective operation of the feed pump and neglect of the blow-off valve, involves the burning, or an explosion of the boiler.

With the New Method, these operations are set aside: thus, blowing off is unnecessary, and the supply to the boiler being first obtained from it, the transit being immediate and the communication incapable of restriction (for if the condensed water was not taken off by the feed pump, the condenser would choke and become inoperative), there can be no decrease in the level of the water, other than that arising from leaks of water and steam. Further, the use of fresh water in a boiler will extend the term of its duration from three and five years to seven and nine.

With a further modification of the condenser, establishing a more diffused current of the cold water, it is evident that a full vacuum may be obtained, as the practicability of attaining this end by external condensation has long since been developed, and with a less proportion of radiating surface than is exposed in the instrument referred to. From the analysis however here given regarding pressures and temperatures, it would appear that a full vacuum, with corresponding reduction of the temperature of the feed water is not necessary; and as such departure from the hitherto practice, furnishes the temperature necessary to prevent any oleaginous deposit upon the surface of the tubes of the condenser, practice and utility are in desired harmony.

A very effective and economical element in steam navigation arises with the operation of this new method, from the absence of scale in the boiler, the presence of which is unavoidable where salt water is used, and to avoid the formation of it, as far as practicable, other than a lower temperature and corresponding pressure are precluded by the waste of fuel and injury to the boiler consequent upon the existence of this scale acting as a new conductor of the heat to the water—whereas, with the use of fresh water, higher pressures can be worked and economy of fuel attained in an increased expansion of the steam.

Reviewing the facts herein presented, we are of the opinion that the operation of the apparatus of Captain Ericsson, as far as developed, was eminently successful, and that, with the modification of the condenser suggested, a higher degree of vacuum can be readily obtained. In view of the very great importance of the successful introduction of this method of condensation in the merchant and naval services, we recommend to your consideration the propriety of sending the Legari on a distant cruise, for the purpose of developing the advantages of the apparatus by continued and extended use.

CHARLES H. HARWELL.
Engineer-in-Chief, U. S. N.

New York, Oct. 31, 1847.
DECOMPOSING POWER OF WATER.

It has long been noticed, that partial decomposition is often observed in attempting to render anhydrous, by heat, certain salts which require a comparatively high temperature for the expulsion of their water of crystallization. This is not limited to those salts which are capable of decomposition by the action of heat alone, but extends to many which, when previously rendered anhydrous, are entirely unaffected by this agent. The chloride of magnesium offers a striking instance of such an action, being almost entirely resolved into its elements, so as to escape from the vessel when the acid, when its solution is evaporated by a strong heat; the anhydrous chloride, when obtained by other processes, is, on the contrary, unaffected by the highest heat.

Even chloride of calcium, a salt of much stronger radical base, is not observed to give off a portion of acid, when all its water of crystallization is driven off by a red heat. In these and many other instances, it seems evident that the escaping water of the salt is the actual decomposing agent, and that the intensity of its action depends solely upon the degree of heat which the salt can receive; it is not removed from the vessel.

Contact of the salt and water, at high temperatures, appears to be the only requisite of decomposition. It was therefore thought probable, that by exposing the salt, even in its anhydrous state, to a high heat, and passing over it a current of aqueous vapour, raised to an intense intensity of heat, and then directing the above-mentioned united into a steaming bath, so that the water remaining anhydrous from the intensity of the heat employed, while the baryta and strontia combined with a portion of aqueous vapour, and were found in a state of hydrates.

In these haloid salts, it is to be observed, that the addition of the elements of water is absolutely essential to the decomposition; as neither the hydrogen which is contained in the acid, nor the oxygen in the base, existed in the anhydrous salt. The action is, therefore, the result of a double decomposition between the steam and the chlorides, as well as of the affinity of the liberated acid and base for each other.

The oxysalts, and the sulphates of magnesia, lime, strontia, and baryta, unlike the haloid salts just mentioned, contain, even in the anhydrous state, all the elements generally considered necessary for the separate existence of the acid and bases of which they are composed: the decomposition of these, however, causes no alteration of their acid; but, as with the chlorides, this effect is immediately produced by the passage of a current of steam over them at a high temperature, the baryta and strontia being left in the state of hydrates, and the other bases anhydrous.

The intensity of the affinity between the acid and base of the respective salts, is curiously illustrated by the gradual increase of the heat necessary for their decomposition by the aqueous vapour. Thus the sulphate of magnesia gives off its acid to the current of steam at a much lower temperature than the sulphate of lime, or any other one of the sulphates of base, and the oxide of lime requires a higher heat for its decomposition, and on this account the greater part of its acid is resolved into sulphureous acid and oxygen gas. The decomposition of the sulphates of strontia and baryta, requires progressively higher heats, which, in the case of the last salt, must be raised even to low whiteness.

The sulphate of lime, as it contains an acid much less volatile than sulphuric, combined with an excess of a powerful base, which adds to its stability, was selected as one of the most difficult tests of this decomposing power of aqueous vapour; for a full white heat, however, its phosphoric acid was slowly digested. This phosphoric acid gave a white precipitate with nitrate of silver, showing that its liberation and subsequent condensation in contact with a great excess of aqueous vapour, had not prevented that change which heat is known to produce.

It might be expected from the decomposition of the salts of baryta, that the sulphates and muriates of potash and soda would undergo the same change with even greater facility. But it was found by experiment, that although the decomposition of these last salts commenced with facility, they were closed to another state at a red heat, yet when a small portion of alkali thus liberated, never exceeded a very small per centage of the residual salt, however long the operation might be continued. Attributing this peculiarity to the volatile nature of the liberated hydrates of potash and soda at high temperatures, substances capable of forming non-volatile combinations with the alkali were mixed with their salts, previously to subjecting them to the action of the steam; the acids were then found to be completely disengaged with facility. The fact that both lime and magnesia, substances capable of forming chemical combination with the metallic character with potash and soda, were found to produce the above effect, was considered as confirming, in a great measure, the hypothesis that the volatility of their hydrates was the cause of the apparent difficulty of completely decomposing the salts of these alkalies.

The subphosphates and subsalts of lime, baryta, and strontia, act in the same manner as lime and magnesia, and in all these cases the chemical combination is so feeble that, when cold, the alkali is disengaged by the solvent powers of water alone.

Alumina, which possesses so much of the acid character with respect to the strong bases, is proportionately more efficient than any of the preceding substances in aiding the decomposition of the alkali salts; it remains with the alkali, when cold, as a soluble aluminate; but is easily precipitated from its solution by a current of carbonic acid gas.

The calcination of potash alum leaves a mixture of alumina and sulphate of potash, which Berthelot long ago stated to be decomposed by the continued action of steam. The superior affinity of the alkali salts remains with the alkali, when cold, as a soluble aluminate; but is easily precipitated from its solution by a current of carbonic acid gas.

The powerful action of aqueous vapour upon anhydrous alum at a high temperature, suggested the possibility that a similar action might take place upon its mineral representative, the double silicate of alumina and potash, or common felspar. It will be remembered that this salt, by the simple substitution of sulphuric for the silicic which it contains, would be converted into anhydrous alum. To the action of heat alone, felspar presents this difference from alum, that the silicate of alumina and potash will not be decomposed by the silica of alumina, but must be decomposed by the silica of felspar; so that to produce an effect upon felspar analogous to that upon alum, the silicate of both the silicate of alumina and of the silicate of potash would have to be removed. Silicic acid, in a free state, having been long known to be insoluble in aqueous vapour, it was thought that, in the nature of things, it might, like the other acids, be disengaged even from a state of chemical combination, by the same agents. Steam was therefore passed slowly, for some time, over small fragments of highly-heated felspar. Beyond partial fusion, no other visible change than a considerable degree of vesiculation in the parts most exposed was produced. These fragments, being finely pulverised and boiled in water, the concentrated solution was strongly alkaline, and proved, by the usual tests, to consist of aluminate of potash.
tion of those of water, can produce a volatile acid and a fixed base, the evolution of this acid and the liberation of this base will be determined by passing a current of aqueous vapour over the substance in a high temperature. When either the acid or base to be liberated forms a compound with water in which heat is transmitted to the decomposing body, the tendency to form such hydrates adds much to the decomposing power of the aqueous vapour. Although potash and soda are not by themselves fixed bases at high temperatures, yet by the use of the substances before mentioned and some combinations which are fixed, and by this means their salts come under the above rule.

The actual number of salts which have as yet been subjected to this mode of decomposition, is not very large; yet, from their peculiar composition with many others, there can be little doubt of the extension of the principle. The chlorides of potassium, sodium, barium, strontium, and calcium, being all thus decomposed, the bromides, iodides, and fluorides of the same and all weaker bases, must probably act in the same manner. The fluoride of calcium, has, in fact, been found to do so, by experiment, hydrochloric acid being freely evolved. In the same manner, from the decomposition of the sulphates, may be inferred that of the seleniates; from the silicates, that of the borates.

The whole of this simple mode of decomposition to the explanation of a great variety of geological changes, is too evident to escape the attention of those conversant with that science. In a future paper I hope to be able to give a more complete account of some interesting facts which have been observed in connection with this subject, and to verify, by experiment, many points which must at present be left to inference and conjecture. I think, indeed, although the existence of this law of decomposition was ascertained in 1842, yet it has only been within a few months that I have been able to give much attention to its investigation, which must be my excuse for the imperfect and hurried manner in which it is now communicated.

---

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

INSTITUTION OF MECHANICAL ENGINEERS.

April 26.—At the quarterly meeting which took place in the theatre of the Philosophical Institution, London, Mr. Crompton, Esq., President, in the Chair, the following papers were read:—

CYLINDER-BORING MACHINE.

"On the Fitting-up of Cylinders for Locomotive Engines, and a Description of a Machine for Boring them." By Mr. C. Byer.

In the absence of Mr. Byer, Mr. Fothergill described the machine introduced at the last meeting, but the consideration of which was not then entered upon, and the object of which was to attain a uniformity in the make, bore, and general size of cylinders, so that, in the event of an accident, they may be replaced by spare ones. To accomplish this difficult task, the machine described was invented. The description of the machine, which would require too long a space to make it intelligible, is briefly:

The bed upon which it is placed is of a common slide-lathe, sufficiently long to carry a double set of driving-gear, and admitting of the sufficient traverse of the boring-cylinder. The boring-bar is supported by three bearings, the former of which is stationary, and firmly fixed to the bed, to resist the end pressure of the cut when boring; the latter are fixed upon the carriage, and travel with it along the boring-bar. To cause the boring-cylinder to move edgewise, a train of wheels descends at the back of the machine to give motion to the shaft, and are transferred by means of a feathered worm, to the worm-wheel and pinion, both of which move loose upon a fast stud of the carriage; this stud serves as a fulcrum for a lever, carrying two opposite pinions, the intermediate pinions. To hold the cylinders while boring, the top of the carriage is formed into a kind of square panel, by means of two plates, placed on the inside, and fastened to the sides of the bearings, and two cross-attachments. These latter are also placed upon their inner faces, and are secured to the sides and top of the boring-carryage, and have holes bored in them when secured in their places, by means of the bend on the bar, corresponding in diameter to the ends of the cylinders to be bored. This arrangement is for the purpose of securing uniformity between the external and internal surface, so that the cylinder be fairly perforated, without the dangerous fault of thick and thin sides.

Mr. Fothergill submitted to the committee diagrams which accompanied the paper, and remarked, that, without offering any criticism on the machine, which appeared to him to be admirable for its purpose, he would merely direct the attention of the members to the great advantages which such an invention would confer on those by whom the cylinders were used. Say, that one of those in use split—by this machine they had the defect supplied immediately.

Mr. McConnell also bore testimony to the advantages of a uniformity of cylinder. An accident occurred to one of the cylinders in use on the line with which he was connected. An order was forthwith despatched to the manufacturer, and in three days he had another, which fitted exactly the place occupied by the first.

ON THE FORMATION OF TEETH OF DRIVERS OF PIN-WHEELS.

The Secretary read a paper, descriptive of "A Machine for Forming the Teeth of Pin-Wheels." By F. Bashford, M.A., fellow of St John's College, Cambridge.

The paper was accompanied by a model. Referring to Prof. Willis's demonstrations, that the proper form for the teeth of spur-wheels is a compound curve of a cycloid and epicycloid, it was shown that no self-acting machinery had been applied to give those forms of metal wheels when mounted on their axes. The principle of the invention submitted to the Institution was the well-known one, that if the pin be supposed to be mathematical lines, the pitch circle of the pin-wheel will be formed in two parts; a solid cylinder surrounded by a tube of iron; and when the tooth of the driver came in contact with the outer case of the pin, it would revolve through a small angle, and thus all abrasion of the teeth of the driver would be avoided.

Mr. McConnell was unable to see wherein the model before them differed from the plan now in use. In fact, it was nothing more than the old cog-and-drum plan. Probably the idea occurred to the inventor without the knowledge of the existing machines, and, if so, he deserved commendation for his ingenuity.

Mr. Cowper could not entirely agree with Mr. McConnell. The teeth, by this machine, were made as a given mathematical rule. That was the only self-acting machine he had seen that struck a real cycloidal.

Mr. Fothergill was unable to see anything in the machine practically different to those longer in use. If, however, the inventor was an amateur, still credit was due to him for the inventive ability he had displayed in the model before them.

CRADDICK'S BOILER AND CONDENSER.

Mr. T. Craddick, of Birmingham, read a paper "On his Improved Boiler, and Condenser—their Suitability for Extending the Cornish Economy, and Preventing Boiler Explosions."

In submitting to the meeting the subject of this paper, it appears desirable to call attention to the well-established practical data, from which, by the Cornish system of generating and using steam, such economical results have been obtained. To this end, a very brief review of the various laws, or principles, immediately bearing upon the subject, seems to be essential for placing the matter in its proper light before the meeting. For this purpose, perhaps the classical mode is the preferable one.

1. The laws relating to latent and sensible heat, when considered in combination with large volumes of water, and subjected to the casualities attending the steam-engine, suggests the diminishing as well as the quantities of water necessary in steam-houses, as far as practical circumstances will permit, as one of the surest means of preventing destructive boiler explosions. The importance which attaches to the suggestions these laws present becomes apparent when we consider the effects in case of explosion, which such an accident may produce, and that such sensible heat contained in the large volume of water necessary in boilers of 50-horse-power and of the usual construction, as the sensible heat contained in so large a volume of water would, supposing the pressure of the steam to diminish from 40 lb. to 30 lb. per square inch, generate a heat of 2,000 pounds of water, equal to 50,000 cubic feet. Here we have a cause equivalent to the destructive and destructive effects exhibited in common and large boiler explosions, but for which this paper refers, reduces the danger from the cause nine-tenths, though the steam be generated in it at a temperature and pressure of 100 lb. per square inch. In this case we find the sensible
heat contained in the water required by such boilers, would give but 5,000 cubic feet of steam at 20 lb. pressure. The boiler under consideration is that which is known as the Windmill, as it eliminates the strain from the reading due to the pressure of the steam—as, on a comparison with the common boiler, in which we suppose the steam at only 36 lb. pressure, the reading force in such common boiler is 6,460 lb.; whilst in the former, even when the steam is at a pressure of 2,000 lb., or but one-sixth of that given in the instance of the common boiler. The most obvious and certain conclusion to which such well-established facts, and absence of any other boilers practicable, unsatisfactory must be the objections raised against high-pressure steam, when generated in such boilers.

4. The laws relating to the expansive action of steam plainly indicate the important effect that the two leading features of the matter before the meeting—viz. that of removing the atmospheric pressure from the exhaust side of the piston on the one hand, and, on the other, enabling us to make use of the high-pressure steam with safety; as by the removal of the atmosphere in non-condensing boilers, an enormous economy is effected, by the whole of the heat being made available; and, by increasing the pressure of the steam at the commencement, can be obtained a further increased economy upon the Cornish system, equal to 60 per cent.

[Mr. Craddock here described, by means of plans, his boiler and condenser.]

Considerable discussion ensued upon the reading of this paper; the principal objections to the conclusion said to be arrived at were raised by Mr. McConnell. It was asked by him, if any trial had been made with the engine in actual work? Mr. Craddock replied, that the trial be deemed most proper to submit to the meeting was that made at the London Works, which was that he believed no safety to be purchased by that objection to the above of the condenser; and that to the authenticity of the indicator figures taken off the engine when there, he had no doubt Mr. Cowper would satisfy the meeting.

Mr. Cowper said, he had taken some indicator figures off the engine, and that it was then doing 20 horse-power—that is, indicator horse-power; the condenser then took 14 horse-power to work it.

Mr. McConnell then raised an objection, that the engine was not tested with the other engines working at the London Works.

Mr. Craddock replied, that he had always expressed a wish that it should be so tested, but the firm not intimating its assent, it was not for him (Mr. C.) to insist upon anything of the kind.

Mr. Smith, Mr. McConnell, and Mr. Cowper said, that the test of pumping water, or some such work, was the best test of power.

Mr. Craddock replied, that he was a little surprised that Mr. Buckle, the representative of an ancient and eminent firm, should object to the indicator as a fair test of the power of the engine, when it was well known that the indicator was the instrument used by them to test the power of their own engines.

It was argued by Mr. Crampton, that the only advantages the double-cylinder engine possessed over the single one was greater steadiness of motion; but this did not compensate for the loss of power, which, he considered, arose from the use of two cylinders, in the steam passing from the one piston, back into the other; and on the other hand, the experiments upon which that subject, and his conclusions thereon, were that the loss amounted to 14 per cent.

Mr. Craddock replied to Mr. Crampton, by admitting a loss in the expansion, a loss between two pistons, but that the engine before the meeting, it was obvious that this was reduced to the smallest possible amount: he further called Mr. Crampton's attention to the great irregularity of motion that would result by carrying the expansive steam into the other piston, and rolling the indicator. Mr. Craddock here referred to an experiment made on the previous evening with the small engine before the meeting; it was scarcely necessary for him to remind the meeting, that in so small an engine, when first started, the friction was considerable; yet it had worked up to its speed, with the steam cut off at 1/80th of the stroke.

Mr. Crampton replied, that the steam would lose all its power before expanding to 1/80th of the stroke.

Mr. Craddock said, if Mr. Crampton would favour him with a call at the Works, he would show him the fact experimentally. He wished further to remind the meeting that, from his own experiments, he was convinced the admission of the high-pressure steam to the cylinders was the chief advantage of one cylinder, much of it was condensed by the comparatively cold metal of such cylinder; and that the water resulting therefrom, being in contact with the metal of the cylinder, did, when placed in communication with the condenser, again assume the form of steam, thereby uselessly carrying much heat from the boiler to the condenser, without producing mechanical effect. But as he had stated his views upon this subject elsewhere, and as it may appear to the meeting a somewhat arbitrary subject, if not an altogether new one, he would not trespass upon the meeting by any further remarks upon it.

Mr. McConnell said, that he was somewhat surprised that after the length of time Mr. Craddock had devoted to the subject under discussion, he had not arrived at some more accurate data, and had not made up his mind as to the real capability and comparative advantages of his boiler.

Mr. Craddock replied, that although he had certainly devoted much time to the practical consideration of the subject, he had not directly deduced such accurate data as would justify him in stating definitely the comparative merits as to economy of coals in the generation of a given weight of steam; but, nevertheless, if Mr. McConnell would favour him with a call at the Works, he had no doubt he would be in a position to show him that he had not been idle, but he had been driving over great points, knowing full well that on these depended the economy.

Mr. McConnell said, that it appeared to him that the condenser was most valuable for some purposes, for instance in the distillation of oil, and then the advantage of high-pressure steam, which enabled them to generate high-pressure steam with safety; and thus, by carrying out the expansive principle, with other consequent advantages, a saving of 29,000,000 sterling per annum may be effected in our own interests.

Mr. Jackson proposed, that in order to test the relative values of the single and double cylinder engines, and set that question at rest—at least so far as that Society was concerned—Mr. Crampton be requested to prepare a paper and diagrams on the subject, to be laid before the members at a subsequent meeting.

Mr. Craddock suggested, that a more conclusive test would be that of an engine having two cylinders, one of which could be readily thrown out of steam, and the other kept warm, and comparing the work done by the engines, and the steam and coal required, in both cases, being accurately weighed—would give the most satisfactory solution.

The request to Mr. Crampton being carried unanimously, be (Mr. Craddock) consented to comply with such request.

HYDRAULIC STARTING APPARATUS.

Mr. Forthooff read a paper, descriptive of "A Hydraulic Apparatus, for Starting Heavy Machines, with a Prime Mover, without producing those Sudden Shocks which the use of Ordinary Clocks occasion." By Mr. Jackson.

A level piston is supposed to be connected with the engine, or other prime mover, and gears into a bevel wheel, to which is cast a rim, which is turned between the worm teeth, on the reflecting wheel in a brass bush: the shaft, however, is provided with four projections, through each of which a hole is bored—the centre lines of these holes lying in one horizontal plane, and meeting in one common central chamber. In these four holes, four pins, which are respectively cast of one piece, are cast in the bore, and, when fixed, the projecting end of each pin passes through a hole in the center holes of the rim. Supposing that the machinery, which is assumed to be connected with the shaft, required to be started, hydraulic pressure is applied to the under rams, by pressing the ram which is in the shaft down upon a small opening in the chamber, by means of a fly-wheel, which, with its nut and screw, forms one piece with the ram—this ram, the nut, and screw, being guided and supported by a brass box, which is screwed into the upper end of the shaft. It is proposed, when the shaft is depressed down, the under rams will gradually and simultaneously press the segments against the internal surface of the rim, with a power proportionate to the force applied at the circumference of the fly-wheel, until the friction produced by such pressure shall be equal to the resistance of the machinery of a similar nature, instead of causing the wheel to break, will have a tendency to make the rim to slip on the segment until the obstacle is removed, or overcome. In order, however, that too great a pressure may not be applied to the lower rams, the upper one and the screw are perforated with a small opening, the extremity of which is closed by a valve, acted upon by a spiral spring, encased in the brass box—so that if, at any time, the pressure exerted upon the rams should exceed that to which the spring is regulated, the water would enter the valve, escape through it, and through an opening in the lid of the latter into the atmosphere, until the balance of the pressure was again established.

Mr. McConnell wished to know, whether there was any other means than that supplied by the safety-valve, if he might so call it, whereby the maximum of pressure could be ascertained.

Mr. Forthooff remarked that, in fact, the machine was a self-acting regulator. A certain amount of resistance was required to make the rams exert the force of 1,200 lbs. on the springs: and the valve carried off the superfluous power. It was required to be regulated by the pressure in the engine, the engine being regulated by the steam pressure, and the steam pressure being regulated by the backward pressure. By the present invention, the pressure was confined altogether to the direction in which it was wanted. Several other members expressed themselves highly pleased with the machine; and after a vote of thanks, which had been passed to Mr. Crappington, and to Mr. Jackson, for their paper and communication, and the diagram, for the use of the members.
PATENT SAFETY BUFFER.

A paper was read "On an improved patent Safety Buffer." By Mr. Chesshire.

Mr. Buckle, in introducing Mr. Chesshire's invention to the notice of the meeting, took occasion to express his satisfaction with the principle of the machine, which, with the spiral break of the worthy president, would, be the means of doing away with railroa accidents. Former notice of the proceedings of the Institution, we have briefly described the principle of the invention. (See Journal, June 1847, p. 190.) It is proposed that every railway carriage should be supplied with a strong moveable rod of iron, solid or otherwise, as might be found most advisable, supported in the centre of the under framework by bearing sockets. This rod is merely to have an "endway motion," and is to have a head at each end, similar to the present side buffers, although it is not intended that these heads should act against each other, except in cases of the most extraordinary and extraordinary travelling state, there will be a space between the safety buffers of some few inches, which would permit the independent action of the side buffers. This safety buffer would be placed in the "van" at the end of the train, and also in the second and third cars, which would have to be fixed against strong elliptical springs will admit of, if such springs should be considered advisable. It was shown, by experiments on a model railway, that the effect of this continuous buffer was exactly that which its inventor claimed for it. A train of carriages supplied with the rods was brought into collision with an ordinary train; and while the former was unhurt, with the exception of the last carriage, which had broken from its couplings, the other was thrown into the utmost confusion. The whole force of the shock, in so far as the former train was concerned, seemed to be conveyed to, and spent on, the last carriage, which the inventor proposes should be filled with goods or luggage.

Considerable discussion followed the reading of the paper and the experiment. The chief objection was—there was not enough uniformity in the size and width of some of the various rails. Mr. Buckle, however, was the most enthusiastic in his praise of the invention, virtually claiming a patent for it, and saying that the shock of the collision could only be conveyed throughout the length of the buffer and to the last carriage, when the train was on a straight line. If, for example, it was on a curve that the collision took place, the centre carriages, or the one where the broadest carriages would have the shock of the cars, and the lives of the occupants of the carriages be sacrificed. Mr. McComb was the principal supporter of this objection. He was, moreover, argued by Mr. Ransome, that the points were the same as those of the former experiment, and that the practical disadvantage, except in one case—namely, as a strengthener of the bottom of the carriages. By the present side buffers, the force of a shock was distributed over the whole train—the first feeling the greatest amount of force. The shock was then transmitted through the carriages from the centre, or the extremity of the train, and the carriages would be thrown into great confusion, and the men upon that, would be sacrificed.

Mr. Chesshioe replied, that, with respect to the induplication of railway company expenses, he was not prepared to apply to the Committee, that the lives of the public were not of the first great consideration; and no expense and no trouble should be allowed to operate against any invention which promised to reduce the number of casualties. As for the principle of the invention he was convinced that it would be a perfect one. Accident seldom took place in curves; there the engineers were always on the look out. The force of a collision must be spent somewhere; and he could not understand how it could be an objection to his invention, that he carried it off from the cars, where damage to life would be done, and conducted it where nothing of the sort was to be apprehended. He was convinced that, if the Institution would recommend some of the railway companies to adopt the invention, it would be found to act most beneficially.

After some further remarks by Mr. Wright, Mr. Peacock, Mr. Crompton, Mr. Cowper, Mr. Fothergill, and other members, Mr. McComb recommended that the consideration of the subject should be handed over to the council, who would discuss the merits of the invention with Mr. Chesshioe, which was agreed to.

ROYAL SCOTTISH SOCIETY OF ARTS.

April 24.—John Burn Murdoch, Esq., F.R.S.E., V.P., in the Chair.

The following communications were read:

1. On the value of Gases from different Coals, and the price of Light in different places; also a new mode of estimating the Consumption of Gases, &c. and of estimating Illuminating Power." By Andrew Frye, M.D., F.R.S.E.

The first part of this paper referred to the illuminating power and durability of gases obtained from English coal, English parrot coal, and from Scottish parrot coal, with which gases, the towns in England and Scotland are supplied, and consequently to the value of these gases for affording light. Taking the illuminating power, and the durability, and consequently also the values of the gas from English coal, with which Newcastle and many other towns in England are supplied, in comparison, Dr. Frye stated, that he found the illuminating power of the English parrot coal as such that from Yorkshire and Lancashire, to be, on an average of numerous trials, 1:7; the durability to be 1:12, and hence the value, bulk for bulk, at 1:05. The value of the gas from the different kinds of Scottish parrot coal varies considerably, according to the place from which the coal is obtained; but, as in the larger towns in Scotland, a mixture of coals of different quality is employed, the gas in these towns is generally very nearly of the same quality. Taking the average of all the trials made at Edinburgh, Glasgow, Greenock, Dundee, and Aberdeen, the illuminating power was found to be 3:23, the durability, 1:58; thus making the value nearly 5, compared with the English coal parrot coal as gas 1, and Scottish parrot coal parrot coal as gas 1; in other apart-
then alluded to the value of these different kinds of coal for affording gas, and consequently for affording light by the combustion of their gases. In ascertaining this, the quantity of gas given off from the coals is taken into account, along with the value of the gases themselves for affording light. In this way he has fixed the value of the coals as follows:—English caking coal, being 1; that of the English parrot coal is on an average 2·3; and that of the mixture of Scottish parrot coal, as used in different towns, as 6.

In the second part of the paper, Dr. Fyfe alluded to the methods of finding the value of gas, and more particularly the coal gas, and to a new mode of determining the durability; in other words, the time required for consuming a certain volume of gas, and consequently the consumption in given times, and by means of which, also, the specific gravity of the gas could be ascertained. From numerous experiments, he proved that, when gas is burned in the same burners, from the same water, with the same height of flame, the consumption is as the square roots of the pressure necessary to keep up the combustion, at the length of flame fixed on; and that, consequently, the time required for the consumption of the same volume of gases is as the square roots of the pressure.

He had also come to the conclusion, that the durability, in other words the time required for the consumption, depends on the specific gravity, and that the same law is applicable; consequently, the specific gravity being known, the consumption can be determined; as the consumption being determined, by the pressure, the specific gravity can be ascertained, the rule being, the specific gravity is inversely as the square roots of the pressures, necessary to keep the gases burning, from similar burners, at the same height of flame.

Dr. Fyfe stated that he had prepared a table of the different kinds of gas, with gases which he had prepared from different coals, and also with the gases found in different towns, and he exhibited numerous tables, showing the very close correspondence between the results obtained experimentally, and by calculation.

It was published an instrument by which the durability and specific gravity, could be by the rates stated, be determined. It consists of a jet burner, of the 40th of an inch in diameter, to which is adapted a scale for measuring the height of flame, and a pressure gauge for ascertaining the pressure under which the gas is burning, at the length of flame fixed on. In this pressure gauge is fixed a glass scale, with a burner, by which the pressure can be read off, to 1/1,000 of an inch. Along with this was a table, showing the consumption of gases in a given time—the time required for the consumption of equal quantities, and the specific gravities, according to the pressures indicated by the gauge. In the table the pressures ranged from 0'100 to 0'250 of an inch, which embraces all the pressures likely to occur with the jet burner stated.

Dr. Fyfe, in conclusion, alluded to a photometer, which, so far as he was aware, is not in general use, and which he believes, with the invention of Professor Bunsen. It consists of a paper screen bescreened with a solution of spermaceti in oil of naphtha, excepting at a part around the centre. A candle placed behind this transmits light in such way as to make the part uncovered easily observed, when another light is placed in front of the screen, at a certain distance, according to the intensity of the light the spot disappears, and the paper becomes uniformly of the same appearance. In using other lights, the distance at which the uniformity on the screen is obtained, depends to a great extent on the intensity of the light, and the illuminating power of different lights is determined by the square of the distances at which they are situated from the screen. Dr. Fyfe stated that he had put this method to the test of experiment, and that the results were extremely accurate, and much more easily managed than the shadow test. He exhibited the illumination gauge burners, described by the use of which, the illuminating power, the durability, and the specific gravity of coal gases are very easily and quickly determined; and hence the value of an instrument of this kind to those travelling from place to place, with the view ofascertaining the value of coal gas in different towns; and of ascertaining the value of different kinds of coal for affording gas, and consequently for affording light by the combustion of their gases.

2. On the Composite Ellipse, as an element in the useful and ornamental arts, being the second of a series of short papers upon the Harmony of Form. By MR. B. TRAM.

Mr. Hay said that the paper and illustrations he now brought before the Society would show the composite ellipse, as he described and arranged it, was an important element in the useful and ornamental arts. He then explained the relation which his composite ellipse bore to the circle, and to the regular ellipse; also his mode of describing it, with an analysis of its composition. For this purpose he exhibited six large diagrams. He then went on to show that its beauty consisted in the variety of its parts being in an equal ratio to their uniformity; and that it was to regulate and classify the various objects of the art. He closed his remarks on The First Principles of Symmetrical Beauty,* classified a series of forty-two of those figures, by an application of the laws of numerical ratio.

Mr. Hay then stated that he had brought the same subject before the Society about thirty years ago, and had shown how the ellipse contained the various parts; and that as it bore upon the humblest productions of the potter's art, the mechanic and the cottager might have, without additional cost, household utensils of forms as beautiful as the finest specimens of the hands of the artist.

Mr. Hay then observed that it had latey been stated in the Society that his composite ellipse had not novelty to recommend it, but had long been familiar to every one who had given any attention to the subject; and that Nicholson's "Dictionary of Architecture" had been referred to in corroborative of this statement. Mr. Hay, however, stated that neither the composite ellipse, his method of describing it, nor its application to the drawing of the various objects of the art, was in Nicholson's "Dictionary of Architecture," or elsewhere, before he exhibited them to the Society, as just stated.

3. "Description of a new Ball Stop-cock for Water Cisterns; and of a Nozzles for Casks or Vats." By Mr. DANIEL EMMS.

The new ball-cock consists of two flat surfaces, ground air-tight, having port holes for the water when in certain positions, and furnished with a spiral spring, that keeps the surfaces in contact. This spring is screwed down to the bottom of the water, until it is lifted off the face, this gives it slight friction on either side, and it is not so liable to get fixed as the present ball-cocks are. The same kind will be of great advantage for gas-works, distilleries, and breweries, where large volumes are required, and will be much less expensive.

* This paper was accidentally omitted in the report of last month's proceedings.

INSTITUTION OF CIVIL ENGINEERS.

April 11th.—JOSHUA FIELD, Esq., President, in the Chair.

The paper read was the second part of a communication made in the year 1841, descriptive of the "Bann Reservoirs, County Down, Ireland." By J. F. BATEMAN, M.I.C.E.

The first part of which a short abstract was read, gave the object of the construction of these reservoirs, which were undertaken with the view of regulating the quantity of water in the River Bann, and more effectually supplying water-power to the flourishing and increasing establishments on its banks; this river, from the bare and naked character of the Mourne mountains, among which it rises, naturally liable to the greatest irregularity in its volume; devastating floods poured down the great valley, where, for a few hours previously, there was not sufficient water for agricultural purposes. Greatly injurious as this must have been to the agriculturist, it was infinitely more so to the mill-owners, who depended entirely on water-power for their manufactories. Mr. Fairbairn was consulted on the subject; he examined the locality, and advised the formation of reservoirs; the author was then appointed the engineer, and, acting in some degree upon the suggestions of his predecessor, whom he continued to consult, the works were undertaken; and which are described in the present paper. The peculiarities in the Act of Parliament, granted in 1835, constituting the proprietors of the mills a joint-stock company, for the formation of the Bann reservoirs, are detailed. The works were originally intended to have been more extensive than have been really executed. The Cottrell and Reavy is alone described; the ground in that spot was admirably adapted for that work, being the bottom of a basin, which was bounded on all sides by rugged hills of granite; in the centre of the basin was a small lake, at the bottom of which was discovered a bed, several feet in thickness, of fossil conifer, similar to those discovered by Professor Silliman, at Massachusetts, North America. This interesting geological fact was first noticed by Dr. Hunter, of Bryantford; the conifer appeared like an impalpable powder, but when viewed through a powerful microscope, they were found to be regular manufactured; and a concurrence of many of them could be observed from the centres in the root-stems. They are described by naturalists as the fossil skeletons of minute vegetables. The situation fixed upon for the reservoir rendered necessary the construction of four embankments, between the hills, so as to raise the water to a height of 35 feet above the level of the lake. The cuts and embankments are a series of a series of observations with rain gauges, continued for two years, for the purpose of furnishing data for computing the extent of reservoir which would be necessary to insure a supply of water throughout the year. The conclusion described the works, which constitute the body of this part of the paper. The reservoir, which was designed as an auxiliary pond, to receive the flood-water of the lower part of the river, and to retain the night water, to be discharged again during the day, immediately above the more extensive mills on the river. A water-cress of considerable dimensions, was constructed to effect this, and an embankment was thrown across the narrow outlet of the lake, the water being admitted through self-acting flood-gates, which closed as soon as the lowering of the river created a current in the contrary direction. The details of the construction of all these works were given in the paper, calculated upon actual experiment, and observation of the quantity of water received, stored, and delivered from the reservoirs, that their construction had increased the value of the mill-power of the River Bann full five-
field, at a comparatively very insignificant cost, as the actual expenditure for the works at Corbet Lough did not exceed £3,300—the lowest economy, consistent with the efficiency and durability of the work, being rigidly kept in view, and the utmost attention being exercised by the resident engineer, Mr. Gooc'h.

May 9.—"Observations on the Causes that are in constant Operation, tending to alter the Outline of the Coast of Great Britain, to effect the Entrances of Rivers and Harbours, and to form Shools and Deeps in the Bed of the Sea." By Mr. J. T. Harrison, M.I.C.E.

After noticing the gradual deterioration which the harbours of Great Britain are undergoing, the paper gave as the causes of these effects, the action of the tides and the tidal waves, which, even in the most sheltered of the former, would produce changes, and that Mr. Gooc'h had had meteorological changes, dwelling principally upon the tides and wind waves. Professor Airy's and Mr. Scott Russell's views on the positive wave of translation (first order), and the oscillating wave (second order), were examined, and the author took the opportunity of the former of these views to state that if the tides were tried, most of the water was in the same direction as that of the wave itself; whilst, in the latter, the motion of the wave water was alternately opposed to, and in the direction of, the wave. The tidal wave was considered as a purely oscillating wave in the open sea, changing its character as it passed into the water, as a wave, and in the sea at Poole, and in the Isle of Wight, were given, to show that such a wave was generated at the entrance of Poole Channel, from the Department of the Manche. The results of a series of experiments upon the waves on transportable materials showed that certain definite forms were assumed by sand or shingle, under given circumstances—for instance, that the roundness of the ends of the waves depended upon the size and character of the wave acting upon it. It was urgent that the end of such a foreshore to be found at 50 or 100 fathoms under water, stretching from Ushant to the south-west coast of Ireland, and that the tidal wave, in its progress up the channel, was to depend primarily upon the material thrown into it by the waves of translation from the headlands. The accumulative action was seen in the carriage of sand through the Straits of Dover to be deposited on the sand banks of the North Sea.

Referring to Mr. Palmer's paper "Shingle Beaches," the destructive, accumulative, and progressive actions of these formations were considered. The cases most favourable for the display of the effective actions of each were adduced. The influence of tides by varying the height of the water, and of an on-shore wind in facilitating the destructive action, by retaining the water, and in the progressive action was shown to prevent, in a great degree, the destructive action; whilst, on the other hand, deep water, whether from a strong in-shore tidal current, or from other causes, had a contrary effect, facilitating encroachments on the coast. The progressive action was shown to depend primarily upon the angle at which the waves strike the beach. The general question of the travelling of shingle, and of its ultimate destination, was considered at great length—instance that the accumulation of shingle at the Cheal Bank was almost certainly due to this cause. The state of the seas, the currents, the rise, and the position of the headlands, were all taken into consideration; and the paper stated that the work of Sir H. De la Beche was not a mere one of the geology of Devon and Cornwall, to show that this process was still in operation. The summary of the arguments in the paper was, that the observed changes in our coasts and the mouths of the rivers were the result of the combined action of the wind wave, and of the tidal wave; and the attention of engineers was particularly directed to these actions in different localities, in order that, by presenting to the Institution the result of their observations, an invaluable collection of recorded facts might be assembled, which would be of great benefit to the progress of geology, that was so much neglected.

May 16.—This evening was occupied with a discussion on Mr. Gooc'h's paper "On the Resistance to Railway trains at different Velocities," read at the meeting on April 18.—[See Journal, ante p. 155.]

The principal speakers were Messrs. Brunel, Gooc'h, Bidder, Locke, Harding and Russell, and their arguments were necessarily so complicated by calculations, as to render it difficult to give a correct outline of the discussion. It was contended on one side that the subject had been so treated in the paper as to make it almost a question of the comparative gauges; that the experiments upon which the arguments were founded could not be received as applicable to railways in general, inasmuch as it was presumed from the statements that the portion of the line was selected as being in the best working condition; that the engine and the carriage were also picked as being in the best order; and that therefore the results could not be applied to those peculiar cases which were tried under a working state of the line; that the amount of resistance per ton was understated by Mr. Gooc'h on these accounts, and that the rate of resistances arrived at by the committee of the British Association, by projecting trains of carriages down inclined planes, was nearer the truth than the expression of resistance arrived at with the locomotive and the dynamometer; that the tables were partly made up from the results of the experiments and by using Mr. Harding's formulae, which had been propounded in other cases as being the effect of the weight of the trains in the late experiments, as compared with those of the British Association, decomposed the value of the deductions; that the atmospheric railway could alone give the resistance due to the frostage, which was not given when a locomotive was used, and yet a positive one was supposed to be behind the engine, the resistance of the train of carriages alone could be arrived at; and that the valuation of the pressure of the wind upon the train at various angles was not satisfactory. Such a general tenor of the discussion was stated that Mr. Gooc'h had endeavoured, as much as possible, to avoid introducing, in any degree, the question of the gauges, and to give the actual results of the experiments, in order that any persons examining them might draw their own conclusions; though the experiments of Mr. Gooc'h were not selected for its good condition; that it was fixed upon by Mr. Brunel himself only the night previously to the experiments, and was not that part which had been originally intended to be used; that the engines and carriages such as could be spared from the working stock and were not picked—in fact, that they were not the best of their class; that therefore the results were not due to peculiar circumstances, but were those of the average working of the line; but that even had the line, engine, and carriages being selected, engineers would, from the results, have been able to make allowances for other cases, and that the value of the experiment would not have been diminished; that it was believed that in descending Wootton Bassets incline by gravity, without the aid of an engine, a greater velocity had been attained than the maximum recorded in the experiments of Mr. Gooc'h; that Mr. Cameron's experiments, dispassionately looking at what resulted from experiment and what from the use of formulae; that it was impossible, with engines of the ordinary weight, as now constructed, with an ordinary train, to limit the experiments to such small numbers as had been formerly used; and that in all cases the locomotive was allowed for in calculating the frostage resistance; that it was expressly stated in the paper that the apparatus for the wind gauge was not so satisfactory as could have been desired, and therefore its results were represented in the tables of Mr. Gooc'h not intended to cast any reflections upon the former experimentalists, but merely to point out the errors into which he thought they had fallen, and to induce, by his experiments, others which should fix more certainly the amount of resistance; this, it was still contended, was less than had been formerly stated, and although other experiments would be necessary to give the question completely at rest, it was unanimously agreed that Mr. Gooc'h's experiments and paper were very valuable contributions, and it was hoped he would continue his observations on this most interesting subject.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

On the 8th ult., a special meeting of the Institute was held, to take into consideration a memorial submitted to the council in April, 1847, urging the formation of the Institute, of a benevolent fund for the less fortunate members. The memorial was presented by Mr. Angell, Vice-President, laid before the meeting a summary of the proceedings which had been taken upon it, the result of which was, that the council had adopted the report of a joint committee (part memorialists, part members of council), authorising the formation of such a fund, and recommending it to the consideration of the members at large. The rule of the Artists' Benevolent Fund, that recipients must be authors of "works known and esteemed by the public," would shut out many deserving members of the profession, and there connected with it. Communication had been opened with the officers of that fund, by some who thought that the desired end might be better attained by an arrangement with them than by a fresh fund. A long discussion followed as to the mode of carrying out the views of the memorialists, and as to the necessity for the fund. An opinion was generally expressed that it was a necessary part of the administration of it to another society. Ultimately, on the motion of Mr. Angell, a resolution was passed, declaring the importance of establishing such a fund, and appointing a committee of nine, to consider in what way it could best be effected, and to report hereafter.

May 16.—Mr. J. W. Papworth read a paper in illustration of some drawings of Ponsente, ancient and modern; and Mr. J. Thomson read some observations on the ancient village church of Leigh-de-la-Mere, Wilt.
ON FLAME AND GASES.

Professor Paraday lately read a paper at the Royal Institution, "On the "Diamagnetic Condition of Flame and Gases."—Mr. Paraday having briefly recapitulated the chief subjects of his recent research into the magnetic condition of matter, proceeded to state a still more recent extension of these researches made by Prof. Bunsen at Venice. Prof. Bunsen has shown that flame, when placed beneath a powerful magnet, becomes diamagnetic (i.e. spreads out in the plane which is perpendicular to the line joining the poles of the magnet). Prof. Paraday's object was—first, to remove certain misapprehensions of his own published opinions in regard to this phenomenon; and secondly, to prove the above mentioned fact by showing that instead of clearing the surfaces of the alloys by means of acid and alkaline solutions as above mentioned, the surfaces should be filed, and the union with the cast-iron effected at the lowest temperature possible, in order that the bar of alloy might not be melted.

"The proportion indicated above for the composition of the alloy or solder is that which appears the most suitable, where the pieces of metal to be united are of moderate dimensions; but when they exceed moderate dimensions, it will be better to increase the proportion of copper employed.

"In the examples given above, it is supposed that the different metals were united together on one side only; but one of these metals may be united at two sides, or at two opposite and adjacent faces, to the other metal, or even covered throughout the entire surface. Further, the pieces of metal may have a curvilinear, angular, or any other form, and the manner of fusing may be varied according to the rules which practice has long since furnished in foundries."

THE EFFECTS OF ZINC ON IRON.

A letter from Mr. James Nasmyth, of Bridgewater Foundry, Patricroft near Manchester, to the Mining Journal, communicates the results of some experiments recently made at the desire of the Lords of the Admiralty, with a view to determine whether old iron that had been galvanized, or coppered, was rendered more durable by the zinc coating. The results of these experiments seem to prove that the quality of the iron is improved instead of being deteriorated by the zinc combined with it.

The following is Mr. Nasmyth's report of the experiments:

"The object of galvanizing iron-wire was to weld it in a bar, and put it to the most severe test. In the first place it was found, that although the iron-wire was quite covered with metallic zinc, which, although partially driven off in the process of welding, yet so far from the presence of the metal, or its oxide, presenting any impediment to the welding of the iron (as in the case of lead), the iron-wire welded with remarkable ease; and the result was, a bar of remarkably tough, silver-grained iron, which stood punching, splitting, twisting, and bending, in a manner such as was not shown by the iron before it, but, of course, not quite so good as to all appearance, actually improved in quality in a very important degree."

"Encouraged by such a result, a still further, and even more severe, trial was made—viz.: by welding up a pile of clipings of galvanized iron-plate, or blister-iron, covered along the former experiments. The presence of the zinc appeared to offer no impediment to the welding, and the result was, a boom or bar of iron—the fracture of which presented a most remarkable and beautiful silver grain—as good, if not superior, in aspect to the finest specimens of 'Low Moor' or 'Bowling' iron. Bloom of this iron were rolled out in rods, and tested in the cable-proving machine, and the result indicated from 5 to 10 per cent. higher strength than the best samples of wrought-iron—thus establishing the fact, that, so far from being detrimental to the strength and ductility of wrought-iron, the contrary is the case."

"It may mention, that bars of iron were heated to a welding heat, prepared for sheathing, in the usual manner; and, on drawing them from the fire, and when quite cool, I unwound them from the welding hot surface, and the welding proceeded with. In this severe test no apparent impediment to the process resulted; the iron was as good as if no zinc had been present."

Mr. Nasmyth infers from these experiments, that some improvement might be made in the manufacture of iron, by the introduction of metallic zinc in the puddling furnaces. In corroboration of this opinion, he addsuce other reasons to the strongest cast-iron made in Belgium, and selected for the casting of guns, is made from an iron ore in which the ore of zinc forms a considerable portion.

Mr. Leighton, of Cwmamman, following up the suggestion of Mr. Nasmyth, has communicated other applications of zinc to iron, which he had devised for the purpose of improving anthracite coal more into use. His object was the preparation of pure oxide of zinc to be used as paint, for iron-working more especially, for making joints, &c., in lieu of white-lead. If it be observed, people could be once induced to make a trial of anthracite coal, worked by a blast, for several manufacturing operations, the value of this peculiar fact would be established. It only requires a beginning; it is quite possible to treat the surface of zinc—very abundant ore, known as blende, or black jact—so that pure oxide of zinc..."
END and sulphuric acid should be prepared by the same operation. This would be very profitable business, and create a consumption for a considerable quantity of the ore; but at the present price of the metal, it would even pay handsomely to prepare oxide of zinc from spelter. Say, in round numbers, 4 cwt. of spelter, worth £2 16s., would yield 5 cwt. of oxide of zinc, which, at the price of dry wood, would be worth £2; the cost of labour and fuel being trivial, there would be a profit of something like 10s. per cent."

SUPPLY OF WATER FROM THE NEW RED SANDSTONE.

A paper "On the Supply of the Town of Liverpool with Water from Shale sunk in the New Red Sandstone," was lately read at the Polytechnic Institution, Colquitt-street. — After some observations, as to the importance of a plentiful supply of pure water, the lecturer remarked that the original source of water in the earth is the rain which falls from the clouds. Though the fall of rain at Liverpool was only about 36 inches per annum, in the interior and hilly parts of the country it was far greater: for instance, in 1845, there fell at Southwark 131 inches; Grassmere, 121; Buttermere, 87; Keswick, 92; Whitehaven, 49; Cockermouth, 47; and at Manchester, the fall was about 11 inches. He had examined various springs in the new red sandstone, and had never found any above the mean temperature of the climate; and concluded, therefore, that those in the new red sandstone were entirely supplied from the rain which falls from the clouds, estimated in that district at 35 inches per annum. Allowing 18 inches for evaporation and vegetation, would leave 18 inches absorbed and stored in the earth every year, giving 392,040 gallons per acre, or 250,000,600 gallons per square mile. He maintained that the strata of the new red sandstone, at a level below the surface of the sea, are naturally, and thoroughly saturated with water; and that any shaft or excavation sunk to that depth, will always, through lateral percolation, be full of water to that height. He considered the most desirable mode would be to sink shafts from 1,000 to 2,000 feet deep, which would pierce a stratum highly saturated with water, and which would be filled to within a short distance of the surface. He objected to the plan proposed by some persons to be adopted, that of bringing surface water from a distance, as all such was impregnated with millions of seeds of animalcule, to the great detriment of public health. In conclusion, he stated as his decided conviction, that the strata of the new red sandstone formation are not yet exhausted of their water, neither do they show any symptoms of exhaustion, neither is it possible to exhaust them, so long as they maintain their natural connection and geological position, as long as they consist of innumerable beds of variable hardness, and of variable porosity; as long as they are capable of lateral percolation; so long as the hydrostatic pressure of the sea enables them to keep their lower beds at the full point of saturation; so long as their upper beds are greedily absorbing the water. He annually pours down upon them more than 500,000,000 gallons of water upon every square mile of their surface.

THE VENTILATION OF TOWNS.

We have received from a correspondent at Liverpool, a description of a plan, which he has for a long time considered, for effectually securing the ventilation of large towns; and if capable of being carried into practice, it would have the effect of not only ventilating the houses in crowded neighbourhoods, but it would also purify the drains, the exhalations from which are frequently the cause of disease throughout large districts. The communication is too lengthy to be given entire; we shall therefore only give in a general statement the main points of it. It is proposed that in each town one or more high, large chimneys shall be built, with which all the main-drains shall communicate; and that the fire-places of each house, instead of having chimneys carried through the roof, shall have flues carried below and entering the chimney. At the bottom of each of the large ventilating chimneys, fires are to be kept burning for the purpose of causing sufficient draught. This plan, which carries out on an extended scale the mode adopted in ventilating the Houses of Parliament and other large buildings, offers important advantages as a sanitary measure, and, at a moderate expense, to be discarded as impracticable without due consideration. The writer, who is an engineer, affirms that he has tested its practicability, by detailed calculations. We will now let him develop the plan in his own words:

"It is proposed, that all house and factory chimneys be discontinued, and be replaced by large, air-tight, handsome, and being discharged at the roof, be made to descend, pass into the house-drains, and through them into the public sewers; the factories having special communication for themselves. It is further proposed, that the sewers be arranged to converge and join into larger or main sewers, which would be conducted through the town, to the highest and least-occupied ground in the district, where these large sewers, or tunnels, would terminate in chimneys of great height and capacity, placed at suitable distances apart; and in these chimneys, fires would be maintained constantly burning, for the purpose of conveying the necessary draught. Besides the communications for withdrawing the smoke from the house-fires, the writer proposes to provide orifices in each apartment, connected with the drains, which could be opened and shut by the inmates at pleasure, and there would also be openings at suitable distances along each court, lane, and street, communicating with the sewers. Still more clearly to illustrate his views, suppose we take the case of Liverpool, to be the situation of the writer's house to be as follows. Let us suppose that four or five large chimneys were erected along the brow of the hill which bounds that town to the east,—one to provide for ventilation of the north-end, one for the south-end, and two or three for the middle district; that leading tunnels were driven downwards towards the river, which tunnels would communicate laterally with, and receive the air and smoke from, the street sewers. Then, let us see how this plan would operate:—Suppose a powerful current upwards, was established in the large chimneys, tunnels, and sewers, it follows that,—Firstly, the sewers and drains themselves would be no longer given up to smoke and exhalations. Secondly, by opening the apertures in the streets and courts, we would withdraw the impure air, and produce a constant influx of pure air, which would descend from above. Thirdly, by opening the orifices in the houses and apartments, although they were crowded with inhabitants, yet the whole would be renewed, and replaced by that both fresh and pure, that no injurious consequences would ensue. Fourthly, there would be no more smoke or sulphurous vapour to destroy health, and soil everything exposed to its vile influence; the murky clouds which envelope our manufacturing towns, would disappear, and give place to clear skies and a pure invigorating atmosphere. But it will be said, there would be serious difficulties to contend with in the execution of such a plan; this is granted—but they are far from being insuperable; in proof of which, the writer will now proceed to consider some of them, only avoiding matters of engineering detail. It may be objected that such a scheme would prove costly: it is not denied that it would require the outlay of a large, though by no means extraordinary, sum of money; but can we expect to realise great benefits without proportionate expenditure? If it cost a million to supply such Liverpool with water, why should we grudge a very much smaller sum to supply the same town with air? The one is surely as essential to the well-being of the community as the other; and the writer is prepared to show that a large saving of money would accrue, which is at present expended by the adoption of such a plan, irrespective of the immense benefits to the public health. There would be no factory chimneys to erect; a great saving in the arrangement for house-fires, which cannot here be detailed; smaller houses and smaller apartments would suffice for any given number of individuals,—consequently, there would be an economy in building arrangements, accompanied by lower rents. The same remark applies to streets, lanes, and courts: look at the enormous sums which would be required to alter and widen them, and by that means improve the ventilation. Then consider the control which would be vested in the authorities over the public health. At present describing the district in larger and in larger thus briefly stated. It is proposed that in each town one or more high, large chimneys shall be built, with which all the main-drains shall communicate; and that the fire-places of each house, instead of having chimneys carried through the roof, shall have flues carried below and entering the chimney. At the bottom of each of the large ventilating chimneys, fires are to be kept burning for the purpose of causing sufficient draught. This plan, which carries out on an extended scale the mode adopted in ventilating the Houses of Parliament and other large buildings, offers important advantages as a sanitary measure, and, at a moderate expense, to be discarded as impracticable without due consideration. The writer, who is an engineer, affirms that he has tested its practicability, by detailed calculations. We will now let him develop the plan in his own words:

"Solvent power of Chloroform.—The powerful solvent capabilities of chloroform are now, by experiment, fully established. Coals, charcoal, coal-tar, copal and gum-lac, bromine, iodine, the essential oils, &c., yield to its solvent power. This property may, it is believed, prove extensively of advantage in many of the fine and useful arts."
LOCOMOTIVE CARRIAGE WHEELS.

Edward Evans, of the Haigh Foundry Company, has obtained a patent for "certain Improvements in the mode of constructing iron wheels."—Granted October 28, 1847; Enrolled April 28, 1848.

This invention consists in a mode of securing the tyre or hoop of the wheel to the spokes or inner rim, without the use of bolts or rivets. The patentee effects this object by using a dovetail groove in the tyre, and a dovetail projection on the rim, which is a method that has been previously adopted, therefore he makes no claim to that; but the peculiarity of his invention consists in making the groove larger than the projections, and filling the interstices with melted zinc. In the words of the specification, the patentee claims "the manufacture of wheels in which the dovetail groove in the tyre is wide at its narrowest part than the dovetail projection on the spokes or the inner rim of the wheel is at its widest part, and the filling the spaces left when the tyre is shrunk on with melted metal or other hard substance." The accompanying section of the tyre and its junction with the wheel, will sufficiently show the form of the grooves and projections. The dark portions represent the zinc or other easily-fusible metal with which the spaces are filled.

LOCOMOTIVE ENGINE.—George Heaton, Birmingham, engineer, has obtained a patent for "Improvements in locomotive engines." Granted November 9, 1847; Enrolled May 9, 1848.—The object of this invention is to prevent the oscillation of locomotive engines on railways; and the patentee endeavours to effect this by the application of counter-balance weights, moving in an opposite direction to the pistons of the cylinders. The mode of applying these counter-balance weights is as follows:—On each end of the axle of the driving-wheels is placed a crank, to which is united a connecting-rod attached at the other end to the counter-balance weight, which is suspended between two rods, so as to swing round it and from it, or it is held between fixed guide-rods, to admit of its sliding easily. The counter-balance weights should always move in the direction opposed to that of the pistons, and should be as heavy as the combined weight of the pistons and the working-gear.

COMPOUND BEAMS OR GIRDERS.—Henry Fielding, Maidstone, has obtained a patent for "Improvements in iron beams or girders." Granted November 9, 1847; Enrolled May 9, 1848.—The patentee constructs his beams partly of malleable, and partly of cast-iron. The lower or tension flanges are made wholly or partly of malleable iron, while the centre rib and upper or crushing flanges are wholly or partly of cast-iron, according to the duties they have to perform. The lower flange may be made of, or strengthened by the addition of malleable iron, and the centre rib and upper flange remain of cast-iron; or, the upper and lower flanges may be of malleable iron, united to the centre cast-iron rib, and further strengthened, when exposed to vibration, by angle-iron; or, the perpendicular ribs may also be composed of malleable iron, when exposed to violent concussions. The malleable iron is united to the cast-iron by hot rivetting, and, in all cases, in such proportion that it shall be able to support, alone, the estimated weight to which the whole girder may be subjected. The lower flange is united secondly, in the application of the preceding principle of construction to the strengthen-long or repairing of existing beams or girders, with such variation of detail as the particular case may suggest; and thirdly, to the construction of beams or girders composed entirely of malleable iron, in which case the flange united to the centre rib by angle-iron, the coupling-joints headed, and the whole are fastened together by hot rivetting.

ELECTRICITY OF MINERAL VEINS.

Mr. Robert Hunt (keeper of mining records at the Museum of Economic Geology) lately delivered a lecture on the "Electricity of Mineral Veins," at the Royal Institution, Albermarle-street.

The lecturer commenced by remarking, that the class of phenomena which would form the subject of consideration that evening, although of the highest interest, had not yet received so great an amount of experimental examination as their importance required; and, as their curious nature was, consequently, not generally known, he trusted that, having spent many days and nights in the mines of Cornwall, in this investigation, he should be able to interest his audience by a narrative of the facts now known, as well as some of a novel character.

As a preliminary of absolute necessity, Mr. Hunt explained the nature of a mineral lode by the aid of a beautiful isometrical drawing of the lead district of Nentafford. A lode was, in fact, a fissure, formed by some disturbance of the earth, and filled with mineral deposits. Three theories prevailed as to the origin of mineral lodes; in the first place, they were supposed to be contemporaneous with the rocks themselves; secondly, it was conceived, that fissures were filled by the sublimation of matter from great depths in the earth; and, lastly, that substances were precipitated from solution in water, which flowed through those great rents in the earth. A mineral lode was not generally composed of metallic substances; on the contrary, they were most frequently found containing a large portion of earthy matter, amongst which the metallic ore was disseminated. Among indications which appeared to support the theory of electrical action in these formations, were to be regarded, the different disposition of these substances on either side of the lode. The electrical theory might be explained in a few words. Ampere supposed that currents of electricity traversed the earth from east to west, and these currents were thought to influence the chemical changes which had gone on during the formation of the lode, and determine the order of arrangement. The most striking conditions which appeared favourable to such a view were, that metals of various kinds were associated with peculiar classes of rocks—tin and copper being associated, in a remarkable manner, with the primary rocks; while lead was found more abundantly in the limestone formations. These rules, although general, were not constant—many striking exceptions might be named. In the remarkable mining county of Cornwall the rocks were granite, kyllas or clay-slate, greenstone, and elvan. The mineral lodes were always most abundant near the junction of the slate and granite rocks; they were generally found in a direction nearly from north-east to south-west; and where they were contrary to this, or nearly in the line of the magnetic meridian, there was almost invariably a great difference in the character of mineral substances contained in the lode. This was shown by reference to the map of Cornwall upon which was marked, that the lead and copper were accurately marked. Again, a very remarkable parallelism was observed in most districts between the directions of the lodes, and the veins of granite proplyhy (elvan) which occurred in their vicinity; and this fact had been brought in support of the theory, which refers mineral formations to the action of subterranean heat.

The various questions which arose out of the phenomena of mineral veins, and their including rocks, had been most ably treated of by Sir Henry De la Beche, Mr. Joseph Carne, Mr. H. W. Fox, Mr. John Taylor, Mr. Hopkins, and others; he would not, therefore, dwell on that part of the subject.

Mr. Hunt next considered, whether any of the conditions known to belong to the rock formations of a mining district were sufficient to produce electrical phenomena. It had been ascertained that, when the temperature was below what is called the isothermal line, the temperature in the earth. By this means, it was evident that any given portion would represent a bar unequally heated. The following table of temperatures, obtained in the rock and lode, exhibited the variations of temperature in the deep mine of Tresawe:

<table>
<thead>
<tr>
<th>Temperature</th>
<th>Description</th>
<th>Value</th>

According to the generally received views of thermo-electric...
action, such differences would be sufficient to produce currents. That was undoubtedly the case in metallic and good conducting bodies, but no such result had been obtained from experiments on granite, slate, slaven, or greenstone—connection being made with them and a very delicate galvanometer, upon which not the slightest indication of any action on the needles could be observed.

When moist, these rocks became over their surfaces conductors; and, by this means, the action on a single pair of zinc and copper plates, not more than an inch square, was detected through a considerable emf in the circuits observed in the lodes themselves. In some bodies, quartz, lime, pyrites, barytes, fluor-spar, argentiferous lead, and quartz, alternated in the most regular order, as was shown by specimens from the mines of Cornwall, Derbyshire, Hanover, and Mexico—present features so analogous to those which often appear in galvanic experiments, that we are compelled to consider as a necessary condition of the electric force was concerned in the phenomena. Specimens of pseudo-morphous bodies from the Cornish mines, and arrangements of brown spar upon quartz, from Schenmitz, quartz upon fluor-spar, and iron pyrites, and the double sulphuret of copper upon large quartz crystals, in all of which a uniform system of arrangement, perfectly independent of each other, was shown—and these were to be referred, in all probability, to the disposing power of electrical currents.

Such were the principal evidences to be adduced in support of the electrical theory. Mr. R. W. Fox was the first to discover and indicate the action of electricity in mineral lodes. By placing copper wires against two portions of a lode, or of two lodes divided by a cross-course, and connecting those wires with a galvanometer, a considerable deflection of the needle was obtained—often to such an extent, that from the violence of the action, it was impossible to note the deflection. In nearly all the mineral lodes of Cornwall, upon which experiments were made, these currents had been detected. Experiments made by Mr. Fox, in Coddberry and Skeers, in Teesdale, gave, however, negative results; and the extremely small size of the lodes at the Mold mines (of which very gratifying evidence was given by Prof. Reich, of Freiburg, obtained very decided results upon the lead and silver lodes of that district; and, in one case, succeeded in detecting a mass of silver ore at some distance behind the rock. Von Strombeck, on the contrary, could obtain no results from the lead lodes over the northern part of the Rhine. In addition to these results, others of a most satisfactory kind had been obtained by Mr. Henwood and Mr. John Arthur Philipps. The lecturer had himself almost invariably obtained very decided galvanometric indications from the copper lodes of Dolcoath, East Wheal Crofty, East Pool, and other Cornish mines—in one instance so powerfully, that the electro-chemical decomposition was produced. Mr. Fox has been successful in procuring an electrolyte copy of an engraved plate by the current collected from two lodes of iron and of copper pyrites, and also in inducing magnetism in a body of iron, as Mr. Pattison, at the wish of the British Association, made a series of experiments and found it to be true that the iron's in the lead districts of the north; but he could not detect any evidence of electrical currents.

It now became a question, to ascertain if these currents of electricity, detected in mineral lodes, were in any way connected with the natural current observed in the lodes themselves, and of Ampere; or, were they of a more local character? The lecturer was induced to conclude, from all his experiments and observations, that these currents were entirely local, and due to the chemical action going on within the lode itself. In all cases where chemical action was present, it is apparent that the current detected by the galvanometer was more energetic than where no chemical change was apparent. In this way might be accounted for the failure of Strombeck on the lead and copper lodes of the Rhine, and of Mr. R. W. Fox himself on the lodes of Teesdale—in all probability, those lodes being in a very permanent condition. It was thought by the lecturer that the fact, that these currents often being found to traverse the lodes in a direct current, contrary to the currents of Ampere, and frequently at right angles to them, militated against those views which referred the phenomena to the action of the earth. The lecturer had also detected currents from piles of ore on the surface, which had been exposed to the influences of the atmosphere; and these currents were certainly only measures of the amount of chemical action going on in the pile.

That these local lode currents might have a powerful effect upon masses of matter exposed to their influences, was highly probable; and he was disposed to refer the conditions in which cobalt and nickel were often found in the cross-courses, between the ends of dislocated lodes, as due to this local chemical electricity. The character of many of the decomposing lodes was next described; and it was shown that, under the influence of the percolation of rain-water from the surface, charged with oxygen, and the action of the saline water rising from below, few lodes admitting water to flow through them could be free from chemical action. He had analyzed the waters of many of the deep mines, and the following were the results of a few of these analyses:

The water from Great St. George contained, in a cubic foot, 590 grains of common salt; that of the United Mines, rising hot, 481 grains; of Dolcoath, 218 grains; of Great Wheel Charles, 612 grains; and the dislocated lodes, as at fathoms, 656 grains; and at the 250 fathom level, 918 grains. This muriate of soda was estimated quite independently of the earth and mineral salts. It was, doubtless, derived by infiltration from the ocean; and, from its quantity, acted, no doubt, powerfully upon the lodes it traversed. Although these currents, detected by the galvanometer, were not regarded by the lecturer as the result of an electrical agency in the formation of mineral veins, yet the evidence obtained by Mr. Fox, by Mr. Jordan, and more recently by himself, that electricity would give to clay a schistose structure and form along a curved line, no doubt, related to some line of electrical action, a miniature lode of copper (of which illustration was exhibited) supported the general view of electrical action. Incidentally, the conducting powers of iron and copper pyrites, galena, and some other minerals, were experimentally shown; and also the decomposition of yellow ore by electrical action.

In conclusion, the lecturer gratified all the main points of evidence, for and against the electrical views, and pointed out many very curious circumstances, evidently dependent upon some peculiar conditions of the adjacent rocks, but which could not be referred, with any certainty, to electrical action. Probably, these currents now nearly determined as in constant flow around the earth, might produce the curious results observed; but a far larger amount of experimental evidence than that yet obtained was required, before this view could be admitted as one of the received facts of inductive science.

NOTES OF THE MONTH.

Baron de Goldsmid's House. — The grand ball-room at St. John's Lodge in the Regent's Park, of which so much has been spoken and written, was last week, for a party given by the Baron de Goldsmid. The effect is reported to have been most admirable. Although Mr. Barry and Mr. Poynter had exerted every care, the effect of light upon the decorations must have caused them some anxiety, and it must be most gratifying to them to have succeeded so completely. The richness of the gilding contributed to the grandeur of the room, without destroying its air of chasteness; and if Mr. Barry be reproached that there is a want of rest in the House of Lords, and too great profusion of ornamentation, the same objection cannot be made against the ball-room. This salon is the great work of the present school of art, and it is with a high degree of satisfaction that the Baron de Goldsmid has been, as usual with him, displayed in the reconstructions of English artists, instead of being lavished upon foreigners, as is too common with our nobility.

Mineral Production of Austria.—The latest published government accounts give the following as the mineral produce of Austria: Gold, 25 cwt.; silver, 547 cwt.; mercury, 1661 tons; iron, 148,579 tons; copper, 2,753 tons; lead, 6,666 tons; litharge, 1,299 tons; zinc, 227 tons; calcamine, 908 tons; tin, 49 tons; antimony, 231 tons; cobalt, 132 tons; manganese, 68 tons; arsenic, 50 tons; plumbago, 1,977 tons; alum, 1,944 tons; sulphate of iron, 5,354 tons; sulphate of copper, 289 tons; sulphur, 1,259 tons; coal, 524 tons.

The Holyhead Steam Packet.—The principal ship of the new Holyhead steam packet Lleynigol, master, Commander Jerry—engineers designed and manufactured by Miller, Ravenhill, and Co., of Blackwall—took place on Monday, the 15th ult. It is stated that, under adverse circumstances, she made four runs at the measured mile, at Long Reach, which
gave her an average rate of speed of 15-415 nautical miles, or nearly 174 statute miles per hour, never making less than 27 revolutions per minute. She then ran to the Norse light, passing the distance from the town pier at Gravenor’s, in one hour and fifteen seconds; and then ran from the Norse light to the New York Lightship, a distance of about 70 miles, with an average speed of 202 statute miles per hour, and her lowest rate at 15-945. The latter, however, in consequence of the throttle-valve being open, was held to be a ball trial, and she was accordingly tried up and down again the 700 knots’ distance along the Hudson at 16,719 knots; and the return trip in 304 minutes, or at the rate of 15,049 knots. Taking the average of the two last runs, the speed of the Leonidas was nearly 187 nautical miles in 24 hours, or at an average speed of 78-1 statute miles per hour.

The New Steam-Ship Basin at Portsmouth. — This national work, which has been constructed with the view of affording to steam-ships a fitting and convenient place of reception, was opened on Thursday, the 25th of May. The first stone was laid January 13th, 1845. Its original design was far from complete, but as the business connected with the establishment was so far advanced, suggestions were made to extend the plans to their present spacious dimensions. Its mean average length is 274 feet, 400 feet wide, and 31 feet deep from the coping, covering an area of more than seven acres. The entrance is 80 feet wide, and the depth of water at previous tides is 21 feet. There is also a fine wharfage outside the basin, in the harbor, where there is water to the depth of 13 feet, which is sufficient to accommodate second-class steamers. There are two inlets on the east side of the basin, long by 200 feet, and 30 feet wide from the coping; these are to enable vessels, whole freight must be completed in a hurry, to be worked upon by the artisans on both sides at once. On the west brink of the basin is a great factory, of handsome architecture, 867 feet long by 170 feet wide, partially or wholly enclosed by a wall. The south wall is a new brass foundry, 90 feet by 110, which has been for some time in partial working. The basin is considered capable of accommodating around its sides nine steam frigates of the first class, and has employed, on the average of 7 months since its commencement, besides an immense body to whom it has given work off the premises, 60 persons engaged. Besides the above materials, there have been used in various parts of the whole about 2,500 tons of cast iron from Staffordshire. The rough cost of the labour already turned out of hand is $600,000.

Glenelg Diving of the Niagara River. — The following extract of a letter we have received from the United States, describes a very curious phenomenon, which recently alarmed the residents near the Falls of Niagara. It is a great pity that people do not so generally alarm at least once a year, fearing that the bottom of the river has been washed away at once the mills ceased to work, and great part of the tables on Table Rock were bare. The river, a little above Goat Island, was bare for half the distance across. A gentleman drove his wagon on the bare rock to the middle of the bed of the river, where to have a foot of water at previous tides would have been certain death. The worst fears were entertained; some believed the whole world was coming to an end—inferior, fear was stamped on every countenance till the cause was explained. The fact was, that a quantity of ice on Lake Erie had drifted to the mouth of the river, and impeded its flow.

Suspension Bridge near the Falls of Niagara. — The first car, suspended by a wire cable, carrying a horse and a group of people, crossed the Falls of Niagara on the 18th of March. Mr. Elliott, the engineer who has undertaken the construction of the suspension-bridge at that place, was the first person who crossed over, amidst the cheers of a large concourse of people. The Toronto Commercial Intelligencer says: "The great and commodious pride that he is the first man who ever crossed in a carraige through the air, on wire, from one empire to another; thereby, it is to be hoped, leading to a happy, prosperous, generous, and reciprocal union—a firm chain of friendship between mother and daughter." We may suppose that among those who experienced alarm at the sudden draining of the Niagara river, noticed above, the shareholders in the suspension-bridge undertaking, were not less frightened than the others.

Communication from the Ministry of Public Works. — A number of the plans proposed for establishing a communication between the passengers and the guard, and through him with the engineer, on railway trains, has been recently patented. The inventor of this plan is Mr. David Tattersall, of Newcastle-upon-Tyne, and it consists in connecting each carriage with the roofs of the next one or the one below, by means of a cable or rope, which is wound on the cylinders of a steam-engine. In order to remove this objection, Mr. Lafond has proposed to him the employment of chloroform in place of ether.

Cause of Rain. — At a recent meeting of the Paris Academy of Sciences, M. Lefrançois explained the causes of rain by referring to natural and artificial phenomena. He supposes that a volume of humid and heated air rising into the upper regions of the atmosphere, expands in the rarer air; consequently, the temperature becomes lower, and the vapor contained in it begins to condense, if it be not already in that state. In this theory, it fails to assign an intelligible cause for the observed phenomena of rain. It is founded also on the questionable assumption, that the portion of the atmosphere near the earth’s surface, heated into the air, is driven into the upper regions, while the air around it is cooled by the pressure of the atmosphere at higher elevations, causes a greater difference
In the relative weights of equal volumes than the different degrees of heat above and below. M. Babinet, indeed, seems to admit this, as the expansion of the humid air he supposes to be caused by the rarer state of the upper part, before he seems to think into coast that the denser and heavier air would not rise into the lighter.

Analysis of Phosphates.—Messrs. Dumas and Pelouze have reported very favourably of the process adopted by M. Raewsky, to ascertain the proportions of phosphoric acid contained in phosphates. The process consists in precipitating the phosphoric acid from an acid liquor by means of the excess of the peroxide of iron, the salt will be precipitated pure, and can consequently be collected in a filter. After a careful washing, if it be dissolved in nitric acid, and reduced to the minimum state of oxidation by the aid of a suitable agent of solution, there will remain to saturate the restored to this state by means of the proportion of permanganic acid necessary to convert it again into peroxide.

Rotary Heels.—A patent has been taken out for rotary heels to boots and shoes, so that, however unevenly a person may tread, the heel may be regularly worn by giving it a turn daily, to expose a fresh surface at the part most trodden on.

Invisible Musicians.—Mr. A. Bain, the ingenious inventor of electric telegraphs and clocks, has obtained a patent for an invention, part of which consists in causing musical instruments to be played by electro-magnetism, without the apparent agency of any musician. He effects this by placing electromagnets under the keys of the instrument, and these magnets are connected with wires some other similar instrument in another room, and when the wire is operated for some time in the same town, the keys of the original instrument are pressed down by the performer, it completes the electric circuit, and induces magnetism in the temporary magnet under the corresponding key of the distant instrument, and that instrument is instantly and soundly played off, and the same may be continued through several instruments, every one of which would be played at the same time by one performer, who would be touching the keys of only one instrument, and that, perhaps, a mile apart from the others. In this way, Mr. Bain’s instrument is proposed to dispense with performers altogether, and to make the printed music play itself. This is done by perforating holes in a sheet of paper, which is drawn over the openings of wind instruments. Whenever the perforated holes come in contact with the inlaid plates, the holes are sounded; and by arranging the perforations at their proper distances, the tune is played.

Manufacture of White Lead.—Some improvements in the manufacture of carbonate of lead have recently been patented by M. Jean Marie Fourcument, of New Bridge-street, Blackfriars. In this process, the carbonate of lead is produced by the decomposition of oxichloride of lead (obtained by the action of sea salt upon protoxide of lead), by means of carbonic acid, which decomposes the oxichloride; an insoluble carbonate of lead being produced, and a solution of chloride of sodium remaining.

Triple Railway Break.—A model of a triple railway break, invented by M. Leignet, has been submitted to the Paris Academy of Sciences. Each part of the break must be successively destroyed before any material damage can be done, and the resistance offered is calculated to be sufficient completely to overcome the momentum of the train. The resistance of the break is independent of the engine-driver, and it is constantly ready to act when occasion requires. The same given to this break is Parachute.

New Rife-Barrel.—A new mode of forming the spiral-inside rifle-barrel has been patented by Mr. Leignet, in which instead of making the barrel in a regular helical form throughout, that form is adopted only in the first half of the barrel, commencing at the breech; the other portion being on an uniformly accelerating geometric curve. The advantages said to be gained by this method, are reduction of the recoil, and a sustained spiral motion without the present liability in rifles of stripping the barrel, and a larger range with the same charge of powder.

The College at Putney.—The Admiralty experiments on coals for the steam navy, are continued at Putney College, in the buildings erected there by government for that purpose. Dr. Lydekker has recently constructed for that college, the largest magnet that has hitherto been made.

Mammot Machine.—The Renfrewshire Reformer notices the machine by Messrs. T. Shanks, of Johnstone, an immense slotting machine for cutting and dressing large structural steel, the cranks and cross-heads of the largest marine steam-engines, finishing them throughout, from the rough block as they come from the forge. The machine is erecting for Messrs. Fulton and Nelson, of Leechfield Forge, and the weight of the single casting which is cut from the image is 28,000 lbs. This was executed by Messrs. John Goldie and Co., of the Hayfield Foundry, and took four months in the moulding.

Manual Power Locomotive.—A Manchester paper states that Mr. Archibald Pearson of Overcloy (a mechanical engineer of that town) has invented a locomotive to be propelled by manual labour, which was successfully driven on several of the streets of Manchester. The carriage was stopped every now and then, to allow parties to inspect the movement of the machine—whereupon the driver to causs the cranks to a most muscular effort, aided by manual dexterity. The machine weighed 8 cwt., and the cranks, and has been worked by one man up an incline of 8 feet in the yard, while twelve persons were in it.

LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM APRIL 27, TO MAY 26, 1848.

Six Months allowed for Enrolment, unless otherwise expressed.

William Newton, of Chancery-lane, Middlesex, civil engineer, for "Improvements in machinery for burning, glazing, and cutting wood and coal, and similar fibrous materials requiring those processes."—April 27.

Edward Walmesley, of Heston Norris, Lancashire, cotton spinner, for "certain improved apparatus for preventing the explosion of steam boilers."—April 27.

William Henry Barrow, of Derby, civil engineer, and a son of Forster, of Stockhom Common, Survey, gentleman, for "Improvements in electric telegraphs and in apparatus connected therewith."—April 27.

Thomas Edmondson, of Leominster, machinist, for "Improvements in marking and numbering railway and other tickets or papers, and in arranging and distributing tickets."—April 27.

Dorothy Pratt, of Worcesters, in the State of Massachusetts, America, for "machinery for connecting railway carriages."—April 27.

James K. Howe, of the city of New York, in the United States of America, for "Improvements in building ships and other vessels."—April 27.

William Henry Barrow, of Derby, civil engineer, and a son of Forster, of Stockhom Common, Survey, gentleman, for "Improvements in electric telegraphs and in apparatus connected therewith."—April 27.

Dorothea Fielding Palmer, of Birmingham, for "a new or improved chalybeate water."—April 27.

Alexander Parker, of Birmingham, experimental chemist, for "Improvements in the manufacture of certain metallic salts and other substances."—April 27.

William John Normannville, of Park Village, Middlesex, gentleman, for "certain improvements in railway or other carriages, partly consisting of new modes of constructing the axle-boxes and journal-boxes, and also an improved method of boiling and finishing the various parts of the wrought iron or other portions of machinery, by the introduction of aqueous, alkaline, cold galvanic, or spurious solutions."—May 2.

Isaac Hares, of Rosedale Abbey, Yorkshire, farmer, for "certain Improvements in machinery for setting the treading and mashing lead."—May 2.

Isiah Davies, of Birmingham, engineer, for "Improvements in steam-engines and locomotive carriages, parts of which are also applicable to other motive machinery."—May 2.

Alexander Southwood Stocker, of York-place, City-road, Middlesex, gentleman, for "certain Improvements in time teachers and boxes, show cards, or holders for matches, trees, pins, etc., and other articles, and in the mode or modes of manufacturing the same."—May 2.

Polidet Baison Selligne, of 6, Boulevard Beaumarchais, Paris, for "certain Improvements in propelling and the machinery employed therein." (A communication from her late husband.)—May 2.

Henry William Schwartz, of Great Saint Helen's, London, merchant, for "Improvements in steam engines."—May 2.

Lewis Doubou Brodie Gordon, of Abbington-street, City, for "an Improvement or Improvements in railways."—May 9.

William McLardy, of Salford, Lancashire, manager, and Joseph Lewis, of the same place, machine-maker, for "certain improvements in machinery or apparatus applicable to the preparation and spinning of cotton, wool, silk, flax, and other fibrous substances."—May 9.

Richard Laming, of Clichy la Garenne, in the republic of France, for "an Improvement or Improvements in the manufacture of caustic acid."—May 9.

Edward Halpigh, of Wakesfield, plumber, for "an invention for measuring water or any other fluid."—May 9.

Vincent Price, of Wardour-street, Soho, Middlesex, machinist, for "certain new or improved mechanical arrangements for obtaining and applying motive power."—May 11.

Charles Hancock, of Falcon-street, Westminster, for "certain improved propellers."—May 11.

James Mule, of Three Friars, Liverpool, for "certain Improved propellers."—May 11.

Thomas Restell, of Tooting, Surrey, watch-maker, and Richard Clark, of the Strand, Westminster, lamp-manufacturer, for "Improvements in chronometers, clocks, watches, and other time keepers."—May 11.

George Armstrong, of Newcastle-upon-Tyne, engineer, for "an Improved water-pressure engine."—May 11.

Mark Smith, of Heywood, Lancashire, power-loom maker, for "certain Improvements in looms for weaving."—May 11.

William Taylor, of Birmingham, merchant, for "an Improved mode of turning up or bending flat pieces of malleable metals, or mixture of metals, by aid of machinery, into parallel lines of metal."—May 11.

George Henry Bursill, of Albion-place, Honsley-road, James Paterson, of Baldwin-street, Cip-road, and John Devold, of Northumberland, engineer, for "certain Improved method or methods of treating masts lignous and other liquids or fluids, and certain improvements in machinery or apparatus for effecting said method or methods of treating masts lignous and other liquids or fluids."—May 11.

Abraham Solomon, of London, merchant, and Randy Assuly, of Rotterdam, Surrey, printer, for "Improvements in the manufacture of gas, tar, charcoal, and certain acids,"—May 11.

Matthew Haggas, of Waterhead Mills, Lancashire, machinist maker, and Joseph Pirk of Huddersfield, Yorkshire, cotton doubler, for "certain Improvements in machinery for doubling cotton and waste cotton, and in doubling and twisting cotton."—May 26.

Moses Poole, of London, gentleman, for "Improvements in propelling vessels." (A communication.)—May 26.

James Parker Perry, of Clarendon-place, Northwalk, gentleman, for "certain Improvements in casing or dressing super eres."—May 26.

James Remington, of Warkworth, Northumberland, civil engineer, for "Improvements in locomotive engines, and in marine and stationary engines."—May 26.

Thomas Richardson, of Newcastle-upon-Tyne, chemist, for "Improvements in the manufacture of naphtha."—May 26.

Piet Huyschote Follet Louis, of Southwark, Survey, gentleman, for "an Impair method or process of preserving certain animal products."—May 26.
IMPERIAL INSURANCE OFFICE, OLD BROAD ST., CITY.

JOHN GIBSON, Esq., Architect.

(With an Engraving, Plate IX.)

The progress of insurance companies, the great interest which is felt by all classes in a prosperous state for the future, the establishment of new offices, and the extension of business, have caused a demand for large public buildings, of architectural pretensions, and capable of giving the required accommodation. Thus, the City, in addition to the halls of its corporations, its banks, and its dock buildings, has now many permanent works in the noble offices erected for transacting the business of the assurance companies. It has been fortunate, too, that with the rise of these establishments, there has been a concurrent improvement in public taste, which has been productive of emulation among the architects, and has given us examples of better class works.

What the club is to the street architecture of the west-end, the assurance office is to the city; and the edifices devoted to the more useful purposes of life, it is pleasing to see, are not inferior to those which are only the appendages of luxury. Indeed, the range of assurance offices in London, constitutes in its architectural, as well as in its moral aspect, a characteristic of which England may be proud. The foreigner has hitherto envied us our charities, our parks, and our clubs; he will now have another feature in the physiognomy of London, which suggests honourable associations in connection with the private and domestic habits of the professional and middle classes, and testifies to their exact and provident care for those to whom their lives have been devoted.

The Sun, the Alliance, the Amicable, the Globe, and the Atlas, are but a few among the buildings which will readily suggest themselves as coming within the class we have mentioned, each the centre of operations of some great institution, in which property to a large amount is insured, or on which thousands of wives and of children depend for provision when widowhood or orphanage may be their lot. Of the architectural merits of most of the buildings of this kind, the question of the propriety of the design may be left to other occasions; we have now to add to our list the office of the Imperial Insurance Company.

The Imperial Fire Insurance Company was formed in 1803, under a deed of settlement by which the capital was declared to consist of 7,400 shares, of £100 each, but on which, only ten per cent. has ever been called. The invested capital now exceeds half a million, to secure a permanent dividend of twelve per cent., payable half-yearly, independently of bonuses which have hitherto been equal to so much more, and accounts for the shares being of greater value than those of any other Assurance Company in London, in point of interest. The Life Office (which, although bearing the same name and carrying on its business under the same roof, is a totally distinct concern) was formed under a similar deed of settlement, in 1800. Its capital consists of 7,400 shares, of £100 each, on which only ten per cent. has ever been paid up; to secure a dividend on which, payable annually, an ample capital is invested in the public funds, independently of an accumulated premium fund now exceeding £700,000, and bonuses which are declared quinquennially.

The directors of these two companies, finding the accommodation afforded by the premises they have hitherto occupied in Sun-court, Cornhill, inadequate to the wants of the respective offices, determined, in September 1846, to erect others on the site they had purchased at the corner of Old Broad-street and Threadneedle-street; for which purpose several architects were invited to furnish designs, and having done so, Mr. Shaw, one of the official referees was called in to assist the directors in their selection: that resolved on the adoption of Mr. Gibson's design, now nearly completed by the Messrs. Piper, who took the contract for the erection.

Mr. Gibson is the architect of the Baptist Chapel in Bloomsbury-street, of which we lately gave the elevation, and who may consider himself pre-eminently fortunate in being able to make his professional debut in two public structures, produced simultaneously. The one, all of which, being drawn, has been executed to the satisfaction of the Imperial Insurance Office, which stands at the corner of Old Broad-street and Threadneedle-street. It is an astylar composition, of the Italian Palazzo style, executed in Portland stone, and has unquestionably made a very great improvement in that part of the city, which must be admitted to have been very unequal in architecture, and inconvenient sharp corner; in lieu of which, that angle is now cut off, and is made to form a distinct and distinguished compartment of the general design, and is so placed as to present itself to the eye in a very striking manner; and, with its two neighbouring buildings—the Hall of Commerce on one side, and the Mentor Assurance Office on the other—forms a rather important architectural group, in which there is certainly no lack of variety,—the Imperial Office being as studiously ornate as the other two are studiously simple, not to say severe and cold in style. Or perhaps we should qualify our opinion by saying, that the façade of the Hall of Commerce would look somewhat cold and bare as an architectural composition, were it not for the panel frieze, which is in a double sense a relief, and which, while it sets off the façade, is in turn set off by its very subdued tone of decoration. A similar universal degree and mode of embellishment in point of sculpture, is also a trait in the design of the Imperial Office, all the key-stones of its ground-floor windows being enriched with carved masks or heads upon them—not a mere repetition of each other, but varying in form—while the cornice of the south-west compartment, between the Threadneedle-street and the Broad-street fronts, will display a relievo, consisting of two sitting female figures, considerably above life-size, with three shields between them, bearing the arms of England, Scotland, and Ireland—which piece of sculpture, and the key-stones just mentioned (amounting in all to fourteen in the two fronts), are by Mr. Thomas, an artist extensively employed at the new Palace of Westminster. Highly satisfactory is it to perceive such attention to artistic finish bestowed upon a building which, had it been erected a few dozen or fifty years ago, would have turned out hand very differently,—both with the minimum of detail and with the minimum of design bestowed upon that, as witness the Alliance Office, in Bartholomew-lane, and the "Atlantic," in Cheapside,—or the City Club-house, in Broad-street; all of which may claim the merit of being as perfectly unartificial—provided unartificial and unartistic be synonymous and convertible terms. The Imperial Office has been enriched with great propriety, the ornaments being in perfect keeping throughout, and at the same time they are profuse and well-executed.

We can now only allude to the interior, which is not yet quite finished; but every attention appears to have been bestowed upon the official arrangements, and every precaution taken to render the Offices fire-proof. The "strong-room" has been fitted by Mr. Leadbeater with wrought-iron doors, filled with a chemical compound for making them perfectly fire-proof, and ventilating gates. This room appears to be a perfect pattern of safety.

CANDIDUS'S NOTE-BOOK,
FASCICULUS LXXXIII.

"I must have liberty
Withal, as large a charter as the wind,
'To blow on what I please.
"

1. One of the essays in the piquant little volume, entitled "Friends in Council," is upon the subject of Public Improvements. As to the essay itself, it is disappointingly brief, and deals too much in, or rather is confined to, abstract generalities. There are, however, one or two remarks introduced in the subsequent conversation between the "Friends" themselves, that deserve to be pointed out. The first of them which I select would furnish matter for a discourse or paper of some length:—"Miterson:
"There is one thing I forgot to say,—that we want more individual will in building. I think. As it is at present, a great builder takes a plot of ground, and turns out innumerable houses, all alike—the same faults and merits running through each: thus adding to the general dulness of things."—Such system of house-manufacturing for the market operates; it must be confessed, very injuriously for architecture. A single design is made to serve for scores—perhaps hundreds, of houses; nor is much study bestowed upon that pattern or matrix design. So that it provides a sufficiently commodious dwelling, with all the useful routine accommodations looked for in a "respectable" house, and a sufficiently tasteful appearance externally—for your builder deals largely in the "tasty," though not in the tasteful,—nothing more is thought of. London houses have no individuality: never do you find a single original or yet idea carefully worked out in any one of them. One advantage of this is, that you are as well acquainted with every nook and corner of your neighbour's house as you are with your own; another, that you are relieved from all responsibility on the score of taste, it being that of the confined builders,—not your own.
II. To continue quoting—in Ellesmere's—not the Earl's—reply, we meet with this somewhat perilsous question:—"By the way, Milverton, I want to ask you one thing. How is it that governments and committees, and the bodies that manage matters of taste, seem to be more tasteless than the average run of people? At small war, it being the same thing, I mean, it would have made a better thing of it than it is. If you had put before them several prints of Fountains, they would not have chosen those." To which Milverton responds: "I think with you, but have no theory to account for it."—Partly, and even mainly, accounted for, it might be, by saying: It is because in all such matters, committees hold themselves to be utterly irresponsible for their acts, and because no one cares to convince them of the contrary, by formally calling them to account. So long as Committees of Taste, or whatever else their actual designation may be, are suffered to carry on their duties amidst Invitations and Commissions, and their decisions are better censured than mere random experimentalizing and blundering, at John Bull's expense? He it is, the British Donkey, though flattered by being drawn as the British Lion, who pays for all.

II. "Now, Milverton," says Ellesmere again, "would you not forthwith pull down such things as Buckingham Palace, and the National Gallery?" To which the reply is: "I would pull them down to a certainty, or some parts of them at any rate; but whether "forthwith," is another question."—As Mr. Blore's Improvement of the Palace had been long before quoted, we are at liberty to suppose that, in the writer's opinion, such improvement does not render pulling down at all the less desirable,—perhaps, even more so than ever. As affairs have since turned out, the times are not at all propitious for schemes of building either new Royal Palace, or even National Gallery buildings, that will match to the full the expectations, it is susceptible of very decided improvement as it now stands,—capable of easily being made what it ought to have been at first. Even at present, it is not so much the "Gallery" itself, as the other buildings and accessories, that render Trafalgar-square a failure. The other side, and the most part vulgar taste, and require to be pulled down quite as much, or even much more, than the "Gallery"—if anything is ever to be made of the Square as an architectural ensemble. As to the west side, the best that can be said of it is, that it serves as a foil to the "Gallery," and is not, like the later additions, itself a thing of defects, it is susceptible of very decided improvement as it now stands,—capable of easily being made what it ought to have been at first. Even at present, it is not so much the "Gallery" itself, as the other buildings and accessories, that render Trafalgar-square a failure. The other side, and the most part vulgar taste, and require to be pulled down quite as much, or even much more, than the "Gallery"—if anything is ever to be made of the Square as an architectural ensemble. As to the west side, the best that can be said of it is, that it serves as a foil to the "Gallery," and is not, like the later additions, itself a thing of defects, it is susceptible of very decided improvement as it now stands,—capable of easily being made what it ought to have been at first. Even at present, it is not so much the "Gallery" itself, as the other buildings and accessories, that render Trafalgar-square a failure. The other side, and the most part vulgar taste, and require to be pulled down quite as much, or even much more, than the "Gallery"—if anything is ever to be made of the Square as an architectural ensemble. As to the west side, the best that can be said of it is, that it serves as a foil to the "Gallery," and is not, like the later additions, itself a thing of defects, it is susceptible of very decided improvement as it now stands,—capable of easily being made what it ought to have been at first. Even at present, it is not so much the "Gallery" itself, as the other buildings and accessories, that render Trafalgar-square a failure. The other side, and the most part vulgar taste, and require to be pulled down quite as much, or even much more, than the "Gallery"—if anything is ever to be made of the Square as an architectural ensemble. As to the west side, the best that can be said of it is, that it serves as a foil to the "Gallery," and is not, like the later additions, itself a thing of defects, it is susceptible of very decided improvement as it now stands,—capable of easily being made what it ought to have been at first. Even at present, it is not so much the "Gallery" itself, as the other buildings and accessories, that render Trafalgar-square a failure. The other side, and the most part vulgar taste, and require to be pulled down quite as much, or even much more, than the "Gallery"—if anything is ever to be made of the Square as an architectural ensemble. As to the west side, the best that can be said of it is, that it serves as a foil to the "Gallery," and is not, like the later additions, itself a thing of defects, it is susceptible of very decided improvement as it now stands,—capable of easily being made what it ought to have been at first.

IV. I find that I have omitted an observation in Milverton's reply to Ellesmere's sneer at the taste of governments and committees, that deserves to be attended to. "I suppose," says the latter, "that these committees are formed by the people of the country, and put up the designs which come before the public, when they are looking at the work done. And this may be some excuse. There was a custom which I have heard prevailed in former days in some of the Italian cities, of making large models of the works of art that were to be put up any time, putting them up in the places where the works were to be put up, and inviting criticism. It would really be a very good plan in some cases."—No, but practicable only for small ornamental works, such as fountains, triumphal arches, public statues, monumental crosses, &c. A full-sized model of such an edifice as the "Houses of Parliament," or even of the new building at Buckingham Palace, would have been rather too curious and costly an affair for an experiment of the kind. Had any other design been chosen for the purpose than the Corinthian column—a model of which would have been altogether superfluous—the Nelson Monument might possibly, if the same kind of experiment were tried, mean removal of a full-sized model of it put up on the spot. Yet, when we consider what a mere farce was played with the model, or what was meant for it, of the Wellington Statue on the Archway, which was ordered to remain up only two days, when it was smashed, lest it should be pulled up with further volleys of censure and derision,—we must pronounce trial by model—at least, when so conducted—to be altogether nugatory. If the statue-committee made a show of "inviting criticism," they showed also wonderful acumen in running away from it, after its very first appearance. The committee cannot have no notion of doing that. Their policy invariably is to stave it off as long as they possibly can. The public, it will be recollected, were not permitted to see the model of the façade of the British Museum, notwithstanding that there was one in existence, and that in the building itself; and notwithstanding that some of the newspapers called out for its being liberated from durance under lock-and-key, and submitted to inspection and criticism. Well, we have now the façade itself, and see both positive faults and numerous short-comings, all which might have been foreseen in the present building, if criticism had been received. It is true, the façade is not generally ill-spoken of,—simply because it is not spoken of at all. It obtains not so much as a syllable of praise in any quarter; and such silence is tolerably expressive of disappointment and disapprobation. The new building at Buckingham Palace is in a far worse case. It has been subjected to mockery and contempt, without a single favourable word for it having been uttered by any one; although there are some who would most readily have done so, had they not stood in awe of general discontent, and been apprehensive that they might incur the ill credit with the public for judgment and taste, by attempting to persuade them that the design is at least not unsatisfactory.

V. So long as committees, and those who have the management of public competitions for buildings, shall continue to be left irresponsible for their doings, there will be no check on such blunders and failures. Persons who intend to act honourably and fairly, do not need to screen themselves behind a curtain, thereby excusing a suspicion that what they do will not bear the gaze of broad daylight. On the other hand, those who care only for the opportunity of exerting their own private influence, without regard to the consequences—ought to be made aware that if they so act, it must be at their own peril. There is scarcely a public competition of any kind that does not occasion complaints of unfair intriguing, and of bad faith on the part of the committee,—complaints that can scarcely be aired, and can only be endured by those that with mere complaints, the matter complained of blows over, without proceeding to the extremity of exposure. All this is intolerable enough; but then, how is it to be remedied? I should say, that what would go very far towards remedying it, if not remedying it completely, would be the making it illegal, for any committee, or other body, to invite architects to a competition by public advertisement, without having a public exhibition beforehand of the designs sent in in the first instance, and without entire publicity in all other respects, the names of the committee being published, and all those being admitted to the competition who are willing to submit their designs. As matters are cunningly managed at present, we only know that Mr. A. or Mr. B.'s design has been selected for adoption; but how many votes, or who were the persons who voted for or against, it is impossible to learn, much less the arguments they made use of. The Army and Navy Club, who, it is to be presumed, call themselves gentlemen and men of honour, have laid themselves open to the impugnation of the most blundering and bare-faced trickery, by calling an unlimited competition in the first instance, and afterwards setting that which they had previously rejected, under the pretence of their own choosing, after the site (at first rather an inconvenient one, and therefore tasking all the ingenuity of the first competitors) had been considerably enlarged, by taking in another house in Pall-Mall, and saying that the Army and Navy Club ought to blush at being convicted of such downright knavery. But I will say no more, because I know that they are behind a curtain, and that the names of the committee cannot be shown up, as they deserve to be, as those of a pack of trickey jugglers. One comfort, if a comfort it be, is, that they have tricked themselves; for from what has
been said of it, they seem to have got a most Pecksmeckian plan for their building. Were I, as thank God I am not, a member of the Art Club, I should be tempted to hang my hat upon the pure vexation. After what they have done, Navy and Knavey are likely to become synonymous words.

VI. The idea of manufacturing the picturesque out of such things as labourers' cottages is not a little absurd; more especially, when considered and by being supposed to have first, that they shall be erected at a minimum of cost; secondly, that they shall be free from all those defects, discomforts, and inconveniences which accompany and contribute to picturesque quality in the works of Vitruvius, which marked in their row state only by unwashed faces and meanness, are touched, trodden, and melted down by time and weather, into objects delightful to the painter's eye, and congenial subjects for his pencil. Dilapidation, or something approaching to it, and touches of lichenous vegetable incrustation, are almost indispensable to qualify a cottage for obtaining an artist's interest and vote. Nor must paucity and smallness of apertures be forgotten. Yet all these beauties, and many others not here enumerated, are only so many defects in the eyes of many well-meaning, but prosaic and anti-picturesque people. In fact, a cottage to look at, and a cottage to live in, are two quite distinct things; the former requires all that constitute so many defects in the latter, and vice versa. While your philanthropist would have no such things as rags in the world, the artist, on the contrary, insists upon them; not, indeed, for himself, if he can possibly help it, but rags he must and will have for his beggars and gipsies. And so it is with regard to cottages. We speak of the other without reference to the subject, and the schemes for improving labourers' cottages secundum artem. Shorn of sundry emphatic words, that may as well be here omitted, one of his observations was: "At this rate, we shall not have a decently down-falling-looking old tenement, nor a properly beggarly how-does-the-best be beard, that even the best cannot speak the truth on the subject, and the schemes for improving labourers' cottages secundum artem."

Since our preceding publication, matters look more and more cheering—riper for reform, and indicating the necessity for it. The Art-Journal scruples not to tell its readers very bluntly that architectural drawings have no business to be in the Exhibition. The editor seems to have made up his mind that there could not possibly be two opinions as to the propriety of excluding them altogether; and, to say the truth, they might almost as well be so, experience the scurvy treatment they now do. As to the ill-will with which he professes to regard them, he says: "It is not exactly the thing for a gentleman to do who conducts an art-journal, and who professes to watch over the interests of art in all its branches,—and some of the lowest of them he takes under his especial patronage: much good may it do them. Considering the quantity it comes from, we are not at all surprised at the ill-will just instanced; but surprised we are, and that in no small degree, at an outrageous instance of similar feeling on the part of the Royal Academy. As the fact has been publicly noticed and animadverted upon by others, our readers will probably have guessed that we allude to a number of Miss Burney's copper plates. They were sent in by its architect, Mr. Ferrey, and turned away! No wonder, therefore, that there is nothing of the kind in this season's exhibition. If there were any other productions of the same class that met with the same fate, we cannot say: it is just as probable as not that there were at least some; yet, whether such were the case makes no difference as to the animus displayed by the Academy. Had more models been sent in than could possibly be accommodated, some of them must, of course, have been excluded. But to reject while there was room—not to suffer so many as one plate to be rejected—was too bad, and showed singular want of tact also. If the Academy were determined not to admit models, they ought at least to have said as much in their advertisements to those who intended to exhibit. That would, at any rate, have been acting straightforwardly. They may have been afraid of the models actually exhibited might fail to obtain notice, the entire absence of them would excite remark. Had none been sent, whatever remark had been made could not affect them, because they cannot compel persons to exhibit. But to act as they have done is nothing less than a solemn blunder, it being certain to lead to explanations and comments that are not at all to the honour of the Academy. If the painters are ashamed of having architecture in their company, let them honestly and openly declare as much, instead of resorting to every sort of mean and dirty trickery in their most secret and base-minded contrivances. The latter can shift equally well without the Academy, there being, most luckily, another royal, and eminently public-spirited body, which only waits for architecture being dismissed from the Academy, to bring it more effectively before the public. Nothing—so we are assured—but delicacy towards the Academy has withheld the Institute from getting up an annual exhibition of architectural designs of every class, upon an adequate scale. Well, they need not now be restrained by delicacy, for it would be entirely thrown away after the "exhibition" of the cloven-foot in the crown, even if the latter had not been made public. But the other answer is that the latter can shift equally well without the Academy, there being, most luckily, another royal, and eminently public-spirited body, which only waits for architecture being dismissed from the Academy, to bring it more effectively before the public. Nothing—so we are assured—but delicacy towards the Academy has withheld the Institute from getting up an annual exhibition of architectural designs of every class, upon an adequate scale. Well, they need not now be restrained by delicacy, for it would be entirely thrown away after the "exhibition" of the cloven-foot in the crown, even if the latter had not been made public.
trust that not only they will properly resent it, but that the Professor of Architecture himself will now rouse himself from his lethargy, and stand up for the honour and the interests of his own art. If he do not do so, the sooner he has a successor the better; for even should it be "Mr. Pecksniff" himself, he cannot possibly do less, and might probably do a little more. Mr. Cockerill is, we have no doubt, a very well-meaning gentleman, and sufficiently well qualified to discharge the duties of his office, so long as difficulties do not present themselves; but he does not show himself to be the man who is both capable of and determined to meet difficulties boldly, and to exert himself energetically in behalf of that art which his professorship at the Academy points him out to the public as the representative. If he has expatiated with the Academy in regard to their treatment of architecture, he does himself very great injustice in concealing it from the world; thereby leaving it to be inferred that he is altogether indifferent to the matter.

After this taste, if so it should be called, though what we have said is neither uncalled for nor unprovoked, we were going to say that we resume, and proceed with our remarks on the subjects exhibited, when, as ill luck, or at any rate luck of some sort or other, will have it, we are perforce, compelled to postpone them till our next number, when we shall lay them before our readers. In the meanwhile, we have at any rate given them something to cogitate upon, inviting those who may agree with us to support us in our opinions by expressing their own, and assuring those who may happen to dissent from them that we are quite ready and willing to receive and listen to their arguments, for we may have to advance that shall countenance the treatment which architecture receives at the hands of that specimen of royalty—the Royal Academy!

**COLLISION OF TRAINS.**

In the following paper we propose to determine the shock experienced at any part of a railway train during a collision, and to propose methods for obviating the mischief that ensues. To simplify our ideas, let us first suppose the weights of the separate carriages equal, and the buffers removed. Let the number of carriages be $N$; the impulse on the first carriage that sustains the shock $R$; $r_0$ the impulse between the $n$th and $(n-1)$th carriage: then the velocity in all parts of the train being the same relatively, both before and after impact, the carriages being supposed inelastic, and the masses of all the carriages equal, we shall have the following equation:

$$r_n + 2 - r_{n-1} = r_{n-1} - r_n$$

for all values of $n$;

or $r_n + 2 - 2r_{n+1} + r_n = 0$;

a linear equation of differences, the solution of which is $r_n = (Cn + C)$; but $r_n$ (the impulse on the last carriage outside) = $0$.

.. $C = 0$; and $r_0 = (CN) = R$.

... $C = \frac{R}{N}$; and $r_n = \frac{R}{N}$.

If the masses of the carriages had been unequal, $m_n$ the mass of the $n$th carriage, we should have had $N$ equations of the form

$$r_n + 2 - r_{n-1} = r_{n-1} - r_n$$

$m_n + 2 - m_{n+1} = m_{n+1} - m_n$, from which to determine $r_n$, &c.

From this we conclude, that in a train of equally-loaded carriages the shock increases directly as the distance of any given carriage from the end of the train farthest from the point of impact.

The design of buffers is to diminish the violence of the shock; that is to say, to change impulse (which is intense pressure continued for a very short time) into a lesser pressure continued for a longer time; but, as we shall immediately show, it is not practically possible to construct buffers capable of thus transmitting the whole or any considerable part of the shock—much, for instance, as is experienced when an express-engine accidentally is turned aside upon a heavy railway-junction. To take an example: Let the express-engine weigh 20 tons; its rate be 40 miles an hour; the stationary-engine weigh 30 tons; then, if $m$, $m'$, be the masses of the trains, $v$ the velocity of the express, and $R = (m + m')v$,

\[
v = \frac{100}{33}\text{ expressed in feet per second} = 60 \text{ nearly};\]

\[
m = \frac{20}{33}\text{ (2940); } m' = \frac{30}{33}\text{ (3240); nearly, in masses of lb. weight.}\]

\[
\text{When } d\frac{dx}{dt} = 0, \text{ and the buffer is driven as far as it will go,}
\]

\[
v = (\frac{P}{m} + \frac{P}{m'}) v'.\]

From this we see the great advantage of having a long play on the buffer; the pressure $P$ will diminish in a ratio varying as the square of the length to which the buffer is played—that is, if the length of one buffer-rod be twice the length of another, and the strength of the spring of the first be only one-fourth of the strength of the spring of the last, the amount of shock destroyed by either will be the same.

The practical effect of buffers, as they are ordinarily disposed throughout a train, is to resolve so much of the impact as they cannot altogether absorb, in a series of impacts of lesser momentum; for let us consider what would happen supposing 3 trains, the several parts of which are separated by buffers, to impinge on a fixed, immovable obstacle. As long as the buffers are all acting, $P = \frac{nF}{N}$; consequently, the pressure on the first pair of buffers is greater than the pressure on those behind. Let $V$ be the velocity destroyed by the total shock, $eV$ the velocity destroyed by the time the first pair of buffers has ceased to act: then a velocity $1 - e$. $V$ has to be destroyed in the first carriage by
a force of impact,—for the pair of buffers behind will be still setting for some little time after the first pair have ceased to act.

Again, let $v$ be the velocity destroyed before the second pair of buffers cease to act; then, as before, the second carriage will be suddenly brought to rest by an impact on the first carriage capable of destroying the velocity $(1+e)v$. In the second carriage. Next, the third carriage will be suddenly stopped; this, likewise, will communicate a shock to the first, though less than it communicates to the second; and so on. These shocks and motions will be somewhat varied by the resiliency of the buffer-springs, and the impulsive friction of the rails against the wheels;—this latter disturbing force we have altogether omitted, as being comparatively insignificant. On the whole, then, it appears that buffers very much diminish the intensity of a shock, although they are incapable of utterly absorbing it, supposing it to be of great intensity.

I. H. R.

ON STONE WALLS AND EMBANKMENTS FOR RESERVOIRS OF WATER-WORKS.

By R. G. Clark.

The intention of this paper is to treat of the pressure of water against walls and embankments of reservoirs for water-works and canals, and to lay down some simple formulae to find the necessary dimensions so as to effectually resist the pressure of the water; the demonstration of these is being omitted; this, likewise, will involve a shock to the first, though less than it communicates to the second; and so on. These shocks and motions will be somewhat varied by the resiliency of the buffer-springs, and the impulsive friction of the rails against the wheels;—this latter disturbing force we have altogether omitted, as being comparatively insignificant. On the whole, then, it appears that buffers very much diminish the intensity of a shock, although they are incapable of utterly absorbing it, supposing it to be of great intensity.

I. H. R.

Ex. Given the height of the wall = 24 feet, and the specific gravity of the material, $g$: to determine $A$.

$$x = \sqrt{\frac{242}{3\times2}}$$
$$= 9.8$$, the thickness required.

III. Let the side of the wall next the water be battered, and the side behind vertical; to determine $A$, the thickness at the base.

Let $A B C D$ be the vertical section, and let fall the perpendicular $C E$.

The momentum of the triangle $C E B$ about $A$ from its horizontal distance of centre of gravity $g$, $\frac{1}{3} a \times b \times (\frac{1}{3} x - b)$.

The momentum of rectangle $D C A E$ about $A$ from its centre of gravity, $\frac{1}{3} a (x - b) \times \frac{1}{3} (x - b)$.

Adding these two together, and substitute for $M$ in equation (1), as in first case, we have, after transposing,

$$a^2 + \frac{b^2}{3} = a^2 + b^2 - \frac{b^2}{3}$$

Ex. Given the height of wall, 24 feet; batter, 4 feet; and specific gravity of stone, $g$: required the thickness of the top and bottom.

By substitution of the above values in equation (3), we have, $x^2 = 92.7$.

Solving this quadratic, we have $x = A B = 92.7$; top, 5.3.

IV. When the wall is battered behind, and the side facing the water perpendicular.

The two first terms of (a) vanish when $B D$ is vertical; $\therefore$ $a M = g a^2$.

The moment of triangle $A E C$ about $A$, by its horizontal distance of its centre of gravity, $\frac{1}{3} a x (x - b)$.

and also of rectangle $C E B$ about $A$, $\frac{1}{3} a (x - b)^2$.

$\therefore$ substituting the sum in equation (1), we have $x^2 = a^2 + \frac{b^2}{3}$.

Ex. Given the dimensions of the wall as in last example; to determine the thickness at bottom:

$$x^2 = \frac{24^2}{6} + \frac{16}{3} = 96 + 5.3 = 101.3$$

$\therefore$ $x = 10.1 = A B$; and $C D = 6$.

For additional strength to the above walls, it would be well to insert at the centre of them one tier of bond, about two-thirds the height from the top, which will then resist the pressure of the water.

V. We shall now give a case where earth shall be required in the construction of an embankment, of the form of a trapezoid, having a vertical clay puddle-wall in the middle, and the slope facing the water being paved with suitable material, with a puddle under. In case of any contraction of the clay, there would be a separation of the clay from the earth; therefore, the triangle $D E B$ should be of sufficient strength alone to resist the fluid pressure, either against sliding or revolving on $D$. The water is supposed to be coincident with the top of the embankment.
Ex. Given the height of the embankment, 30 feet; specific gravity of material = 1 1/4 (water being unity); to determine the base DE of the triangle DEB; also the whole width of bottom, when it has a horizontal surface AB at top, 3 feet wide.

\[ s = 1 1/4; \quad BD = a; \quad BE = \sqrt{1 1/4}; \quad 2a = 16 1/2 \] feet required;

therefore, the whole width \( FE = 36 \times 4 \).

**THE CIVIL SURVEYORS AND THE MILITARY SURVEYORS.**

The Surveyors' Association is proceeding vigorously in its defense of the professional rights against aggression, and we are very much that they had taken this course at an earlier period, for we long since pointed out to them the course of invasion which the military employees of the government were carrying on against the public. Among the late allies of the government jobbers is our contemporary, the *Athenæum*, usually among the foremost advocates of sound and enlightened policy; and we have no other means of accounting for the remarks contained in the number of the 17th June, than by the supposition that its sympathy in the cause of sanitary reform has been taken advantage of by some of the jobbers, to feint on the editor a misstatement of the case. It is by placing upon the jobbers the responsibility of the sanitary reforms that the jobbers hope to hide their own designs, representing that there is an attempt to prevent the sanitary plans from being carried out in the most efficient manner; whereas the same issue is pleaded against them. The *Athenæum* cannot be expected in its literary capacity to take part in all the details of such a case; it is quite excusable that it should give way to the arguments of the military engineers. We do, however, hope that the editor will re-consider the case, and not give the weight of his advocacy to a course of policy which is eminently calculated to retard the progress of sanitary reform.

At the present day, there is an assumption on the part of the government functionaries, that it is the government which has effected the great sanitary reforms already made, and that none but government functionaries can carry them out; whereas, the whole statement is utterly untrue. The great improvements in sewage made by the exertions of members of the engineering profession, before the government had any share in the administration; and the plans now being carried out are those emanating from the officers of the old commissions. What the government is attempting to do is, first, neglect the case; and, second, usurpation, in assuming the administration of the sewers to a new set of irresponsible commissioners, instead of establishing representative commissioners. The government has, indeed, been guilty of another new era of sanitary reforms, with which they force as much to do as a successor has with the construction of a sparrow's nest; the new era of sanitary reform, and the new lights on sewage engineering, having emanated not from government, but from Messrs. Roe and Phillips, who originated the present cheap and efficient plans, and carried them into practical execution. So, similarly, the plans for the supply of water by constant service did not emanate from the government, but from the hydraulic engineers. Hitherto, all that has been done in sanitary engineering, as in every other department of engineering, has been done by the civil engineers, and not by the government engineers; and it never can be done efficiently except by the civil engineers. For this reason alone, we should view with jealousy any attempt to supersede the civil engineers.

The *Athenæum* seems to have lost faith in the assumption that the military engineers have a superiority in their professional capacity, whereas the issue is not whether they have a superiority, but whether they have an equality. Wherever the military engineers have been put to the test, they are found most inefficient; their engineering work in Canada, the Engineers are far from as desirable to them, or satisfactory to the nation; their volume of scientific papers is principally the production of civilians, or civil engineers; and their surveys hitherto, although they cannot be subjected to any rigid test, have nevertheless been attended with serious disasters. In the engineering world, the military engineers have no professional standing or reputation.

The *Athenæum* does not seem to be aware that we have in London, engineers competent to conduct a trigonometrical survey, which involves the nicest points of astronomy, and requires all the resources of mathematical analysis,—when a reference to the Institution of Civil Engineers is quite sufficient to show the mathematical capabilities of its members; and if the *Athenæum* had adverted to the evidence as to this, given from time to time in its columns, it would not have had any difficulty in saying who were competent to conduct the survey. If, however, the military engineers are under a slur in their professional capacity, it must be recollected that such as they are, they are not the parties who carry out all the details of the survey, which are done by the body of privates, many of whom are got from hedge schools in Ireland. If the *Athenæum* had been aware of this, it would not have missed of the inferior attainments and little experience of a great many of the lower surveyors,—the worst of whom are, we believe, some of the best men of the government corps, who leave it as soon as they learn something, and set up for themselves. Even in the operations which are going on, hardly an officer is left behind the scene. It would be a comparative cost, the general charges of the body of military engineers must be added to the special estimates. If he were not trying to uphold a job, he would not quibble upon it. We are, however, most surprised, that after the declaration in the House of Commons, the government have determined to put the country to an expense for this military survey, while the progress of the ordnance survey will be impeded.

The *Athenæum* has been likewise misled upon the point that the case of the surveyors has been decided by a competent and independent court; whereas, the decision as yet has been an approval of Mr. Edwin Chadwick's scheme, by Mr. Edwin Chadwick's own board,—and this is what the associated surveyors are trying to upset; for they consider, in common with the great body of the profession, that they have not yet got a hearing, and they are now "trying for a hearing," in which we hope they will be supported by the *Athenæum*, which we do not, we believe, have countenanced Mr. Edwin Chadwick's plans if it had been informed of the whole truth of the case.

The *Athenæum* boldly says, that "as the nation builds its own ships, it may manufacture its own things, which can be done with its own workmen, why should not work make its own survey?" We answer, that the government has ships and machinery made elsewhere, cannon cast elsewhere, and many other things made elsewhere; and that, on the other hand, whatever is done by the government, is neither done well nor cheaply. The ordnance works, the dockyards, the post-offices, and the mint, would be a disgrace to any merchant or partnership or joint-stock company. In the present case, the military surveyors have quite enough to do in the north of England, where they are wanted to finish the ordnance survey.

**Import and Export of Metals.**—It applies from the return of the imports and exports of lead, copper, tin, and silver in the House of Commons, that the total quantity of lead ore imported was 507 tons, of which 400 tons were from France, and the remainder principally from New South Wales. Pig and sheet lead imported amounted to 3,922 tons, of which 216 tons were from Cornwall, and the remainder re-exported. Of British lead there were exported 8,529 tons, of which France took 1,756 tons; Russia, 1,754 tons; East Indies, 1,053 tons; and Holland, 806 tons. The total quantity of foreign copper ore imported was 41,490 tons, if 2,284 tons were from the United States, and 28,231 tons from Chile, and 6,454 tons from Cuba, and the remainder being 8,290 tons. The quantity of metallic copper imported was 515 tons; retained for home consumption, 70 tons. The quantity of copper exported was 13,842 tons.—The total quantity of tin imported was 1,363,510, of which 58,631 tons were from China, and 516,739 tons from Spain, and the remainder being 218,820 tons; the total quantity of zinc imported was 12,769 tons; and exported 886 tons British, and 3346 tons foreign.
NOTES ON ENGINEERING.—No. IX.

By Homesham Cox, B.A.

Synoptic Tables for calculation of Earthworks in Level and Sidelong Ground on Railways.

No earthwork tables have hitherto been published for the express purpose of facilitating calculations for SIDELONG GROUND. The present is an effort to supply this want, which is much felt on account of the number and complexity of the operations usually required for adapting the published tables to the cases referred to. According to the existing methods, it is necessary when the ground slopes laterally, to calculate the areas of the sections, and extract the square root previously to reference to the tables. By the method here proposed, these antecedent calculations are wholly avoided: the numbers are taken from the table without any previous computation, and require only to be multiplied by the natural and artificial slopes.

The tables are also easily applicable in calculation for LEVEL GROUND; and it is believed that for both purposes the method will be found very simple and expeditious. The tabular numbers are calculated for every half foot. When greater exactness is necessary, the calculator is referred to the admirable tables of Mr. Bashforth. The manuscript computations for those tables have been kindly placed at the disposal of the present writer, and have enabled him to check the accuracy of a great part of his own results.

It is not intended to demonstrate at length the formula of computation, as they depend on well-known theorems: the following brief account of them is sufficient for the present purpose.

Let A C D B be a section in a railway cutting in level ground, C D being the formation level, and A, B, D, the artificial slopes. At A B is horizontal, the points A, E, and B, are all at the same vertical height above the formation level: call this height $a$, measured in feet.

Let a similar section be taken at a distance along the railway of 66 feet, or one chain from the above, and let the vertical height there be $b$ feet. The solid content in cubic yards of the solid terminating in E D B, is $\frac{1}{2} (a^2 + ab + b^2) r$.

The solid content is $\frac{1}{2} a \times r$; $r$ being the "slope" of the embankments, the measurement of which will be explained more fully presently; $w$ the width in feet of the formation level.

Next, let A C D B be a section in sidelong ground—that is, ground inclined laterally or transversely to the railway. Here there are two sets of heights to be considered—those on the right hand, and those on the left hand of the railway; and there are two "slopes"—that of the natural ground depending on the inclination of either A C or B D. Call the natural slope R, and the artificial slope (as before) r. If a and A be the heights (in feet) of the points A and B respectively, above the formation level C D, the area of the triangle AFC = $\frac{1}{2} (R + r) a$; and of the triangle BFD = $\frac{1}{2} (R - r) b$.

Similarly, if another section be taken at a distance 6 feet along the railway, and $i, b$, be the corresponding heights, the areas of the two triangles similar and similarly situated to A FC, B FD, respectively, are $\frac{1}{2} (R + r) b'$; and $\frac{1}{2} (R - r) b'$.

The solid content (in cubic yards) of the solid terminating in A FC = $(R + r) \frac{1}{2} (A^2 + A B + B^2) r$.

The larger of the accompanying tables gives values, or $\frac{1}{2} (a^2 + ab + b^2)$, for every half foot of the two heights, up to 50 and 60 feet, respectively. The smaller table gives values of $\sqrt{a} \times$ by various widths of the formation level.

METHODS OF USING THE TABLES.

For Level-lying Ground.—Multiply the tabular number in the larger table corresponding to the heights of two successive sections a chain apart, by twice the slope, and add the number from the smaller table, corresponding to each height separately. The result is the number of cubic yards required. For instance, let the heights be 294 feet and 45 feet; the base, 50 feet; and the slope 2 (to one). In the larger table, the number corresponding to 294, 45 is 1710. This multiplied by twice the slope 4 = 6840. Add, from the column for base 50 in the second table, the number for 294 (which is 1089); and also the number for 45 (which is 1650): and the total (8572) is the quantity of cubic yards required.

The following is an example of the quantities corresponding to four sections, a chain apart, the corresponding heights being 16, 204, 30, and 444 respectively; the base, 33 feet: the slope, 24 (to one)—consequently, all the tabular numbers are to be multiplied by twice 24 (or 5).

Answer 21098

When the sections are at greater or less distances than one chain apart, quantities between each two sections must be multiplied by the corresponding distances. For instance, suppose the sections had been 14, 9, and 3 chains apart: repeating the sums in the last column of the above scheme, we have

<table>

51914 Ans. required.

For Sidelong Ground.—Here the larger table alone is used.

There are two sets of heights, those on the right-hand side of the railway, B; and those on the left-hand side, A (Fig. 2). These sets are to be kept quite distinct. Multiply the tabular numbers corresponding to the greater heights by the difference between the natural and artificial slopes, and the tabular numbers corresponding to the less heights by the sum of artificial and natural slopes: the difference between these products is the result required.

For instance, let the natural slope be 9 (to one), and the artificial slope 14 (to one): the sum of the slopes is 23, the difference 5. Also, let the heights be: 1st section, 204, 10; 2nd section, 22, 30. The two major heights, 204, 52, are taken together; and the two minor heights, 10 and 30, are taken together. The number in the table for the first pair is 1707; which, multiplied by 5, gives 8535. The height for the second pair is 229; which, multiplied by 8, gives 1823. The difference of the two products, or 430, is the answer required.

Where the slopes remain unchanged for several successive sections, the sums of each set of the tabular numbers may be multiplied by the slopes, instead of multiplying each tabular number separately. For instance, let the natural slope be 5 (to one); the artificial slope, 1 (to one). Also, let the heights be, first section,
If the sections were at unequal distances apart—say 2, 1, 3 chains—each tabular number would have to be multiplied by the corresponding distance. The above example would then be modified as follows:

</tbody>
</table>

Total 13543 Total 669

Subtract 36868 6795

To extend the large table where either height exceeds 60, take four times the tabular number for half the given heights. For instance, the tabular number for {100, 90} is four times that for {50, 50}. To extend the small table, where either height exceeds 55, add the tabular numbers for any two heights which together make up the given height. For instance, the tabular number for 50 is the sum of the tabular numbers for 50 and 10, or of those for 55 and 5, &c.

To find the tabular number in the greater table, look for either height in the horizontal row of index figures, and for the other height in the vertical row of indices. The tabular number required is beneath the index and opposite the other. In the small table used for level-lying ground, only one index figure is used: the tabular number required is opposite it in the column designated by the given width of the formation level. For other widths than those given in the table, multiply the number to "base 1 foot" by the given width. **Example:** The number for height 27 to base 29 is 29 X 33.

**Measurement of slopes.**—The slopes on railways are measured by the horizontal distance corresponding to one foot vertical rise. If, for instance, the rise of one foot correspond to a horizontal distance of 2 feet, the slope is 2 to 1. The same mode of measurement is adopted here for the natural inclination of the ground. For the artificial inclination of the sides of the embankment or cutting.

**Change of the natural slope may occur in sidelong ground where the surface is very irregular. The sections ought to be taken so near that the difference of slopes at two successive sections may not be considerable. Now, by using exclusively the greater of these natural slopes with the actual heights, the result would be too large: by using the smaller of them, too small. But as the results obtained in these two ways will not in general widely differ, the truth may be taken as a mean between them.**

The difficulty arising from change of natural slope may however, in general be avoided. For the upper surface of the ground being undulating and irregular, the natural inclination is represented by equalising lines drawn so that the small curvilinear areas in excess and defect may balance each other. These equalising lines being in some degree arbitrary in position, may in general be drawn at the same inclination for several sections together.

ON THE APPLICATION OF SCULPTURE AND SCULPTURED ORNAMENT TO ARCHITECTURE.

By H. B. Garling.

At a meeting of the Royal Institute of British Architects, held on the 29th of May, the following paper was read:—"Essay on the Application of Sculpture and Sculptured Ornament to Architecture, and the Factors which inculcate and influence these Results generally, both with regard to Beauty of Embellishment and Propriety of Style." By Mr. H. B. Garling; for which the Silver Medal of the Institute was awarded.

If from the study of some individual branch of fine art, we proceed to consider how to combine any two or more of them in the same composition, with the largest effect,—in investigating the relation they bear to each other, the means by which the impressions conveyed by the one are influenced by its connection with the other, and the sources from whence our ideas of beauty or grandeur in each department result, we cannot fail to remark the close and striking analogy which exists between all the various branches into which fine art is divided, whether by the impressions they produce upon the mind, or the means by which those impressions are effected. We shall find that though varying in the organ by which they address the imagination, or the vehicle by which they convey their impressions to the mind, they influence the same feelings, strike as it were the same chords, and depend upon varying form in only, to produce effects substantially the same.

Whether it be architecture or sculpture, painting, music, or poetry that engages our attention, it is but the expression of one and the same sentiment—the collecting and arranging in the most effective manner, the giving form and substance, as it were, to those ideas and images, from which result our impressions of the sublime and beautiful.

Though we may be various in all, this common origin and aim, yet between the connection is obvious; and the assistance they afford to each other, when skillfully combined, more natural and effective.

Thus, if to the symmetry and proportion of architecture we add the graceful terminations and flowing lines of sculpture, or the relief and rich variety of pictorial embellishments, we enhance the value of each by placing it in its most effective position, and surrounding it with suitable and appropriate accessories.

To the artist it is, therefore, an important as well as an interesting investigation to consider how the architect and sculptor may unite their labours with the most successful result; and what rules we must observe in the treatment of each department to produce a harmonious and effective combination.

If we commence our investigation by tracing the distinguishing features of these arts in each, then proceed from the materials bequeathed by its predecessor, the first that engages our attention is the colossal architecture of the Egyptians. The distinguishing features of these extraordinary edifices are so well known as scarcely to need description: interesting as they may be, we must reserve our consideration and speculation on other points, to the artist they afford but scanty materials for study, and still less for imitation and example.

That the germs of beauty and proportion may be traced in a certain propriety of decoration and regular disposition of parts may, perhaps, be denied; as also that certain effect of grandeur may have been attained; the results of colossal size both in the general mass, and also in the details of the composition. Yet they exhibit a style of art so circumscribed in its object, so limited in its resources, and so much fettered by conventional ideas and principles, as to limit the advancement beyond a certain point—forming, in fact, a perfect refutation of the social condition of the people with whom it originated.

If from Egypt we turn to Greece (where exquisite refinement of taste and feeling were combined with a social condition more favourable to progress than in the former country), we shall find the powers of the artist rapidly increasing with the demand for their employment, and the scope afforded for their exercise. Aiming at the attainment of beauty by nicely-Adjusted proportions and propriety of decoration, and attaining grandeur and dignity of effect, not by a few parts and variety of design, we observe even in their earliest efforts the germs of that perfect mastery of all the resources of art, which subsequently ripened and expanded into the inimitable productions of the age of Pericles.

Apart from the merits of each in its particular department, the principles they observed in combining architecture and sculpture in one composition claim our most careful attention. Whether forming the graceful terminations of the acroteria, or filling up the voids of the pediments, or metopes of the Doric entablature, or decorating the walls in long continuous friezes of the Ionic and Corinthian Order, we observe how admirably the sculptural accessories complete the general outline of the masses, fill up every void space with rich and appropriate decoration, and relieve the more regular forms of the architecture with the most pleasing variety of lines; imparting poetry or feeling to the whole composition, and in giving a most important degree the character aimed at by the architect.

The rules observed in the treatment and distribution of sculpture by the artists of Greece, obtained throughout the whole of the best period of classic art. The triumphal and monumental buildings of antiquity are particularly interesting, as exemplifying the views and ideas of artists of the most acknowledged skill and judgment. The mausolea of Halicarnassus, of Hadrian, and of Augustus, the Antonine and Trajanic columns, the triumphal arches on the Via Sacra, the commemorative monuments in short of every class, when carefully considered, will be found to possess a character admirably adapted to the purposes of their erection: but in the application of these ideas to our own times, we must ever keep carefully in view the particular circumstances which guided them in the forms and arrangements they adopted. After a long period toward the decline of the Roman empire, the abandonment of true principles became apparent in all its departments—in none more so than in the treatment of sculptural accessories,—their meretricious character and the profusion of ornament (often exceedingly coarse and inelegant) designed to keep pace with the true dignity of style and so happily attained in the works of a better period. Of these abuses the latter examples of Roman architecture, particularly the baths and even to a greater degree the gorgeous remains at Balbec and Palmyra, afford remarkable instances.

The political convulsions which for centuries distracted the world, so completely buried in barbarism and ignorance every class of literature and every vestige of art, that scarcely any production worthy of the name can be recorded. This destruction of art has to be considered as having contributed a great deal toward the principle of taste being abandoned, and its most essential rules being completely lost sight of, all hope of further progress was staid; and thus, though for a time its extinction was most complete, this very circumstance may be said to have paved the way for its regeneration on better principles, at a subsequent period. By it was annihilated all mere conventional rules, and by it was destroyed every false standard of excellence; and the absence of precedent compelled the artist to go back to the study of nature, the only source from which, in early ages, he can, and in all ages, he should, derive his ideas, however remote in his judgement, or collect experience from the works of others: and from this constant reference to nature alone, we must trace that freshness of feeling and vigour of conception with which the early productions of art and literature teem, and which we strive in vain to catch when the French classic was at its height. The rules were refined and enervated, and its structure more artificial and complicated.

Art will invariably take its tone and expression from the character of the age in which it is produced; it is an influence the artist cannot resist; it forms the very atmosphere he breathes; and from it the constitution of his mind takes its tone: the experience of the past offers no exception, the character of art at the present day confirms it.

As the arts gradually emerged from the obscurity in which they were buried (fostered by a patronage peculiarly favourable for the development of their loftiest powers), they began to assert their true position and exercise their legitimate influence upon society; and while the monuments of classic art were rapidly falling to decay, another style of architecture arose, based on principles of construction and of composition almost diametrically opposite to those of classic art as the source from whence it sprang, the purposes to which it was dedicated, and the character of the age and people amongst whom it originated. The sculptural accessories are no less different in character than the architecture with which they are associated. These sculptural accessories (often vigorous in conception, and consisting principally of isolated figures, stiff and constrained, sometimes even restored to life by conventional and prescribed ideas of symbolism than by rules of artistic composition), convey ideas more by symbollical arrangement than by a combination of action and expression; of this perhaps some few examples may be given in the most striking examples. Thus in the sculptural decoration of medieval architecture we observe a style of art too subordinate in
its character, too circumscribed in its views, and too much fettered by conventional forms to expand and assert an independent position; aiming solely at the expression of devotional feeling by the adoption of simple forms. These remarks do not apply to the artists of the modern Italy; for, following the model of the antique, united to these sentiments the lofty expression of intellect and ideal perfection; and thus produced a distinguishing merit and charm in their works. In the revival of the classical style in Italy, we, in the treatment of the two arts of architecture and sculpture, meet with the observance of the same principles which guided the artists of classic times; but not, however, carried out with the same refinement of feeling and correctness of taste. The vigorous and fertile imagination of the great Italian masters (though it enabled them to trace out their own path, and to identify the formless mass of the materials, without, however, tamely copying their model) often betrayed them into irregularity, which marred the effect of their most successful works; while by artists of inferior talent, exaggerated action and expression, eccentricity, and extravagant conceits, were too often confounded with the bold original forms and veins of truth. Of these defects the palaces and churches of Italy afford innumerable instances, which will immediately occur to those acquainted with the works of these masters. It cannot, indeed, be denied, that the peculiarity of the Italian style admitted a freedom of treatment in this respect; but, on the other hand, has not exposed it to inadmissible in correct and regular compositions; but at the same time it will be obvious that there is a limit to these irregularities, which can only be assigned by good taste and discriminating judgment to the particular part of the artist himself.

The first and most important principle to observe a perfect accordance in style and character with that of the building to which we apply it, that it not only should illustrate its object and purpose, by intelligible and appropriate allegory, but convey it also by feeling and sentiment, even to the minutiae of execution, (for the skilful architect and skilful artist only admits that the main features of his building to the purpose for which it is designed, but also expresses it in every member, and moulds every detail in exact accordance). But to produce that harmony and propriety (which is the essence of all the healthful feelings of the productions of art), we must in addition, distribute it so judiciously through the composition, and so nicely adjust it in proportion and position, that it shall appear an integral portion of the design,—the work as it were of one hand, and so completely the expression of the whole, that a communication of feeling with every part, even when the composition is removed by its removal: that neither by disproportionate size, nor too prominent a position, it should obtrude offensively on the eye; nor by the opposite extreme, appear to retort too much and lose its legitimate effect and place in the composition. The regulation and nice adjustment of the parts can consist in the simple device, since every individual case will require a different treatment, but it must altogether be attained by that refinement and correctness of taste on the part of the architect which can only result from a careful and accurate study of the best models, united with the greatest and discriminative taste.

As a subordinate and purely decorative feature, it will be of the utmost importance that the outline of the sculpture should be regulated by, and accord most accurately with, that of the architecture; and that it fill up with precision those circumscribing lines within which it is inscribed; that there be no protuberance, undue projection, or ungraceful deflection in the contour, either in itself, or in combination; and that it do not interfere with, or break off those main lines which indicate the constructive features of the building, or the continuity of which expresses the arrangement and unity of the composition. It will also be found a point of considerable importance, in combining sculpture with architecture, to adopt a sober and subdued style of composition in the position and arrangement, particularly in the treatment, of the draperies and accessories, not only in isolated figures and in those which form the terminations and crowning members, but also in the composition of the friezes and pediments. The confusion produced by exaggerated action or intricate grouping will be immediately detected by its decomposing and harsly contrasting, without relieving the lines of the architecture, and on the other hand must be avoided a manner of straggling arrangement, and the stiff effect arising from perpendicular and horizontal lines. The value of sculpture as a decoration (independent of the sentiment it conveys) consists much in the relief it affords by carrying up the eye with its graceful terminations, what would otherwise be void and blank, with varied and undulating lines and forms of the most exquisite beauty. The success with which the artists of Greece moulded and adapted these requirements will prove that, when properly treated, they tend neither to cramp the ideas nor to shake the invention of the artist.

If it be necessary to observe these rules in the treatment of great masses, it will be found still more so in the case of isolated figures; and the infringement of them produces still more ungraceful effects. On the revival of art in Italy, distortion and exaggerated action and expression were too frequently confounded with originality and vigour of execution; and we are continually meeting with that most grievous instance of the infringement of these rules and the ungraceful effects resulting therefrom.

In placing sculpture in juxtaposition with architecture, it is obviously a point of no small importance to consider the scale thereof, which is to be used in combination with that of the building; and to demonstrate with argument, that with which every artist must be acquainted; viz., that magnitude is relative rather than actual, and that by skilfully proportioning details, or by placing in juxtaposition features, with the size of which, by habit, experience, or the ordinary features of the composition are merely increased in actual size, and the same relative proportions observed, the scale by which we measure is increased in nearly the same ratio. We may also observe, that the undue exaggeration of the human figure beyond its natural proportions, so far from invariably producing the effect of impressiveness akin to those resulting from actual deformity; the proportions these parts, however, a point which must depend solely upon the judgment of the artist, and one for which no rule can be laid down: a careful study of the best models and an accurate observation and study of the works already executed, will form the best and perhaps the only guide.

When we observe how necessary to produce a pleasing and harmonious effect (even in isolated works, which are to be considered as complete in themselves and not affected by external circumstances), are the duly balancing the corresponding parts of the composition; the skilfully contrasting and combining forms and lines of varying contour; the duly filling-in and adjusting every part so as to give one outline to the mass, however varied in detail,—it is obvious, that in combination with architecture, the mass must be respected; this must be exaggerated, by contrast with the regularity of the lines and masses with which it is associated; and to this point, therefore, the artist must direct his most diligent attention.

In designing groups and figures which crown and form the termination of the composition, it will be found of the greatest importance that the figures in every aspect appear in perfect equilibrium, and firmly planted and balanced on the pedestal on which they stand, devoid of any protuberance or projection, either in limb or drapery, which may appear to throw the mass more on one side than on the other. It will for this purpose be necessary to study the work from every possible point of sight from which it can be seen; since we have continually to observe that though perfect when viewed in some positions, this due equilibrium of the mass is disturbed when seen in others, and, when, in reality and mechanically speaking, it is duly poised.
this important point, the works of the artists of the revival above alluded to (though masters of perspective and perspective effects) afford innumerable instances; while of consummate skill and science in meeting these requirements, the inimitable productions of the Grecian chisel afford at once a most striking example, and to the art a model of the variation of circumstances; are ascertained by an accurate observation of the effects of certain combinations; and are inseparably connected with the productions of certain results as cause and effect in mechanical appliances in the physical world. It is the attribute and characteristic of true genius intuitively to know, and instinctively to apply them, however necessary experience, careful observation, and diligent study may be to mature the judgment and refine the taste. To conform to them will exercise its ingenuity rather than restrict its powers, while their due observance will give force and precision to its efforts, by directing them in the right channel, and by preserving it from those irregularities which mar the productions of genius unaided by experience and education.

RESISTANCES TO RAILWAY TRAINS.

EXPERIMENTS DOWN INCLINED PLANES BY GRAVITY.

Some experiments have recently been made on the retardation of trains on inclined planes; and as the subject has been much discussed, a brief analysis of the results may be acceptable—an account of the experiments themselves will be found at the end of this paper. It is to be observed, that the circumstances under which they appear to have been conducted, render uniformity and certainty in the conclusions from them very difficult, or rather absolutely impossible.

In the first place, to get a general law of resistance by experiments on inclined planes, it is absolutely requisite that the line should be straight, the air calm, and the distance traversed considerable. Of the resistance of curves, and wind in motion, nothing can be known till the resistance in motion shall be ascertained. To begin with the more complex enquiry is to entangle the subject with phenomena, respecting which ignorance virtually is confessed, by the very circumstance of making the experiment.

It is imperative necessity that the distance traversed should be considerable—and we urge this point the more strongly, because it applies, not only to the present experiment, but also to former experiments on the narrow-gauge railways. The report to the British Association on Railway Resistances (1837) contains the following important remark, which is worth repeating.

"In every case hitherto examined, the uniform velocity which may appear to have been attained under such circumstances, is somewhat less than that attained on the same plane, when the train has commenced the descent at a considerable velocity; it may therefore be doubted, if trains running in order to have attained a uniform state of rest on planes on which the experiments have been made, may not really be travelling at a very slowly accelerating velocity, and as the lengths of such planes of one inclination do not enable this to be ascertained with certainty, it has been deemed better to exclude such results. The same rule has been followed for similar reasons in analysing the other series of experiments on inclined planes referred to in this paper."

This remark applies to the experiments before us, and also to those undertaken by Mr. Wyndham Harding on the Croydon Atmospheric Railway. Of course, it is only where the mass or the train is small, that the resistance soon begins to tell; the effect of the inertia of large trains travelling at high velocities, is best seen by considering the distance they will move when subject to the enormous pressure of the break.

The present experiments being subject to these various sources of error, disreparancies which greatly diminish the value of the conclusions indicated. For instance, in each of the first nine experiments (except the 6th and 8th, which may be altogether disregarded on account of the disadvantageous circumstances under which they were conducted), there occurs an unexplained increase of velocity at the distance 84. This may, perhaps, be attributable to local circumstances; but what is more important, is the fact that the alteration of the gradient from 83 to 85 makes no perceptible alteration of the speed, is out of the question for trustworthy experiments the present season. This consideration furnishes a convincing proof of the danger of drawing deductions from the apparent uniformity of motion for short distances. If the resistance in pounds per ton for a given velocity
We do not bring into the comparison the experiments of the Gauge Commission, in which the resistance is derived from the consumption of water by such an arbitrary and dangerous process, that we feel justified in rejecting that evidence entirely. Neither can Mr. Wyndham Harding's experiments on the Croydon Atmospheric Railway, by the difference of barometric pressures, be admitted into the comparison for the rapid increase of resistance with increase of speed, rest almost entirely on these experiments, and therefore, as we think, on an insufficient foundation.

The following results are obtained from several distinct experiments:

<table>
<thead>
<tr>
<th>Miles per hour</th>
<th>Resistance 1b. per ton</th>
</tr>
</thead>
<tbody>
<tr>
<td>61</td>
<td>52-6</td>
</tr>
<tr>
<td>53</td>
<td>41-7</td>
</tr>
<tr>
<td>50</td>
<td>36</td>
</tr>
<tr>
<td>47</td>
<td>33-7</td>
</tr>
</tbody>
</table>

In the first place, the results obtained by the barometer are inconsistent with themselves; the resistance at 33 miles an hour is fifteen per cent. more than at a less velocity of 53 miles. The only experiment at upwards of 60 miles an hour, allows an increase of resistance so disproportionate, as naturally to induce suspicion; at all events, a single result, so inconsistent with all previous observation, ought not of itself to be sufficient evidence of a general law. Moreover, this very experiment was conducted under circumstances most unfavourable to a satisfactory conclusion. The distance traversed was 31 miles, the time of transit four minutes and a half, and the recorded velocity fluctuated from 32 to 61 miles. And yet this anomalous trial is the mainstay of the theory of high resistances at high velocities! We have already shown the great effect of the inertia of trains at the highest velocities, and the extreme uncertainty of any conclusions from the apparent uniformity of motion; that the uniformity is apparent only and not absolutely certain, the brief duration of the experiment and its great fluctuations so striking a conclusion.

It is important to observe, in confirmation of this view of the subject, that the barometric method of calculating resistances, always gives results which, as far as they can be compared, exceed those obtained by any other method.

On the whole, we are inclined to an opinion, from the insufficient evidence before us, that the resistance does not increase so much with the velocity as has sometimes been contended; and that the resistances per ton, do not differ widely on the broad and narrow gauge. The advantage, if any, belongs to the former; principally, we imagine, on account of the comparative smoothness of motion over longitudinal sleepers. There can be no reasonable doubt, that comparing the longitudinal and transverse sleepers, when both are in perfect order, the former, by giving more perfect support to the rails, render them less liable to vibration and concussion. It may be laid down, as a general rule, that whatever increase in the regularity of motion from the reducing of the resistance. One of the consequences of this rule is, that the resistance of trains is diminished by diminishing their lateral oscillation. On this subject we have not space to speak at length; it is sufficient to observe, that the tendency to oscillate depends on what is known in navigation as the pitch of the vessel; this is therefore diminished by diminishing the height of the vessel, and by reducing the proportion of the height of the centre of gravity to the distance between the points of support.

(Abbreviated from the "Morning Herald.")

We return to the consideration of this interesting and important practical railway investigation. As we have previously stated, the question of the resistances to railway trains at certain velocities, is not a mere scientific question, but one in which the convenience and accommodation of the public is at stake. The materials of the South Eastern narrow-gauge railway, and reported in his paper presented to the Institution of Civil Engineers:

<table>
<thead>
<tr>
<th>Miles per hour</th>
<th>Resistance 1b. per ton</th>
</tr>
</thead>
<tbody>
<tr>
<td>50</td>
<td>22</td>
</tr>
<tr>
<td>58</td>
<td>26</td>
</tr>
<tr>
<td>43</td>
<td>19</td>
</tr>
<tr>
<td>36</td>
<td>less than 10</td>
</tr>
</tbody>
</table>

These results agree very well with those obtained in 1846, by Mr. W. Harding, as the dynamometer of the South Eastern narrow-gauge railway, and reported in his paper presented to the Institution of Civil Engineers:

<table>
<thead>
<tr>
<th>Miles per hour</th>
<th>Resistance 1b. per ton</th>
</tr>
</thead>
<tbody>
<tr>
<td>29</td>
<td>10-5</td>
</tr>
<tr>
<td>37</td>
<td>18-3</td>
</tr>
<tr>
<td>45</td>
<td>21-7</td>
</tr>
<tr>
<td>46</td>
<td>21-3</td>
</tr>
</tbody>
</table>

To complete the comparison, we select those of the experiments of the British Association which were made at velocities above 30 miles an hour, on inclined planes on narrow-gauge lines:

<table>
<thead>
<tr>
<th>Miles per hour</th>
<th>Resistance 1b. per ton</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>23-4</td>
</tr>
<tr>
<td>34</td>
<td>25</td>
</tr>
<tr>
<td>32</td>
<td>22-5</td>
</tr>
</tbody>
</table>

It is to be observed, that these rates of resistance considerably exceed the former.
much greater uniform velocity than 53 miles per hour, even under very unfavourable circumstances, can be obtained down 1 in 100, by gravity; and that consequently the foundation on which many railway engineers have reared the very pillars of their theory of high rates of resistance at high velocities, is utterly without substantiability,—that, indeed, it is a mere fallacy, which will hereafter be numbered amongst the delusions and visions of practical men.

The whole of the following experiments were made with ordinary working trains, and the object was not to collect minute data from which any scientific results might be deduced, but simply to prove,—exclusive of the results of experiments made by either broad or narrow gauge engineers,—that what has been considered up to the present as an essential cause giving resistance to the resistance to railway trains descending inclined planes by force of gravity, is a mere "circumstance," which, although applicable to narrow-gauge trains, is utterly inapplicable to broad-gauge trains. The diversities in the rates of speed shown in the workings given below arose, no doubt, from a great variety of causes. Nearly the whole of the portions of the line over which the experiments were made consisted of a series of curves, and of cuttings and embankments. The carriages were of different weights, and may occasionally have been well or badly coupled. On one day the trains were running in the morning, on another in the evening, for starting and ending in some of the experiments there was a slight head wind, in others a moderate side wind from the right, or a moderate side wind from the left prevailed, and during three of the experiments there was a brisk side wind. The speed, too, at which the trains were running when the steam was shut off would, in relation to the weights of the carriages, as well as to the direction of the wind, enter into the causes of these diversities of speed. We shall, however, not hazard a single opinion on these matters, but confine ourselves to demonstra-
tions of the high resistances at high velocities is worthless in respect of the resistance due to broad-gauge trains descending inclined planes by their own power.

In the experiments made down the Wootton Bassett incline with the dynamometer carriage, constructed under the directions of Mr. Treadwell, the carriages were weighed to 10 tons each. In no one of the experiments given below, which were made with the ordinary passenger trains, did any of the carriages amount to this weight—that is, they were not full of passengers. The engines employed belonged to an old class, and weigh, road-worthy, about 23 or 24 tons.

It has been objected against the experiments made down the Wootton Bassett incline with the dynamometer carriage, that the distance over which a uniform or increasing velocity was attained, viz., 10 or 11-16ths of a mile, is too short to produce a useful practical result. It must be remembered that the incline took the rates of speed not only down the mile and one-eighth of the fall of 1 in 100, but down the next seven-eighths of a mile, which are on a fall of 1 in 660 only. The fall of 1 in 100 commences a few chains beyond the 85th mile-post, and terminates a few chains beyond the 85th mile-post. Thence to the 86th mile-post, the fall is 1 in 660. The first experiment was made with a train consisting of four passenger-carriages, three horse-boxes, and one luggage-wagon, weighing about 50 tons. The engine was the "Orion." The table gives the working for the quarter mile immediately preceding the 85th mile-post, as well as from the 85th to the 86th mile-post. The rails were dry, and very little wind was stirring. It will be seen that the speed for upwards of half-a-mile down 1 in 660 is very little different from the uniform velocity down three-quarters of a mile in 1 in 100. We merely record the fact, leaving those who have more time at their command than we have ourselves to explain or suggest the causes.

The second trip was with a train of four passenger-carriages and a horse-box, weighing about 45 or 46 tons, and was attached to the "Mars" engine—rails dry and weather calm. The third trip was with the same engine, with three passenger-carriages, one luggage-wagon, and two horse-boxes, weighing about 45 or 45 tons. The fourth experiment was made with the "Firebrand" engine. The train consisted of three passenger-carriages and a luggage-wagon, weighing about 36 tons. The carriages were well filled with passengers. The fifth experiment was with the "Orion," with four passenger-carriages, three horse-boxes, and a luggage-wagon, weighing about 59 or 60 tons. The steam was not shut off in this case until the engine was within a few chains of the 85th mile-post. The sixth experiment was with the "Load Star." The train consisted of four passenger-carriages and a luggage-wagon, weighing about 41 or 42 tons. A brisk side wind prevailed on this occasion, and the same result was produced as in the previous experiment, where a side wind affected the train, viz., alternating rates of speed.

The seventh experiment was with the "Bellaqua," with four passenger-carriages and a luggage-wagon, weighing about 41 or 42 tons. A brisk side wind prevailed on this occasion, and the same result was produced as in the previous experiment, where a side wind affected the train, viz., alternating rates of speed.

The eighth experiment was with the "Firebrand," with a train of four passenger-carriages and a luggage-wagon, weighing about 45 or 45 tons—rails dry; slight side wind.

The ninth experiment was upon the Bristol and Exeter line from the 174th to the 176th mile-post. This portion of the line is on a fall of 45-50 feet per mile, or about 1 in 120. The engine employed was the "Load Star," and the train consisted of four passenger-carriages and a luggage-wagon, weight about 41 or 42 tons. The descent was commenced at a speed of about 36 miles per hour—rails dry, and slight head wind.

In this experiment the velocity dropped to about 20 feet per mile, less than that down which the narrow-gauge trains have never yet maintained a uniform velocity of more than 36 miles per hour, increased from 53-3 to 42-4 or 48-4 miles per hour. And yet we have little doubt we shall still find practical men contending for the high rates of resistances which some of the narrow-gauge part party unreasonably assume to be due to all railway trains travelling at high velocities.

The eleventh experiment was from the 1728 to the 1708—viz., two miles. The engine employed was the "Saturn," and the train consisted of five passenger-carriages and a luggage-wagon, weighing about 56 or 57 tons. For about two-thirds of a mile the train traveled over a fall of about 6 chains of 1 in 90, and another fall of about 7 or 8 chains of 1 in 82. The rest of the distance is on a fall of 1 in 90. The average velocity of the train through the White Ball Tunnel, 49 chains in length, and which immediately precedes the inclines over which we took the working of the train, was 42-5 miles per hour. It will be seen that this speed was increased to 50 miles an hour at the 1708th mile-post.

The twelfth experiment was a second run down the 1 in 120, between the 174th to the 175th mile-post. The engine employed was the "Firebrand," and the train consisted of four carsriages and a luggage-wagon, weighing about 44 or 45 tons—rails dry, and moderate side wind.

The thirteenth and last experiment was with the "Milo," and a train of three passenger-carriages and a luggage-wagon. Weight, about 34 or 35 tons. A brisk side wind prevailed.

In this experiment the steam was shut off at the 1728 mile-post, which is in the White Ball Tunnel.

**REVIEWS.**

[SECOND NOTICE.]

What Mr. Stevenson calls "Notes on the Illumination of Lighthouses" may more rightly be called another work, and one not less important nor valuable than the account of the Skerryvore Light. Indeed, he calls the former Part II. He begins it by a short history of lighthouses, in which he shows a great deal of learning; and as by the former part every one will see that he is a hard-working man, so by this they will see that a man may be able to understand Homer in Greek, and yet be a good engineer.
We both think of those who are wrong, those who wish to make the engineer a man of book-learning only, and those who want to make him a borer under the name of a working-man. Brunel, Robert Stephenson, Locke, the Rennies, Walker, and many more, have shown that to be a great engineer, and to make great progress, there is no place for a man of commonplace education. We'Ve should always put the two together if we could,—we would have the man of learning and the working-man.

Mr. Stevenson's way of commenting on the classics is rather a new one,—rather unlike the Byzantine school, Scaliger, and the Revival critics, or the great High Dutch lights of this day. Some of these workmen have put forth the bold thought, that the Cyclopes were the keepers of lighthouses; some bolder still, that by the Cyclops was shadowed forth the lighthouse itself. Mr. Stevenson's answer, is, that in the ninth book of the Odyssey, and at the 145th line, Homer tells us that in the darkness of the night, the fleet of Ulysses went ashore on the Cyclopean island. Mr. Stevenson looks at it with a workman's eye, and he says if there had been a lighthouse, the ships would not have struck in the dark. The words he brings forward show that it was pitch dark, and give no hint of a lighthouse; and therefore we think of Mr. Stevenson, and in the teeth of the commentators. He has not, however, taken the trouble to set his Greek into English, so that his working readers may understand it.

What Mr. Stevenson says of the lighthouses of our days is the more worthy of being read, as he has seen many of them himself, and looked at them with the eye of a master.

Speaking upon lighting, Mr. Stevenson says, that down to a very late time there was to burn wood or coal in chafing dishes on the tops of high towers or hills. Many now living know that the Isle of May light was of that kind, before it came under the care of the Board of Northern Lights in 1860. For forty years after the time of Euston, the fires were lighted only with oil and candle. These lights were therefore very weak, and there were no means of knowing one light from another, so that the seaman might shape his way. Even now, it often happens that seamen mistake lights, and by going inside, instead of outside, or by going around instead of straight ahead, the vessels are wrecked. The new lighthouses were of little more good than to give warning that land was near; so that ships, if they could, lie by or put out to sea until daylight.

Mr. Stevenson now speaks of flammable. He says:—

"Solid substances which remain so throughout their combustion, are only luminous at their own surface, and exhibit phenomena, such as the dull red heat of iron, the dull red heat of coal, the purpose of producing heat than light. But by using substances which are formed into inflammable vapours, at a temperature below that which is required for the ignition of the substances themselves, gas is obtained and a flame is produced. The principle is this:—gas is a combustible substance from which it is evolved, owing to its being formed at a temperature considerably higher than that of the surrounding air, than which it is necessarily rarer. Of this description are the several kinds of gas, the burning of the various substances which are generally employed in the illumination of lighthouses. In the combustion of oil, wicks of some fibrous substance, such as cotton, are used, into which the oil ascends by capillary action, and being supplied in very thin films, is easily volatilized into vapour or gas by the heat of the burning wick. The gas of pit-coal has been occasionally used in lighthouses; it is conveyed in tubes to the burners, in the same manner as when employed for domestic purposes. There are certain advantages, more especially in dioptric lights, where there is only one large central flame, which would render the use of oil impracticable, or render the use of oil in the form of a deposit, which is an object of considerable importance, would thus be rendered less variable, and could be more easily regulated, and the inconvenience of the clock-work of the lamp would be wholly avoided. But it is obvious, that gas is by no means suitable for the majority of lighthouses, their distant situation and generally difficult access renders the transport of large quantities of coal expensive and uncertain; whilst in many of them there is no means of erecting the apparatus necessary for manufacturing gas. There are other considerations which must induce us to use a dioptric gas as the fuel of lighthouses: for, however much the risk of accident may be diminished in the present day, it still forms a question, which ought not to be hastily decided, how far we should be justified in running even the most remote risk of explosion in establishments such as lighthouses, whose sudden failure might involve conseqiences of the most fatal description, and whose situation is often such, that their re-establishment must be a work of great expense and time. Gas is, besides, far from being suitable in dioptric lights, to which, in many cases (especially when these accommodations are employed near coast), the olive oil is chiefly used; and a species of the former has lately been successfully introduced into the lighthouses of Great Britain."

Sperm oil is that which has been hitherto most burned; but colza oil will, it is thought, be found much better, and that a saving of one-half can be made. It was Mr. Joseph Hume, when characterizing, or rather he was a commoner, the Colusa Lighthouses, who showed that colza oil was cheaper. Since then, Mr. Stevenson has tried it, and has told the Northern Lighthouse Board that it will give a saving of £2,396 yearly; but since that, colza oil is worth more, and Mr. Stevenson is not so strong in his feeling about it.

Of the Drummond and Voltia lights, the writer says:—

"The application of the Drummond and Voltia lights to lighthouse purposes is, owing to their prodigiously intense, a very desirable consumption; but it is surrounded by so many practical difficulties that, in the present state of our knowledge, it may safely be pronounced unattainable. The uncertainty which attends the exhibition of both these lights, is of itself a sufficient reason for coming to this conclusion. But other reasons unhappily are not wanting. The smallness of the flame renders them wholly inapplicable to dioptric instruments which require a great body of flame in order to produce a degree of divergence sufficient to render the duration of the flash in revolving lights long enough to answer the purpose of the mariner. Mr. Frensel made some experiments on the application of the Drummond light to dioptric instruments, which completely demonstrated their unfitness for this commercial work. He found that the light obtained by the focus of a great annular lens was much more intense than that produced by the great lamp and lens; but the divergence did not exceed 30°; so that, in a revolution like that of the Corduan light, the flashes would last only 1½ second, and would be, therefore, too short to suit the practical purposes of a revolving light. The great cylindrical reflector in fixed lights of the first order, was also tried with the Drummond light in its focus; but it gave coloured spectra at the top and bottom, and only a small bar of white light was transmitted from the centre of the instrument. The same difficulty is met with in respect to the Drummond light with the reflector for the purposes of a fixed light, and even if this cause did not operate against its application in revolving lights on the catoptric plan, the supply of the gases, which is attended with almost insurmountable difficulties, would make it impossible to maintain the light precarious and uncertain in the last degree."

The Drummond light is produced by the ignition or combustion of a ball of lune (4 inch diameter) in the united flames of hydrogen and oxygen gases, and is equal to about 264 of Argand lamp with the best spindled oil. It derives its name from the late Lieut. Drummond, R. E., who first applied it in the focus of a paraboloid for geodetical purposes, and afterwards proposed it for lighthouses. (See his account of the light in the Phil. Trans. for 1826, p. 324, and for 1830, p. 383.) The Voltia light is obtained by passing a stream of Voltia electricity from a powerful battery between two charocal points, the distance between which requires great nicety of adjustment, and is the chief circumstance which influences the stability and the permanency of the light. The Voltia light greatly exceeds the Corduan light in this respect; it also has a much greater comparison of the same kind as in its effect and in its effects; but the ratio of their power has not been accurately determined. It was first exhibited in the focus of a reflector by Mr. James Gardner, formerly engaged in the Ordnance Survey of Great Britain."

After speaking of what Argand did, and of the burner he made, which was such a great step, Mr. Stevenson comes to the reflector:—

"The name of the inventor of paraboloidal mirrors and the date of their first application to lighthouses, have not been accurately ascertained. The earliest notice which I have been able to find, is that by Mr. William Hutchinson, the pious and intelligent author of a quarto volume on 'Practical Seamanship' (published at Liverpool in 1791), who notices (at p. 93) the erection of the four lights at Bridstone and Hoylake, in the year 1763, and describes large parabolic moulds, fashioned of wood and lined with mirror-glass, and smaller ones of polished tin-plate, as in use in those lighthouses. Mr. Hutchinson seems to have understood the nature, properties, and effect of the instrument, and to have given a good account of the mirrors in use, and in acquaintance with many of the most important circumstances to be attended to in the illumination of lighthouses. Many claims to inventions rest on more slender grounds than might be found in Mr. Hutchinson's book for concluding that he had invented the paraboloidal reflectors and applied it to the lighthouse; but, in the absence of any statement as to the date when the mirrors were really adopted, the merit of the improvement must, in justice, be awarded to others."

Mr. Teulier, a member of the Royal Corps of Engineers of Bridges and Roads in France, is, by some considered the first who hinted at the advantages of paraboloidal reflectors; and he is said, in a memoir dated the 25th June 1783, to have proposed their combination with Argand lamps, ranging on a revolving frame, for the Corduan lighthouse. Whatever foundation there was in the charge of Mr. Teulier that this plan was actually carried into effect at Corduan, under the directions of the Chevalier Borda; and to him is generally awarded the merit of having conceived the idea of applying paraboloidal mirrors to lighthouses. These were important steps in the application of lighthouses, as not only the power of
the lights was greatly increased, but the introduction of a revolving frame proved a valuable source of differences in the appearance of lights, and, in this way, has since been the means of greatly extending their utility. The exact date of the change on the light of the Cordouan is not known; but as it was made by Lenoir, the same young artist to whom Borda, about the year 1789, entrusted the construction of his reflecting circle, it has been conjectured by some that the improvement of the light was made about the same time. The reflectors were formed of sheet-copper, plated with silver, and had a double ordinate of 31 French inches. It was not long before these improvements were adopted in England, by the Trinity House of London, who sent a delegation to France to inquire into their nature. In Scotland, one of the first trials of the Northern Lighthouses Board in 1766, was to substitute reflectors in the room of the coal-light then in use at the Isle of May in the Firth of Forth, which, along with the light on the Cambrse Isle in the Firth of Clyde, had, till that period, been the only beacons on the Scotch coast. The first reflectors employed in Scotland were formed of facets of mirror-glass, placed in hollow parabolicoid hollows of plaster, according to the designs of the late Mr. Thomas Smith, the Engineer of the Board, who (as appears from the article Reflector, in the Supplement to the third edition of the "Encyclopedia Britannica") was not aware of what had been done in France, and had himself conceived the idea of this combination. The same system was also adopted in Ireland; and in time, variously modified, it became general wherever lighthouses are known.\r
\r
The reflectors used in the best lighthouses are made, says the writer, of sheet-copper plated in the proportion of six ounces of silver to sixteen ounces of copper. They are moulded to the paraboloidal form, by a delicate and laborious process of beating with mallets and hammers of various forms and materials, and are frequently tested during the operation by the application of a mould carefully formed. After being brought to the curve, they are laid round the edge by means of a strong bezize, and a strap of brass which is attached to it for the purpose of preventing an accidental alteration of the figure of the reflector. Polishing powders are then applied, and the instrument receives its last finish.

The frame generally used in reflectors, is from an Argand fountain-lamp, whose wick is an inch in diameter. Much care is bestowed upon the manufacture of the lamps for the Northern lighthouses, which sometimes have their burners tipped with silver to prevent wasting by the great heat which is evolved. The burners are also fitted with a sliding apparatus, accurately formed, by which they may be removed from the interior of the mirror as the time of cleaning them, and returned exactly to the same place, and locked by means of a key. This arrangement, as shown in figs. 1 and 2, is very important, as it insures the burner always being in the focus, and does not require that the reflector be lifted out of its place; every time it is cleaned; so that, when once carefully set and screwed down to the frame, it is never altered.

It will please our readers very much to find in Mr. Stevenson's book, the many clever tools which are used, and care which is taken to make the lamps and lights as good as may be. He has written a good deal about feeding the lamps with oil, and indeed everywhere he has showed that he is master of his work, even in the smallest things. It was said of the Duke of Wellington, that even to the horses' shoes he knew everything in his army, and that he thought nothing beneath him which he had to do with the welfare of his men; and so should it be with the engineer; and this is the way in which he can truly become a working-man. Mr. Stevenson may not perhaps have put on a fustian coat, nor spent his time in filing, rasping, and fitting; but an engineer may be a working-man without that.

Lights are found by seamen so useful, that they are always carried on board for every voyage; but it becomes very troublesome to know one from another. A light must be thought good enough to the benighted mariner the land he has made, as the sight of a hill or tower would have shown him in the day; therefore, it becomes needful that each should be readily known, so as not to be mistaken.

Catastrophic lights are susceptible of nine separate distinctions, which are called fixed, revolving white, revolving red and white, revolving red with two white, revolving white with two reds, flashing, intermittent, double fixed lights, and double revolving white lights. The first exhibits a steady and unvaried appearance, which is proper only to any change of position for which a use is made for it, of the same sizes smaller than those employed in revolving lights. This is necessary in order to permit them to be ranged round the circular frame, with their axes inclined at such an angle, as shall enable each to illuminate every part of the horizon. The revolving light is produced by the revolution of a frame with three four sides, having reflectors of a larger size grouped on each side, with their axes parallel; and as the revolution exhibits once in two minutes, or once in a minute, may be required, a light gradually increasing to full strength, and in the same gradual manner decreasing to total darkness, its appearance is extremely well marked. The succession of red and white lights is caused by the revolution of a frame whose different sides present red and white lights; and these, as already mentioned, afford three separate distinctions, namely, alternating fixed; twirling white and red; the succession of two red lights after one white light. The flashing light is produced in the same manner as the revolving light; but owing to a different construction of the frame, the reflectors on each of eight sides are arranged in the form of a circle, and the line connecting two adjacent snows to the perpendicular, a disposition of the mirrors which, together with the greater quickness of the revolution, which shows a flash once in five seconds of time, produces a very striking effect, totally different from that of a revolving light, and preventing the appearance of the flash over, having been as long and sinking. The brightest and darkest periods being but momentary, this light is farther characterised by a rapid succession of bright flashes, from which it gets its name. The intermittent light is distinguished by bursting suddenly into view and continuing stationary for a short time, after which it is suddenly eclipsed for half a minute. Its striking appearance is produced by the perpendicular motion of circular shades in front of the reflectors, by which the light is alternately hid and displayed. This distinction, as well as that called the flashing light, is peculiar to the Northern Lighthouses Board, and was first introduced by the late Engineer of the Northern Lights Board. The double lights (which are seldom used except where there is a necessity for a leading line, as a guide for taking some channel or avoiding some danger) are generally exhibited from two towers, one of which is higher than the other.

At the Calf of Man, a striking variety has been introduced into the character of leading lights, by substituting, for two fixed lights, two lights which revolve in the same periods, and exhibit their flashes at the same instant; and these lights are, of course, susceptible of an extreme variety of combinations, that of two revolving red and white lights, or flashing lights, coming into view at equal intervals of time. The utility of all these distinctions is to be valued with reference to their property of at once striking the eye of an observer, and being instantaneously obvious to the same.

Although colour is needful, it is in itself a very great evil, for the coloured screens stop much of the light. Several colours have been tried, but red, blue, and green have alone been found useful; and the two latter only at such short lengths, that they are altogether unfruitful for sea-lights. Even the red lights take up from four sevenths to five sixths of the whole light, which is a very great loss; and the deeper the red, the greater the loss of light,—while the less red there is, the less can it be seen by the seaman. Red lights ought, therefore, to be used as little as may be. In Scotland, instead of a red screen or disc, a chimney of red glass is used.

We now come to the use of lenses, upon which the writer says:—

"One of the earliest notices of the application of lenses to lighthouses is that recorded by Smeean in his 'Narrative of the Eddystone Lighthouse,' where he mentions a London optician, who, in 1758, proposed grinding the lighthouse out to a radius of ten to six inches, but that the cost of making the figure and the quantity of light absorbed by the glass, which was of impure quality and of considerable thickness, rendered its effect so much inferior to that of the parabolic reflectors then in use, that after trying some strange glasses and lenses and revolving lights, he was compelled to abandon the project. Lenses were also tried at the lights of Portland, Hill of Howth, and Waterford, by Mr. Thomas Rogers, a glass manufacturer in London; who possessed, it is said, the art of blowing mirrors of glass, and by a new method silvered over the convex side without quicksilver.

The merit of having first suggested the building of lenses in separate
pieces, seems to be due to Condorcet, who in his *Éloge de Buffon*, published so far back as 1773, enumerates the advantages to be derived from this method. Sir David Brewster also described this mode of building lenses in 1811, in the *Edinburgh Encyclopedia*; and in 1822, the late eminent Fresnel, a Frenchman, in his *Traité du Phénomène de Condorcet*, explained his method by Sir David Brewster, explained, with many ingenious and interesting details, the same mode of constructing those instruments. To Fresnel belongs the additional merit of having first followed up his invention, by the construction of a series, and, in conjunction with M.M. Arago and Auvray, making a powerful lighthouse in its focus, and instead of finally applying it to the practical purposes of a lighthouse.

To show Fresnel’s system fully would take more room than we can give, and many wood-cuts, and we are sorry that we must leave it alone, and send our readers to Mr. Stevenson’s book, an excellent thing in full, as Fresnel’s brother having put his papers in Mr. Stevenson’s hands.

One of Mr. Stevenson’s own works was with the Isle of May light.

“Having been directed by the commissioners of the Northern lighthouses to convert the fixed catoptric light of the Isle of May, into a dioptric light of the first order, I proposed that an attempt should be made to form a true cylinder, instead of a polygonal belt for the refracting part of the apparatus; and this task was successfully completed by Messrs. Cookson of Newcastle in the year 1800. The line of the lighthouse is drawn from the *Leuchtturm*，“the light house, to the line joint at which they are cemented. With the exception of those trifling changes, the idea at first entertained of the construction of the instrument was fully realised at the manufactory of Messrs. Cookson.”

Speaking of Fresnel’s lamp, used in the French lighthouses, Mr. Stevenson wrote:

“The only risk in using this lamp arises from the liability to occasional derangements of its leathern valves that force the oil by means of clockwork; and several of the lights on the French coast, and more especially the Cordouan, have been extinguished by the failure of the lamp for a few minutes, an accident which has been happened, and scarcely can occur with the fountain lamps which illuminate the reflectors. To prevent the occurrence of such accidents, and to render their consequences less serious, various precautions have been resorted to. Amongst others, an alarm is attached to the lamp, consisting of a small cup pierced in the bottom, which receives part of the overflowing oil from the wicks, and is capable, when full, of balancing a weight placed at the opposite end of a lever. The moment the machinery stops, the cup ceases to receive the supply of oil, and, the remainder running out at the bottom, the equilibrium of the lever is destroyed, and it falls and disengages a spring which rings a bell sufficiently loud to wake the sleeper should he chance to be asleep. It may justly be questioned whether this alarm would not prove a temptation to the keepers to relax in their watchfulness and fall asleep; and I have, in all the lamps of the dioptric lights on the Scotch coast, adopted the converse mode of causing the bell to cease when the clockwork stops. There is another precaution of more importance, which consists of having always at hand in the light-room a spare lamp, according to the use of the lamp for the focus, which may be substituted for the other in case of accident.”

In the French lights, “these distinctions depend upon the periods of revolution, rather than upon the *characteristic appearance* of the light; and therefore seem less calculated to strike the eye of seamen engaged on the coast of Great Britain and Ireland. In conformity with this system, and in consideration of the great loss of light which results from the application of coloured media, all distinctions based upon colour have been discarded in French lighthouses.

The distinction, in fact, only four in number, viz.: fixed; fixed varied by flashes; revolving; with flashes once a minute; and revolving with flashes every half minute. To those might be added, revolving, with bright periods once in two minutes, and perhaps flashing once in five seconds (as introduced by me at the Little Ross, but I cannot say with much success), and a variety of sequences (as recommended in a recent digest). My own experience would lead me to reject the distinction called ‘fixed, varied by flashes,’ which I do not consider as possessing a marked or efficient character.”

For putting lights on a shore, Mr. Stevenson lays down a few laws for the engineer, which will be found very useful for those of other orders who may have to build lighthouses in our settlements abroad:—

“1. The most prominent points of a line of coast, or those first made on over-sea voyages, should be first lighted; and the most powerful lights should be adapted to them, so that they may be discovered by the mariner as long as possible before his reaching land.

2. So far as the attention to distinction, revolving lights of some description, which are necessarily more powerful than fixed lights, should be employed at the outposts on a line of coast.

3. Lights of precisely identical character and appearance should not, if possible, occur within a less distance than 100 miles of each other on the same line of coast, which is made by over-sea vessels.

4. In all cases, the distinction of colour should never be adopted except from absolute necessity.

5. Fixed lights and others of less power, may be more readily adopted in narrow seas, because the range of the lights in such situations is generally less than that of open sea-lights.

6. In narrow seas also, the difference between lights of the same appearance may often be safely reduced within much lower limits than is desirable for the greater sea-light; and there are many instances in which the distance separating lights of the same character need not exceed 50 yards, or less, and there are parts of coast on which even a much less separation between similar lights may be sufficient.

7. Lights intended to guard vessels from reefs, shoals, or other dangers, should in every case be placed, where practicable, to the seaward of the danger itself, as it is desirable that seamen be enabled to make the lights with confidence.

8. Views of economy in the first cost of a lighthouse should never be permitted to interfere with placing it in the best possible position; and, where the view is not sufficient, it will generally be found that the most efficient course is to delay the work until a sum shall have been obtained sufficient for the erection of the lighthouse on the best site.

9. The position of the light on the sea should not, if possible, for sea-lights, exceed 200 feet; and about 160 feet is sufficient, under almost any circumstances, to give the range which is required. Lights placed on high headlands are subject frequently to be wrapped in fog, and are often rendered useless at a time when lights on a lower level might be perfectly efficient. But this rule must not, and indeed cannot, be strictly followed, especially on the British coast, where there are so many projecting cliffs, which, while they subject the lights placed on them to occasional obstruction by fog, would also entirely and permanently hide view lights placed on the lower land adjoining them. In such cases, all that can be done is carefully to weigh all the circumstances of the locality, and choose that site for the lighthouse which seems to afford the greatest prospect of advantage to use of the light. As, however, it is expected, in questions of this kind, the opinions of the most experienced persons are often very conflicting, according to which the various elements which enter into the inquiry.

10. The best positions for lights are not to be sought rarely to be neglected for the sake of some neighbouring port, however important or influential; and the interests of navigation, as well as the true welfare of the port itself, will generally be much better served by placing the sea-light where it ought to be, and adding, on a smaller scale, such subsidiary lights as the channel leading to the entrance of the port may require.

11. It may be held as a general maxim, that the fewer lights that can be employed in the illumination of a coast the better, not only on the score of economy, but also of real efficiency. Every light that is uselessly erected may, in certain circumstances, become a source of confusion to the mariner, and, in the event of another light being required in the neighbourhod to give warning of shoals expected, it is not to be foreseen that much good can be got from the lights which existed previous to its establishment. By the useless erection of a new lighthouse, therefore, we not only expend public treasure, but waste the means of distinction among the neighbouring lights.

12. Distinctions of lights, founded upon the minute estimation of intervals of time between flashes, and especially on the measurement of the duration of light and dark periods, are less satisfactory to the great majority of coasting seamen, and are more liable to derangement by atmospheric influences. It is therefore to be recommended to draw distinct periods of five and one second interval, and revolving lights of half a minute, one minute, and two minutes, are much more characteristic than those which are distinguished from each other by intervals varying according to a slower series—40”, 10”, 20”, 40”, etc.

13. Harbour and local lights, which have a circumscribed range, should generally be fixed instead of revolving; and may often, for the

This is a new edition of a very well known book. An editor who undertakes the revision of the scientific works of another writer, undertakes an onerous and difficult task. If he alter and interpolate freely, he may be charged with disrespect towards his author; if, on the other hand, he adheres too faithfully to the text, he becomes responsible for the original errors, as well as for all which he himself may happen to commit.

Dr. Olinthus Gregory, of the Woolwich Military Academy, published the first edition of his "Mechanics for Practical Men," in 1823; and eight years after, a subsequent edition, in which he says, "I have corrected a few errors which had escaped my notice in the former impression." The work commences with an elementary treatise on arithmetic and algebra, and the remainder is devoted to geometry and the mechanical sciences. This part of the work is, in his own phraseology, "synoptical." The definitions and principles are exhibited in an orderly series, but investigations and demonstrations are only sparingly introduced. So much the greater, then, the importance of accuracy. Where results only are given, the reader must trust entirely to the authority of the writer: the careful, self-investigating author, he adores too faithfully to be a trusting fool, is possible means of ascertaining the accuracy of the conclusions. They must be taken on trust. Like bank-notes, they may or may not represent sterling value; but in the absence of direct information, their circulation depends entirely on the credit of the issuer.

We pass over the definitions and principles. It is well known, that the accuracy of formulae is something more than a matter of mere speculative interest—that, on the contrary, it has a real and tangible importance, quite apart from theoretical considerations. It was at one time thought that mathematical investigations of questions of engineering and practical matters—were curiously—learned pastimes. Now it is found, that if a bridge be constructed according to insufficient formulae, it not only ought theoretically to fall down, but practically will do so. If, on the duty of a steam-engine for a given quantity of fuel be inaccurately computed, not only are the laws of science infringed—but the pocket of the owner of the engine suffers also. In this way, scientific accuracy comes to have a practical importance, a real money value: and those who prided themselves that they were "practical men," and thanked heaven that they never troubled themselves about scientific theories, and that they were all very well for college-students, and people who have nothing else to do,—discern factually that their self-congratulation is premature.

These considerations render us very anxious that the theoretical sciences should not suffer the practical engineering injury by misplaced confidence: and with this object, we proceeded to the more particular examination of the work under review,—premising that, as far as we have compared it with the preceding edition, most of the errors appear to be Dr. Gregory's originally, and not by imputation only; and it is nothing but fair to suppose that the latter was actuated by a feeling of deference towards his author.

We pass over the treatises on arithmetic and algebra without examination; being altogether elementary, they may be presumed to be correct. Our criticism commences with the definitions of Curves.

A cycloid or trochoid is an elegant mechanical curve, first noticed by Descartes, and an account of which was published by Mersenne in 1615. It is in fact the curve described by a sail in the rim of a carriage-wheel while it is in a state of revolution under the influence of gravity.

Cycloids or trochoids are used as synonymous words! They are names of curves essentially different: for the former, the tracing point is on the circumference of the generating circle—for the latter, the tracing point is within or beyond that circumference.

If the generating circle, instead of rolling along a straight line, is made to roll on the circumference of another circle, the curve described by any point in its circumference is called an epicycloid.

It is not called an epicycloid except when the generating circle is equal to the fixed circle, and rolls on the exterior of it. In the other cases, the curve generated is either a Hypotrochoid, Epitrochoid, or Hypocycloidal. The definition of an epicycloid, this mistake is aggravated, by representing the rolling curve as much larger than the fixed circle. It is of the very essence of mathematical definitions that they should be precise and comprehensive; and in no part of mathematics is this exactness of definition more necessary than in ma-
chanics. What will our mathematical readers say of such a definition as the following?

"When the forces that act upon a body, destroy or annihilate each other's operation, so that the body remains quiescent, they are said to be in equilibrium, and are then called pressures."

This is clumsy and incomplete, to say the least. It is assumed, the text continues, that each body affects the others. The body is at rest—the case of uniform motion is overlooked. Besides, the word pressure is restricted to statical forces, whereas it is properly applied to dynamical forces also.

* * *

Vis viva, or living force, a term used by Leibnitz to denote the force or power of a body in motion; or the force which would be required to bring it to rest.

Leibnitz never did anything half so absurd as is here said of him. Vis viva is not a force (or power) for Dr. Gregory previously states that the words force and power are synonymous.

* * *

The second problem of the chapter on Statics, the calculation respecting the strain on tie-beams and struts is totally erroneous. It is not worth while to state the problem here, as we could not make it clear without labouring too much the words. To the reader who has the work before him, it will be sufficient to state that the error arises from considering the forces at one end of the strut and tie-beam, and neglecting the forces at the other end of each. The conclusion is manifestly erroneous, for when the tie-beam became indefinitely long, it would be vertical, and the tension equal to the weight suspended; the strain on the strut at the same time became zero.

* * *

If the particles or bodies of any system be moving uniformly and rectilinearly, with any velocities and direction, the centre of gravity is either at rest, or moves uniformly in a right line.

This is not true. Does the author mean to assert, that if two bodies be moving with different velocities in straight lines perpendicular to each other, the common centre of gravity moves in a straight line?

In discussing the pressure of earth against walls, the line of rupture and the natural slope are said to be synonymous—they are entirely different things; the line of rupture being that which defines what is technically termed the wedge of maximum pressure. In the next paragraph is discussed the pressure exerted against the wall by the prism resting on the natural slope; whereas, by the very definition of natural slope, the prism exerts the frictional being of the exact amount necessary to sustain the weight.

The section on the stability of the arch discusses the conditions for a case of rupture which is mechanically and geometrically impossible, for there are only three joints of the crown, the loadings symmetrical, and the piers incapable of sliding. In the last of the formulae in this section, the right-hand side of the equation has double its proper value.

The preliminary part of the chapter on Dynamics has been rewritten—not however, as we think, with great success. The confusion of ideas respecting vis viva is really marvellous, considering how simple the real signification of the phrase is. Mr. Law says, first, "Mechanical effect is measured by the product of the mass or weight of the body into the space over which it has moved." Then he defines the vis viva of a moving body as "the whole mechanical effect which it will produce in being brought to a state of rest." This definition is by no means satisfactory. First, the mass on weight are spoken of as convertible terms. Next, coupling the two definitions, the vis viva is said to "produce the mass or weight multiplied by the distance." This is a strange way of putting it; however, if we look out the word mass, and for distance read "twice the distance," the idea intended to be conveyed is tolerably correct, where the motion is vertical and the only force is that of uniform gravity. For bodies acted on by variable force, and for curvilinear motion, the definition is totally inapplicable.

In place of an enunciation of the three laws of motion, we have the following experiments as the foundation of dynamics.

* * *

From carefully conducted and often-repeated experiments, the following results with regard to bodies in motion have been obtained:

1. If a body of a certain weight, and moving with a given velocity, meet another body of double that weight, and moving with half the velocity, the two bodies will destroy each other's motion, and both will be brought to a state of rest.

2. A body of a certain weight and moving with a given velocity, being subjected to a uniformly retarding force (i.e., a uniform force acting constantly in a contrary direction to the body's motion), will move over a certain space in being brought to rest, and will occupy a certain time in doing so; then another body of the same weight, but moving in the opposite direction of the former, being subject to the same uniformly retarding force, will move over one quarter of the space moved over by the former, in being brought to a state of rest, and will occupy in doing so half the time. And another body of the same weight, but moving with a third of the first, will move over one ninth of the space and occupy one-third the time of the first, in being brought to a state of rest.

The second experiment would be analogous to that of trying whether all points in the circumference of a circle possess the property of equidistance from the centre! It is in a manner of definition that they should have. But the mere definition of uniformly retarding force leads to the inference here indicated as the result of numberless experiments. The conclusion depends on mere geometry, not on any law of mechanics. If a horse set off at a constantly diminishing speed—say, 20 feet the first second, 40 feet the next, 48 feet the next, and so on—it requires no knowledge of mechanics, but a simple arithmetical computation, to ascertain how far he has gone, and the time which has elapsed, when his velocity is reduced to 20 feet a second. In the same way, if a body be acted upon by a uniformly retarding force—that is, one which diminishes the velocity at an absolute rate—the law of motion is assigned a priori, and it requires no experiment to determine the distances corresponding to subsequent rates of velocity. The rule that the distance traversed by the body comes to rest is proportional to the square of the velocity destroyed, depends on purely geometrical computation.

In the section on Motion on Inclined Planes, we find the following:

"Each particle of matter is a rolling body resists motion in proportion to the square of its distance from the axis of motion, nor in any other proportion. It is incorrect to say that matter resists motion; it neither resists nor assists it, but is perfectly impasive and inert. The force of inertia, as M. Poisson observes, is an incorrect phrase, springing from inaccurate notions of the properties of matter—it, in fact, implies an idea that matter has some inherent property of altering its own motion."

In the section treating of Pendulums, it is asserted, that if a body suspended from a fixed point by a flexible string be made to vibrate, it will always rise the same vertical distance as it has descended. This is of course true when the motion is not disturbed; but it is added, that if the motion of the string be intercepted by a projecting peg, so as to shorten the radius of the arc in which the body moves, the same property is generally true. It is obvious observation that the peg may be so near the vibrating body, that the radius becomes too short to allow the body to regain its original height. Moreover, the string receives a jerk; and therefore, unless it be perfectly elastic, there is a loss of vis viva.

After a confused and inaccurate definition and table of values of the radius of gyration for several bodies, we have the following lucid explanation of the principles of rotation:

"If the matter in any gyration body were actually to be placed as if in the centre of gyration, it ought either to be disposed in the circumference of a circle whose radius is R, or at two points R, R, diametrically opposite, and each at a distance R from the centre."

All that can be made out of this is, that if the body be in one place, "it ought to be" in another. The only inference from such a statement is a querulous determination on the part of the writer to be dissatisfied with the position of the body under all circumstances. The feeling is that of the wolf toward the lamb in the fable—a general disinclination that the body should have any position. Several preceding sentences gave rise to the suspicion that the author did not clearly understand the subject on which he was writing—the sentence just quoted converts suspicion into certainty.

The following are the definitions at the commencement of a chapter on Central Forces:

1. Centrifugal force is a force which tends constantly to solicit or to impel a body towards a certain fixed point or centre. (2.) Centrifugal force is that by which it would recede from such a centre, were it not prevented by the centripetal force. (3.) These two forces are, jointly, called central forces. Centrifugal force is not, as here stated, directed towards a fixed centre. It is normal to the path of motion; and, therefore, there is
only one particular case—that of circular motion—in which the above definition is satisfied. In elliptical and other kinds of motion it is violated at every instant. This consideration is of itself sufficient to show that the third definition is also incorrect. Central forces are always taken by mechanicians to be forces directed from one fixed point to another—that is, centrifugal force is not considered a central force.

The laws of motion about centres of attraction are applied to cases to which they have no relation. The following problem is an instance:

"If a fly, 2 tons weight and 16 feet diameter, is sufficient to regulate an engine when it revolves in 4 seconds; what must be the weight of another fly of 12 feet diameter revolving in 2 seconds, so that it may have the same power upon the engine?"

It seems scarcely credible that the solution of this problem is derived from the law of motion of a free body in a circle about a central force—that "the forces are as the distances or radii of the circles directly, and the forces inversely." Could it be believed, that a student who had read mechanics for six months, would apply a law, which is wholly independent of the mass acted upon, to a problem in which the mass is the most essential particular? By such logic, the following relation between the weights of the two fly wheels is established:

\[ W_D = \frac{d}{c^2} \]

where \(W, w\) are the weights, \(D, d\) the diameters of the wheels, and \(T, t\) the times occupied in revolution. Now, to show the absurdity of all this, we have only to express the times in terms of the linear velocities, \(V\) and \(v\), and the above equation becomes:

\[ \frac{Wv^2}{D} = \frac{wv^2}{d} \]

which leads to the conclusion, that for two fly wheels of equal weight, that having the greatest velocity must also have the greatest diameter—a conclusion to which our practical readers would probably demur.

It would take too much space to explain all that appears objectionable in the work before us. Mr. Law certainly has the credit of rendering the new edition somewhat better than the preceding, by introducing De Pambour's investigations of the power of the steam, and he observes with regretment of arrangement.

In the paper on the Strength of Materials, which is almost entirely re-written, Mr. Law gives some valuable views of the subject, which cause us to regret that he has not exercised keener criticism in other parts of the work. In estimating the transverse strength of materials, an ingenious theory is proposed, for representing the total forces of tension and compression in any section of a girder by solids, of which lines proportional to those forces are the horizontal ordinates. Unfortunately, he overlooks the fact that the total force at any horizontal compression or tension is equal and opposite. He assumes also that their moments are equal—whereas this is incorrect. This error vitiates equation (1), page 378, and all that depends on it.

Our review must close here, not from want of subjects for further comment, but because of the space we would occupy. We have done little more than point out, in the briefest possible manner, a few errors here and there; and have avoided general observations, lest our criticism should appear unduly severe.

---

This is the conclusion of a work of which the first portion was reviewed once, vol. X., p. 45. It will be remembered, that the distinguishing feature of Dr. Alman's subject is an earnest advocacy of the merits of the high-pressure steam-engine, which he contends, is for all purposes and under all circumstances, superior to the low-pressure engine. He proposes to increase the steam-pressure greatly beyond the limits now usually assigned to it; and, as his observations are the result of long practical experience in the manufacture of engines, and in superintending their working, they are at least deserving of consideration. His arguments are those of a careful and judicious observer, and the details of his experience, which he has laid before his profession with no ordinary amount of energy and ability.

In the present portion of the treatise, our author describes the form of the boiler and furnace adopted by himself, and which he recommends as models for general adoption. We must demur, however, to the notion of a model engine, and to any one outline of construction prescribed for universal practice. The steam-engine would lose much of its value if the arrangement of its parts were immutable. The diversity of forms which may be given to it, and the facility of adapting them to local exigencies, render the steam-engine the most convenient, as it is the most economical, of all engines.

The principle which characterizes Dr. Alman's boiler, is the circulation of hot water through the tubes, and the return to the boiler of the water which has been carried upwards in a liquid form with the current of steam. The dots in the figure will sufficiently explain the relative position of the tubes. \(c, d\) are two capacious vessels above them. The ends of all of them communicate with \(c\) the "separator," into which, therefore, the steam generated, and the water mechanically mixed with it, are carried. At that end of this vessel where steam and water are admitted, violent ebullition goes on; but as the capacity of the boiler is large, the water and steam become more and more separated as they progress to the further end, whence they pass quietly by their respective pipes to the receiver \(d\), in which an undisturbed water-level is maintained. From \(d\), the steam passes off to the engine, and the water is returned to renew its labyrinthine course through the tubes of the boiler.

Our author assures us that he has determined the efficiency and economy of this invention, by actual and careful experience. The advantage which he claims is, chiefly, that of having a tube system similar to the ordinary one, yet not liable to excessive ebullition or boiling dry. The tubes are of small diameter; consequently, their heating surface bears a higher proportion to the volume of water in them, than would be the case with tubes of a larger diameter. This circumstance, Dr. Alman says, is a most important point for the preservation of steam. At the same time, the tubes lie so far below the water-level, that a want of water in them is scarcely likely to occur: and if it did, it would take place first in the higher tubes, which are the least exposed to heat.

A still strike some of our practical readers, that this mode of construction, and the smallness of the tubes, must render them exceedingly liable to be impaired by the accumulation of deposit. We are told, however, that this is by no means so formidable a difficulty as it may at first sight appear, as the story concretion is confined to the upper tiers of tubes, and the arrangement affords easy access to them. It is however allowed, that tubes of so small size as those here described would not be applicable to marine boilers, in which a great deposit from salt water takes place.

After a minute description of the boiler, the writer proceeds to an examination of improvements of the furnace. He does not deem of much importance the "smoke nuisance," as it is emphatically termed in England, and declares the legal restrictions to which engine owners are subjected in Germany, to prevent them from injuring the air, while the bituminous furnaces down their neighbours' throats. "The English," says he, "continue to live well among their smoke, and find themselves well off on it; they neither turn up their noses nor get asthma, but they live, and live long." We, however, who live in England, are not easily to be persuaded that the vitiation of the air by smoke is a slight evil. The pollution of the air in London and the manufacturing districts, inflicts mischief of which the magnitude can only be appreciated by actual observation. The cities of the continent, by the limits of their size, and the comparative insignificance of the nuisances carried with them, are of little importance in the injury in question, that it is not surprising that a foreign writer should speak slightingly of it. But the thousands who annually fall victims to the chimney-polluted atmosphere of this metropolis, give mournful proof that it is no false sentimentality—no popular prejudice, that have at length rendered the sanitary regulation of manufactures an irresistible obligation on the legislature. Dr. Alman considers all the self-acting contrivances for consumption of smoke useless; and deems it vain to expect that any future inventions for the purpose will succeed. It is sincerely to be hoped, that an attention to the subject will not be given up in despair. There can be no question that much improvement has already been effected, and that the combustion of fuel is conducted in a more complete and perfect manner now than it was a few years ago. When the necessity of further experiments appears to us so apparent, we are no doubt of the advantage which will accrue from our mechanicians to greater efforts and to the discovery of methods which, we are convinced, have not yet been attained, because the inquiry has been partially or feebly conducted.
The subject next considered is the engine itself, in which several improvements are proposed. According to our author's principle of confining himself to one exclusive model for every part of the steam-engine, he here selects the oscillating-cylinder for universal adoption. The history of these cylinders as given by the translator is curious, and affords interesting testimony that a divergence of opinion with regard to them is not a new phenomenon. In this country, as in many other parts of the globe, steam-engines have been constructed with cylinders of various and differing forms. We do not think it necessary to enumerate all the varieties of the engine on which the advantages as necessarily serious; but that it exists, and is unavoidable, is obvious from mere inspection of a diagram showing the relative positions of the cylinder and crank.

The advantages of the oscillating-cylinder are: 1st, its simplicity, arising from the omission of the beam, parallel motion, and other parts; 2nd, the facility of construction, the fitting being in a great measure effected by the lathe; 3rd, compactness, and consequently suitability for steam-vessels; 4th, comparative lightness; 5th, the consequent portability; 6th, the omission of parts of the latter; 7th, the simplicity of working; 8th, the diminution of friction; 9th, the saving of grease for lubrication; 10th, the little repair required; 11th, the facility of discovering and rectifying any error of adjustment; 12th, the omission of guides for the piston-rods; and lastly, the direct and advantageous transmission of force.

There is one remark to be made on this enumeration of the advantages of the oscillating-engine, which, though simple, deducts greatly from its claims to pre-eminence. The greatest part of the metal claimed for it is not used exclusively, but is common to all kinds of direct-action engines.

Among the prominent features of Dr. Albam's views, is the preference which he tells us that long experience has induced him to assign to hemp packing for the piston. On the contrary, the opinion of many men of practical work is, that hemp packing is not capable of high-pressure engines, he considers the one method of cooling and the other of miraculous perfection which has been obtained in the manufacture of these engines.

Other objections to metallic packing are not to be thus disposed of. The cylinder and the piston are frequently of different metals, and therefore liable to different rates of expansion; consequently, the adjustment of the packing, though perfectly accurate when the metals are cold, becomes untrue after they are heated. Dr. Albam denies that the packing grinds itself steam-tight by working; on the contrary, he believes that if any imperfectness exist originally, it is aggravated by use. We are however inclined to believe that he speaks on this point from limited experience, for while the elasticity remains unimpaired, it presses against the cylinder any irregular protuberances which may exist, and the adjacent parts are protected from attrition till these be worn down to an even surface. With regard to the unevenly distributed, those parts most forcibly pressed against the cylinder will wear thin and be destroyed before the portions of the packing subjected to less pressure.

The liability of the packing to lose its expansive power, either by the generation of gases and losing its mobility, or by the destruction of the elasticity of the springs, is strongly insisted upon. It is also asserted that the complexity and number of the parts render them liable to get out of repair, and that they can never fit so closely as to be perfectly steam-tight. Hemp packing is preferred on account of its simplicity; and the author states, as a result of his experience, that a packing of rope, of loose unbleached flax, thoroughly lubricated, works well and remains steam-tight under high pressures. We will not absolutely assert that there are not circumstances under which this kind of packing may be used with advantage, but many of Dr. Albam's judgments have arisen from observing the working of metallic packing of inferior construction; and probably, if he were acquainted with the great improvements which have been effected in England in this part of the steam-engine, he might be induced to modify his opinions.

There are many other topics of the treatise before us deserving attention, but we must content ourselves with remarking, generally, that the very original views taken by the author are not those of an ingenious schemer merely, but of one who combines originality with practical knowledge, and enhances both by the eloquence of his arguments, in the methodic arrangement of his paragraphs, and the distinct statement of the results of his experience.
THE CIVIL ENGINEER AND ARCHITECT'S JOURNAL

Many excellent works on subjects connected with the profession of the civil engineer have at various times been published. But while the wants of the more advanced portion of the profession have been comparatively well supplied, the junior members have been left, at their entrance on the practical duties of their calling, almost without guidance. The many operations of the various branches of this branch of engineering are treated in a practical manner of the minor, though most important operations which form the principal duties of the assistant engineer, has long been felt; and we are glad to find that this requirement has been satisfied by Mr. Haskoll, in the work before us.

In the first part, published in 1846, the subjects of setting-out the centre line, taking the permanent section, boring, and the various operations preliminary to breaking ground, were discussed; in the second part, the author has devoted his attention to the setting-out of works, the subject of earthwork, the formation of the permanent way, and the many operations necessary while the railway is in progress of construction. These various topics are treated in a clear and practical manner: every variety of work, whether on the skew or straight, on a straight line or curve, is considered, and the methods of setting-out, and the precautions necessary during the execution of the work are also given. The author advocates the "rough and ready" system, but inculcates a careful attention to accuracy in every particular. This course more commonly adhered to, we should not so often hear of failure in works, causing often loss of life, and always great expenditure of capital.

The following passage will illustrate the author's views on this subject:

"Let me persuade the young practitioner, that the gratification he will feel at finding the string-courses of his bridges and viaducts at their true height and gradient, or the formation of a tunnel at the intended level, will alone amply reward him for the trouble, and no pedantry of a reputation for accuracy, which he will not fail to obtain in the opinion of a judicious chief, as also in the estimation of directors. Let him beware of the vaunts of 'rough and ready' men ('rough work and readiness to blunder'), who disguise their incapacity by plugging the practice to obtain truly correct levels; for if there be any truth, rational speaking, in this excuse, the greater should be the engineer's care to avoid errors, and not to do his work in a slovenly manner, whereby he may double and treble his 'mistake'; and he will find that contractors, masons, bricklayers, &c., will be careful and attentive, exactly in proportion to the care and attention which he himself bestows on the works. This observation applies exactly in the same sense, and to the same extent, in setting-out works. He will, moreover, have the satisfaction of knowing, that his mind is not a subject of reproach, that an engineer's work may be made to him; on the contrary, an error of this kind carried out can be considered little better than wilful neglect of duty."

After giving an example of a section book, containing columns for the half-widths, distance, total rise, finished levels, excavation, and embankment, on one side, with a sketch of the surface, and notes of the position and particulars of bridges, culverts, &c., on the other, the author adds the following hints:

"The pocket section being prepared so far, we should, as soon as the works of construction are determined on, insert notes from the working drawings, or otherwise, of the angles of skew at which the line crosses roads, canals, &c.; the spans of arches on the square and skew, the rise of the arch, the depth of arch stones, of puddle, if any; also, if the works be on an inclined plane, the rise or fall from centre to centre of pier; memoranda also, of nearly similar nature, should be made of girder bridges, culverts, drains, and other works occurring along the line. The notes on the plans are more than necessary; because, when on the works, the drawings, when required, are often mislaid, or partially defaced or destroyed. It must be added, however reluctantly, that the tracings with which contractors and sub-contractors are supplied, are often wrongly figured; and the site of construction, amidst the moving to-and-fro of masons, labourers, and 'navvies,' is not the place where such errors may be most readily detected and corrected."

The second chapter is devoted to earthworks; and here the author shows a practical acquaintance with the various considerations that determine the course to be taken in the treatment of this most important feature of the works of a line of railway. We subjoin a few extracts on cutting and embankment:

"The determination of slopes for earthwork is one of the most uncertain subjects the engineer has to contend with, if he be anxious to reduce as much as possible the quantity of excavation, in order to keep the amount of land to be disposed of in the lowest form of expense; but this reduction is attended with one great danger—namely, a 'slip,' which will often, for a considerable length, occasion a double and treble quantity of excavation, and the purchase of a corresponding quantity of land."

The slopes of cuttings and embankments will, of course, vary with the depth and character of the materials; in deep and soft chalk, the danger of slips is greater. In some cases, the ground is too uncertain; in solid, rocky masses, it will stand perpendicular; friable, it may require slopes of 1 to 1; —shear will stand at 2 to 1, if the stratification be horizontal and dry; but when wet and sandy, there will be gravel and clay; clay will bear a slope of 2 to 1; the most treacherous earth to be met with in excavating; we have known it for many months to stand perpendicular for a depth of 40 feet, and suddenly slip off, determining a slope of 3 to 1; there is no doubt, that one of the most dangerous practices of excavators is to allow a gullet of this depth and nature to stand for a great length of time without lightening the sides, nor should it under any circumstances be allowed. A thin bed of clay will very often occasion the slip of material of a better nature."

The best materials for the formation of embankments are gravel and sand, both from the facilities they offer for drainage, and their more rapid final consolidation; —soil, shaly earths are unfavourable, but if hard and dry they form good embankments, and settle well at slopes of 1 to 1; —vegetable earths, or what is termed soil, must be entirely rejected for the embankment, from their being so easily converted into soft mud; landowners, however, are always ready to carry these away, but care should be taken to preserve a sufficient quantity for sloping slopes; clays mixed with a quantity of stones, are by no means a bad material, and when dry, will form a sound embankment, though rather long in consolidating; —wet clay is as bad as pest, if not worse; it should never be allowed to be used under any circumstance whatever; a few waggons of wet clay, tipped in a deep embankment, will do more mischief by its slipping, and saturating all other materials laid on it, than one or even two thousand of good stuff will rectify, besides becoming for many years a continual source of settlement, and perhaps of danger, on that portion of the line. Where the less favourable materials must be employed for forming embankments, it is well to make it appear to the forming of embankments at an embankment to its full height and width, and to leave a few feet in height to be raised up with drier materials, if conveniently at hand; isolated masses of this description are often found in excavations, otherwise very inferior materials, which may be successfully employed for the purpose.

Two tables are given at the end of this chapter, which will prove of great assistance in estimating earthwork. The chapter on setting out of works goes very completely into the whole subject, and will render most valuable assistance to the young engineer; indeed, the information therein contained can be found in no other book than the one before us. After tables of experiments, by George Rennie, Esq., on the strength and other properties of various materials, now for the first time published, are given the specification and drawings of a very elegant and scientifically designed laminated arch, over the river Ouse, on the East Anglian Railway, designed by J. S. Valentine, Esq.; and at the end of the book are placed many tables of a useful character.

Mr. Britton, who takes in a wide range of subjects in his antiquarian ken, has added a new book to the many on the vexed question of the authorship of the Letters of Junius. This discussion does not come within our scope;—but it does to record the labours of one who has contributed so much to architectural literature.

Many of our readers will care very little about a system of railways for Ireland, though this little work deserves attention for what it says on that subject, but it requires notice as being the only attempt yet made to apply statistically to a given case the doctrine that railways can be made by means of existing resources, and that they are of a reproductive character. An additional value is given to it, that it contains the latest statistics on railway subjects, and many novel applications of them.

Among the chief points discussed, are the number of persons temporarily employed and permanently employed; the saving and reproduction on agricultural resources; the effect of extending the area of supply by extending the radius of communication; the average contribution and mileage of each head of traffic; the pecuniary or capital resources of Ireland; the correspondence between traffic estimates and traffic returns; and the existing traffic on Irish lines of road.

The following is a curious illustration of railway economics, and supplies evidence on a question which has been often mooted:—

"Mr. Porter, in the new edition of his work on the Progress of the National Trade, has given a table of the statistics of traffic generated by several railways, and by appending to them the actual traffic from the returns made in 1845, we shall be able to see how far the estimates have been borne out. The estimates for the railways constituting the Midland Railway, are as follows:—"

<table>
<thead>
<tr>
<th>Passengers</th>
<th>Cattle</th>
<th>Sheep</th>
<th>Merchandise</th>
<th>Coal</th>
<th>Cash by Land</th>
<th>Cash by Water</th>
</tr>
</thead>
<tbody>
<tr>
<td>Birmingham and Derby</td>
<td>145,747</td>
<td>7254</td>
<td>27,105</td>
<td>14,947</td>
<td></td>
<td></td>
</tr>
<tr>
<td>North British</td>
<td>18,612</td>
<td></td>
<td></td>
<td></td>
<td>12,924</td>
<td>28,000</td>
</tr>
<tr>
<td>Midland Counties</td>
<td>255,424</td>
<td></td>
<td></td>
<td></td>
<td>12,924</td>
<td>28,000</td>
</tr>
</tbody>
</table>

Total estimated: 480,095; 7254; 27,105; 161,855; 285,000.

Midland Railway, 1845: 1,600,145; 80,000; 130,000; 371,154; 313,844.

The Midland Railway traffic included, likewise, 30,000 pigs, and 16,200 tons of lime. The merchandise carried by water was estimated at 355,738 tons, and this, and a great quantity of coal, are still carried by water, so that the railway has, as it were, created an amount of traffic.

The estimates and returns for the Manchester and Leeds Railway stand thus:—

<table>
<thead>
<tr>
<th>Merchandise</th>
<th>Coal</th>
<th>Cash by Land</th>
<th>Cash by Water</th>
</tr>
</thead>
<tbody>
<tr>
<td>Estimates</td>
<td>207,888</td>
<td>106,486</td>
<td>358,938</td>
</tr>
<tr>
<td>Returns</td>
<td>1,674,046</td>
<td>507,852</td>
<td></td>
</tr>
</tbody>
</table>

Thus the traffic on the railway is greater than that previously moving by land and water, although the canal traffic is as great as before.

The estimates and returns of the York and North Midland Railway stand thus:—

<table>
<thead>
<tr>
<th>Merchandise</th>
<th>Coal</th>
<th>Cash by Land</th>
<th>Cash by Water</th>
</tr>
</thead>
<tbody>
<tr>
<td>Passengers</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Estimates</td>
<td>185,660</td>
<td>55,100</td>
<td>88,689</td>
</tr>
<tr>
<td>Returns</td>
<td>401,752</td>
<td>351,024</td>
<td>87,639</td>
</tr>
</tbody>
</table>

The traffic in this case resembles that of the Manchester and Leeds in its results.

The following are the estimates and returns of various other railways:—

This will be found useful as a book of reference, on account of the facts and figures it contains, and the mode in which they are applied, as it is the only work which has yet embraced the subject of railway traffic in a practical and comprehensive manner.

REGISTER OF NEW PATENTS.

REDUCTION OF COPPER ORES.

Charles Low, of Roseberry-place, Dalston, Middlesex, gentleman, for "Improvements in the manufacture of zinc, copper, tin, and other metals."—Granted November 4, 1847; Enrolled May 4, 1848.

The title of this patent is more comprehensive than the specification, as the patentee disclaims all parts of the title, excepting that relating to copper. The object of the improvements is to quicken the manufacture of copper from its ores, and to diminish the loss of metal. In reducing the ores a compound is employed, consisting of oxide of manganese, plumbago, nitrate of potash, nitrate of soda, and lime, and carbon. On some of these materials the patentee states to be oxide of manganese forty-two parts, plumbago eight parts, nitrate of potash, nitrate of soda, or lime, two parts, and carbon fourteen parts; the carbon to be used, the patentee prefers to be either anthracite coal or wood charcoal. The mode of operation is as follows: the ore is roasted in the usual manner and then melted; and when in this state, the composition of the four materials named is introduced into the furnace and well mixed with the melted ore. The composition is introduced in the proportion of twenty-five pounds weight to one ton of ore operated upon, and acts as a flux. The slag rises more rapidly than ordinary, and the surface of the melted mass, and is then to be skimmed off. When the workman perceives the metal is in a sufficiently forward state of manufacture, a second quantity of the composition in equal proportions is added, and the mass is again stirred and skimmed. The additions of the composition are repeated if necessary, until the copper is in a sufficient state to be removed and operated upon in the usual manner. Should it be considered desirable, the composition may be introduced at any of the subsequent meltings of the ores, either in addition to, or without being introduced at the first melting. The patentee does not confine himself to the precise proportions specified of the materials, nor to the precise mode of operation described, but claims the employment of the compound of oxide of manganese, plumbago, nitrate of potash, nitrate of soda, or lime, and carbon.

DRESSING ORES OR MINERALS.

William Brunton, jun., of Poole, Cornwall, civil engineer, for "certain apparatus for dressing ores or minerals."—Granted November 16, 1847; Enrolled May 16, 1848.

This invention consists in the application of centrifugal force combined with the upward impulse of water in the dressing of small ores. The first part of the apparatus consists of a tank from the bottom of which a square; then a fine sieve, having a wire or perforated metal bottom, the apertures being in size to the ore about to be dressed. This sieve is fixed upon an upright shaft or spindle, revolving in a bearing at the bottom, and having a turned journal at its upper end. The depth of the annular space between the inside of the tank and the sides of the hole in the sieve is immediately under the bottom of the sieve a partition, extending about one-third of its area, crosses the tank, and having communication with the discharge pipe of a force-pump. On the opposite side of the tank is a receptacle for the ore, and this is supplied by an instrument termed a "skimmer," its lower end forming a mouth, and equal in breadth to the semi-diameter of the sieve; the stem being hollow, and bent at a certain portion of its length (turning downwards), so that anything passing through it will be deposited in the receptacle attached to the tank. A rotating motion being given to the sieve by means of a shaft and pulleys fixed upon the upper end of the upright spindle, and the sieve being charged with ore or mineral by means of a hopper placed above it, the mouth of the skimmer is so regulated that, as the whole revolves, the water is forced upwards through the sieve by the action of the force-pump. The ore, by excess of weight, falls through the bottom of the sieve into the tank, and the waste is carried into the mouth of the skimmer, in consequence of the rotating force, and passes thence through the pipe or stem into the adjoining receptacle.

The treatment of water which is carried with the waste returns into the tank, and is sufficiently close to be used again. The area of the piston of the pump should not be less than one-third the area of the sieve, and from 60 to 100 impulses should be given by the pump before the skimmer is set to work; by this means the particles are raised, separated, and adjusted according to their specific gravity and bulk. Should the "orey" stuff be larger than the apertures of the sieve, the feed from the hopper is shut off by a little door that closes its mouth, and a shoot being placed on or
SMELTING COPPER ORES.

WILLIAM BIRKMYRE, of Southdown, Cornwall, for "Improvements in smelting copper and other ores."—Granted November 16, 1847; Enrolled May 16, 1848.

The chief object of this invention is to remove the nuisance arising from the sulphuric and sulphurous acid vapours, and from the vapours of arsenic, during the smelting of copper ores. The process is thus described:—A double iron forge is constructed upon the usual principles, the ash-pits being furnished with a leaden cistern, filled with water, to abate the nuisance arising from the sulphuric and arsenious acids, when drawing out the munda ashes. Over the charging-door for the munda, is an air-hole, of its being filled with the pause necessary for combustion. The size of the double iron pyrites kiln should be 13 feet long, 7 feet 6 inches wide, and 8 feet high, and each furnace should be 5 feet in diameter, and of an octagonal form, lined with fire-bricks. Above the charging-door for the munda, is a second one, to take out the usual large and small ores, and copper, 4 feet 6 inches long, 3 feet 6 inches wide, and having a rim round it three or four inches deep. This is so placed as to enable the air and acids to pass freely out of the top of the furnace into a vitriol chamber, which is placed over the kilns. The vitriol chamber should be 160 feet 6 inches long, 11 feet 6 inches wide, and 8 feet deep, divided into three compartments, technically called "bottoms." The acid in that compartment nearest to the kiln being impure, should be kept apart, but the acid in the second and third compartments will be found to contain good vitriol. The chemical of the kilns will be found capable of producing two tons of copper per diem, by means of munda, and, at the same time, of three tons of vitriol of a specific gravity of 1·847. The copper ore being broken into pieces, about the size of walnuts, is put into the tray by means of a shovel or hopper (the furnace being charged with iron pyrites and previously kindled). After a lapse of six hours the other kiln is to be charged in like manner, and so on alternately. For every 8 cwt. of munda ashes withdrawn, add a charge of 10 cwt. of munda containing 40 per cent. of sulphur, as for every 32 parts of sulphur it gains, it gains only 32 parts of oxygen; but in copper ore, the process carefully completed, it gains as much in oxygen as it loses in sulphur; some copper ores it is stated will gain as much as four per cent. About 14 cwt. of ore should be placed in the tray, and the charge should be spread out into a body of from one to two inches thick, which should be turned over now and then, in order that every part of it should be exposed. After being submitted to the process for one hour, it is to be turned into a leaden cistern, supplied with hot water from the cooling cisterns underneath the kilns, to undergo the process of lixiviation. The tray is then again charged with ore, and the process is continued. It requires two roasting and lixiviation by the electro-metallurgic process to obtain the pure copper. Another method of calculation is, when the pulverized copper pyrites are exposed in the tray, pour upon them a hot solution of nine parts of saltpetre, and eight parts of vitriol, or equal quantities of saltpetre and vitriol to half the quantity of the ore. By this system, the deoxidation of nitrogen, necessary for making vitriol on a large scale, is separated, and the oxidation of the ores accomplished. The patentee claims all the improvements made, and also the employment of wire-gauze or sieves for sifting the products; also the arrangement of vessels for receiving the heaviest portions of products. Ninth, the arrangement of the oxidizing chambers so as to allow of the products being collected without the necessity of entering them. Having been the first to manufacture this manure out of collecting zinc-white, the patentee next proceeds to an explanation of that part of the invention which relates to the yellow of zinc and green zinc. As the manufacture of zinc-yellow forms the subject of a previous patent, he merely remarks that hydrochloric acid may be used instead of sulphuric acid. To form zinc-green, yellow (having been produced by the patented process), is diluted with a suitable quantity of water, and mixed with a certain quantity of prussian blue (previously mixed with a suitable liquid), either in a hot room, or in the presence of a cold state. Green of zinc will thus be formed, the colour of which will be as durable as the blue itself. These pigments may be employed for painting of any kind.
ROTARY ENGINES.
ISAAC KINSEY, of Ludgate-hill, London, merchant, for "Improvements in the construction of rotary engines, to be worked by steam, air, or other elastic fluid." (A communication.)—Granted November 11, 1847; Enrolled May 11, 1848.

The principal feature in this form of rotary engine is a "piston-wheel," provided with any desired number of pistons upon its periphery. The pistons are formed radially from the centre of the piston-wheel and bear against the interior of a stationary cylinder. From the curved periphery of the piston-wheel to the interior of the stationary cylinder, there are stops which pass into the cylinder, the ends of which bear against the periphery of the piston-wheel or the pistons, and thereby render that portion steam-tight. The form of these stops or "piston-stops" makes the pistons act actually to recede from the interior of the cylinder until they become flush with the interior surface of the cylinder, and thereby allow the pistons to pass them without obstruction. Immediately that a piston has passed a stop, the stop is again projected into the cylinder to act as a surface, against which the steam acts to propel the piston-wheel forward. The patentee claims—first, the employment of the piston-wheel, upon which the number of pistons shall always be one more than the number of steam-stops on the cylinder, there being one steam-port and one exhaust-port for each steam-stop; the steam acting upon one or more pistons at the same time. Secondly, the mode of moving the sliding or steam-stops by a cam or cama, corresponding in form to the periphery of the piston. Thirdly, the connecting all the steam-ports with the steam-pipe, so that steam shall have access to the cylinder at the same time by the same passages for the steam-ports. Forthly, the connecting all the exhaust-ports with the main exhaust-pipe, so that steam may be exhausted from all the ports of the cylinder at the same time by the pistons passing the ports. Fifthly, the connecting all the ports with the steam-pipe, by a branch-pipe provided with a suitable shut-off valve. Sixthly, the mode of packing the pistons by means of a central metal-piece acting against two side pieces, having bevelled edges.

COMBUSTION OF FUEL.
RICHARD CADE, of Kennington, Surrey, chemist, for "Improvements in the combustion of fuel and in applying the heat so obtained."—Granted November 25, 1847; Enrolled May 25, 1848.

The object of the first part of this invention is to divide the gases and the smoke resulting from the combustion of fuel in the furnaces of numerous small stoves by causing them to pass through apertures in the heated fire-bricks or lumps before they pass into the chimney. The great heat of the fire-bricks thus effectually ignites the unconsumed gases and smoke. The fire-bricks enclose the fire-place at the portion between the fire-place and the hearth of the same passage. The stop or cover over the fire-door to be regulated at pleasure, for the purpose of admitting a supply of atmospheric air in a heated or other state above the fire-bars, for the combustion of the fuel and the gaseous products. The second part of the specification relates to reverberatory furnaces, and consists in supplying through the numerous apertures in the sides and the ends of such furnaces above the fire-bars, any requisite supply of atmospheric air in a heated or other state, for the purpose of more effectually accomplishing the combustion of the fuel in the fire-place—the mode of construction described by the patentee being to form a passage or channel around three sides of the furnace, the fourth being open to the hearth of the furnace; this passage or channel is formed within the back of the fire-place at the top place and the passage being of fire-bricks or lumps, it is through these fire-bricks or lumps that the apertures are made through which the supply of air is admitted from the passage to the fire-place above the fire-bars. The patentee states he is perfectly aware that the manner of supplying the atmospheric air has before been adopted and employed with respect to reverberatory furnaces. The third improvement noticed in the specification relates to a more effectual and more economical arrangement of apparatus for the heating of water, and for the warming of rooms or buildings. This improvement consists in the mode of arranging the bars in the back of the grate or fire-place to prevent the fire from lying immediately against the tubes containing the water. There are top and a bottom vessel connected together by these rows of vertical pipes or tubes, through the interior of which there is a communication between the vessels. From these vessels pipes communicate to warm apartments, buildings, or to other similar apparatus. The rows of vertical pipes or tubes connecting the vessels are placed immediately at the back of the fire-place, the flame and heated air passing amongst them in its way to the chimney in front of the pipes; these pipes or tubes are also provided with bars for the purpose of preventing the fire from acting immediately against them. These bars are placed in vertical positions; the horizontal section being convex in front against the fire and angular behind the pipes; these pipes may be of fire-clay or metal, but the patentee prefers the former. Above the fire-place, the front of the fire is perforated or pierced with a number of small apertures, for the purpose of admitting air to assist the action of the apparatus.

MANUFACTURE AND PRESERVATION OF TUBES.
PIERRE ARMAND DE COMTE DE FONTAINEMOULIN, of South-street, Finsbury, for "certain Improvements in the process and machinery for making, uniting, and preserving metallic and other tubes or pipes."—Granted November 18, 1847; Enrolled May 18, 1848.

The specification of this invention is extremely minute in describing the different processes of manufacturing and preserving pipes, and the patentee claims seven distinct improvements, the enumeration of which claims will give a general idea of their character. The invention consists, first, in making and uniting metallic pipes by means of a certain improved clasp. Fourthly, uniting metallic pipes by inserting in the claps employed for the purpose certain compressible substances for preventing the escape of gas and fluids. Fifthly, uniting metallic pipes, by using a helix for elevating without flattening the leaden elbow. Seventhly, in the process of preserving iron and cast-iron pipes from oxidation by means of galvanic action.

CASTING WROUGHT-IRON.
WILLIAM RORKE, of Dudley, Worcestershire, for "a new mode of treating and applying wrought-iron."—Granted November 18, 1847; Enrolled May 18, 1848.

The object of this invention is to obtain the form required which the facility of casting affords, retaining at the same the qualities of wrought-iron. Having previously prepared the moulds to be used, he employs the said moulds for moulding articles when made of cast-iron, the melted wrought-iron is to be run into the mould. The articles are then of a brittle nature, and deficient of malleable properties, to impart which the patentee next proceeds to treat or anneal them in an annealing furnace. For this purpose the articles are piled in an iron box lined with fire-bricks, leaving sufficient room to surround the articles with a quantity of Cumberland red ore, or other iron ore, or charcoal reduced to a fine powder, the articles being so completely covered as to prevent all admission of the air. In this state they are to be subjected to the required heat for a sufficient length of time to give the required malleability, in which great care must be observed by the workman, and until he has sufficient practice to perform it without, it is advisable to employ a small bar or trial-rod composed of the same metal, which may be withdrawn from time to time, to ascertain the state of the iron and detect the completion of the process, when the articles may be removed. When the density and close compactness of texture obtained by the use of wrought-iron is not required, he mixes a proportion of cast-iron therewith, according to the quality of texture of metal necessary for the article proposed, but in no case to exceed the weight of wrought-iron used; and when it is necessary to impart to the articles manufactured the nature and temper of steel, he mixes with the wrought-iron a portion of cast-steel, but in no case to exceed the weight of wrought-iron employed. These mixtures of wrought and cast iron, or wrought-iron and cast-steel are said to be cast in moulds, and treated or annealed in the same manner as that described for the manufacture of articles entirely of wrought-iron, when they will be found to have acquired the ma-
The patentee does not claim as his invention the melting of wrought-iron, this having been practised already to a limited extent; but he claims the treating and applying wrought-iron by melting the said metal itself, or with a mixture of cast-iron or steel, and the reproducing malleability in the castings of the molten iron by annealing them in the manner described.

**INLAYING METALS.**

Cyprien Marie Tessier Du Motay, of Paris, for “Improvements in inlaying and coating metals with various substances.”—Granted November 4, 1847; Enrolled May 4, 1848.

The invention is exceedingly verbis, and it consists of fifteen articles, showing different modes in which the invention may be applied. The object of the invention is to produce ornamental designs on various articles, by depositing metal thereto after the articles have been properly prepared by marking or cutting out the intended design; and which articles, when finished, have the appearance of being richly ornamented with inlaid work. This method of ornamenting, by inlaying in metal, is known in France as “damasquinure.”

The work produced by this invention is very durable, and not liable to be worn away by cleaning or friction; it being quite equal in solidity to the inlaid work produced by the ordinary means, and even superior in point of finish.

Before depositing the metal intended to form the design, the patentee commences by producing designs, either in intaglio or in relief, upon the body of the article to be ornamented, those parts where no metal is to be deposited being coated with a varnish.

When inlaying of one metal only is required, the patentee proceeds as follows:—The metal is first cleansed, and then immersed in a bath of the metal, to be deposited by the galvanic current. When the metal has been deposited to a thickness equal to the depth of the hollow parts of the design, it is withdrawn from the solution and washed in water, and dried with sawdust, or by any other convenient means, and the damaskened surfaces are laid bare, by means of freestone, or by filing, scraping, or by any other means which will remove the layer of superfluous metal, in order to uncover the inlaid or damaskened work.

Damaskened or inlaying in several parts may also be produced by means of pressure. For this purpose, a piece of metal, with an even surface, is covered without soldering, either by immersion or by electro-deposition, with several sheets of different metals; each of these layers is of a certain thickness, according to the depth of the parts of the die which are in relief. The last coating being deposited, the piece of metal is lifted from the metal solution, washed, and wiped dry. When dry, it is to be submitted to the action of pressure or stamping by means of dies or matrices, the intaglio parts of which are of equal depth and the relief of different heights, or reliefs of equal heights and intaglios of various depths. These must be calculated in such a manner, that by reason of the penetration of the projecting parts of the die to a greater or less depth, the layers of metal (being, in certain parts, driven to greater or less depths) may, on the surface being laid bare, be of the same level as the inlaid surface.

In order to produce devices or ornaments to be inlaid in wood, marble, &c., by the ordinary means, the patentee proceeds as follows:—He takes a plate or sheet of any metal, and coats it, first, with a layer of copper, of suitable thickness; then with a coating of zinc; and upon that another of copper: and so on until the desired thickness is obtained. As the successive coats of metal entirely cover the tin core, parallel layers of metal are thus obtained, which differ from each other, both as regards the different kinds of metal and their various thicknesses. On cutting the sheet thus produced into thin strips, in the direction of its thickness, designs will be produced consisting of parallel lines of tin, copper, and zinc. With regard to other devices or ornaments, such as roses, stars, circles, &c., these can be produced by taking a metal core, of a certain length, either solid or hollow, and of the form desired to be produced, and coating it with successive and alternating layers of different metals; and when these deposits have been made to the required thickness, they are cut into thin discs. If the core, of whatever form, or metal, be solid, the parallel layers of metal will only be on its outside; but if it be hollow, they will also be inside, as the metal will be deposited on both sides.

**HYDRAULIC LIFTING-JACK.**

Registered by Mr. Simmons, and Manufactured by Messrs. Thornton and Sons, of Birmingham.

Under the head of the proceedings of the Institution of Mechanical Engineers at Birmingham, in the Journal for March last (page 87), we gave a short account of this jack, and now are enabled to give an engraving of it, which better explains its use. It is stated by the inventor, that one man with the jack can lift from 15 to 20 tons.

A is a hollow vessel forming the base of the jack, and also a reservoir for the water. B, the cylinder; C, the ram; D, the pump; E, the plunger; F, the stopcock; G, the pump-levers; H conical pointed pin; I, a small air-tap. Before using the jack, tighten the pin H, and open the air-tap I. When it is requisite to lower the weight, slacken the pin H. When the jack is not in use, close the air-tap I. Should the water get too low, take out the tap I, and fill the cylinder when the ram is down. The ram can be pressed down by hand when the pin H is slack.

Ms. WHISHAW’S TELEGRAPHIC INVENTIONS.

We were present in the course of last week at a private view of the numerous contrivances invented by Mr. Whishaw for telegraphic communications. A great part of these inventions apply only to the communications at short distances, and of these an improved speaking tube is the most readily available. The improvements consist in using gutta-percha tubes of various diameters, and in applying removable whistles at each end, to afford a convenient means of calling attention when a communication is to be made. In a tube, two hundred feet long, coiled round so that the two extremities were near each other, the facility with which sound is transmitted was very strikingly exemplified. The slightest effort of the breath sounded a whistle instantaneously, and by blowing at one end, a musical instrument was played at the other as readily as if it had been applied to the mouth.

The chief peculiarity of the telegraphs exhibited, is the application of moveable ‘‘codes’’ to the face of the same instrument; each code consisting of all conceivable questions and answers on any given subject. The fixed dial contains the letters of the alphabet, the titles of the codes to be referred to, and several questions and answers of common occurrence, or most likely to facilitate the communications. The index of the dial may be moved by electrical agency or, for short distances, by mechanism, to be worked by the hand; and when the subject matter contained in any of the codes is to be communicated, the operator causes the index to point to that code marked on the dial. The codes are printed on large card-boards, and have circular apertures in the.
centre, through which the index and dial can be seen when placed on the instrument. The questions and answers are printed radially, so that a great number are contained within the range of the index in its circuit; and as it stops at any one, a whole sentence may be at once indicated. Should any word not on the code be required, the index is made to point to the word "spell," and afterward the index indicates, letter by letter, of the alphabet that form the word to be communicated. One plan of operating is by water-level indicators, the water in two vertical tubes being elevated or depressed till it stops at the signal wanted. Another telegraph, which however requires great delicacy in the manipulation, consists of two chronometers, each of which has a lever and hand pointing to radially-placed words and sentences on the dial. It is essential to the accuracy of the working, that the two chronometers should move synchronously, for if there be the least deviation, it would transmit incorrectly. Supposing that the hands of the two dials at a distance from each other, are always pointing to the same words, in their revolutions,—whenever the transmitting instrument points to the sentence required, the operator is instantly to sound a bell at the distant station by means of electricity; and the observer there must notice at what sentence the hand is pointing when the bell sounds. If both operators be not very prompt in making and observing the signals, a wrong message would be communicated. This difficulty, however, Mr. Whishaw thinks may be overcome, and he has had much practical acquaintance with the difficulties in working telegraphs during a connection of some duration with the Electric Telegraph Company.

THE "ART-JOURNAL" versus ARCHITECTURE.

Not content with excluding architecture, and all notice of it from his columns, although he brings more industrial art, as it is called, prominently forward, showing numerous specimens of it in every number of his publication, the majority of which are calculated to diffuse exceedingly bad taste among the public,—the editor of this journal appears anxious to get architecture thrust out of the Royal Academy. Some short time since it was tested against architects being elected members of that body; and he now tells us that architectural drawings have "no business" to be in its exhibitions. This is very much like saying that there ought to be no exhibitions anywhere of such productions—the Academy's being the only one where they are admitted. It is to be hoped, however, that this marked insult will now arouse architects, more especially the leaders in the profession, and those who are members of the Academy, to a sense of their duty, and of what they owe to themselves personally, at least to their brethren. Should not the new editor, instead of giving us thus to understand, and will fully justify at least one-half of the Art-Journal's opinion, by showing that at all events they have "no business" in the Academy.

What is the Professor of Architecture about, that he can patently put up with the present state of matters with regard to architecture at the Academy? Hardly can he be ignorant of it, or not perceive how greatly it calls for correction; nevertheless, he makes no effort at all to correct it. Had he bestowed himself at all, we should of course have heard of it; moreover, if he had, and had done so ineffectually, we should have heard of his resignation—which would be far more honourable to him than is the making himself a cypher,—not only without influence, but without even so much as a tongue or a voice.

Whatever are all—however the enmities attached to the Professorship of Architecture may be, they cannot be such as to be of any moment to Mr. Cockerell. So long as the situation confers honour on him who holds it, it is worth having, whether any enmity at all be attached to it or not. But rather quite the reverse, for he attends it, and he who holds it is expected to sit by very tamely, and be all kinds of aghast and animated put upon architecture, without so much as attempting to check them.

There is, indeed, no danger of either the Professor or the Academy being called to account for the dereliction of their duty in regard to architecture, by the public press—that is, the newspapers; architecture being the very last thing to excite their attention or engage their sympathies. Yet if they, therefore, think that they are released from all responsibility to public opinion, and that their conduct excites no animadversion in other quarters, they are very much mistaken.

As to the editor of the Art-Journal, he ought to be hanged—in effigy, at least—by the architects. But, somehow or other, archi-
teets invariably show themselves to be the most placidly wise imaginable. Whenever their own personal interests are touched, or at all endangered, they are generally sensitive enough; but when it is only the credit of their art and their profession that is concerned, they show themselves to be the most torpid and sluggish of mortals.

The Disputed Invention of Tubular Bridges.

We regret to perceive, new success has attended the bold experiment of constructing tubular bridges, that attempts are being made to deprive Mr. Robert Stephenson of the merit so justly his due, as the original designer of the plan, and the superintendent of its execution. Mr. Fairbairn, who, with Mr. Eaton Hodgkinson, assisted Mr. Stephenson in working out the design, claims to have the merit of all but the "original idea;" and he maintains that the working out of the idea and the development of the principle, as well as the greater portion of the construction, are the results of his labours. He states, also, that the original idea of Mr. Stephenson was a cylindrical tube, to be supported by chains; which plan, he says, can be proved would never have succeeded; and that it was only by a long series of inductive reasoning, founded on experimental research, of which he claims the exclusive merit, that the present strength and form of the Conway and Britannia tubular bridges were established.

It is of great importance not only to Mr. Stephenson, but to civil engineers and inventors in general, that these claims of Mr. Fairbairn should be estimated at their proper value. The original idea of overcoming the difficulty of taking the railway across the Menai Straits, by the construction of a tubular bridge, is admitted to be due exclusively to Mr. Stephenson. Mr. Fairbairn and Mr. Eaton Hodgkinson were employed by him to assist in its construction, and to make the experiments necessary to determine the best form for obtaining the requisite strength. He must, of course, have expected, from their known skill and experience in the strength of materials, that they would be able to afford important assistance in devising the means adapted to overcome the difficulties which such a novel structure necessarily presented. The experiments they made were subject to Mr. Stephenson's approval, and may be said to have been conducted under his superintendence. The mode of making them would however, for the most part, be necessarily entrusted to Mr. Fairbairn and Mr. Hodgkinson; who were not employed as mere mechanical agents, to act strictly under directions, but as practical men of science,—expected to bring their skill, ingenuity, and mathematical knowledge to bear on the important work entrusted to them, and to arrange the details by which the original idea of Mr. Stephenson was carried into effect. That Mr. Fairbairn has amply fulfilled what was expected from him, and has, under Mr. Stephenson's superintendence, completed the task ably, skilfully, and successfully, is a great merit, of which he may well be proud. Beyond this, he ought not to be permitted to claim the exclusive merit, that he is the inventor of the original idea, for it appears to us that a machinist or a draughtsman might with nearly equal pretension claim to be the inventor of apparatus, or the architect of a machine, or making the machine plans,—as Mr. Fairbairn claims to be the inventor of the apparatus, or the architect of a machine in making the machine plans, as Mr. Fairbairn itself. We trust Mr. Fairbairn will be satisfied with the more moderate claim of having contributed to the perfection of the invention, the same as Mr. Stephenson, and upon the same principle of equally dividing the credit and the reward.
ON CHEMICAL AND ELECTRICAL FORCES.

BY PROFESSOR FARADAY.

Professor Faraday has this season delivered a course of seven lectures at the Royal Institution, "On the Allied Phenomena of the Chemical and Electrical Forces." The last lecture of the course was given on Saturday, the 17th of July, and we now subjoin a brief sketch of the whole, showing the mode in which it was treated, and describing the principal experiments by which it was illustrated.

The first lecture was devoted entirely to explanations of the character and illustrations of the nature of chemical force, commencing with its simplest and least distinct form. By the action of chemical affinities, the conversion of one substance into another of different composition is thus denoted. Difference between mechanical force, or the force of gravitation, which produces molecular action and aggregation of masses, and the action of chemical forces, which takes place among the particles of matter. At the same time it was pointed out on this occasion that the opinion was not altogether an uncommon one that if the juxtaposition of the two bodies, not identical, be shown several experiments in which chemical action is effected by mechanical force, of which the explosion of fulminating powder by percussion afforded an example. The illustrations of chemical action in its subtlest form, be shown to be closely allied to mechanical force, as the aggregation of the particles of water, he said, depends on the same forces as the most energetic chemical action; the difference between them being only in degree. As an illustration that chemical action takes place during the process of sticks, he described certain phenomena which took place if water in a glass vessel in which a long tube was inserted. The vessel and the tube being quite filled, he inverted the apparatus, to mix the spirituous wine with the water, when contraction of the volume of liquid was manifest by the tube being no longer full. Among other exemplifications of chemical action, were the salification of two gases (muriatic acid gas and ammoniacal gas) on being mixed, and the conversion of two limpid liquids (bleaching spirits) into a cloud by mixing. These results of chemical action, Professor Faraday observed, are the production of compounds distinct from, and frequently quite dissimilar to, the original substances that enter into combination. To show in a striking manner the peculiar powers that may be attached to a compound, he gathered some copper and iron filings, and then separated the iron from the copper by means of a magnet; whereas in a chemical compound, no mechanical force can separate the combined particles, and they can only be resolved by chemical means. By the combination of the two elements, Faraday illustrated the reproduction of the elementary substance of a compound after it had been apparently destroyed, in the following manner. He put some iodine into a glass flask, which, on being heated, emitted the purple or violet-coloured fumes peculiar to that substance. He then added zinc and water to the iodine, when a combination took place, in which the properties of the iodine were apparently lost, and by no application of heat could the violet fumes be produced. On the addition of sulphuric acid, however, it was set free from the zinc, and its fumes were again perceptible. That there is no destruction or change in the particles of matter produced by chemical action is generally admitted, but the Professor observed, that some philosophers still cling to the notion of the existence of combination in the form of a state of suspension in a fluid. But this opinion, he maintained, is not founded on fact, for there can be no creation of power without the creation of matter.

In the second lecture the consideration of the different actions of chemical forces was resumed in the commencement, and then its gradual transition into electrical force was developed. In the first place, the Professor pointed out the difference that exists between the force of gravitation and chemical force in the active constitutions of their actions for which attention never ceases to act at any moment, chemical affinity, on the contrary, often lies dormant for ages, until circumstances arise that bring it into action. Several experiments were performed to illustrate this, and also to show that the nature of chemical action may be reversed by very small variations of temperature, and the other conditions under which it takes place. A mixture of nitrous and oxygen gases, for example, produces no change on either litmus or turmeric paper, but when a stream of these mixed gases issues from a tube, and is exposed to a tempera- ture of about 200° C., then a litmus paper exposed to the current is reddened, thus proving the presence of an acid. When the same stream of mixed gases is heated, the previously reddened litmus paper is restored to its original blue colour, and turmeric paper is turned brown, showing that the direct opposite property has been given to the gases, which then become alkaline instead of acid. When approaching to those chemical actions which are accompanied by the development of electricity, Professor Faraday first exhibited the action of the combination in the reproduction of the acid on pieces of iron and zinc, which metals having a greater attraction for the acid than the copper itself, entered into combination with the acid and liberate the copper. He afterwards exhibited a yellow oxide of iron poured on a piece of zinc, which decomposed the water by attracting its oxygen, with which it entered into combination, and liberated the hydrogen as gas. On introducing a few shillings into the glass, the vigor of the action increased, and the decomposing power of the zinc seemed to be transferred to the silver, from which metal copious streams of hydrogen gas arose. A more obvious exhibition of the extension and transfer of chemical action from one metal to another was effected by the deposition of copper on silver from a solution of the sulphate of copper. When a piece of silver is immersed alone in a solution of sulphate of copper, no action whatever takes place, and it might so remain for any length of time without sensible change. As soon as a piece of zinc or iron is brought in contact with the silver in the solution, the copper is deposited on the silver as readily as on the zinc; and when this deposition is made on an amalgamated zinc, the effects of decomposition are transferred entirely to the silver and none of the zinc is deposited on the amalgamated zinc. This effect is equally produced, whether the two metals are brought into contact in the solution, or when connection between the two is made by means of a wire. The action of the metallic sulphuric solution is obtained to make a wire red hot. The deposition of the needle at any part of the connecting wire where it may be placed, shows that the action occurs along the whole course of the wire, and exemplifies one of the positions which the Professor wished to establish, viz., that the distant and local actions are identical. This new class of phenomena, Professor Faraday said, was, in his opinion, attributable merely to another exhibition of chemical force, but he should, in deference to received usage, denominate it electrical force, instead of metallic force.

The greater portion of the third lecture was occupied with the considerations of the decomposing power of electricity, in which its action seems the reverse of that of chemical force. The latter power acts by the affinities of the particles of one substance for those of another, and the results of its action are the actual effect of the chemical force, on the contrary, resolves compound bodies into their elements, and may act at a distance from its exciting cause. Numerous illustrations of the decomposing power of this battery were afforded, particularly of the most curious of which was the decomposition of nitric acid by the following arrangement: A glass vessel was divided into three compartments by diaphragms of blotting-paper, and filled with diluted nitric acid—three of these needles being connected together. When the wires from the negative and positive poles of the battery were inserted in the two coloured divisions of the vessel, the nitric acid became decomposed, the chlorine passing to one end, and the hydrogen to the other. The effect was repeated in all parts of the vessel, and the decomposed acid in the end to which the chlorine was determined, whilst the middle compartment, through which the current must have passed, remained unchanged. The decomposition of iodide of potassium afforded a striking example of the rapidity with which any body undergoes the influence of electricity. Across a piece of paper, wetted with a saturated solution of iodide of potassium, Professor Faraday drew rapidly one of the wires from the battery, when a strong brown mark was left, showing that the iodide had been decomposed. By pressing a coin on paper similarly prepared, and then touching it instantaneously with the wire of the battery, an impression of the coin was left on the paper, caused by the decomposition of the iodide, where the parts most in relief had touched the paper. The operation was repeated with little effect, of the voltaic battery; and though chemical decomposition does not take place excepting where the current is interrupted, yet the power is always active in its circuit through the connecting wires. The decomposition of a magnetic needle, when placed parallel to the wire and conducting the current, for example, exhibits an influence at every part of the circuit, and the plate of the voltaic battery were shown to have the same power as the conducting wire, in deflecting the suspended needle from its ordinary position of north and south. This current of force throughout was noticed by Professor Faraday as one of the many instances in which electrical force differs in its action from chemical force, which is always local, though the two forces are really identical. The constant evolution of electricity, when we least suspect its presence of such an agent, was curiously exemplified by cutting a raw beef-steak with a steel knife and a silver fork, the knife and fork being connected by wires with a voltmeter. As soon as the knife touched the meat, a current of electricity was evolved sufficient to deflect the needle of the voltmeter. The combination of iron, copper, and silver, produced a still more powerful effect on the needle.

In the fourth lecture the alliance between the chemical and electrical forces exhibited in the evolution of light and heat, formed the principal point to which the Professor directed attention, and he illustrated the subject by numerous brilliant experiments. The light and heat produced by violent chemical action, of which a burning candle is a good example, form no essential part of the action that takes place among the combining bodies, but are merely transferred to the free space as the result of the combination. In the same manner, the light and heat evolved during combustion of substances by the voltaic battery, are the result of the combination of the plate with the oxygen of the exciting liquid. To explain the light the combination of pieces of charcoal were exposed to the action of the battery. The intensity of the light thus evolved was contrasted with the flame of an argand lamp, which was scarcely perceptible in the overpowering splendour of the voltaic spark. The combustion of iron-leaves, or iron-wire, of platinum, and of mercury, formed other dazzling exhibitions of the heat and light evolved by the voltaic battery, when the two poles were brought into contact with the...
metals. The heat thus generated is owing, Professor Faraday observed, to the passage of electricity through the substances acted on, and to the resistance they offer to its passage, for when the conductors are sufficiently large and perfect to afford a free passage to the electricity, no effect of heat is produced by the passing of the current; but if the wire be thick, or if it be cut by the heat. The water being an imperfect conductor of electricity, offered sufficient resistance to its passage to bring into action the heating and light-giving powers of the voltaic battery; but when a thin sheet of copper was made a better conductor, by missing an inch of wire through which it was sent, the effect was greatly diminished. In the preceding lecture, Professor Faraday showed that wires proceeding from the opposite ends of a voltaic battery possess different properties; the decomposition of the water into oxygen and hydrogen took place at the opposite poles, though the tube containing the fluid in the forked-tongue self could scarcely be heard. In the other experiment a rod of metal passed through the floor of the lecture-room, and at the farther end it bore against a box. A tuning-fork, when struck and applied to one end of the strip of wood, vibrated with a quick and easy motion; and when the other end was touched, the tuning-fork itself could scarcely be heard. In this lecture-room, there is a similarity also between vibrations and electrical shocks, as may be proved by striking a bar of iron when holding it near one of the points of vibration, the jarring sensation bearing a close resemblance to an electric shock. This vibratory sensation is felt yet more strongly when a wet string is fastened round the wrist, and some one pulls the end of it through the fingers.

In his lecture Professor Faraday said he was about to direct the attention of his auditors to a different condition of the electric force from that in which he had hitherto considered it, wherein the phenomena not only differ from, but are in many respects directly opposed to those which have been considered of late. The voltaic forces are the same. In the first place, he exhibited voltaic electricity in a higher state of tension than he had before done, by employing a water-battery, consisting of a great number of pairs of plates, by which a very strong electric current was generated. The electric current from the water battery was passed through the water, thus showing, that without any direct connection with the battery, the electric shock is felt by fishes when the water swins in is made part of the circuit. In the second place, Professor Faraday took a platinunated eel from "gymnastes electricus" at the Polytechnic institute, from which he had obtained all the effects of an ordinary voltaic battery. The eel itself does not feel the shock it communicates to the water, nor does it suffer anything but a momentary disturbance. The eel, though in the circuit, has no more effect on the electric current from the voltaic battery passed through the water, it exhibits as much annoyance as any other fish. Professor Faraday observed that the effects of electricity on the nerves of animals, give an insight into the phenomena of life, since they seem to prove that nervous irritability, on which the action of the muscles depend, is caused by electrical influence, though by what means the electricity is generated remains unknown.

The commencement of the fifth lecture was occupied with exhibition of the phenomena of electricity, when the circuit is not interrupted. The simplest evidence, that a constant action is going on in the conducting wire, is afforded by the deflection of a magnetic needle, when a wire that conducts electricity is passed near it. The magnetic needle is made by coating a needle with iron filings and then toasting them, so as to form a mass of iron. Small pieces of bent iron resting on the needle, became magnetic when the electric circuit was completed, and when the wire was twisted several times round the needle, the electric effect is increased, the magnetic effect is the stronger. The electric current of the battery is passed through the water, it exhibits as much annoyance as any other fish. The impact of a piece of metal with a certain mass was shown to excite electricity by its causing the leaves of the electroscope to diverge. We can scarcely touch anything without exciting this power, which, however, is not perfect in the development of its development, in this instance, is precisely the same force which produces the greatest amount of air by the electrical force of excitement, and that effect caused by the electric charge to be distinct, for what is termed frictional electricity is excited by the motion of two bodies in contact, while the electric force is produced without the agency of body comes and goes on without the agency of friction, by current. Having given illustrations of the similarity of the electric phenomena produced by friction and by friction, the Professor dwelt on the apparent difference between them. One remarkable difference, is, that the substances which excite frictional electricity is excited by heat, and that the substances used in the production of electricity are not the same after having developed the power as before; whereas frictional electric cannot be excited without chemical action, and an apparent destruction of the contact. Another illustration of the phenomena of voltaic and of frictional electricity is exhibited in their conduction through various substances. Water, for instance, which is so imperfect a conductor of voltaic electricity, will readily conduct the whole quantity excited by a powerful electrical machine, through the moisture contained in a wetted piece of paper, but the dry paper will not enter it. This substance was exhibited by several experiments, the most remarkable of which were the following: A small metal ice-pail was placed on an insulated stand, and then a metal ball, suspended from a piece of silk, was placed over the pail. The electricity instantly diffused itself on the outside of the ice-pail, and there was none within; for when the ball was again lowered into the pail and withdrawn, it produced no effect on the electroscope, but when the ball touched the outside the instrument was strongly affected. In the other experiment a wire-gauze vase was substituted for the ice-pail, with exactly similar results. When an electrical machine is excited, every
person within sight of it is more or less affected by its influence, and a conductive fluid is induced in their bodies to ward the machine of a different kind from that developed by the conductor; and on the opposite side, or that farthest from the machine, electricity of the contrary kind is induced. This induction of positive and negative electricity on distant objects as Professor Faraday has proved, has practical consequences. He had, he said, been often consulted by Government as to the propriety of having metal roofs on the powder-mills at Waltham Abbey, and he had always objected to them as dangerous, because a thousand lives would be at stake in the event of the electricity passing down the pipe, though the ball was far too distant from the conductor for any spark to pass between them. This experiment was repeated several times, and each time with the same success.

The point to which Professor Faraday directed attention in the seventh and concluding lecture was, the cause of the difference between the phenomena of voltaic and of frictional electricity, his object being to prove that they are really identical. The marked difference between frictional and voltaic electricity, which were dwelt upon so much in the preceding lecture, are caused entirely by the different degrees of intensity in which the force is developed, and Professor Faraday showed, in the concluding lecture, that, by diminishing the intensity of voltaic electricity, the phenomena of frictional electricity are similar; the great difficulty in showing these effects being caused by the very small quantity of electricity that can be evolved in a given time even by the most powerful voltaic machines, is in theory the same as that which occurs with the Law of the sparking of the spark. From this it is evident that the phenomena of frictional electricity may be made to resemble those of the voltaic by diminishing the intensity of the voltage. Though the machine employed was a plate of glass, about four feet in diameter, which yielded a rapid succession of strong sparks five inches long, it would require about five million turns of the dynamo in order to produce a quantity of electricity equal to one gram of water in the voltaic battery. The different appearances of the sparks emitted in the highest state of intensity by the electrical machine from those produced by the discharge of electricity accumulated in the Leyden jar, and the alterations in the length and the light of the sparks may undergo by being transmitted through various media, were shown in numerous experiments. Thoough the rapidity of the electric spark is evidently very great, it far exceeds, in reality, the appearance to the eye, for the duration of the spark itself is much less than the light of a moment, and is a prolongation of the effect. It has been ascertained by Mr. Wheatstone, that the duration of the light of the spark is less than the millionth part of a second, and Professor Faraday exhibited the mode by which this fact had been ascertained. A concave mirror, provided with a focus, was placed so as to revolve with great rapidity by multiplying-wheels, and when in action a bright light from the combustion of lime was reflected to a focus on the ceiling. The rapidity of the motion caused the light to form a circle, in the same manner as the turning rapidly round of a lighted stick or of any other bright object seems to form a circle, in consequence of the impression on the retina remaining until the effect is renewed by the return of the light to its former place, When an electric spark was substituted for the luminous stick, the motion was seen to be equally rapid and circular, and the duration of the light was produced. The velocity of the mirror and the number of successive sparks being known, an approximation can be obtained to the duration of the light. It is in consequence of this instantaneous duration of electric discharges that they can produce many of the effects of voltaic electricity, and if the continuous action of the latter during a second could be concentrated one million times its effects would be almost equal. By diminishing the intensity of frictional electricity whilst retaining its quantity, Professor Faraday ignited gunpowder, which was blown away without ignition by the undiluted discharge. The following experiment afforded a good illustration of the different actions of frictional and voltaic electricity caused by the concentration of force in the former. A gold thread twisted with silk was defagrated by a discharge from an electrical battery without injuring the silk, the action having been so instantaneous that there was not time to burn the silk, though the metal was destroyed by the heat evolved. When similar gold thread was exposed to the action of the voltaic battery, the silk was instantly consumed by the wire being made red hot, whilst the metal remained. The stational character of frictional electricity, Professor Faraday illustrated by applying a conducting substance to draw it off from the machine as quickly as it is excited, and the imperceptible effects of such a current prove how small the quantity of electricity excited really is, and it is only by allowing it to accumulate that we are sensible of phenomena of the electricity. Thunder is owing to the facility with which Franklin electricity can be accumulated, and thus reserved in store for an instantaneous discharge. Some specimens of the effects of lightning were exhibited on the lecturature; a ladder which guides the cutting tools of the mill to perform the most delicate and elaborate work with great speed and at a cheap rate. Messrs. Sewell and Capel contributed a large collection of models of paddle-wheels and screw-propellers. Messrs. Maudslay and Field also contributed an interesting model of a vessel, a heliometer, and a model of the Great Britain steamers, fully-rigged, and containing five-similes of the engines, with the screw-propeller complete, and working by means of condensed air, the whole only weighing low.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

May 29.—AMBROSE FOYNTN, Esq., V.P., in the Chair. A paper was read "On the Application of Sculpture and Sculptured Ornament to Architecture." By H. B. Garling, Associate. Being the Essay to which the Medal of the Institute was awarded on 21st February, 1846; and which was read in the presence of the President and four other members of the Institute. The method of the treatment of the temple of Minerva, with its magnificent frieze, is the best that has been attempted. The same spirit can be discerned in the design of Mr. Bond's new London Bridge, which is a most admirable example of the skill with which a great public work can be executed in the country. The paper was received with much approbation.

June 12.—SIR WYNN PLYMOUTH, Esq., V.P., in the Chair. A paper was read "On the Theatres and Porticos of Ancient Rome." By the Rev. Richard Burges, B.D.

June 26.—A paper was read "On the Triforium of the Medieval Churches." By the Rev. R. Willis, M.A.

This evening's meeting closed the session.

Institution of Civil Engineers.

May 30.—Mr. Field, the President, in the Chair. The accustomed annual conversations of the President, which was herefor held at the residence of the President, was this year held at the House of the Institution in Great George-street, a change which we do not approve of; as also the one limiting the conversation to one evening, which led to the rooms being most inconveniently crowded—so much so, that many of the numerous models and works of Mr. Vignoles were not shown. On the walls of the theatre we observed three faithful portraits, by Lucas, of Mr. George Stephenson, Mr. Robert Stephenson, M.P., and Mr. Bidder; they were contributed by Messrs. Graves, for whom they are about being engraved. The Electric Telegraph Company—Mr. Bain, Mr. Brett, and Mr. Reid—contributed instruments exhibiting their various systems of telegraphic communication, electric clocks, and electric printing. Mr. Rand's press, for raising at one blow the collapsible tubes or capsules. Mr. Whitworth's beautiful machine for knitting stockings was worked by a young girl sent up from the factory of Messrs. Ramsone and May, of Ipswich, and formed an attractive object. The models of greater interest were those of Mr. Stephenson's wrought-iron tubular bridge erected at Conway; with that of the masts and yards of steam-boats, and the floating landing stage, with its long approach over the mud banks, all to be supported upon Mitchell's screw piles, for the Humber Ferry. Mr. Brunel's excellent truss, of 110 feet span, used by him in the Somerset Bridge, on the Bristol and Exeter Railway. Mr. Fowler's plan for opening or shutting simultaneously four gates for a level crossing on the line of the Manchester, Sheffield, and Lincolnshire Railway. Messrs. Taylor, Williams, and Jordan's model of their machine for carving by machinery ornamental objects, figures or groups, such as we have previously noticed. This machine is the reverse of a lathe which guides the cutting tools in order to do the work of the hand with the greatest possible accuracy and facility.
Among the remaining models, we observed Messrs. Blake and Varley’s atmospheric pile-driving machine,—Mr. Varley’s rotating air-pump,—Mr. S. P. Bidder’s simple and effective coal-drops,—Mr. Dodd’s rail-straightening machine,—Mr. Southam’s wedge and screw lift,—Mr. Thornton’s improved hydraulic lifting-jack,—Mr. Wetherell’s iron-tread tracks,—Mr. Constable’s fire-engine, Bogard’s new locomotive, Treadwell’s new Railway, with the drawing of the system of manufacturing it,—a model of a folding boat, of which each side was made of two thicknesses of water-proof cloth, filled in on Capt. Light’s principle with very buoyant reeds, rendered non-absorbent, and consequently rendering the boat incapable of sinking, even when full of water, and even when partially torn by accident. The expedition in search of Sir John Franklin has been furnished with boats of this description, in order that they may be easily transported across the ice, and may bear injuries which would destroy a wooden boat. The Commodore has exhibited a collection of their products from the rough material throughout all its stages of manufacture to the finished articles. Mr. Chubb’s safety chest and locks and keys,—Mr. De la Rue’s ingenious locks and bolts,—Mr. Defreville’s improved dry gas lighter,—the new Aerodrome barometers,—and numerous other interesting models and specimens.

June 20.—Joshua Field, Esq., President, in the Chair.

"On Harbours of Refuge." By the Right Hon. the Earl of Lovelace.

The paper consists chiefly in a succinct review of the Reports of the Commissioners on Sluices, and Harbours of Refuge; giving the opinions of the naval officers and civil engineers on the necessity for harbours, in certain situations, and the naval qualities possessed by those positions—the possibility of constructing harbours in them, and the nature of the harbours necessary for the accommodation of supplying fleets from storms in peace, and the enemy during war, appeared to be admitted, particularly at the present moment, when the disturbed state of the continent and the relentless character of our near neighbours were forcibly stated. The most obvious and practical suggestions pointed out were, that of Dover was the only one yet decided upon, although great works are contemplated at Portland, where, from Mr. Rendel’s designs, a system of construction would be adopted, which would be both economical and stable. The second point would be a development of the system of whose labour it had been difficult hitherto to use sufficiently. The various projects of floating breakwaters, and other artificial shelter for vessels, were then examined, and were generally condemned, as entirely insufficient for the object proposed.

The questions relative to the movement of sand, the shifting of the silt, and the deposit of silt in Dover Bay, and other places, were treated at great length, and reasons given for the various forms of construction, and of the projects for meeting the difficulties induced by these circumstances.

The next question was the place of the harbour, and the mode of construction of the works. After quoting all the authorities on both sides, including the naval officers, the commissioners, the civil engineers, and the scientific writers, the preference was given to a large harbour, with two entrances, one for the ships to enter under cover, and the other for the tide to flow through it, to prevent any very considerable deposit of silt, but so constructed as to afford shelter to the vessels within. The pier walls inclining the harbour to be built vertically up from the bottom, or with a very slight inclination in their height to overcome the effects of the waves, and, finally, the condition of reposée, which, it was shown, was not less than four or five to one, and that it only attained solidity after a lapse of many years, even with a due admixture of small materials to fill up the interstices, and after constant supply of water, which would be the real, internal remoulding. The importance of Capt. Washington were quoted, to prove the failures that had occurred at certain harbours in Ireland, where it was stated that the long slopes had been destroyed by the sea, and had ruined the harbours they were intended to protect. The proceedings at Harlebury and Plymouth were followed in great detail, with a view to deducing arguments against the long slopes, and in favour of vertical sea-walls.

The protest, by Sir Howard Douglas, in favour of long slopes, was examined at length, and the arguments used on both sides were analysed with skill and candour.

Colonel Emy’s theory of the effects of the “fleut du fond,” was carefully examined; and, without going to the entire length that he did, it was admitted that the effects produced were as he described them, and that the subject, as he had brought it forward, was well worthy the attention of civil engineers.

The placing a vertical wall upon a substratum of rubble, in the form of a long slope, was shown to be pregnant with mischief, and had never been possessed of adoption of the system at Cherbourg had been a matter of necessity rather than of choice.

Mr. Alan Stevenson’s clever experiments, on the force of waves striking opposing bodies, were given; and it was urged, that the force shown to be developed by a barrier would not be equally applied on a vertical wall, but which would tend, and, if the accumulated force upon a slope, upon which it would naturally break. In conclusion, it was urged that, although for Dover, which was the spot where two arms of water take possession of an island on the order of the invasion, but to maintain our present naval supremacy, it might be permitted to expend a large sum of money; yet it would not do to have several Dover; and, therefore, it behoved the authorities to consider carefully the site, the plan, and the method of construction, before commencing works, in which, in the present state of engineering science, the experiences of the past should be used to avoid the errors that had occurred in former and similar works.

In the discussion which ensued, and in which the principal civil engineers engaged on great hydraulic works took part, after justly complimenting the Earl of Lovelace, for the very able and impartial analysis he had made of the evidence contained in the Government reports, and the documents in his power, the speaker, referring to the most actual circumstances and conditions of the works which had been insituated as failures; and it was shown, that from being expensive or useless works, they had been completed within the original estimates; and that wherever the cost had been overriden by the nature of the defective materials, which, being on the spot, it had been obligitory to employ, and not from the use of the long slope, which, as compared to vertical walls in similar situations, was shown to be more durable, and to have been, in many instances, successfully substituted for vertical walls, after they had succumbed to the assaults of the raging tides.

INSTITUTION OF MECHANICAL ENGINEERS.

June 18.—J. E. McConnell, V.P., in the Chair.

ON THE BALANCING OF WHEELS.

Mr. McConnell read the following interesting paper on the above subject:—The paper treated on the balancing of wheels as a very important matter, as most of the accidents from carriages jumping off the line, had arisen from the balance in the wheels of the engine. The first portion of paper was a criticism of a paper which was read in the Institution of Civil Engineers, by Mr. Phillips, of Birmingham, on examining a lathe in the turning-rooms of Earl Craven, the pulley of which he found to be out of balance. This he remedied, and the lathe worked well again. Mr. McConnell instanced several railway engines which had been built, to show that a vast amount of proper balance had been made in the wheels of the engine. He then proceeded to illustrate the usual method of balancing the wheels of locomotive engines, which he considered an improper one, and on the whole to experiments with another model, pointing out the desirability of obtaining an accurate balance in the piston and piston-rod. In the course of the paper, Mr. McConnell exhibited various experiments with a model railway carriage and explanatory and illustrative of the working of a locomotive in which the wheel was made with wheels in balance, the motion to which was given by a spring, and the sustained regularity of the motion was unexceptionable. In the second experiment, a small piece of iron was inserted in the wheels, and the balance consequently destroyed—the natural tendency being to cause a jumping and jerking motion, to obviate which was the object sought in this contrivance. Similar experiments were made, to show the necessity of adopting a similar system of balancing the piston and piston-rod, in order to obtain a proper balancing of the wheels.

In explanation, Mr. McConnell said, that the wheels could be properly balanced together. First, one wheel was balanced, and then they put the other wheel on that side of the engine at which it in the other wheel. The other way round. The matter was first placed before Mr. Robert Stephenson, that gentleman considered it of no service, and it met with much opposition; but since that time Mr. Stephenson, and many other gentlemen, had adopted the system recommended in (Mr. McConnell’s) opinion, was not the correct one. When a locomotive-engine was connected, and the driving-wheels and working part attached, it was lifted upon, by the action, and then set slowly in motion, balance-weights being added until it moved at a certain speed without oscillating, and it became perfectly settled on its centres. That plan might answer tolerably well, but it was the really true mode of balancing wheels. He considered that great evil resulted from the piston and piston-rod not being in balance; it had been the cause of accidents in several cases where the engine did not leave the rails when the wheels were in balance. If the engine attained a certain velocity—the piston-rod moving 1,000 feet a minute—this momentum became so great, that the engine must jump; and if the engine were, in consequence, out of balance, they could see between the wheel and the rail. They had an engine at Wolverton, fitted up with those correcting-weights, and it had been tried, for the first time, that morning on blocks. The engine at a certain speed on the blocks, threw itself down, and they were not able to run it so fast as might be wished; but, on attaching the balance-weight, the motion of the engine was completely neutralised.

Mr. Middleton said, that this appeared to be the system of balancing which was adopted, and which, as the notice of the North-Western Railway, some years ago, by Mr. George Heath, and against which hitherto there had been much prejudice. He felt convinced that it was one of the best methods ever suggested for securing the safety of the locomotive, and that any engine might be obviated by the adoption of this, or some similar plan of balancing the wheels of engines and carriages. It was supposed that the North-Western line had disapproved of Mr. Haeston’s plan, but he was happy to find that there was now some probability of Mr. Haeston reaping the reward of his industry by the use of his patent.

Mr. Cowper said, that a system of balancing wheels was used by the
Eastern Counties Company eleven years ago; but this was decidedly a superior plan to any he had ever seen, and in many respects superior to the plan he had seen of Mr. Heathcoat's.

Mr. M'COWAN, Mr. Thompson had expressed his entire approval of the utility of the proposed mode of balancing wheels, and had already given orders for it to be attached to an engine he was now constructing.

LIGHT ENGINES—LIGHT TRAINS.*

The Secretary read the following paper on the above subject, by Mr. SAMUEL, engineer of the Eastern Counties Railway:—"The small locomotive, lately introduced on the Eastern Counties Railway, having attracted much attention, I have been requested to furnish a short description of it; and, at the same time, to offer a few observations on the practicability of the principle to the conveyance of passengers. This carriage was constructed under my superintendence, for the purpose of conveying myself and inspectors on the lines of the Eastern Counties Railway, and thereby avoiding the great expense of special engines. The total length of the carriage is 13 ft. 6 in., and includes machinery, water-tank, and seats for seven passengers, on one frame, which is hung below the axle, and is carried on four wheels, of 3 ft. 4 in. in diameter, the floor being within nine inches of the level of the road. It is propelled by two cylinders, 33 inches in diameter, with a 6-inch stroke, placed on each side of the boiler, and acting on a crank axle. The boiler is 5 ft. 6 in. in diameter, by 4 ft. 3 in. in height; containing a fire-box, 16 inches diameter, by 14 inches high; and 36 tubes, 3 ft. 6 in. long, by 1½ inches diameter; giving 40 square inches of fire-door on the fire-box, and 62 square inches on the tubes. The engine is fitted complete, with link-motion, feed-pumps, &c.

The water-tank is placed under the seats, and will contain 40 gallons. This carriage is capable of conveying seven persons, at the rate of 80 miles an hour. It has, at times, attained a speed of 44 miles. The consumption of coal is only $1 per mile; and the weight of the whole machine does not exceed $56 cwt., including coals and water. The result of observations, which I have made for some time, have brought me to the conclusion that the whole, it is not remunerative, and, in some cases, is even worked at a loss. I have, therefore, led to consider whether the expenses might not be reduced, by the introduction of a system of steam-carriages more suitable to the amount of traffic to be conveyed. It is easy to see, however, that while we can reduce the dead weight of the trains and engines, in proportion to the number of passengers, the less will be the expense of repairs, both of the carriage stock and engines, and of the way and works of the line. The average weight of a train, on the branch railways, is 50 tons; the number of passengers, conveyed by each train, is not more than 40 on any of the branches railways in England, excepting in the very northern parts of the country. The number of passengers, conveyed by each train, is usually 30 to 40 passengers, and on the branch railways, 50 tons; the number of passengers, conveyed by each train, is usually 40 to 45. Mr. Cowans considered this engine peculiarly calculated to be worked with economy on the branch lines, as it would tend very much to make them pay, by economising the locomotive expenditure.

Mr. BUCKIE, inquired, how the distance of the wheels would suit the present turn-tables?

Mr. SAMUEL, said, it was usual, at every terminus, to have a large turn-table, suited for engine and tender; and, where there was not such a conveniences, they could make a triangle, which would be as good. The increased speed obtained on these trains would obviate the necessity of frequent changes of carriages; and he estimated the average cost of conveying the passengers would not exceed one-fifth of a penny per mile. Many of the branch lines did not pay, and some economical principle was needed to effect that object. In answer to further questions Mr. Samuel said, that he proposed to work the goods traffic in a similar manner.

Mr. M'COWAN still thought that the rails should be equal on these branch lines, and to work the engines on the main lines, in case they went over them; the wear and tear would also be less on strong rails.

Mr. COOPER considered the ordinary rails in use were too light, and that the present price of iron, he thought it bad policy to lay down light rail.

The meeting expressed their entire approval of the engine for all the purposes of the ordinary branch lines of railway.

NOTES OF THE MONTH.

Daguerreotype Plates.—The plates prepared by depositing silver by electrical agency have been found far superior to the ordinary prepared plates. The most adopted by Mr. Kilburn to test the superiority of the electropolished metal is to deposit silver, by a small battery, on one-half of a regular prepared plate, and to operate the sensitive coating, and to go through the usual process of taking a picture. He says that the lights and shadows on the half that has been electro-plated will be much more clear and distinct, and that in comparison with that portion of the plate, the other will be much inferior. The requisite time of exposure is also found to be reduced about one-third.

Aerial Navigation.—Mr. Pitt, of Lantock, Oxfordshire, has published plans and descriptions of an "Improved Archimedean Balloon," whereby it is proposed to move the air by paddle-wheels, set in motion by a steam engine. This aeronautic machine will indeed be a "monstrous balloon," as it is proposed to give it buoyancy sufficient to raise thirteen tons; and it is to be 120 feet long, exclusive of hemispherical ends. Mr. Pitt conceives there will be little difficulty in steering this mental ship, but he seems altogether unknown of the absence of a guiding resistance, for though he may be able to turn the machine round, that would be of no avail in steering, unless there be some resisting force superior to that of the wind.

Railway Opacity.—One of the lines of rails of the Bolton, Blackburn, and West Yorkshire has been opened. The Tiverton branch of the Bristol and Exeter line was opened on the 12th June.

Compromise of the Gauge Question.—It has been decided by a committee of the House of Commons, "that the double gauge shall be laid down

* This paper fully supports our remarks in the "Journal", for December last (Vol. lxxi. p. 280).
from Penny Compton to Wolverhampton, the mode of laying down to be such as the Railway Commissioners may approve." By this decision, says the "Railway Chronicle," the settlement of the gauge question, to attain which a commission was appointed in 1845 and legislation took place in 1846, is sent to the wind. "...Thus, diversity of gauge is being allowed to take root in the most perilous form which it could adopt—namely, the double gauge system."

**New Atmospheric Railway.**—A working model of Messrs. Harlow and Young's atmospheric railway has been recently exhibiting, and it works very satisfactorily on a length of 150 feet, with a four-inch tube. The peculiarity of the invention depends on the formation of the valve. The tube is cast with a conical slide-valve, similar to the slide-valve of a steam-engine. The sides of the opening are so cast, that one side presents a horizontal groove, and the other a tabular face, both planed perfectly true. On the tabular face the slide-valve moves when forced on the groove by the pressure of the coulter, consisting of bars of iron, in a full-size working tube, proposed to be 4 or 5 feet in length. At each end of these bars a semicircular opening is turned through half their thickness, forming, when two abut against each other, a circular orifice in which is placed a disc of a cylinder, perfectly true with the under surface of the bars, and thus presenting a sort of rule joint without any fixed axis, and forming collectively a loose chain which slides over the opening, and renders it air-tight. To each of these bars, or links, a shape of weight is applied, which is merely of sufficient power to press the valve into its place, after the passage of the coulter. The whole is covered by a top plate, to keep out grit, wet, snow, &c., with the exception of a small space to allow the coulter to pass, which is not much thicker than a saw blade, and which connects the leading carriage with the plug in the usual manner.

**Preservation of Wood for Railway Sleepers.**—Messrs. Hutin and Bostiguy have obtained a patent in France, for the preservation of wood intended for railway sleepers; the process of which depends on filling the pores of each annual growth, by ships, ends having thus been reached. The process is thus described: "Immerse the ends of a piece of wood in some liquid carburetted hydrogen, such, for instance, as the oil of aschit, which penetrates quickly some distance into the wood. 2. Set this carburetted hydrogen on fire, and at the moment the flame has burnt out, plunge the wood to the height of a few inches into a hot mixture of pitch, tar, and shalm, which will be slightly drawn up between the fibres, and form at each extremity of the wood a kind of hermetic seal, unalterable by water, and protected with tar by the pressure of the face by the ordinary methods."—A process nearly similar was not long since communicated to the Paris Academy of Sciences, by M. Gemini. In this plan, tar is used for the purpose of filling the pores of the wood, without the necessity of enclosing the substructure, wherein is a disadvantage by high-pressure steam. A vacuum is thus produced, and additional force is given to the tar in its penetration of the fibres of the wood by a force-pump. M. Gemini observes that a separation takes place between the solid portion of the tar (the pitch) and the oily portion; and that the first penetrates only an inch, whilst the oily matter will penetrate throughout the whole substance of the wood.

**The "Divining Rod."**—"It is a practice not uncommon in the mining districts of Texas, for which it is used, to determine the "divinings," or by this supposed to be attracted towards the metal on walking over the surface of the ground. The following letter, in the "Mining Journal," signed "H. F. Penny, Notting-hill," thus describes the modus operandi, as having been successful in cases: "I am neither a miner, nor have I ever been deceived, this is one of the things that philosophers cannot account for:—

"I have witnessed the operation of the divining rod, in a manner most conclusive and satisfactory to my own mind. I went, accompanied by Mr. H., first to Whif, Jave, the London wood, capital of which is what they call a duffer. He ordered one of the men to cut half-a-dozen wedges, of the requisite shape, from a neighbouring hedge, and we then proceeded to a field, across which the lode lay. We each held a rod, and walked abreast, the captain in the middle. Upon crossing the lode his rod bent downward, and, to my surprise and delight, I felt, at the same time, mine pressing against the flesh of the finger, but would not go lower. Mr. H. remained perfectly stationary! We tried it again and again with the same result: the captain's rod bent more than mine. We then went to another mine beyond Perran, and sent for a labouring miner from under-ground, who is a celebrated duffer. We had another gentleman, a Mr. C., with us, an old farmer, a clerk of this mine, and myself—thus making six, all armed with the divining rod. The loder's rod was found to be a shot, completely inverted! Mine went down gradually, but its pressure was quite perceptible, until one of the limbs of the rod, close to my fist, actually broke off, from the great force of the miner's hand in operation. Now, holding my hand over the ground, the remainder of the rod bent down and to move it downwards by any voluntary motion, much less to break it. Mr. H.'s remained as usual, quite stationary, as also the clerk's; the farmer's and Mr. C.'s acted nearly as powerfully as mine, very much to the astonishment of the people present, so that it will not act with one person out of 50, or, perhaps, out of 100.""}

**The Magnetic Telegraph.**—Mr. Nathaniel Holmes, who is in the employment of the Electric Telegraph Company, has made an improvement in the magnetic telegraph which promises to be of great utility. The invention described by himself in a letter to the Athenaeum—"It may be effectually produced in the following manner. The expenditure of battery power to one-tenth of the amount required by the present mode of working on the long circuit a distance of 200 miles, with an equivalent of 240 pairs of plates, 24 pairs of duty, much more effective results—the reduced intensity not suffering so much the effect of bad insulation. The most important point, however, of the economy of power when it is applied to the numerous stations through the kingdom, and the increased facility of working through a much smaller area of circuit resistance. The addition consists in the substitution of a single small steel lozenge, three quarters of an inch long, for the 5-inch astatic magnetic needles, placed between two small coils, which gives signal a free fault from the slightest vibration of the needle, a thing which has been said—the pendulous action of gravity being limited, from its better adapted form."

**Telegraph Profiles.**—The profits of the New York and Washington Telegraph Company are reported to amount to $1,000 dollars per month. The Western Telegraph Company is, however, said to be doing a better business than that.

**LIST OF NEW PATENTS.**

**GRANTED IN ENGLAND FROM MAY 30, TO JUNE 16, 1846.**

**Six Months allowed for Enrolment, unless otherwise expressed.**

- William Sacken, of Camden Town, Middlesex, gentleman, for "Improving in dry cleaning, and in preventing the increase of the heat of the process."—May 11, 1846.
- Jasper Wheeler Rogers, of Nottingham-street, Dublin, civil engineer, for "Improvements in methods and machinery for the preparation of gas as a fuel, and in connexion with certain substances as a compact or mastic."—June 1, 1846.
- Richard Christopher Manuell, of Grease road, Surrey, gentleman, for "Improvements in the confinement of vehicles used on railways or on common roads."—June 1, 1846.
- Thomas Hunt Barber, of King-street, Cheapside, for "Improvements in making artificial fur."—A complete specification June 1, 1846.
- James Barham, of Stratford, Essex, manufacturer, for "Improvements in the construction of vehicles used on railways or on common roads."—June 4, 1846.
- Thomas Borden Burton, of Sheffield-street, manufacturer, for "Improvements in machinery for bending and fitting plates or bars of steel, iron, and other materials, to be used for locomotive engines and carriage springs, and other purposes."—June 1, 1846.
- Henry Adcock, of Moorpark-street, London, civil engineer, for "Improvements in furnaces and fire-places."—June 5, 1846.
- William Brindley, of Birmingham, manufacturer, for "Improvements in the construction of articles of paper-maché."—June 6, 1846.
- Richard Barnes, of Wigan, Lancashire, gas engineer, for "Improvements for manufacturing gas for illuminating purposes, and for which improvements is applicable for distilling, pyrolytic, and other similar purposes."—June 6, 1846.
- Joseph Foot, of Spital-square, Middlesex, alk manufacturer, for "Improvements in making skirnels of silk."—June 6, 1846.
- Joshua Proctor, Westhead, of Manchester, manufacturer, for "Improvements in manufacturing into fabrics."—June 8, 1846.
- Thomas Dalton, of Coventry, silk dyer, for "Improvements in the manufacture of plumes, gimp, and bolus."—June 8, 1846.
- Paul Marie Daruy, of Paris, in the Republic of France, for "Improvements in oblique power."—June 8, 1846.
- Richard Wasi and George Vernham, both of Epsalfd, Middlesex, engineers, for improved steam-engines, which may be also worked by air and other fluids."—June 10, 1846.
- John Miller, of Hertford-street, Covent Garden, gentleman, for "A new and inexpensive method of manufacturing loom stockings, and all kinds of stuffs, of which improvements is applicable to means by which, whether on land or water." (A complete specification June 13, 1846.
- James Taylor Best, of Exe-street, Exeter, civil engineer, for "Improvements in the construction and arrangement of engines and machinery for propelling boats and vessels, with a means of preventing ino-on of the boilers, parts of improvements are applicable to land purposes."—June 15, 1846.
- William Hunt, of Dodger Hill, Wrexham, chemist, for "Improvements in apparatus for processes connected with the distillation of petroleum and salts."—June 15, 1846.
- Sir Henry Hart, Commissioner of Greenwich Hospital, Rear-Admiral in the Navy, in "Improvements in apparatus for preventing what are called 'smoky chimneys.'"—June 15, 1846.
- Joshua Rose, of Darton, Yorkshire, manufacturer of patent improvements, for "Improvements in the manufacture of patent improvements, for "Improvements in the manufacture of fuel, and in the construction and arrangement of apparatus for raising and rendering steam, boilers, ovens, &c. in the manufacture of tea, the consumption of carbonic acid, the manufacture of gas for illumination, and the consumption of all other gases and products."—June 15, 1846.
are levers keyed on the shaft E, and connected at their lower end by levers to the slide-blocks h, h, k, k, are levers also keyed on the shaft E, and having each an arbitrary extremity. On the shaft Q are two cams, one of which works a lever on one side of the shaft, and the other cam works the other lever k, on the opposite side. One of the cams, through the medium of the levers j, j, and the links before referred to, causes the roller f to pass over the selecting-bar 8 and the selecting-bar 9, on which the roller to recede from them, until by a catch employed in the ordinary way in the Jacqard looms, the roller f is made to turn through one-sixth of a revolution, and is then retained in that position by the pressure of the spiral spring and flat foot above referred to, 4, 4, are brackets attached to the depressor P at the back of the machine, seen best in fig. 1. m, a bar resting on the brackets i, i, and connected by rods with the sliding-blocks h, h, which, on receding, cause the bar m to bring all the selecting-bars e into the position for depressing the rams, as seen in fig. 11. n, n, are levers having their fulcrums on studs secured on the frame; one end of these levers is connected by a rod p, with the lever Z, Z; the other end is furnished with a roller which is acted upon by a cam u, on the shaft Q, (see fig. 8). φ, φ, are the holding-down levers, adjustable laterally on the shaft Y, so as to admit of one of them being placed on each side of every punch. φ, ψ, are rods connecting the levers n, and Z. By adjusting the length of these rods, the levers φ, φ, are made to press upon plates of different thicknesses, so as to hold the plates down while the punches are being withdrawn. q, q, levers turning on the fulcrum-bar D, for holding down the plate, in order to keep the selected rams, while the levers q, q, s, a broad but rather thin bar, extending through the series of punch-bars P, shown by dotted lines in figs. 7, and 2. The punch-bars P are made with slots, through which the bar s passes, and these slots must be about two inches longer than the width of the bar s, in order to allow the roller t, to pass under the bar down when the bar is at the bottom of its stroke. t, t, are links connecting the bar s with the levers q, q, u, u, are levers which depress the holding-down levers φ, φ, through the medium of the levers n, n, rods p, p, and levers Z, Z, and hold down the plate while the selected rams are working. T, the punch-ram connecting-rod M, connecting-rams, fitted to the eccentric necks of the shaft Z, and connecting to the punch-bars, P, P, Q, the cam-shaft R, a spur-wheel, on the cam-shaft, and having on one side two projections, which project upon the press-ram, V, on the cam-shaft, T, the punch-ram-depressors L, the connecting-rod M, by knuckle-joints at the base of the connecting-rod U, a slide-bar, on which are mounted three transverse-wedges, which carries the plate to be punched. V, V, two slide-bars, to carry one side of the traverse-frame. W, a bar of iron, fastened with short wedges to the bed B, to carry the die-plate X, into which the dies a, are inserted, and prevented from rising by the roller y, see fig. 11. a, a, are levers, carrying the holding-down levers, or stoppers, o, o, Z, Z, levers on each end of the shaft Y. a, a, the levers into the punch-holders h, b, bolted to the rams P, as in the detached view, fig. 5. c, c, pieces bolted to the bed to act as stoppers for the punch bars, h, h, having a roller x, x, (fig. 1), are the selecting slide-bars, which are allowed to pass through the card-plate, enter the card-roller f, about being pushed backward by them; the card-roller has in its case six sides, and the belt of Jacquard plates, after passing over it in the usual manner, passes over a round roller suspended in a swing-frame, at such an angle as shall keep the belt moderately tight, whilst the roller f advances towards and recedes with the selectors. g, g, brackets projecting from the depressor j, and carried up and down with it. A, A, slide-blocks, in which are journals the round roller f. The side g, g, of these blocks is fitted with a round of iron, thus, f, f, with a flat foot, being enough to extend over two of the six pins in the ends of the card-roller, against which the flat foot of the rods is made to press, by spiral-springs coiled around them in the usual manner employed in the Jacquard-loom, which is generally known, and need not be further described. t, t, (fig. 1), are two sets of guide-blocks, for the selectors e, one on each side of the depressor, adjustable laterally by set-screws on flat bars, extending across the machine; the use of these blocks is to carry the selecting-bars e which are round at the end that enter the position it in the position it is in the selected positions; the centre portion of each selecting-bar is a solid piece of iron, projecting as much below the round stem as will, when the selecting-bar is driven backward by a card-plate, permit the depressor T to complete its downward stroke without the selecting-bar touching the ram, P, under it. A, A, in consequence of the elaborate character of the two engravings, we are obliged to postpone giving one of the plates until next month, but when the volume is bound up, the two plates will appear together.
I. In that very amusing, but slovenly and in parts rather dull congeries of gossip, entitled "Nollekens and his Times,” Museum Smith speaks of a certain "happy possessor of some of the worst fragments of the antique in the kingdom, who employs a mere mason to put them together, and is perfectly satisfied though a right foot has been most ingeniously placed upon a left leg!" Who the "happy possessor alluded to was, I know not, but I do know that, mutatis mutandis, the entire article as forcibly, or in general far more forcibly, to the stupid, and tasteless, and bungling, bungling-up of architectural odds and ends—whether antique or mediæval, classical or ecclesiastical—into a design intended to pass as an unexceptionable specimen of the particular style which is professedly imitated, but generally caricatured more or less when so treated, second-hand, and not contrary to meaning and purpose also. Would that in architecture no greater blunders were ever committed than that of sticking a "right foot on a left leg,"—in which case the artist might fairly have excused himself by swearing point blank that it was not the right foot.—Our being imitators at the present day might be forgiven; but we are not so much imitators, as mere copyists, incapable of entering into the spirit or meaning of our models,—which are to us little better than blind guides, simply because we ourselves follow them blindly, and without the least regard to widely-altered circumstances. What more may, under circumstances of time and place, be expected, never we consider.

Yet if we really studied our models, we should find—at least, in all those most deserving of being studied—every part well meditated and adapted to the express occasion. How far we in that respect imitate those who have gone before us, I leave it to the impartial reader to judge for himself.

II. In his above-mentioned book, Smith is pleased to say: "Men of true taste visit a mansion only upon the report of its statues, busts, and pictures. The architecture of a house unsaddened by such productions of art, would not induce the general traveller to drive twenty miles out of his road, nor even five. How few allusions, indeed, was the Marquis of Lansdown's, Lord Pembroke's, Lord Egremont's, Lord Farnborough's, Sir Abraham Hume's, Mr. Peel's, (now Sir Robert), and many other noble mansions have, if totally destitute of their fine collections of statues and pictures!"—No, no, it would be"architecturally destitute of anything worth mentioning,"—Nothing whatever of architectural interest in the "noble mansions" themselves; and, secondly, because if there were, your "general travellers" have very little, if any taste at all for architecture. I was the other day in a house here in town,—one that I may say is "architecturally destitute of pictures and statues," with the exception of a basso-relief by Lough, over a chimney-piece in one of the rooms, is in itself all picture—as superior to Peel's as a pine-apple is to a pippin. For my own part, whenever I go over a house for the first time, I have no other eyes nor thought—nor if I had, I have not time—for anything but the architecture itself. As to pictures and statues, any dowdy house may be bedizened out with them, and still be, as a house, as dowdy as ever,—a perfect cluster of 'Cs': very convenient, very comfortable, very commodious, very correct, very comme-si-fian, and very (most of it) and very (most of it), I confess.

III. In his anecdotes relative to Conway, Nollekens's biographer says that, after quitting Pall-Mall, "he (Conway) fitted up his new residence (No. 20, Stratford-place) in so picturesque, and indeed so prickly a style, that I regret drawings were not made of the general appearance of each apartment; and have so far rescued them from complete oblivion. Instead of which, he merely goes on to astound us by enumerating some of the costly articles of furniture and vev
such talented creatures "must live," and cannot possibly be interdicted from exercising pro malo publico what they are pleased to call their "talent," the ultimate injury to art and to public taste is greater than the benefit. I remember a priggish young Oxford student boasting in company of the many eminent men who had been men of letters, and who, when they wrote, and cut nothing out of anything, put it all out to him—"But you don't say a word of the thousands and tens of thousands of blockheads which it has also turned out," adding, sotto voce, and "and I take you to be one of them."

V. In a letter on the subject of the the Architectural Publications, I correspond, as the Observer says, after quoting what is stated in that Society's prospectus, as to the paucity of architectural works in this country: "Surely the thumb-screw must have been applied to extort this confession!" When a remark to the same effect—that is, animadverting upon the scarcity and inferiority of English architecture—was addressed to him a short time ago in the Westminster Review, a gentleman who now figures among the "Promoters" of the above-mentioned Society, thought proper to contradict it publicly at one of the meetings of the Institute; nevertheless, what was then deemed an injurious calumny, is now proclaimed to be the fact. Indeed, it is wonderful that any one should have had sufficient hardihood to dispute it. For a certain class of architectural books, there has been a considerable demand and corresponding degree of supply, of late years; but they are merely elementary ones, and besides, almost all of them are in the Gothic style, and the other Gothic style, architected, of which it would not be worth looking at; whereas, in a first-rate mansion, at least—every part of it, except the entirely private and domestic rooms, should be laid out with studied regard to effect, and to variety of effects—without, however, departing from the essential rules of composition, character, and beauty. It is all a picture—strikingly beautiful in itself, charming, captivating, before it receives its finishing touches in the way of furniture and other accessories. At present, as they are left by architects, rooms (even those in the best houses) are little better than blanks,—large enough to contain the biggest roof that could possibly be filled in; in doing which, they may chance to empty your purse before you are aware of it—or if they do not actually do that, they are likely to disgrace your taste by cramming your rooms with a medley of ill-assorted articles, agreeing only in being all alike very expensive and elderly.

IV. In anecdoting some of the former residents in St. Martin's-lane, Smith notices No. 60, as the house once occupied by Chippendale, the most famous upholsterer and cabinet-maker of his day, to whose folio work on household furniture the trade formerly made constant reference. It contains, in many instances, specimens of the style of furniture so much in vogue in France in the reign of Louis XIV, but which, for many years past, has been discontinued in England. However,—I entreat my reader to mark this,—"as most fashions come round again, I should not wonder, in time, to see the best of the best, and spend the money of the world by Thomas Hope, Esq., if we were to see the unmeaning scroll and shell—work with which the furniture of Louis' reign was so profusely encumbered, revive; when Chippendale's book will again be sought after with redoubled avidity, and as many of the copies must have been sold asasted-paper, the few remaining will probably bear a high price." Smith's apprehension is already to a considerable extent verified; and that same Louis Quatorze taste, which, although dignified by such title, is essentially both puerile and barbarous, corrupt and unprincipled—quite contrary to every sound principle of sound art, seems to be now spreading through all branches of decorative design and ornamental manufactures; some recent specimens of which, though cried up by those who professing to guide public taste ought to know better, are chiefly remarkable not for elegance or beauty of form and combination in any respect, but rather for the revolting thinglessness of what has been quantingly termed "the deprecation of elegance;" which singular perversity of taste is the more unaccountable, as well as lamentable, now that we have Government Schools of Design. Really, if such institutions produce no better fruits than the specimens adduced to prove their existence, they are entirely at a loss to account for. The instruction there given, no more qualifies for producing artistic design, than learning to read and write qualify for a literary career. Were things left to take their natural and healthy course, very few except those who really possessed talent—or who saw a profit in the game—would think of resorting to it. Where talent really exists, such institutions are no doubt highly beneficial, by enabling it to develop itself; but then, on the other hand, they are mischievous, inasmuch as they turn out upon the world a great many more who are quite talentless, though furnished with a certain degree of manual proficiency; and as
tural societies almost innumerable—nevertheless and notwithstanding all these favourable symptoms, architectural study—at any rate, a truly architectural study—is hardly it is because we in this country are so poor that we cannot afford to indulge in those book-luxuries, which our certainly not wealthy continental neighbours do. The plain truth is, that notwithstanding all our present chattering about art, we know nothing about it. It is more less as if that a bull, I return the compliment, by calling him a great calf.

VI. If architectural works, corresponding in character with those which are at one time to be published in this country, and which up to the present time have had to be brought about upon the continent, and long enough are not, it is to be attributed, some will perhaps say, to their being supplied to us by the continent itself. That such publications as those of Schinkel, Kleuse, Gartner, Famin, Gauthier, Letarouilly, Cogognara, Canina, Castina, Dieho, Runge, Gladbach, Tietz, Joly (Chambre des Depots), Calliat, and others, are known here, there can be no doubt. One or two of them are stock-books with English booksellers. Yet, whether they have been imported to such extent as to render all home-production of the same sort quite unnecessary, may very well be doubted. Granting, however, such to be the fact, the consequence is, the continent gets nothing of a similar kind from us in return; wherefore, foreign architects, who would probably be benefitted by some exchange of ideas with us, are left to suppose that English ones produce nothing worthy of being shown, or that we bear the test of art sufficiently when we are to expect nothing from others. We can very well afford, it may be said, to let other countries entertain whatever opinions they please of us, in the matter of architecture and art. Very true; why, then, some among us so sors, so piqued, and so touchy, whenever it happens to us that foreign men or even foreign states publish anything, expected to show us the performances of contemporary talent. Were the Architectural Room three or four times larger than it is,—or, what would be better still, there were two sufficiently spacious rooms, one of which might be set apart for what is mere architectural portraiture, there would be no objection to productions of the latter description being admitted, provided they were worthy of being so, either on account of intrinsic interest or freshness of subject, or superior ability and charm as regards artistic execution.

Unfortunately, the reverse of this is the case: buildings that have not been shown again and again both in book-engravings and drawings, and also in copies from them, till we almost sicken at the bare mention of their names) are allowed to find admission at the Academy, in hundredth-edition representations of them. And not only are such things admitted, but they are treated with more or less respect, but many of them—and perhaps some of the staidest or else more trivial in subject, are allowed to occupy better places than drawings which show us, or rather would show us what we have not before seen, were they not hung where they cannot be seen themselves. As we have already observed, this is the unhappy case of No. 1094, the new Coffee Room of the Carlton Club-house; while, as if on purpose to render that case a still more scandalous one several large frames, which contain only very uninteresting views of architectural ruins, are placed very conspicuously near upon the "line. Had No. 1094 been differently done, it would have been very fairly might have been done, under the name of Mr Sydney Smirke, with the information that the encaustic embellishments were by Mr. Sang, it would, we suspect, have been very differently treated. Well, let us hope that it will be admitted again next season, for it certainly cannot be rejected as having been "already publically exhibited," unless being publicly put out of sight is just the same as being "publically exhibited." The Angels seem to think that they are at liberty to do just as they please in the Architectural Room, and commit all sorts of absurdities there without incurring the slightest censure. For both we know all enough that the architectural drawings are never spoken of by the public in any but a most approbation of the way in which the rest of them are done, however among them may be as drawings, are below mediocrity as designs. If it be the policy of the Academy to bring architecture—that is,
architectural drawings, into still further discredit and disfavour with the public, as a step towards such works being excluded altogether, after its being voted to be beneath the dignity of a Royal Academy to admit them into its exhibitions, much as we may admire the artfulness of such policy, we must repudiate its treachery.

To begin—as it is now high time for us to do, our notices of such drawings as we can now speak to, we will first of all mention those which belong to what is invariably the most scanty, though assuredly not the least interesting or least important class of subjects, we mean Interior. One of them, whose title excites curiosity about the most, is, as has been already hinted, the old one of the Fifth Courtyard of St. Peter's. The next, No. 1117, "The Drawing Room and Corridor of the Army and Navy Club-house," Mears, Allom and Cross, fares very little better, it consisting of two small drawings in the same frame, which being only slightly tinted in sepia, and hung up considerably above the eye, are hardly observable. Of these two subjects we prefer the "Corridor" one, as manifesting, besides taste and considerable novelty also, more judgment with regard to due gradation of effect than the usual mistakenly ambitious practice of making the approach to the apartments in a club-house or private mansion far more impressive and important—architecturally speaking—than the rooms themselves,—pompous prefaces to that, if not actually pauperly, more or less common-place. We question whether the actual Club-house now in progress will be able to show anything half so full of effect and scenic, yet not at all extravagantly or forcedly, as the room itself, but rather quite the reverse. The "Mears, Allom and Cross" style of design would have been. At the same time, we think there was more than one other design offered that was upon the whole still better than theirs. However, the Club, or perhaps the City—The Hermitage, who wields that club, and against whom all the arguments of criticism are directed, is of the whole. We may find that we have passed over in its numerical order, an interior placed conspicuously enough, therefore not at all likely to be passed by unnoticed on the wall, viz., No. 104, "Design for the Interior of a Room, decorated with Illustrations of the Coldstream Guards," H. Shaw. This design is so old as its title is oddly worded. The drawing is a large and pains-takingly laboured one; the "interior" of the room shows what is meant for florid Tudor Gothic in all its floridness, in which flags and heraldic embellishments bear a prominent part; still it is not by any means to our taste, and "illustrations" if not illusory Coldstream Guards, for their especial admiration. As No. 1000, "Drawing of an Ancient State Palace belonging to the Company of Fishmongers," by the same exhibitor, it may properly enough come in for notice immediately after the preceding. Its title is so old as its object is evidently antiquarian and not at all architectural. It is, in fact, little more than a highly-laboured drawing of a more curious than tasteful needle-work relic. What business it has to be here in one of the very best situations, we do not understand; on the contrary, marvel indeed, not that there is at all, as we would get rid of some of the architectural designs which were turned away in order to make way for such a very old-ladiesh affair as this. Perhaps it took the fancy of the old ladies in the Academy.

No. 1000, "Entrance Hall and Staircase of the British Museum," as decorated by L. W. Collens, is a large and most captivating drawing, and strange perhaps to say tolerably well-placed. As to its subject, it is not so acceptable as one less known would have been, the Museum being freely open to every one; and so far, we could wish that Mr. C.'s drawing had changed places with Mr. C.'s little pictures being not only "penetrable stuff," but their beauties as carefully secluded from gaze profane and critic's eye, as are those of an eastern harem. In itself, the Museum staircase is not particularly striking—striking only by comparison with the plainness and bareness of the other part of the building—the King's Library alone excepted. Faithful, too, as is Mr. C.'s representation, it is a flattening one, because of the hall itself it shows nothing more than what serves as fore-ground to the staircase, which is seen directly in front. All disturbing circumstances—all that detracts from or interferes with the scenery on the stairs themselves is thus shut out of sight. You are at liberty to fancy that it displays itself thus on first entering, or that if not at one extremity of the hall, it comes in at least at the centre of one side of it.—No. 1229 gives another staircase; viz., that at Beaumaris Park, Leicestershire, W. Railton. The fancy of white paper can be said, at least, in regard the design itself, or the manner in which the view is taken. The style adopted is the heavy, cumbrous Elizabethan, whose quaint carved-work is far more costly than elegant, although it costs an architect nothing.—no study or thought, if he be content merely to copy without studying how to refine upon such style, and bring it into keeping with modern taste and notions as displayed in all respects throughout a modern residence.—No. 1288, "Design for an Entrance Saloon, adapted to the English climate," W. Railton, is a puzzle in every respect. In which particular it is more adapted to our climate than any other room, we are unable to guess; unless it be that its excessive gaudiness and flutter of colours is intended to counteract the chilling influence of an English sky. Nor is the architecture at all better than the taste shows. Embellishments it regards colour. The room has the look of a tawdry tavern "saloon." We have got to the end of "Interiors," for we do not comprehend under that designation those of churches, both old and new; the former of which are of course mere views, not the designs of those who here exhibit them; while the latter, which might else include to afford some exercise for inventive power and imagination, are, thanks to our modern ecclesiologists, their pedantry and their prudery, strictly bound to imitate, and as far as possible facsimilize, the old ones;—wherefore, to ecclesiologists and to Mr. Urban, we leave them. The only design of that class which struck us at the time, or which we can now call to mind with any distinctness, is 1183, "Highbury New Church, now erecting" by T. Allom. That this is a very charming drawing—one distinguished by its artistic treatment, we hardly need say, its author's name being a sufficient guarantee for such merit; but it has also great interest in other respects. The Minister here is the Rev. Mr. Mead, artistically—all the spirit and better qualities of the style—Gothic or mediaeval, as now matter of course, are preserved. The view here given of the church is, however, so exceedingly picturesque and episodical, that we cannot judge from it what the structure is or will be; and whether it may be allowed to turn at once to another and quite different one, by the same architect—viz., No. 1229: "Continuation of a Design for Improving the Property on the Banks of the Thames, &c." This we take to be altogether "a castle in the air"—too gigantic an idea to be, not indeed, an impracticable one, but not the slightest chance of being seriously thought of at all in our time, or Mr. Allom's. When he conceived it and was at work upon his drawing, Louis Philippe was upon his throne: that Louis is so no longer; neither is Ludwig. Tempora mutant, urbs et Europae hic et inde—a cry which we are getting weary of. To speak more architecturally and critically, we may observe, that for improving property on the banks of the Thames, we should read "on the north bank of the Thames," because, like every other which has had a similar object in view, Mr. Allom's scheme provides for improvement whatever for the south or opposite bank of the river, the spaciousness and utility which the latter would become more offensive than ever, were they to be confronted by, and looked at from terraces and quays on the north side, flanked by such façades as are represented in this design.

There is more than one good drawing and very fair design for houses in the Elizabethan manner or in a Dutch-Pennsylvania style,—which we are unable now to particularise, but among which, if our memory deceives us not, as for reason explained it may do—is No. 1116, "A House now erecting at Southend, Suydenham, H. E. Cox and E. Goodwin. There is another drawing apparently by the same hand, but of a design by a different exhibitor, though in the same style, and similar also in many other respects; yet which it is we cannot undertake to say, the pencil notes in our marked catalogue being nearly effaced. To confess the truth we must now hurry on to Finis, and content ourselves with merely indicating a few thoughts—"the imputation of dulness and mediocrity, or even worse, with which the architectural part of this year's Exhibition is chargeable.—No. 1119, "The Stoke Station, now erecting from the designs, and under the superintendence of H. A. Hunt," G. Buckler, has considerable merit in parts, but is very unequal, and therefore unsatisfactory as a whole. Here again the style is Elizabethan; and did the drawing represent a bond fide production and monument of that age, it would be interesting enough; but as a design at the present day, it partakes too strongly of the futility of the Chinese tailor over all the holes and all the stitches which make up a pattern of an English one. Considerable praise is due to No. 1211, "Court-yard of a Gentleman's Farm-house, lately erected," and No. 1213, "Design for a Chapel at Edmonton," both by F. W. Oridsch; also to No. 1270, "Additions to Frankleigh House, Wilts." H. & C. Having there, although there are some cases where the Chinese tailor in it, we confess to relishing Mr. Harkiss's design for a House about to be erected at Aldermaston, Berks., No. 1217. Pity that it is of the "olden time" and not of our own; for if we
continue to go on thus, the nineteenth century will be positively a blank in the history of architecture, as, unlike that of Elisabeth, the reign of Victoria an absolute nullity. With No. 1292, "New Buildings in the Temple," S. Smirke, we are by no means so well satisfied. Not only are they more continental than English in physiognomy, but they do not at all accord with any thing near them; on the contrary, are quite a patch stuck upon that range of buildings which they are intended to carry on and complete. While others are facading and defacing Soane's works, Mr. Smirke seems to be anxious to undo or else go quite counter to Sir Robert's doings.

ON TRIGONOMETRICAL FORMULAE FOR FINDING THE LEVEL OF TWO DISTANT OBJECTS.

By R. G. Clark, C.E.

The object of this communication is to exhibit some simple formule, that may at one operation serve to determine the levels of distant objects with respect to the station from which the angles are taken. The subject may be considered thus: we have on a vertical plane $HAD$, the given angles $HAC, HAD$, from $A$ the sensible horizon, and the given height $CD$, to determine the level of $D$ at the base with respect to $B$, the base of the station $A$.

(See fig. 1.)

There are two cases: firstly, when the vertex $A$ of the station is above the level of the summit of the object $CD$; and, secondly, when the vertex $A$ is below the level of $C$.

1st. Let the given angle of depression $HAC = \beta$; also the angle $HAD = \theta$; then the height of the object $CD = h$; and $HD = y$.

Then by the triangle $CAD$ we have

$$\sin(\theta - \beta) = \frac{h \cos \theta}{\sin(\theta - \beta)} = A.C.$$

By the right-angled triangle $AHC$, we have

$$\sin \beta = y - h = \frac{h}{\sin \beta} = A.C.$$

Fig. 1.

Equating the above values of $A C$,

$$\frac{h \cdot \cos \theta}{\sin(\theta - \beta)} = \frac{y - h}{\sin \beta}.

Therefore, $h \cdot \cos \theta \cdot \sin \beta = (y - h) \cdot \sin(\theta - \beta) = \sin \theta \cdot \cos \beta - y \cdot \cos \theta \cdot \sin \beta - h \cdot \sin \theta \cdot \cos \beta + h \cdot \cos \theta \cdot \sin \beta$.

By transposing, $y \cdot \sin \theta \cdot \cos \beta = \cos \theta \cdot \sin \beta$.

Hence $y = \frac{h \cdot \sin \theta \cdot \cos \beta}{\sin(\theta - \beta)}$ or $y = \frac{h \cdot \sin \theta \cdot \cos \beta}{\cos(\theta - \beta)}$.

Dividing each side of (1) by $\sin \theta$, we have

$$\frac{h}{\sin \theta} = \frac{y}{\cos \theta} \cdot \cot \beta$$

Therefore,

$$\frac{h}{\cos \theta} = \frac{y}{\cot \beta} = \frac{h \cdot \cot \beta}{\cot \theta} = \frac{h \cdot \cot \beta}{\cot \theta} = \frac{h \cdot \cot \beta}{\cot \theta} = \frac{h \cdot \cot \beta}{\cot \theta}$$

The formula (2) may be adapted for logarithmic computation, thus:

$$\log y = \log \sin \theta + \log \cos \beta + \log \cosec(\theta - \beta) + \log h.$$

The equation (3) can be effected by natural co-tangents, to be found in Hutton's "Mathematical Tables." An example is subjoined to elucidate the equation (2).

Ex. It being required to determine the level of two objects by angles of depression from the sensible horizon, taken at the summit of an edifice, as St. Paul's, the height being 404 (see fig. 1); the angle $HAC = 8^\circ 20'$; the angle $HAD = 8^\circ 30'$; and the height $CD = 300$.

Here $\theta = 8^\circ 30'$; $\beta = 8^\circ 20'$; $\theta - \beta = 8^\circ 10'$; and $h = 300$.

By formula (2) we have

$$\log \sin 8^\circ 30' = \ldots = 9.169702$$
$$\log \cos 8^\circ 20' = \ldots = 9.999265$$
$$\log \cosec (8^\circ 30' - 8^\circ 20') = \ldots = 11.045501$$
$$\log 300 = \ldots = 2.477121$$

$2.491589 = \log HD = \log 491.7$.

Therefore $491.7 - 404 = 87.7$ feet.

Hence $B$ is 87.7 feet above the level of $D$.

2nd. When the summit of the station $A$ is below the level of the vertex $C$ of the object $CD$, fig. 2.

Let $H = y'; DC = h'$; the angle $HAD = \theta$; and the angle $HAC = \beta$; and proceeding exactly the same manner as before, we have

$$y' = h' \cdot \sin \theta \cdot \cos \beta,$$

or $y' = h' \cdot \sin \theta \cdot \cos \beta \cdot \cosec(\theta - \beta)$.

And $y = \frac{h}{\cot \beta}$

The only difference being in the signs.

Hence $DC = AB = \text{height of one object above the level of the other}$.

Fig. 2.

Remark. When the angles are taken to seconds, it is more advantageous to use (2) and (4), as the case may be, to ensure greater accuracy. To solve the foregoing question by the First Case of Plane Trigonometry would require thereby more than two operations: hence the manifest value of the above formulæ.

The subject is a valuable exercise to the young student in surveying, as giving him proper ideas of the utility of trigonometrical formulæ for the means of rendering operations more simple for computation.

ISOMETRICAL PERSPECTIVE.

It is to be regretted that isometrical perspective is not in more general use amongst engineers and architects; but the infrequency of its application to designs of machinery and buildings, arises in a great measure, perhaps, from the difficulty usually experienced in properly representing curved lines. In this kind of perspective, we know that a circle inscribed within a square is represented by an ellipse touching the centre of each side of an oblique parallelogram, as in the annexed figure. Now, there is no instrument which can be set to describe such an ellipse, unless we first discover the transverse and conjugate diameters $a, b$, and $c, d$, somewhat troublesome preliminary. It is, therefore, much to be desired that an instrument could be contrived, whereby the draughtsman would be enabled to produce the ellipse with no more trouble than the simple measurement of the radius of the circle to be represented. Perhaps the following suggestion may supply that desideratum:—

To a block of metal $a$, let there be two projecting pieces, $c$ and $d$, each one carrying a pair of radius-bars $e, f, g, h$; let those bars exactly agree in length, and let each pair be so united by a pin passing loosely through the projecting piece, that their centre lines form an angle of $90^\circ$. Then, if $e$ and $g$ be made to carry a straight bar $k$, and $f$ and $h$ an arch $l$, having a tongue $m$, which bears upon $k$, we shall have an instrument by means of which we can describe an isometrical ellipse; and the mode of using it will be to press upon $a$, with the thumb of the left hand, and with the fingers of the same hand turn the arm $m$, and thereby the two pairs of radius-bars—while at the same time the right hand holds a pencil point in the corner $a$, at the crossing of $m$ and $k$. The pencil will thus be made to describe half the isometrical representation of a circle, whose radius is equal to that of
At Inishy harbour, Argyllshire, in 1843, I had a talus-wall to form a breakwater, which covered a sandy beach to the depth of from two to three feet. At another place, the rock was not only to be bared, but a navigable channel, twenty feet wide, and in some places as deep as eight feet in the rock, together with a small tide-basin, were to be excavated to the level of the low-water springs. The sides also were frequently subject, even during the summer months, to a very heavy surf.

The excavation of the tide-basin, which formed the landward part of the work, was effected by means of a series of dams, consisting of walls, built of porozolano rubble. These were to be built in order-tight, and to answer remarkably well in every respect; but they required, for their protection against the waves, a considerable bulwark or breakwater of Pierreis perduea to shelter them from the waves.

In the excavation, however, which had to be undertaken seaward of the breakwater of Pierreis perduea, any attempt to reduce the water during the whole of the tide, was what I never considered practicable. A trial was accordingly made to effect the excavation by means of a low wall, composed of a clay-rubble, resembling in its object those low dams consisting of logs of wood bedded in clay, which are often adopted in harbour-works, and which are only intended to keep out the tide during the first part of the flood, and to be pumped dry before the operations of the next tide are begun. But after many attempts with this clay-wall, it became quite evident that it would not be possible, with its assistance, to carry on the necessary excavations to nearly the high-water level of low-tide. This was due principally to two causes. First, because sand and shingle were, during almost every tide, washed in large quantities over the top of the wall into our excavation pit; and, secondly, because the waves washed out the clay from among the stones, so as to render the barrier no longer barrier.

Being now compelled to set about some other way of carrying on the work, I had recourse to the simple method shortly to be explained, and which more than realised my expectations. Before giving a description of this method, however, it will be interesting, as well as still further explain the proceedings, to quote a few lines relating to somewhat similar difficulties, from a Report upon the Harbour of Peterhead, which was drawn up in the year 1806 by the late Mr. John Rennie:—

"The next material object of consideration," says the Report, 
"is that of deepening the harbour, which at present cannot well accommodate vessels more than 12 feet of water in the spring-tides, but in neaps is not sufficient to render this harbour more extensively useful, it would be advisable to have 17 or 18 feet of water over the greatest part of its bottom, and particularly along the west quay. The mode of performing this kind of work will be different, according to the difference of situation. Those places where the tide ebbs from the surface, and continues so for some time, may be done by blasting, or by loosening the stones with quarrying tools in the usual manner; but in those parts where the tide seldom leaves the bottom, and in which, after a short time, dams are constructed, the best of all would be enclosing large spaces by cofferdams, and working at all times of tide by quarrying tools or blasting, as might best suit; but in some situations this would be inconvenient, as the dams would be in the way of vessels going into and coming out of the harbour. In such situations perhaps the simplest and most expeditious mode would be to use cast-iron cylinders of 7 or 8 feet diameter, having strong canvas fixed to the lower flange, which might be kept to the bottom by bags of sand in places where there was but little agitation; but where there is much, an outer cylinder might be sunk thereunto to keep from the situation."

The cylinders proposed by Mr. Rennie were, no doubt, quite adequate to the special purpose and locality for which they were designed, and they unquestionably possess some advantages not to be gained by other means; but, on the other hand, they are attended with difficulties and disadvantages which preclude their adoption in the present case. Those objections were the limited area, the weight and unwieldiness of such cylinders, their inexpressible nature and unalterable form, as affording no means in themselves of adaptation to the very irregular rocky bottom which was to be excavated, and what was of much consequence, the necessity which must have attended the removal of the partitions of rock, or those parts which would necessarily be left between the different compartments of the cutting. The last two objections, it may be remarked, refer equally to wooden caissons, or other contrivances on the same principle.

In the present case, then, the following requisites were to be provided for. In the founding of the talus-wall, all that was required was some method which would enable the found-stones to be laid as deep in the sand as possible, for which purpose the dam did not require to be absolutely water-tight, provided it were

---

* An abstract of this paper was given in the Journal of February last, p. 42.
capable of excluding from the inside the sand which was so liable to replace what was removed from the interior. For the excavation of the rock, on the other hand, it was necessary that the dam should be water-tight, and suitable for taking out all the partitions; and both situations required piles for fitting close to the irregular bottom, and those piles needed some support other than the soil into which they were to be driven.

To effect such objects, it was clear that the means to be adopted must be at once easily managed and efficient. For although, where there is time for their employment, many complicated and troublesome refinements of construction are forced to answer purposes which might have been attained by simpler means, or by less cumbersome arrangements, yet I was well aware that in the hurry and bustle attending tidal operations and night-work, nothing can be tolerated but what is in every respect easily managed and truly efficient.

In the accompanying diagrams, A G represents a frame of double waling-pieces connected at the angles by the uprights I I, and bound together by the long bolts L, with forelocks and washers, while E F shows similar double-framed walings for the inside of the dam, and of smaller dimensions, with their uprights D, and connecting bolts K. These frames being placed in the required position, the one frame inside of the other, the piles C are driven down.

The dam was 12 feet long by 10 feet broad inside, so that five men were able to work in the interior. If it was to be fixed within low-water mark, the two frames being placed in the water, were guided to the spot by the men in charge, and whenever they were in the desired position, the men at once moved the frames to the bottom, by driving down a pile at each corner. After this was done, all the piles were placed between the frames and driven down, and keyed up by the small piles called "closer." Four iron jumpers J, were then driven down to their proper places outside of the frames, and edge planks for preventing the clay were slipped down upon the jumpers through iron staples, which were fixed to the planks. After this, good clay (which should have some gravel mixed with it, to protect it from the wash of the sea) was pumped hard between the planks and the cofferdam, after which the mast N was erected, and the water taken out by means of the iron scoop shown in the drawing, which not only was used in taking out the stuff, but proved far more efficacious than any pump we ever had. Indeed, to get the dam pumped dry was for long the greatest difficulty we had to contend with. But Mr. William Downie, to whom I gave the charge, soon removed this difficulty, by using the scoop instead of a pump. The capacity of the scoop was about 37 gallons, and they generally made nine deliveries a minute, so that we found this method greatly more expeditious than any other.

As the excavation proceeded, the piles were from time to time driven down, and when the rising tide began to come over the pile-heads, or to rise above the clay, the men, before leaving their work, placed the flooring or "deck," as it was called, within the piling, with the ends of the planks resting upon the top of the inside of the floor. On this deck, ballast (or fristia) O of this deck, ballast (consisting of stones of a convenient size) was deposited to prevent the whole frame from being floated up,—the quantity so deposited varying with the height of tide, or appearance of the weather. As each compartment of the excavation was completed, and before the dam was removed, the rock below the two rows of piles which adjoined the cutting was completely taken out, and the piles driven down to the bottom of the excavated pit, and left standing. When the dam was taken up, the frames were, for the next compartment of cutting, again superimposed upon one of the rows which had been left standing in the last pit. In this way no rock could possibly escape being removed; and when the frames were to be put down anew, there was no difficulty (although the pit was entirely covered with sand) in knowing exactly the position which they were to occupy, as the piles which had been left standing were an infallible guide.

One advantage peculiar to this description of dam is its cheapness,—its portability,—its ready adaptation to a sloping, or even to a very irregular bottom,—the ease and certainty with which the partitions between the different pits are removed,—and the double-framed walings that support and direct the driving of the piles. Wherever excavations require to be made in a rocky beach, covered by a stratum of sand, however thin, there need not be any hesitation in adopting this form of dam, as there is no kind of lateral support, such as stays or shores wanted, the structure containing within itself the elements necessary for its stability. It possesses, indeed, all the properties of a caisson, and has the further advantage of accommodating itself to an irregular bottom.

I may observe, in conclusion, that although this form of construction is specially adapted to marine works, in the execution of which it has proved a most valuable auxiliary, the same principle might also be carried to a greater extent, and be rendered fit, with little trouble, to answer for a variety of works,—such as underfooting quay walls, founding bridges, and in removing fords or other obstructions from the beds of rivers. The application of a double-framed coiling I have also found in itself a very useful application in several situations, and for a variety of purposes.

* Since this paper was printed, a cofferdam on the same principle and thirty-five feet square, has been made near Fort Erie, on the removal of the "ferd," under my direction, much difficulty has hitherto been experienced, from the constant flow of the river.

† Before lifting the cofferdam, the pit was filled with sand, to support the piles that were driven down in a chain, which, when the works were done, was cleared out by means of a water-worn, provided for the purpose of leaving permanently open the navigable current.

‡ In situations also, where there is a considerable depth of water, and where, consequently, the frames must be made as to stand high above the ground, it will be found of great advantage to place the outside of the frames between A and G. This will not only make the dam more water-tight, but have the effect of binding and strengthening the framework.
THEATRES AND PORTICOS OF ANCIENT ROME.

Paper read at a meeting of the Royal Institute of British Architects, June 12th. By the Rev. Richard Burgess, B.D.

In looking among my antiquarian and literary stores to prepare a subject for the Institute, I again found that it was not necessary for me to go out of old Rome, for although in a series of papers spread over some twelve years, I have led you "over steps of broken stone and temple," and placed you in forums, baths, or halls, I have never yet described to you the theatres and porticoes which formed so important a feature in the architectural beauties of Rome.

The amphitheatre was an edifice unknown to the Greeks, the theatre was hardly ever naturalized among the Romans, and with the exception of some tragedies, ascribed to Seneca, which are lost, it does not appear that a single Roman tragedy was ever composed upon a Roman subject. Porticoes, which were generally in the vicinity of theatres and circuses at Rome, are the natural growth of a climate subject to great heat and sudden rains; we lose in these northern regions that great ornament of a city, the portico. Our admiration is limited to arcades and covered markets, which it must be confessed are more for use than ornament. But I return to the theatre. The ancient and modern drama differ as widely as the buildings in which they are respectively set, and I shall hardly succeed in making my Roman theatre intelligible, unless I first indicate a few of the leading features which run through the Greek drama and its Roman descendant. The subject is by far too vast and intricate for me to attempt anything like an essay upon it. I may group upon the topics of my own invention, the most important of which have been accomplished. As a general rule, there was no change of scene during the piece. In every tragedy there was a body called a chorus, who took no part in the action of the piece, but being groused upon, generally expressed what might be called descriptive dialogue. The audience, who were not in the theatre, did not come upon the stage, but occupied the orchestra, varying the dialogue which they sometimes held with the actors by choral songs and dancing. These terms of stage and orchestra I shall shortly have to explain.

Dramatic entertainments, both in Greece and Rome, formed part of the public expenditure, or they were exhibited gratuitously by some wealthy or ambitious citizen. The theatres, therefore, were of immense size, for they were meant to contain (in Greece, at least) the whole male population of great cities. The performance was not confined to the months of the year in Greece; but Roman luxury, at a later period, invented the awning, which was only described to you, when I read a paper on the Colosseum, how this awning was contrived to cover such an immense space; and I must be allowed to suppose that you have not entirely forgotten the description of any of the magnificence of this edifice. The mistake, not long after the defeat of Xerxes. From this they began to increase in number, and we have the remains of several yet existing, both in Greece and in that part of Italy which was Greek in language and customs long after it came under the Roman domination. The space occupied by the amphitheatre in Rome, to which I shall shortly direct your attention. A theatre became so necessary an appendage to a town, that Vitruvius gives systematic directions concerning the selection of a site. In his fifth book, cap. 3, we have the following:—When the forum is finished, which should be the aim of all, we shall find that the theatre may be erected, to exhibit sports on the festival days of the immortal gods, for the spectators are detained in their seats by the entertainment of the games, and remaining quiet for a long time, their pores are opened and imbibe the draughts of air, which, if they come from marshy or otherwise unhealthy places, will pour injurious humour into the body. Neither must it front the south, for when the sun fills the concavity, the enclosed air, unable to escape or circulate, is heated, and then extracts and dries up the juice of the body. It is also to be carefully observed that the place should not be dull, but one which may be "made as clearly as possible." One cannot let pass this quotation from the great architect of the Augustan age, without remarking that the selection of a site for an important public building was considered by Vitruvius as falling within the province of the architect. A healthy place for the theatre selected, we come next to consider its shape and disposition.

The form of the Greek theatre originated, as is thought, in the natural recess of a hill-side, and most of the theatres whose vestiges I have visited in Greece, occupy that position. Mantua, but even more in the smaller ones in the interior, from which we may imagine that it was another exception in Asia Minor; but it was evidently the practice to lighten the labour of erecting such buildings by making use of a ravine, or locality adapted to the purpose. At Megalopolis I was able to trace the whole cavea or hollow of the theatre, partly cut out of a hill; but the seats are overgrown with thick brushwood. The same economy is observed in most of the Greek stadia also, and even the council of Areopagus sat on seats, cut out of, or inserted into Mars' Hill. At Nicopolis, near Prespes, the form of the theatre on the hill-side is preserved, and much of the prosconium. At Samothrace we have a most singular and extensive example. The cavea, also at Ephesus we get to the slope of Mount Prion, which overlooked the Temple of Diana, in the plain of the Cayster, before we find the theatre. Whilst the Greeks, however, hewed seats out of the rock, or excavated to a depth suitable to their purpose, as the moderns do, the Roman architect, finding that the beauty of the theatres upon arches, and massive walls rose (as we see the theatre of Marcellus still existing at Rome), with two or three orders, like the Colosseum. The hollow which originally was adjusted according to the nature of the ground, in no definite curve, was afterwards straightened to a semi-circular form, and cut the cavea by lines drawn from its extremities converging towards the centre of the circle, by which arrangement more space was made in width for the oecum or stage. The oecum was fitted up with rows of seats rising in succession, so as to afford each tier an uninterrupted view: the whole was divided, as in the amphitheatre, into flights by sectores, or spaces, which were termed praecinctio, or precincts.

The praecinctio ran round the whole, and afforded an access from one flight to another. The entire area was again cut into sub-divisions, called spesores, in Latin, cunei, from being formed like wedges: the lines which effected those sub-divisions were called iacentes; the smallest, which ran in the circumference of the oecum, were called cuneis led from the bottom to the top of the theatre, and they all converged to the centre of the orchestra. The lowest seats were considered the best, and were, in fact, the reserved seats for the magistrates and persons of office. As the audience rose in height, it descended in quality, until it reached the open portion at the very top, which has its counterpart in our shilling or sixpenny gallery. This portico, however, in an uncovered building was of some use, in confining the sound and giving shelter to the spectators from a passing storm. The oecum, or cavea, such as I have now described, would contain, in some of the larger theatres, as many as 50,000 spectators, or upwards of 30,000 to 40,000 spectators, which is the capacity of those whose remains are yet to be seen in Rome. I now come to the other part of the theatre, which is more complicated and more difficult to describe. In Greek we have to deal with the three terms of oecum, spesor, and spesorarium. In Latin these three correspond to the corresponding terms of orchestra, pulpitum or scena, and postscenium, to which we are to add the porticus. I shall content myself with describing the Roman arrangements, and simply pointing out where the Greek theatre differed. Taking the cavea to be a semicircle, the concave side, in which the games were held, and this space, bounded by the diameter, was the orchestra,—not so called from anything relating to music, but because it was the place for the dancers. In the Greek theatre the segment was less than a semicircle; but if the circle be completed and a square inscribed in it, whose sides are parallel to the diameter, the side

The本文是一篇关于古罗马戏剧和柱廊的文章。作者首先介绍了古罗马戏剧和柱廊的特征，以及它们在城市中的重要性。接着，作者详细描述了希腊剧院的起源和发展，以及罗马剧院的设计和布局。文章还提到了一些具体的例子，如在Megalopolis和Ephesus的剧院。最后，作者比较了希腊和罗马剧院的不同，指出罗马建筑师在设计时更多考虑了空间的优化和交通的便利。
THE CIVIL ENGINEER AND ARCHITECT'S JOURNAL.

[August,

farthest from the corea fixes the front of the stage; but in the Roman theatre the diameter itself determines the front of the stage, or pulpium. The stage, therefore, in the Roman theatre, is broad rather than narrow and made deeper. The length of the stage was two diameters of the orchestra. The depth was rendered necessary on account of the greater number of persons assembled upon it; for the Romans put both the chorus and the musicians upon their stage. The points from whence the pictures on the curia began to ascend the corea were fixed by the vertices of four equilateral triangles, inscribed within the circle (when completed) of the orchestra. In the Roman theatre, as we have already observed, the front of the stage was called the pulpium; and it was from that part that the interlocutors spoke. Some think that the pulpium was a little elevated above the level of the stage; but at all events, the word has passed into use for designating a place to speak from in our sacred edifices. The lowest range of seats was raised above the area of the orchestra (one-sixth of its diameter), and the seats themselves did not exceed 1 ft. 4 in. in height. The stage in the Roman theatre was only elevated 5 feet above the seats in the orchestra; in the Greek theatre it was double that height. I have only hinted at the geometrical precision with which all these things were defined, and I shall relieve you from such dry details by a reference to the drawings behind me. The posticumium speaks for itself: it was a large room or hall, and was arranged behind the orchestra, and where apartments or compartments were provided for them. From the posticumium were passages into the porticoes or gardens, which generally surrounded the theatres: but to these I shall have occasion to refer when I have finished the history and description of the theatres of Italy. The pulpium and the posticumium were the edifices constructed with a magnificence which surpasses all belief. The wealth which supplied those theatrical exhibitions was generally the plunder of rich provinces: easily earned, and as easily disposed of, there was a great demand for them, and consequently a still more lucrative appointment. All the bribery and corruption that ever came before a committee of an English House of Commons sink into insignificance compared with those times "when Rome was free." The treating of our "worthy and independent electors" at the open house of the candidate, was economy and parsimony compared with the lavish expenditure of a candidate for the honours and emoluments of a Roman governorship; and we cannot, doubt, that whilst those worthy citizens were feasting for whole days at the expense of a Scaurus or a Curio, they would be less apt to find the foreign candidate predominant in their exclamations into the polite language of modern Europe, the air would have resounded in the midst of those entertainments with "Vive la République!" It was not until the year of the city 699 (that is, within 63 years of the Christian era), that a theatre of solid masonry was built at Athens. Both in Rome and in Pompey on his return from Asia, at the close of the Mithridatic war; but even Pompey found it expedient to pay a deference to the popular feeling. "Therefore," says Tertullian, "Pompey the Great, less great by his theatre only, when he erected that stronghold of wickedness, dreading lest the spectacle should injure his memory, he built a temple to Venus on the top of it, and when he invited the people to come to the dedication, he did not call it a theatre, but the Temple of Venus, to which, he said, "we have subjoined seats for seeing shows." The seats were therefore consequently called in Latin, the Venusium, the temple of Venus, and this call either a pious fraud or a legal fiction. A piece of marble was found, in 1855, near the site of Pompey's theatre, on which Marilzone read the words, "P neces Picturias." This building was erected in the third consulate of Pompey, and when the inscription came to be placed on the frieze, a dispute arose whether it should be cox. tertio or tertium. The matter was referred to Cicero, who advised the disputants to settle the controversy by writing cox. tertio.

At the dedication of his famous theatre, Pompey produced twenty elephants; and when he was accused in the senate of introducing too much luxury into the city, he convinced the conscript fathers that it was an economy to build a solid theatre at once instead of raising a temporary structure on every occasion of giving shows. The Temple of Venus served very well as a pretext for making seats, gradus spectaculorum; but it could not equally be alleged for erecting a solid stage. It was not until the reign of Tiberius that this part of the theatre was added, and finally completed by Caligula. It was dedicated anew by the Emperor Claudius, who restored it after a fire, and it reached its greatest splendour in the time of Nero. To the north of the palace of Nero, and from the north of Germany to render submission to the emperor, were taken to Pompey's theatre in order that they might see the greatness of the people. It contained, according to Pliny, 40,000 spectators; and when Titidates, king of Armenia, came to Rome, Nero caused the temple to be opened, and the gilded statues of the Romans to be yielded to the vanquished Asiatic. It passed through a succession of events until Theodorus commissioned Symmachus to rebuild it; but not long after it shared the fate of the rest of the splendid edifices of Rome, and finally came into possession of the Ursini family, who occupied it as a theatre until 1569. In the fifteenth century, an inscription, found with the name of Pompey, directed the antiquary to find out its site. Another indication of the place where this theatre stood was given in the finding of the famous statue which is now in the Palazzo Spada. That statue was found under the porticus wall of a house, and lying across in such a way as to give two proprietors of the house a claim to the treasure: not able to agree about dividing the spoil, they came to the resolution of cutting Pompey in two, and each man taking his own half. The matter having reached the ears of Cardinal Capodizze, he hastened to Pope Julius II. to inform himself of the judgment that had been pronounced upon the statue. The papal chamberlain dispatched a messenger with all haste, and sent 500 scudi to be divided between the litigants, instead of Pompey. Flaminian Yacca, who relates this anecdote, says the statue was found near the Portico de' Cavali, in the Curia Vetuliana. The statue did not stand in the theatre, but in the Curia where the Pope built as an appendage to it; and the belief still obtains that it is the statue at the feet of which Caesar fell. Being thus directed to the site of this famous building, we find ourselves in the immediate vicinity of the circumference of the theatre, near the porta della Valeria. From near that church to the Palazzo Pio, the site is marked by a gradual rising of the ground, but no vestiges meet the eye. In order to see the remains of Pompey's theatre, we enter the court-yard of the Palazzo Pio, and descending into the vaults upon which the Palazzo is built, we find ourselves, at a depth of 40 Roman palms above the marble floor of the theatre. This is particularly the case at the point of the six columns of the colonnade, which are hallowed out of the natural rock, and they are pointed at the angles with large blocks of peperine stone. One of the cunei, or sections of the corea belonging to the lowest tier, may be perfectly traced; and after ascending to the court-yard again, and upon entering the stables, we see a second story of arches for supporting the seats, the construction of which is remarkable for its solidity; and it would not be difficult to trace, among the modern buildings and in the cellars of the Palazzo, at least one-half, perhaps two-thirds, of the whole corea. I will not stay to describe to you how Rome in the time of this building was sunk up to the ground in the ruins of Pompey, but the ground-plan of them, although they have almost vanished from off the face of the earth. In the sixteenth century there was found behind the church of SS. Cosma and Damiano a plan of ancient Rome, done in marble, and which had served to encrust the walls of the Temple (as it is supposed) of Romulus and Remus. This marble slab, where the ground-plan of all the public buildings was laid down, was found broken into fragments; some of them irrecoverable; others, gathered up with care and put together, presented an idea of a building. They now encrust the walls of the staircase of the Portico, an admirable imitation of the Portico of the Piazza Capitolina.* The two fragments most perfect happen to represent the Theatre of Pompey and the Portico of Octavia. By a reference to that fragment of the Piazza, you will only see the ground-plan of the theatre, but also of some other buildings which were attached to it. Vitruvius cites the Porticus Pompeiana as an example of what a portico should be, when attached to a theatre for the convenience of the actors, or for the people to take shelter in, in case of rain. We know, from Martial, that Pompey's Portico had a hundred columns. Eusebius calls it, in concise language, "Hexastylon." The Piazza Capitolina imitates some of those columns, but the fragment is imperfect. This celebrated portico was painted by artists of renown—Antiphus, Pausias, and Nicias—the subjects being suited to the atmosphere which Ovid's lovers breathed. About the portico were rows of plane trees,

*These fragments were first engraved and illustrated by Bellarrio, and are reproduced at the end of book iv. of the "Grotius Roman Antiquitates."
interspersed with stone statues of beasts; and a fountain threw up, or poured out, its sparkling waters. The Pianta Capitolina exhibits two rows of columns, running in a direction towards the river, and not unlikely conducting to a grove along the banks of the Tiber. Besides these appendages to the theatre, there was the Curia, the Quirinal, the Tarpeian Rock, the "Regia Theatri" of Suetonius: but I must forbear to expatiate beyond the proper limits of my subject. A careful inspection of that part of Rome where all those buildings stood, with the aid of the Pianta Capitolina and the antiquarian notices which I have cited, might still furnish a fine subject for the genius of a restoring architect; and when we consider that those extensive and magnificent buildings (whose very remains, at the end of nineteen centuries, excite our wonder) were erected out of the private resources of a single individual, it will be long before we find in another republic of man, who may vie in wealth, taste, and splendour, with citizen Pompey.

I shall pass quickly over the next theatre, which time and floods have not spared. It was erected in the twelfth year of the Christian era, by Cornelia Balbus, in compliment to Augustus, and was capable of containing 33,000 spectators. I am not aware that a vestige of this theatre remains, but Piranesi took considerable pains to ascertain the site, and found some remains of one of the cunei. The Palazzo, and Monte Cenci, now point to where it stood, and Camuccini, one of the oldest of Roman antiquaries, who probably had some of his title indited in the Tiber, it frequently suffered from inundations. We are not aware of any portico attached to this theatre, but there was a crypta Balbi, which stood near it, and of this there are some remains.

The third theatre which adorned imperial Rome was that of Marcellus, and along with it I take the portico of Octavia: when I have given you some account and description of these two objects, I shall relieve you from this tedious conversazione.

The remains of the theatre of Marcellus are worthy of the architect. Adorned with statues of the gods of the upper and lower twelfth, are conspicuous, though mutilated and disfigured by the dusky habitations into which they have been metamorphosed. The first order is nearly half interred, but the capitals of the Doric columns, as well as the entablature, are well preserved in several palaces, and especially within the specimen of the Ionian order, as it was brought to perfection in the time of Augustus. Within those arches which formed the ambulacra, as in the amphitheatres, the gradus spectaculorum rose, and some of the cunei may be traced to the stables of the Osteria della Campana. The materials are tufo, mingled with brickwork, resembling those in Pompey's theatre, and one may perceive by a solitary column in the Via Savelli, standing at an angle with a piece of wall running in the direction of the scena, that the stage and its outworks have not touched the very banks of the river. The Palazzo Orsini, formerly inhabited by Augustus, is the site of the stage. Piranesi has calculated the capacity of this theatre to contain 25,000 persons: it was therefore the smallest of the three. Julius Caesar, perhaps, laid the foundation of this edifice; but it was left for Augustus to complete it, and he dedicated it with the name of the Young Marcellus. In the act of the dedication it is said that 700 wild beasts from Africa were consumed, and then, for these first time in Rome, there was seen a tamed tiger. We have an account of a fire having partly destroyed this theatre, but we hear very little of its history until Pierleone, in the twelfth century, made it a fortress. It passed successively into the possession of the Savelli and Orsini families, and then, no recent day, suppose it has existed for several centuries otherwise than it now presents itself: in "Carnucci's Antiquities," we have a drawing of it, bearing date 1585, and it is there exhibited just as we see it at the present time. I may mention that its exterior walls are of travertine stone. The 25,000 spectators are now replaced by some workers in charcoal, and some mules, the former occupying the places reserved for the magistrates, and the mules having taken possession of what was the orchestra. Near to the theatre of Marcellus stood the famous Portico of Octavia, to which I have finally to call your attention. And although we are now told by ancient historians that the remains of Rome, among stinking fish, in order to see the remains of this splendid work, it will amply repay us for our excursion, and stamp indelibly upon our memories the flavour of the Poeschera and the conservative habits of the Jews who live within the Portico of Octavia.

The first marble building ever erected at Rome was a portico which stood on this self-same site. It was built by Metellus Macedonicus: two temples were comprised within it. The architects were two Spartans, whose names were Saurus and Batrachus. They not only contributed their skill, but, as they were rich men, they employed their wealth also in the undertaking. The only reward for their services which they solicited was that their names might be mentioned in an inscription on the temples; but this honour being refused, they contrived to introduce their names into the sculptural work; and probably much enlarged; the fragment of the Pianta Capitolina, with the mutilated inscription "CVS OCTAVIAE," gives us the plan of those splendid works. Bellori, in his illustration, computes about 270 columns. I confess I cannot make out that number with the utmost stretch of my feeble imagination, but none of you will object to see the rare and magnificent ruin of a temple and the ruins which still exist, adjusted on the dark tints, which show them in their proper places. By this plan it will be seen that the principal remains consist in six large columns of the vestibule or entrance (and who that has seen Rome has not admired the magnitude and elegance of those Corinthian columns), eight more columns of the exterior row of the peristyle, which are only to be seen by contending with the fish-stalls made out of the spoils of the portico; and there are also further remains of one of the temples to be seen in a Vico behind the church of St. Angelo: perhaps, though not certain, it was that of the Emperor Augustus, of which the bust of the priest of the Temple of Juno; the other was dedicated to Jupiter.

I must now leave you to raise up from this ground-plan, and from the splendid vestiges which remain, the elevations and architectural views of the portico and its temples; but even your powers could not reduce to the design, or affix on their respective walls, the works of art which once adorned the Portico of Octavia. In the Temple of Juno was her statue, made by Dionysius and Polydes; and a Venus by Phileicus of Rhodes. In the corresponding Temple of Jupiter was the much admired and still adored figure of Minerva, those of Timarchus. There was a group representing Pan and Olympius wrestling together, the work of Heliodorus; and perhaps the Venus of exquisite beauty which Pliny tells us adorned this portico (the work of Phidias) may be the very Venus de Medici palaces at Paris, that is said to have been sent thither as a gift on the occasion of the marriage of the princess of Tuscany and the Duke of Orleans. In a part of the building called the Schola Octavia was the famous Cupid of Praxiteles, which called forth the eulogia of Cicero, Strabo, and Pausanias. It is more than probable that several of those statues perished in the fire which took place in the reign of Titus, and still more might be lost in that which happened under Septimus Severus. The paintings which adorned the walls and vaults were not lost celebrated. There was the famous work of Artemon representing Hercules ascending from Mount Oeta to Olympus, having put off his mortality with the consent of the gods; there were other statues of gods and goddesses, which were grouped around the noble Hesion; and Alexander and Philip, with Minerva. You may exhibit to us an elevation restored; a few columns will direct you to complete the portico, and a medal will give you a finish for the pediment. You may square us of the base of the columns, and the capitals, the entablatures, and urns; and you may festoon or triglyph the entablature—but you cannot paint afresh the works of Artemon and Antiphus, nor mould again the forms which the innate flash of the mind of a Phidias or a Praxiteles could produce. You must therefore be content with the bare recto and inscribe upon the very best edifice I can describe, "Stat nominis umbra." But you will remark in the enumeration of the names of those celebrated artists, that they were all foreigners, and Rome owed her most splendid works of art—I may say all of them—to the Greeks; and they owed much of their glory to the Syntians and Cypriotes. It is, in fact, a mistake to attempt to nationalise either the art or science. If there be such a thing as communism in the world, it exists in the realms of genius, and no petty jealousy should ever attempt to exclude the foreigner who brings its originality of thought and genius to adorn a country of which he is not a native. The Romans do not distinguish art; they excelled in gladiators, but they were inferior in sculpture, and painting, and architecture: by admitting foreigners they ended by taking the lead in architecture, at least; and perhaps the study of Emilius might have furnished a work worthy of the best Greek.
THEORY OF STEAM-ENGINES.

Account of the experiments undertaken by order of the Minister of Public Works, France, upon the recommendation of the Central Committee upon Steam-Engines, to determine the principal laws and numerical data which enter into the calculation of Steam-Engines. By M. V. Reonaux.*

Introduction.—The theoretic calculation of the work done by steam-engines is founded upon some incontestable principles of geometry, mechanics, and upon several physical laws which were drawn from having been, up to this time, established upon certain bases. The authors who have written upon the theory of these machines, have been obliged to admit as the basis of their calculations, laws which ought only to be considered as hypotheses to which physical phenomena are reduced, and not treated thereby, but treated as such hypotheses. Thus, when the work really done by a machine is compared with that deduced from the theory, we always find, even in the best machines, a considerable deficit. A great part of this deficit is to be attributed to the disturbances produced in the physical conditions, by the very motion of the apparatus; it is due to the loss of active force (force vive) occasioned by the cooling of the steam; to the resistance which is developed during its course through tubes of irregular forms, and in its passage through openings, more or less contracted. Finally, there are losses connected with the force in the creation of the different pieces of which the machine is composed. But a great part of the difference may well be occasioned by the inaccuracy of the fundamental laws which have been admitted into the calculation.

Mechanics have, for a long time, greatly desired a general investigation for the purpose of establishing these fundamental laws upon a series of direct experiments executed with the means of precision which physical sciences now present. I had for some time formed the determination of devoting myself to this work, and by several times I have had for my object to connect the experimental researches, which I have however served only to show me that precise results could only be obtained by means of large apparatus, whose expense of construction far surpassed the very narrow means which we have at our disposition in our physical laboratories, and I should have been completely stopped in the execution of my projects, if the Minister of Public Works (upon the suggestion of M. Logrand, under Secretary of State), had not, with a kindness which will be appreciated by all the friends of science, placed at my disposal the funds necessary for the execution of this long and laborious work.

In order to show clearly what are the principal laws upon which the theory of steam-engines rests, it appears to me necessary to explain, in a few words, the principles of this theory. All known systems of steam-engines may be divided into four classes:

1. Engines without expansion, and without condensation.
2. Engines with expansion and Introductory experiments.
3. Engines without expansion, but with condensation.
4. Engines with both expansion and condensation.

The first three classes, may, in a theoretic point of view, be considered as particular cases of the fourth class, which presents the most complex case, and with which it is necessary for us to pay attention. We shall suppose an imaginary engine, which is not subjected to any external cause of cooling, nor to any loss of active force by friction, contractions of orifices, &c. &c. We shall suppose the boiler to be of very great capacity in comparison with the cylinder; then the steam may be considered as absolutely constant in the boiler during the motion of the machine; the heat of the furnace reproducing, constantly, the quantity of steam consumed by the machine.

Let $x$ be the surface of the piston expressed in square metres, $s$ the space described by the piston from the instant of the arrival of the steam in the cylinder, with the tension which it has in the boiler, until the moment at which we are examining it, $P$, the constant pressure of the steam in the boiler, expressed in kilogrammes and referred to a square metre of surface; $c$, the capacity, in cubic metres, of the part of the cylinders described by the piston from its starting point to the height, $x$, $V$, the total capacity of the cylinder.

A first law, which it is important for us to know, is the law which connects the elastic forces with the temperatures.

We will distinguish two periods during the stroke of the piston: during the first of these the cylinder communicates freely with the boiler; the total pressure of the steam upon the surface of the piston is $Pw$.

If the piston advances by a quantity $dx$, the element of work produced will be $Pw dx = P d s$.

The whole quantity of work produced during the first period, that is, from the beginning of the motion of the piston until the introduction of the steam is stopped (corresponding to a capacity $V$, described by the piston in the cylinder), is $P V$. During the second period, during the expansion, no more steam comes from the boiler, but the steam contained in the cylinder continues to press upon the piston; as this rises, the steam occupies a larger space, its elastic force diminishes, and its temperature is lowered by the absorption of latent heat during its dilatation.

Experiment has not decided what are the laws which govern these variations; but one of the following cases must happen:

First case.—The quantity of heat absorbed by a kilogramme of liquid water at $0^\circ$ (32° Fahrenheit) in passing into vapour (which, for the sake of simplicity, and without condensation, is the same, whatever may be the pressure, provided the vapour be at its maximum of density. If this law be exact, the steam will

* We are indebted to the "Franklin Journal" for the translation.
always remain in a state of saturation during the whole period of the expansion; the pressures of the steam will vary in the inverse ratio of the volumes, and they will constantly present the relations to the temperatures which connect the temperatures of saturated steam with its elastic forces.

Second case.—The total heat of the steam increases in proportion as its elastic force is greater. As we suppose that the steam is not subjected to any external cooling influence, it is evident that, in proportion as the steam dilates into a larger space, it will require a smaller quantity of total heat to keep it in the state of vapour. Consequently, during the dilatation, there will be a disengagement of a certain quantity of latent heat, which will become sensible to the thermometer, and will raise the temperature of the steam above the point which corresponds to its saturation. The temperature of the steam will then be more slowly reduced than in the former case; the steam will be found overheated during the expansion, and the pressure of the steam upon the piston will diminish more slowly than it would according to the law of Mariotte.

Third case.—The total heat of steam is less in proportion as its elastic force is greater. If this law were true, there would be a precipitation of liquid water during the expansion, the steam would remain constantly saturated, but the elastic force would decrease more rapidly than according to the law of Mariotte.

In the absence of decisive experiments to show the accuracy of one of these three hypotheses, mechanicians have generally adopted the first, which is at the same time the most simple and the most precise. This hypothesis assimilates the expansion of steam to that of a gas in a vacuum, whose walls constantly restore to the gas the quantity of heat which is absorbed in the latent state during its expansion, so that its temperature remains invariably.

The work developed during the expansion is then calculated in the following manner:—Let be the volume of the steam, and its pressure at a given moment; $dx$ the space described by the piston while the volume becomes $v + dv$; the element of work produced will be $p dv = d$. At the commencement of the expansion, the volume is $V$, and the pressure $P$, and as we admit the law of Mariotte between the volume of the steam and its elastic force during expansion, we shall have

$$ p = \frac{PV}{v}, \quad d = p \, dv = PV \, \frac{dv}{v}; $$

and the whole work produced, while the volume of the vapour passes from $V$ to $V'$, is

$$ \int V' \, PV \, \frac{dv}{v} = PV \log \frac{V'}{V} = P \, V \log \frac{P}{P'}.$$

This is the expression for the work produced during the period of the expansion. The total quantity produced during a complete stroke of the piston, is then

$$ PV \left(1 + \log \frac{P}{P'} \right).$$

We have heretofore attended only to the pressure which is exerted upon the faces of the piston, but the other face is constantly submitted to a pressure which exists in the condenser. We will suppose this latter pressure to be constant during the stroke of the piston, and represent it by $f$. The amount of resistance which it will have produced during the stroke of the piston, will be $fV' = fP'. \, \frac{V}{P}$. So that the moving power will be expressed by $PV' \left(1 + \log \frac{P}{P'} - f/P' \right)$.

If $n$ represents the number of strokes of the piston per minute, the power developed during this unit of time, will be expressed by

$$n \, PV' \left(1 + \log \frac{P}{P'} - f/P' \right).$$

But the accuracy of the formula depends upon the accuracy of the hypothesis which we have admitted, and it is necessary to determine by direct experiments—

II. The quantities of heat which must be given to a kilogramme of water, at 0°, to vaporise it, under different pressures.

These quantities of heat are composed of two distinct parts—the heat necessary to raise the temperature of the liquid water from 0° to the point at which the change of state takes place, and the latent heat of vaporization. If we wish to distinguish these two parts of the total heat of steam, we must determine by experiment—

III. The capacity of heat of water at different temperatures.

Finally, if the total heat of steam is not constant under all pressures, in order to calculate the effect of expansion, we must still learn—

IV. The specific heat of the vapour of water in different states of density, and at different temperatures.

The theoretic power of a steam-engine may be estimated, by stating the amount of power which it is capable of giving for each kilogramme of steam consumed.

To do this, let $w$ be the weight of a cubic metre of steam under the pressure $P$, and at the temperature $T$; $x$ the weight of steam consumed by the machine in one minute. We shall have

$$w = \frac{w}{V},$$

and consequently the power given by the machine, from a kilogramme of steam, will be expressed by

$$P = \frac{1}{x} \left(1 + \log \frac{P}{P'} - f/P' \right).$$

But in order to calculate, under all circumstances, the value of $w$, we must know—

V. The law according to which the density of saturated vapour of water varies under different pressures.

VI. The co-efficient of dilatation of the vapour of water, in its different states of density.

Mechanical philosophers generally admit that the weight ($w$) of a cubic metre of steam, under the pressure $P$, and at the temperature $T$, may be calculated by applying to saturated steam the law of Mariotte, and the law of the uniform dilatation of gases. Now these two laws are not applicable rigorously exact for the permanent gases, and it is to be feared that they are completely false for saturated vapours. Finally, the method most generally adopted to compare steam-engines, consists in stating the work which they perform for each kilogramme of fuel consumed. To do this, we must know the weight ($K$) of steam under the pressure $P$, which a kilogramme of fuel can develop under the circumstances in which it is employed; and we then have, for the work performed by a kilogramme of fuel, $P' \, K \, \frac{w}{w} \left(1 + \log \frac{P}{P'} - f/P' \right)$.

The quantity $K$, depends upon a variety of circumstances which we cannot now discuss, such as the quality of the fuel, the nature of the furnace, the arrangements of the boiler, etc.

To sum up then, the theoretic calculation of steam-engines requires the knowledge of the following laws and data:—

I. The law which connects the temperatures and elastic forces of saturated steam.

II. The quantities of heat which one kilogramme of liquid water at 0° absorbs, in being converted into saturated steam, under different pressures.

III. The quantities of heat which one kilogramme of liquid water at 0° requires to elevate its temperature to that at which it assumes the state of steam, under different pressures.

IV. The specific heat of the vapour of water, in different states of density, and at different temperatures.

V. The law according to which the density of saturated steam varies, under different pressures.

VI. The co-efficients of dilatation of steam, at different densities.

Before commencing the search for these different laws, it was necessary to treat several preliminary questions, so as to fix with certainty the indispensable auxiliary data, and, above all, to define clearly the conditions which must be fulfilled by the thermometers, by means of which we measure the temperatures, in order that these instruments may be rigorously comparable.

These preliminary researches obliged me to undertake successively, long series of experiments, the necessity of which I was far from foreseeing when I undertook the work. I was in fact obliged to undertake the re-determination of a great number of data, which, for the most part, appeared to be fixed with complete certainty by the researches of my predecessors, and as to which physical philosophers entertained no doubts whatever.

The whole of these researches will be published in a series of detached memoirs. I intend to deliver the result of my labours, to sum them up in a report, which will be addressed to the Minister of Public Works, in which the results will be presented under a form suitable to the especial view with which the work was undertaken—that is, the theoretic calculation of steam-engines.

My experiments frequently required the assistance of a great number of observers. I was frequently obliged to avail myself of the kindness of several of my students, among whom it gratifies me to cite especially MM. Bertin, Grassi, Bertrand, Liassiaux, and Silberman. Let me be permitted to return to them, thus publicly, my thanks.
true the law of Mariotte, that the elastic force of a gas varies inversely as its volume, when the temperature remains the same. The fifth method was adopted to measure directly the augmentation of volume due to the changes of temperature.

The first method was similar to that used by Rudberg, in his first series of experiments, and by Dulong and Petit, in their comparison of mercurial and air thermometers.

The apparatus consisted of a glass cylindrical reservoir, from 23 to 30 millimetres in diameter, and about 110 millimetres long, containing from 800 to 1,000 grammes of mercury. To this was soldered a capillary stem, of which the diameter varied in the different experiments, from $\frac{1}{8}$ to 2 millimetres. This was bent at its lower end, and drawn out to a fine point. The greater part of the stem was immersed in a vessel of water boiling under the usual atmospheric pressure, and filled with perfectly dry air, by exhausting it from 25 to 30 times, by means of a small pump, and re-filling it with air which had passed through two tubes, each one metre in length, filled with pumice-stone, saturated with concentrated sulphuric acid. This being done, the apparatus was suffered to stand from half an hour to an hour, the water being maintained in full ebullition; the capillary stem was then closed by the blow-pipe, and the height of the barometer noted. The reservoir, with its stem, was then inverted upon a stand, so that the point of the stem dipped to some distance in a cup of mercury, the cup was broken off under the mercury, and the reservoir surrounded with pounded ice, and left in its condition for an hour or more. The volume of the air (now contracted so as to fill only a part of the reservoir) was reduced to the temperature 0°. The end of the stem was then again closed by a little wax, the barometer again noted, the position of the surface of the mercury in the cup marked by a point adjusted by a screw— the cup was then removed, and the reservoir and its contents suffered to take the temperature of the surrounding air. The air in the reservoir above the level of the mercury in the cup was then measured by the cathetometer. The reservoir and its contents were then weighed, entirely filled with mercury, first boiled to free it from air and moisture, the point again immersed in mercury, and the reservoir surrounded with pounded ice for one or two hours, when it was satisfactorily ascertained that the whole apparatus had taken the temperature 0°; the ice was removed, the mercury which was discharged by the rise of temperature was received in a capsule, and the apparatus placed in a boiler, as at first, and brought to 100°. The mercury expelled was collected in the capsule, and the height of the barometer at the moment of ebullition noted. By this means, all the data necessary to calculate both the dilatation of the air, and that of the glass vessel which contained it, were given.

In performing these experiments, M. Regnault observed a serious cause of error. When the point of the stem was broken under the mercury, he observed that a small quantity of air leaked into the reservoir, even when the point was plunged to the depth of 1 metre under the mercury. This air was a portion of that which remained in contact with the glass tube, not being wetted by the mercury, allowed, as it were, a tube of air from the point to the surface. This difficulty was obviated by attaching to the glass stem, plates of well-cleaned brass, to which the mercury adhered, and thus the entrance of air was prevented. In addition to this, a layer of sulphuric acid was sometimes poured upon the surface of the mercury, before the point was broken, and was carefully removed before the point was again closed. Equal care was taken to prevent the air enfilming the pincers used to break the point, from getting access to the interior. In this way the results of the experiments were obtained, the most of which gives for the volume of 1,000 measures of air, at the temperature of 0°, when heated to 100°, 1'36923.

The highest number obtained in any experiment, was 1'36689.

The lowest .... 

1'36349

The difference is 0'00140

or about $\frac{1}{7}$ of the mean.

The lowest number was above the mean result obtained by Rudberg. M. Regnault believes that this may probably be due to the phenomena of the entrance of the air which is breaking the point during the taking place in the experiments of the Swedish professor, and he remarks that the error would be greater in proportion as the quantity of air operated on was less. He also states that he believes the first experiments of his own series were affected by this phenomenon, and as an evidence of this, states, that from the moment that he succeeded in preventing it entirely, no experiment gave a number below 1'36923.
The second series of experiments was tried with an apparatus differing but little from the one just described. The reservoir was a glass globe of from 350 to 400 cubic centimetres, soldered to a thermometer stem, about 36 centimetres long; upon this thermometer stem the copper tube was soldered so as to make the whole a single piece of about 23 cm. long, a piece of tube very regular in its diameter, about 50 millimetres long, and of a diameter sufficiently large to present but feeble capillary action. The thermometer-tube was bent at right angles, and drawn out to a point. The first operation was to gauge the apparatus carefully, and to ascertain its coefficient of dilatation. This was done by filling it with mercury at the temperature $0^\circ$, then submitting it to a temperature of $100^\circ$ collecting the mercury expelled, and weighing this, and the quantity which remained in the bulb.

The other air was then determined very much as before. Eighteen experiments were tried in this way, the mean of all of which was $1:36663$; the maximum, $1:36708$; minimum, $1:36595$; the difference, $0:00123$, or $\frac{123}{100000}$ of the mean.

The third series of experiments was performed with an apparatus imitated from that described by Rudberg in his second memoir. Upon a shelf within a copper alembic, the cover of which is firmly fixed upon an appropriate support, is placed a glass cylindrical reservoir, 35 millimetres in diameter and 170 millimetres long; to its upper extremity is soldered a thermometer-tube, which passes through the cover of the alembic, and another observation may be had by reversing the experiment. To do this, reconnect the drying apparatus with the copper tube, the mercury will fall in the vertical tube in connection with the globe, but must be kept at $0^\circ$ by pouring mercury into the other vertical tube; when equilibrium has been made, remove the branch of the copper tube, then replace the ice by boiling water, and repress the dilatation of the air by pouring more mercury into the vertical tube; when you are satisfied that the air has taken the temperature of boiling water, read the barometer, and measure the difference of the heights of the mercury in the two vertical tubes.

The mean of six experiments tried in this way gave $1:3665$ for the coefficient of dilatation: the maximum result being $1:36710$; the minimum, $1:36530$; difference of the mean.

In the fourth series of experiments the dilatation was determined under very different pressures; in fact, during the first period of every experiment, the air is under the atmospheric pressure 0:760 metre when at $0^\circ$, and only under the pressure of 0:550 metre when at $0^\circ$. In the second period, the air at $0^\circ$, is under the atmospheric pressure 0:760m., and when heated to 100$^\circ$ under the pressure of about 0:40. It is even easy to arrange the apparatus so that the experiment may be tried under still greater differences of pressure.

Fifth series of experiments. In all the experiments hitherto described, the dilatation of the gas was determined indirectly from a direct measurement of the augmentation of its elastic force when brought to a constant volume at a higher temperature, assuming the gas to be an ideal fluid and free from all internal resistance. In the present direction, the gas enclosed in an eminently elastic envelope should dilate freely without changing its elastic force, and the augmentation of volume must be carefully measured, the gas being at all the same temperature. It is difficult to see how these conditions can be realized in practice, but it may be done approximately by following the method adopted by M. Pouillet in his air pyrometer.

The apparatus used by M. Regnault was a great extent similar to that just described, but the iron cap into which the two vertical tubes were cemented was differently adjusted. It had two stop-cocks, by one of which the barometric tube could be made to communicate at pleasure with the exterior, while the other, which was placed under the tube in connection with the globe, was so bored that it might make a communication either between the two tubes or between this second vertical tube and the external air.

The two tubes were placed in a glass vessel which could be filled with air at such a temperature that the two mercury columns were equal and at a uniform temperature. The experiment was conducted as follows: The globe being surrounded with ice, and the communication with the drying apparatus opened, the level of the mercury was brought to the mark 95 on the vertical tube; the communication between the two tubes being open, the mercury would of course be at the same
height in both tubes; the communication with the drying apparatus was closed, the barometer and the temperature of the water around that of the globe. The globe was then brought to 100°; the mercury in the vertical tube was of course depressed, and in order to keep that in the barometric tube at about the same level with it, its stop-cock had to be opened and the mercury suffered to flow out; the two columns were thus kept nearly at the same height, that in the first the air was drying, being brought up to the mark \( \delta \), and the exact difference in the heights of the two columns was carefully noted, as well as the height of the barometer, and the temperature of the water in the surrounding vessel. In order from this experiment to determine the dilatation of the air, it is only necessary to know the capacity of the globe, and of its stem as far as the mark \( \alpha \), and that of the vertical tube between \( \alpha \) and \( \delta \); these are all easily determined by the weight of pure mercury necessary to fill them.

Four experiments tried in this way gave a mean dilatation of 1.36708; the maximum being 1.371; the minimum 1.36695; difference \( \delta \) of the mean. The co-efficient of dilatation given by this fifth method is sensibly greater than that got from the others. This circumstance is not accidental, as in the second part of the memoir similar differences are shown for other gases, and in certain cases these differences are very considerable.

M. Regnault then proceeds to the discussion of his formula, for the purpose of determining the probable error in his results, and he shows that in the first three series—principally owing to the uncertainty of the readings of the barometer within a millimetre, the maximum probable error is about \( \delta \), which is about the greatest difference between the maximum and minimum results in any one series. The two last series include the same source of error, and another arising from the uncertainty of the temperature of the air in the capillary tube, which, however, he believes may be altogether neglected in his experiments, the apparatus having been carefully arranged so as to make this a very small fraction of the whole volume of air under experiment.

He finally assumes 0.003665 as the mean co-efficient of dilatation of dry atmospheric air as determined by the first four series of experiments, and remarks that the number 0.00367 given by the fifth series must be adopted in experiments where the gases dilate freely and preserves its original elastic force. He also gives as a fraction easily recalculated, the remark of M. Babinet that 0.00366566 should be expressed by \( \frac{1}{22} \).

**PART II.—On the Dilatation of some other Gases under Pressures near that of the Atmosphere.**

Physical philosophers admitted that all gases had the same co-efficient of dilatation, but since so serious an error in the numerical value of this co-efficient had been shown, it was necessary to submit this law also to verification, the result of which was to show its incorrectness. The experiments were tried chiefly by the methods I. and IV. under constant volumes, and V. under constant pressure. It is necessary to describe them in detail, as M. Regnault has done, not merely because the gases were purified; suffice it to say that all necessary precautions were taken, and the general results were as follows:

Co-efficient of Dilatation from 0° to 100°

<table>

</tbody>
</table>

He also describes an apparatus, an easily-imagined modification of method IV., by which the difference in the co-efficient of dilatation of any two gases may be at once shown.

**PART III.—On the Dilatation of Gases under Different Pressures.**

It has been generally admitted that the dilatation of gases is constant between the same limits of temperature, no matter to what pressure they may be submitted; consequently, that it is altogether independent of their initial density. But it is difficult to decide to what extent these experiments upon which this is founded. Several observers having obtained the same value for the co-efficient of dilatation of air, under different barometric pressures, concluded that the co-efficient of dilatation of gases was constant under all pressures; but the barometric variations in any place are not sufficiently extensive to permit so general a conclusion to be thus deduced.

Sir Humphrey Davy is the only philosopher who has studied the dilatation of gases under very different pressures. (Phil. Trans. 1823, vol. ii, p. 204.)

He states that he found the same dilatation for air taken with the densities \( \frac{1}{2}, \frac{1}{4}, \frac{1}{6}, \frac{1}{8}, \) and 2; but his experiments were not made by a sufficiently delicate method to allow his results to be considered exact.

The experiments of M. Regnault upon this subject were tried with much of the care and attention to the temperature characterizing the studies before described, as methods IV. and V., with such modifications as the peculiar circumstances of the experiments rendered necessary: and the conclusion at which he arrived was that "the air dilates, within the same limits of temperature, by quantities which are greater in proportion as the density of the gas is greater; that is, in proportion as its molecules are brought nearer to each other."

The following tables exhibit the results of his experiments upon air, carbonic acid, and sulphuric acid:

**Dilatation of Gases under different Pressures, determined by the method of Constant Volumes. (II. and IV.)**

**PART IV.—On the Dilatation of Gases under different Pressures, determined by the method of Constant Volumes.**

The general conclusions of this memoir are as follows:

1st. The co-efficient of dilatation of air, 0.0375, heretofore admitted by philosophers from the experiments of M. Gay Lussac, is much too great for dry air under the ordinary atmospheric pressure. The co-efficient 0.0344, which is the mean of the experiments of M. Hudde and G. H. Laves, is not too small, and when the co-efficient of dilatation of air is deduced by calculation, from the changes of elastic force which the same volume of gas undergoes when carried from 0° to 100°, its value is 0.0365. But when this co-efficient is deduced from the changes of volume of the same mass of gas in passing from 0° to 100°, its elastic force remaining constant, we find a value rather higher: that is, 0.0370.

2nd. The co-efficients of dilatation of the different gases are not equal, as has hitherto been admitted; they present on the contrary, notable differences, as may be seen by the numbers before cited. There is often obtained for the same gas, very different values for its co-efficient of dilatation, according as it is deduced immediately from the observation of the change of volume which the same mass of gas undergoes between 0° and 100°, its elastic force remaining the same, or calculated from the variation in the elastic force of the gas between 0° and 100°, its volume remaining constant.

3rd. The air and all other gases, except hydrogen, have the greater co-efficients of dilatation in proportion as their density increases.

4th. The co-efficients of dilatation of the different gases approach nearer equality as their pressures are lighter; so that the law may be considered a limiting law which is applicable to gases in a state of extreme dilatation; but which is farther from the truth in proportion as the gases are more compressed, or, in other words, as their molecules are brought nearer together.

(To be continued.)
CONTRIBUTIONS TO RAILWAY STATISTICS,

In 1846, 1847, and 1848.—By Hyde Clarke, Esq.

No. I.—PASSENGERS AND FARES.

Having published an analysis of the Railway Returns for 1845, I have taken the earliest opportunity after the appearance of those for 1846 and 1847, of giving a similar analysis of them, under the same title of "Contributions to Railway Statistics," which I hope may prove equally acceptable to practical men as the former series.

The following are the totals of passengers in the years ending 30th June:

<td></td>
<td>3rd class</td>
<td>40</td>
</tr>
<tr>
<td></td>
<td>Mixed</td>
<td>16</td>
</tr>
</tbody>
</table>

The gross returns, in each year, from passengers, goods, &c., were as follows:

<table>
<thead>
<tr>
<th>Year</th>
<th>Revenue</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>1842-3</td>
<td>£4,535,199</td>
<td></td>
</tr>
<tr>
<td>1844-5</td>
<td>5,074,674</td>
<td></td>
</tr>
<tr>
<td>1846-7</td>
<td>8,510,898</td>
<td></td>
</tr>
</tbody>
</table>

Mr. Hackett, in Herapath's Railway Journal, the receipts for the years ending 31st December, have been as follows:

<table>
<thead>
<tr>
<th>Year</th>
<th>Revenue</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>1842</td>
<td>£4,341,781</td>
<td></td>
</tr>
<tr>
<td>1844</td>
<td>4,584,982</td>
<td></td>
</tr>
<tr>
<td>1846</td>
<td>7,684,747</td>
<td></td>
</tr>
<tr>
<td>1847</td>
<td>9,949,681</td>
<td></td>
</tr>
</tbody>
</table>

The following will show the totals of the Railway Department and of Mr. Hackett for the same period:

<table>
<thead>
<tr>
<th>Class</th>
<th>Revenue</th>
</tr>
</thead>
<tbody>
<tr>
<td>Railway Department</td>
<td>£4,530,401</td>
</tr>
<tr>
<td>Mr. Hackett</td>
<td>8,510,898</td>
</tr>
</tbody>
</table>

Except in the first two years, it will be seen that Mr. Hackett's totals are below those of the Railway Department, for the reason already given.

<table>
<thead>
<tr>
<th>Year</th>
<th>Revenue</th>
</tr>
</thead>
<tbody>
<tr>
<td>1844-5</td>
<td>£142,588</td>
</tr>
<tr>
<td>1845-6</td>
<td>406,007</td>
</tr>
<tr>
<td>1846-7</td>
<td>916,119</td>
</tr>
</tbody>
</table>

These figures show that any error in Mr. Hackett's figures must be on the safe side; and if we take the difference for the year 1847-8 at 300,000l, this will give as the gross yearly traffic for the year ending 30th June last, 5,700,000l, or nearly ten millions sterling.

The increase of passengers receipts in each year is as follows:

<table>
<thead>
<tr>
<th>Year</th>
<th>Increase</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>1844-5</td>
<td>2537,047</td>
<td></td>
</tr>
<tr>
<td>1845-6</td>
<td>746,874</td>
<td></td>
</tr>
<tr>
<td>1846-7</td>
<td>422,787</td>
<td></td>
</tr>
</tbody>
</table>

The increase in the number of passengers in each year stands thus:

<table>
<thead>
<tr>
<th>Year</th>
<th>Increase</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>1844-5</td>
<td>18,702,651</td>
<td></td>
</tr>
<tr>
<td>1845-6</td>
<td>9,999,730</td>
<td></td>
</tr>
<tr>
<td>1846-7</td>
<td>7,561,180</td>
<td></td>
</tr>
</tbody>
</table>

The gross increase of revenue in each year stands thus:

<table>
<thead>
<tr>
<th>Year</th>
<th>Increase</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>1844-5</td>
<td>£1,135,804</td>
<td></td>
</tr>
<tr>
<td>1845-6</td>
<td>1,555,855</td>
<td></td>
</tr>
<tr>
<td>1846-7</td>
<td>945,317</td>
<td></td>
</tr>
<tr>
<td>1847-8</td>
<td>1,200,000</td>
<td></td>
</tr>
</tbody>
</table>

Mr. Hackett has shown (Herapath's Journal, 3rd series, vol. X., p. 92), that the number of miles of railway on which his figures are taken, and the average traffic per mile, are as follows:

<table>
<thead>
<tr>
<th>Mile</th>
<th>Miles opened</th>
<th>Traffic per mile</th>
</tr>
</thead>
<tbody>
<tr>
<td>1842</td>
<td>1,532</td>
<td>£5,036</td>
</tr>
<tr>
<td>1843</td>
<td>1,586</td>
<td>5,081</td>
</tr>
<tr>
<td>1844</td>
<td>1,790</td>
<td>5,323</td>
</tr>
<tr>
<td>1845</td>
<td>2,043</td>
<td>5,030</td>
</tr>
<tr>
<td>1846</td>
<td>2,610</td>
<td>5,093</td>
</tr>
<tr>
<td>1847</td>
<td>3,449</td>
<td>5,131</td>
</tr>
<tr>
<td>1848</td>
<td>5,330</td>
<td>5,422</td>
</tr>
</tbody>
</table>

(Half-year.) The last line has been made up from other data.

The capital expended on railways has been likewise given by Mr. Hackett, from which we can learn the amount expended in each year.

<table>
<thead>
<tr>
<th>Year</th>
<th>Capital</th>
<th>W. G. S.</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>1842</td>
<td>£32,380,100</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1843</td>
<td>£57,635,100</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1844</td>
<td>£65,489,100</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1845</td>
<td>£71,646,100</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1846</td>
<td>£83,155,100</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1847</td>
<td>£109,528,800</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The total amount of railway expenditure from 1842 to the end of 1847 was £75,646,700.

The total amount of railway income in those years has been:

<table>
<thead>
<tr>
<th>Year</th>
<th>Income</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>1842</td>
<td>£4,341,781</td>
<td></td>
</tr>
<tr>
<td>1844</td>
<td>4,827,655</td>
<td></td>
</tr>
<tr>
<td>1845</td>
<td>5,584,982</td>
<td></td>
</tr>
<tr>
<td>1846</td>
<td>6,649,224</td>
<td></td>
</tr>
<tr>
<td>1847</td>
<td>8,169,000</td>
<td></td>
</tr>
</tbody>
</table>

Add from Railway Returns 865,984

Total receipts for 1847-8 | £32,884,181 |

Of course the whole of this income cannot be treated as real capital, no more can the whole of the expenditure; but it is a significant fact, that while the whole expenditure has been £75,646,700, the whole income has been £38,884,181, or more than two-thirds of that amount. This is deserving the attention of those who direct their attention towards the subject of railway capital.

It may be noted upon the decrease in the mileage receipts, that it is to be accounted for from the greater economy in working expenses allowing of lower fares, and from the progress of railway improvement allowing lines to be more cheaply constructed. It will be found that the net return is not less in 1847 than in 1845.

In "Irish Wants and Practical Remedies," by Humphreys Brown, Esq., M. P., (p. 63), is given a table of the estimated passenger and goods traffic of several English lines, as given before the House of Commons. This I have extended as follows:

<table>
<thead>
<tr>
<th>Name</th>
<th>Total Revenue</th>
<th>Goods, Tons</th>
</tr>
</thead>
<tbody>
<tr>
<td>Midland</td>
<td>£500,985</td>
<td>101,845</td>
</tr>
<tr>
<td>Lancashire and Yorkshire</td>
<td>207,900</td>
<td>109,486</td>
</tr>
<tr>
<td>York and North Midland</td>
<td>185,600</td>
<td>3,247</td>
</tr>
<tr>
<td>London and Brighton</td>
<td>226,444</td>
<td>45,765</td>
</tr>
<tr>
<td>London and South Eastern</td>
<td>317,252</td>
<td>63,079</td>
</tr>
<tr>
<td>Great North of England</td>
<td>75,158</td>
<td>32,138</td>
</tr>
<tr>
<td>Great Western, and Bristol and Exeter</td>
<td>921,145</td>
<td>209,503</td>
</tr>
<tr>
<td>Lancaster and Preston</td>
<td>106,957</td>
<td></td>
</tr>
<tr>
<td>Glasgow and Ayr</td>
<td>597,470</td>
<td>121,027</td>
</tr>
<tr>
<td>Hull and Selby</td>
<td>19,562</td>
<td>93,875</td>
</tr>
<tr>
<td>London and Cambridge</td>
<td>591,344</td>
<td>72,214</td>
</tr>
<tr>
<td>Dundee and Aberdeenshire</td>
<td>200,727</td>
<td>51,999</td>
</tr>
<tr>
<td>Sheffield and Manchester</td>
<td>335,444</td>
<td>84,050</td>
</tr>
</tbody>
</table>

Total | £4,135,836 | 1,039,804 |
The traffic realised on the above lines in 1865 was as follows:

<table>
<thead>
<tr>
<th>Name</th>
<th>Passengers.</th>
<th>Goods. Tons.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Midland</td>
<td>1,899,416</td>
<td>715,372</td>
</tr>
<tr>
<td>Lancashire and Yorkshire</td>
<td>1,674,946</td>
<td>507,859</td>
</tr>
<tr>
<td>York and North Midland</td>
<td>464,735</td>
<td>351,022</td>
</tr>
<tr>
<td>London and Brighton</td>
<td>788,386</td>
<td>65,747</td>
</tr>
<tr>
<td>Lancashire and South Eastern</td>
<td>728,896</td>
<td>313,119</td>
</tr>
<tr>
<td>Great North of England</td>
<td>196,722</td>
<td>234,198</td>
</tr>
<tr>
<td>Great Western, and Bristol and Exeter</td>
<td>1,093,088</td>
<td>295,563</td>
</tr>
<tr>
<td>Lancaster and Preston</td>
<td>135,344</td>
<td>26,999</td>
</tr>
<tr>
<td>Glasgow and Ayr</td>
<td>943,078</td>
<td>128,376</td>
</tr>
<tr>
<td>Hall and Selby</td>
<td>253,402</td>
<td>227,869</td>
</tr>
<tr>
<td>London and Cambridge</td>
<td>534,206</td>
<td>44,572</td>
</tr>
<tr>
<td>Dundee and Arbroath</td>
<td>207,187</td>
<td>31,484</td>
</tr>
<tr>
<td>Sheffield and Manchester</td>
<td>1,168,448</td>
<td>32,000</td>
</tr>
<tr>
<td><strong>Altogether</strong></td>
<td>10,868,503</td>
<td>2,731,180</td>
</tr>
</tbody>
</table>

The results are as follows:

| Estimated traffic on 931 miles, 4,135,834 | 1,038,504 |
| Realised traffic, 1845, 10,868,503 | 2,731,180 |
| Excess over estimates, 6,723,667 | 1,712,575 |
| Increase per cent. | 160 | 170 |

In Mr. Brown's book on a length of 709 miles the same increase of per centage is shown, namely, 160 per cent. on passengers, and 170 on goods.

The whole traffic in 1845 was 33,791,254 passengers, and of goods, &c. 11,600,000 tons. Supposing the proportion to be the same, the number of passengers carried in 1845 more than was provided with means of conveyance before the existence of railways was 29,800,000, and the number of tons of goods conveyed was 7,900,000. Thus the railways not only accommodated the full number of passengers for whom conveyances already existed, but carried the above enormous number in addition, besides a great quantity of goods. It will be found that this calculation is, however, far from representing the amount of accommodation now afforded.

Taking the later returns, where they are available, we shall find the increase still greater, as in 1846 for instance:

<table>
<thead>
<tr>
<th>Name</th>
<th>Passengers.</th>
<th>Goods. Tons.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Midland</td>
<td>2,468,110</td>
<td>900,895</td>
</tr>
<tr>
<td>Manchester and Leeds</td>
<td>2,157,173</td>
<td>522,177</td>
</tr>
<tr>
<td>York and North Midland, and Hall and Selby</td>
<td>927,201</td>
<td>357,414</td>
</tr>
<tr>
<td>London and Brighton</td>
<td>927,201</td>
<td>357,414</td>
</tr>
<tr>
<td>London and South Eastern</td>
<td>1,074,730</td>
<td>116,385</td>
</tr>
<tr>
<td>Great North of England</td>
<td>239,587</td>
<td>433,867</td>
</tr>
<tr>
<td>Great Western, &amp;c.</td>
<td>2,767,239</td>
<td>350,000</td>
</tr>
<tr>
<td>Lancaster and Preston</td>
<td>1,622,012</td>
<td>180,000</td>
</tr>
<tr>
<td>Glasgow and Ayr</td>
<td>1,091,371</td>
<td>293,304</td>
</tr>
<tr>
<td>London and Cambridge</td>
<td>923,413</td>
<td>110,348</td>
</tr>
<tr>
<td>Dundee and Arbroath</td>
<td>317,092</td>
<td>21,059</td>
</tr>
<tr>
<td>Sheffield and Manchester</td>
<td>1,646,227</td>
<td>158,000</td>
</tr>
<tr>
<td><strong>Altogether</strong></td>
<td>13,718,503</td>
<td>3,530,441</td>
</tr>
</tbody>
</table>

The lines for which there are separate returns in 1847 are as follows:

- Great Western, &c. 231 miles.
- Glasgow and Ayr, 182 miles.
- Lancaster and Preston, 204 miles.
- Dundee and Arbroath, 164 miles.
- Sheffield and Manchester, 87 miles.
- South Eastern, 67 miles.

The traffic stands thus:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Realised 1845</td>
<td>5,139,041</td>
<td>604,641</td>
</tr>
<tr>
<td>1846</td>
<td>2,000,000</td>
<td>400,000</td>
</tr>
<tr>
<td>1847</td>
<td>7,382,586</td>
<td>1,256,061</td>
</tr>
</tbody>
</table>

The actual increase of traffic depends upon the length of time given for its development, beginning at 160 per cent. and going up to 230 per cent., and in the case of the selected railways even more. Taking the increased accommodation to passengers at 160 per cent., this would give the following as the increased number of travellers provided with travelling accommodation in each year:

- 1844, 17,400,000
- 1845, 20,800,000
- 1846, 27,000,000
- 1847, 30,000,000

If the proportion be taken at 200 per cent., the number accommodated by railway for whom no accommodation was before provided, would be 34,000,000.

The following shows the proportion of traffic on railways in each year for which accommodation by coach, &c. was provided, and for which no accommodation by coach, &c. was provided:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1844, 10,300,000</td>
<td>17,400,000</td>
<td></td>
</tr>
<tr>
<td>1845, 12,000,000</td>
<td>20,800,000</td>
<td></td>
</tr>
<tr>
<td>1846, 16,000,000</td>
<td>27,000,000</td>
<td></td>
</tr>
<tr>
<td>1847, 21,000,000</td>
<td>30,000,000</td>
<td></td>
</tr>
</tbody>
</table>

Reckoning that each passenger is on the average carried 50 miles, each male adult in this country will be carried that distance six times in the year; an extension of accommodation which will have a great effect on trade and on the distribution of labour.

It appears from the averages given in the returns of the Railway Department, that there has been a still further reduction in fares on most of the lines, and an increase in the average speed per mile.

The total increase on each class of passengers is as follows:

- 1845, 1846.
- 1st class, 599,831 586,191 413,460
- 2nd class, 2,190,139 2,615,240 1,709,223
- 3rd class, 1,952,231 2,544,736 1,785,276
- Altogether, 6,052,281 7,358,895 5,903,960

It is to be observed that these figures cannot be absolutely relied on, as the proportions of each class cannot be fully shown on account of the confused state of the returns published by the Railway Department.

The total increase on each class of passengers between 1844 and 1847 has been as follows:

- 1st class, 1,697,382
- 2nd class, 5,463,602
- 3rd class, 14,647,718
- Altogether, 23,848,661

This is probably more than the whole traffic of the country in 1825, and it shows at any rate that there has been a great increase in the accommodation given to the working classes.

The number of first, second, and third class passengers in 1847 on the leading lines was:

<table>
<thead>
<tr>
<th>Name</th>
<th>Passengers.</th>
<th>Goods. Tons.</th>
</tr>
</thead>
<tbody>
<tr>
<td>London and North Western</td>
<td>1,112,970</td>
<td>5,323,380</td>
</tr>
<tr>
<td>South Eastern</td>
<td>667,360</td>
<td>1,953,105</td>
</tr>
<tr>
<td>Midland</td>
<td>445,260</td>
<td>1,250,321</td>
</tr>
<tr>
<td>London and Blackwall</td>
<td>298,210</td>
<td>1,279,165</td>
</tr>
<tr>
<td>Lancashire and Yorkshire</td>
<td>216,791</td>
<td>1,981,279</td>
</tr>
<tr>
<td>Great Western</td>
<td>459,734</td>
<td>1,986,524</td>
</tr>
<tr>
<td>London and Brighton</td>
<td>425,948</td>
<td>1,198,895</td>
</tr>
<tr>
<td>Dublin and Kingstown</td>
<td>554,897</td>
<td>1,296,092</td>
</tr>
<tr>

Total: 129,500 755,000 103,000

The number of cattle sold in Smithfield in 1846 was 213,652, and of sheep 1,527,990, so that the railways must have engrossed a considerable part of the cattle traffic. For the conveyance of cattle to the London market the railway companies receive at least £75,000.

Great reductions have been made in the charges for the conveyance of cattle since 1845. The charges are as follows:—

<table>
<thead>
<tr>
<th>Region</th>
<th>Cattle</th>
<th>Sheep</th>
<th>Swine</th>

</tbody>
</table>

The following will show the progress of the cattle traffic of the principal companies:—

<table>
<thead>
<tr>
<th>Region</th>
<th>Cattle</th>
<th>Sheep</th>
<th>Swine</th>
</tr>
</thead>
<tbody>
<tr>
<td>London and North Western</td>
<td>1845</td>
<td>235,925</td>
<td>95,345</td>
</tr>
<tr>
<td>1846</td>
<td>299,426</td>
<td>139,200</td>
<td>54,087</td>
</tr>
<tr>
<td>1847</td>
<td>329,426</td>
<td>144,200</td>
<td>50,000</td>
</tr>
</tbody>
</table>

The total receipts for cattle traffic in each year were as follows:—

<table>
<thead>
<tr>
<th>Year</th>
<th>Cattle</th>
<th>Sheep</th>
<th>Swine</th>
</tr>
</thead>
<tbody>
<tr>
<td>1845</td>
<td>235,925</td>
<td>95,345</td>
<td>31,699</td>
</tr>
<tr>
<td>1846</td>
<td>299,426</td>
<td>139,200</td>
<td>54,087</td>
</tr>
<tr>
<td>1847</td>
<td>329,426</td>
<td>144,200</td>
<td>50,000</td>
</tr>
</tbody>
</table>

The advance in cattle traffic was made in 1846; but the progress was not so great in 1847, as there was a positive falling-off in the number of swine carried. The greatest increase is in the conveyance of fat stock and sheep.

The following are the proportions of cattle carried in each year:—

<table>
<thead>
<tr>
<th>Year</th>
<th>Cattle</th>
<th>Sheep</th>
<th>Swine</th>
</tr>
</thead>
<tbody>
<tr>

The Belgian cattle traffic from the returns was as follows:—  
Cattle.  Sheep.  Swine.  
1843, 28,629  33,620  
1844, 12,951  39,060  
1845, 7,597  29,704  

The gross saving of animal food on the cattle convoyed by railway in 1847 was as follows:—  
On 500,000 cattle, 30,000,000 lb.  
On 3,000,000 cattle, 15,000,000 lb.  
On 16,000,000 cattle, 7,500,000 lb.  
Total, 43,000,000 lb.

In the late report on Smithfield market, some evidence is given bearing on the question of the conveyance of cattle by railway:—  
Mr. R. B. Lewis says that the last quarter of dead meat brought to the London markets in consequence of railway communication. By means of the railways, great quantities of hind-quarters of mutton are sent up from the country, as the butchers there kill large quantities of sheep and sell the fore-quarters and heads to the population there, and send the hind quarters by railway to London.  
Mr. Langham, a butcher, said that country-killed meat is better than town-killed meat, and that it comes in excellent condition from Scotland. It is the general opinion of butchers that this is the case.  
Mr. Hicks, the salesman, said that he has a very large quantity of meat sent up from the country by railway, and that it is not damaged by the journey even in hot weather. He has used the electric telegraph to obtain a supply of meat from the country. A communication was sent the same night by the country grasier that he would send up 600 or 700 stones of meat by the next morning's train. At 1 o'clock in the morning it started from Ipswich, and before 5 o'clock it was in his premises in Newgate market on sale, having been alive the day before. Mr. Hicks has sometimes 300 carcases on a Monday.  
Mr. Langham likewise states, that since the railways have been opened a country trade in meat has been growing up. Beasts have been sent from Smithfield to Liverpool, and he has seen immense quantities of meat going down to Birmingham. The south country also is supplied from the London market with beef brighton in particular. The brighton butchers are frequently seen in Smithfield purchasing cattle, which they take down with them the same day. Sometimes as many as 300 or 400 beasts have gone down by the Birmingham railway on a Monday.  
These facts will show the nature of cattle traffic on railways.

"The Westminster Review," No. XLVII.:  
"The New Houses of Parliament."  
Although political topics and subjects of a grave utilitarian cast form the staple of this periodical, with only occasionally an article of a lighter cast, the "Westminster" has in its time, and especially under its present editor, contributed more largely to architectural formation and criticism than almost any other. In fact, the "Edinburgh" has scarcely once, during the whole of its long career, touched upon that connected with architecture. One prevalent fault in the Review articles of the kind, is the dull and insipid prose in which they are skilfully, or as much as may be the case, allowed, although all that the writer has to communicate would perhaps occupy not more than a couple of pages. In the present instance, we have found no such cast to make: the writer comes at once to the point, and criticizes in succession (besides the new New Houses of Parliament) the New Treasury Buildings, Buckingham Palace, the alterations by Mr. Ore, the British Museum, and the Royal Exchange; and his remarks are upon the whole so good, as far as they go, although we do not subscribe our own opinion to every one of them, that we wish he had entered more into particulars with regard to the three last-mentioned structures. How they and the "Houses" themselves are spoken of, except as regards ability on the part of the writer, we have not yet said. With respect to the Palace, indeed, it may be taken for granted that his opinion is anything but favourable, that unhappy building being absolutely universal derision; but the writer turns the same critical eye to the others also—and not least of all, or rather more especially so, upon the House of Parliament, which proves that he does not take his name from the vulgar flatteries of the public press, heaped upon Mr. Barry and his "great work." In short, he expresses himself bitterly and dispassionately, and as far as may be, the only one who is so, for even among our own acquaintance—those, too, whose judgment in matters of architecture is entitled to some deference—we have heard opinions equally strongly in disfavour of it. One serious complaint alleged against it is, that however well the flourid and exuberant embellishments can be seen on the river-front may shine or sound in description, or show itself in an elevation drawing, it is all but entirely lost in the building itself—that there is abundant sculptural decoration of some sort or other may be seen, but it cannot be at all made out. The decoration is, besides, not only beside the general ensemble, but to the present state of art, and the distance of the nearest accessible point from which it can be seen by the public, is so profuse, as quite to destroy "emphasis." While this is to be regretted for artistic reasons, it is also to be condemned for financial ones. "Excessive expenditure being the characteristic of a successful building, it is in the narrowest sense of the word, is a matter of froze, to be barely to any purpose at all. Surely the water-side of the building might very properly have been made some degrees less ornate than the other fronts, and still have been sufficiently finished-up, and sufficiently dignified and imposing,—nay, even more useful, if it is to possess that characteristic of a successful building which is supposed to be the very essence of successful building, viz., "fitness."" In the case of the House of Parliament, there is an extraordinary amount of attention paid to that part of the front, and the distance from it that can be seen, which is more extensive in the case of the new front of the British Museum, notwithstanding that it is decked-out in Ionic pomp, or what is meant for such. In the House of Parliament, the architect has fallen into the contrary extreme of error; and anxious to avoid the approach of "emphasis", has incurred that of extravagance.

Besides wasteful excess of decoration, the writer in the "Westminster" urges against the "Houses" what he considers two capital and now irreparable defects; one of them being the want of greater loftiness in the river-front, more especially as the situation itself is very low; the other, the position of the Victoria Tower. No doubt, when all the towers in the rear of the river-front shall come to be completed, and the shed, coffer-dam and other obstructions are cleared away, some expression of loftiness, as well as a rather picturesque outline, will appear to the eye; but then that will again be counteracted by the much greater loftiness and bulk of the Victoria Tower. If exigencies of plan required that the royal entrance should be just at the south-west corner of the pile,—if it was impossible to bring in that entrance as the central feature of the design, it was perhaps, by forming a commodious carriage approach to it along the terrace—there was at all events no imperative necessity for carrying up such an enormous tower over it as is now intended to be done. It is true, in many medieval edifices which have grown up by
degrees, and consist of parts added to the original plan at long
intervals of time, very great incongruities and discordant con-
trasts may be found, and may be pleaded as some sufficient pro-
cedent. But the "houses" will have been of the original plan, laid down by the architect from the very outset; and so far from aiming at variety and contrasts in his elevations, Mr. Barry has most studiously attended to perfect
regularity of composition and uniformity of features,—at least,
such is the case with regard to the river-front, which, although a
secondary one in regard to its situation, will barely be secondary
in regard to display. Nevertheless, so lofty a structure raised at
one corner of the general mass as the Victoria Tower will be,
must inevitably show itself as a striking irregularity,—an archi-
tectural excessiveness, and apparently an after-thought,—at least
to those who may not happen to know that it was so planned from
the very first.

With regard to the river-front, the question now is: How can it
be rendered accessible to the public, so that its elaborate ornamenta-
tion can be fairly seen and enjoyed? At no very great distance
in time, perhaps, and owing to the very insecure condition in which it
now is, Westminster Bridge will be taken down, and either consi-
derably lowered or rebuilt further off from the Houses of Parlia-
mament; in which case, Bridge-street will be converted into a cul-de-
seau, similarly to the streets which run from the south-side of the
Strand down to the river; consequently, the "houses" will no longer
be looked down upon from the bridge—but then how is their
river-front to be looked at all, except from a boat on the river itself?
The only way of enabling the public to contemplate that
facade, will be to form a second terrace or quays for foot passengers,
advancing about fifty feet into the river, and perhaps the same
number of feet lower than the terrace between the advanced extremities
of the building itself. Unless something of that kind were to be done,
quite as much would be lost as gained by the removal of the present
bridge; to say nothing of the great inconvenience attending the
interfering with such a long-established line of communication and
traffic.

That we agree with the Westminster" in much or most of what
it says, both in regard to the Houses of Parliament and the other
structures which it notices, we freely admit. And it is pleasant to
use the pronouns that are upon the whole in accordance with our
own entertainments by others. Speaking of Buckingham Palace, the
"Westminster" observes that the Marble Arch "might have been
advantageously incorporated with the design by an artist of re-
source and genius," and again, of the British Museum, that the
central portico or octastyle ought to have been loftier than the
other colonnades, both which ideas have been brought forward in
sketches in this very Journal. Although we should not have been
displeased at his noticing that circumstance, supposing him to have
been aware of it, we do not accuse the writer of making use of "our
thunder," on the ground that he might have been disposed to meet
with the concurrence of opinion, and to find that we are not altogether soli-
darity in our own. Here we will conclude, by earnestly recommend-
ing a perusal of the article in the "Westminster" to our readers.

It certainly bears rather severely upon Mr. Barry, but he, if any one at all, will have
bear on his part to bear unpalatable
truths. Of flattery and adulation he gets enough, or more than
enough—more than may be altogether wholesome for him. An
occasional draught of "bitterness" will therefore do him no harm.

of one central buffer in lieu of the two side ones, as hitherto
used; this the patentee constructs in combination with the draw-
link. The annexed diagram represents this arrangement. A, A,
are the buffer-plates of adjoining carriages; they are attached to
the buffer-rods B, B, the ends of which are made of the looped
form shown, for the purpose of admitting the loop of the connect-
ning-links C, C. The buffer-plates, A, A, are made with holes
through their centres, through which are passed the double-ended
hooks D, when the carriages are required to be connected, which
are hooked to the links C, C, upon the buffer-rods B, B. Immedi-
ately behind the loop are cut threads, upon which work the nuts,
E, F, upon which are loose collars, that do not revolve with the
nuts, and the loose collar is hooked to the links C, C. When it is
required to connect two carriages, the buffer-plates are brought
together, the two nuts are turned up to the looped ends of the buffer-rods, and the double hook inserted and hooked
on to the links; the nuts are then to be turned back until the links and the hooks become tight. Instead of passing the traction
rods entirely through the carriage as hitherto, the patentee proves
the rod B, only through the end-frames F, F, of the carriage,
where the helical spring G, is placed upon the rods, and acts as
the buffing-spring. The patentee claims as his third improvement,
the employment of helical springs or other elastic substances, incom-
bination with adjusting-screws, for making the coupling of rail-
way carriages; also the combination of a double-joint with the
adjusting-screws. The patentee's fourth improvement consists in
constructing the axle-box and the axle in such manner that the
lubricating material employed shall be retained in contact with the
journal and the bearing, and thereby prevent a considerable por-
tion of the waste which has hitherto taken place with axle-boxes
as usually constructed. He constructs the axle of one piece or
of two pieces, as in the usual way; the brass forming the bearing
is properly fixed in, and the end of the axle is inserted into the axle-
box and rivetted back; the outside against the journal is turned
with a flat or taper shoulder, against which is fitted and placed a
metal ring; between the ring and the back of the axle-box is
inserted a ring of vulcanised indiarubber, or other similar sub-
stance, thereby preventing the escape from the axle-box of any
considerable portion of the lubricating material employed. The
fifth improvement consists of a means of enabling any of the pas-
sengers in railway carriages of a train to signal and communicate
with the engine-driver or guard, by the aid of electricity. To the
middle partition of each railway carriage, near the roof, is fixed a
small voltaic battery, by means of which the passengers are en-
able to bring into action an electro-magnet, that explodes a per-
cussion-cup or rings a bell.

REGISTRATION OF NEW PATENTS.

RAILWAY LOCOMOTION.

Richard Wight, of Lower Brook-street, Grosvenor-square, for
"Improvements in apparatus to be applied to railway carriages
and engines." Granted December 22, 1847; Enrolled June 22, 1848.

The apparatus consists of five distinct applications to railway
carriages and engines for different purposes. The first part con-
stitutes the construction of apparatus whereby the motion of
steam is transmitted to the carriage wheels; the second con-
stitutes the construction of apparatus whereby the motion of
steam is transmitted to the locomotive wheels; the third consti-
tutes the construction of apparatus whereby the motion of
steam is transmitted to the connecting rods or shafts; the fourth con-
stitutes the construction of apparatus whereby the motion of
steam is transmitted to the buffer-plates; the fifth consti-
tutes the construction of apparatus whereby the motion of
steam is transmitted to the buffers. The patentee claims the
improvement of conveying the power of working the break
of carriages and causing them to act simultaneously upon the wheels
throughout the whole train; also the construction of box-coupling
for connecting the shafts, and the power to the breaks. The
second improvement consists in the employment, in railway carriages,

COKE OVENS.

Georges Aimé Michel, of Epieds, France, for "Impro-
vements in the production and application of coke, and in the manufac-
ture of coke." Granted December 15, 1847; Enrolled June 15,
1848.

The application of the heat evolved during the formation of
coke is the object of this invention. Several ovens are combined
together, which are provided with fire-bars that occupy only a
small portion of the area of the bottom. The ovens are separated
from each other by partitions, and in the upper parts there are
openings to permit the flame and products of combustion to pass
from one oven to another; and there are openings in the top of
each oven, through which the flame and heated gases ascend, in
order to heat gas-retorts, lime-kilns, steam or other boilers, or
other apparatus, situated above the ovens. The patentee
states, that by means of this invention the heat may be more ad-
vantageously obtained and applied than before. When the ovens
are at work, the charges of coal are introduced in succession, in
such manner that the charge in two or three of may be in a high
state of ignition when fresh coal is put into the other. The operator will know when to withdraw a charge, by the flame coming on the surface; as soon as this is the case, the charge is to be withdrawn and cooled with water; a fresh charge of coal is then to be put in the other, and the process being repeated, the charge will soon be ignited by the heat of that oven and the flame from the other ovens. The ash-pit doors are to be kept closed at all times, except it be found requisite to introduce air to expedite combustion; and the ash-pit door of the oven, into which the air is to be admitted, is opened.

STEAM-BOILER FURNACES.

HORACE F. BAKER, of Boston, United States of America, for a "steam-no ash waste, and boiler furnace."—Granted December 22, 1847; Enrolled June 29, 1848.

The annexed diagram represents a longitudinal vertical section of the furnace, as applied to the cylindrical boiler of a high-pressure engine. The fire-box, \( a \), is placed at one end of the boiler. At the end of the fire-bars there is placed a vertical grate \( q \), which reaches nearly to the bottom of the boiler, for the purpose of preventing ashes from being carried into the reverberatory chambers; in the addition of which, the peculiarity of the invention consists. The bottoms of these chambers are placed below the level of the fire-bars, and the number of them may be four or more as required. They are of a parabolic form, for giving revolving motion to the gases and other inflammable matters, thereby retaining them till consumed; \( e \) is a plate of iron placed in an inclined position, whereby it receives the direct force of the entire flame from the furnace, part of which is deflected against the bottom of the boiler, while the remainder is turned downwards, and caused to circulate in the chamber below. Openings are left at the upper part of the plate \( e \), between it and the bottom of the boiler, which allows the flame to pass along; \( f \) and \( g \) are air-channels, for the admission of atmospheric air or oxygen, in order to ensure the perfect combustion of the gases. These channels are carried into the brickwork at the side of the boiler, through which they may be conducted, and furnished with valves, if necessary, for regulating the quantity of air; \( h, A \) are curved plates, which extend across the furnace, the openings in which are so arranged that, while part of the heat and flame passes along immediately in contact with the boiler, part also is deflected against the bottom of the boiler, and the remainder is directed down into the hollow bottoms of the reverberatory chambers. Gratings \( i, i, i, i \), are placed in the bottom of each of the reverberatory chambers, to allow any small particles of incombustible material to escape, that may be carried over by the draught. These gratings open into a pit \( k \), below, which must be kept closed. The fire having been ignited, the flame and gases evolved will be carried over and through the vertical bars \( c \), and will come in contact with the plate \( e \), by which they will be deflected against the boiler, and also turned downwards into the hollow bottom of the first chamber \( d \), causing them to revolve and be retained a short time, to further the combustion. They then pass over the upper part of the air-distributing box, on the further side of which are numbers of small openings, whence the atmospheric air issues, as indicated by the arrows, the current of air or oxygen causing the un-combusted volatile product to be converted into flame, which, by the force of the current, impinges on the bottom of the boiler. The gases are also in this next chamber caused to revolve by the curved shape; and they are distributed by the plate \( k \), in the next chamber, where they are again retained a short time, the revolving in these chambers causing the heated particles to be brought in contact with the boiler, the last reverberatory chamber being also furnished with an air-distributing box \( g \), which is supplied by channels through the brickwork. From the fourth chamber the in-combustible product is conducted by a flue at the bottom of the boiler to the chimney.

AXLE GUARDS AND BUFFERS.

CHARLES DE BERCOUR, of Arthur-street West, City, engineer, for "Improvements in carriages used on railways."—Granted January 5; Enrolled July 3, 1848.

These improvements in railway carriages relate only to the axle-guards and boxes, and to buffers. The patentee constructs his axle-guards in such a manner, that the wooden surface shall be presented as a guard for the axle-box (which is of cast-iron) to rub against. For this purpose he secures two uprights to the main framing of the carriage, at a distance from each other suitable for receiving the axle-box, which has a flange, its whole depth on each side embracing both sides of the uprights. These wood uprights forming the guard, are strengthened by plates of iron, placed on each side, the width of such plates being less by the breadth of flange on the axle-box, than the wood against which they are bolted; thus the face of the axle-box slides flush with the face of the axle-guard. The upper parts of these plates are carried up the side of the frame, to which they are secured. The springs are of the kind previously patented, and consist of a series of India-rubber rings, separated by plates of metal. This spring is placed between the uprights of the axle-guard, the bottom plate being supported by vertical rod resting in a step on the axle-box, immediately above the centre of the bearing, being within the grease-box, which forms part of, and is cast in one piece with, the axle-box. The wood faces of the axle-guards and the chases in the sides of the axle-boxes must be rendered particularly smooth, in order to prevent abrasion of the surface of the wood. The second improvement consists of a mode of making the conical centres of plates used for separating the rings of India-rubber in the buffer and other springs. In making these plates the patentee forms a thin disc of metal of the required diameter, having a hole in the centre larger than is necessary for the buffer-rod; he then incloses this plate in a suitable mould, in which is poured a quantity of soft metal, such as zinc and tin, in order to form the conical centre of such separating-plates. The soft metal mould, being larger in diameter than the hole in the centre of the plate, it consequently becomes securely imbedded in the soft metal centre, which is cast with an opening suitable to receive the buffer-rod or other spindle, according to the purpose it may be intended for. The third part of this invention relates to what the patentee denominates a long-range buffering apparatus, which is connected to a van truck, and placed between the engine and tender and the train of carriages, in order to protect the train as much as possible from violent concussion. The range of resistance in this apparatus is to the extent of several yards, and, unlike other buffers, it is not attended by any recoil. The resistance is given usually by the friction of the arms which are being supplied by the driving spur-wheels themselves. The pins to which the connecting-rods are attached, and which have hitherto been fixed to the cranks upon the ends of the shaft, are, by the patentee’s arrangement, now fixed to the bosses of the driving-wheels, and the entire resistance of the buffer. The invention consists in the construction of the valves for pumps for raising or lifting or forcing water, as applied to an air-pump. The patentee proposes to form the passages through the bucket, radiating from the centre; the passages being in pairs, having a thickness of metal between them; the bucket being covered by a valve, which is composed of a thin piece of steel or other flexible metal, one end of which is firmly secured to the inner part of the bucket, while the other part rises from its seat, when required to allow the flow of water. The patentee...

SCREW PROPELLERS AND PUMPS.

EDWARD HUMPHREYS, of Holland-street, Surrey, engineer, for "certain improvements in steam-engines, and in engines or apparatus for raising, exhausting, and forcing liquids."—Granted January 4; Enrolled July 4, 1848.

The improvements in steam-engines have reference solely to the mode of driving the screw propellers of steam-boats. The apparatus and the driving multiple wheels are so arranged, that the cranks usually employed are dispensed with, the place being supplied by the driving spur-wheels themselves. The pins to which the connecting-rods are attached, and which have hitherto been fixed to the cranks upon the ends of the shaft, are, by the patentee's arrangement, now fixed to the bosses of the driving-wheels, and the entire resistance of the buffer. The invention consists in the construction of the valves for pumps for raising or lifting or forcing water, as applied to an air-pump. The patentee proposes to form the passages through the bucket, radiating from the centre; the passages being in pairs, having a thickness of metal between them; the bucket being covered by a valve, which is composed of a thin piece of steel or other flexible metal, one end of which is firmly secured to the inner part of the bucket, while the other part rises from its seat, when required to allow the flow of water. The patentee...
claims in respect to the first part of his invention—First, the placing the direct-acting marine steam-engines between a line drawn through the centre of the piston-rod, and a parallel line drawn through the adjoining bearing, or in the spaces usually occupied by the crank in ordinary engines; also the connecting the piston-rods to the driving-wheels, without the aid of cranks.

**LAP-WELDED IRON TUBES.**

JOSE CUTLER, of Birmingham, civil engineer, for "certain improvements in welded iron pipes or tubes to be used as the flues of steam-boilers."—Granted January 13; Enrolled July 13, 1848.

The object of the patentee is to produce lap-welded iron tubes or pipes, so formed as to give increased strength to those parts which are exposed to wear without additional weight to the entire length of the tube, and thereby to obviate the evils to which boiler-tubes are at present exposed. He makes the internal diameter of the tube greater at one end than at the other, instead of its being the same, or uniform throughout, as has hitherto been the case; the external diameter remaining, however, the same, and uniform throughout the entire length of the tube. The tube will, of course, be cylindrical upon the exterior, and conical upon the interior surface. The increased thickness of metal at the one end is to be drawn from the remaining portion of the entire length of the tube. As no local operation is affected at one head, the ductility of the iron of which the tubes are composed shall remain unimpaired.

The "modus operandi" is as follows:—The patentee employs a series of grooved rolls, moved by suitable toothed wheels and a mandril, with a conical bulb or head of the stem of which is of increasing diameter towards the opposite end. The skelp, after being properly prepared, as is usual in the manufacture of lap-welded iron tubes, is heated and passed between the first of the series of rolls. It is then welded over the conical bulb, and forced, at the same time, over the center of the mandril. This mandril is held by a grip attached by a hinge thereto in a stop, so as to allow of its being lowered and passed, after the conical bulb has been removed between the second series of rolls, the diameter of the groove of which is smaller than that of the first series. The tube, with the mandril still inside, is then passed through the third series of rolls, the groove of which is smaller than that of the second series. The object of these successive rollings, after the skelp has been welded on the mandril, is to remove any irregularities upon either of the surfaces, and to make the edges of the tube perfectly smooth and uniform. The tube is then taken to the drawing bench, in front of which is a stop, and against which the pipe rests. The stop is furnished with a hole to allow of the passage of the grip of the mandril, which is held by a pair of pliers; and, the bench being made to move while the pipe remains stationary, the mandril is withdrawn. When it happens that the mandril is too tightly to the tube, it is generally heated in a muffle or furnace, so that to cool the end which rests against the stop, and repeat the above operation, or to roll it cold between three rollers, as is usually done in straightening shafting.

**MINING APPARATUS.**

Pierre Auguste Puts, of Paris, for "Improvements in apparatus for raising bodies in mines."—Granted December 25, 1847; Enrolled June 22, 1848.

The principal feature in this invention is the application of atmospheric pressure to the raising of weights, and to the draining of mines. The first plan by which the patentee proposes to raise bodies is by having a vertical air-tight tube in which there is a solid piston, to the under part of which the weights to be raised are to be attached; and the upper part of the tube being exhausted, the atmospheric pressure below will force up the piston and its load. In the drawings attached to the specification, two pistons are represented, one following the other in the ascents. When the upper one reaches the top it is relieved of its load by means of an air-valve. The water passes through the pipe, and is forced up a step higher to a small reservoir placed for the purpose. The next pump above repeats the operation, drawing the water from the reservoir, to which it has been previously raised by the pump below, and so on till the water arrives at the top. The action of the pumps is reversed on the descent of the air from the mine, and to the cylinders, on the upper side of the pistons. Another part of this invention relates to the raising weights in mines by a series of vertical rods, which are attached to each other, forming one continuous rod to the bottom of the pit. Two of these combined rods are placed side by side, and suspended at the top by two chains, attached to, and passing round, wheels supported over the mouth of the shaft. These wheels have a semi-rotary movement imparted to them from a steam-engine, by which means a continual reciprocating motion of the two rods is kept up. Hooks or notches are formed on the vertical rods at regular distances,
corresponding with the height the rod is lifted at each movement. Each bucket to be raised by these rods is furnished with two spring-hooks, which take into the notches on the rods and suspend them while ascending; the bucket being suspended from the lowest notch, is elevated by the first movement, till the spring-hook slips into the second notch on the other rod. The rod by which it has been previously lifted, descends, thereby transferring the whole weight to the other rod, which immediately raises it another step, the changes being performed alternately in this way until the bucket reaches the top.

STEAM-ENGINES.

Charles William Siemens, of Manchester, for "Improvements in engines to be worked by steam and other fluids."—Grant distant December 29, 1847; Enrolled June 22, 1848.

The chief object of this invention is the saving of fuel by a means proposed for regeneration of the steam and for condensing it by successive exposures to water of different temperatures. There is no regular boiler employed, but the steam is generated in the first instance in a small flat chamber, placed close to the cylinder; the direct action of the fire being against a cast-iron chamber containing the bottom of the cylinder, and having considerable space between the two, which is filled with lead. The flues are continued two rounds round the cylinder, and then under the steam-generating chamber. The cylinder is fitted with a jacket, through which the steam has access to both sides of the piston, the area of the upper side of which is diminished one-half by a trunk which works through a stuffing-box in the top, and admits of the connecting-pipe of the vapor, the difference in the two areas causing the piston to ascend. The steam having been thus admitted to the cylinder, is suffered to escape by a series of double-beat valves, which are lifted by a series of cams on the main shaft; the steam is thus admitted successively into eight different regenerating-chambers, which are utilized immediately under the generator. The steam, as admitted to the upper chamber, will be of the greatest pressure, and the valve is suffered to remain open a very short time, the next in succession opening immediately, the duration of which will be somewhat longer, which goes on increasing, the pressure of the steam is also gradually reduced; the ninth valve opens to the atmosphere or to the condenser, and remains open till the engine is past the centre. These several chambers are each fitted with shallow horizontal tracts, into which water escapes from the generator above, passing on to the other. The heat thus communicated to these chambers regenerates the steam, which is again admitted to the same cylinder, or to another cylinder, should it be a double-cylinder engine, by the same set of valves, which are opened by another set of cams on the opposite side of the shaft, in the inverse order to that before explained, the lowest pressure being allowed to act first. The last is opened by the fire to which it also assists in the regeneration of the steam. The next part of the invention relates to the condensation of steam in ordinary condensing-engines. The condenser is subdivided by horizontal partitions, into four or five separate compartments, the steam being admitted by a cock having a hollow plug, which is opened to the cylinders. This plug opening to the separate compartments of the condenser in succession, beginning at the lowest, the injection water is admitted to the uppermost, where it completes the condensation of the steam, and from which the air-pump exhausts a portion of the injection; and the condensed water instead of being carried off by the air-pump, is received between two pistons working in a barrel between the upper and second chamber, by reason of the upper piston being above the top of the cylinder or barrel. This water is by the down stroke of the air-pump admitted to the chamber immediately below the injection chamber, and in which a portion of the steam is suffered to escape. Each of the partitions is fitted with similar apparatus for transmitting the condensed water from one chamber to the other, till it reaches the lowest, where the steam is first admitted. A portion of the steam on entering that chamber will be condensed by the water, and that portion condensed through all the separate chambers, and having the heat derived from several successive charges of steam from the cylinder, it will have attained a great heat, and may be introduced to the boiler. The quantity of water required for injection will thus be materially reduced, and may render it applicable for locomotion or for artificial heating of the steam which remains in the cylinder after its high-pressure effect is spent through the blast-pipes in the chimney. The last part of the invention relates to an improvement in the chronometric governor, patented by Mr. Siemens, in December, 1848. The improvement consists in the adaptation of an expanding fly-wheel to the governor, instead of the pendulum-ball with which it was originally constructed. This fly-wheel is formed in four segments, and by centrifugal action they are caused to expand or recede from the cone. When the centrifugal force takes place, by reason of the increased velocity, bell-cranks are actuated by the segments, so as to force a conical friction-break against the cone fixed to the frame-work. The friction caused by this break tends to retard the velocity of the shaft and segments, and the pressure which is exerted to drive the shaft being constant and independent of the velocity of the prime mover, limits the velocity of the expanding-wheel, causing nearly a uniformity of motion, if sufficient power be at all times transmitted to the shaft.

REPLY TO THE REVIEW OF DR. GREGORY'S "MATHEMATICS FOR PRACTICAL MEN.

Sir,—In the criticism upon the new edition of Dr. Gregory's "Mathematics for Practical Men," which appeared in the last number of this Journal, the writer has in such positive terms denounced as incorrect certain portions of that work, involving principles not however peculiar to itself, but which have originated with, or been demonstrated by, all the principal mathematical writers, that I think myself called upon to offer the following remarks to prevent your readers being misled upon the subject.

Your reviewer commences his criticism by expressing his surprise at my using the words cycloid and trochoid synonymously; I am not, however, the only person who has done so, for Dr. Hutton says: "Trocloid is the same curve as what is more usually called the cycloid."

Professor Barlow says: "Trocloid is the same as cycloid, that term being derived in a similar manner from cyclos, a circle; it is, however, by some authors, used to denote exclusively the prolate cycloid."

Your reviewer then proceeds to find fault with my definition of an epicycloid, which is as follows: "If the generating circle, instead of rolling along a straight line, is made to roll upon the circumference of another circle, the curve described by any point in its circumference is called an epicycloid." p. 179.

Dr. Hutton says: "But if, instead of the right line, the circle roll along the circumference of another circle, either equal to the former or not, then the curve described by any point in its circumference is what is called the epicycloid."

Now Professor Barlow gives the properties of epicycloids when the generating and quiescent circles are not commensurable, which they always would be if equal and Dr. Young, in an "Essay on Cycloids" (the attentive perusal of which I would recommend to your reviewer), speaks of epicycloids in which, while the generating circle remains constant, the other becomes either infinite or evanescent. If, then, your reviewer is right, it follows that Dr. Hutton, Professor Barlow, Dr. Young, and many others (whom I have not space to quote), are wrong.

He then goes on to say, that I have aggravated the mistake "by representing the rolling curve as much larger than the fixed curve," whereas it is really much smaller in both my figures (157 and 158); from which it is very evident that he has mistaken the fixed for the rolling circle.

Your reviewer next finds fault with one of my definitions, as being "clumsy and incomplete, at the least," and asks, "What will our mathematicians read say of such a definition?" Now, one of our most justly-esteemcd mechanical writers, Professor Moseley, has given a definition so precisely synonymous, that I transcribe both his and my own for the purpose of comparison:

Professor Moseley's Definition. "When more forces than one are applied to a body, and their respective tendencies to communicate motion to it counteract one another, so that the body remains at rest, these forces are said to be in equilibrium, and are then called pressures." p. 187.

Your reviewer objects to the sense in which I here use the word "force," and adds, "When the forces do not act upon a body, destroy or annihilate each other's operation, so that the body remains quiescent, they are said to be in equilibrium, and are then called pressures."

33
Your reviewer next takes up the subject of *vis viva*, on which I said:

"*Vis viva,* or living force, a term used by Leibnitz to denote the force or power of a body in motion; or the force which would be required to bring it to a state of rest." p. 108

Professor Barlow says: *Vis viva,* or living force, is used by the same author [Leibnitz] to denote the force or power of a body in motion. 19

Dr. Hutton says: "*Vis mortis,* and *vis viva,* are terms used by Leibnitz and his followers for force; understanding by the latter, that force or power of acting which resides in a body in motion."

Notwithstanding, however, the extorted testimony of Professor Barlow, and Dr. Hutton, that Leibnitz used the term *vis viva* as here stated, your reviewer is perfectly sceptical upon the point, and boldly asserts "that Leibnitz never did anything half so absurd as is here said of him; that he did do so, is however a matter of fact, for here are his own words:"

"Hence the quique duplicis: alias elementalis, quae et maritum apellat, quia in eo nondum excitat motus, sed tantum sollicitudinem ad motum, quas est globi in tubo, aut lapidis in fune, etiam cum adhuc vinculo tenetur; alia vero via ordinaria est, cum motu actuali conjuncta, quam voco vivam. Et *vis mortuam* quae ad extremum revocatur, et *vis vivam* a centripeta; et vis quam clausura tantum se restituere incipit. Sed in percussione, quae nascatur a gravii jam aliquidque cadente, aut ab arce ad aliquidque resistentia, aut a simulaci causis vis est viva, ex initio vis mortuum impressionibus continuum nata. Et hoc est quad in *magni* fundamentis locutiones insidibus videtur dixit, sicquit, si cum simplici gravitatis nihon compararetur. Eti autem impetus cum vi viva semper sit conjunctus, differre tamen hunc, infra ostendetur." 20

Not content, however, with denying that Leibnitz said that, your reviewer goes on to prove that he did say, your reviewer denies that *vis viva* is a force at all, and says that it is a mere technical term; Dr. Whewell, however, says, "The *vis viva* of a body in motion is a force;" and Professor Moseley, "That the difference between the aggregate work of the accelerating forces of a system, and the total of the *vis viva* accumulated or lost in the system. Therefore, either your reviewer is wrong, or else both Dr. Whewell and Professor Moseley.

He next states that, "in the second problem of the chapter on Statics, the calculation requiring the strain on tie-beams and struts is totally erroneous," to which I answer that the calculation is correct, and that your reviewer is wrong; as he will find if he refers either to Tredgold, 14 Dr. Whewell, 19 Professor Moseley, or Professor Wallace, ("who quotes from Dr. Gregory the very passages which I have incorrectly quoted.")

Your reviewer then extracts the following proposition relating to the centre of gravity:—

"If the particles or bodies of any system be moving uniformly and rectilinearly, with any velocities and directions whatever, the centre of gravity will either be at rest, or move uniformly in a right line." p. 193

Emerson says: "If two or more bodies move uniformly in any given directions, their common centre of gravity will either be at rest, or move uniformly in a right line." 21

Dr. Whewell says: "If there be several bodies, which either all attract and are attracted by a single body or all attract each other, these may be in such a manner that the common centre of gravity will either remain at rest, or move uniformly in a straight line." 22

He then asks a question; "Does the author mean to assert, that if two bodies are moving with different uniform*] velocities in straight lines perpendicular to each other, the common centre of gravity moves in a straight line?" To which I answer very decided, "Yes, I do; and if you are at all sceptical upon the point, if you refer to Emerson's "Principles of Mechanics," p. 67, you will find the truth of my answer demonstrated."

The next objection of your reviewer is to my use of the term, line of rupture; which, however, I prefer to apply to the actual case of rupture of the ground, which takes place when the wall falls, and which then obtains the form of the line determined by the maximum pressure is only an imaginary line, not that on which the ground would really separate.

Your reviewer has quite misunderstood Dr. Gregory, when he asserts, that the conditions upon which he examines the stability of the bridge are "the two points of rupture, equal distant from the crown, the loading symmetrical, and the pier incapable of sliding," no such conditions being assumed, or indeed necessary.

The next paragraph of your reviewer requires no comment from me; the obvious mis-quotations of my words does as much violence to common-sense and grammatical construction, as it exhibits the desire to pervert the meaning of what I actually say.

He then states that I have given certain experiments (which he extracts) 23 as the foundation of dynamics and, in place of an enumeration of the three laws of motion, which is not the fact: I have merely employed them to illustrate the necessity of regarding time in estimating the forces of moving bodies: see Atwood, 24 Barlow, 25 and Hutton.

Your reviewer next finds fault with my using the expression, "the particles of matter resist motion;" and he says that Dr. Whewell repeatedly uses a similar expression—"the inertia of the particles to resist the communication of motion;" and that M. Poncelet, in the introduction to his Mécanique Industrielle, has revived the term *vis inertie,* and has associated with it the deifying forms for indicating the resistance to the acceleration or retardation of a body's motion.

Your reviewer next takes objection to the assertion, that (neglecting the effects of friction) if a body suspended from a fixed point by a flexible string, have its path altered by a projecting pin; it will rise to a height equal to that which would have done if not so interfered with; Dr. Young, however, speaking on this subject says: "We may alter the form of the path in which it descends, by placing pins at different points, so as to interfere with the thread that supports the ball, and to form in succession temporary centres of motion; and we shall find in all cases, that the body ascends to a height equal, to that in which it descends, with a small deduction on account of friction." 26

After stating that Dr. Gregory's definition of the centre of gyration is "confused and inaccurate," although identical (as he will find by reference) with that given by Dr. Hutton, 21 by Emerson, 22 and by Professor Barlow, 23 he proceeds to show by reference to the "fable of the wolf and the lamb," that one of the propositions relating to the centre of gyration cannot be correct, and arrives at the certain conclusion that the author (as also Emerson, from whom the present statement is taken) did not clearly understand the subject on which he wrote.

Emerson's Proposition.

"If the matter of any gyrating body were actually to be placed in its centre of gyration, it ought either to be disposed of in the circumference of a circle, whose radius is 5 S, or else into two points, diametrically opposite, and equal and equidistant from S." 27

Your reviewer merely says; "This is not true."

Proposition Criticized.

"If the matter of any gyrating body were actually to be placed in its centre of gyration, it ought either to be disposed in the circumference of a circle whose radius is R, or at two points R, R, diametrically opposite, and each at the distance R from the centre." p. 230.

Your reviewer next informs us that centrifugal force is not actually directed toward a fixed centre, in which I perfectly agree with him, and am not aware that any person has stated the contrary.

He then points out an error of Dr. Gregory's, relating to fly-wheels, which had escaped my observation, and one of my own, in question (1) page 57, which should read E + D = E + A + D; but which fortunately does not affect any other part of the subject.

He then states that the total forces of longitudinal compression and tension are equal and opposite; this, however, only the case when the applied forces are perpendicular to the beam, for when

inclined at any angle, Professor Moseley has shown that the
difference of the forces of compression and tension is equal to the
resultant of the applied forces multiplied by the sine of the angle
which it makes with the normal to the neutral line at the
point of rupture."

In conclusion, if your reviewer is right, it follows that Dr.
Hutton, Dr. Young, Professor Barlow, Dr. Whewell, Professor
Moseley, Professor Wallace, Emerson, and Tredgold, one and all
of them, must be wrong; but I think that any reasoning man will
require something more, to convict him of such an absurd
conclusion, as these men, who have hitherto justly been regarded
as authorities on the subject, are, false, than the mere denial of
an individual writer. Considering, then, with whom it is that your
reviewer is at issue,—not with Dr. Gregory and me, but with all
the first mechanical and mathematical writers who have lived;
would it not have been wiser, had he assumed a little less positive
tone in his attempts to lay down the law?

London, July 15, 1848.

I remain, &c.,

Henry Law.

---

Mr. Law cannot accuse us of want of good nature, for we print his letter at full length. We had no original prejudice against Dr.
Gregory's book. The author has a kind of celebrity from his position at Woolwich, and from having written copiously, which, though he has based many of his statements on Professor Moseley's assertions, as if to imagine him capable of compiling a book like the present without
gross and systematic blundering. The first two or three mistakes occasioned a little surprise, but were charitably attributed to
inadvertence. It was only slowly and reluctantly that we yielded to
the conviction, that the book was radically and essentially
unsound, and that a real mathematician could not by any chance have
written it.

Still, we clung to the hope that Mr. Law was guilless of the various
delinquencies to which he had given his editorial sanction. It was,
at least, a good-natured excuse—a pious fraud, to delude
ourselves and readers with—that he had uttered false coin, not
well knowing it to be spurious. Alas! even this pleasing self-
delusion is destroyed.

The various subjects of discussion are not questions of auth-
ority, but of reason. If Newton, Lagrange, and Laplace were to
arise from the dead, and assure us that they had discovered the
ordinary multiplication table to be incorrect, not even their united
testimony would produce conviction in our minds. We may as
well set out by avowing, that if those illustrious names were quoted
in support of Dr. Hutton and Mr. Law, even they would not produce the slightest change in our convictions. We should feel
perfectly certain that their words were misquoted, or strained
beyond their intended signification, or,—(out it must come) that
they had lost their wits.

Our task is a very simple one as regards the definitions; it is
to refer Mr. Law to places in which he will find them correctly
drawn. That Barlow, Hutton, and Young, have fallen into the
same mistake as Dr. Gregory, only corroborates an opinion inde-
pendently arrived at—that they were just the men to do so. The
distinctions between the cycloid and the trochoid are given
correctly, and in exact accordance with our criticism, in Hall's
"Differential Calculus, and in page 137 of the "Examples on the
Differential Calculus," by the late D. F. Gregory, fellow of Trinity
College, Cambridge, one of the most profound analysts in Europe
—and therefore a very different mathematician to Dr. Gregory of
Woolwich.

Professor Pescock, in his collection of Examples on the Cal-
culus, distinguishes in a similar manner, between the cycloid and
the trochoid. The other curves in question are thus defined by him,
page 192:—

"If one circle revolve upon another as its base, and in the same plane
with it, it is called the Epicycloid, which becomes the Epitrochoid when
the describing point is in the circumference of the revolving circle. If a
circle revolve in a similar manner upon the concave part of the circum-
ference of another circle, the curve described by a point in its plane is
called the Hypocycloid, which becomes the Hypotrochoid when the point
is in the circumference."

The definition of equilibrium criticised by us, begins "When
forces that act upon a body destroy or annihilate each other's
operation, so that the body remains quite stationary." If we accept
the words as they have been generally adopted by persons
who speak and write the English language, it is here asserted that
if the forces acting on a body destroy each other's operation, the
body must be at rest. It is wearying to have to repeat the cor-
rection of so obvious a blunder, but we have again to tell Mr.
Law, that the case of uniform motion has been carelessly over-
looked by his author. On Dr. Whewell's authority, it is declared
that statical forces are called pressures; but he does not deny that
we asserted, that dynamical forces are called pressures; and
repeated instances of such a use of the expression, may be
found in his works.

Dr. Gregory's assertion as to the manner in which Leibnitz used the
term vis viva, is said to be confirmed by Barlow and Hutton.
However, we need not inquire at second-hand what Leibnitz, did,
or did not say, because his very words are quoted at length. Now,
does Mr. Law really mean to assert that in the Latin quotation
vis viva is called a force? If so, all we can reply is, that he dis-
plays considerable fortitude under trying circumstances.

The Latin quotation first specifies the cases in which the two
things called vis mortua and vis viva respectively exist—the former
where there is no motion, and the latter where there is motion.
Then it is added, that "where a body has been some time falling, or
a bow has been some time unbending itself, or in any similar case,
there is a vis viva, generated from the continuous infinite impres-
sions of vis mortua,"—a perfectly distinct recognition of the truth
which we asserted, that vis viva is not force, but something generated by it.

Of course, the true interpretation of the phrase must be obtained
from the context—not from an arbitrary translation of the word
viva, which has a great diversity of meanings.

A few words on the application of the principle of vis viva is so
clear, that it is really marvellous that Mr. Law did not perceive
that he quoted an authority decisive against him. He says vis
viva is a force; Moseley, that it is equal to a certain amount of
work of forces: "work" being previously explained to be the pro-
duct of force and distance, and distance equal to that which
the vis viva is not said to be work, but to be equal to work. Twenty
shilling is equivalent to a sovereign, but they are not a sovereign,
but differ from it in weight, size, colour, and almost every other
particular, except current value.

We will follow the example of printing the contradictory state-
ments side by side. The case then between the authority last
quoted and our present correspondent, stands thus:

Mr. Law.

Vis viva of a body "is the whole mechanical effect which it will
produce being brought to a state of rest."

Professor Moseley.

The difference between the ag-
gravity weights, and the resisting forces of the system and that of the
retarding forces is equal to one-
half the vis viva accumulated or lost in the system.

The discrepancy between the "whole" in the one quotation, and the
"one-half" in the other, would be a fatal objection to Mr.
Law's views if no other existed.

The following definitions, in which, be it observed, "force" is
not even mentioned, are conclusive as to the use of the phrase vis
viva among modern mathematicians:

"The vis viva of a particle is the product of its mass and the square of
its velocity."—Earsham's Dynamics, page 127.

"Since the publication of D'Alembert's work, the term vis viva has been
used to signify merely the algebraic product of the mass of a
moving body and the square of its velocity."—Walton's Mechanical
Problems, page 257.

"The sum of all the bodies of a system each multiplied into the square
of its velocity is called the vis viva of the system."—Whewell's Elementary
Treatise on Mechanics, page 292.

"The term vis viva is still used to express the product of the mass and
the square of the velocity."—Pratt's Mechanical Philosophy, page 202.

"Un apelle force viva d'un point matériel, ou, plus généralement, d'un
corps dont tous les points ont la même vitesse, le produit de son masse par
le carré de cette vitesse."—Posseco Traité de Mécanique, tom. ii., page 29.

The proposition respecting tie-beams was condemned by us because
some of the forces acting on the beam and strut are neglected; and we showed
as corroborative proof of the incorrectness of the solution,
that it led to an absurdity. Of all this our correspondent takes
no notice; but refers us to Moseley and Whewell. If it is true,
that both these references were relevant, which they certainly are not,
they would not justify a palpable and obvious error; and we must
tell Mr. Law plainly, that we should have had far more respect
for him as an opponent, if he had made the necessary correction,
instead of endeavouring to entangle us in quotation, to authorities so
dear to him. As for Professor Wallace's adoption of the
problem, we can only say that in this instance he has made an un-
fortunate selection.

By inserting the word "uniform," in quoting our remarks upon
page 193 of the "Mathematics for Practical Men," Mr. Law
makes us talk nonsense. However, we freely admit that we have

356
From the manner in which Mr. Law meets our criticism upon his author's erroneous definition of centrifugal forces, we infer that he finds there is no tenable defence. He also candidly acknowledges, that in respect of his former, he has nothing further to say of them. Our remark on the equality of the total forces of compression and tension in a beam, were manifestly restricted to the particular case under examination—that where there are not appreciable horizontal forces acting externally on the beam. On the other hand, in respect of the latter, he never discusses any question on its own merits. He contented himself with appealing to authorities. This course is at least dexterous, for with the unlearned an array of imposing names is but too apt to carry conviction. The authorities quoted, are, however, easily disposed of; several of them are of little weight when opposed, as we have shown them in several instances to be, to the most profound continental writers. The rest of the citations are either irrelevant, or make directly against Mr. Law's tenets. Had he suffered the controversy to rest on its own abstract merits, our task would have been much more to ourselves, and more satisfactory to the cause of truth. It would be an insult to his understanding, to suppose that he did not perceive that many of the errors which he defends by quotations were, in reality, indefensible in any other way. Causality and perverse ingenuity, however well suited for mere disputation, are never the weapons of a man of science.

Mr. Law seems very fond of appealing to Woolwich Professors. Why did he not quote Mr. Davies or Mr. Rutherford—gentlemen who have acquired for themselves reputations not confined to the regions of Woolwich? It is very unfortunate, that the only works written by Woolwich men which we have lately had to review, have been anything but very creditable to the scientific character of that institution; and this the more to be regretted, since, as we have already hinted, inaccuracy in conceiving physical ideas, and clumsiness in developing them analytically, are not common to all the Professors—at least to all the Teachers—of the Royal Academy.

**SANITARY LAWS AT HOME AND ABROAD.**

The most destructive scourges of the human race are the epidemics and contagious diseases produced by polluted atmosphere, and the congregation of men in crowded cities. Famine and the sword slay their thousands—the pestilence that walketh at noonday and in darkness its tens of thousands. The ravages of war and want are, partially at least, within human control; but when the diseases acting among nations which kill; which make the very quickest “pestilence,” human skill and energy are all but powerless against him. This sudden destruction, moreover, is not all that is caused by the infected air and artificial habits of populous places. The maladies indirectly induced, the remote consequences of a morbid habit of body which renders a kind of soil for the future seeds of death, the degeneracy of sickly offspring who reap in a later generation the bitter fruit sown by their parents—these are among the penalties which the denizens of large towns too often pay for inhaling the hot vapours of the foundry or furnace, or breathing the stagnant air of crowded courts and lanes, where overhanging house tops shut out the pure breath of heaven.

Prevention is almost the sole defence against these evils; for when once developed, they are either too sudden or too deeply rooted to admit of effectual remedy. A curious chapter in the history of the internal economy of states is that which the various sanitary provisions adopted under different forms of government. Nations working for the same end, the public health, seek it by entirely different means. On the Continent, where the rights and liberties of individuals seldom constitute a serious obstacle to State purposes, the most stringent sanitary regulations have long existed and the surveillance of police, which is almost unknown in England, constitutes the principal means of effecting them. Here, the public jealously of state interference, and a sensitive regard for the rights of property, have long prevented the institution of a properly organized sanitary system under Public Health Act, which will soon be the law of the land, makes the first provision for such a system in England; and it becomes, therefore, interesting to compare it with the machinery adopted for the same purpose by our continental neighbours.

The scheme printed side after the next paragraph, amount to this: If a body be in one place, quoth Emerson, it ought to be somewhere else. To which Dr. Gregory responds, Amen.
functions of these former and latter are entirely distinct, they may be
stated separately.

The Central Board of Health consists of three commissioners, and
the President is the first Commissioner of the Woods and
forests for the time being. These, and purchase private surren-

dation of one-tenth of the rated inhabitants of any town, may direct
an examination as to its sewerage, drainage, supply of water, &c.;
and after hearing the representations of parties locally interested,
may report to her Majesty. An order in Council may then be
made requiring the application of the Act in cases where
existing local Acts are not infringed upon, and the local boundaries
are intended to remain unaltered. This order simply directs that
the Act, or any part thereof, is to be put in operation.

Where, however, it appears necessary to alter the constituted
local boundaries for the purposes of the Act, or to apply in case
where local boards are not known by the order in council is
not made; but the General Board of Health have power to make
such a provisional order for the application and execution of the
Act as they may deem fit. This provisional order cannot be carried
into effect until it have been sanctioned by Parliament. The orders
issuing either from the Privy Council, or from the General Board
of Health may, from time to time, be amended or extended, after
due notice to persons locally interested.

The only other functions of the General Board are to determine
appeals from certain decisions of local general boards, and to regu-
late the manner of calling in and out, by certifying to, upon the request of
the local boards, that certain places of interment are dangerous to
health, and appointing a time after which it ceases to be lawful
to bury in such places.

The Local Boards have much more diversified duties. When
the whole or any part of the town is governed under this act is within a corporate
borough, the corporation constitutes the local board. In other
cases, it is selected by rate-payers. The offices assigned to it are
chiefly these—to appoint inspectors of nuisances and officers of
health—to prepare maps exhibiting a system of sewerage—to as-
sume the cost of sewerage and sewers— to alter, extend, and cleanse the same—to cleanse and water public
streets—to provide for public health insurance—to register or provide and
regulate slaughter-houses—to prevent (subject to an appeal to the
general board) the establishment of noxious manufactures, and the
erecting, expanding, or erecting the manufacture of
large building, without proper means of ventilation—to register, and
if necessary, cleanse, or disinfect common lodging-houses—to
restrict the use of underground cellars as dwelling-rooms—to
level and pave streets—to move water or gas pipes, provided that
their use and efficiency be unaffected—to prevent (subject to ap-
peal to the General Board) the laying out new streets of ob-
jectionable width and level—to purchase premises for the purpose
of widening streets—to provide public walks and pleasure-grounds
—to construct water-works—to compel occupiers of houses to
receive a proper supply of water; and so on. Rates, for gratication,
are to levy rates for the purposes of this act.

In cases of damage by the acts of the Local Board, compensation
is to be made; and if its amount be disputed, it is to be settled by
arbitration. The bye laws of the local boards are to be sub-
mitted to the Secretary of State for the Home Department for his
approval.

It will be seen that in the actual administration of the act, little
or nothing is assigned to the Central Board. The power is almost
entirely in the hands of the Local Board, which is not amenable
to the General Board for acts of omission or commission, except
in one or two instances above referred to, in which appeal may be
made. And as the Local Boards are popularly selected, the power
of putting the act in force ultimately belongs to the great body
of inhabitants of the districts affected. There seems, therefore,
little reason to fear that people will be compelled to be clean, and
drink wholesome water, and breathe fresh air, against their own
free-will and consent.

On the Continent, however, the popular voice is not heard on
these questions; and the power of enforcing measures for public
health, is vested almost exclusively in central or government boards. In
England, the greater stringency of sanitary regulations with France and
Germany, the practical effects of them have been even more imperfect
than in England. In Paris and Vienna, the sewerage, drainage,
paving, lighting and cleansing of streets, are far less complete than
in London. In Paris, there are no cattle markets within Paris, and the slaughter-houses are
removed to the suburbs. Vitriol manufactories, and similar
abominations, are not suffered to pour their pestilential vapours
into the very heart of the city, nor consume human life and vege-
tables in the close vicinity of this metropolis. Intra-
mural burials have long been prohibited in Paris, and are of very
rare occurrence.

The sanitary state of the capitals of France, Austria, and Eng-
land, is partially indicated by the rate of annual mortality. It
was the returns of the Registrar-General, published in 1844, that the average annual mortality for every hundred inha-
bilants of

Vienna, is about 4-988 per cent.

Paris (department of the Seine) 3-058

London 2-398

But, of course, the rate of mortality is influenced by many other
considerations besides sanitary regulations; the vicissitudes of
climate and the habits of the people having important effects on
the duration of life.

It is comparatively recently, that Paris assumed the appearance
of a well lighted and well paved city. The idea of paving it is said by Fodére, a copious writer on the hygiene of France, to have
originated with Philip Augustus, who, looking out of his palace
window one rainy morning, and surveying the marshes in which
his capital was built, conceived the brilliant idea that it would be
better to build a city on the site of them. So early as 1486 an ordonnance of the French Prieuré of Paris prohibits
the erection of noxious and offensive manufactories within the town;
and the records of French municipal law refer to many subsequent
regulations of a similar kind. No very effectual or important
measures have been taken, till the time of Louis XVI, the
revolution; and to Napoleon, the most uncompromising of
reformers, is due the credit of founding the present system of law
regarding public health. His attention having been directed to the
insufficiency of the existing laws on the subject, the Academy of
Sciences was summoned, and the class of physical and mathematical
science reported to the Government, on the effects of various
manufactures on the health of the people. On this report was
founded an imperial decree of 1810, subsequently confirmed by a
royal ordinance of 1813, which, with some modifications suggested
by the evidence, establishes the health code of Paris. For an account of it we have consulted, amongst other
works, that of Fodére, last cited; "Traité des Etablissements d'Urbanisme" (8vo, Paris, 1833),
"Père Duchatelet's Prostitution dans le Vile de Paris" (8vo, Paris, 1838); and the "Hygiène Publique," of the same author.

The principal feature of the decree of 1810 was the division of
noxious and offensive trades and manufactures into three classes,
the first consisting of those so prejudicial to health and vegetation as
to be required to be moved to a distance from human habitations;
the second consisting of those which occupy less space in the
three last classes. The distinctions between these three classes are carefully defined, and
the exactness of the definition is practically of great importance,
as the mode of applying for licenses for their establishment are
different for each. The formalities necessary previous to the erection
of a manufacture of the first or most dangerous class are very
numerous and stringent. After notice publicly advertised of the
intended application for license, the Mayor of the commune (or in
Paris the Commissioner of Police), reports on the nature of the
localities infected, the distance of habitations, and the character
of the processes to be employed. This investigation is technically
termed the inquiry de commodo et incommode. His report is referred
to the Conseil de Salubrité, a body which takes cognizance of
the establishment of all manufactures, which are "classified," or
included in either of the classes above-mentioned. The Conseil de
Salubrité delegates a sub-commission of its own members, to
examine the locality of the proposed manufacture, in company
with the Mayor, and to report upon the nature and importance of
the manufacture, its salubrity, or inconvenience, the rate of flow
of water required in its processes, the sufficiency of the apparatus,
the merits of the principles on which it is constructed and applied,
and the provisions thought necessary to prevent the introduction of any
conditions on which license should be granted. This report of the
sub-commission is presented to, and discussed by, the general
board. Among the other functions of the Conseil de Salubrité
included the inspection of barrack, prisons, markets, and other
public buildings. In Paris there are similar bodies at Marseilles, Lille, Bordeaux, and other large
towns.

The Architect-Commissary is another public officer who discharges
most important and valuable duties. A detailed plan of the pro-

1.8 A.P.
THE CIVIL ENGINEER AND ARCHITECTS JOURNAL.
of impure substances which can be deposited in it during the period.

In Austria the sanitary institutions of the whole empire are placed under one general system, which appears to be carried out with the greatest effectual manner. The laws relating to public health belong to the best part of the imperial code; and there are few countries in the world of which the medical institutions are conducted on such a magnificent scale. The administration of them is entrusted by the Austrian Government to a duly qualified corps of officers, the officers of whom, known as is a chief officer, called the Proto-Medicus; and in every circuit there are sub-officers, who constitute boards of health for their own districts. The functions of the Proto-Medics are to inspect medical institutions, hospitals, lunatic asylums, and prisons, to regulate the medical police, and report on epidemics. The poor-law system of Austria provides for the gratuitous supply of medicine to the poor, and the attendance upon them by the district medical officers.

The Austrian police inspect all food exposed for sale, and have the power of examining houses and lodges to ascertain that they are in good and healthy condition. All burial grounds are required to be at a distance from towns, and the instances in which burial in family vaults is permitted are exceedingly rare.

The vicinity of Turkey renders the quarantine laws of Austria very strict. A military cordon of 4,500 men is always maintained on the Turkish frontier, and the number can be increased to ten times the number in times of danger. Owing to the vigilance thus exercised, it is asserted that the plague has not crossed the frontier for upwards of a century.

On the whole review of the Continental and English sanitary systems, the essential distinctions between them appear to be that the Continental is carried out by central, the latter by local, government; the former makes public health a matter of state policy, the latter of popular discretion. Our own system has the advantage of pleasing the governing power in the hands of those whose personal observation renders them the best judges of local wants, and generally the most sagacious. For the purposes of health, the question whether they will prove also the most strenuous promoters of sanitary improvements, must be determined by experience alone. In numerous cases, the intelligence of the people will dictate, that public health be regarded as the paramount object. Other local bodies, from motives in many cases, for providing the means of health, or from apathy, may decline to exercise vigorously the powers of the most confided to them. Yet, these cases will be exceptioned; for the most prejudiced and the most indifferent must learn, sooner or later, that sordid neglect is never cheap. Health is wealth; for health gives energy and hope; and these beget industry and frugality, which are the sources of all wealth. But equal to and disorder are life-consuming, and the very canker-worms of social existence: they beget sloth and indifference—and these are spendthrift: they beget crime and disease—and these destroy.

**WATERLOO EXTENSION OF THE LONDON AND SOUTH-WESTERN RAILWAY.**

The extension of the London and South-Western Railway from Nine Elms to Waterloo-bridge, was opened on the 11th ultimo. It appears to us that it would have been far better if the Waterloo Station had been made as the vacant ground adjoining, north of the present Waterloo terminus, and the principal entrance in York-road. The entrance to the railway would then have been as near to Westminster and Hungerford-bridges as it is now to Waterloo-bridge, without increasing the distance to the latter place, or the length of the railway. This alteration might now be easily made; it would save nearly half-a-mile, and eight minutes' walk, to foot passengers from Westminster and Charing-cross; the present approaches might be retained for a good depot—and if a steam-boat pier were made adjoining to the railway approach, the most delightful of the two would be made with the steam-boats to come direct from London-bridge to the pier, the extension of the railway to London-bridge might be abandoned, and thereby nearly a million sterling saved. This would, we are sure, enhance the value of the shares, and give confidence to those capitalists in the city who are now alarmed at the apparent reckless manner in which funds are being expended by railroads on branches and extensions.

The works of this undertaking were commenced in July 1846, by Messrs. Leé, the contractors, who engaged to complete the whole...
STEAM-ENGINE GOVERNORS.

We give the following extract of the Daily News, from the police reports of the Manchester and Bolton police, in allusion to the following errors in our Journal, and to state that we were much surprised, after the exposure of the letters therein given, that Mr. Cousins should have had the audacity to send us the paper for publication. Immediately after its receipt we reported the matter to the police; and since then we have had a confidential and trustworthy paper on Steam-Engine Governors, which Mr. Cousins sent us previously to the appearance of the police report. We trust that Mr. Woods' laudable resolution may deter others from attempting a similar proceeding. It is fortunate for Mr. Cousins that he had such a lenient magistrate to hear the case.

Manhole-House, July 23, 1848—Alleged Attempted Extortion of Money.—Mr. R. B. Cousins, of No. 4, Bedford-place, Old Kent-road, appeared to answer a charge of having offered to prevent the printing and publishing of certain matters touching the complaint with intent to extort money. The charge was brought upon the 6th and 7th Vic., cap. 46, sec. 3, and it was stated, for the prosecution, that the defendant had by means of the following letter endeavored to accomplish his purpose:

[Letter not transcribed.]

Upon the receipt of this communication I was induced to withhold the pamphlet from publication, unless some settlement was arrived at; and I now desire to hear from you as to the propriety of withdrawing the pamphlet, and also as to the amount which I may be asked to pay as compensation for the injury which it is supposed I have suffered.

R. B. Cousins.

To Joseph Woods, Esq.

Upon the receipt of this communication Mr. Woods sent to the writer a note, to which the following answer was returned by that gentleman:

[Note not transcribed.]

The letters were published in error. The printer has, however, been restrained from further proceeding.

SAFETY IN LANTHAMS.

The safety in lathoms, as ofdesigne on for the Magazine Journal the following description of a mining lathom that he has invented. The annexed drawing is a representation of the safety-lanthom—it is adapted to burn composition candles and keeps the air pure. The same principles can, however, be applied to oil lamps, if any party prefer oil to candles. The front is made of strong glass; the back of polished tin—the two lateral sides of wire gauze, soldered to the framings, having 900 apertures in a square inch of the gauze. It will do coarser, but the state is made safes. Over the wire gauze sides are fixed covers of tin, which is soldered to the lathom, which entirely cover the sides, and are kept fast by a small hump at the bottom. The lower edge of each tin cover is bent inwards to rest against the gauze sides in such a way that the tin cover is about a distance of 1 inch from the wire gauze. Suitable space is thus provided to allow of the passage of air for the supply of the light. These wire gauzes are useful to protect the wire gauze from injury and dirt, as well as to stop any current of air, or "blowers," of gas from blowing out the light. No direct current of wind can have any effect upon the light, because the wire gauze is soldered into the lathom but obliquely at each corner. The gauze is held between four short wires, soldered in the die of a moveable socket, which is fixed in a socket soldered to the bottom; this socket gauze is useful for retaining any waste fat that may run down; it can be lifted out when the lathom is not in use. The central part is a large ring, by which the lathom is carried and hung up. This ring is kept cool by a simple, but effective, contrivance. A piece of tin, bent into the form of an inverted cone, is soldered inside the lathom, which causes the hot ascending air to flow through the lathom, without getting too near the sides. The gauze lathom will never become red hot, and the invention, consequently, is of great value.

The Sope Plant.—In California this plant is used by the people for washing every description of clothing in cold running water. In using it, the women, out of the roots of the bulbs, rub them on the
clothes, when a rich and strong fibre is formed, which cleanses most thoroughly. To propagate the plant the bulbs are set in a rich soil, and grow luxuriantly in the soft bottoms of valleys or bordering running streams.

**Better Sheathing.**—A correspondent of the Mining Journal states, as the consequence of his experience, that, in the treatment of the sulpharates of copper, there should be one calcining, one roasting, one smelting, and one refining—four operations in all; and that care be taken that no iron tools are used in the ladles for the latter. In the refining of copper require only two operations—smelting and refining; but if copper perishes be mixed with the carbonate, it will require three operations instead of two. By attention to these operations all foreign matter will be dissolved. The production of good malleable and pure copper depends on the refiner; the copper is brittle before, and should be stirred with a wooden rod. It requires considerable care to keep the metal a proper heat until the moulding is finished, to give it due ductility, and to avoid breaking it. To avoid overheating in smelting, in general, most smelters go too far in the refiner, which renders the metal fibrous, and the result is serious lamination on one side of the sheet. If the copper ore is properly treated in the above operations, this metal is decidedly the best for ships’ bottoms. The copper ore is also much increased by careful treatment, and the sooria comes out cleaner.

**Method of Welding Iron, Steel, and Sheet-Iron.**—In an earthen vessel melt borax, and add to it ¼th of sal-ammoniac. When these ingredients are erected vertically at any convenient part of the anvil, an iron plate and let them cool. There is thus obtained a glassy matter, to which is to be added an equal quality of quicklime. The iron and steel which are to be soldered, are first heated to redness; then this compound, first reduced to powder, is laid on the spot which is to be soldered, and runs like molten lead. The pieces are then placed in the fire, taking care to heat them at a temperature far below that usually employed in welding: they are then withdrawn and hammered, and the surfaces will be found to be thus perfectly united. The work of this process, as well as may be applied to welding sheet-iron tubes, never fails—*Rec. de la Soc. Polytech.*

**Dolly Electric Telegraph.**—A patent has been recently granted in this country to M. Dujardin, of Lille, for a new kind of electric telegraph in which the dearness of data is ruled out, the apparatus consisting of a piece of wire fixed to a magnet, and it marks dots on a revolving traversing cylinder. The dots, by a previous alphabetic invention, are made to signify letters, each letter being characterised by a certain group of dots. The process is complicated, and must necessarily be a slow one; nor does it appear that it has been to have been adopted. The system of M. Morse, which accomplishes the same object more efficaciously, and with a much less complicated mechanism; Mr. Morse’s alphabet consisting of short and long strokes, by which means the letters of the alphabet may be indicated by a small number of marks than by any dots of the same size.

**Time Signals.**—Mr. Torrope, of Edinburgh, has patented an apparatus for giving notice of the approaching departure of railway trains, so as to supersede the use of bells or whistles. The apparatus consists of a hollow pole erected vertically at any convenient part of the station, where it may be most advantageously seen by both those at the station itself, as also by those hastening towards the station. Upon the outside of this pole is placed a large ball, the pole passing through a hole through the centre of the ball, and being fixed to the top of the post. A spring is also placed down the pole, suspended by cords, attached at the bottom of the pole to a clockwork movement, having a pendulum, the vibrations of which regulate the descent of the ball upon the pole. When the spring of the clockwork is wound up, the ball begins its descent at the top of the pole, which then begins to descend. The ball, falling to the bottom of the pole, being regulated in its velocity by the clockwork and pendulum. The time of its descent will therefore be regularly the same each time the ball is raised to the top and then allowed to descend. The ball being raised to the top of the pole at the adjusted period of time (say ten minutes before the departure of each train), and then allowed to descend, the position of the ball upon the pole during its descent will give notice of the length of time to elapse before the departure of the train. During the night a lamp is put to the place of the ball.

**Difference.**—An invention recently tried in the Court of Queen’s Bench, the question was raised whether the variation of three degrees in the inclination of a wood pavement constituted an infringement of the patent right. The defendants (Duffield and Co.) were licensees under Bankhead for laying pavements, and the plaintiff entered into a covenant with them to pay certain royalties if they infringed upon the principle of Parky’s patent. The principle was the inclination of the fibre of the wood to the horizon; and that described to be from 40 to 42 degrees. The defendant’s pavement was laid at an angle of 40 to 42 degrees, and at a bridge at Chalk-farm; and the blocks they laid down were at an inclination of 73 degrees. The contention for the plaintiffs was, that although the inclination was not within the precise words used in the deed, still the action could be maintained, as it was the slightest difference between 73 degrees and 70 degrees.—Mr. Justice Wightman, in summing up, observed, that if parties chose to bargain in specific terms they must abide by their bargain, and though in practice the two inclinations mentioned coincided, still the dedication of the covenant was such that unless, unless the inclination adopted by the defendants was within that limit, the plaintiffs on that ground were not entitled to recover. The jury therefore gave a verdict for the defendant, the plaintiffs having liberty to move to enter a verdict of 50l. 1s.

**College for Civil Engineers.**—On Tuesday the 18th ult., the yearly examination of the students of the College for Civil Engineers was held at a Putney, and was attended by H.H.H. the Duke of Cambridge, and many of the aristocracy, to the large number of over 100 persons, advancing in public opinion. We inspected the drawings, models, workshops, and other practical departments, which we are happy to say show considerable advancement in the knowledge of engineering. We were shown on such an occasion, and an Institute of Architects, to the latter year, in the workmanship of such schemes as the locomotive and air-line. A model of Hero’s rotary-engine; for in an establishment like the college, it is better to be too far behind-hand, than to be suspected of running after what savours of visionary projects.

**LIST OF NEW PATENTS.**

**GRANTED IN ENGLAND FROM JUNE 24, TO JULY 18, 1848.**

**Six Months allowed for Enrolment, unless otherwise expressly ordered.**

Deane Samuel Walker, of London-bridge, merchant, for "Improvements in the manufacture or handling of brewing-stocks, and of all kinds of cafe-au-lait," June 24.

Henry Archer, of St Albans, Worcestershire, for "Improvements in the manufacture of certain metals from certain ores," June 24.

Richard Clark, of the Strand, Westminster, lamp manufacturer, for "Improvements in the manufacture of gas-burners," June 24.

Frederick William Mowbray, of Leicester, paper-dealer, for "Improvements in the manufacture of leather," June 25.

John McElwain, of Glasgow, for "Improvements in water works," June 25.

Joseph Skerry, of Great Yarmouth, for "Improvements in the manufacture of coal," June 26.

Eliza Beardsmore, of Harrogate, for "Improvements in the manufacture of soap," June 26.

John Martin, of Killyleagh, County Down, Ireland, manufacturer, for "Improvements in the manufacture of paper," June 26.

William Edward Newton, of Chancery-lane, Middlesex, for "Improvements in the manufacture of pewter," July 1.

Walter Orbe Palmer, of Southwark, for "Improvements in the manufacture of space," July 1.

John Stowell, of Fleet-street, London, civil engineer, for "Improvements in the manufacture of soap," July 1.

George Beals, of Edinburgh, builder, for "Improvements in the manufacture of soap," July 1.

Anthony Forrester, of Bath, for "Improvements in the manufacture of soap," July 1.

Walter Parke, of Pembroke, Hereford, brick-maker, for "Improvements in the manufacture of bricks," July 1.

John Snow, of Kent, for "Improvements in the manufacture of soap," July 1.

Matthew Kirby, of Upper, engineer, for "Improvements in the manufacture of soap," July 1.

Felix Alexander wound* de la Resraud, of Paris, engineer, for "Improvements in the manufacture of soap," July 1.

Jesse Ross, of Leicester, agent, for "Improvements in apparatus for dibbling and other agricultural purposes, part of which improvements is applicable to propelling vessels," July 1.

William Edwards Stark, of London-district, City, gentleman, for "Improvements in the manufacture of electrical apparatus, and in the application of electricity and magnetism for the purposes of lighting and signalling, as also in papers and stations for conveying and transmitting telegraphical communications between distant places and places otherwise than by electro-magnetism," July 1.

Joh Loussouze, of Passage, Touffy, Paris, jeweller, for "Improvements in the manufacture of Jewellery," July 1.

James Patrick, of Liverpool, dock-master, for "Improvements in the manufacture of metal," July 1.

Jean Louis Lamensode, of 30, Passage Touffy, Paris, jeweller, for "Improvements in the manufacture of Jewellery," July 1.

Charles Purcell, of Liverpool, dressmaker, for "Improvements in the manufacture of metal," July 1.

Joseph Spencer, of Northampton, engineer, for "Improvements in the manufacture of metal," July 1.

Johann Arnold Rieckel, of Leicester-district, Leicester-square, Middlesex, gentleman, for "Improvements in the manufacture of metal," July 1.
THE CIVIL ENGINEER AND Architect's Journal

No. 131—VOL. XI.—SEPTEMBER, 1848.

CANDIDUS'S NOTE-BOOK,
FASCICULUS LXXXV.

"I must have liberty
Within, as large a charter as the winds,
To blow on whom I please."

I. Architects are apt to pay by far too little attention to locality, aspect, and other circumstances which influence the effect of buildings;—such, for instance, as distance—too little space for obtaining a satisfactory view from any point, or so much that it looms diminutive in comparison with the objects with which it is to be seen, whether shown in a model or a drawing of it (that is, an elevation), promises. Neither the model nor the elevation conveys, or can convey, the slightest idea of locality; and even if recourse be had to perspective and pictorial representation, the probability is, that there is a space, whether real or imaginary, that has passed off under the insusceptible and innocent name of artistic liberties. Liberties of the kind are, however, sometimes carried so far as to amount to downright lies—an ugly word, it must be confessed; but the imposition so practised is a far more ugly thing. And surely it amounts to nothing less than a lie, and is not a mover, but rather a stover of a frost that will always be in shadow throughout the whole day, kindled-up and illustrated by sunshine, with all its details sparkingly touched and brilliantly brought out. In Mr. Blore's view of the new building at Buckingham Palace, the sun is made to shine from the north-east; which, not to call it a miracle, is at any rate a piece of great compliment on the part of that luminary—a direct testimony to the all-commanding talent of that Mr. B. Such deceptions are, it would seem, not lies, but merely poetical and graphic fictions; and we ought to congratulate ourselves upon getting anything poetical at all, where the design itself is so terribly prosaic.

II. Localities have so much to do with the actual appearance which a building makes, that unless some information be afforded in regard to it we are totally ignorant and unsuspicious of many circumstances that require to be understood. If a building has been seen, it is of course known how it is situated with respect to other buildings; whether in an open space or in a street; and if a street, whether it is a wide one or a narrow one; or if an open space, whether it is a regular or an irregular one. It is desirable also to know what is its aspect, for it makes a very considerable difference whether a portico or colonnade faces the north or the south—the east or the west. Therefore, if a building is known to us only by means of plans and other drawings of that kind, conceptions of a certain devolution of its parts and its effect on the locality may be derived therefrom. As the plans do not show itself, most picturesquely, were it a worthy piece of architecture, instead of being the abomination it now is. When looked down upon from the parapet of the road, it would be seen rising statellity from a deep substructure. And that west front and the present roof of it, all so lovely and graceful, would, put together, would produce a fine palatial mass, and in combination with Waterloo-bridge, a most striking and noble group of architecture. The river-front itself, which now looks only like the fragment of an unfinished design, would gain in importance by becoming one of a consistently grand design. Besides all which—but let us have done with "besides." We have "Marble Arches," and "Nelson Columns," and "Wellington Statues," and a good many other things that shall be nameless, to show how freely tens-of-thousands have been flung away on very small objects and absurd objects. Let us, then, put an unspeakable public edifice that will serve as a monument of our notable economy and frugality. Therefore, since so it must be, let it even be Somerset-place. Let the foreigner who gazes with astonishment at such an achievement by individuals as Waterloo-bridge, look with astonishment of a different kind—with scornful wonder at the paltriness that is allowed to disfigure and disgrace a government building which might, with comparatively little cost, be rendered a uniformly noble pile.

IV. My good friends, the architects,—the friendship between us is, I know, of the most intimate kind, my own share being marked more by boisterous freedom than by courtesy—still I say my very good friends, the architects, may be said to have contrived to outwit and enslave themselves. So long have they gone on preaching up the accrued and superstitious doctrine that it is not safe to follow established forms and proportions, or from the precise letter of the mechanical; that even those who could do so successfully, dare not even attempt it, so greatly do they stand in awe of the sneers of the whole tribe of

madman, had he advised that the terrace-front should be returned and continued northward, in order to form a west facade that might possibly some time or other be exposed to view, on the side most oft being favoured by such a disposition. He could no more have the idea that Waterloo-bridge would be erected, than that such architecture as King's College would be brought so closely into contact, as to be made to appear part of his design. The bridge has certainly rendered one service to Somerset-place, since it enables us to have a view of the river-front and its terrace. But the formation of the street leading to the bridge has laid open to sight what was never meant to be seen at all, and therefore now detracts sadly from the grandeur of the facade which is beheld in connection with it. The disparity between the two is nothing less than alarming. To feel confident that it is not to that which we should have some experience on beholding a costly sideboard and a kitchen-dresser cheek-by-jowl in a dining-room. The juxta-position which here presents itself is not like that of "pears upon an Ethiope's arm," but of a wanton face upon a consideration of a Blackamoor,—the head of Hebe upon a portion of the carved carcase of a horse—sight to perceive Chambers and Pecksniff arm-in-arm together: no disrespect is intended to the former, he being sufficiently excused by what has been stated above. Still, that is no excuse for our neglecting to do what the greatly-altered locality of the building renders so highly desirable. If it is not worth while to observe the appearance-sake, to bestow a decent architectural exterior on the exceedingly unsightly and disfiguring range of building alluded to, how can we reconcile ourselves to the enormous outlay for mere display of architectural impropriety, and which, after all, does not produce any corresponding degree of effect? Either the "Houses" accuse us of the most niggardly meanness for allowing Somerset-place to remain in the disgraceful and unfinished state which it is; or Somerset-place accuses us of the most abstruse and graphic conceit, in crowding such a profusion of minute details and carved-work into that front of the "Houses" where they are quite lost, and where a few boldly-touched finishing would have told quite as well—perhaps even much better. The west wing of Somerset-place, on the contrary, though at present a most offensive piece of work, and may remain so,—is most admirably situated for architectural display. There is not any spot in the whole metropolis which affords so many of the requisites for a fine architectural scene. That side of the buildings of Somerset-place is favoured, not only by aspect, but by due space before it—neither open, as to take off from the principal face of the building, nor insufficient for viewing it as a whole. To these advantages, other peculiar and accidental ones may be added: the building descends so much below the level of Wellington-street, or the roadway leading to the bridge, that the street becomes as it were a continuation of the bridge, and the view of the building from the bridge is that which one would see first; it would show itself, most picturesquely, were it a worthy piece of architecture, instead of being the abomination it now is. When looked down upon from the parapet of the road, it would be seen rising statellity from a deep substructure. And that west front and the present roof of it, all so lovely and graceful, would, put together, would produce a fine palatial mass, and in combination with Waterloo-bridge, a most striking and noble group of architecture. The river-front itself, which now looks only like the fragment of an unfinished design, would gain in importance by becoming one of a consistently grand design. Besides all which—but let us have done with "besides." We have "Marble Arches," and "Nelson Columns," and "Wellington Statues," and a good many other things that shall be nameless, to show how freely tens-of-thousands have been flung away on very small objects and absurd objects. Let us, then, put an unspeakable public edifice that will serve as a monument of our notable economy and frugality. Therefore, since so it must be, let it even be Somerset-place. Let the foreigner who gazes with astonishment at such an achievement by individuals as Waterloo-bridge, look with astonishment of a different kind—with scornful wonder at the paltriness that is allowed to disfigure and disgrace a government building which might, with comparatively little cost, be rendered a uniformly noble pile.
Incapable, who scout the idea that it is possible for any other than the backers that have been, and who shall be in the future of artistic conception to produce that, though different in character, should be equally beautiful in its peculiar way. Unhappy architects! ye have locked yourselves in, and flung away the key that would open the door and send you forth—the worthy and real, gifted among your region—a true light. Unhappy architecture!—such architecture, also, for thou art now fettered, and delivered over to the tender charge of thy jailor, PRECEDENT!

V. Precedent is adhered to even for that lawless, hybrid style which denounces Elizabethan. No, indeed, has有人 attempted to draw up a formal code of rules and regulations for it; perhaps, because it would have been that very great labour to attempt to systematize so chaotic a mass as the various examples of it constitute; any one of which, however eccentric and exceptional, must have been received as, so to say, elevated and authoritative, and, therefore, allowed to have its convenience; no more being required than to follow Precedent merely piece-meal, and patch up a design out of odd-and-ends, taken at random, and put together without any regard even to general consistency of composition. The name "Elizabethan," at once sanctifies all absurdities and all crudities; it operates as a talisman and an ague against the shafts of criticism. It is in vain to object to that offensive inequality of design which results from plainness and coarseness in some features, and studied ornateness, perhaps finicality, in others. The greater the incongruity, it would be said by Wren, the more parti-utmost and most convenient latitude is freely allowed: forms and features strongly partaking of the latest-expiring Tudor style may be mixed up ad libitum with ultra-Italianized ones; no matter how incoherently, when incoherence is thought to belong to, not architectural, but mere "vexillum," or merely of a different style. Elizabethan possesses one great recommendation in common with the pure Grecian style. What it is you shall learn by-and-by—that is, in my next Fasciculus; till which appears, I leave you to cogitate upon the matter, and solve the riddle, if riddle it be, the question of who should be said to have the advantage in the interim, it will not greatly matter. Putting, like a frugal hostess, that dainty bit "by for supper-time," what I now say is, that we do not at all avail ourselves as we might do of the opportunity which Elizabethan architecture holds out to us,—of the convenient pretexts of Buonarotti, Colen Campbell, and Vanbrugh, and the Italiens or early Cinque-cento ideas which, although, they show themselves only here and there partially, and more or less imperfectly, strongly mark those examples in which they occur to any extent. In reverting to Elizabethan, we have considered it rather as being the latest stage of exploring Gothic, than as the incipient one of a quite different architectural system; which, had it been allowed to proceed as it originated, and to develop itself freely and naturally out of its first rudimentary shoots, instead of being put into the hot-house of Palladio and Jones, would doubtless have produced other and different effects which have attended such "forcing" system. When Elizabethan was recommended as the style most of all suitable for the new Houses of Parliament, people—and architects among the rest, were puzzled to know what was to be understood by such name. Was it to be interpreted literally or literally? If the former, it of course excluded every style that had been used before or up to the period of Elizabeth's reign, unless Elizabethan and Ante-Elizabethan mean one and the same thing, and unless Elizabeth reigned before she was born—a mystery I willingly leave to wiser heads than mine. On the other hand, if Elizabethan was to be interpreted literally and literally, it would seem to imply that the style to be adopted might be either that which was actually employed during the latter half of the 16th century, or which afterwards came up in the earlier part of the following one; and the way for which had been opened by the influences and tastes of the previous Elizabethan period. It is perhaps just as well that the taste of Elizabeth's grandfather—at least, that of his age—was preferred to that of her own. Nearly all the competitors for the Houses speedily Elizabethan, and no doubt very precociously; and we, perhaps, have occupied them until now elaborate out of it aught that would have been both worthy of and suitable for the occasion.

VI. Some are so very sensitive and captious about terms and names, that I wonder they do not about to be curiously dismembered of the "Lancet style." It cannot, indeed, be said to be a very blunt one; on the contrary, it is sharp enough—so sharp as to pierce an ear that is at all refined. It must surely have been invented by Dr. Sangrado, or other practitioner of phlebotomy. Or it must have originated with the Company of Barber-Surgeons, so truly barbarous is it in sound. If not so, it must have been applied in sneering derision by some such critics as those who make themselves merry with the "barm-bawlers" in Longchamp place, and Barry's dumb-idots in Trafalgar-square. Lancet-style!—horrible name; suggesting ideas of bloodshed, at least of blood-letting! Let it be reformed by all means; more especially as people are now more and more appropriating terms for those introduced by Rickman, notwithstanding that they have obtained general currency among us. If "Perpendicular" is to be transformed into "Rectangular"—style, surely "Lancet" will no longer be tolerated by "ears polite," or ears archological. Let a General Council of Archology be held forthwith; let the Institute assemble in solemn or somnolent concave, to devise some less odiously vulgar name for what is now called the Lancet style. Should they not be able to think of one, still, they might possibly dream of one; or else they go to sleep to very little purpose indeed.

NOTES ON ENGINEERING.—No. X.

By HOMER SHAW, B.A.

The Dynamical Deflection and Strain of Railway Girders.

There is no subject in practical science which has been more elaborately investigated than the theory of the statical transverse strength of beams. It has fortunately happened that two different classes of investigators—mathematicians and experimentalists—have cooperated in the research: and the result of their united labours has been a valuable and comprehensive system of knowledge. But the dynamical strength of beams, or their capacity of sustaining weights moving rapidly over them, has never been satisfactorily discussed. There does not appear to be extent a single theoretical investigation of this subject—and the deficiency is due to two causes: it occurs partly because the subject has but comparatively recently grown into importance; partly because of its excessive and insuperable difficulties when investigated by the exact methods of theoretical mechanics. The following paper is a contribution to a more accurate knowledge of this important
question, which has at length attracted the attention due to its influence on the security of railway traffic. The necessity of further inquiry seems to be generally acknowledged among engineers; and by the recommendation of a public meeting in the city of London, on the 29th of June, 1847, a government commission has been appointed for the very purpose. The minute expresses a doubt "whether the experimental data and the theoretical principles at present known are adequate" for the "designing iron bridges, when these are to be traversed by loads of extraordinary weight, or at great velocities."

There seems to exist great discrepancy of opinion as to the effect of the velocity of transit. Some have imagined that it may become a source of safety, by causing the railway train to pass over the girders has had time to yield. Others, again, have estimated the effect of the moving load as highly as six or seven times that of the same load at rest. In the following investigations, these opinions will be shown to be incorrect: they are here cited merely as indications of the extreme uncertainty prevalent on the subject.

The method of inquiry about to be explained consists, not in determining the dynamical strain absolutely, but by comparison with the corresponding statical strain. The results will consequently be much simpler than they would be if the dynamical strain were estimated independently. The given load at rest upon a beam of given length will be always taken as one of the known data of the problem. The determination of this statical deflection, as it forms the basis of all the remaining calculations, is the first point of inquiry.

When a beam is not affected by a permanent set or defect of elasticity, its length from theory and actual experiment, that the deflection by a weight resting at its centre is very nearly proportional to that weight—that is, if a given number of tons deflect it one inch, double the number of tons will deflect it two inches. This result is arrived at by Professor M. V. C. M. F. N. and M. Navier in his "Résumé de Leçons de Construction," by independent methods. Its near accordance with practical truth has been abundantly confirmed by experiment, as may be verified by reference to numerous published accounts of actual observations on the subject, and especially as it is the result of the admirable "Experimental Researches on the Strength of Cast-Iron." This work gives the results of an exceedingly large number of experiments, made by the author and others, on the transverse strength of beams loaded at their centres; and although these beams were of very different forms and dimensions, the law indicated is nearly observed in all of them. Whether the section of the beam be rectangular, triangular, or T-shaped, with the vertical rib either upwards or downwards, the constant ratio, in each beam, of each deflection to the corresponding load is nearly maintained, and the same remark applies to beams forming useful for railway purposes—that of an upper and lower flange connected by a vertical rib.

It will be found, however, by reference to the tables in Mr. Hodgkinson's work, that the actual deflections are somewhat more than the theoretical law would make them. This discrepancy may be accounted for by attributing it to the defect of elasticity, which the ordinary theory of beams does not consider. As this defect is not generally very great, it will here in the first instance be neglected: the deflections will primarily be estimated as if the elasticity were perfect; and subsequently the modifications due to defect of elasticity will be taken into consideration.

**Work Done on the Deflection of a Beam.**

The "work done" by a moving force may be defined to be the product of that force into the distance through which it acts. A familiar instance of the use of this measure is the Steam-Engine, where the work done receives the particular name of Horse-Power. If the pressure on the piston was in pounds, the work done would be expressed in foot-pounds. The same idea is applied to the deflection of the beam, where the measure of the distance through which it is exerted (in feet) would, if divided by 33,000, give the horse-power. But in the steam-engine, and all other practical instances, where the pressure is not uniform, but varying, it is impossible to calculate the work done by this direct multiplication. If the factor of moving force be altering, we may resort to either of the following methods of ascertaining the work done by it,—we may multiply its average value by the distance through which it acts; or, when that average cannot be ascertained, we may consider the whole distance divided into equal portions, so small that it may be supposed without sensible error—that the pressure is at least uniform while it acts through each portion in succession. The aggregate work done, is the sum of the work done on each of these portions—that is, it is the sum of the products of each portion of the distance and the corresponding pressure.

This process of summation, when carried out with the greatest possible accuracy, is equivalent to that of mathematical integration; in which case, the work done by a varying pressure may be defined, in mathematical language, to be the integral of the product of the pressure, and its "virtual velocity." The work done in deflecting a beam by pressure at its centre is easily ascertained, if that pressure be assumed proportional to the deflection. Calling the deflection $x$, and therefore the pressure $a x$ (where $a$ is a constant depending on the dimensions &c. of the beam) we have—

$$\text{work done} = \int_0^x a x \, dx = \frac{a x^2}{2} = \frac{a}{2} x^2.$$ 

Now $a x^2$ is the pressure or weight which would statically maintain half the deflection $x$. Hence, the work done in producing a given deflection is equal to the work which would statically maintain half the deflection, multiplied by the whole distance of deflection.

The value of this rule will appear hereafter.

**Distinction of Gradual and Instantaneous Loading.**

When experiments are made on the strength and deflection of beams, they are generally loaded very gradually at their centres. Each additional to the load is allowed to produce its full effect before more be imposed. Consequently, at every stage of the experiment, the instantaneous pressure which the load at the centre of the beam at rest on the beam is always just equal to its weight, and is never increased by any momentum arising from downward velocity.

But if the load be suddenly and at once placed on the beam, or if it is gradually built up, the effects are entirely altered. The deflection is greater than the same load would produce if gradually applied; for when the beam has reached the point of statical deflection, the momentum acquired by the downward motion, urges it further; and the descent of load continues till it be brought up (so to speak) by the increased resistance of the beam. Afterwards, the beam and load rise again, as the deflection has been carried beyond the degree at which it can be statically maintained.

In the case here supposed of instantaneous loading, nothing like impact or sudden collision occurs. The pressure at the centre must be laid on the beam—it is merely supposed to be placed originally in close contact with the beam, and then suffered to instantaneously rest upon it.

For the sake of elucidation, one or two instances of analogous action may be cited. If a common balance have its fulcrum above the points of suspension of the scales, and a weight suddenly rest in one of the scales, the lever will turn through a much greater angle than if the same weight were applied in small successive portions.

A string is capable of sustaining vertically a weight from one end of the beam by its own pull, it will be stretched; if the whole weight is laid upon the beam at once, it will be stretched to a much greater extent than the previous load. If the string is now turned and fastened vertically in water, and a weight is placed at the lower end, the string will be extended to a much smaller extent than before. If the cylinder be raised a little above its position of equilibrium and then let go, it will sink twice the distance it has been raised, if the motion be suddenly stopped, the resistance of the water is equal to the hydrostatical pressure. If the cylinder be raised a little above its position of equilibrium and then let go, it will sink twice the distance it has been raised, if the motion be suddenly stopped, the resistance of the water is equal to the hydrostatical pressure.

In the same way, in a perfectly elastic horizontal beam, loaded at its centre, the effect of instantaneous loading is double that of gradual loading. For, by a known principle of mechanics, when a material system moves from one position of rest to another position of rest, the work done by the accelerating forces is equal to the work done by the accelerating forces. For any small deflection of a beam by instantaneous loading, its position of ultimate deflection is one of instantaneous rest, for immediately before it arrives at that position, all the parts of the beam descend, and immediately after, ascend. Also, the work done by the accelerating force is the weight actually resting on the beam, multiplied by the space of deflection: and the work done by the retarding forces is, by what has been said above, "equal to the weight which would statically maintain half the deflection, multiplied by the whole distance of deflection." Therefore, putting the two amounts of work done equal to one another, we see that the weight actually upon the beam that which would statically maintain half the deflection. In other words, the deflection is doubled by instantaneous loading.

**Transit of a Single Weight.**

We now proceed to examine the effect of the transit of a single
weight along the girder, and first of all to show that its effect cannot exceed that which it has just been estimated to produce, if stationed at the centre of the girder and allowed to descend freely from the undeflected position—in other words, it will be proved that at whatever rate the weight may travel over the girder, its ultimate strain and deflection cannot be more than double the corresponding statical effects produced when it rests at the centre of the girder.

There is a general rule of constant use in engineering, which, expressed in practical language, states that power is never gained, but only modified, by the intervention of machinery. This rule may be more scientifically expressed and extended by tracing it to its origin—it is a particular case of the principle known in theoretical mechanics, as the Conservation of Vis Frat. This principle may be formally enunciated by employing the phrase “work done,” as defined above; and it then assumes this form of enunciation—that the vis viva gained or lost by a system in moving from one position to another, is equal to twice the difference between the work done by the accelerating, and that done by the retarding, forces in the same interval.

From this it follows, that where there is no gain or loss of vis viva, there is no difference between the work done by the accelerating and retarding forces respectively. Hence, if the parts of the system be moving at the same velocity in the second position as in the first, or if both positions be positions of rest—the aggregate deflection due to the integral of the retarding forces is equal to that done by the accelerating forces.

A very simple case will illustrate this theorem. If a locomotive travel a mile along a railway, and its velocity at the end of the mile be the same as at the beginning of the mile, the work done by the forces which resist the motion in the aggregate just equal to the horse-power developed in the steam-cylinders. And this equality holds good, however the engine have moved in the interval—whether on a straight level road, or on severe curves and gradients—whether the speed were uniform or very irregular—whether the steam were on the whole time, or the engine during large parts of the journey moved by its momentum only. The intermission of the moving force and all other irregularities disappear in the result. To establish equality between the work done in moving, and that done in retarding, the engine must be so adjusted that the engine be raised or slowed down the end of the mile, than at the beginning of it.

Another illustration will serve to show the extreme generality of the principle in question. If a certain quantity of water have to be raised a certain height, the amount of work actually requisite for effecting the object is in all cases equal to the weight of water multiplied by the vertical height. This amount of necessary power or work is incapable of being diminished by any mechanical or hydraulic contrivance. The water may be contained in a vessel which is raised to the required height, and drawn up an inclined plane or by a spiral path; or the water may be raised by an Archimedean screw, or by buckets attached to the periphery of a revolving wheel, or by a hydraulic-ram, or by a force-pump; or lastly, it may be thrown up in a jet, as from a fountain or fire-engine. But it is physically impossible, by these or any other methods, to diminish the requisite amount of labour.

It is, of course, easy to increase the amount by a waste or unprofitable expenditure of labour, such as is caused by friction of the machinery, or the mutual action of the particles of water among themselves. But supposing no waste of force to occur—supposing all the power usefully employed in simply raising the water without doing anything else; then the amount of that power is in all cases just what has been stated—the weight of water multiplied by the vertical distance through which it is raised.

The rule is of universal application, and there is no other principle which gives such great and constant utility in practical science; for it embraces all cases of motion with which the engineer happens to be concerned—cases where the motion either ceases, or has the same values, at regularly-recurring intervals.

The case before us, of the transit of a weight along a girder, is a particular case of this general law of Conservation of Work. For this principle enables us immediately to consider the effect of a weight moving along the girder, and that of the same weight stationed at its centre, and descending. If the deflection be the same in both cases, the work done by the descent of the load in both is the same. If, however, the descent be smaller, the weight has gained the effect of descent: and this is true, whatever be the path of descent. Now, it has already been shown, that in the case of instantaneous loading, the work done by the descent of the weight is equal to that necessary to produce in the beam the deflection which twice the weight would statically maintain. Hence, the travelling weight can do no more.

The value of this conclusion appears the greater, when it is considered that it avoids all hazardous hypotheses as to the forms assumed by the beam during the transit. However the beam may be bent—whatever may be the nature of its vibrations and internal action, this is certain—that when its elasticity is unimpaired, a weight travelling along it cannot, under any circumstances whatever, more than double its corresponding statical deflection. To suppose it capable of doing more, is to suppose the physical impossibility of a gain of power.

But though the travelling weight cannot, under any circumstances, produce more than double the statical deflection, it is evident that it will not do; for the deflection beyond its statical amount; and, on the other hand, when the weight travels with excessive rapidity, it will not have time during the transit, to sink even the distance of statical deflection. To take another case, if the load is indefinitely great, the descent of the weight must be indefinitely small; for even if it fell freely, and there were no beam to support it, the distance of descent in an indefinitely short time is inappreciable.

**Effect of the Inertia of the Beam.**

There is, then, between the exceedingly high and the exceedingly low velocity, some particular intermediate speed which produces the greatest possible deflection. Before, however, considering what that velocity is, or endeavouring to establish a direct relationship between it and the deflection, it will be necessary to examine more particularly the case just referred to—where the velocity of transit is so great, that the weight has not time to sink beyond a certain degree.

Now, there are two ways in which this consideration of time might be supposed to affect the amount of deflection. The first is that already stated, where the period of transit is so short, that even if the weight descended freely, without support from the beam, its descent would be inconsiderable. This case may, however, be at once excluded, when it is considered that at all practicable railway velocities of transit in the time of less than 80 feet could not be much less than one second, that a body would fall freely upwards of 16 feet in that time, and that its actual descent (equal to the deflection of the girder) is only a few inches.

But there is another way in which the consideration of time may be supposed to affect the amount of deflection; it is that not time enough to overcome the inertia of the beam. This case requires more particular examination.

A person skating over a weak piece of ice may sometimes, by moving rapidly, glide over it safely before it have time to break—that is, before the pressure of his body have impressed on the ice the downward motion sufficient for it to attain the point of fracture while he is passing over it. Now, by the general principles of mechanics, the same pressure which, acting for a given time, would produce a great velocity in a small mass, will produce but little in the case of a large mass. Therefore that the inertia of the ice may, in the case supposed, be a cause of safety, it must be large in comparison with the pressure acting on it; that is, the mass of ice acted upon must greatly exceed the mass of the man’s body.

In the same way, in order that the inertia of a gird orer might be a cause of security, the mass of the girder must be very much greater than that of the train passing over. But it will be shown that the mass of the former does not, for heavy loads, exceed that of the latter so greatly as to perceptibly diminish the deflection. In some cases it is, sometimes used for the purpose of increasing the inertia of the girder by laying on it heavy ballast, and by this means the structure is rendered stouter,—that is, the slight lateral oscillations and other irregularities of motion are reduced. But it travels with a very small velocity, and the lateral movements that can be diminished by adding to the weight of the girder. Its mass, and that of the permanent load upon it, is not in general so large as to materially influence the main, or vertical, deflection, when produced by nearly as heavy a load as it will safely bear.
When the train passes over the girders, the centre of gravity of the whole system sinks, the impressed moving force downwards being the weight of the train, and the motion of the centre of gravity being resisted by the elastic force of the girders.

To take a case every way unfavourable to the conclusion which we wish to establish, let the greatest deflection be 3 inches, and the velocity of the train so great that the weight passes over the girders in a second of time. This would be the time of transit over a girders 80 feet long, at the rate of a mile a minute. Now, the extreme deflection may be supposed to be accomplished in half the time of transit, or the centre of the girder sinks 3 inches in half a second. The centre of gravity of the whole system at no time sinks so much as the centre of the beam sinks, for its two ends do not sink at all. On the whole, it seems an ample allowance to suppose the maximum vertical descent of the centre of gravity of the beam 1 inch. Now, to find the work which would alone produce this velocity, we must have an equation of the type, excluding the retarding force.

By the ordinary rules for calculating the rectilinear motion of bodies, if a given mass M originally at rest be acted upon at its centre of gravity by one uniform force f moving through a space \( s \) in the time \( t \),

\[ M \times f = \frac{1}{2} f s^2. \]

Suppose the force to be that of a small weight. The mass of this weight will be found (on substituting numerical values and putting gravity \( = 32 \)) to be only the 32d part of \( M \), if the latter move through 14 inch in half a second.

The beam is usually constructed to bear a pressure considerably exceeding this. In that case less than one 32d of the work actually exerted by the travelling weight would suffice for the mere acceleration of the beam; and we come to the conclusion, that even at the highest practicable velocity, the power required to set the beam in motion subtracts very little of the power producing deflection. In other words, when the mass of the load is not small compared with that of the beam, the deflection is never materially influenced by the inertia of the beam.

**Influence of the Velocity of Transit on the Deflection in the case of a Single Weight.**

Having arrived at the important conclusion that when the travelling weight is large, the inertia of the beam is of no consideration, or that the effective moving forces are inconsiderable compared with the impressed forces, we might suppose the mutual pressure between the beam and the weight statically equal to the force which the former by its elasticity exerts in an upward direction to resist deflection.

But, in fact, the mutual pressure between the beam and the weight is an unknown force, not generally susceptible of exact determination. During the first part of the motion, the weight does not, so to speak, exert its full pressure on the beam, for the surface yield-ends before the beam descends. But, in fact, the mutual pressure, the pressure in question exerts a superior power, to destroy the momentum previously acquired by the descending weight. The weight then moves downwards, first with an accelerated, and subsequently with a retarded, velocity; or the pressure is of the nature of a variable force, and in the latter stage greater, than the effect of gravity.

The path of the weight is likewise unknown, for the motion is made up of two parts—the motion along the beam, and the motion of the beam itself. If, indeed, it be assumed that the motion is always along the beam, or that at every instant the curvature of the beam has, at the point of mutual contact, the same tangent as the path of the weight, the problem would be capable of solution. The investigations of Professor Moseley and M. Navier have determined the curvature of the beam sufficiently to affect the forces of the moving weights; and therefore, its pressure, which is equal to its centrifugal force, the effect of gravity, might be ascertained.

The hypothesis which would lead to these results is, however, arbitrary and unsafe: and besides, the curvature of the beam as mathematically determined, is not exactly that which occurs in actual practice, where the elasticity is always more or less imperfect. The difficulty is however of no great importance, because, as will be presently shown, it does not occur where the moving body is not a single weight, but a long train. And the subject is here referred to, merely to show the almost insuperable difficulties of determining the motion of a single weight along an elastic beam.

**Uniformly Distributed Load.**

We have hitherto considered the effect of a single weight pressing only at one point of the girders. The more important practical case, where the pressure is applied to a considerable surface, remains to be examined.

In entering upon this inquiry, the consideration of horizontal motion will be in the first instance excluded. The distinction between the effects of gradual and instantaneous loading has been already pointed out, in dealing with a single weight; and the comparison may now be extended to the case of an uniformly distributed load. If this load be gradually laid on, it produces less deflection than when laid on at once. A series of weights applied simultaneously all along the undeflected girder, will move vertically downwards, and acquire momentum which has to be destroyed by an increased exertion of the elastic forces of the girder. In this case, as in that of a single weight, the ultimate deflection and pressure will be doubled, as will be demonstrated by analogous principles.

The beam, as before, supposed to be perfectly elastic, the central deflection is proportional to the weight of the uniformly distributed load. If \( a \) be the length of the beam, \( x \) the central deflection, \( u \) the weight of a unit of length of the load, we may put \( u a = s x \), where \( s \) is a determinate constant.

Let \( a \) and \( y \) be co-ordinates of any point in the surface of the beam, which is supposed to have the same curvature as its neutral axis. Then as the curvature is always exceedingly small, \( u d y \) is the weight of an element of the load, and \( u d y d x \) represents the product of this weight and its virtual velocity, when the beam is displaced through a small vertical distance \( d x \). The product of all the pressures and the corresponding virtual velocities is equivalent to

\[ \int u d x d y, \]

taking \( y \) between the limits 0 and \( a \). It may mathematically be shown that this integral is equal to \( u a d x \), where \( x \) is the vertical ordinate of the centre of gravity of the load. Also, from the equations given by Professor Moseley, in his "Principles of Engineering," Art. 374, it may be shown by a simple process, which is here omitted for the sake of brevity, that \( x \) is proportional to \( s \), and may therefore be put \( = \beta x \), where \( \beta \) is a determinate constant.

Hence, \( a u d x = s \beta x d x \).

The integral of this, between limits 0 and \( s \), is the total work done in producing the central deflection. This integral is equal to

\[ a x^2 = s \beta x^2. \]

Or the "work done" is equivalent to that produced by a weight which would statically maintain half the deflection, moving through the whole space which the centre of gravity actually described. Hence, by the same reasoning as applied to the case of a single weight, the *statical deflection* and *pressure* are doubled by instantaneous loading.

**Transit of a Continuous Load.**

By combining the conclusion just arrived at with the principle which has here been termed the Principle of the Conservation of Work, it is readily seen that the statical strain and deflection cannot be more than doubled, at any horizontal velocity, for a uniform load of the same length as the girder. Indeed, the dynamical will in general be considerably less than double the corresponding statical effects.

It has been shown that where the weight of the load sustained is nearly as great or greater than that of the beam, the forces required to produce motion in the beam is inconsiderable compared with the actual deflecting forces. The beam itself, therefore, is then always nearly in a state of equilibrium, and its form nearly the same as that which would be statically produced by the external pressures.

The curve of deflection is concave in every part, and therefore that no part of the beam sinks while another part is rising—that all the parts sink together, and all rise together. The vertical motion is so extremely small and gradual, that there can be no danger in assuming that all the parts arrive at their lowest position at the same instant. It follows then, as previously to that instant the motion was downwards, and subsequently upwards, the beam in its lowest position is at rest, either instantaneously or for a definite period.

In the position of rest, the pressures on the surface of the beam are in statical equilibrium with its internal forces. At the same time, the pressure produced by the travelling load is the same as if the curve of deflection were a fixed curve.

**Effect of Centrifugal Force.**

When a body, moving along a fixed curve, is acted upon by no forces but the pressure of the curve and its own weight, the pressure on the curve (by the known principles of mechanics) is
equal to the centrifugal force, plus the normal component of the weight. The curvature of a deflected girder is in general so exceedingly small, that it will be quite safe to assume the pressure equal to the centrifugal force, plus the weight itself. The curve assumed by the surface of the beam depends on the forces acting on it; and we here suppose the beam to be at rest, although the load upon it is in motion. Hence, the elastic forces of the beam are in statical equilibrium with the pressures on the curve.

The origin of co-ordinates being at one end of the beam, and the axis of $x$, measured vertically downwards, at any point $(x, y)$ of the curve, the tangent of the angle of horizontalinclination is
$$\frac{dx}{dy}$$
which is always very small. Hence, neglecting the square of that quantity as inconsiderable compared with unity, we may put the inverse of the radius of curvature at the point $(x, y) = -\frac{d^2x}{dy^2}$. (The sign never changes, as the curve is everywhere concave upwards.)

From the theory of perfectly elastic beams, it appears that
$$\frac{d^2x}{dy^2}$$
is, at every part of the beam, proportional to the moment about $(x, y)$ of all the pressure acting between that point and either extremity of the beam. Hence, the pressures between $(x, y)$ and the origin are the centrifugal forces and the weights acting downwards, and the pressure of the abutment acting upwards. The moment of all the centrifugal forces may be first ascertained.

Each small portion of the load may be supposed to act independently of the rest, or to press on the curve with its own weight and its own centrifugal force. Let $m$ be the mass of an element of the load. Calling $V$ its linear velocity, it appears from what has been already said about the radius of curvature, that $V^2 \frac{d^2x}{dy^2}m \cdot d'y$ is the centrifugal force of that element. The moment of this centrifugal force is $-V^2 \frac{d^2x}{dy^2} \cdot (y' - y)$ $m \cdot d'y$.

The moment of all the centrifugal forces about point $(x, y)$ will be found by integrating this expression between the limits $y = 0$ and $y' = y$. So it may be ascertained that the moment of these forces is
$$m \cdot V^2 \left(y \tan \beta - x\right),$$
where $\beta$ is the horizontal inclination of the curve at the origin. $y \tan \beta - x$ is the length of a vertical line drawn downwards from the point $(x, y)$ to meet the tangent drawn from the origin; and is very small.

The weight of the portion of the load upon the horizontal length of the beam, is $m \cdot g$; and its moment about the point $(x, y)$ is the same as if the weight were collected at a point half way between $(x, y)$ and the origin, and therefore equals $\frac{m \cdot g}{2} \cdot x$.

Also, if $P$ be the pressure of the abutment, $P \cdot y$ is its moment; and representing the constant, by which the radius of the curve has to be multiplied to render it equal to the sum of the moments, by $E$, we have
$$E \frac{d^2x}{dy^2} = mg \cdot \frac{y'}{2} - P \cdot y + m \cdot V^2 \left(y \tan \beta - x\right).$$

This equation is integrable in its present form; but as the last term of it is very small, we may make an alteration which will tend, without the simplification of the result. The centrifugal pressures cannot under any circumstances be great compared with the other forces, as may readily be foreseen by considering that in all cases of actual practice, the curvature is very small on account of the very small proportion which the central deflection bears to the length of the beam. For any central deflection previously assigned, the curve would be very little altered if the centrifugal pressure were uniformly distributed. Therefore, in the above equation, the small term $m \cdot V^2 \left(y \tan \beta - x\right)$ is neglected in estimating the radius of the curvature merely. Now, as it appears from the "Mechanical Principles of Engineering," Art. 374, that when the beam is subject to any uniformly distributed pressures whatever,
$$\frac{d^2x}{dy^2} = \frac{24}{D} \frac{y'}{\delta},$$
where $\delta$ is half the length of the beam, and $D$ is its central deflection. The curvature of the beam, when it assumes its permanent form under the influence of a passing load, will not greatly differ from that which this equation indicates. Of course, this hypothesis does not suppose the distribution of the centrifugal forces to be actually uniform—it merely presumes that the curvature of the beam, for a given deflection, is nearly the same as if the pressures were so distributed.

From the equation last given, the value of $\frac{d^2x}{dy^2}$ at the centre, is $-\frac{10}{44}$. Therefore, at the centre, a weight moving with velocity $V$, has a centrifugal pressure $= V \cdot \frac{24}{10} \cdot \frac{D}{\delta}$. Times its mass.

To ascertain the whole effect of centrifugal pressure, we have evidently the expression
$$\int m \cdot V^2 \frac{d^2x}{dy^2} \cdot dy = -m \cdot V^2 \cdot \frac{24}{\delta} \cdot \int (y' - y) \cdot dy,$$
integrating between limits $y = 0$ and $y = y'$.

From this, it appears that the total centrifugal pressure is $\frac{32}{10} \cdot \frac{V^2}{\delta}$, which becomes $\frac{m \cdot g \cdot \frac{1}{4}}{10^4} \cdot D$, if $y' = 32$.

Now, if $T$ be the number of seconds in which either end of the load traverses the beam, $T = 2a$, and $\frac{1}{a} = \frac{4}{T}$. Substituting this value, and remembering that the total weight on the beam is $2m \cdot a$, we find ultimately,

$$\text{Centrifugal pressure on whole beam} = \frac{1}{\delta} \cdot T \times \text{the weight}.$$
Defect of Elasticity.

It now remains that something be said of the defect of elasticity, and the modifications of the above results when applied to jointed or compound structures. The ordinary mathematical theory of the girders is based on the law of perfect elasticity, known as Hooke's law—namely that the elastic force is proportional to the extension or compression.

It appears from experimental inquiries, subsequent to, and more extensive than, Dr. Hooke's, that this law is not quite true. The elastic force in reality less than the law would assign it to be. Mr. Hodgkinson, in his recent published "Researches on cast iron," Art. 106, seems inclined to think that the elastic force may be expressed by 

\[ F = -\alpha \Delta x \]

where \( \alpha \) is the measure of compression or extension, and \( \alpha \) and \( \Delta \) constant empirical coefficients. That this hypothesis is near the truth may be inferred from the consideration, that if the elasticity of a series in ascending powers of \( x \), all terms involving high powers must be very small, as the elastic force is always nearly equal to the first term, and \( x \) is very small. It may, however, be worth while to remark, that if \( x - bx^2 \) be taken to express correctly the elastic force, the same value of \( x \) gives the tension \( T \) will not, when reckoned negatively, give the same value for the pressure. In order that this may be the case, only uneven powers of \( x \) must be involved.

But whatever of elasticity be assumed, this is easily ascertained—that where the elasticity is imperfect (that is, where it is less than in proportion to the extension or compression), the deflecting pressure of a girdler will be less than in proportion to the deflection. In cast-iron girders, cast in one piece and in metal of good quality, the defect of elasticity is small; and consequently the deflection produced by the load is small. When deflected girders are used in jointed structures, compounded of several parts connected by rivets or bolts, this is by no means the case. In them, the defect of elasticity must be great; and the deflection will therefore increase at a considerable higher rate than in proportion to the external pressure. If, for instance, 2 tons produce a girder 2 inches deflection, 300 tons will produce considerably more than 3 inches deflection. Or, if 300 tons produce 3 inches deflection, 600 tons will produce considerably more than 4 inches deflection. How much more can be ascertained only from actual experiment.

It is very important that this distinction between simple and compound girders should be always taken into consideration, for the neglect of it would lead to very erroneous conclusions respecting the strength and deflections of the girders. In such cases, it should be remembered that the calculations respecting the strength of girders formed in pieces and supported by tension-rods, formulas which determine the strength of simple, unjointed girders, are inapplicable to these structures, and are not likely to give an answer to the amount of their real strength.

Where, however, the compound-girder is so well constructed, that its curvature, when deflected, is regular and free from sudden inflections, the formula given above for the dynamical pressure of long trains on perfectly elastic beams, will apply with considerable accuracy. In this case, the deflection will be independent of the weight of the train, and be a variable of the curvature, and the radius of curvature, and will, therefore, be of less importance, in proportion as the curvature is more uniform, and the radius of curvature greater.

Now, if \( V \) be the velocity of a mass \( m \), moving round this curve, its centrifugal force becomes \( mV^2/a^2 \); and if \( T \) be the number of seconds in which any part of the mass describes the distance \( a \), 

\[ V^2 = \frac{1}{T^2} \]  

Substituting this value, and putting \( g = 32 \), the centrifugal force is equal to \( \frac{\pi}{4T^2} \times \text{the weight}. \) This formula applies to horizontal railway curves, as well as to the vertical curves of a beam. Confining attention however to this application of it, we see that a very considerable reduction of the pressure of the weight may be effected by curving the upper surface of the beam. Suppose, for instance, that the time of transit were one second (\( T = 1 \)), and that it were practicable to give the rails such a
convexity that the rise at the centre was one foot (c = 1). Then, from the formula, it appears that the centrifugal pressure would be one-fourth the weight, or that only three-fourths the weight pressed on the beam.

It may be remarked that this law has most important effects on such stupendous structures as the tubular bridges for the Chester and Holyhead Railway. The Conway-bridge, after it was constructed, sank eight inches at the centre by its own weight; this depression was anticipated and corrected by a previous upward convexity of the tube. But in this, and in all analogous cases, a rise or convexity, considerably exceeding the natural depression, would tend greatly to security: because, the curve being convex, an increase of the velocity would diminish, instead of increasing, the pressure of a given load. It may therefore be safely asserted, that it contributes to the security of girders to give their upper surfaces as great a convexity as is consistent with other practical requirements.

General Conclusions.

The close of these investigations, it may be convenient to recapitulate the general conclusions derived from them. They comprehend the following laws for the motion of very heavy loads at practical velocities over horizontal girders.

1. If the girder be perfectly elastic, the pressure exceeds the weight on the girder by a fraction of the weight, not more than one-fifth the actual deflection (in parts of a foot), divided by the square of the number of seconds in which either end of the load traverses the girder.

2. In compound and imperfectly elastic girders this fraction is increased.

3. The influence of the inertia of the beam on its deflection is considerable.

4. In all girders, a convexity of their upper surface, or rise of the rails from end to centre, may be made to materially diminish the pressure.

These conclusions will, it is believed, furnish a tolerably accurate idea of the influence of moving loads upon railway girders. The only subject on which no definite investigation has been attempted, is the defect of elasticity in jointed girders. The modes of construction of compound girders are so numerous, that to establish any general law respecting them is obviously impossible—no accurate knowledge can be derived of the law of elasticity or deflection in these cases, but by direct experiment.

No pains have been spared to render the views here expressed correct. They have occupied many months of reflection, and have been subjected to the careful revision of the author's mathematical friends. As the great object has been to exclude all operose mathematical investigations, it will be readily understood that the subject, by constant corrections and simplifications, has assumed an entirely different shape to that originally given to it.

This value of CD is often required in problems of this class, giving (in Mr. Clarke's illustrative example) the horizontal distance of the point of observation from the observed object. It likewise occurs in determining the height of an object, as a hill, upon a horizontal plane.

From substituting the above value of CD in the equations,

\[ A D = C D \cot A \text{ and } B D = C D \cot B \]  

we obtain

\[ A D = \frac{c \sin A \sin B}{\sin C}, \quad \text{and } B D = \frac{c \sin B}{\sin C} \]

I have left these expressions in sines and cosines, instead of changing the denominator into the factor cosec C. There is no doubt that the better form of working, when C does not contain seconds (with the ordinary tables I mean, for surveyors seldom use tables to seconds), is the form which Mr. Clarke has adopted: but in the other case it is somewhat questionable.

As, however, this is a mere question of experience—perhaps, too, of habit—A formula so simple, and so easily derived, can scarcely be new. Still, I do not recollect to have noticed it elsewhere.

Another variation of the same general problem is often useful. It is, where the segments of the base AB, and the angle C, are given, to find the perpendicular CD.

ON MR. CLARKE'S SURVEYING PROBLEM.

The problem proposed and solved by Mr. Clarke, in last month's Journal, p. 230, is by no means so new as he appears to think. The form under which the problem is most usually presented, is—the base and the angles at the base; to find the perpendicular, and the segments into which it divides the base.

Mr. Clarke's angles \( \theta \) and \( \gamma \) are the complements of the angles at the base of the triangle C A D, as is obvious. (See his figure, p. 230.)

The following investigation of the question is taken, almost literally, from the 17th edition of "Hutton's Course"; and it will be at once perceived to be more brief and simple than Mr. Clarke's.

Let CD be the perpendicular from the vertex to the base, and denote the angles of the triangle, as usual, by A, B, C, respectively. Then, by right-angled triangles, we have:

\[ C D \cot B = \frac{C D \cot A}{A + B} \]

\[ C D = \frac{c \sin A \sin B}{\sin (A + B)} = \frac{c \sin A}{\sin C} \]

Put \( DA = a; DB = b; ACB = 2 \gamma; \) let \( CD \) bisect \( BCA; \) and denote \( N C D \) by \( \theta \), and \( CD \) by \( x \). Then we have

\[ B C D = \theta + \gamma; \text{and } A C D = \frac{\pi}{2} \]

\[ \theta = \pm x \tan (\theta - \gamma); \text{and } \theta = \pm x \tan (\theta + \gamma). \]

Wherefore,

\[ a = \pm x \tan (\gamma - \theta); \text{and } b = \pm x \tan (\gamma + \theta) \]

and hence, \( \sin (\theta + \gamma) = \frac{a - b}{\pm a + b} \sin \theta \) and \( \sin (\theta - \gamma) = \frac{a + b}{\pm a - b} \sin \theta \)....

Whence the angle \( \theta \) becomes known, and is very easily computed; and hence the perpendicular \( CD \) is obtained from either of the preceding equations:

\[ x = \pm a \cot (\theta - \gamma), \quad x = b \cot (\theta + \gamma). \]

But I need not further dilate on so simple a subject.

5th August, 1849.
THEORY OF STEAM-ENGINES.

(Continued from page 240.)

SECOND MEMOIR.—THE DETERMINATION OF THE DENSITY OF GASES.

The common method of determining the density of a gas consists in weighing a glass globe of great size:—

1st. When the globe contains perfectly dry air of a known temperature, and under a known atmospheric pressure:

2nd. After having exhausted it by means of the air-pump, so that the inclosed air exerts only a very feeble pressure, which, as well as the temperature of the sphere, is noted:

3rd. After having filled the globe with the gas perfectly purified, the atmospheric pressure and temperature being again noted:

4th. After having again exhausted the globe, noting, as before, the pressure and temperature.

By which four weighings, and their accompanying observations of pressures and temperatures all the data necessary for determining the density of the gas are given. But this method requires the exact knowledge of several elements, the determinations of which present generally great uncertainty.

In the first place, the temperatures which the air and the gas present at the moment of closing the globe, must be very exactly known; but that is generally supposed. When having a thermometer placed near the globe is very defective; the temperature indicated by the thermometer may be totally different from that of the air in which it is bathed, and still more from that of the gas which fills the globe.

MM. Dumas and Boussingault, who have lately (Ann. de Chim. et de Phys., 3d série, tome iii., p. 270) very successfully endeavoured to determine the densities of certain gases, place the thermometer intended to determine the temperatures of the gases in the very centre of the globe; and for more security, they cause that temperature to be constantly noted, by making the globe in an inclosure formed by a large cylindrical vessel of zinc with double walls. The annular space left between the walls is filled with water, at a temperature differing but little from that of the surrounding air. With this arrangement, we may admit that the temperature of the gas is known with sufficient accuracy.

But the greatest uncertainties exist in the weighings of the globe; for we must weigh the globe in the air, and, to have its true weight, we must add to its apparent weight that of the air which it displaces. And, in certain cases, this latter weight is greater than that of the gas which fills the globe, so that it must be known in at least equal exactness. We are, up to a certain point, masters of the gas which we pass into the globe. We may prepare it so as to be sure of its purity; but it is not so with the external atmosphere; we are obliged to take it as it is. In a close chamber the air may change its composition very perceptibly; its temperature, and some degree of humidity which it contains, vary incessantly. MM. Dumas and Boussingault thought that they had completely avoided the errors arising from this source, by placing below their balance a large chest lined with lead, in which the globe suspended from one of the scales of the balance floats. A very sensitive thermometer is placed in this chest, and gives the temperature of the air. This arrangement is certainly far preferable to allowing the globe to hang freely in the air of the room; the globe suspended in the chest is kept from the currents of air, which render the weighings very uncertain, and the temperature of the air in which it is placed changes but slowly; but it does not do away with the errors arising from the changes in the composition of the air, and these are by no means negligible, especially when we are working with very light gases—such, for instance, as hydrogen.

At the same time that MM. Dumas and Boussingault were weighing gases, M. Regnault was also engaged in the determination of the density of steam under different pressures, and especially under very feeble pressures. He was struck with the uncertainties with which the ordinary methods of weighing gases present, especially owing to the great surrounding air, which seems to have attracted but little attention from men of science, and he was led to a method which presents a degree of certainty and precision which those heretofore used do not offer.

He avoids completely, and by a very simple artifice, the uncertainties which arise from the changes in the air in which the globe is weighed. In place of equipping it by means of weights on the opposite scale, he balances it by means of a second hermetically-sealed globe of the same kind of glass, hung from the opposite scale. All the variations which take place in the air then affect the two globes in the same way, whether the changes of temperature, barometric pressure, or composition of the atmosphere. It is not, therefore, required at the moment of weighing to watch the thermometer, barometer, and hydrometer; it is sufficient to wait until the two globes are in equilibrium of temperature, and when this is the case, it continues indefinitely. If, however, in consequence, a very definite character by which to know when to read the weighings. This method presents also another advantage, that is, of avoiding the error arising from the different amount of moisture deposited upon the globe during different weighings. As the globes are made of the same glass and equally clean before the commencement of the experiments, they may be assumed to condense the same amount of moisture when bathed in the same air, and consequently will remain in equilibrium.

The globes had a capacity of about 10 litres (22 gallons). The globe in which the gas is to be weighed has a stop-cock adjusted to it, so that it may be exposed to the temperature of boiling water without leakage. It is weighed when full of water, first in the air, and afterwards in water of the same temperature as that which it contains; thus is obtained the weight of water displaced by the globe.

Before closing the second globe, a quantity of mercury was introduced into it so as to render it about 10 grammes (154.38 grains troy) heavier than the other. The two globes thus adjusted were submitted to several tests, in order to be sure that they satisfied the required conditions; they were left hanging for fifteen days under the balance scales, and the equilibrium was rigorously maintained all this time, although in the interval the temperature of the air had changed from 0° to 17° (32° to 62° Fahr.), and the barometric pressure from 741 to 771 millimetres (29.8 to 30.8 inches.)

The general mode of operating was as follows:—A vacuum as complete as possible being made in the globe, it is placed in communication with the apparatus for producing the gas whose density is to be determined, and the stop-cock is opened in such a way that the gas in the apparatus preserves a slight excess of pressure. When the globe is filled with gas, it is again placed in communication with the vacuum, the stop-cock is then closed a second time with the gas. In order to avoid any correction for temperature—a correction which would require the knowledge of the co-efficient of dilatation of the gas, and that of the globe—the globe is placed in a zinc cover and completely enveloped in melting salt. As soon as closing the globe, it is placed in communication with the atmosphere, so that the gas may place itself in equilibrium with the external pressure.

The globe taken out of the ice is carefully washed and dried, and hung from the scale of the balance. It requires a long time (often more than two hours) for the globe to take exactly the temperature of the surrounding air, and for its surface to cover itself with its normal amount of moisture. The balance used was able to appreciate with certainty a half milligramme when charged with one kilogramme upon each scale. It was placed over a large chest, such as used by MM. Dumas and Boussingault. At the end of the chamber, the observer did not touch the glass, but observed the oscillations of the index at a distance, with a telescope.

M. Regnault then notices the electric effects produced by wiping the globes, and the effects upon the weighings; he avoided it by wiping the globes with a napkin dipped in distilled water, and tested them by the gold-leaf electrometer. The pressures were measured by an apparatus which he describes under the name of a barometric-manometer. It consists of two tubes, one of which is an ordinary barometer of 20 millim. (0.8 in. diameter,) made very carefully; the other is a glass tube of the same diameter, which may, by a lead tube, be connected with the vessel in which pressure less than that of the atmosphere is to arise; they plunge below into a cistern of mercury having a partition, so that the two instruments may be separated at pleasure by drawing off the mercury in the cistern of the manometer below the top of the column of mercury. They are exposed for fifteen days.

* That is, equal to one four-millionth of the total load. Query, whether this sensitiveness was determined after the globes had been hanging from the scales, and the balance in action for fifteen days? 35
partition; this is necessary during the exhaustion of the globe, and the re-admission of the gas, for these operations produce such great oscillations in the barometer as to introduce small quantities of air into the difference, and it is observed that the nitro- gen of the exhausted globe is weighed with the precautions that have been indicated. If P represent the weight of the gas when the barometer stands at H, and p that weight when the elastic force in the globe corresponds to a barometric height h, the weight of the gas at O°, and under the normal pressure of 760 mill. is (P-p) - H.

To obtain a new weighing of the same gas, the exhausted globe, enveloped in ice, is placed in connection with the apparatus for generating the gas, and the series of operations which have been pointed out repeated. The gas, however, becomes purer at each operation. M. Regnault found that it is only from the fourth filling that the gas presents rigorously the same weight. It is desirable to satisfy one's self whether the gas upon which we are operating follows the law of Mariotte, at pressures below those of the atmosphere; this verification is absolutely necessary if the density of the gas is to serve for the determination of atomic weights. For the law of the volumes of gases, and the simple ratios which exist between their densities and atomic weights, exist rigorously only when the gas— that is, in a state of extreme dilatation; we must therefore seek the anomaly in these laws does not commence already near the atmospheric pressure.

This is done by measuring the weight of the gas, with great care, at different degrees of elastic force, as marked by the comparison of the manometer and barometer.

Finally, by this means we may determine the weight of the gas which, at the temperature of 100° and under atmospheric pressure, and thus determine the density of the gas when compared with air at 100°. This new density must be exactly the same as that calculated for O°, in order that it may serve in the calculation of the atomic weights; for it is necessary for this purpose that the gas should have the same-co-efficient of dilatation as the atmospheric air; at all events the weight of the gas which fills the vessel at 100° compared with that which fills it at O°, permits us to calculate the co-efficient of dilatation of the gas.

Again, in order to determine whether the gas follows the law of Mariotte, at the temperature of 100°, we have only to repeat the former experiments, filling the globe at this temperature, instead of at O°.

M. Regnault then recapitulates the advantages of this method, which are,—that it gives the density of the gases with more precision, and far less trouble, than the methods formerly used; it gives these densities at identical temperatures at O° and 100°, that is, at the fixed points of the thermometer, and consequently gives immediately the co-efficient of dilatation of the gas; and, finally, it permits us to determine with great exactness, whether the gas follows the law of Mariotte, at the temperatures of melting ice, and boiling water.

He then proceeds to give the detail of all his experiments, without a single exception, in order to allow the reader to judge of the degree of precision obtained by this method. It is not necessary that we should give these details—or those of the processes by which M. Regnault purified his gases; they were such as might be expected from one so familiar with all the minutiae of physical science.

He first determined by nine experiments the weight of pure atmospheric air, freed from carbonic acid and watery vapour, which filled his globe at the temperature of O°, and under the barometric pressure of 780 mill. (59·944 inches). The mean of these experiments was 12·7719 gr. The minimum, 12·7744. The maximum, 12·7816. The difference, 0·0098 or 0·007 gr. very small as the mean; and he remarks that it is probable that a great part of this error is due to the variations which occur in the composition of the atmosphere. He regards it as unfortunate that men of science should have selected the atmospheric air, whose constitution is known to vary, as the standard of densities for gases. In place of some gas which could always be obtained perfectly pure, such as oxygen, which would be the more convenient since this gas is already chosen as the basis of the tables (adopted by continental chemists) of chemical equivalents.

Founded upon this determination of the weight of a given volume of air, it is possible to determine the density of different gases, and his results are as follows—

<table>

</tbody>
</table>

Densities determined by Dumas and Bunsen.

If we calculate the theoretic density of carbonic acid gas, admitting the atomic weight of oxygen 16, and hydrogen = 1, we determine the value 1·1219. If hydrogen = 2, the number 1·2594, which approaches the density found for this gas under the pressure of 224·17 mill. (less than nine inches).

The density found at the temperature 0° and normal atmospheric pressure leads to an atomic weight for carbon 75·6 which approaches very nearly the number 76·44 (0·1129, if hydrogen = 1) which chemists for a long time admitted from the experiments of M. Berzelius.*

We see, by this example, how much circumspection is necessary in deducing the value of the atomic weight of a gas from its density.

Three experiments to determine the co-efficient of dilatation of the air between 0° and 100°, gave as the result 0·03663, which differs but little from the value obtained in the First Memoir.

An attempt to verify the law of Mariotte showed slight differences in which the weights by experiments were always a little lower than those got by calculating the density by means of Mariotte's law from the observed elastic force; but these differences were always within the limits of the errors of observation.

The co-efficient of dilatation of carbonic acid gas between 0° and 100° is 0·003713. (In the First Memoir, the determination by the method V., in which the gas preserved the same elastic force at 0° and 100°, as in the present case, was 0·003709.)

The experiments to determine whether carbonic acid gas obeys the law of Mariotte at pressures less than that of the atmosphere, gave the following results—

By experiment, calculated by Mariotte's law.

so that it appears that carbonic acid gas deviates notably from the law of Mariotte at ordinary temperatures, but conforms to it with the limits of experimental errors at 100°.

Third Memoir.—DETERMINATION OF THE WEIGHT OF THE LITRE OF AIR AND OF THE DENSITY OF MERCURY.

In the preceding memoir, the densities of the different gases were determined, referring them to that of air assumed as the unit; but the great numbers of determinations of the absolute weight of these gases: this is easily obtained when we know the absolute weight of air under the normal conditions, that is at a temperature of 0°, and under a pressure of 760 millimetres of mercury.

The weight of the litre of dry air under the normal conditions was determined by MM. Biot and Arago, with all the care which they could take—they found that at Paris this weight was 1·299541 gr. (Memoire de l'Academie des Sciences for 1808. Biot Traite de Physique, tom. i, p. 387.) This number has been generally adopted.

But if we reflect upon the imperfection which the theory of gases and vapours still presented at that time, and the great number of uncertain corrections which they were obliged to introduce into their calculations; and if we note that they operated upon air charged with aqueous vapour, for which they endeavoured to allow by a correction; and that, in spite of the most minute precautions, this circumstance must necessarily introduce great disturbances into their experiments, we shall understand how absolutely necessary it was to make new determinations of this important doctrine, which will be frequently used in the following investigations.*

In the preceding memoir, the weight of the gas which filled the globe at 0°, and under a pressure of 760 mill., was determined with great care; it will be enough then to find the capacity of this gas

* Berzelius himself now acknowledges the error of his former determination, and the atomic weight of carbon 75·72 or 6·01 (H = 1), which amounts to an admission of Dumas's determination. (Bunsen Traite de Chimie, Seconde Edition Francaise, 1843, tom. i, p. 203.)

** The French lire is equal to 0·222 of the imperial guinea.
at 6°, to determine immediately the weight of the litre of air. 

Now, according to the principle upon which the French system of measures was established, the kilogramme is the weight of a litre of distilled water, freed from air, at the temperature of its minimum density (which is at 4° and 0°), and it will suffice to determine the weight of water at 4° which fills the capacity which the globe presents at 0°.

To do this M. Regnault operated in the following way:

The open globe was weighed upon a good balance; its weight was found to be 2 gr., or the surrounding temperature being 42°, and the height of the barometer reduced to 0°, 757·99 mil. A small quantity of water was introduced into the globe, and the globe exhausted by means of the air-pump, and at the same time heated. In this way the atmospheric air was completely expelled by the vapours of water which was constantly developed. The stop-cock of the globe was then closed.

On the other hand, perfectly pure distilled water was boiled in a large globe to free it completely from the air which it always holds in solution at ordinary temperatures. Upon the tubules the ice first globe was fixed by caoutchouc a glass tube, twice bent, one of whose branches descended to the bottom of the vessel in which the water was kept boiling. On opening the stop-cock of the globe, the boiling water entered it slowly, without coming into contact with air; it was consequently perfectly free from that gas.

The globe being completely filled, the recurred tube was removed, and replaced by a tube having a bulb which was kept filled with the boiling water, and furnished the quantity of water necessary to keep the globe filled as its temperature lowered.

When the globe, filled with water, had come down to the surrounding temperature 0°, it was placed in a zinc vessel, and completely surrounded with melting ice, care being taken to pack the ice in proportion as it melted, upon the walls of the globe.

The globe was left in the ice for a time varying from 6 to 18 hours; the stop-cock was then closed, the bulbed tube detached, and the tube filled with water, carefully stoppered.

The globe was placed in a large vessel filled with water at a temperature a little above that of the chamber in which the balance was; it was left for two hours, so that it should take nearly the temperature of the chamber. As the water contracts in proportion as its temperature rises from 0° to 4°, it follows that the globe could be kept closed without danger of breaking. When the globe had acquired the temperature of the chamber, it was weighed, and this weighing (the temperature of the room and the height of the barometer being noted) gives the means of calculating the weight of water at 4°, which fills the capacity which the globe presents at 0°.

According to the experiments of M. Pierre (Annales de Chimie et de Physique, 3d série, tome xv., p. 348), if the density of water at 0° be taken as 1, at 4° it is 0·999881.

When we can calculate the weight of the water at 4° (its maximum density), which fills the capacity which the globe presents at 0°. Three experiments give the following results:

I. 9881·960 grammes.

II. 9881·113

III. 9881·299

The third weighing gave a number probably a little too high, because the globe was intentionally left a little but a small time in the ice, in order to see what influence this circumstance would have upon the result. On this account, M. Regnault adopts the mean of the former experiments, viz.: 9881·086.

Desiring to ascertain whether the correction made to reduce the weight of water from 0° to 4° was sufficiently exact, M. Regnault made two direct experiments, which gave a mean differing only 0·139 or 0·0011 from the result of the calculation. The capacity 100,000 of the globe at 0° was therefore 9881086 lit., and since (see Second Memoir) the weight of the air which filled it at 0°, under a pressure of 760 mil., was 197781 gr., the weight of the litre of air, under these normal circumstances, is 1·00197 gr. Or, 1·0023187 gr. 9·881086 " a value nearly less than that which was heretofore admitted from the experiments of M. Biot and Arago (1·0023941). From this and the numbers obtained in the preceding memoir for the densities of the gases we deduce, that at Paris the litre of Atmospheric Air weighs 1·2926718 grammes.

" Nitrogen " 1·265167

" Oxygen " 1·429802

" Hydrogen " 0·089578

" Carbonic Acid " 1·777414

Strictly considered, these values are only correct for the locality in which the experiments were made—that is, for a latitude of 46° 50' 14" and a height of 390 metres above the level of the sea.

M. Regnault finds the weight of the litre of air, under the parallel of latitude 45°, and at the same distance from the centre of the earth as that at which his experiments were tried, = 1·292697.

And assuming this as the standard, we have for any other latitude, and any other distance from the centre of the earth, the formula

\[ \frac{1}{w} = 1\cdot292697 (1 + 0\cdot00001883) \left(1 + 0\cdot0002837, \cos \lambda\right) \]

Or, more simply

\[ \frac{1}{w} = 1\cdot292673 (1 + 0\cdot0002837, \cos \lambda) \]

In which \( w \) is the weight of the litre of (the litre is 61·99098 cubic inches); \( R \), the mean radius of the earth = 3,966·196 metres; \( \lambda \), the height of the place of observation above this mean radius, expressed in metres; and \( \lambda \), the latitude of the place.

Applying this formula to the level of the sea, in the latitude of Philadelphia (39° 36' 31''), and assuming the radius of the earth at this place to be 3,676,633 metres.

The weight of the litre of air will be 1·2914392 grammes.

And assuming the litre as 61·99098 cubic inches and the gramme as 15·433159 grains troy.

The weight of a cubic inch of air will be 0·028891 grains troy.

Or, assuming Mr. Haussel's determination of the weight of a cubic inch of water, 292·6934 gr.): water is 774·63 times heavier than air.

Density of Mercury.

The density of mercury has been determined several times by M. Regnault, and with the greatest care; as he wished to satisfy himself whether that liquid, purified by the means employed ordinarily in the laboratories, presented a constant density.

A glass globe, of a capacity of from 290 to 300 cubic centimetres, was filled with mercury. The globe terminated in a capillary tube of about 2 mil. diameter, upon which a mark was made, and this tube was surrounded by a larger one which was used as a funnel. The funnel could be hermetically closed by a ground glass stopper. The globe being filled with mercury, this liquid was boiled, and suffered to cool. The globe was then placed in ice for several hours, and the level of the mercury brought exactly to the mark. As soon as it was satisfactorily ascertained that the level of the mercury did not change, the mercury was suffered to take the temperature of the air, and its weight determined. The same globe was then filled with distilled water, first boiled to deprive it of air. It was suffered to cool, the funnel being kept full of boiled water, and closed with its stopper. The globe was then surrounded with ice, and when the water had taken exactly the temperature 0°, the water level was brought to the mark, and the sides of the funnel wiped with filtering paper. The closed globe was then placed in water having nearly the temperature of the surrounding air, so as to bring it more quickly to the temperature of the air in which it was to be weighed.

The three determinations of the density of mercury, which are reported, were made at very different times, upon specimens from different sources, and in three different globes:

The first specimen was mercury designed for the construction of a standard barometer for the observatory of Paris. This mercury came directly from the mine; it had been twice distilled in an iron vessel, and then suffered to flow in the cold for four days. This liquid was then poured in the air-pump, and dried in the air-pump. The density of the mercury at 0°, compared with that of water at 4°, was 13·59399.

In the second experiment, the mercury employed was that used by M. Regnault in the construction of his barometer. This mercury was distilled several years ago, in an iron retort, and has water to the glass. This portion, which was not taken into account, was considered as making a part of the weight of the air, and necessarily made that weight too great. (see Biot's "Traité de Physique," tome i, p. 867.)
been kept in glass vessels. It was frequently purified by shaking it in flasks with concentrated sulphuric acid, then washing with much water. Its density at 0°, compared with that of water at 4°, was 13-5958.

III. Recently, M. Regnault has determined the density of mercury prepared with the greatest care by M. Millon, by the calculation of crystalline nitrate of mercury in a porcelain retort. The metal was then shaken up with concentrated sulphuric acid, to dissolve the oxide. Density of the mercury, 13-5962. Thus we find for the densities of these three specimens of mercury:

I. 13-5958
II. 13-59578
III. 13-59602

These densities may be considered as identical.

MM. Biot and Arago found the density of mercury, 13-598593.

The density differs but little from those which we have found. The little difference ought probably to be attributed to the uncertainty of the corrections which these illustrious physical philosophers were obliged to make in their method of operating.

It is often necessary, as in measuring heights by the barometer, to know the ratio of the density of mercury to that of air.

Now 1 lit. of air at 0°, under a pressure of 760 mill., weighs 1-28317 gr. 1000-000000 m., mercury at 0°, 135973; the ratio of the densities of mercury and air at the temperature 0°, and under the pressure of 760 mill. observed at Paris, is then 105132. At the level of the sea, and in latitude 48°, it becomes 105172; and at the level of the sea, at Philadelphia, 1059773.

(To be continued.)

CONTRIBUTIONS TO RAILWAY STATISTICS,
In 1846, 1847, and 1848.—By Hyde Clarke, Esq.

(Continued from page 245.)

No. III.—COAL TRAFFIC.

Coal traffic is one of the largest and most important items of railway transit; but here, as elsewhere, the returns published by the Railway Department are insufficient to show the whole amount. This is the more to be regretted, as the great reduction in the price of coal by railways has largely increased the demand for household use, as well as for manufacturing purposes. The monopolies of the canal proprietors, and of the wharfingers connected with them, have been broken up, and each year some new operation throws open a fresh district.

Coal traffic is of three kinds: from the colliery inland; from the colliery to the sea; and from the sea-shore inland.

The following shows the gross tonnage of coals, coke, and culm on the undermentioned lines for the years ending 30th June, 1846, and 1847.

* Supposed amount. † Imperfect return.

The quantities enumerated amounted to about 8,900,000, or nearly 9,000,000; the number enumerated in 1845 being 7,000,000 tons. The amounts received for the carriage of coal in the years ending June 30, 1846 and 1847, were as follows:
North Union, 20,000* 20,000*
North British, 20,000 1,371
Preston and Longridge, 46,283 —
Poston and South Shields, — 65,736 71,842
Stockton and Darlington, 782 247
Stockton and Hartlepool, 20,261 33,472
Clarence, 3,235
South Eastern, — 6,554
Scottish Midland, — 349
Shrewsbury and Chester, — 10,571 10,469
St. Helen's, — 24,447 28,020
Taff Vale, — 406 376
Ulster, — 3,220 5,567
West Cornwall (Hayle), — 13,523 19,184
Wishaw and Collens, — 14 350
Whitehaven, — 36 253
Wlscoustrn, — 111,364
York and Newcastle, — 16,179 19,637
York and North Midland, — 12,693

* Estimated amount. ♂ Imperfect return.

This constitutes a total of nearly £330,000, so that the gross total is most probably nearly £700,000, being the sum received by railways on account of the conveyance of coal. Amongst the lines omitted are the following:

Great Western, Edinburgh and Glasgow, Glasgow and Ayr, London and South Western, Eastern Counties: Colchester, Monkland and Kirkintilloch.

The rates of charge vary much on the several lines, depending on many circumstances, so that it is impossible to institute an accurate comparison. In some cases, the coal-owners supply their own locomotives and wagons, and are charged with toll only. In others, they supply wagons only. In others, they are charged with an additional rent for wagons. In many cases the company hauls and supplies wagons.

The following shows the quantity of coal carried in the year ending June 30, 1847, at each rate of charge:

<table>
<thead>
<tr>

* Estimated amount. ♂ Imperfect return.

The following shows the quantity of coal carried inland from the sea in each year:

<table>
<thead>
<tr>
<th>Eastern Counties: Cambridge,</th>
<th>1845</th>
<th>1846</th>
<th>1847</th>
</tr>
</thead>
<tbody>
<tr>
<td>Colchester</td>
<td>15,000</td>
<td>15,000</td>
<td>15,000</td>
</tr>
<tr>
<td>Eastern Union</td>
<td>20,000</td>
<td>20,000</td>
<td>15,000</td>
</tr>
<tr>
<td>Ipswich and Bury</td>
<td>20,000</td>
<td>20,000</td>
<td>19,000</td>
</tr>
<tr>
<td>Norfolk</td>
<td>6,000</td>
<td>15,000</td>
<td>15,000</td>
</tr>
</tbody>
</table>

On the whole, the rates for the carriage of coal are lower than they were in 1846; only a small quantity of coal is carried on the higher priced lines.
**THE CIVIL ENGINEER AND ARCHITECT’S JOURNAL.**

<table>
<thead>
<tr>
<th>South Eastern</th>
<th>35,519</th>
<th>45,330</th>
<th>71,723</th>

</tr>
</tbody>
</table>

The quantity of coal carried inland by means of railways has increased.

The saving in coal supplied to the city of York, in consequence of Mr. Hudson’s railway measures, is not less than £30,000 yearly.

In the south-east of England, which is supplied mostly from the Northumberland and Durham coal-fields, the quantity carried upland by railway may be reckoned as follows:

<table>
<thead>
<tr>
<th>Year</th>
<th>Tons</th>
</tr>
</thead>
<tbody>
<tr>
<td>1845</td>
<td>120,000</td>
</tr>
<tr>
<td>1846</td>
<td>162,000</td>
</tr>
<tr>
<td>1847</td>
<td>240,000</td>
</tr>
</tbody>
</table>

How trivial this is, may be seen from the quantity of coals imported into London, which is thus shown:

<table>
<thead>
<tr>
<th>Year</th>
<th>Tons</th>
</tr>
</thead>
<tbody>
<tr>
<td>1825</td>
<td>1,521,091</td>
</tr>
<tr>
<td>1835</td>
<td>2,599,816</td>
</tr>
<tr>
<td>1845</td>
<td>3,461,199</td>
</tr>
</tbody>
</table>

It will be seen that in the supply of the inland districts the railways have proved very effective; but they have done as yet very little for those districts which are supplied from the sea. This must be attributed to the inability of the railway companies to give their attention at present to this branch of traffic; but when they do, a complete revolution must be effected in the supply of coals. The only lines from which we have detailed returns are the South Eastern and South Western, which show a great increase in the quantity of coal carried. There is every reason to believe that a great traffic is growing up in the Eastern Counties district—not less than 55,000 tons: but the returns do not show this fully.

**No. IV.—COKE TRAFFIC.**

The traffic in coke must be considerable in some districts, but there is a want of detailed returns. It is a lucrative branch of revenue to the Midland Railway Company.

The following shows the traffic in coke in each year on the under-mentioned lines:

<table>
<thead>
<tr>
<th>Year</th>
<th>Tons</th>
</tr>
</thead>
<tbody>
<tr>
<td>1844</td>
<td>1845</td>
</tr>
<tr>
<td>1846</td>

<th>£</th>
</tr>
</thead>
<tbody>
<tr>
<td>1846</td>
<td>22,010</td>
</tr>
<tr>
<td>1847</td>
<td>22,118</td>
</tr>
</tbody>
</table>

**No. V.—IRONSTONE AND IRON TRAFFIC.**

These form great branches of mineral traffic, but the extent of them is very imperfectly expressed in the returns.

The traffic in ironstone and the following railways in the years ending June 30, 1845, 1846, and 1847, is shown below in tons.

<table>
<thead>
<tr>
<th>Year</th>
<th>Tons</th>
</tr>
</thead>
<tbody>
<tr>
<td>1845</td>
<td>229,010</td>
</tr>
<tr>
<td>1846</td>

</tr>
<tr>
<td>Whitchurch</td>
<td>1402</td>
</tr>
<tr>
<td>It is estimated amount.</td>
<td></td>
</tr>
</tbody>
</table>

The returns for the Ballychoven railway include iron likewise.

The amount of iron received in each of those years was as follows:

<table>
<thead>
<tr>
<th>Year</th>
<th>Tons</th>
</tr>
</thead>
<tbody>
<tr>
<td>1845</td>
<td>1846</td>
</tr>
<tr>
<td>1847</td>
<td>1847</td>
</tr>
<tr>
<td>Ballychoven</td>
<td>6,931</td>
</tr>
<tr>
<td>Furness</td>
<td>5,353</td>
</tr>
<tr>
<td>Newcastle and Carlisle</td>
<td>28,901</td>
</tr>
<tr>
<td>Taff Vale</td>
<td>2700*</td>
</tr>
<tr>
<td>Dilton, Aberdare</td>
<td>5,907</td>
</tr>
<tr>
<td>Whitehaven</td>
<td>900*</td>
</tr>
</tbody>
</table>

The rates charged for the conveyance of ironstone and iron-ore are as follows:

<table>
<thead>
<tr>
<th>Location</th>
<th>Rate per ton per mile</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ballychoven</td>
<td>2.25d.</td>
</tr>
<tr>
<td>Newcastle and Carlisle</td>
<td>1.37</td>
</tr>
<tr>
<td>Taff Vale</td>
<td>1.16</td>
</tr>
<tr>
<td>Whitehaven</td>
<td>1.25</td>
</tr>
<tr>
<td>Wishaw and Coltness</td>
<td>2.23</td>
</tr>
</tbody>
</table>

The traffic in iron for the three years is as follows:

<table>
<thead>
<tr>
<th>Year</th>
<th>Tons</th>
</tr>
</thead>
<tbody>
<tr>
<td>1845</td>
<td>7,881</td>
</tr>
<tr>
<td>1846</td>
<td>14,065</td>
</tr>
<tr>
<td>1847</td>
<td>40,000</td>
</tr>
<tr>
<td>Glasgow and Ayr</td>
<td>25,000</td>
</tr>
<tr>
<td>Lancashire and Yorkshire</td>
<td>9,000*</td>
</tr>
<tr>
<td>Maryport and Carlisle</td>
<td>2,937</td>
</tr>
<tr>
<td>Shrewsbury and Chester</td>
<td>9,486</td>
</tr>
<tr>
<td>Slamannan</td>
<td>861</td>
</tr>
<tr>
<td>Taff Vale</td>
<td>88,493</td>
</tr>
<tr>
<td>Whitehaven</td>
<td>1,833</td>
</tr>
<tr>
<td>Wishaw and Coltness</td>
<td>73,429</td>
</tr>
</tbody>
</table>

The amounts received are as follows:

<table>
<thead>
<tr>
<th>Year</th>
<th>£</th>
</tr>
</thead>
<tbody>
<tr>
<td>1845</td>
<td>148,166</td>
</tr>
<tr>
<td>1846</td>
<td>148,166</td>
</tr>
<tr>
<td>1847</td>
<td>148,166</td>
</tr>
</tbody>
</table>

The iron carried is mostly pig-iron.

The rates for the carriage of iron are as follows:

<table>
<thead>
<tr>
<th>Location</th>
<th>Rate per mile per ton</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ballychoven</td>
<td>2.5</td>
</tr>
<tr>
<td>Newcastle and Carlisle</td>
<td>1.80</td>
</tr>
<tr>
<td>Taff Vale</td>
<td>1.00</td>
</tr>
<tr>
<td>Wishaw and Coltness</td>
<td>1.00</td>
</tr>
<tr>
<td>Whitehaven</td>
<td>1.00</td>
</tr>
</tbody>
</table>

A considerable quantity of dress and slag is carried, but there are only returns on the Wishaw and Coltness railway:

<table>
<thead>
<tr>
<th>Location</th>
<th>Tons</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dress</td>
<td>110,084</td>
</tr>
<tr>
<td>Wishaw and Coltness</td>
<td>1,068</td>
</tr>
</tbody>
</table>

The traffic of the Glasgow iron district in coals, limestone, ironstone, iron dress, and slag carried by railway was in 1846 and 1847 as follows:

<table>
<thead>
<tr>
<th>Year</th>
<th>Tons</th>
</tr>
</thead>
<tbody>
<tr>
<td>1846</td>
<td>2,500,000</td>
</tr>
<tr>
<td>1847</td>
<td>2,500,000</td>
</tr>
</tbody>
</table>

The traffic of the Welsh iron district in coal, limestone, ironstone, iron dress, and slag carried by railway was in 1846 and 1847 as follows:

<table>
<thead>
<tr>
<th>Year</th>
<th>Tons</th>
</tr>
</thead>
<tbody>
<tr>
<td>1846</td>
<td>2,323,000</td>
</tr>
<tr>
<td>1847</td>
<td>2,323,000</td>
</tr>
</tbody>
</table>

The traffic of the Furness iron district consists solely in the shipment of ironstone to South Wales, to the extent of 106,301 tons in 1847.

**No. VI.—COFFER AND TIN TRAFFIC.**

The traffic in copper and tin ores is confined to the Cornwall lines. There are no data now to show this. In 1845 I estimated it as follows:

<table>
<thead>
<tr>
<th>Year</th>
<th>Rate</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bodmin and Wadebridge</td>
<td>1.00</td>
</tr>
<tr>
<td>Hayle</td>
<td>4.00</td>
</tr>
</tbody>
</table>

**No. VII.—LIMESTONE AND LIME.**

The following shows the quantity of lime carried in the years ending June 30, 1846 and 1847:
The following shows the amounts received for the carriage of lime:

<table>
<thead>
<tr>
<th>District</th>
<th>1846</th>
<th>1847</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abroath and Forfar</td>
<td></td>
<td></td>
</tr>
<tr>

<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Newcastle and Carlisle</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>York and North Midland</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The traffic in limestone and lime in 1847, so far as details exist, may be calculated as follows:

<table>
<thead>
<tr>
<th>District</th>
<th>Tons</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abroath and Forfar</td>
<td>1,000</td>
</tr>
<tr>
<td>Ballachy</td>
<td>1,000</td>
</tr>
<tr>
<td>Farsness</td>
<td>2,441</td>
</tr>
<tr>
<td>Great North of England</td>
<td>2,800</td>
</tr>
<tr>
<td>Llanelli and Llandilo</td>
<td>279</td>
</tr>
<tr>
<td>Maryport and Carlisle</td>
<td>1,029</td>
</tr>
<tr>
<td>Midland</td>
<td>4,020</td>
</tr>
<tr>
<td>Newcastle and Carlisle</td>
<td>1,000</td>
</tr>
<tr>
<td>York and North Midland</td>
<td>1,000</td>
</tr>
</tbody>
</table>

The total enumerated in 1845 was 139,544 tons.

The total quantity of building and paving stones in 1847 was as follows:

<table>
<thead>
<tr>
<th>District</th>
<th>Tons</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abroath and Forfar</td>
<td></td>
</tr>
<tr>
<td>Ballachy</td>
<td></td>
</tr>
<tr>
<td>Farsness</td>
<td></td>
</tr>
<tr>
<td>Great North of England</td>
<td></td>
</tr>
<tr>
<td>Llanelli and Llandilo</td>
<td></td>
</tr>
<tr>
<td>Maryport and Carlisle</td>
<td></td>
</tr>
<tr>
<td>Midland</td>
<td></td>
</tr>
<tr>
<td>Newcastle and Carlisle</td>
<td></td>
</tr>
<tr>
<td>York and North Midland</td>
<td></td>
</tr>
</tbody>
</table>

The amounts received for the carriage of limestone and lime in 1845, 1846, and 1847, were as follows:

<table>
<thead>
<tr>
<th>District</th>
<th>1845</th>
<th>1846</th>
<th>1847</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abroath and Forfar</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Ballachy</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Farsness</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Great North of England</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Llanelli and Llandilo</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Maryport and Carlisle</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Midland</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Newcastle and Carlisle</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>York and North Midland</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The total receipts for the carriage of limestone and lime in 1847 were not less than £11,000, but there has been a falling-off in the Midland traffic.

The rates for the carriage of a ton of limestone and lime are as follows:

<table>
<thead>
<tr>
<th>District</th>
<th>Rate</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abroath and Forfar</td>
<td>£2.4d</td>
</tr>
<tr>
<td>Llanelli and Llandilo</td>
<td>1d</td>
</tr>
<tr>
<td>Maryport and Carlisle</td>
<td>1s 10d</td>
</tr>
<tr>
<td>York and North Midland</td>
<td>1s 5d</td>
</tr>
</tbody>
</table>

The greatest traffic in limestone and lime is carried on the following companies:

<table>
<thead>
<tr>
<th>Company</th>
<th>Tons</th>
</tr>
</thead>
<tbody>
<tr>
<td>Midland</td>
<td>55,677</td>
</tr>
<tr>
<td>Newcastle and Carlisle</td>
<td>40,260</td>
</tr>
<tr>
<td>York and North Midland</td>
<td>14,000</td>
</tr>
</tbody>
</table>

The limestone traffic on the Midland line is on the old North Midlands line.

No. VIII.—STONE TRAFFIC.

The number of tons of building and paving stone carried in the years ending June 30, 1845, 1846, and 1847, distinguished in the returns, is as follows:

<table>
<thead>
<tr>
<th>District</th>
<th>Tons</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abroath and Forfar</td>
<td>30,000</td>
</tr>
<tr>
<td>Chester and Birkenhead</td>
<td>2,800</td>
</tr>
<tr>
<td>Maryport and Carlisle</td>
<td>10,000</td>
</tr>
<tr>
<td>Midland</td>
<td>1,000</td>
</tr>
<tr>
<td>Newcastle and Carlisle</td>
<td>1,000</td>
</tr>
<tr>
<td>York and North Midland</td>
<td>1,000</td>
</tr>
</tbody>
</table>

The figures given by no means represent the gross traffic in building and paving stones for each year. From an examination of the detailed figures, there seems to have been a falling-off in the use of building and limestones in 1847, although the gross quantity carried on railways increased.

The total quantity of building and paving stones, limestones, and lime carried on railways in 1847 was as follows, according to the enumerated returns:

<table>
<thead>
<tr>
<th>District</th>
<th>Tons</th>
</tr>
</thead>
<tbody>
<tr>
<td>Building stones</td>
<td>404,000</td>
</tr>
<tr>
<td>Limestones and lime</td>
<td>146,000</td>
</tr>
</tbody>
</table>

The enumerated traffic gives the enormous quantity of 500,000 tons of stones carried, but the whole quantity carried must be nearer 1,000,000 tons.

The amounts received for the carriage of building and paving stones stand thus:

<table>
<thead>
<tr>
<th>District</th>
<th>Tons</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abroath and Forfar</td>
<td>1,000</td>
</tr>
<tr>
<td>Chester and Birkenhead</td>
<td>1,000</td>
</tr>
<tr>
<td>Maryport and Carlisle</td>
<td>1,000</td>
</tr>
<tr>
<td>Midland</td>
<td>1,000</td>
</tr>
<tr>
<td>Newcastle and Carlisle</td>
<td>1,000</td>
</tr>
<tr>
<td>York and North Midland</td>
<td>1,000</td>
</tr>
<tr>
<td>(North Shields Branch)</td>
<td>1,000</td>
</tr>
</tbody>
</table>

* Half-year, 61,000 tons.  † Half-year, 6,000 tons.  ‡ Half-year, 6,000 tons.  $ Half-year, 6,000 tons.

**PLAN-PRICKING INSTRUMENT.**

Sirs—Amongst other duties, I am engaged in making a most extensive and minute survey of a large city, showing every house and all the drainage throughout, the scale being very large—1 inch to 100 feet; and I am preparing duplicate fair copies of each sheet, which is being done by pricking through all the sheets at once, the original working drawing being placed uppermost. In doing this with the common pricker, I found that the draughtsman did not hold the pricker perpendicular; consequently, the lower sheets could not be accurate copies of the original. To obviate this, I have contrived an instrument, by which any attention on the part of the draughtsman in keeping it perpendicular is not required: all he has to do is to be careful that he pricks through the proper points of the plan correctly; the holes are then sure to be vertically under one another, let the sheets of paper be ever so numerous.

**STREET PAVING.**

Sirs—It is not necessary at this time to revive the controversy formerly raised between the respective advocates of wood and stone paving; experience or experiment—that great test of truth—will, ere this, have determined the opinions of most persons, as to the relative value or conditions of applicability of the two systems. It may not, however, have been considered how far combinations of the two might be made with advantage—adapted especially to certain cases.

To the repairing of Holborn-hill, consequent on the recent removal of the houses on the north side of Holborn-bridge, brings to consideration the inconveniences—nay, dangers, occurring to the carriage traffic on declivities such as this, with any mode of paving hitherto adopted.

The placing of the granite stones obliquely to the line of surface, whereby the edges of the stones formed a series of sharp angles or steps (thus giving a rough surface and good foot-hold for horses drawing up, and obstructions to the too rapid sliding of wheels down the hill), appeared a vast improvement—and truly would be so; if the uneven surface thus obtained were not rapidly worn off by the continued traffic, and especially by the action of the drags on the wheels of carriages descending the hill. Thus the surface soon becomes smooth and slippery, whatever be the material used or form of laying, whenever the material is of one and the same kind, and consequently of equal wear throughout.

If, however, we employed materials, in conjunction, of different characters and rates of wear, we should then maintain inequalities of surface, affording continuous foot-hold for horses, and obviating existing defects.

Suppose that between each course of granite paving there were placed a thin course of wood, then the difference in the wear of the two would give the effect desired.

The annexed sketch shows the arrangement. A course of granite stones, A, to be laid in the usual way across the road, being about three inches in thickness; following this with a plank of wood, B, one inch thick, and of the depth of the granites; then following on with stones and planks in alternate courses.

Let us not stand arguing doubts and probabilities, but put the question to the true test of experiment. This can be done within a small space, and at little cost.

Hampstead, August 8, 1848.

J. L.
EXPERIMENTS ON COALS.

Report on the Coals Suited to the Steam Navy. By Sir Henry de la Beche and Dr. Lyon Playfair.

Experiments necessary to ascertain the true practical value of coal involve a very large series of observations, extended over a considerable period, and directed to special objects of inquiry. The qualities for which particular kinds of fuel are pre-eminent being so varied, it is impossible to deduce general results from a limited series of observations. Even in the economical application of coals, their evaporative value, or their power of forming steam, one variety of coal which may be admirably adapted from its quick action for raising steam in a short period, may be far exceeded by another variety, inferior in this respect, but capable of converting a much larger quantity of water into steam, and therefore more valuable in the production of force. A coal uniting these two qualities in a high degree might still be useless for naval purposes, on account of its mechanical structure. If the cohesion of its particles be small, the effect of transport or the attrition of one coal against another by the motion of a vessel might so far pulverise it as materially to reduce its value. Even supposing the three qualities united, rapidity and duration of action with considerable resistance to breakage, there are many other properties which should receive attention in the selection of a fuel without the combination of which it might be valueless for our steam navy.

There is an important difference existing between varieties of coals in the bulk or space occupied by a certain weight. For the purpose of making dry the ash adhering by specific gravity alone, because the mechanical formation of the films of coal may enable one of less density to take up a smaller space than that occupied by another of a higher gravity. This is far from an imaginary difference, being sometimes as great as 60 per cent, and not unfrequently 40 per cent. The mere theoretical determination of the density of coals would therefore give results useless for practice. The space occupied between two varieties of coals, often equally good as regards their evaporative value, differs occasionally 90 per cent.—that is, where 80 tons of one coal could be stowed, 100 tons of another of equal evaporative value might be placed, by effect of which the attention of the mechanical engineer is naturally directed. These facts are mentioned merely to show that a hasty generalisation should not be made, and to account for our drawing attention to these various points as a means of preventing the selection of a fuel from any one quality. We do not, in the present stage of this inquiry, consider it proper to offer any recommendation of our own as to particular kinds of fuel, leaving the experimental facts to decide for themselves.

After preliminary experiments had proved that no practical result could be attained by mere laboratory research, it was determined to test each variety of coal on a scale of sufficient magnitude to check the theoretical views by the practical results. As it was impossible for either of us to devote our whole time to this inquiry, our services being required by other official duties, we appointed assistants* to superintend its special parts, under our general direction.

It will be obvious that there are several circumstances which must receive attention before the true evaporative value of a fuel can be obtained. Thus, the water in the tanks has a varying temperature during the day, dependent on atmospheric changes, and is always different from that in the boiler. The temperature of water in the boiler also varies with the external temperature, and the circumstances under which the experiments are made. The shape of a Cornish boiler favours an inequality in the temperature of the water in its various parts, the colder and denser water sinking to the bottom, and having a tendency to remain there; so that the temperature of water at the surface is far from being the mean temperature of water in the boiler, the difference between the surface and bottom water being, on an average, 70°. Other circumstances naturally affect the evaporative powers of the coal, as for example the fact that all the water exposed to the action of the fire in the boiler is not converted into steam, and that wood is used to light the fire. Another circumstance of considerable importance, is the expansion or contraction of the boiler from an increase or diminution of the temperature. In the early stage of these experiments, those conducted by Messrs. Wilson and Kingsbury, it was thought unnecessary to make a correction for this variation in conditions; but on ascertaining experimentally

* The assistants employed were Mr. Wilson, Principal of the Royal Agricultural College, Mr. Kingsbury, Mr. J. Arthur Phillips, and Mr. Hutchinson. Mr. Wrightson, a pupil of Liebig, was entrusted with the analyses of the coal, Mr. Galloway analysed the gases, and Mr. Hawe also assisted in the analyses.

that the difference was as much as 69'625 lb. of water in the contents of the boiler, between the temperature 150° and 212°, it became desirable to make an allowance for it, even when the difference between the initial and final temperature was not greater than 10°. Other circumstances of less importance, but influencing the results, have been neglected, because the application of such corrections would have only complicated the results, and would have had little practical value when the errors of observation in such approximate experiments remain so large. Among these may be mentioned the quantity of gases evolved during combustion, the elevation in temperature of the air entering the fire-place, the barometrical and hygrometric conditions of the atmosphere, the radiation from the boiler (very small in amount, owing to its brick covering), the hydraulic state of the water, or, the heat necessary for obtaining mechanical draught in the chimney. In most of these cases the necessary observations have been made, to enable the corrections to be applied, should it afterwards appear desirable.

In making the calculation for the evaporative value of a fuel, the quantity consumed was divided into two portions, the first being that necessary to raise the whole mass of water exposed to the fire from the mean temperature to 212°, the second portion being that required to evaporate the water taken from the tanks at the temperature of 212°. To effect this to be done, the mean temperature of the whole mass of water was ascertained—that is, the temperature of the water in the boiler at its initial temperature after being mixed with the tank-water at its average temperature. W the weight of water from the boiler at temperature t; W the weight of water in the boiler at temperature t', this being obtained from surface temperature corrected by experiment; t, temperature after mixture.

Then $t = \frac{W}{W + w} t'$.

The correction for the wood was made from data procured by Messrs. Wilson and Kingsbury, but it can only be employed for the particular wood used, as in subsequent experiments the evaporative value was found very different from another quality obtained. The co-efficient of the evaporative power of the wood may be deduced from experiment, in which a certain weight of water was raised from a known temperature to the boiling point, and then a certain portion of it evaporated. The following formulae have been used by Mr. Kingsbury for the calculation:

$N$ is the total weight of wood used in raising $(W + w)$ (the weight of water in the boiler, and of that let down from the tanks during an experiment) from the mean temperature $t$ to $212°$; then it is necessary to find the weight $N'$ necessary to evaporate $w$ from $212°$.

Then $N' = \varepsilon$, the evaporating power.

Let $m$ be the weight of water required to raise $W + w$ from $t$ to $212°$, the number 1000 being assumed as the latent heat of steam. $N'$ to evaporate $W + w$ from $212°$, to evaporate $W + w$ from $212°$, $N'$ to evaporate $W + w$ from $212°$.

Then $m + N' = N$. Now $\frac{1}{212 - t} \approx \frac{N}{m}$.

But $N = \frac{W + w}{w} \cdot N' = \frac{w}{W + w}$; $N = \frac{W + w}{w} \cdot N' = \frac{w}{W + w}$.

$N = N' \left( \frac{W + w}{W + w} \right)$

$= \frac{N' \left( 212 - t \right)}{\left( W + w + l \right)}$.

$= \frac{N' \left( 212 - t \right)}{\left( W + w + l \right)}$.

Introducing the value of $t$ as given by the first formula, $(212 - t)w + (212 - t)'W = e$.

$N' = \frac{N}{l}$.

If $q$ be the quantity of wood used in lighting the fire, $q\varepsilon$ will be the weight of water evaporated from $212°$ by the wood, and must be deducted from the weight of water evaporated in calculating the work done by the coal.

The co-efficient of the evaporative power of the coals, or the
number of lbs. of water which one lb. of coal will evaporate from 212°.

Let \( P \) be the total quantity of coal consumed, then the work done by \( P \) will be to raise \( W + w \) of water from \( t \) to 212°, and to evaporate \( w - q \) from 212°.

Let \( m \) be the weight of coal required to raise \( W + w \) to 212°, from \( t \) to \( n \), and to evaporate \( w - q \) from 212° to \( n \).

Then \( \frac{w - q}{n} = E \), the evaporating power.

Now \( P = m + \frac{212 - t}{n} \)

But \( \frac{n}{W + w} = \frac{1}{P} \cdot \frac{w - q}{(212 - t) + (w - q)} = \frac{w - q}{W + w} = \frac{W + w - (212 - t)}{212 - t} \)

Introducing the values from which the mean temperature \( t \) was obtained (first formula), we have eventually

\[
(W + w) I + (212 - t) W - 1tq = E
\]

in which \( W \) is the weight of water in the boiler;
\( w \) is the weight of water drawn from the tanks;
\( t' \) the corrected initial temperature of water in the boiler.

In the preceding formula, the latent heat of steam has been taken 1000, the number generally used in this country; but after all the calculations had been made on the basis of the experiments by Messrs. Wilson and Kingbury, and the results sent in to the Admiralty, Regnault's excellent memoir on the "Latent Heat of Steam" was published. It became necessary, therefore, to use these new results in the future experiments. These, so far as the supply to the present inquiry, are reduced in the following table:

<table>
<thead>
<tr>
<th>Air Thermometer Centigrade</th>
<th>Number of Units of Heat abandoned by one kilo. of water in descending to 70°</th>
<th>Air Thermometer Fahrenheit</th>
<th>Air Thermometer Centigrade</th>
<th>Number of Units of Heat contained in one pound of water at 70°</th>
<th>Mean Specific Heat of Water between 70° and 90° Cent. or between 68° and 90° Fahren.</th>
<th>Specifice Heat of 1000 lbs. of Water at 90° Cent to the temperature T°</th>
<th>Latent Heat of Steam to the temperature T°</th>
<th>Specific Heat of Steam in 1000 lbs. of Water to the temperature T°</th>

</tbody>
</table>

It also became desirable to introduce new corrections, which the progress of the inquiry showed to be desirable. Thus, Mr. Phillips' careful experiments determined the alteration in the capacity of the boiler at different temperatures, and correction was in future made for this difference. The alteration in the capacity of the measuring tanks was also estimated, whenever the temperature differed \( t' \) from that which was assumed. Another cause of error, for which allowance should be made, is any difference which may exist between the initial and final temperature at the beginning and close of the experiment. This difference being known by observation, the correction may be applied from the table of expansion of the water in the boiler, given. Introducing these new corrections into the experiments for ascertaining the co-efficient of the heating power of the wood, the following are the formulas used by Mr. Phillips:

\[
(W + w - w')(l + w') t + (w - w) t' = E
\]

Where \( W \) is the weight of water in the boilers at commencement of experiment;
\( w \) is the weight of water in boiler at close of experiment;
\( l \) is Co-efficient of the latent heat of steam;
\( t \) is Quantity of heat necessary to raise the water in tanks from its mean temperature to that at which it is evaporated;
\( t' \) is Quantity of heat necessary to raise the water in the boiler from the initial to the final temperature;
\( E \) is Co-efficient of the heating powers of wood.

But when the initial is lower than the final temperature, the formula becomes:

\[
(W + w - w') l + W l + w t' + (w - w) t' = E
\]

All the terms retaining their original value except the last, in which \( E \) is placed by \( E' \) (or the heat necessary to raise it from the final temperature to that at which the water was expanded), and must be regarded as having a negative value, while \( E' \) becomes positive.

If now \( g \) is the weight of wood used in lighting the fire, the formula for estimating the evaporative power of the coal will be

\[
(W - E + w - w') l + (W + w - w') l + w t' + (w - w) t' = E' P l
\]

And

\[
(W - E + w - w') l + W l + w t' + (w - w) t' = E' P l
\]

As the experiments are strictly comparative, and under like conditions, the want of the other corrections, to which we have alluded above, will not fail in examining the results; while the above correction would have introduced a refinement into the experiments which never could be obtained in practice, and which, in fact, would be useless and unwarrantable while, as previously remarked, the errors of observation in all such approximative experiments remain so large.

The only omitted correction which in appearance might be supposed necessary for practical purposes, is that for the hygroscopic condition of the fuel. Had wood been employed, this must have been done; but the hygroscopic nature of coal is very much less than that of wood. The latter contains 4% of its own weight of hygroscopic water; and the heat necessary for the evaporation of this quantity might be shown by a simple calculation, to be nearly equal to 4% of the total heat obtained by the combustion of the wood. The hygroscopic water in coal is however very small, as will be seen by the following determinations of some of the Welsh specimens experimented upon:

<table>

Had we introduced corrections for these small quantities, practice would have been misled; because the coals will rarely reach the dry state, and in the worse case, when they were packed in hogsheads and kept under cover,—it was found unnecessary to correct for any inflammable gases flying up the chimney, because repeated analyses of the chimney gases proved them not to contain any combustible constituent; the only products of combustion being carbonic acid, oxygen, and nitrogen. The quantity of free oxygen in the chimney varied from \( \frac{1}{4} \) to \( \frac{1}{4} \) of the oxygen which combined with the fuel; in other words, nearly twice the quantity of air passed through the fire than that which is strictly necessary by theory.

With regard to the selection of the coals for trial, we have to refer to Mr. Wilson's letter. This letter gives the information obtained in a tour made by Professor Wilson for the purpose of ascertaining the best coals fitted for trial in the South Wales coal district, and the ports from which they can conveniently be shipped. This district was selected because the varying character of the coals, from the bituminous to the anthracite, offered those which were most likely to combine the qualities desired for...
The economical results obtained by evaporation in the best-applied practice are ascertained to be only a small part of the theoretical result following from the actual quantity of heat capable of being generated. Still, as a comparative statement, it is necessary to contrast the economical heat given out by a coal with the theoretical quantity. The cause of the difference between the applied and theoretical quantities is, at least in a great degree, obvious, and does not by any apparent difference prove the fallacy of calculation. Before the comparison can be made, it is necessary to have a knowledge of the composition of the respective coals; of this we subjoin a table. (See Table III.)

Chemists differ as to the mode of calculating the theoretical heating values of coals, but, as an approximate rule, without insisting on its absolute accuracy, their calorific values are found to stand in relation to the quantity of oxygen required for their complete combustion. This may be estimated experimentally by heating the coal with an excess of lime; or it may be determined by calculation from the known equivalents of the combustible ingredients of the coal. From the quantity of lead reduced by the coal, the oxygen employed in its combustion may be estimated, and the calorific values stand in direct relation to this quantity. The amount of oxygen necessary to combust the combustible constituents may more accurately be determined by elementary analysis; and thus calculated, the results are generally found to be about \( \frac{1}{4} \) greater than those indicated by experiment with the lighthouse. The calculation from the elementary analysis depends upon the circumstances, that 6 parts, or one equivalent, of carbon requires 16 parts, or two equivalents, of oxygen for combustion, while 1 part of hydrogen requires 8 parts of oxygen; it is only necessary, therefore, to subtract from the hydrogen a quantity corresponding to the oxygen contained in the coal to enable the calculation to be made on these principles. As the calorific values and their equivalents are so complex, it is useful to refer them to the heating power of pure carbon, a part of which requires 2 266 parts of oxygen for combustion, and is capable, according to Desprez, of heating 78 15 parts of water from its freezing to its boiling point. The calculation may be simplified by multiplying each part of lead obtained by 2 265, which gives at once the weight of water capable of being heated between these temperatures by a unit of the coal used in reducing the lighthouse. On these principles the following table is constructed. (See Table IV.)

With regard to the practical application of fuel, such a table could not supersede experiment, as the economical values of the coal depend also on adventitious circumstances connected with their physical as well as their chemical condition. This table, while on the whole it agrees with and confirms the practical results of experiment, still differs in a marked degree in one or two instances; this difference arising as much from the chemical as from the physical differences of the coals. Thus, if by destructive distillation, which occurs in furnaces before combustion, a large quantity of the constituents of the coal are rendered gaseous, so much heat is expended in that act that the heat developed by the after-combustion is frequently not greater than that abstracted during their formation, in which case a thermo-neutrality occurs. To ascertain the proportion of fixed and volatile products in the various coals, a very difficult and elaborate process was adopted; but the tediousness and chances of failure in this kind of analysis have induced us to include the number of coals (those given in Table V.), especially as for steam purposes it was sufficient to determine the percentage of coke, as stated in Table II.
exceptions, which might have been expected, they on the whole show that the work capable of being performed by the coke alone, is actually greater than that obtained by experiments with the original coal.

The whole system of manufacturing coke is at present very imperfect. Besides losing the volatile combustible substances, which under new adjustments might be made of much value, an immense quantity of ammonia is lost by being blown into the atmosphere. Ammonia and its salts have been found to be a valuable agricultural improvement, and it is their comparative high price alone which prevents their universal use to all kinds of cereal cultivation. By the construction of the most simple kind, the coke ovens now in use might be made to economise much of the nitrogen which invariably escapes in the form of ammonia to the air. To the economy of this kind, we have appended to Table VI two columns (H and J), showing the quantity of ammonia (N₂H₃), and its corresponding quantity of commercial sulphate (NH₄NO₃), which each ton or the respective coals may be made to produce. When it is remembered that the price of sulphate of ammonia is about £13 per ton, or that 100 tons in cooking is capable of producing, on an average, about 6 tons of this salt, its neglect is highly reprehensible.

By the preceding data, the actual value of the coals will be considered as that which is theoretically possible, that loss of combustion proceeded under circumstances which prevented any loss of heat. The actual duty obtained by a pound of coal from the boiler employed may be easily expressed by the number of pounds raised to the height of one foot. This result may readily be obtained by the simple formula—

\[ W \times 6957 \times 782 = x, \]

W representing water, of which \( \eta \) pounds are evaporated by a pound of coal. This formula is deduced from the fact that \( \eta \) pounds of water multiplied by 9637, or the co-efficient for the latent heat of steam at 212°F, indicates the number of pounds of water which would be raised 1°F Fahrenheit; and the number 782 arises from experiments on the mechanical force denoted by the evaporation of a pound of water at 1°F, and force being equal to 179 lb., raised to the height of one foot, according to the careful experiments of M. Joule, on the friction of oil, water, and mercury.

The theoretical value of the coals, with reference to the number of pounds of water which one pound of fuel will convert into steam, is obtained by the formula—

\[ C \times 19368 + (H - B \times 62470) = 9637 - 9637 \]

in which \( C \) is the quantity of carbon, \( H \) the quantity of hydrogen in a unit of fuel, and \( B \) the quantity of hydrogen corresponding to the oxygen contained in the coal. These multiplied by their heating powers, according to the results of Dulong, and divided by the latent heat of steam, indicate the number of pounds of water that can be converted into the latter by a pound of coal. The numbers thus obtained can be changed into the expression of mechanical force, by the previous formula.

The result of these calculations are thrown into Table VI.

The best Cornish engines are stated to raise 1,000,000 lb. to the height of one foot, by every pound of coal consumed; so that only about \( \eta \) of the actual force generated becomes available, or only \( \eta \) or \( \eta \) of the force theoretically possible, is applied in practice. The various experiments made on boilers, with regard to the evaporative power of coal, have not given very uniform results.

Smestow, in 1772, with one pound of Newcastle coal, evaporated 7-88 lb. of water from 212°; Watt, in 1788, came to the conclusion that 2 lb. of water might be evaporated by the same quantity of coal; and later (in 1840), Wickstead found that 1 lb. of Merthyr coal could be made to evaporate 9-493 lb. of water from 80°, which is equal to 10-746 lb. from 212°. In some experiments made on the boiler of the Lam's engine, at the United mines, in Cornwall, evaporated equal pound of coal, with a trial of six months, to evaporate 10-29 lb. of water from 212°, this being the reduction of the result given, viz., that 234,210 cubic feet of water at 120° were evaporated by 700 tons of coal. Statements have indeed been made that 14 lb. of water have been evaporated by 1 lb. of coal burned in a Cornish boiler; but this is the utmost quantity theoretically possible, it is difficult to conceive that it has been realised in practice, even in the best-constructed steam-engines.

* The co-efficient for the latent heat of steam at 212°F is generally taken at 1000°, but the actual number is from the recent experiments of Regnault on this subject, as given in Table I.
### Table VI.—Showing the Actual Duty, and that which is theoretically possible, of the Coals examined.

It is of much importance in an economical inquiry on coals, to obtain exact information as to the effects likely to be produced upon them by stowage and continued exposure to high temperature, not only as regards their deterioration, but also as to the emission of dangerous gases by their progressive changes.

The retention of coal in iron bunkers, if these are likely to be influenced by moisture, and especially when any accident wetted with sea-water, will cause a speedy corrosion of the iron, with a rapidity proportionate to its more or less efficient protection from the influences of carbonic acid, a compound of carbon or coal forming with the iron a volatile couple, and thus promoting oxidation. The action is similar to that of the tubercular concretions which appear on the inside of iron water-pipes, when a piece of carbon, not chemically combined with the metal, and in contact with saline waters produces a speedy corrosion. Where the "make" of iron shows it to be liable to be thus corroded, a mechanical protection is generally found sufficient. This is sometimes given by Roman cement, by a lining of wood, or by a drying oil driven into the pores of the iron under great pressure.

Recent researches on the gases evolved from coal, prove that carbonic acid and nitrogen are constantly mixed with the inflammable portion, showing that the coal must still be uniting with the oxygen of the atmosphere, and entering into further decay.

Decay is merely a combustion proceeding without flame, and is always attended with the production of heat. The gas evolved during the progress of decay, in free air, consists principally of carbonic acid, a gas very injurious to animal life. It is well known that this change in coal proceeds more rapidly at an elevated temperature, and therefore is liable to take place in hot climates. Dryness is unfavourable to the change, while moisture causes it to proceed at increased rapidity. Sulphur and pyrites (a compound of sulphur and iron) is present in considerable quantity in coal still changing under the action of the atmosphere, a second powerful heating cause is introduced, and both acting together, may produce what is termed spontaneous combustion. The latter cause is itself sufficient, if there be an unusual proportion of sulphur or pyrites present.

The best method of prevention, in all such cases, is to ensure perfect dryness in the coals when they are stowed away, and to select a variety of fuel not liable to the progressive decomposition to which allusion has been made. This is, however, a subject of much importance to the steam navy, that it continues to receive our careful attention; and, beyond these general recommendations, it would be premature to offer any decided course for adoption, from the present limited series of observations.

Several varieties of coal were transmitted from Formosa and from Borneo, for analysis, the results of which are contained in the accompanying table. The quantity of each kind was so small, that no experiments could be made on their evaporative value. We extract from the preceding table the following results:

THE HOUSES OF PARLIAMENT.

That so important an edifice and national work as the "Houses" about to be erected, born in parliamentary debate and out-of-door criticism, is only natural, especial opinion is divided, some speaking in terms of unqualified admiration, while others see much cause for dissatisfaction, and express it accordingly; and some of the rudest critics of all whom Mr. Barry and his building have had to encounter, are among the members of the "Houses." Messrs. Cockerell, Nash, Sharpe, and Henry, and Sir D. Corney, whose unfavourable opinions gain formalities because they go forth to every nook in the kingdom where a newspaper finds its way. Last month we spoke of an article on the "Houses" in the "Westminster Review," and which, by-the-bye, is now known to proceed from the pen of Lord Ellesmere; and in the interval another has appeared in the "Mechanic's Magazine," of similar tendency. Whether this latter will call forth any remonstrance against it from the "Builder" remains to be seen; for at the present time of our writing, opportunity for reply to it has not arrived. The "Magazine" takes up the "Builder" pretty sharply upon two points. The first of them is the attempt on the part of the last-mentioned publication to set aside Lord Lovelace's objections to the position of the Victoria Tower at a corner, and the most remote corner, of the Houses; these are that such a position for it was dictated by the plan adopted by Mr. Barry; whereupon the "Magazine" is somewhat sarcastic, and to say the truth, Mr. Barry has no cause to feel particularly grateful towards a defender who exculpates him, by removing the fault from him and throwing it upon the plan. If the defect in the arrangement was due to the plan itself, and not to the architect. If the internal arrangement which first presented itself to the architect occasioned what is an incongruity in the exterior, the very natural question is: Why did he not, instead of adopting it, deviate from it so as to bring in the main entrance porch in some more congenial situation?—and objectionable it seems to be, for even his champion, as the "Mechanic's Magazine" calls the "Builder," does not pretend to say that it is not so, but merely that it is to be excused by being attributed to the plan.

The point upon which the "Mechanic's Magazine" is rather strong and severe with the "Builder," is the unguarded assertion that, although it is so now, it does not follow that the Victoria Tower will always be at the extreme corner of the edifice. The actual possibility of extending the buildings and carrying them on farther southward, by pulling down the houses on the east side of Abingdon-street as far as might be required, is not to be disputed. The probability is a very different matter,—more than can now be foreseen, and is, besides, what Mr. Barry himself neither does nor ever has contemplated; the Victoria Tower standing as the conclusion and final part of the whole. As the "Mechanic's Magazine" remarks, the south-west is now finished, at least in its lower part, so as to render it impossible to prolong the building, and thereby remove that Tower from its position as an extreme point in it. Done it could be, but only by undoing what is equally beautiful and harmonious on the south side, the Royal porch, which would have to be blocked-up and built up against.

The Royal entrance is now fixed beyond the possibility of change for it. Yet, it is not even now too late to consider some other points in the design. For instance, although the position of that important entrance may be justified by necessities of internal arrangement, and although it is very properly made a striking feature in the design, the necessity for erecting over it a tower of very unusual magnitude, and thereby proclaiming afar off the "eccentricity," as the "Mechanic's Magazine" term it, of that portion, is at all apparent; and, especially, as that huge structure will be for sight than for any real service. We incline, therefore, to the opinion of the "Athenaeum," that it would be more advisable now to abandon the idea of that ambitious Tower, and terminate the Porch a little above its present height. Either some curtailment, we fancy, of Mr. Barry's plans must take place, or the ultimate completion of them must not be looked for by the present generation.

Could the Tower in question have been introduced in the centre of the general plan, it would have given not only pyramidal grouping, but the propriety of line of building there was in the composition. Marked verticality of lines in such an imposing feature, so placed, would have been opposed to horizontality of lines in the principal front. The lofty upright mass and the horizontally-extended façade would have balanced each other, and mutually set each other off. Other towers there now will be, rising up behind the river-front; but how far they will agree with it, and with the larger tower also, is doubtful. If we mistake not, they are intended to be tapering and spirey in outline—consequently of quite a different character from the compact solidity which marks the Victoria one; and it is always possible that what is at present the chief of the front to be erected will appear at the end as not so also. At least, there is reason for apprehending that the arrangement of the several towers will appear very irregular, if not confused, and occasion an unpleasant discord with the studied regularity and uniformity of the principal front—principal at least of the whole building, though he who takes in that it is to appear in some degree a merely secondary one. If there must be a tower that shall, by its superior bulk, greatly predominate over all the others, it surely ought to show itself in some central situation,—central as regards one of the fronts, if not central as regards the entire plan; otherwise, it will appear to have been left to chance to determine and "dictate" the respective situations of those features, instead of their being arranged with some regard to that symmetry which is observed in the main, as far as it was possible to do, and which at present stamps the whole of the east side of the edifice.

It will perhaps be said that the position of the Victoria Tower was known from the very first: it has been shown again and again in the various engravings and cuts innumerable, copied or made up from the view of the future building given by the architect himself; its grandeur has been admired, without exception being taken at its situation. Yet, though no objection has been made all along, now comes Earl Lovelace with a very strong protest against that Tower. Wherefore was his Lordship so tardy with his remonstrances? or how happens it that no one else could perceive, or perceive, care what is in the rear?—or, what is the defect in the general design? The position of the Tower could hardly have been overlooked by, or indeed have failed to strike, the most careless observer who glanced at any of the published views. Very true; but merely seeing with the eyes, is quite a different matter from seeing with artistic vision. It is not every one who can see, in the latter sense of the word, what is actually before their eyes. Many, again, don't care to see, even if they can do so. Others, though they may be somewhat dim-sighted, have very convenient spectacles of criticism through which they gaze, and perceive either the all beauty, all formity,—either transcendent excellence, or ridiculous monstrosity.

The many, who have no opinion of their own, are overawed by this kind of dictatorial, one-sided stuff which calls itself criticism, and is presented to them in the imposing form of type and printed paper. While those who are capable of judging for themselves either do not care to raise a dissentient voice amidst the general hubbub of applause, or condemnation, as the case may be; or else have not the opportunity of doing so. With respect to the "Houses," both the "Westminster Review" and the "Mechanic's Magazine" have repeatedly expressed the opinion, that it is not to be expected that the design may ever be raised bestowed upon them in other quarters. It must be allowed that both these articles dwell almost exclusively upon defects, or what their writers consider such: yet surely there is nothing particularly strange in that, the object of both being to open people's eyes to many circumspect, and what have not hitherto been sufficiently noticed. If to point out only faults and objections be invidious, by the same rule, to pass them entirely over, and point out only merits and beauties—would that all of them were where they could be seen!—may be called syphonetic: so that between the two we may arrive at a tolerably correct and sober judgment.

BOROUGH OF LIVERPOOL.

Report to the Health Committee of the Borough of Liverpool, on the Sewerage and other works under the Sanitary Act, by the Borough Engineer, (James Newland.)

The facts detailed in the Report of the engineer of the Liverpool corporation afford a strong commentary on the claims of the military engineers. We have heard a great deal about the irresponsibility of the Associated Surveyors, and the superior responsibility and guarantee of the military engineers; and Mr. Chadwick rest it upon what is likely alleged to be a most serious defect in the contrary view, from our experience of the two classes, and this Liverpool affair comes in confirmation. The fact is, the military engineers are virtually irresponsible—they cannot be made to perform their work properly or punctually; while the civil engineer, at Liverpool for instance, is responsible in his professional character and capacity, and liable to be dismissed by his employer if he
do not give satisfaction. From the misconduct of the Ordnance functionaries, the corporation of Liverpool are put to the trouble, expense, and delay of a second survey—and, to make it worse, they have no remedy. Whether the metropolitan survey will turn out better we have our doubts; but it remains to be seen. At all events, the Treasury will have to make good any short-comings of the Ordnance surveyors.

If the Ordnance have been unable to do their work properly and in time at Liverpool, what security have we against delay in the general and metropolitan surveys? To the great disgrace of the government, engineers have long had to use the northern sheets of Mr. Cary’s survey; and now this dilatory body, having proved itself incompetent in its past duties, is to have more thrust upon it. Why do not the Associated Surveyors get Mr. Wyld to move for a parliamentary committee of inquiry into the general management of the surveys carried on by the Ordnance?

This Report is a sufficient specimen to show that civil engineers are not incompetent for sanitary duties, and we hope it will not be forgotten, for doubtless Mr. Chadwick will next propose that military engineers should be chosen to lay down the lines of drainage, and carry out the details under the “Health of Towns” Act.

The Report may be divided into the following parts:—

Sewage and drainage, what are the necessary conditions to produce a perfect system.

Description of the borough of Liverpool in relation to the river Mersey and the docks—the effects of discharging the sewage into the docks and river.

Schemes for constructing a new sewage.

Lists of all the existing sewers, showing their size and length—of new sewers required.

Estimates for forming the new system of sewage.

On the application of the sewage water for fertilising the soil.

On the form and size of sewers and drains. From this part of the report we make the following extracts:—

Sewers and Drains.—The proper size and forms of sewers and drains is a subject which of late has excited much controversy. In so far as the house drainage is concerned, the question lies within narrow limits; for if all the liquid refuse of a house passes through a soil-pipe of 2½ or 3 inches diameter, there is surely no need of the drain which receives it being made much larger. If more than one pipe enters a drain, the question is still a simple one; and although, by calculation, the corresponding increase of capacity for every additional pipe which enters the drain could be readily determined, practice would hardly admit of the refinement which would so nicely adjust the increments; and it is easy so to proportion the drain pipe in each case with the materials in practice at our disposal, that it shall be no larger than the quantity of water available under the particular circumstances of the case shall thoroughly flush. Pipes of from three to six inches internal diameter, are amply sufficient for service drains, as one of six inches, with a fall at the rate of one in forty will, according to the ordinary formula, discharge, in half-a-minute, as much water as is due to a family of six individuals for a whole day, even on the liberal scale of five cubic feet per head.

The drains of streets should, in my opinion, be double in all the streets above twelve yards wide; and in such cases I would construct them in the bottom of the side trenches for the water and gas pipes, as shown in the annexed engraving. By this arrangement are insured diminished capacity and cost, and economy in the expenditure of the paving, elsewhere insisted on. The first cost of the double trench is about double the ordinary cost, but it can be balanced by the saving in the service drains; and in regard to the paving, it is impossible sufficiently to estimate the saving, if, in connection with these side trenches, the more durable manner of paving recommended be introduced.

The sewers proposed to be used in this case consist of a semi-circular underpart, formed of stone ware, or some of the other materials which will afterward be noticed, and a semicircular cover, as shown in the above engraving. The joints I propose to form with the pitch of coal-tar, in rains of a rainy state; and where any part of the drain requires to be inspected, a hot iron or a little blasing straw will soften the cement so much as to admit of the cover being removed. Service drains are connected with the side drains by means of sockets formed in the latter.

The report proceeds to denote the different forms of sewers and the junctions, which are also similar to those described in the Journal for March last, p. 77. It then gives the area of land drained into each of the main sewers.

From observations made while Beacons’ Gutter sewer (5th by 4 ft 6 in.) was opened at its outlet, for the admission of the new sewer in Great Howard-street, it was found that the water was only 201 inches deep, after twelve hours of heavy rain.

The extent of drainage into that sewer is 993-3 acres, of which about one-fourth is built, and three-fourths unbuilt. Now, by the formula most approved, the diameter of sewer necessary for this drainage, with the given fall of 1 inch in 17 feet, while the length of the whole sewer part is only 4 ft. 6 in., and the depth of water in it was somewhat less than a third of its longest axis, even after the continuance of heavy rain for twelve hours, when it may be reasonably supposed the whole earth would be saturated, and every drop of rain fall into the sewer. All calculations for the capacity of sewers proceed on the assumption, that it is necessary to provide for the contingency of a rain flood, estimated at the enormous fall of five-eighths of an inch in half-an-hour. Now, that such a flood may occur is possible; but it would be easy to show, that if it did occur, it could not get into the sewer, and therefore there is no necessity to make provision for it; and it requires merely a glance at the streets of a town built on sloping ground like Liverpool, during even a moderately heavy rain, to be convinced, that a great part of the rain drains directly by the surface of the street into the river, and never enters the sewers.

As all formulae, then, are founded on imperfect experiments, and give results far above what experience shows to be necessary, they are obviously uncertain guides, and it is better to trust in the observations of what actually takes place. This, in fact, is experimenting on the largest and most proper scale.

The Report afterwards makes some observations on surface drainage and paving. If the streets of a town be unevenly paved, putrid exhalations will constantly arise. A smooth, non-absorbent, hard surface, without hollows or joints, is what health demands. Macadamised streets are the worst: the absorbent material soak up the impurities of the air, which, purifying itself, is exchanged for pure air; and the road wears fast under great traffic—in wet weather it is covered with mud, and in dry weather the air is loaded with dust. It is the most expensive to keep in repair, and costs four times as much to clean as a paved road. Boulder paving is the best and cheapest; and in the scale of cost, Streets of the first class and in regular courses are the best: whereas the road is steep the courses should be of stone 3 inches wide, with joints ½ inch wide, filled up with cementitious substance, impervious to water. In streets less steep, the stones may be increased and the joints decreased. On a level, the stones may be increased to 6 inches in width.

To insure stability, the courses should be made nearly wedge-form. They should be in contact at their base and for about one-third of their height, and the width of the joint should be obtained by diminishing the width of the upper surface of the courses. The joints should be bedded hard with macadam or clean shingle, and then filled with a coarse kind of asphalt, composed of the pitch of gas-tar and small gravel. The joint should not be filled quite flush with the surface of the stones, but left slightly hollow, as in the figure (c). If the expense of the asphalt be objected to, limewash may be used to fill the joints. The lime should, for this purpose, be such as will set under water.

For the foot-pavement, Caithness stone, 1½ inch thick, with sound joints, is recommended in preference to Yorkshire stone 3 inches thick.

A good foundation to a road is in no less essential than a good surface; hence failure of the latter cannot be due to want of firmness in the former. Softness or elasticity in a foundation will permit the surface to yield under the wheels of a carriage. The rise and fall forms a new obstacle to be overcome, and causes an increased amount of friction to be opposed to the movement. Besides, by the friction of the pavement against the earth, the earth is forced up between the stones, and covers the road with mud. It is worth while, then, to be at a little extra cost in the preparation of the
foundation, when so much depends upon it; and I think the following plan is the best adapted to secure perfect firmness. A level bed is prepared for the materials, and on this a pavement of common soft rock is laid by hand. The deepest stones are used for the centre, and the size is diminished towards the side, so as to bring the top line nearly to the intended transverse section of the road. The stones are all laid on their broadest edges lengthways across the road, and their thickness should not exceed four inches. When the setting is completed, the irregularities are broken off by hammers, and the interstices filled in with the chips. On the foundation so prepared, a three-inch stratum of small broken stones is to be laid, and on this a stone base will afford it a coating of clean gravel should be spread, and the whole rolled with a heavy roller until consolidated, when it is in a condition to receive the covering of paving stones. The under pavement would be still further improved by running the joints with good lime grout before laying on the ballasting; and in the case of macadam roads, the previous ballasting is not required, the macadam being laid directly on the pavement.

The objection to a street formed and paved in a manner so permanent as that described, is, that it requires to be frequently broken up for laying or repairing water and gas pipes and making branch sewers, and cannot be reinstated in so perfect a manner. But water and gas pipes should not be laid in the carriage way, but in trenches formed along the sides of the streets, as shown in the foregoing engraving, and the sewers should be double and laid in the bottom of these trenches. The advantages of this mode of forming streets I have before pointed out, and shall now merely exhibit a statement of the comparative cost of the two modes. The calculation is made for a street fifteen yards wide, and the actual cost of both modes is given:—

| Estimated cost of side-trenches for gas and water pipes, and sewers. |
|---------------------------|-------------------|-----------------|
| Yards Brickwork, in one linear yard, at 5s. 6d. per yard superficial | £1 1 0 |
| 10 Yards Brickwork do. do. at 2s. 6d. per cubic yard | 1 0 0 |
| Cast Iron Baskets do. do. at 5s. 6d. | 2 1 0 |
| Side Stainings (every 40 yards) at 1s. 6d. | 1 2 0 |
| Total | £2 8 0 |

| Estimated saving in the cost of laying down gas and water pipes, and excavating for sewers by using side-trenches. |
|---------------------------|-------------------|-----------------|
| In the Linear Yard. |
| Main Sewer, 10 yards excavating, any one-half, at 1s. 6d. | £0 10 0 |
| Gas Pipes do. | 2s. 6d. | 0 3 3 |
| Water Pipes do. | 3s. 6d. | 0 3 3 |
| House Drains do. and Pipes | 9s. 6d. | 0 9 0 |
| Branch Pipes (Gas and Water) do. | 2s. 6d. | 0 7 6 | £1 8 0 |
| The difference of expense | £1 0 0 |

The excess of the cost of the trenches is £1 per linear yard of street; but to counterbalance that cost, there is the saving in keeping the street in repair and cleaning it—the convenience and the non-interruption of the traffic—and to these it is impossible, in the present state of information, to assign a money value.

For cleansing streets, the Report recommends washing them with water, and carrying the slush off by the sewers, instead of carting the sweepings; by which means an enormous saving will be effected.

The water channels ought to be formed with smooth-faced stones 10 inches wide and 6 inches deep, and from 2 to 4 feet long, laid to the lines of the curved line of the cross-section of the street, which can be laid at 6s. 6d. the superficial yard. (See b in the engraving on previous page.)

Gully-Grates should all be trapped, and the grating-bars either be so close as not to admit stones and other matters which might impede the flow of water in the drains, or the longitudinal openings may be crossed underneath by small wires, forming, with the bars, a series of reticulations, which will prevent the passing of any large substance. The kind of trap which experience proves to be efficient is alluded to in the next paragraph.

All traps which depend on the agency of water, are liable to get out of repair, or to require care and attention to maintain their efficiency. For if the water be allowed to dry up, the gasses have free passage; and if it be allowed to remain long in the trap without being changed, it becomes impregnated with the gasses, and yields them again to the air: constant change of the water is thus essential to the perfect action of such traps. The forms of water traps are very numerous; but probably the most simple and efficient for house drains, when the drain pipe is not too large, and the supply of water abundant, is the plumber’s trap, which is a pipe bent to the sigmoid curve, as in fig. 3.

Where the quantity of water passing through a pipe is very small, and yet the pipe requires to be large enough for an occasionally-increased discharge, some trap, which can be opened to admit of any deposit being cleaned out, probably to be preferred, and I have hitherto used the one represented at 9, fig. 4. This is merely a modification of the former, and answers well. It is made of earthenware. Where the fall of a sewer is not great, and the house drains are apt to be filled with back-water, the flap valve is the most effectual preventive which I have tried. It answers admirably for keeping out back-water, and fits so tightly that no gas can escape. These valves can now be had made entirely of earthenware. The gully
grates should have no water traps, but in their place should have flaps valves of the same kind as the house drains. Figs. 6 and 7 show the kind of gully grate and valve used. The grate, it will be seen, is vertical, the face of it being in the same place as the face of the curb, and the top of it forming a portion of the curb; the flap hangs vertically, and acts so promptly, that the smallest quantity of water opens it. This form of vertical gully grate assures more efficient drainage of the surface of the street close behind a house, even after the fall is great, the water would shoot past them without entering. I have prepared drawings for a gully grate, valved on the same principle, to suit steep streets where new gutters are required; but to existing gutters I propose to apply the valve, in the simple manner explained by the drawings. Fig. 8 shows a proposed adaptation in a gommon, which is removed from its original site, and a length of pipe with a flanged attached connects the new opening with the former cospel, which is bricked up until its bottom forms a continuation of the drain; this I have used in a gully grate for the perfect success. Fig. 8 shows the proposed new grate for steep streets.

For flashing and washing the sewers it is proposed to lay a main along the summit of the town, kept continually full of water from a reservoir, and when a sewer requires flashing, a sluice is to be opened, and the water allowed to rush down in a flood, carrying all impurities along with it.

Besides flashing for the underground filter, it is necessary to provide the means of washing all impurities from the surface of streets and courts. For this purpose every court should have a branch, with a stand-pipe at its upper end for the purpose of water supply. Every side street should be watered at such distances apart that its whole surface may be washed over with the aid of a short hose. From these stand-pipes also the streets should be watered. Ultimately, fountains should be erected in every available situation, purifying the air, the motion of jets, and cleaning the water channels and sewers by their constant flashing effect.

In my former report I submitted the following method of arranging stand-pipes in the streets, by which their situation might be so readily and distinctly known in the event of an accident, as to ensure from the difficulty of discovering them. At present, the water-pipes have three kinds of apparatus to which hose may be attached—the common plug, the hydrant, and the Gavin plug. The common plug consists of a conical socket screwed on the pipe, which, when, with a cover, the plug is so designed to hold which the hose is attached; it has also a cock for regulating the discharge. These stand-pipes are portable, and are carried by the firemen to the nearest place where the water is required. The hydrant is a more simple apparatus which consists merely of a branch from the main pipe, with a stop-cock and an opened end, with a screw coupling, to which the hose is directly attached. The Gavini plug differs from the other two in being also a cock; a stand-pipe is required in using it. All these have their conveniences. The Gavini plug is a ready apparatus; but besides the disadvantage of being not so high, the stand-pipe being made of a tin sufficient amounts of water may be exposed to the roadway, of being subject to be acted on by frost; and for its cover being attached to the pipes, the latter are apt to be injured by vibration and concussion. The stand-pipe is liable to derangement, or being carried off, which is rendered very objectionable. The Gavini plug and the hose are in boxes under the surface of the ground, there is sometimes no little difficulty experienced in finding their place. Further, the eye which requires to be formed round the metal box seldom wears uniformly with the general surface of the road (in the macadamised roads especially), but projects above the surface, and forms a very obvious obstacle to the traffic.

My opinion is, that the apparatus, in any proper system of supply, should be conspicuously placed, readily distinguishable, by night or by day, from everything else, and always ready for use, without any apparatus, which may be mislaid or forgotten at the very instant they are wanted. With this view, I beg to submit the apparatus exhibited in figs. 1, 2, and 3. I propose that several lamp-posts in each street should be made receptacles for the water apparatus, sufficient to supply all the houses within its sphere. In each lamp pedestal I propose that an upright hydrant be fixed, with a coil of hose, sufficient for washing the streets, or filling the watering carts, constantly attached. The cock-box I would fix in the footway, always on the same side of the lamp-post, and at a constant distance from it. In the event of a fire, the firemen’s hose would be instantly attached to the hose of the stand-pipe by a coupling screw. The pedestals for the water apparatus being square, and those for the common lamps being round, would point out at once the place of the water apparatus; and, if necessary, the side pipes of such lamps might be of coloured glass, as a still greater distinctive mark by night. Every superintendent of scavengers and every fireman would be provided with a key to the door of the pedestal, and the bell of the hose would be easily heard, and no delay in using the water for any purpose. In places where lamp-posts are not required, the pedestals merely (fig. 3) might be used, and these might also be used as guard posts at the entrance to narrow streets.

The lamp pedeslats will still more useful by the label attached to their tops, as shown on the sketch. On these would be cast the names of the streets, and on the centre panel the distance in miles and furlongs from the Exchange. Coach and car fares might be thus regulated. On the plinths too would be made the permanent bench-marks needed in the law, with their height above the dock sill, expressed in feet and decimal parts. By these means, the simple lamp-post may be made a very useful as well as a very ornamental object.

The Report contains some judicious advice on the best mode of cleansing streets, emptying cesspools, dust-bins, lay-stalls, &c.; regulations for the width of streets and height of houses; limiting the population.

The limitation of population per acre being once established, is easily convertible into a rule to determine the area that a house should occupy. The width of a street due to the class of houses being fixed on the principle laid down above, the remainder should be allotted to the houses, the passages before-mentioned, and the gardens or back-yards, as the case may be. On the statistics of health in Great Britain, we shall find that, in towns exhibiting the average rate of health, the area allowed to every inhabitant is about 25 square yards. If we assume 5,38 (the Liverpool average) to be the number of inhabitants in each house, and allow 25 yards to each inhabitant, we shall have 150 yards as the minimum area which health demands to be allowed to every house. Now houses of the class usually built in third-rate streets are 5 yards wide in front, and the width of the street due to these is 6-6 yards. Of the quantity allotted to each household we have thus 423 yards due to the street and lane, and 17 yards, or an area of 234 yards deep by 5 yards wide, due to the house and yard. Of this the house will probably occupy 10 yards, leaving 13 yards in depth, or 65 square yards for the garden or back-yard and its erections. This, then, the former will be required to maintain at a state of health of the town districts of Britain, when houses are built in streets with any other source of air and light than what the streets afford; if, however, open spaces are left, such as courts, squares, and the like, the problem being simply to allot a certain number of yards to every inhabitant, a deduction concomitant with that area may be made from the amount allotted to the yards or gardens, provided that, as before stated, the houses be so arranged in respect of these open spaces as to receive the full benefit of them.

From the remarks on buildings we give the following extracts:

Every house should have a water closet; but the water closet should be adapted to the place it is to occupy, and the health of the users. Water closets present in common use are essentially of two kinds, the valve and the pan closet. The former has been long held in high esteem and is expensive; the latter is the cheaper article, and I think undeservedly undervalued. Both are open to the objections which it is necessary to inquire how they can be made to fulfill their design in the best possible manner, that is, to carry away the soil instantly, not only into through the drain and sewer. This will obviously depend on the quantity of water that is discharged along with the soil. Now, in the closets in use, the quantity of water retained in the basin and discharged with the soil is so small as to be inadequate to carry the soil away, and reliance is generally placed on the wash or stream that is sent after it. This stream is generally discharged by a 1⁄4 inch pipe, while the soil pipe is 3 inches in diameter, and consequently it has little flushing power. This is the defect in all existing closets, the attention of the makers being directed invariably to the increase of the wash, and not to the maintaining a sufficient quantity of water. The closets proposed in the following, in order to succeed, must be formed round the metal box, which, with its supports, and the pipes behind, c, are formed of glazed earthenware in one piece. In the pipe at d is fixed a box containing a collar of leathers, through which a brass or copper tube a slides;
this tube is open at both ends. To the end of the pipe the soil pipe is attached. When the sliding tube is in the position shown in dotted lines in Fig. 11, water admitted into the basin will rise to the height of the top of the tube, and if more be added it will escape through the tube, which thus forms an overflow. When the tube is depressed by the closed handle to the level of the basin, the water is held and wholly discharged. This simple and ingenious water closet, which may also serve as a sink for cottage dwellings, is the invention of Mr. Kirkwood, plumber and mechanist, of Edinburgh. I have fitted up several of them, and one which I own is in constant use at one of the new offices in Corwallis-street since their opening, has given perfect satisfaction.

I have proposed to use tubes of earthenware or glass, ground, in place of the brass tubes, for the sake of cheapness. I have also proposed to modify it so far as to convert the sliding tube into a turning one, so as in fact to form a basin in the ground into the same material, thus dispensing with the stuffing-box. Other modifications will present themselves to those who give attention to the subject, the principle being steadily kept in view of receiving the soil in a large quantity of water, which, when discharged, shall be sufficient to carry it, not only into the drain, but through it.

The other water closet is adapted for back yards, courts, and public necessaries. It is designed on the same principle. In Fig. 4, a, a, is a large tank, formed of stone, slate, or iron, or other non-absorbing material. Its bottom is made to slope to one end, where the mouth of the soil pipe is inserted, and closed with a plugged valve c. To this valve a chain is attached, and, being passed over a pulley, it has a handle fixed to its other end. It is a supply for the tank only, the surplus water running off without the slightest effect on the contents of the tank, so that the tank is not liable to be decomposed; from the time it is allowed to remain it becomes to a certain extent dissolved and diffused in the water, and when the contents of the tank are discharged, being, so to say, thrown out of water, it emits no bad odours. They cannot go wrong, and, from being directly under superintendence, and their action being independent of the user, they cannot suffer from ignorance or neglect. A closet on this principle has been fitted up at the public offices for the work people out of doors, and answers its purpose admirably.

To the advocates for employing the Ordnance for making the Survey of London, we beg to direct their particular attention to the following observations, which ought to have, if anything would, some weight with the government, in reference to sanctioning the employment of the Ordnance in doing that which can be much better done by agents and engineers.

With regard to the survey of the borough, I beg to state, that I have been actively employed on it, with a large staff of surveyors, since June last (1847.) There is now completed the triangulation of the greater part of the whole area within the Parliamentary boundary, and the detailed survey of about two-thirds of that area; about half of which is plotted to a scale of twenty feet to the inch. The reasons which led to the adoption of a scale so much larger than that recommended by Government are known to the committee; but as the necessity for the large scale has been questioned it may be as well to explain it to the undersigned Sanitary Commissioners. Evidence has been adduced involving grave charges against the Corporation of Liverpool, I shall take the liberty, briefly, to allude to the subject, and shall show by a simple statement of facts, with circumstances these facts can scarcely be controverted.

I have first to remark, that in the evidence referred to, there is an obvious confounding of two things—general sewerage schemes, and the sewerage of a town. For the one a contour, general, or block plan, on a small scale, so that the whole area may be comprehended in one view, is what is required; and for the other, the details of the structural arrangements to a large scale—the larger the better, so that every minute peculiarity may be seen and provided for. In designing improvements, therefore, both plans are necessary, the small index may for the ascertaining the drainage areas, the outfalls, and the main lines of sewers and gas and water pipes; the large plan for the details. For the first purpose, extensive areas, a scale sixty inches to the mile is totally useless, as being too large; on the other hand, a scale of each inch is useless for the second purpose. Its adoption would necessitate the re-surveying of every portion of the town in detail, as the works are carried on. Thus, even for the sewerage of the town of Liverpool, a scale of sixty inches to the mile is not sufficient; but the Council of Liverpool, under the Sanitary Act, have not only the control of the sewers, but are also surveyors of highways, guardians of public property and have the control of the water supply. In adjusting the levels of streets, plans and sections are required drawn to a scale so large as to exhibit, clearly and distinctly, the details of accesses and approaches to the buildings on each side. Such a plan admits also of the boundaries and divisions of property being minutely detailed, and allows of the inspection of sewers, gas main, and water pipes, and in short the whole structural peculiarities of the locality to be represented without confusion. It is in fact a working plan. I shall briefly recapitulate these reasons.

It obviates the necessity of separate detailed surveys for improvements.

II. It enables the perfect detail to be shown of parts which most require improvement in lines, levels, and sewerage, and also for the supply of gas and water.

III. It admits of the perfect measurement of the boundaries and divisions of property, enabling the authorities to guard against future encroachment.

IV. It shows the structural arrangement of the streets, with the complicated lines of water and gas-pipes, sewers, and service drains.

Doubling, all these might be shown on a plan of 100 inches to the mile; but if the scale of a plan, like many other efforts of ingenuity, would be more curious than useful.

I here cite the portion of the evidence referred to.

Captain Yolland says—"At the present moment the Corporation of Liverpool, who are engaged in carrying out sanitary measures for the town of Liverpool, have abstracted a number of assistants from the Ordnance Survey that will answer the purpose of carrying on this very necessary work, at rates of pay varying from 600 to 700 per cent. over what has been furnished by the Ordnance Survey Department, almost at a nominal price, with a skeleton plan of the town of Liverpool on this scale, with some altitudes inserted at the corners of streets."

"In this event the present administration of Liverpool desiring to have an additional and accurate survey, they having already those outlines which are sufficient for all purposes of drainage—I imagine it is to project their schemes."

The Commissioners are anxious to ascertain what it would cost to procure the metropolis sufficiently for the purpose of drainage and sewerage; therefore it was that the question was asked, why the people of Liverpool should be anxious to have a more complete survey than is necessary for those purposes?—All I stated, as having been given to the Liverpool Corporation, were skeleton plans, not embracing every alley and every court.

"It is the Liverpool Corporation own a great deal of property in Liverpool, do they not?—I do not know."

First, as to the abstraction of surveyors—the only surveyors employed by the survey of Liverpool, who were known to me to be on the Ordnance Survey, are two, and these applied for employment, recommended to the favourable consideration of the Committee by the officer under whom they were at the time. One other surveyor applied as a person out of employment, whom I afterwards discovered to be engaged on the Ordnance Survey at the time of his application, and we have other men who at some period or other have been employed in the Ordnance surveys of England and Ireland, but all of whom had been engaged in railway surveys between leaving the Ordnance and being employed by me. All the surveyors, with the one exception, where he was engaged in a work of a very different character, were engaged in a work of surveying assisted by testimonials of their character and capability from persons in whose employment they had previously been. So far then for the truth of the statement as to the "absence" of assistant surveyors.

With regard to the amount of salary paid the assistants, I may state, that it is invariably commensurate with the work done, and ranges from £30 to £150 per annum. This highest amount is, I suppose, somewhat about 200 per cent. above what is paid in the Ordnance departments to civil servants. Capt. Yolland asserts that the salaries paid in Liverpool are 700 per cent. above those of the Ordnance staff; where he got his information as to the amount of these salaries I know not; he certainly did not apply for it either to the treasurer or to me—the only parties who could have informed him rightly.

The whole of the evidence relating to the getting up of surveys for sanitary purposes is an attempt to prove that it can be more correctly and more advantageously done by the Ordnance Survey.

But, to verify calculations of this kind, let the actual and not the estimated cost of Ordnance surveys be produced. Every one knows that to produce anything in extreme haste increases immensely the cost of production. The Council of Liverpool, finding that the detailed Ordnance survey of the town was not completed, and being refused liberty to make a tracing of the portion alleged to be finished, urged by necessity, had no alternative but to proceed with a survey of their own, although perfectly aware that the project would much increase the cost. However, the cost of what is done is known, and the cost of completing the whole can be correctly calculated, it would be useful, as a test of the comparative expenses of what may be called private and public plans, to ascertain what the price of the plan would be if the country had already paid for the incomplete plan of Liverpool, and how much it will yet cost; how long it has been in hand, and when there is a reasonable prospect of its completion.
the mile; and on this contour line at four feet altitudes have been laid down. These contours involved the observation of a great many levels, and a laborious calculation. A copy of this has been made for Mr. Hawkenly, for the purposes of the water supply.

Besides this work, belonging especially to the survey required by the Act, a very large amount of detailed surveys and the sections, to meet the emergencies of the time, working drawings of sewers, and of the new offices in Cornwallis street, and many highly finished drawings to illustrate the reports made by me, have been executed by the skilled draughtsmen. Most of these have been derived from the original surveys, and from the invaluable documents, their execution has not a little interfered with the progress of the larger work. The street surveys and sections required for the adjustment of the larger plans have not yet been completed.

The work being now so far advanced, and the completion of the contour plan having enabled me to make the necessary estimates of the cost of the sewerage, a reduction may be made in the surveying staff, if it should be thought desirable. The list of the new staff I have submitted in the estimate of the expenses of the Engineer’s Department for the ensuing year.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

INSTITUTION OF MECHANICAL ENGINEERS.

The following papers were read at the last monthly meeting held at Birmingham:

BONE CRUSHING MACHINE.

Mr. Buckle proposed that, in selecting his present subject, he had had in view the desirability of imparting an agreeable variety to their proceed- ings. The object of the machine was to endeavour to attract the attention of manufacturers to the usefulness of a machine for pressing bone dust, which has been found to be a most efficacious manure, and which is shipped across the sea from the Baltic. Some of the larger firms engaged in the manufacture of bone dust, and who have made careful inquiries of the manufacturers of bone dust, feel that the natural and usual method of crushing bones for this purpose is not always satisfactory. A new method of crushing bones was therefore proposed by Mr. Buckle, who suggested that the bones might be crushed in a machine similar to the ordinary bone-crushing machine, but with a number of rollers inserted between the teeth of the rolls, so as to crush the bones into smaller pieces. The advantage of this machine would be that it would not require the use of a large amount of labor, and would be more economical in the use of water.

The proposal was seconded by Mr. Paton, who suggested that the machine might be adapted to the crushing of mineralized bones, which are frequently used in the manufacture of bone dust. Mr. Buckle agreed that the machine could be adapted to this purpose, and suggested that the rollers should be made of iron, and that the teeth of the rolls should be made of steel. The machine was then ordered to be made, and to be tested in the works of the manufacturer.

HIGH-PRESSURE BOILERS.

"On High-Pressure Boilers, and on Boiler Explosions." By Mr. Smith. — At the last meeting I laid before you a tracing and description of the steam-boiler which recently exploded near Dudley, and though time did not permit any discussion as to the merits or demerits of the construction of the boiler itself, I thought it would be of interest to describe the construction, formation, and dimensions, cannot be safely used for high-pressure steam, say 40 lb. or 50 lb. per square inch. I make this assertion, because the great diameter of the outer shell renders it very liable to be torn asunder by internal pressures. Taking also into consideration of such dimensions that it may be forced out of form and suddenly collapsed by external pressure, and if that system of boiler were to be made safe by a large reduction of the diameter, it would make steam insufficiently powerful for the purpose they are intended—namely, to use the great quantity of blast heat that escapes from the puddling furnaces.

The next question is how to use such a boiler as I recommend in preference to those on the above principle, being much better adapted for generating and safely containing high-pressure steam, and I think more convenient in every other respect for the above system of heating. The boiler is 33 feet long, and 4 ft. 6 in. diameter, with two tubes or flue-pipes under it, each 36 feet long, and 1 ft. 8 in. diameter, and attached to the boiler by vertical pipes 10 inches diameter. The flue-pipes are made in a bent form, so as to be highest in the middle, and dropping as they are bent, and the water is carried in the water tubes. A great advantage of this is that it suffi- ciently explains every other particular connected with this boiler, so that further description is unnecessary; I shall therefore now only point out a few of the advantages it possesses over the system of boiler before referred to.

1st. The diameter of this cylinder being small, they may be made of much thinner plates, and still be perfectly safe with a greater pressure of steam.—2nd. The heating surface is large, and concentrated without any water circulation, so that in a very small area of land performing water being much larger, there will be less difficulty in maintaining its proper level. —4th. The steam and water spaces and heating surface is proportionate to the heating surface, which is an object of the first importance in the construction of all kinds of steam-boilers, as it is well known that where any difficulty is in performing that operation, the chances are that it will either be imper- fectly performed, or for the want of sufficient surface, that cause of many of the fatal explosions that so frequently happen with land boilers:—1, Mal-formation for the working pressure and quantity of vapour re- quired; 2, Want of proper care to fit every boiler with proper steam valves, and dodges, in and on account of cylinders. It is a lamentable fact that many boilers are still in use, which are extremely liable to accident from either of the above-mentioned causes; and I think the following reasons will to a great extent account for so bad a state of things existing in a country where so much engineering skill may always be procured to rectify such defects.

"1. Respecting mal-formation, I would state that parties about making erections for steam-power, generally make the first outlay of capital a certain fraction of the cost of their engines so that they are just calculated to do the work required, and nothing to spare. Shortly afterwards, however, some extra machinery is introduced into the establishment, and the engine is increased in size. The original pressure of the extra load is immediately put upon the safety-valves of the boilers, and this practice is repeated from time to time, as each little additional machine may require the extra power. It is quite extraordinary that so much work is done in this manner: the first instance are at last a mal-formation for the increased pressure, and working in a highly dangerous state, while the unsuspecting opera- tives may be seen crowding round to warm themselves at meal times, when the danger is probably at the greatest pitch.

2. Respecting defective steam and water indicators, I have always observed that land engine boilers are not so efficiently fitted with these instruments of safety as marine and locomotive boilers, although I think it very necessary that they should be so fitted, so that when the pressure is too great the firemen can be immediately informed of the fact. I have often seen engines are very frequently left to the charge of one individual, with other duties besides that require much of his time and attention; whereas the indicators of marine and locomotive boilers are constantly under the eyes of one or more well-proved character and ability for the services re- quired; and, moreover, engineers of a higher class are always resident in the principal stations, invested with power to examine engines, and inspect the whole machinery. I have shown, on the present day, the indicators which I consider necessary for a high-pressure boiler in ordinary circumstances, which are as follows:—One feed-cock or valve; one float-water gauge, with stand and wheel, and counterbalance weight; one stop-cock, with float and float-pipe, and float-water gauge, and two safety-valves, one locked up. For low-pressure boilers, I think the open top feed-pipe, with open pipe also for the float-water wire to work through, is a very perfect apparatus to prevent the steam from rising too high, or the water from falling too low."

3rd. Respecting keeping of boilers clean, I have seen that process very imperfectly performed, and often altogether neglected in establishments where a sufficient number of spare boilers are not provided, and time not spared enough to get the boiler cleaned down for men to remain in it to do the work properly. But I believe the greatest cause of neglect in this most
imported sugar is its being generally looked upon as a thankless sort of job, the engineer-man always considering it an extra duty, for which he claims extra allowance, and the master considering that he pays him sufficiently for courting it. The work with his steam engines is, in this respect, of great importance. The steam boilers are subjected to the same kind of wear and tear as the engines, and thefew years ago Mr. Yatelafer works were so heavily fired that the boilers were in constant danger of explosion. The practice of “hot-blast” will by this means cost literally nothing, and it is estimated that if the plan be carried out through all the iron-works in England and Wales, there will be an annual saving of £1,200,000, without taking into account the advantage of the increased efficiency of the engines. The hot blast is introduced into the boilers and the heating tubes. Even this saving might be increased, for present the heated gases are permitted to escape uncondensed; and by a judicious admission of air to supply the required oxygen for combustion, the heating might be at least doubled, while some of the furnaces in Belgium were economically managed several years ago, the heat of the consumed gases being employed in various processes.

A Dry Condenser.—Mr. Joseph Price made a communication in the Mechanical Section, of a plan that he has lately adopted in the construction of marine engines, and which he then made public for the first time. The engine constructed by Mr. Price combines the effects of high pressure and of condensing engines. The steam is worked at a pressure of about 20 lb. to the square inch, and it issues from the cylinder, after having done its work in the condenser. The condenser consists of a chamber containing several pipes, through which the water passes as the vessel is propelled forward, and by this means the pipes are kept cool. The steam emitted from the cylinder meets, as Mr. Price expressed it, with a “cold reception” in the water. Mr. Price remarks that the water at the bottom, when it is forced again into the boiler by a small force-pump. In this manner the boiler is constantly supplied with fresh water, even at sea, and there is consequently no incrustation. This arrangement of the condenser and the admission of the used spirits of wine instead of water, if the waste by leakage could be avoided.

Low-Pressure Atmospheric Railway.—A large model of a low-pressure atmospheric railway was exhibited in the Mechanical Section, by its inventor, Mr. Struyve. In this plan the original mode of atmospheric propulsion is adopted, passengers being all enclosed within the atmospheric pipe. It is proposed, however, to construct the atmospheric current of brick-work, and it is to be illuminated by windows; so that the passengers, though inclosed, will not be excluded from daylight. A shield is fixed to the front of the carriage, and any wind is deflected by it; and as the requisite pressure need only be very low, there is no necessity to be particular about the shield being air-tight at the edges—indeed, it is intended that it should move without any friction against the sides. With an area large enough to admit the railway carriages, it is calculated that a pressure of six-tenths of an inch would be sufficient for ordinary speeds, and it is proposed to obtain that amount of exhaustion by large pumps somewhat like gasometers, which work up and down in water, and expel the air there in large U-shaped pipes. The estimate for constructing a railway of this kind is £7,000 per mile.

The Iron Works of Pennsylvania.—It was stated by Professor Rogers, of Pennsylvania, in the Geological Section, that the annual quantity of iron produced in that state exceeds the whole annual produce of South Wales; the estimated quantity is 1,000,000 tons.

The Colouring Property of Madder.—Dr. Edward Schenck presented to the Chemical Section his third report on the colouring property of madder. The extractive matter of madder-root contains several different substances, only one of which, however—the alicazine—possesses the property of colour; all the others, indeed, tend to impair the colour yielded by alicazine; and the chief use in addition to madder in dyeing is, that it combines with the other substances, and renders them harmless. Patas, or other alkalies, would have a similar effect; but as lime is cheaper, there would be no advantage gained in substituting alkalies. It was suggested that a practical application might be made of the analysis, by extracting the alicazine in a separate state, freed from the injurious agencies, in which condition it would be a better and more durable pigment might be obtained, especially in the madder root, and plants have, however, been so recently made, that no practical results can as yet be expected.

The Effect of Light in Photography.—M. Claudet and Mr. Hunt brought before the Chemical Section some curious facts relative to the effect of light on photographic pictures. In describing Daguerreotype pictures, it is usual to say that the plate, after being exposed for the proper time in the camera, presents no image, and that it is not till after exposure to the vapour of mercury that the picture is developed. M. Claudet has ascertained that the plate becomes white, and that it is not till after exposure to mercury vapours that a plate exposed to those rays, after having been in the camera, the picture is developed nearly as powerfully as when mercury is used. Not only have the red, orange, and yellow rays the property of bringing out the invisible picture, but they also as accelerators, in the same manner as light, although only after the plate has been exposed to light for a short time, the only effect being an increase in the intensity of the image. The red light alone, however, seems to produce no effect on a sensitive Daguerreotype plate, and some curious images of the
sun, reddened by a London fog, were exhibited by M. Claudet, which explained that fact in a remarkable manner, for the sun appeared as a black spot in a luminous sky. In an image of the solar spectrum the red rays were black, the orange and yellow dark, and the brightest parts were those in the blue and violet bands of the spectrum, and in a space considerably beyond the extent of luminous rays. Mr. Hunt announced that the results of investigations in which he is still engaged lead him to the conclusion that light has no part in the production of photographic pictures, and that in fact light obstructs the formation of such pictures instead of producing them. In confirmation of this opinion, he stated that when attempting to take the solar spectrum on photographic paper, all parts of the paper were blackened excepting that wherein the spectrum fell, the paper on that part having been protected from the action of light.

MINERAL GUANO.—As the sources of animal guano become exhausted, fresh supplies of that manure are discovered in the mineral kingdom, which promises to last for ages. The discovery of a large bed of phosphate of lime in Spain was two years ago considered an important addition to agricultural wealth, but since then the phosphate of lime has become more available, and Captain Ibbetson in a recent examination of the green sand formation of the Isle of Wight has discovered a rich stratum of the mineral manure, containing about 30 per cent. of phosphate of lime. As this is very accessible, it promises to become of great value, and there is no doubt that similar stores of the phosphate may be found in other parts where the green sand formation is situated.

REGISTER OF NEW PATENTS.

EXPANSIVE ROTARY STEAM-ENGINE.

ROBERT WILSON, M.A., of Greenock, for "Improvements in certain kinds of rotary steam-engines, part of which improvements are applicable to rotary engines worked by water or by the wind; also an improvement in safety-valves for steam-boilers."—Granted January 12; Enrolled July 15, 1848.

The chief object of this invention is to introduce the principle of working steam expansively into rotary engines. This is proposed to be effected by causing the steam which has first acted by impact in one direction against the vanes of a wheel, to operate again by reaction in opposite directions in issuing out of the intervals between the vanes. The figure represents a side elevation of an engine constructed according to this part of the invention, and having one-half of the cover or side removed, in order to exhibit the internal construction. The circular case is rendered steam-tight, and has an entrance-passage at I, for the steam. There is also an eduction-passage at K, through which the steam in an expanded state is allowed to pass away into the air, or else into a second engine; and although the induction-passage k appears very near to the entrance-passage I, yet the steam does not pass directly to K, but passes nearly all round within the circumference of the casing, in succession, before the steam arrives in a very expanded state at the eduction-passage K. In addition to the curved vanes gg, there are other curved vanes rr, fixed within chambers nn, which the patentee calls reversing-chambers, and which with the said fixed vanes are for giving to the current of steam the directions in which it is to act over and over again against and between the curved vanes gg. Some of these reversing-chambers are disposed in an outer circle mm, which are also furnished with stationary vanes rr; the moving vanes gg therefore revolve between two separate circles of fixed vanes. All these vanes being truly arranged in their several circular rows, with the edges of this vanes in conformity therewith, the interior edges of the fixed vanes in mm, and the exterior edges of the vanes rr, in the chambers nn, are close to the edges of the moving vanes gg; but at no part of its circumference is it allowed to touch or come in contact with the fixed vanes rr. In order to give freedom to the vanes gg, which are made of thin metal plate, they are united by means of flat circular rings, which are as close as possible to the moving parts without actually touching. The effect of these rings is not only to strengthen the vanes, but also to subdivide the whole of the passages into narrow semicircular courses, in order to direct the currents of steam. The steam from the boiler enters the case at I, and is first directed into a curved course at m, which is divided into three spaces in order to compel the steam to proceed in three currents towards the axis of the wheel; but owing to the curvature of the vanes, the three currents of steam, when they are passing out from these spaces, are caused to change the direction of tangents to the semicircular curvature of the moving vanes gg, against which the steam will first make its impact by acting against the concave sides, which deflect or turn the current of the steam which now issues from the spaces between the vanes gg, into the inner circumferences, and in receiving it in the chamber n1, when the direction again becomes reversed owing to the semicircular curvature of the boundary of that chamber, so that the steam will be turned towards the vanes gg, proceeding in a tangential direction to the wheel in order to act again on the vanes gg, by the action of the steam, reversed, and in reaching the next reversing-chamber n2, in its second impact will, therefore, be in an expanded state, and will enter into a greater number of spaces between the vanes gg, exerting a re-action in so issuing, when it is again received into another reversing-chamber n3, wherein the steam is still further expanded, and becomes again reversed in its direction to the chamber m3, from which it passes as before to chamber n4, where it is still further expanded, reversed, and divided into numerous streams continuing a similar course through the different chambers m3, n4, m4, n3, and so on throughout the circumference, being proportionately expanded in each chamber till at last it escapes through the eduction-passage K. By the continual impact and reaction of the steam, a rapid rotary motion is communicated to the wheel. Another part of this invention relates to improvements in rotary engines of the object of joining the two wheels so as to combine together two revolving wheels, having curved vanes added to the wheels, in circular rows in a very similar manner to the vanes gg, already described, but the circular row of vanes is larger than on the other wheel, so that one circular row is surrounded by the other. These two wheels are inclined within the vane in the one being reversed to that of the other. The current of steam which has passed through the curved spaces between the vanes of one wheel, and has changed its direction in so doing, will enter into the curved spaces between the vanes of the other wheel; and the steam in so doing will act by impact and reaction to turn both wheels round, but in contrary directions of rotation. The fourth improvement relates to rotary-engines to be worked by water or wind, the mode of action being by impact and by re-action. They are arranged in a similar manner to the last described. The fifth and last part of these improvements relates to safety-valves for steam-boilers, which the patentee constructs with columns of mercury contained with a cluster of numerous tubes of iron or glass disposed side by side, the passages through which the tubes are kept effectually stopped by having the orifices at their lower ends immersed at the different levels inherent in the different columns of mercury contained in a cistern to which the steam has admission. The mercury will effectually prevent any escape of steam, so long as the pressure is no greater than intended. But if the pressure of the steam depresses the level of the mercury below the lower end of one of the tubes, then the steam will force its way up that tube; and if the steam still increases in pressure, the surface is depressed still lower, so as to get below the level of the lower end of another tube, and so on; more of the tubes will become opened, one after another, as the pressure may require.
PROPELLING BLADES.

GARDINER STOW, late of King-street, Cheapside, now of New York, gentleman, for “Improvements in apparatus for propelling ships and other vessels.” (A communication.)—Granted January 11; Enrolled July 11, 1845.

In this invention an attempt is made to combine the screw-propeller with the paddle-wheel. The paddle-wheel, though placed on the sides of the vessel, like the paddle-wheel, is formed on the screw principle. Its form consists of a series of curved blades, set at an angle of 45° with the propeller-shaft, which is placed parallel with the vessel’s course, similar to the ordinary screw-propeller; but instead of being submerged, it is sustained by bearings projecting from the vessel’s sides (there being one on each side of the vessel), at such a height from the line of flotation, that simply the curved blade, or about one-seventh of the whole diameter, will be immersed. These curved blades are severally portions of a screw, and are supported from the shaft by radial arms, being further strengthened by stays extending in the direction of the length of the shaft. These propeller-shafts are each furnished with bevelled wheels, which gear into corresponding wheels on the main or engine-shaft, lying across the vessel, as the ordinary paddle-wheel. As these propellers are caused to rotate, the curved blades will be successively brought into contact with the water, one end thereof entering first, the concurrent angle propelling the vessel onwards, and as it leaves the water, the next blade in succession will be immersed, maintaining a continuous and uninterrupted propelling power.

MARINE STEAM-BOILERS.

THOMAS, EARL OF DUNDONALD, Vice-Admiral in Her Majesty’s Navy, for “Improvements in marine steam-boilers, and apparatus connected therewith.”—Granted February 11; Enrolled August 11, 1848;

The principal features of this invention are the application to marine-boilers of the principle adopted for consuming the smoke in other boiler-furnaces, by admitting a stream of hot air behind the bridge, to burn the gaseous products, and the removal of the steam-cabinet from the top of the boiler to the end of it, thereby lessening the height. His lordship claims seven separate parts, which may be thus briefly noticed. Firstly:—The more perfect combustion of the gaseous products at their entrance into a tube-chamber, constructed according to a former patent granted to him, by combining a stream of uncondensed hot air with such products. Secondly, the constructing boilers with the steam-reservoir placed below the level of the water in the boiler in lieu of the steam-cabinet as usually constructed above the boiler. Thirdly, the drying of the steam by its being exposed to a portion of the smoke by passing it through the chimney. Fourthly, a mode of preventing the priming of steam-boilers by means of a plate or separator placed within the boiler, the end being below the surface of the water in the boiler. Fifthly, the right of making and using a spiral or centrifugal separator; which, however, he reserves for another shape, and still retain the principle of the invention,—namely, the separation of the water from the steam, and the mode of carrying off such separated water back to the boiler, without being obstructed by a contrary current of steam, by means of a pipe or channel from such spiral separator to the boiler. Sixthly, he claims a mode of working the propellers of steam-vessels by means of short propeller-shafts. And, lastly, a mode of constructing boat-boilers and apparatus.

VALVES AND PLUGS.

JOHN FREDERICK BAYTMAN, of Manchester, for “certain improvements in valves or plugs for the passage of water or other fluids.”—Granted January 18; Enrolled July 18, 1848.

The chief object of this invention is to make a valve suitable for the water-pipes, the valve being made of smaller specific gravity than water, and being opened by being forced down by a plug. The claims of the patentee will sufficiently explain the structure of the valve. He claims, first, the application for the passage of water and other liquids; a globular valve, of a lighter specific gravity than water, constructed of a coating of vulcanised india-rubber, gutta percha, or other suitable elastic substance, so that the valve shall be closed by the pressure of the liquid. Secondly, the use and application of a globular valve of this specific gravity with a coating of vulcanised india-rubber or other elastic substance, so that the valve shall be closed without the aid of machinery, by the pressure of the liquid. Lastly, the opening of the valve against the pressure of the liquid, by means of a plug or key, through which the liquid will flow from the valve, the plug or key being attached to the fixed part, without the aid of any screw or thread.

PREPARATION OF BAR-IRON.

WILLIAM RUSSELL, of Lydbrook, Gloucestershire, iron-master, for “an improvement in the preparation of such bar-iron as is used in the manufacture of certain kinds of rod-iron.”—Granted January 29; Enrolled July 29, 1848.

This invention may be very briefly described. The object is to remove from the surface of ordinary bar-iron the spil or scale, which is found to be very injurious in making the billets from which wire-rod-iron and bar-iron are afterwards made. The scale is removed by passing the bar-iron through a kind of draw-plate called a “cleaner,” composed of grooves formed in the shape of the letter “V.” In conducting the operation, the iron is first made into lumps of about one hundredweight and a quarter. It is then removed to the hammer, where it is reduced by hammering to short bars of five or six inches square. It is next passed through the rolls in the usual manner, and reduced to bars of about one inch and a quarter square. In passing through the two last finishing grooves in the rolls, opposite which the cleaner is placed, the lower half is slightly lowered in order to admit of the entrance of the bar to the rolls which draw the bar through. During this finishing operation, pressure is exerted to bring up the cleaner by means of the lever and shaft, thereby scraping the iron on all its four sides, and actually removing all the spil and scale from the surface. The bar is then passed over the upper roll, and is introduced through a smaller groove in the rolls, when the operation of scraping is repeated, as before.

THE GRESHAM PROFESSORSHIP.

We have seen with great regret the decision as to the Professorship of Geometry in Gresham College, because it is an indication of a return to the old system, which it was held forth should be abandoned, and the College restored to its former efficiency and rank in the scientific world. A decision more lamentable than that now made could hardly have been come to, for it is a total abnegation of scientific attainment and exertion as a qualification for the Professorship.

Among the candidates were Professor Moseley, Rev. Morgan Cowie, Mr. Fots, the Rev. Pelham Dale, and Mr. Edkin. Professor Moseley took high honours in mathematics at Cambridge, is the author of a work on the “Mechanical Principles of Engineering,” and is a professor in King’s College, London. The Rev. Morgan Cowie took higher honours, and was the second in his college. Mr. Fots, afterwards Fellow of St. John’s College, and Moderator of the Examinations in the University of Cambridge. He now holds the appointment of Principal in the College for Civil Engineers. Mr. Fots and the Rev. Pelham Dale have devoted themselves to mathematical studies, and have published papers on scientific subjects.

Mr. Edkin took a law degree at Cambridge, and has since been a teacher in the City of London School. The Gresham Committee have appointed Mr. Edkin to the vacant Professorship. It is not attempted to be put forward that Mr. Edkin is entitled on the ground of his scientific superiority, but he is said to have given satisfaction as a master in the School. It may be added, that he is related to an influential member of the Common Council.

It may happen, albeit Mr. Edkin has as yet given no proof of his competency, that he may make as good a professor as Mr. Moseley or Mr. Cowie; but whether he do or not, the appointment is equally unjustifiable.

These professorships are not simply appointments of men competent to discharge the duties, but they are rewards for previous exertion; and when properly awarded, their beneficial influence is great, because, as all candidates must comply with the conditions of having given practical and public proofs of competency and distinction, a powerful stimulus is given to the industry of those who are entering, and there is a curb on the indolent. In University College, the way in which the appointments are
made is very simple. A committee is appointed, not of members of the Council, but of the professors of the faculty in question, who draw up a report, stating the education of the candidate, the honours he has obtained, the character he has held, and the character he has published and the character of them, and the unexposed paper, illustrative of his studies and researches, which he has submitted to them. Thus all the materials for coming to an impartial decision as to the merits of the candidates are laid before the Council, and their appointment is made in accordance with the report. Therefore, therefore, by this system, be not cannot, and no jobbery.

The Trustees of Gresham College have not adopted any such course, and they have not even the poor and usual plea of favouring a member of their own College, because their College has no alumni. The appointment resolves itself into the gross breach of a public trust, and it is necessary that measures should be taken to prevent its recurrence. The University of London has no legal jurisdiction in this case, but it has a moral interest in seeing justice done; and we recommend that a memorial should be addressed to the Senate, and another to the Committee of Council on Education, praying that they will take measures to obtain relief. These memorials should be signed numerously by literary, scientific, and professional men, and by citizens of London, and they may result in some better system for the future. It will be easy for the University of London to provide for the examination of future candidates, leaving the appointments to the Trustees, who will thus be put under a moral and public responsibility, to which they are not now subject.

If Gresham College were properly administered, how useful might it be to the younger professional men and mechanics of the metropolis. The Chair of Geometry, once held by Briggs and Wren, ought not to be without a competent successor; and by giving an adequate number of lectures on that great beneficient subject, and the very serious want of mathematical instruction in some degree be supplied. Those who know the good that has been done by Lord Brougham's Evening Classes for Schoolmasters, at University College, would earnestly wish the system of evening instruction to be extended. As a recent example of the way in which these classes work, we may mention that a school has been opened in the Mechanic's Institute, under the direction of one of these graduates, and in which the children of members are taught at fourpence per week.

Those who advocate literary institutions for the working-classes have been seriously impressed by the evident consequences of giving desultory instruction, which prevails in such places, and which has the tendency of unsettling rather than of strengthening the minds of young men; but no measures have been taken to establish institutions in which, by a course of lectures or two lectures shall be given, in regular courses, on the higher branches of education in the faculties usually known as arts and philosophy. This can be done and ought to be done.

Payne's Process for rendering Wood Fireproof.—On Wednesday, August 2, an experiment was exhibited at Whitehall-wharf, Westminster, for rendering wood fireproof. Mr. Payne, whose patented process for showing that his wood-processing process is as effectual for the preservation of wood from destruction by fire as from the ravages of insects, dry-rot, &c. Two small houses were constructed, one of ordinary deal boards, and the other, treated by Mr. Payne's process, and each fitted with fire-proof and shavings. Both were kindled at the same time. The house composed of the unprotected wood caught fire very soon, and in about half an hour was completely consumed; while the Payne's house burned slowly as the fire in it having gone out of itself, and left only some slight marks of charing on the inside of the boards. The liquid employed by Mr. Payne (by preference) is sulphate of barium or calcium.

The Revolution of Diamond. Professor Faraday lately gave a lecture on this subject at the Royal Institution, in consequence of M. Jacquelin having, in the course of last year, succeeded in converting diamond into a substance possessing the appearance, physical character, and electrical properties of carbon. Having attached a piece of hard-glass-retort carbon to the positive wire of Bunsen's battery of 100 elements, he placed it on a small piece of diamond. He then armed the negative wire with a cone of the same carbon, and, by dexterous manipulation, enveloped the diamond with electric flame. After a short interval, the diamond underwent a sort of explosion, became disintegrated, softened, and was actual coke. (Comptes Rendus, June 14, 1847; Ann. de Chimie, tom. xx., p. 469.)—On this experiment Professor Faraday made the following remark: "The property possessed by certain substances to assume totally different forms without undergoing any chemical change. The Professor adverted to the case of sulphur, which becomes brittle when suddenly cooled from its first state of a liquid but is subject to a second state of fusion.—3. As to the source of heat employed. Professor Faraday dwelt on the beauty and power of the voltaic arc as a furnace, producing by experiment that diamond could be converted into carbonic acid gas by passing of a current of electric gas through the arc as it is heated. The Professor stated that neither this heat nor any other of that of the voltaic battery, except that of the solenoid, was sufficient to convert diamond into coke. The fusion of rock crystal by a current of oxygen sent through an ether flame was noticed; and it was shown that this powerful heat was inferior in intensity to that of the battery.—3. The condition of the diamond when thus converted into coke. It becomes absolutely weightless, and may be changed into coke its spec. gr. is 2.679. It loses its insulating power. Professor Faraday here alluded to some experiments by M. Karsten (Archives des Sciences, 1847), proving that certain compound bodies were conductors or not according to their preparation. He stated that this was the only case analogous to carbon.—4. As to the philosophy of the change of the diamond's structure. Referring to M. Gassiot's demonstration that the heat is greatest at the positive pole of the battery, Professor Faraday suggested the possibility that the particles of diamond might, under the influence of the intense heat, tend to form vapour having a sensible and assisting expansive force, and that in their axial position as regarded the enveloping discharge they might assume a state having relation to a dia- moment. He regarded that this idea merely as a philosophical conjecture. Finally, he referred to Graham's supposition, that the difference between diamond and coke might be accounted for by their known difference in their electrical difference of specific resistance. The above experiments of M. Jacquelin, on the conversion of diamond into coke, Mr. Naunyn first, in a communication to the Mining Journal, that he "had long since discovered that coke was diamond, in as far as the cohesion possesses of one of the most useful and promising properties of diamond in respect to its power of cutting glass—owing, doubtless, to the extreme hardness of its ultimate particles, or minute crystals of which a mass of coke is formed. We are apt to consider only the substance, by which we can crush it, and pulverize it with facility; but if we examine into the actual hardness of the minute, plate-formed crystals, which compose a mass of that substance, we shall find that they are possessed of a most remarkable degree of hardness, nearly equal to that of glass with the closely-packed cells to the crystal to the diamond." He feels certain, that when the extreme diamond-like hardness of coke is made known, that the fact will be laid bold of, and turned to good account as a most cheap material for all grinding purposes, such as required for many processes in the arts—to say nothing of its useful application to the sharpening of a razor, as a very superior stop powder; for which purpose however, the coke must be reduced by evaporation to the most minute and impalpable powder.

NOTES OF THE MONTH.

The Ordnance Maps are now undergoing the process of being electrotype; they are to be sold at the low price of 2s. per sheet, or 6d. per quarter sheet, and are to be issued as they are electrolyted, quarterly. The first series has just been published, and comprises part of Middlesex, Kent, Dorset, Sussex, and Cheshire.

The Metropolitan Streets Act has passed the House of Commons, and is now in the Lords. The purport of the Act is to embrace into one Commission all the cities of Middlesex, Kent, excepting the City and the Regent's Park Commission—why the latter is to be omitted, we are at a loss to conceive. The measure, which we long ago advocated, will be incomplete if that division be not included, as the district runs right through and bisects the Westminster division. It is a sewer of ample capacity and depth to drain all the upper division of the old Westminster Commission. It commences near Primrose-hill, passes through the vicinity of Regent's-park, Portman-square, and Charity, and winds its way beneath the Thames near Whitehall and Scotland-yard. If transverse sewers be formed in the New-road, Oxford-street, and Piccadilly, nearly the whole of the Borough of Marylebone will be drained into it, without any great expense being incurred. We trust it is not too late to introduce that Commission into the Act. The district of the new Commission is to extend to the distance of 19 miles in a straight line from St. Paul's Cathedral. We do not like the idea of the Commission being empowered to make their own bye-laws as to pavements—this is very objectionable, to say the least of it.
LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM JULY 20, TO AUGUST 22, 1845.

Chevalier Alexandre Edouard de Mott, of Caudett-street, Midddlesex, for "Improvements in apparatus for lighting by electricity, parts of which may be made use of in the apparatus for giving light by electricity."—July 20.

David Napier, and James Murdoch Napier, of York-road, Lambeth, engineers, for "Improvements in marine engines, also in barometers, and in certain other measuring instruments."—July 20.

William Thomas, of Chesapeake, London, merchant, for "Improvements in the manufacture of marble, and in marble pavements,"—July 20.

John King, tallow merchant, of Messrs. Sass and Son, Bankside, and Henry Marchard, operatice engineer to the said Messrs. Sass and Son, for "Improvements in gas meters."—July 20.

James Hancock, of Brompton, Middlesex, gentleman, for "Improvements in apparatus or machinery for giving shape and condition to plastic substances."—July 20.

John Greet, of the New North-road, Middlesex, engineer, for "Improvements in apparatus or machinery in the manufacture of cast-iron bolts, and in machinery for cutting wood for those purposes."—July 20.

George Walter Fryst, of the city of Rochester, state of New York, in the United States of America, gentleman, for "Improvements in the manufacture of printing-ink."—July 20.

Richard Abbey, of Biscigh, Buckingham, brewer, for "Improvements in preserving frogs and other little fresh-water animals,"—July 20.

Edward Gribben Wilson, of Bury, Lancashire, tin-plate worker, for "Improvements in the construction of the drums or rollers used in the machinery for drawing, applying, applying, or passing, tin-plate, wrought iron, brass, copper, and other similar substances."—July 1.

James Higginbotham, of Goodman's Fields, manufacturer, for "Certain improvements in Jacquard machinery for figuring fabrics and tissues generally, and apparatus for transmission of designs in said Jacquard machinery, parts of which are applicable to playing cards, playing-piece cards, concert band cards, and the like, etc."—August 5.

David Aikman, of Macleodfield, Chester, merchant, for "Certain improvements in the application of glass and glazed surfaces to nautical, architectural, and other similar purposes."—August 7.

Sarah S. L. Crofoot, of Birmingham, merchant, and James Edward McColl, of Wolverton, Buckinghamshire, engineer, for "Improvements in steam-engines, and in the improvement in steam-engines of engines, engines, or engines together, and in accompanying engine engines or wagons together, also improvements in effecting a communication between one part of a railway train and another, by signals or otherwise."—August 7.

Duncan Maclean, of Goodwin's Fields, manufacturer, for "Certain improvements in Jacquard machinery for figuring fabrics and tissues generally, and apparatus for transmission of designs in said Jacquard machinery, parts of which are applicable to playing cards, playing-piece cards, concert band cards, and the like, etc."—August 7.

David Newbon, of Macleodfield, Chester, merchant, for "Certain improvements in the manufacture of cast-iron bolts, and in other similar vessels of wood."—August 7.

James Robertson, of Great Howard-street, Liverpool, Lancashire, cooper, for "Improvements in the manufacture of cast-iron bolts, and in other similar vessels of wood."—August 7.

Samuel D'Arcy, of the firm of Hannah Lee and Son, of Park-bridge, Lancaster, iron manufacturers, for "Certain improvements in the manufacture of malleable iron."—August 7.

Joshua Couch, of Harleston, Norfolkshire, agricultural implement maker, for "Improvements in seeders."—August 16.

William Thomas Hanley, of Clerkenwell, philosopher, instrument-maker, and David George Foster, of Clerkenwell, arsenal, dealer in metal, merchant, for "Certain improvements in telegraphic communication, and in apparatus connected therewith, parts of which improvements are also applicable to printing and machinery."—August 10.

David Newman, of Macleodfield, Chester, merchant, for "Certain improvements in the application of glass and glazed surfaces to nautical, architectural, and other similar purposes."—August 12.

James Varley, of Bury, Lancashire, engineer, for "certain improvements in steam-engines."—August 12.

James Henderson, of Surrey Canal Dock, millwright, for "Improvements in machinery for cleansing and polishing rice, pearl barley, and other grain and seed."—August 12.

William Galloway and John Galbraith, manufacturer and James Alfred Emsley, of the same place, engineer, for "certain improvements in steam-engines."—August 14.

Edwin Thomas Trimann, of the Haymarket, London, dentist, for an "Improved method of cleansing and fixing artificial teeth and gums; and of supplying denticule in the mouth."—August 15.

James Warren, of Moutouges-terrace, Milne and road, Middlesex, gentleman, and William Perry of St. John's Wood Mansfield, and James Alfred Emsley, of the same place, for "Improvements in the construction of bridges, aqueducts, and roadways."—August 15.

Thomas Delarue, of Banhill-road, Middlesex, manufacturer, for "Improvements in producing ornamental surfaces to paper and other substances."—August 15.

William Galloway and John Galbraith, manufacturer and James Alfred Emsley, of the same place, engineer, for "certain improvements in steam-engines."—August 17.

Thomas Delarue, of Banhill-road, Middlesex, manufacturer, for "Improvements in producing ornamental surfaces to paper and other substances."—August 17.

Thomas Richardson, of Newcastle-upon-Tyne, chemist, for "Improvements in the composition of certain preparations to be used in the treatment of diseases of the lungs."—August 21.

William Young, of Queen-street, Cheapside, lamp manufacturer, for "Improvements in cleansing spirits and other similar articles."—August 21.

James Barrow, of Stamford Bridge, Yorkshire, for "Improvements in preparing and engraving surfaces, also in the construction of cylinders adapted for engraving, and also for certain improvements in machinery for preparing such cylinders."—August 21.

Richard Shaw, of Gold's Green, West Bromwich, in the county of Stafford, railway wiper, for "Improvements in the manufacture of iron into tyres, bars, rounds, nails, and rivets, and also for improvements in cutting bolts and splinter bolts."—August 21.

John Bethell, of Parliament-street, Westminster, gentleman, for "Improvements in the manufacture of flour, and vegetable substances, and also stones, chalks, and pumice, bone-dry."—August 21.

Alexander Angus Croll, of the Gas works, Tottenham, for "Improvements in the manufacture of gas, and in apparatus for raising, forcing, and conveying water and other fluids."—August 21.

Alonso Bucaneparte Woodcock, of Manchester, for "Improvements in steam-engines, and in apparatus for raising, forcing, and conveying water and other fluids."—August 21.
whit...; the platform and saws, and figs. 9 and 11, enlarged views of the steam-cylinder and driving-hammer.

The apparatus and machinery consist of the following parts:—

*Firstly,* the steam-boiler, A, similar to a locomotive-boiler, with steam-chest on the top. This boiler stands upon a platform B.

It may be proper to observe, that notwithstanding the energetic blows which this machine showers down on the heads of the piles, in consequence of these blows being given by so massive a hammer as 35 cwt., and at the moderate velocity acquired by a fall of only 38
Steam-Pile-Driven. (With an Engraving, Plate XIII.)

Patented by Mr. James Nasmyth, and Manufactured by Messrs. Nasmyth, Gaskell, and Co., of the Bridgewater Foundry, Patricroft, near Manchester.

Public works are acquiring such magnitude even in their details, that the demand for new and improved machines is so numerous, that they are constantly taking greater requirements on the resources of mechanical engineering. It has been a matter of dispute frequently whether a particular class of works belonged to the architect or the civil engineer; and Professor Hoek goes the length of claiming the hole dominated by civil engineering as belonging to architecture, there may now come forward and claim many of these works as a province of mechanical engineering. Thus, a still greater incenady to the separation of the professions of the architect and engineer is created. The tubular bridges over the Conway and Menai, the High Level Bridge at Newcastle, iron and screw pile-athouses, and suspension-bridges, are more the production of a mechanical engineer than of the architect. As a specimen, we in our August number account of the ingenious patent aquaduct machine, invented by Mr. Roberts, for punching the bates of the tunnel at Conway, for the purpose of saving time and labour; and in our present number we publish the engravings of another powerful machine, invented by Mr. James Nasmyth, for driving piles by the aid of steam, and which has been used with great success in the construction of the High Level bridge at Manchester, for cutting off the surface of the piles as they are driven. The saws are worked by the bevel gear, fixed on to the middle shaft, E.

With respect to the action of this machine, in order to describe it with clearness, we shall suppose that the pile-driving part of the machine is placed in a vertical position. The four-legged H, J, J, has been wound up by the small engine D, and the gearing P, and let down upon the shoulders of the pile K, and the steam admitted under the piston in the cylinder H, by means of the jointed wrought-iron pipes L, L, which serve to convey the steam from the boiler A to the cylinder B, and whose height is determined by the sliding-clamps f, f. l, L, are steam-pipes from the top of the boiler A, to the pile-driving cylinder H, jointed together by swivel joints of cast-iron.

Fourthly, horizontal saws M, M, fixed in to the underside of the pile-driving part of the engine, for cutting of the surface of the piles as they are driven. The saws are worked by the bevel gear, fixed on to the middle shaft, E.

With respect to the action of this machine, in order to describe it with clearness, we shall suppose that the pile-driving part of the machine is placed in a vertical position. The four-legged H, J, J, has been wound up by the small engine D, and the gearing P, and let down upon the shoulders of the pile K, and the steam admitted under the piston in the cylinder H, by means of the jointed wrought-iron pipes L, L, which serve to convey the steam from the boiler A to the cylinder B, and whose height is determined by the sliding-clamps f, f. l, L, are steam-pipes from the top of the boiler A, to the pile-driving cylinder H, jointed together by swivel joints of cast-iron.

Any consideration of the great works of civil engineering, even on such a scale as the Eddystone Lighthouse, will show how much depends on overcoming the mechanical obstacles which stand in the way. Time is money, and money again often saves time; and too attention to these points enables an engineer to execute his works cheaply and well. At the present time, a great deal depends upon the rapid and economical prosecution of works, and it becomes doubly important to call in the aid of mechanical science wherever, as in the cases already named, it promises to do the work more effectively and cheaply.

The merits of the steam pile-driver now before us consist, in the first place, in the direct manner in which the elastic force of steam is employed as the agent by which the “monkey” (or block of iron which strikes the head of the pile) is lifted to the height required for that purpose; and secondly, in the very peculiar, original manner in which the pile itself is made to act as the only support for the active or blow-giving portion of the apparatus; by which arrangement, the entire dead weight of the apparatus in question is turned to most important account as a “counterpoise,” to assist the pile in sinking into the ground when in the act of being driven; this dead weight also acting very importantly as an anti-recoil agent, so far as its entire weight (three tons) can accomplish that object. Thirdly, in the peculiar manner in which the pile-driving part of the apparatus is permitted to sink down along with the pile, and guide it in its descent, so as to prevent the pile twisting, or in any respect swerving from the true position given to it at the commencement of the operation of driving. Fourthly, in the peculiar manner in which a vast increased degree of energy is given to the blows of the monkey beyond that which is due to the height through which it falls.

The engraving exhibits an arrangement of the “Patent Steam-Pile-Driven,” for driving two piles in two continuous lines, without the necessity of a previously-existing gangway, the machine making its own way as it is moved forward. Fig. 1 is a side elevation; figs. 2, 3, 4, figs. 2, 3, having b, c, c, showing the engine and platform; fig. 5, a plan of the timbers which carry the platform and saws; and figs. 6 and 7, enlarged views of the steam-cylinder and driving-hammer.

The apparatus and machinery consist of the following parts:—

Firstly, the steam-boiler, A, similar to a locomotive boiler, with steam-chest on the top. This boiler stands upon a platform B, supported on iron wheels, running on iron rails, placed on the pilings of timber b, fixed on to the top of the piles as they are driven; and vertical guide-posts C, c, e, c, e, on the sides of the engine.

Secondly, a small steam-engine D, placed horizontally in the centre of the platform, with connecting-rod d, driving a crank r, and pinion d', on the crank-shaft, that takes into a cog-wheel, fixed on one end of a shaft E, with pinion e' on the other end of the shaft. F, f, upon which are fixed two pinion-wheels f', f', that take into cog-wheels f', f', fixed on the axles of two spiral-fluted barrels f', f', upon which are coiled the chains f', f', for lifting the steam-pile, driving-cylinder, and hammer. Upon the ends of the shaft D, are two spiral-fluted barrels G, for the ropes or chains g' to lift the piles into their place.

Thirdly, the pile-driving apparatus, consisting of a cylinder H, with its piston-rod passing out at the bottom, and directly attached to a block of iron or monkey I (weighing about 35 cwt.), placed inside of a square wrought-iron case, which acts as a guide to the hammer in its rising or falling, and rests upon the shoulder of the pile K at j; and at the same time, grasps the neck and shoulders of the pile with great tightness, so that it cannot twist or swerve from the position which the vertical guide-posts C, c, e, c, e, maintain it, and which is clamped tight to the pile by the slinging-clamps f', f'. I, L, are steam-pipes from the top of the boiler A, to the pile-driving cylinder H, jointed together by swivel joints of cast-iron.

As soon as the pile is driven to the required depth, the apparatus is again wound up by the small engine D; and the next pile selected, which may have the same height held by the engine D and gearing G, ready for driving (as seen in fig. 1), is then pointed or placed in its proper situation. The locomotive gear is then put in motion, and the apparatus lowered down on to the shoulders of the pile in question. The hoisting-chain f', is then let free, so that the apparatus may be free to rest on the shoulders of the pile, and follow down along with it as before. The steam is now again let into the cylinder H, and the driving proceeded with as before. The ease and dispatch with which the entire process is proceed with requires to be seen to be duly appreciated. The piles are driven into heavy masses of soils and under circumstances which would have put all the attempts of the ordinary pile-driving machines at utter defiance.

As soon as the pile is driven to the required depth, the apparatus is again wound up by the small engine D; and the next pile selected, which may have the same height held by the engine D and gearing G, ready for driving (as seen in fig. 1), is then pointed or placed in its proper situation. The locomotive gear is then put in motion, and the apparatus lowered down on to the shoulders of the pile in question. The hoisting-chain f', is then let free, so that the apparatus may be free to rest on the shoulders of the pile, and follow down along with it as before. The steam is now again let into the cylinder H, and the driving proceeded with as before. The ease and dispatch with which the entire process is proceed with requires to be seen to be duly appreciated. The piles are driven into heavy masses of soils and under circumstances which would have put all the attempts of the ordinary pile-driving machines at utter defiance.

It may be proper to observe, that notwithstanding the energetic blows which this machine showers down on the heads of the piles, in consequence of these blows being given by so massive a hammer as 35 cwt., and at the moderate velocity acquired by a fall of only 35...
3 feet, they do not the slightest damage to the pile-head; so much is this the case, that the pile-heads have actually a neater appearance after being driven than before.

In respect to the means employed for giving to the blow of the maul a greater degree of energy than such as would be due to its fall through 3 feet, this object is accomplished by having the top of the cylinder H made air-tight, and by having a set of openings at h. The instant the piston passes these openings in its upward action, all further motion in that direction is terminated by the compression of the air then confined in the space between the top of the piston and under-side of the cylinder cover; which compressed air, on recoiling, adds to the force of the blow all the energy it would have acquired by falling from the height to which the monkey would have been carried by the momentum given to it by the upward direction by the lifting action of the steam acting upon the under-side of the piston.

We have much pleasure in appending to our description a copy of a certificate by Mr. Stephenson.

"Nasmyth's Steam Pile-Driving Machine has for some time past been employed in piling the foundations of the High Level Bridge at Newcastle-upon-Tyne, and at the Viaduct over the river Tweed, considered merely by themselves, just as articles of furniture are looked at and examined in a show-room where they are exposed for sale,—they are there brought together without any regard to artistic keeping and effect. The consequence of which is, they do not serve to set each other off to advantage; but, on the contrary, there is much that is wanting in harmony with all the rest. We refer to a collection of studies of various ornamental details, and other mere material of design, but we miss a well-studied and consistent whole. The most opposite and conflicting sorts of architectural character are brought into contact with each other. Barn and hall-room are strangely mixed up together. In the chancel, and the two chapels at that end of the church, decoration is not only carried to such extent as to cause all the rest to look unusually cold and bare, but fails to produce the amount of richness aimed at. When added up, the total does not answer to the value of the several items as taken by themselves.

II. In architecture, incapacity for producing new ideas shelters itself under the plausible pretence of a reverential regard for old ones. Because excellent ideas have been produced before our time, we are told that we have no occasion for any of our own. Aught that partakes of innovation is set down as both unhistorical and dangerous; which is assuredly most comfortable doctrine—highly convenient, and therefore comfortable, because merely to copy is easy and safe; whereas, to attempt to emulate is a difficult as well as a doubtful matter. We do well, therefore, to protest against innovation—that is, for architects to profess to look up to and admire, were in their day very gross innovators; by gross, I mean wholesale innovators. The history of the art shows a series of innovations from first to last; that ‘last’—final and conclusion of it as a creative art, seems to have been already reached; and all that is now left for us is merely to repeat, perforce, what has been done before. Whatever may be the case with the twentieth, the nineteenth century will not shine in the history of architecture; or if it is to do so, it must now set about it in earnest, for half its time is already gone. Bad or good, the Elizabethan period had a distinct architectural character of its own; whereas, the present Victorian one has none, but is “everything by turns,” of most chamelion quality, but without any distinct, self-acquired, character. The present age is content with merely making use of the works of many predecessors brought out and accumulated. Satisfied with benefiting to live upon the interest, we do not seek to improve the capital. In fact, to such a pass has architecture been brought, that further progress for it in any direction is impossible, so long as we persist in our present posture of view—of power and powers as a fine thing. No matter what style we take up, we are expected to treat it literally—to adhere to it servilely, instead of being allowed to infuse any fresh ideas into it, or even, by varying its tourmure, to adapt it to greatly-altered purposes and occasions.

Provided the above stalemate is not correctly copied from the former buildings, we are quite satisfied, though the structure so compounded be full of incongruities as a whole,—prosaic and unartistic.

III. One consequence of the present rage for the merest copyism is, that we ourselves produce no structures that will deserve to be studied hereafter as original models and architectural records of the age in which they were erected. Even our most monumental edifices will not be monuments of our own time,—of our own ideas moulding and organising the fabrics we rear. Future antiquaries will be greatly puzzled some centuries hence, to determine dates from the styles which buildings exhibit. At any rate, they will set down this inquiry as that in which architecture is displayed itself chiefly in mimicry and masquerade. This is what is not particularly pleasant to contemplate, though it is what we have to thank the present race of antiquaries for, and others whose opinions and influence as engineers control the free-agency of architects, who, whatever they might have done by timidity or resistance to such domineering dictation, can hardly help themselves now. They have suffered their necks to be put into the yoke; so, however hard it may be to bear, they must now endure it with what patience they can. As that we look forward to, is to its being shaken off by some bold and independent spirit not gifted with genius only, but with the opportunity of manifesting it decidedly, however it may run counter to the minikin theory and doctrine of established rules. But as miracles are not to be looked for and calculated upon like the return of comets, we cannot with any sort of hope look forward to the accomplishment of anything.

CANDIDUS'S NOTE-BOOK,
FASCICULUS LXXVI.

I must have liberty
Withal, as large a charter as the wind,
To blow on whom I please.*

I. The lately-opened Catholic Cathedral of St. George's does not say very much for Mr. Pugin's artistic talent and taste. Satisfactory as are many of the separate parts and ornaments when considered merely by themselves, just as articles of furniture are looked at and examined in a show-room where they are exposed for sale,—they are there brought together without any regard to artistic keeping and effect. The consequence of which is, they do not serve to set each other off to advantage; but, on the contrary, there is much that is wanting in harmony with all the rest. We refer to a collection of studies of various ornamental details, and other mere material of design, but we miss a well-studied and consistent whole. The most opposite and conflicting sorts of architectural character are brought into contact with each other. Barn and hall-room are strangely mixed up together. In the chancel, and the two chapels at that end of the church, decoration is not only carried to such extent as to cause all the rest to look unusually cold and bare, but fails to produce the amount of richness aimed at. When added up, the total does not answer to the value of the several items as taken by themselves.
present fettered by prejudices—in reality the merest cobwebs, but twisted together till they become as bulky as cables. If my views and opinions are erroneous, let them be opposed; yet no one it seems cares either to oppose or to accommodate me. Well! if I am not flattered, even by contradiction, neither am I discouraged. Happily those who expect nothing, for they shall not be disappointed; and that state of beatitude is mine.

II. As it is now too late to protest against the barbarism of stripping the great public buildings of London of their architectural character, the Quadrant being by far the most scenic part of the whole line,—let us hope that the columns themselves will be preserved, that is, re-erected, so as to form some ornamental structure elsewhere. Of this, however, nothing can be seen by any visitor at present but shops and shop-keepers—and the latter show themselves to be somewhat unreasonable, because it was they who came to the colonnades, and not the colonnades to them. Their removal would be less matter of regret, were we but assured that the columns would now be so applied, that ample amends would be made to us for what we shall lose in Regent-street. If no better and more utilitarian purpose can be suggested for them, they might be employed to form an open screen of two lines of columns, inclosing the court-yard in front of the British Museum. Sir Robert Smirke's building itself would gain materially thereby; insomuch as it would be there much better situated than it is now, so picturesquely through the range of Doric columns in front, which being, besides, on a lesser scale, would serve to give greater importance to the Ionic colonnades behind. To the very excellent suggestion here volunteered, it will be objected—and objections are always as cheap as suggestions themselves—that the Quadrant columns are only Roman-Doric, while the façade of the Museum is pure Greek-Ionic. That ultra-Grecianism is affected for it, is not to be denied; but there is even now a great deal in the general design that is anything but pure Greek in physiognomy. Neither are its columns, with their homely and ordinary house look, nor the two little bits between them and the main building, would be able to reproach the Quadrant columns with being too undignified and uncandid to bear them company. Still, one thing may be confidently predicted: I therefore prophecy that my idea will not be accepted, nor even so much as taken into consideration. Happy the architect whose predictions are sure to be verified, and such state of beatitude, I repeat, is mine.

THE NATIONAL GALLERY.

Whatever general truth there may be in the paragraph which appears in my recent number of the Art-Journal, informing us that the present National Gallery is to be altered by Mr. Barry, from its correctness as to particulars may be questioned. What seems to vouch for such piece of intelligence being more than a mere vague, unauthorised report, is the express statement of the sum to be expended—viz. £50,000; to which the architect is to be limited, the exact amount to be determined after consultation with the Government. Mr. Barry has another story added to the building. How the latter can be accomplished without destroying the lantern lights in all the rooms now constituting the upper-floor, puzzles both ourselves and others to conceive. There appears to be no other alternative or mode of alteration in that case, than that of lighting the present rooms from their sides, or rather their two ends, in the front and back of the building; which would hardly be any improvement as far as they are concerned, nor perhaps much, if any at all, to the exterior. It has all along been the fashion—we can call it nothing else—to decry and abuse the National Gallery, more especially its façade, as if that were not merely the chief, but the sole disfigurement of Trafalgar-square,—as if St. Martin's Church, and the other buildings on the east and west sides of the "Square," were absolute paragons of architectural taste and excellence. Even those who affect excessive admiration for the "Church," affect to be scandalised at Wilkins's façade of the "Gallery." Ask them, why? and they soar upwards—fly into a towering passion,—and from that altitude, look down upon you with scorn most supreme. Even that lump of pretentious cockamamie and dulness, the "College of Physicians and Union Club-house," if it does not obtain admiration, at least escapes censure, which is levelled exclusively against that scape-goat of Trafalgar-square, the National Gallery. However, the latter is to become a "Deformed Transformed;" and poor St. Martin will need the whole of his cloak to spread over and shelter the insignificance of his Church.

As to one material point connected with the proposed alteration we are left in entire doubt, not being informed whether the whole of the additional story is to be appropriated to the "Gallery," or the projection of it at the east-end of the plan, bestowed upon the Royal Academy. Whatever may be done to it, the building can never, in our opinion, be rendered adequate to the now greatly-increased, and henceforth likely to become still greater, requirements for the national collection of pictures. Does the plan before the public give up to the "Gallery," and the Academy turn out to provide for itself elsewhere. For exhibition rooms, the Academy needs only a longitudinal extent of plan at the rear of a very moderate-sized front towards the street, for the walls being invariably covered front to back, the rooms themselves might be of the very plainest description,—both in construction and appearance not at all superior to ordinary show-rooms, auction-rooms, and similar places. Therefore, if the space now required for the "Gallery" demands it, we should say, turn the Academy adrift to shift for itself. It does not open its doors gratuitously to the public: why then should it expect to be in any way supported by the public,—or, what is just the same thing, by government? At any rate, there is no necessity for the Academy's continuing to occupy so considerable a portion as it does of the building, now that the whole of it is required for the national collection of pictures.

The paragraph in the Art-Journal does not speak at all doubtfully, as of rumour that requires confirmation; therefore, unless it should be contradicted, we may presume that there really exists a definite scheme for the purpose of altering Mr. Wilkins's edifice; and that, consequently, government do not entertain any idea of erecting a new National Gallery, as has been talked of by many, and by some fully expected. There have been various rumours on the subject, one of them being that a structure for the purpose would be projected within the enclosed area in Leicester-square. In what is now stated, there is far more of probability and likelihood, although the Art-Journal speaks only upon a "we understand." Let it be based upon what it may, that "understanding" assumes some degree of shape and colour. For the present, I shall only distinctly put upon Mr. Barry's design has been "submitted to the authorities;" and not only approved of, but, as it would seem, actually determined upon before the public were aware that anything of the kind was in contemplation. It is not, indeed, very easy to reconcile this with what is said in another page of the same publication, where we are told that Mr. Pennefather being directed to examine the lower rooms of the present Gallery, with a view to the collection being deposited there, reported their total unfitness for such purpose, and recommended that a plain temporary building, calculated to last about a year, should be erected, and that the interim parliament should make the expense of £15,000 to £20,000 for a permanent edifice. One tale contradicts the other: either Mr. Barry's design, or Mr. Pennefather's suggestion, is thrown out. If there is to be a new building in some other situation, the present Gallery will remain untouched; and vice versa, if the latter is to be carried out, another story will be added to the building. Between the two schemes lies doubt: error there is as to one of them, and error there may be as to both. Still, something appears to be in agitation or contemplation; therefore, it is not at all amiss that public attention should be directed to it at an early stage of proceedings.

Most may be of opinion, and some are or have been in full expectation, that let be done whatever might—whether a new National Gallery is to be erected, or the present building enlarged, the work would, like the "Houses of Parliament," be the subject of competition. The occasion itself is a public one, and of a kind to exercise talent in an ordinary degree; a structure for the purpose being something altogether sui generis. Of almost every other kind of buildings the examples and instances are so numerous, that general conventional ideas may be taken from them; but with respect to Picture Galleries the case is quite different. For them there are no models; neither have any studies been provided, or aught of any moment on the subject been written and published. Some of the most celebrated public buildings in the world are in buildings which, besides being a

what requires considerable study and foresight. In temporary exhibitions, pictures must be hung up as well as they can be. The disposing them on the walls is of necessity a work of such hurry, that it is little to be wondered at if it is frequently attended with awkward mistakes, such as putting a good painting nowhere out of sight, and an inferior one just upon the line. Even if it be detected, there is no time for correcting the error, because to do so might render it necessary to alter the situations of a score of other pictures.

In a permanent gallery, on the contrary, more especially one claiming to be considered a public museum of art, where nothing, it is to presumed, is admitted but what is worthy of being studied—at least, of being noticed as a work of art,—the utmost attention ought to be given before-hand to what is required by the collection itself. Should this last be already fully formed, to provide properly for it becomes a comparatively easy task; whereas, for one that is increasing, regard should be had to future growth. When Mr. Wilkins—or rather, perhaps, those who employed him—thought measure of it, our national collection was merely in its infancy. Thanks to Mr. Vernon, the child has nearly all at once started up into a tall striding,—has quite outgrown his former "fit," which suit suits him no longer; so Mr. Barry is now it seems to enlarge it, and convert it as well as he can into a becoming toga civile. If he can do so without reclaiming from the Academy the part of stuff they have got possession of, he must have far more talent in point of contrivance than most of his professional brethren.

After all, we may possibly have been put quite on a wrong scent. Should which turn out to be the case, all we can say is, that the mistake does not lie at our door. We leave those from whom we got it to trace out the author of it; nor should we be greatly surprised to find it traced home— if mistake it really be—to that confounded, universal mischief-maker, Mr. Nosomy!

---

COLLISION OF TRAINS.—No. II.

In our last paper (p. 197), we considered the law and amount of collision in a train of carriages of equal weights, and provided with a single engine in front. We now propose to examine the effect of an engine behind, the other circumstances of the problem remaining the same.

As a first and introductory example, let us suppose a single carriage, weight 4 tons, having a pair of buffers in front, with a foot play to each, and each with an extreme strength of 4 tons (the law of resistance of the buffers being assumed to vary as their compressed, and impose on a fixed obstacle with a velocity of 60 feet per second). Let us now determine how much of this velocity will be destroyed by the time the buffers have ceased to act.

Let m be the mass of the carriage; p, the pressure on the head of either buffer when it is compressed to an extent x; v, the velocity, in seconds, of the carriage;—then, the mass of the buffer being neglected as small in comparison with the mass of the carriage,

$$m \frac{dv}{dx} = -2p$$

Now, 4 tons is the value of p when x = 1; and since p has been assumed to vary as

$$p = 4x; \quad m \frac{dv}{dx} = -8x; \quad m \cdot v^2 = c - 8x^2.$$ 

If the accelerating force of gravity be taken at 32 feet per second,

$$m = \frac{g}{8}; \quad v^2 = c - 8x^2; \quad v = 8c - 64x.$$ 

When x = 0, v = 60; \quad 8c = 3800.

When x = 1, the buffers cease to act, and v = 3600 - 64; or, c = 394 nearly; consequently, only half-a-foot of velocity is destroyed.

Let us next consider the case of a train of n carriages, each provided with a pair of buffers before and behind; and with an engine, weight r tons, attached to the last carriage; and let us suppose this train to impinge on a fixed obstacle at the rate of V feet per second; and from these data seek approximately the amount of velocity destroyed in the rearward engine by the time the buffers are used up.

In order to make the problem general, we will assume the weight of the carriages each = w, and the extreme strength of the buffers = h tons; also their extreme play 5 feet. By the time the engine behind has moved forward a space s, after collision has commenced, let 2p be the pressure on the buffers of the rearward engine. We shall now show that p is always less than $$\frac{P}{n}$$, where n is the number of pairs of buffers, and P the pressure on any buffer compressed to an extent x. For let $$x_1, x_2, x_3, \ldots, x_n$$ be the extent to which are simultaneously compressed reckoning from the carriage which first sustains the shock; $$\mu_1, \mu_2, \mu_3, \ldots, \mu_n$$, the pressures of the buffer-heads corresponding to the compressions $$x_1, x_2, x_3, \ldots, x_n$$. Now we have shown in our last paper that the pressures of the buffers, and therefore $$x_1, x_2, x_3, \ldots, x_n$$, decrease as we recede from the end of the train nearest collision.

$$x_1 > x_2 > x_3 > \ldots > x_n; \quad \mu_1 > \mu_2 > \mu_3 > \ldots > \mu_n; \quad p = \mu_1; \quad p < \mu_2 = \mu_2 - \mu_1; \quad p < \mu_3 = \mu_3 - \mu_2; \quad \ldots \quad p < \mu_n = \mu_n - \mu_{n-1}.$$ 

$$n'p < n(x_1 + x_2 + \ldots + x_n); \quad \mu' < \mu = \frac{\mu n'}{2}.$$ 

Therefore, if v be the velocity of the rearward engine, by the time the buffers are all used up,

$$\frac{\mu}{32} \cdot (v^2 - c^2) < 2p n'n'^2.$$ 

As an example, let $$n = 1$$, as before; $$n = 10$$; $$n = 40$$ (including buffers of engines before and behind); $$r = 20; \quad V = 60; \quad \mu = 4.$$ 

$$v^2 - c^2 < \frac{32}{40} \cdot 300^2 \quad \mu n'^2 < 32 \times 4 < 512.$$ 

If V = 60, \quad $$v^2 > 3088; \quad v > 56.$$ Or, the velocity of the rearward engine has been diminished by less than 3 feet a second.

If V had been put = 30, which is equivalent to about 90 miles an hour, still v would have had a value of 20 feet a second, or twelve miles an hour. In either case, it is clear that the shock of the engine behind would have been most destructive—in the first case frightfully so.

To recapitulate the results of our investigation, it appears, first, that when a train with a single engine is violently checked, the first carriage will sustain the greatest damage, and the effect of the buffers will be to increase the number of blows on the first and succeeding carriages, but to diminish their intensity. Secondly, that when an engine is attached behind; the last carriage after all the buffers are used up—having first to sustain the shock of the rearward engine proceeding with a diminished but still considerable velocity, if the original velocity of the train had been greater—will probably be the most seriously injured of all the carriages. A double shock will in this case have passed along the train—at first, by the sudden stoppage of the first carriages before all the buffers are used up; and then from the blow from the rearward engine after all the buffers are used up.

Since writing the former paper on this subject, we have seen a model of a break, by Mr. Bishop, which by an ingenious and simple contrivance is capable of being applied to all the carriages simultaneously, and almost instantaneously. We earnestly recommend the adoption of some such method of suddenly occasioning a powerful retarding force, as a most efficient means of avoiding casualties and coroners' inquests.

NOTES ON ENGINEERING.—No. XI.

By HOMER SHAH COX, B.A.

The Strength of Hungenford Bridge.

The security of a Suspension Bridge erected in the very centre of the metropolis, and liable to sustain the weight of a very large number of persons, is a subject possessing a scientific interest commensurate with its practical importance. The moment the question has been greatly increased by two independent circumstances—first, that it has been the subject of serious doubt and acute discussion; and secondly, that the traffic of the bridge has recently received an important accession by the opening of a railway terminus in its immediate vicinity.

There are some parts of the theory of suspension bridges exceedingly complicated and difficult, and others perfectly simple. Among
the latter is the estimation of the statical strain to which a chain is subjected when its weight and all its dimensions are known. This particular branch of the question may be set at rest without much difficulty. The object of the present paper is to do this by methods distinct from those which have been adopted in the previous discussions of the question.

Sir Howard Douglas, who first publicly moved the subject of the sufficiency of Hungerford Bridge, has ably calculated the strength of the chains, on the assumption that the form of them is the "common catenary"; this method, as I understand, is such as has been here adopted, and the result is somewhat considerable mathematical skill in its application. The mode about to be employed may be readily used in general practice, as it does not require a knowledge of mathematics; and the agreement of its result with that obtained by the process referred to tends to their mutual confirmation.

In suspension bridges, the central deflection is always small compared with the span between the points of suspension. It follows that the curvature of the chain is very small; and whether it be considered a catenary, a parabola, or even the arc of a circle, the deviation from the real form will not be considerable. It is very usual, for the sake of simplicity, to assume the curve to be a parabola, and that assumption will be here adopted after a few remarks tending to prove its accuracy.

If the horizontal distance of the weight of the chain and its load on the bridge were uniform, the curve would necessarily take on the line of a catenary. This may be easily shown from any standard treatise on mechanics which refers to the subject. Now, when the bridge is crowded, the load on the platform is uniformly distributed horizontally. This is also the case with the weights of the platform itself, and the chairs, and the carriages; and the curve of the deflection is that of the chains themselves, of which the links are horizontal at the centre, and inclined more and more up to the points of suspension. But practically this inclination is never so great; for instance, in Hungerford Bridge at the points of suspension, as will be presently shown, the tangent of the angle of inclination is about \( \frac{1}{4} \). This gives the cosine of the angle less than \( \frac{1}{4} \) or 15 feet measured along the chain there, nearly corresponds with 17 feet measured horizontally. This shows that the hypothesis of horizontal distribution, even for the chain alone, does not involve any considerable error; and when the mass of the load on the platform which is really so distributed, is taken with it, the deviation from the truth must be inconceivable.

On this assumption, then, the vertical line through the centre of gravity of half the chain and its load is situated midway between the centre of gravity of the platform; or the horizontal distance of this centre of gravity from the abutment is equal to one-fourth the span. Therefore, the moment about the point of suspension of the weight of the load and the chain is equal to the product of that weight and one-fourth the span.

At the centre of the horizontal: its vertical distance below the point of suspension is equal to the deflection of the chain. Therefore, the moment of the deflection about the point of suspension is the product of the tension and the deflection.

The angles determined are equal, the total effect to turn the half-chain about the point of suspension being equal to the weight, and this effect being resisted by the effect of the horizontal tension. (The platform not being rigid, contributes nothing to the ultimate support of the load.) Also, in Hungerford Suspension Bridge, the deflection is 50 feet, and the quarter-span 186 feet. Consequently, the horizontal tension \( H \) = \( \frac{50}{186} \) x 106 lbs.

Hence the weight of the half-span is \( \frac{50}{186} \) or nearly five-seventeenths of the tension at the centre of the chain.

On the authority of Mr. Cowper, who is believed to have obtained authentic and accurate information, it is stated, in Part 93 of this Journal (June, 1846), that the total sectional area of the chains at their centre is 596 square inches. The Bridge is supported by four chains, two on each side of the platform, and the above is the sum of the sectional area of all four together. The horizontal tension is supposed to be uniformly distributed over these 1986 inches.

Wrought-iron bars become sensibly stretched and impaired when subject to a tension of 17 tons per square inch. They will not bear that strain permanently; and in practice it is not considered safe to subject them to a greater tensile force than 9 tons per square inch. Letting the horizontal tension which the four chains together can safely bear be \( 9 \times 596 = 2664 \) tons; and the greatest weight of the half-span must, by what has already been said, be \( \frac{50}{186} \) of this, or very nearly 788 tons. Consequently, for the whole-span, the greatest total load = 1576 tons.

This is, in fact, nearly the load to which the bridge is actually liable to be subjected. The weight of the chains (716 tons) added to that of the platform, parapet, rods, &c., and a crowd covering the platform with a weight of 100 lb. to the square foot, gives, according to Mr. Cowper, a load at about fifteen hundred tons. We come to the conclusion, then, that when the bridge has its full load, the statical tension at its centre is nine tons to the square inch.

The following method was adopted to test the accuracy of the hypothesis on which this conclusion is founded. By a known principle which applies to catenaries of every form, the tangents at any two points of the curve meet in the vertical line through the centre of gravity of the intervening portion of the chain. Consequently, if the assumption be true that the vertical through the centre of gravity of each half-chain bisects the half-span, the tangent at the point of suspension ought, if produced, to meet the platform midway between its centre and extremity. The observation of this fact would be a crucial test of the above conclusions. This test was satisfactorily performed in the following manner. The inclination of the chain at its summit was observed with a telescope from various positions on the Bridge, and that position was noted in which the inclination of the chain at its highest point coincided with the axis of the telescope. That position of the observer's eye for which one end of the highest link covered the link next below, and the other end of this covered the link below, was taken as the position of the point of suspension. (Applied for the sake of mutual confirmation to the points of suspension at both towers), it was ascertained that the centre of gravity of each half-chain was about six feet nearer the end, than the centre, of the platform. The advantage of this method of observation is that, if an error of 10 or even 20 feet would not have made a considerable difference in the result, while the errors of observation were certainly far within those limits.

It is important to observe, that if the Bridge were loaded with its usual load, if one end of the highest link covered the link next below, and the other covered the link below, the inclination of the chain at its summit would coincide with that above assumed, even more closely than it did at the time of the observation.

To ascertain the tension at the points of suspension, we have the following rule, applicable to catenaries of every form. Add \( \sqrt{2} \) to the horizontal tension; and of the weight on the half-span: the square root of the sum of the tension at the points of suspension which, therefore, in the case before us, is \( \sqrt{9 (2664^2 + (778)^2)} \) tons.

After obtaining this square root, divide it by 9, and the result is 308, for the number of square inches over which the tension at the summit must be distributed if the tension be 9 tons per square inch. The actual sectional area of the chain at the points in question is very near this—only 312 square inches. In the above calculations, the structure has been supposed to be in a state of equilibrium. The vibrations of the several parts of the chain, arising from the rapid motion of traffic, or the action of the wind, would certainly increase the strains greatly, though no attempt is now being made to calculate that important effect. The foregoing method shows, with all the precision requisite for practical purposes, that both at the centre and extremities of the chain the tension of the metal is 9 tons per square inch, when the bridge is fully loaded. The fairest way of stating the conclusion from these investigations appears to be this:—If the permanent tenacity of the metal be so great that it may be safely subjected to a greater strain than 9 tons per square inch, then the excess is a provision against accidental disturbances. It, however, 9 tons per square inch be the utmost strain which the metal will safely bear, no margin is left for security against the effects of rapid motion.

THE WATER-GAS.

Some time has elapsed since a patent was obtained for a process of making illuminating gas from water; but the plan was not carried into practical effect, and dropped out of public notice. The invention has since been more freely brought before the public, and in a manner calculated to attract attention, by being made the subject of lectures delivered by Mr. Ryan at the Polytechnic Institution. The process itself is a very curious one: and though the expense may probably render it a less economical mode of supplying gas than coals, where they are to be purchased at a cheap rate, yet, in many parts of the country, it is probable that the water-gas may be the cheaper of the two; and as its purity and illuminating power exceed those of the carburetted hydrogen.
obtained from coal, it is well that the mode of making it should be generally known. To those who are unacquainted with the chemical composition of water, it may seem strange that water should be rendered the source of fire; but to most of our readers it must be well known that water is composed of hydrogen, the most inflammable of bodies, and of oxygen, which, when in the form of gas, is the most inflammable of all. A plan of obtaining hydrogen gas from water, by passing steam through a hot tube containing iron has been long known. The rationale of that process is, that the steam when in contact with heated iron becomes decomposed, the oxygen uniting with the iron to form an oxide of that metal, and the hydrogen liberated in the form of gas. It is the best mode of obtaining hydrogen gas in a state of purity; but for the purpose of illumination, such gas is of no purity. The flame, though emitting great heat, is scarcely visible. The illuminating power of coal-gas depends on the carbon it contains; and the more carbon is contained in a barrel of gas, the greater is its illuminating power. It is owing to the great proportion of carbon in turpentine, that it affords such a brilliant light in the "camphine" lamps, the only difficulty in the burning of that substance being to produce perfect combustion; otherwise the abundance of carbon causes volumes of dense smoke. To render the water-gas illuminating, it is necessary, therefore, to combine it with a portion of carbon; and it is this part of the process in which the principal novelty of the invention consists. The apparatus employed in the manufacture of the gas is exhibited in the diagram. It consists of a furnace, in which are three long iron retorts placed perpendicularly. Two of these are nearly filled with coke and old iron chains, or pieces of iron. Water is admitted into the first of these, and being converted into steam, it is then decomposed by the iron, and the steam which is liberated is absorbed at the same time, some portion of carbon from the heated coke. The gas and residual steam are then passed into the second retort, where a similar process of decomposition and of further carbonization takes place; and it then issues into the third retort, where it is brought into contact with heated tar, and absorbs from it a large portion of carbon. The carburetted gas is then forced through some vertical tubes, to permit the deposition of superfluous tar, and is conducted into the gasometer ready for use. The illuminating power of this gas is estimated to exceed that of ordinary coal-gas, 25 per cent.; and its freedom from sulphur and other impurities renders it far preferable to coal-gas. Respecting the economy of the process, Dr. Ryan says nothing; and we believe that it was on this point that the invention failed to be practically useful when first introduced. The cost of the fuel to heat the retorts, of the iron to decompose the steam, the cost of the tar to carbonise the gas, would, we fear, amount to more than the cost of coal, in most parts of England, for making the ordinary kind of coal-gas. In many circumstances, however, we conceive this mode of generating illuminating gas may be advantageous, especially when the purity of the gas consumed is an object of importance.

ON ISOMETRICAL PERSPECTIVE.

By R. G. CLARK.

The object of this article is to communicate an easy method, by construction, for determining the transverse and conjugate diameters of an ellipse touching the sides of an oblique parallelogram, being the isometrical projection of a circle inscribed in a square.

Draw the isometrical parallelogram A B C D, and its two diagonals A C and B D; bisect O C in m, also bisect A m in N, and then with the radius A N and centre N, describe a semicircle cutting O B, produced in R. Again, with centre O, radius O R, describe a semicircle a R cutting A C in a and c; then will a c be the transverse diameter required of the ellipse. In like manner, bisect O D in m, and B E in r, and with the centre r, and radius r E, describe an arc cutting O C in t; again, with centre O and radius O t, describe an arc cutting D B in s and d, then will b d be the conjugate diameter required.

The above may be demonstrated thus:—Because the sides of the oblique parallelogram respectively touch the curve, they are tangents to it. By the properties of the Conic Sections (see Dr. Hymer's elegant treatise), we have A O × M O = O A O; but M O = m O, therefore a O = A O × m O. Also, by the property of the Circle, we have a O = O B 2. A similar mode of proof applies to the conjugate diameter. After the diameters are thus determined, the curve can be easily trammelled in the usual way. It would also be well to state an easy rule, by calculation, founded on the above construction.

RULE.—Multiply the diameter of the circle by 1.294 for the transverse diameter, and by 707 for the conjugate diameter.

Ex.—Given the diameter of a circular turn-table = 14' 5", to find the transverse and conjugate diameters of its isometrical representation.

Here, by the rule, 14'5 × 1.294 = 19'748 transverse diameter.

14'5 × 707 = 10'25 conjugate diameter.

The previous method of construction, however simple, I have not before met with in any work on isometrical perspective. The rule by calculation is easily deduced from the construction, making the isometrical diameter, or the given diameter, of the circle equal to unity: Thus, because the isometrical angle O A B = 30°; therefore B O = 1/4 A C. Hence O A = √(1 − .25) = .866; therefore, a O = A O × M O = .866 × .433 = 3.749. By extracting the square root of each side, we have a O = .612; consequently, the transverse diameter a c = 1.228. Also, B O = 1/4 B O = .605; hence b O = .338; consequently, the conjugate diameter b d = 707. These are the numbers given in the rule. I have not seen this rule in Jopling's treatise, but there is a table given of diameters, with the same figures to the Diameter 1. It will be observed, that all the lines that are in the figure are not required in the construction, but only the two diagonals: the other lines are only drawn to assist in the demonstration. The method given by Professor Farish in his paper on Isometrical Perspective, in Gregory's "Mathematics for Practical Men," is very tedious, both by construction and calculation.

EXPERIMENTS ON CEMENT.

A good deal of attention has recently been directed to the merits of a cement called "Portland" cement, manufactured by Messrs. Aspden and Robins, of Northfleet. On Monday, the 18th ult., a numerous body of architects, builders, &c., assembled at the town premises of these gentlemen, in Great Scotland-yard, to witness a number of experiments with the cement, both alone and in combination with sand, in different proportions; the following are some of the trials made:

Best Stock Bricks Cemented against the Wall.

Experiment 1.—17 stock bricks were cemented together with roman cement (all cement) and projected before the face of a wall, as fig. 1. They broke down with 7 lb. placed on the end.

Experiment 2.—11 stock bricks, cemented together with 1 sand and 1 roman cement, broke down with 7 lbs. placed on the end.

Experiment 3.—38 bricks, cemented with neat, patent portland cement, broke down with 14 lb. placed on the end.

Experiment 4.—30 bricks, cemented together with 1 portland cement and 1 sand, broke down with 15 lb. at end.

Experiment 5.—22 bricks cemented together with 1 portland cement and 2 sand, broke down with 168 lb. at end.

Experiment 6.—25 bricks, with 1 portland cement and 4 sand, broke down with 56 lb. at end.
Experiment 1. — 28 bricks, with 1 portland cement and 5 sand, broke down with 74 lb. at end.

Experiment 2. — 14 bricks, all portland cement, with a wheel of 9 cwt, in the centre, broke down with 17 lb. at end.

Experiment 3. — 16 bricks, cemented together with 1 portland cement and 1 sand, and suspended at both ends, broke down with 15 cwt. placed in a scale suspended on the centre. (See fig. 2.)

Experiment 10. — A block of portland stone, 2 ft. 11 in. long, and 9 by 9 inches, broke with a weight of 38 cwt. (See fig. 3.)

Note. — A block, cemented with roman cement, would not bear the weight of the stone, in a similar position.

Fig. 2.

Fig. 3.

Trials in a Hydraulic Press.

Experiment 11. — A block, all portland cement, 18 inches high and 9 by 9 inches, bore a pressure equal to 108¾ tons on the square foot.

Expt. 12. — A mixture, 1 sand and 1 cement, ... 80 tons sq. foot.

Expt. 13. — A mixture, 4 " 1 " 80 " "

Expt. 14. — A mixture, 7 " 1 " 44½ " "

Expt. 15. — A block, all roman cement, broke at 22½ tons.

Expt. 16. — A mixture, 4 parts sand and 1 roman cement, would not bear any pressure.

Expt. 17. — A block of portland stone, 1½ in. x 1 in., broke up at 32 cwt.

Expt. 18. — A block of the portland cement, the same dimensions, broke with 18 tons.

New Screw-Cutting Machine. — A plan of cutting iron screws is stated to have been invented by Mr. H. Gates, of Chicago, Illinois, by which the power of one man will cut per day, 100 half-inch, 500 three-quarter inch, 400 one inch, and 300 one-and-a-half inch bolts. The advantages claimed for this plan over the common die are, its dispatch in doing work; its durability, having cut over 4,000 bolts with one die, without any repairs; instead of jamming or driving the thread into shape it cuts it out, the same as in a lathe, leaving the thread of solid iron, which cannot be stripped off as is usual with those cut by the common die, and it will do the work by once passing along the bolt, making the thread perfect. The die, it is said, can be made by ordinary workmen, with far less expense than the common die, and when made, is not at all liable to get out of repair.

REVIEWS.

At present, we can hardly pretend to give an opinion as to the merits of a series of architectural illustrations from the three engravings in this first Part; nor are we able even so much as to say to what extent it is intended to carry the publication, and what will be the entire number of plates, there being neither prospectus nor advertisement on the wrapper to afford that somewhat desirable information. What strikes us at the very first as objectionable is, not that the plates are published miscellaneously while the work is coming out, but that it seems they are intended to be bound up so, instead of being duly arranged according to some sort of order and sequence. The subjects contained in this Part I. are: Plan of the Principal Floor, the Royal Court (a perspective view), and an Elevation of the lower part of the Victoria Tower, which are designated in the heading of the descriptive letter-press accompanying each of them, as Plate I., II., III., respectively. Wherefore, although the descriptive letter-press itself is not paget—which looks as if it had been intended to leave it to purchasers to arrange the subjects ultimately to their own fancy—such accommodation is now frustrated by the plates being numbered in the letter-press, and in our opinion quite uselessly, there being no corresponding numbers on the plates themselves, so that the binders can be guided only by their titles. We almost fancy that the " numbering " must have occurred through mere oversight; and if so, now that the very great inconvenience attending it is pointed out, it ought to be abandoned at once,—should which be done, cancels ought to be given of the descriptions already published.

As matters have been managed, Plate I. is a Plan of the Principal Floor; but surely that will not be the only illustration of the kind, or else the work will be singularly defective and unsatisfactory. Hardly can we believe that it is not intended to give some other plans—at any rate that of the ground-floor, it being quite indispensable for properly understanding the structure. The floor immediately above the principal one ought also to be shown. Besides which, there are many portions of the Principal Floor itself which require to be exhibited upon a larger scale, and much more in detail; the scale of the general plan being no more than that of an inch to 120 feet, which is so small that it is impossible to measure from it with any sort of accuracy some of the lesser rooms;—wherefore it would not have been amiss had the respective dimensions, according to actual measurement, been inserted in the " Key to the Plan. " With regard to the plan itself, it does not extend beyond Westminster Hall; consequently, it shows how what is to be done on the west side of the Hall, along Margaret-street and New Palace-yard. Nor is the plan quite so distinct as it might be, owing to all the parts that are under roof being shaded, and only the open courts and areas left plain or white. So far indeed distinction is made in the covered parts of the plan, but there might just as well have been greater distinctness also produced by making the walls considerably darker than the rest. In our opinion, shading of the kind might have been dispensed with altogether in what is an upper-floor plan, it being quite sufficient to treat the ground-floor one in that manner. Or— for the disagreeable doubt now comes across us—is this plan to be the only illustration of the kind? We will not believe that it is until we can no longer disbelieve it. Even a ground-floor plan will not be quite satisfactory unless it is made to show—except that be done in a separate situation-plan, on a lesser scale—the relative position of Westminster Bridge, Henry VII.'s Chapel, and other circumstances of the peculiar locality. Else, how are those who are quite unacquainted with that locality, to form any notion of it? A publication like the present, more especially its subject being taken into account, is not likely to be confined to this country, but will be eagerly turned to abroad, wherever the fame of the Palace of Westminster and its architect has reached; and how are those who possess no other information than what they can derive from plans, to understand the difficulties which the architect has had to overcome, and the cause for what must strike them as being defective and unsatisfactory in the disposition of the west or principal land-side of the edifice? For our part we should say, that besides a general situation-plan, there ought also to be a plan of all the buildings as they existed before the fire. And undoubtedly a plan of the kind ought to be inserted in this publication, if only as a historical document.

Plate II. shows, in a perspective view, a part of what is called the Royal Court, it being that into which the state carriage and
other royal equipages drive and turn round when the sovereign goes to parliament. Here we see on the east side, the large bay window of the Chamber of the House of Commons, a part of the south side of the court, where the windows on the principal floor belong to the office of the Lord Great Chamberlain. The archway through which the carriages pass from the porch beneath the Victoria Tower is quite in a corner, at the southwest angle of the court. The interior of the court is not at all remarkable, except on the west or gallery-side of it, where the two archways below (one of them leading into the Chancellor's Court) the small octagonal staircase turret, the oriel window with solid wall in the compartment between the buttresses on each side of it, broken only by arched and apsed panels, containing royal armorial bearings, form, together with the range of lofty windows above (those in the upper part of that side of the gallery), form a sufficiently picturesque and piquant combination,—such as can hardly fail to captivate the admirers of the olden time. What the other elevations of the court, which are not shown in the view, may be, the description does not inform us. To say the truth, the descriptive letter-press is exceedingly meagre, dry, and bald; and has, besides, the disadvantage of consisting only of detached scraps.

Plate III., the elevation of the royal portal or entrance-porch in the lower part of the Victoria Tower, exhibits, on a tolerably adequate scale, the exceedingly rich details of that part of the structure; in the character of whose open arch we fancy we recognise a resemblance to that of the beautiful Erpingham Gate at Norwich. If its beauty be judged in its details, the peculiarities which does justice to the structure itself; for it conveys no idea of the strikingly fine effect produced by an open arch of such magnitude (30 feet high) to its apex), on the exterior of a building. The plate being a mere outline one, the picturesque contrast of light and shade is quite lost; therefore, although it is not like in its effect, one need not marvel at a mistake as to suppose that the arch itself is filled-up by the lesser arch and gate seen on the further plane of the elevation, it would have been better that plane been entirely, though slightly, shaded—because then the opening of the arch, when it would have been distinctly defined. There, indeed, the section of this porch is seen to the same extent as the elevation; and we also desiderate a fully detailed plan, to show the groinings of its vault.

However interesting and excellent the materials for it furnished by Mr. Barry may be, the publication does not seem to have been planned with much judgment or foresight. The separate "History" of the Palace of Westminster is by Mr. H. T. Ryde; but who is the general editor, or who writes the descriptive portion of the letter-press is not said,—it is certainly nothing to boast of. As to what calls itself "Introduction," that might, in our opinion, have been spared, as it strikes us as being in wretchedly bad taste—a tissue of vulgar bombastic commonplace, and puff.

Since the above was put into the printer's hands, we have seen Part II., which came out only a very few days after Part I., and which gives us three more plates. The first of them exhibits to us in perspective a portion of the exterior—viz., the "South-Wing Towers" of the principal or east front; yet, although carefully done by a very competent architectural draughtsman (Mr. J. Johnson), and although we cannot but commend the diligence bestowed upon the drawing, the engraving is not altogether satisfactory. What has been alleged by some against the building itself, makes itself here felt; for the multiplicity of the details and enrichment spread over every part, is such as to occasion no small degree of confusion and indistinctness. This is especially the ease with regard to the upper part—the towers and the roof, where the different forms and surfaces do not define themselves at all clearly. More divided general effect as to light and shade, and greater vigour of touch, are required. In fact, the ordinary mode of lithography—that here employed—is hardly capable of doing justice to such a subject, for it shows poor and flat in comparison with that improved method in which the "shades," as they are technically termed, play the principal part, after being now perfected, and to that more energetic and pictorial mode of lithography, we feel dissatisfied with the one here practised. With the next plate—the Interior of the Royal Porch—we are made to feel very much so; for whether it be that the impression we have got is a defective one; or whether the material is not well treated; or whether the perspective for projecting the work will be equally useful for engineers in the commercial steam service. We think it likely to be very serviceable for those classes to whom it is addressed, and we therefore recommend it to our readers who feel an interest in the subjects to which it refers.

The object of this little book is to diffuse information on marine engineering, particularly to enable persons to prepare for the examination to be obtained in that subject. The whole work will be equally useful for engineers in the commercial steam service. We think it likely to be very serviceable for those classes to whom it is addressed, and we therefore recommend it to our readers who feel an interest in the subjects to which it refers.

Mr. Templeton suggests as one of the uses of this little book, that although it is not professedly useful for the higher branches of the profession, it may be found available as a ready prompter, for refreshing the memory on points of practice. By keeping up the standard of attainments among working-men, we think Mr. Templeton will do some good.
GEORGE STEPHENSON.

On the death of a great man it is a good time to think of what he has done. We are struck by the loss: the thought comes gloomily that he who so lately stood among us, whose smile still beams upon us, whose sayings are fresh in our ears, and whose looks have not faded, is no more. He spent his days here and sought another world. We begin to tell over his words and deeds, the great and good things he has done, his strength and his failings, his sorrows and his joys;—we hasten to snatch a last look before the bright remembrance is dimmed.

George Stephenson was no last-named man, in strength of body and mind unbroken, that it is hard to believe he lies in the cold grave; and the more so while his works speak so loudly of him. In mind he is among us, if not in body,—indeed, his remembrance cannot so soon leave. The last duties have been paid—the earth is closed upon him, and his name is written on the firmament. The newspapers have told of his birth and his death: but his brethren have yet much to think over. He has given the engineers of England a European name; he has opened for them a new field of employment at home, a wider field of honour and of wealth abroad, and they owe him heartfelt thanks.

When we look to the man, our hearts are stirred within us. We begin with his loveliy birth, we witness his great rise, his wonderful works, but still more his kindly feelings; we wonder how he did so much from small beginnings, and every young man learns to look now in more modest flames to the great man. All this is thought, therefore, a few words may be in good time now, gathered from the several books and papers in which they lie scattered, and which may perhaps be a spur to those able to do something worthier of the man.

His life is none the less useful as being that of a working-man, who by his own straight-forwardness raised himself to the topmost height; and as he began without school-learning, and in a private way, it opens many of those questions which have been much written upon of late years as to the teaching of engineers, and how far they may be the sad miles to the great talents. George Stephenson, too, as, unlike many men of learning, he was most happy in earning wealth, and in keeping it, in a good name, and in the love of his household, it may be worth while to ask why he should have had a better lot than other men, and what share an upright and manly end had in helping to build clock and locomotive. Many, indeed, think that at a clever man may do as he likes, and that he need put no value on his work, nor trouble himself whether his deeds be right or wrong, but may be a good and successful engineer notwithstanding. Stephenson's life will tell us something on all these heads.

I. BOYHOOD.

GEORGE STEPHENSON was born in 1781, at a small and lone cottage between Claro-Heaute and Wylam, in Northumberland, and within nine miles of Newcastle, in the colliery district. He was one of several children, the son of poor people, who had long dwelt in the same neighbourhood, and who were very respectable.

The elder Stephenson is said to have been a collier, but by other more likely account his colliery parents were people of high character is best proved by the early life of the son, but most by his behaviour towards them.

Schooling they were ill able to give him, and it is not certain that he learned to read before he began to labour; but he had that best kind of teaching which comes from the heart. An open and upright mind was the true groundwork on which his greatness was built, and he owed it to the humble home in which he was brought up.

We pride ourselves now-a-days that we have spread national schools over the land, and that we have taken care for the right bringing up of youth; and we think it much better that we can now learn to read and write. It may however well be asked, how far this alone is good; for we have struck a blow at that homeschooling, under which for so many hundreds years Englishmen have been bred. Formerly, the cottier had the whole care of his children; and the mother was held answerable for their offspring, and if these ended ill, the shame was a by-word among the neighbours. Now, the child is handed over to the schoolmaster, without whose teaching life is held as nought, and whose reading and writing are to breathe worth to the boyish mind. It is no longer said learning is better than rosey wit, but that it stands in the stead of everything, and is worth itself. The work of father and mother is now at an end; and if any ill befall, they answer they sent the child to school, and if any be in the wrong it must be the schoolmaster. This is telling more than is believed, and is one of those things which is sapping England. How often

must it be said that reading and writing are not to bring a child up, while its body and its soul are untaught? and better is it to have the homely English breeding of George Stephenson than the mock useful-knowledge-schooling of Dr. Bell or the Prussians.

If not taught to write, George Stephenson was taught to be a good son, and an upright man; and thus in after-time to find in his looks and words the same which he found in after-life. In common with his brothers he was early set to work to earn his share of the household food—so early, that his first earnings were only two-pence a day. He led the horse at the plough when almost too young to stride across the furrow;—riding him to his work betimes in the morning, when many children were still asleep, and had not begun their boyish play.

So lowly were his first endeavours, that they were given to the ploughshare or the coal-heap. Sometimes he wrought at picking bats and drawing from the coal; and he was so young, and so young-looking, that he had often to hide himself when the overseer went round, lest he should be thought too little to earn his small living. From twopenny a day he rose to fourpence, and at length to sixpence a day,—as a great rise, and perhaps as fraught with brightest hopes and swelling pride, as when in after-years his locomotives ran on the living rails. The railway became the undertaker of iron roads between London and the millions of the north, and kings and statesmen smiled on the wonders he had wrought.

In his boyhood he was most marked among the playmates of the hungry in the frontmost hour of toil and pastime,—and indeed we need not wish for more. His mind was not tasked beyond its strength, nor made to yield unripe fruit. The healthy growth of his body enabled him to work out whatever his powerful mind spurred him to do; and for twenty years of his life (from forty to sixty) he never failed in the tasks which the unbroken strength of youth can seldom master.

It is said that he early showed a mechanical turn, and that he mended the clocks and watches of the pitmen, and even made their shoes,—to eke out his boyish earnings; but it seems more likely that the watch of his locksmith belonged to a lad at the time. Art started in him, for he had shown such a happy knowledge, it is hardly likely that his skill should have been so little thought of, as until his manhood it seems to have been.

Shortly after he had come into his teens, he worked for a breakman for Waterrow pit, on the tramway between Wylam and Newburn. By this time his father had removed from Wylam to Walbottle. The lad now set up his first servant, which was no other than a great dog, whom he taught to bring his dinner daily from Walbottle colliery to the tramway.

He said even at this time to have helped in keeping his father and mother,—a homely deed, but one of which he had a greater right to be proud than of any engineering undertaking. A right English feeling in his love of kindred was always lively in his mind, and it showed itself in his fondness for his father, his son, and the children of his brothers, and in his deep esteem for his mother. He was an earner, and yet so humble that it is almost incredible to me how he earned to make his own way, he was so less so that those about him should get forward—nay, if it might be, even before him; and while his mind was still unbroken, he left his son to carry out alone the great works in which they had begun together.

II. KILLINGWORTH.

The Stephensons went to Willington and Killingworth, at which latter is a colliery belonging to Lord Ravensworth and his partners. Young George was now put to be stoker to a colliery engine, at one shilling a-day, and as he himself told—"In my younger days I worked at an engine in a coal-pit. I had then to work early and late, often rising to my labour at one and two o'clock in the morning. I was boarded at Killingworth, and while there in London and at the Queen's Head hotel, and talk over old times.—"Do you remember, George," asked his friend after dinner, "when you got your wages raised?" "Well," said Stephenson, "what about that?" "You came out

of the office all smiles, and told us you’d got your wages raised to 12s. a week, and you were a man for life. Now, you would find it hard to live on less than that a week.” “Yes,” answered he, laughing, “I dare say I should.”

It was, however, a great step, for it had a share in his teaching. He was at home with the steam-engine, and with his searching mind he was storing up that knowledge which was to be most useful to him. It was good going to a working-school for a great engineer such as Erindale’s in Millwall, or Watt’s in his native Glasgow. His mind was awakened: he did not stand listlessly by to feed the fires—but the engine lay before him as a book wherein to read its workings, to master its powers, to know its weaknesses, to act its working. There was something in the steam-engine which is a spell and a charm to the brain—something more and something else than the love of the sailor for his ship; such as the weaver feels not at his loom, nor the smith before his anvil. The smith or the weaver is the maker—the hammer or the shuttle works as his hand lists; but the steam-engine stands as with life and breath within it—working of itself, earnestly, steadily, and manfully, by day and by night, in its youth and in its elder years, when scores of men who wrought with it have sickened and breathed their last. To the working-man it is a thing of care and love, and its sight seems to give might to those who behold it, and to teach them the cunning which is in its own make. Thus, boys who watched strengthened it with cords and rods of iron; thus, a toy in the hands of Watt, it claimed his life for its care, and grew to unwonted growth;—thus, time after time, after master and workman nursed its childhood, and helped it onwards to its mightiest strength. It is the boyhood of these. The weaver does not better the loom; but day-by-day some slow workman gives his small need of help to the steam-engine.

The next step that we know of in Stephenson’s onward path was his getting seventeen shillings a week. Whether this was at Wriggleton or at Worksop or either, we do not know, but soon afterwards he was at Killingworth, with a shilling a week more, and sometimes putting to his slender earnings a little for his over-time or for piece-work.

He had now grown up to manhood, and to a good name among his neighbours, being, as those who now live remember, a hard-working and upright man, having the trust of his masters and of his fellow workmen.

One of the first deeds in which he is said to have shown his skill was at Killingworth. The sheaves over which the ropes work at the pit were much fretted as they were then made, and the ropes wore quickly away. Indeed, the ropes which elsewhere lasted three months, wore out at that pit in a month. This was a heavy outlay to the owners, and much trouble to the work-people. Many ways were tried, but fruitlessly; and at length they gave up all hope of a cure, and as the evil was getting worse, they bargained with Stephenson to find out whence it arose; and having done so, he set to work and put the sheaves to rights, so that a rope was saved in two or three months. 

By this time he began to feel his own worth, and to yearn after something better than his then way of living; but he thought that to better his means, no other way was so good as to learn more, and fit himself for higher tasks. He had it in hand moreover to go to New England, whither the stream of settlers did not flow so fast as it does now, and where therefore greater hopes were held out to the skilful workman who chose to leave the Old World so far behind. In the beginning of this age, it was a greater task to go to America than it is now to go to New Zealand; and it shows young Stephenson’s boldness that he undertook it. Nevertheless, it is not likely that it was his own thought, but that of one of the two brothers to be his fellows in the undertaking. One of these, named Wood, gave Stephenson a knowledge of writing and of numbers, which it therefore seems he did not learn until his manhood. It was the wish of Wood and Stephenson to try their hands in the New World at mechanics and farming, for which latter he had set at times a love. If we remember that in those days the trip to America was costly, and that no one could go free, we may see that Stephenson must have had some thrift, when he was able from his slight earnings to save wealth enough for such a task. It shows, too, that he was not given to drinking or to waste, but had an eye for the good. For it was said that he was a good housekeeper, and that he was not weary of his walks he stopped to look, and could not help saying to some of those around, that if they would let him, he could, to use his own words, “set them to the bottom.” He was at first laughed at, but at length they left him to have his way; and he went through with it so as fully to answer to what he had held forth.

This gave him a name among the neighbours as a skilful man; and he was no less happy with an engine which had been put up to pump water at a pit, but would not do its work, for it could not be made to pump. As is said at all such times, the skill of the master is too much for the workmen; and the pit master came in as the last doctor, to make the cure, and make it more wonderful. He said he could make the engines pump in a few hours; and though not believed, he did so, to the delight of the overseers. Whether this was the same work as that already named we cannot say, for by some it is told as not being large. The writer says it was a large

condensing-engine, made to draw water from the pit, and which had gone wrong. After several fruitless trials to mend it, Stephenson had the rashness to undertake the job, which he did fully—and moreover made some improvements in the engine. Stephenson himself had made many improvements in the engine and work. This, however, is sure—that he had got the trust of the pit-owners; and, having a better hope of livelihood, he gave up the thought of settlement abroad, and made Killingworth his home for some time.

When he was twenty-two years old, he wedded a young woman of the neighbourhood; and in 1803, his son Robert was born; but he had no other child. In the life of another man, the birth of a child would not be worth naming; but with his fatherly fondness, the child became the apple of his life, until he grew up to be his fellow-workman, to earn a great name, and to hold the secret among the mighty of the land which the father would not take. All went so happily with George Stephenson, that everything seemed to fit him. He was able to give his only son that breeding and that schooling, which, if he had had many children, would perhaps have been beyond his reach—though it is hard to spell what never happened. This, however, we may say—that Robert Stephenson owes his greatness to the unshared care of his father, who shaped his mind from earliest years to the full strength of manhood. Paintings have been drawn of the fondness felt by a mother in watching the growth of a child; to this extent there is not even dearer in the father, like George Stephenson, who, in the son of his youth, not only sees, but shares, in the growth of a great and manly mind. The mother can but be as a looker-on, and cannot feel his deeds to the full; but the father, while watching with the eye of a master, the heart, and partakes of every pleasure and pain that happens; for, in the common way of things, a man wades late in life, and the son comes upon the world only as the father is leaving it, and before the strength of manhood has ripened to its full.

The engine man had now become a stripping engineer, and began to look out for a way many thou and that he had tried his hand on most kinds of colliery work. It is said that he laid down some tramways, or wagon-ways as they are named in the north, and made some improvements in them. He was now getting a good name among the neighbouring land and coal owners, and got on the high-road to engineering. Instead of being pinned to the stake, as a workman by the day or week, it was open to him to rise as others had done around him, and to make his way as a mining engineer. The colliery school was a better one for breeding great engineers than even that of Cornwall; for it had all that Cornwall had, and more too. The Cornwallian could learn the steam-engine, pump-work, and mine surveying; he saw enough of sinking, and driving, and draining. The Northumbrian, however, while he had all these to learn by, having a greater bulk to move, had to look more to the roads and ways on which so many thousands had to travel, and leading to the ship-side. Hence, in Northumberland, many men had turned their skill towards the roads and wagon-ways, to the rails and sleepers, and to the works and bridges by which they were borne over the rivers and hollows. Both had the same school in the works of the millwright and the iron-founder, but the Northumbrian was better off; because, instead of the outway, small towns of Truro, Redruth, and Camborne, he had near him Newcastle, on the high road from London to Scotland; and having its booksellers, schools, and men of learning. He was much nearer to the world than his Cornish brother, truly at the Land's End. The north, therefore, has given us more civil engineers than the west, though the latter has its Trevithick and its Woolf.

By Lord Ravensworth, and others, Stephenson was employed in putting up steam-engines, and sloping planes under-ground; and in one pit, two of three engines were made to do the work of nearly 100 horses. We have seen that Stephenson had a love of knowledge, by what he had learned with Wood; and we know that he must have schooled himself much at this time, from what he soon afterwards did. It is true, he was not fond of reading, but he always liked to know everything thoroughly; and he did not leave out anything whereby what he undertook could be well done. It was always his wish to go to the ground-work, and to build steadily; and he had a great dislike for those engineers who undertake anything carelessly and suddenly; and he more than once noticed the miscalculations of hundreds of engineers, for want of studying the laws of mechanics, and knowing that a pound could only weigh a pound. It was on that sound knowledge and skill that his trust in himself in after-life was built, and that he was able fearless to stand up before the House of Commons and the people, in his great struggle for the locomotive against the lights of the day.

III. THE LOCOMOTIVE.

Stephenson was now getting beyond his thirtieth year, his mind strengthened by knowledge, and by the trust that what he might do would reap its full reward. His child was growing up to boyhood; his wages were still so slender that he could do but little for his schooling. He had at this time a very great want of learning, and he made up his mind that he would put his son to a good school, and give him good breeding. "I was, however," says he afterwards at a meeting at Newcastle, "a poor man; now you think I did not betook myself to mending my neighbours' clocks and watches at night, after my day's work was done; and thus I got the means of bringing up my son." This he might well say with boasting, for it is one of the bright lights in his life.

The greatest draught of coal on the tramways, and the heavy trains which went forth from the pits, had the sets of minds of many at work to use steam instead of horses to draw the loads. The stationary engine worked well on the incline, but the steam-horse was called for to run throughout from the pit-mouth to the ship-side. In 1788 or 1789, Dr. Robison, then a young man, had hinted to Watt to put steam to work wheel-carriages. Watt, however, had other things on his mind, though he named it in his patents of 1769 and 1784; but as Watt had a dislike for high-pressure steam, that may be one cause why he never made a locomotive.

About 1785, John Theophrastus Cugnot, a Lorrainer, showed a model of a steam-carriage to the Count de lace. He afterwards went to Paris, and got the help of the Duke de Choiseul. In 1769 he built an engine at the cost of the King, and it was tried in 1770. It moved with such strength, that it knocked down part of a wall while it rolled in its way; therefore some thought that the power was too strong to be kept within bounds, and not fit for common use. It is said the engine was given up and put in the Arsenal Museum, and is now kept in the Conservatoire des Arts et Métiers. It would be worth while for any engineer who may be in Paris to look after it.

In 1790 or 1793, Murdoch made a model of a steam-carriage at Redruth. This was perhaps the beginning of Trevithick's, who is said to have been brought up under Murdoch, and who knew him well.

In 1786, Oliver Evans laid a plan for steam-wagons before the commonwealths of Pennsylvania and Maryland, and the latter gave him a privilege for fourteen years—yet he was never able to get money enough to build a wagon. All that he did was in 1804 to put wheels on a steam dredging-machine he had made for cleansing docks, and which he made to move slowly, though in a certain way.

On March 24, 1809, Trevithick and Andrew Vivian took out a patent, which among other things was for the use of high-pressure steam for carriages, and by which the weight of the engine was to be very great. A carriage was made and run in Cornwall, and another in London. Another carriage was also made, which was worked on the Merthyr Tydfil Railway, and "drew after it as many carriages as carried ten tons of bar-iron, from a distance of nine miles, which it performed without any supply of water, at that contained in the boiler at the time of setting out; travelling at the rate of five miles an hour." The engine had an eight-inch cylinder, and the piston a four-feet-six-inches stroke.

These engines fell into disuse, from the one on the Merthyr Tydfil railway blowing up, having been made (against Trevithick's orders) without a safety-valve, and likewise from the wrong belief which got about that the wheels had no bite on the rails, and could not work up a slope.

One of Trevithick's engines was sent, singularly enough, to George Stephenson's birth-place, to Mr. Blackett, of Wylam; and thus it came within his sight. This happened most strangely, and most luckily, for the mind of Stephenson was now brought to bear on the great work of his life. The finding of Trevithick's model by Urville was strange, and most fruitful in the deeds it brought about; but perhaps we owe more to the Wylam engine. On some ground or other, the engine does not seem to have been put to work on the tramway, but was used to blow a cupola in an iron-foundry at Newcastle.

fly-wheel to secure a rotary motion in the crank at the end of each stroke. If Mr. Blackett did not however work this engine, he had another of the same kind made and set upon his tramway at Wylam; and in 1813 it worked by the adhesion of its wheels on the rails, thus upsetting the belief that the engine could not so work.

On the 30th December, 1812, William and Edward Chapman took out a patent for an engine, with additional wheels to work upon a chain stretched across the middle of the railway the whole length. This engine was tried on the Heston tramway, near Newcastl, but given up.

On the 22d May, 1813, William Brunton, of Butterley, took out a patent for a locomotive with legs. This was tried and worked. In 1811, Mr. Bleinkopf had hit upon the plan of having a cog-wheel and cog-rail to overcome the adhesion.

Blackett was first at work experimenting on the Wylam railway with an ill-made engine of Trevithick’s, which was found to be very troublesome, as the irregular action of the single cylinder made jerks in the machinery, so as to shake it in pieces. Still, the whole of the coals were taken down the tramway by this kind of engine. 31

By this time George Stephenson was likewise at work; and Lord Ravensworth and the Killingworth owners had such trust in him, that they gave him the money to make an engine in the opening of 1814, and on the 25th or 27th July, 1814, 32 it was tried on the tramway. Stephenson said Lord Ravensworth and his partners were the first to intrust him with money to make a locomotive engine. 33 “We called it My Lord. I said to my friends, there is no bound to the speed of such an engine, if the works can be made to support it.” 34

The engine had two cylinders, each eight inches diameter and two feet stroke; the boiler was cylindrical, eight feet long and thirty-four inches diameter; the tube twenty inches diameter, passing through the boiler. The cylinders worked two pairs of wheels by cranks placed at right angles, so that when the one was in working, the other was at its dead points,—by which means the propelling power was always in action. The cranks were held in this position by an endless chain, which passed round two cogged wheels placed under the engine, and which were fixed on the same axles on which the wheels were placed. The wheels in this case were three, one in front and two in rear. 35

The trial was made on a piece of road laid with the edge-rail, rising about one in four hundred and forty, and was found to drag after it, besides its own weight, eight laden wagons, weighing altogether about thirty tons, at the rate of four miles; and after that time it kept steadily at work. The application of the two cylinders made the working of the engine regular, and secured the steady progressive motion which was wanted in the engine, there being only the single cylinder and fly-wheel. 36

It was not till the next year that Stephenson took out a patent for rail, and here we find that he had worked of the patent laws as bearing upon our poor workmen. Had it not been that his first engine was not perfect, he could have had no patent, and would have reapéd no fruit from his days and nights of toil, as he could not raise the money to pay the heavy fees which are drawn from the patent pot. Blackett and another of the trials he wanted money, and for which he was beholden to the kindly feeling of Lord Ravensworth: much happier than Oliver Evans, who fruitlessly sought in America and England for the means wherewith to start his steamwagon.

Here we may rest for a time, and think a little as to what led Stephenson on in the world. No man could be worse off for money or means: he had no powerful kinsmen, no wealth left him by a father; his earnings were barely enough for the wants of himself and his son; his standing was lowly; he had no rich schoolfelloows or friends who had known his childhood. Within twenty years from this time he had, however, got together houses and land, and at his death left behind him wealth which he never durst have hoped for. Brindle was not so happy in the end, neither was Trevithick, nor Dodd. Watt began in a small shop—but he belonged to the same class, and it was the hard task that put him up from the lowest depths of life. If, however, he gathered riches, he owed it to the fostering care of Boulton, without whom he would have spent his income in undertakings which had not within them the seeds of wealth, whatever else could be said for them. He would have made the finest machinery for copying

Statuary; he would have tried to the utmost cures for illnesses of the lungs by breathing gasses,—but he would have died worth not one halfpenny.

Fulton wandered through the Old World and the New, begging kings and commonwealths to give him the means of building steamships. We have seen that the utmost luck of Oliver Evans with his steamboat was to have it without use to him, and to turn the wheels of a ballast-engine. Dodd, after planning two of the greatest bridges on the Thames, and spending thousands in bringing steamboats into use, died unhappily.

Trevithick, after trying one thing after another, and finding friend after friend to help him in his work, two years after Stephenson’s beginning at Killingworth, leave England for the West Indies; whence he did not come back, and that penniless, until Stephenson had laid down the Stockton and Darlington Railway. Trevithick was taken up by Mr. Blackett, a bold and daring man, and sent a locomotive to Wylam, which, like most things in which he had a hand, was so wonderfully made that it was put to other uses. Mr. Blackett made another, and Stephenson had it as a model to shape something better. Trevithick began better than Stephenson: he had friends in Cornwall and in London; and he sought not to have left to Stephenson to work out the locomotive engine and the railway. Trevithick was a man of unhappy and always unlucky; always beginning something new, and never ending what he had in hand. The world ever went wrong with him, as he said,—but in truth, he always went wrong with the world. The world had done enough for him, had he known or had he chosen to make a right use of any one thing. He found a partner for his high-pressure engine,—he built a locomotive,—he had orders for others for Mertthry Tydfil and for Wylam,—he set his ballast-engine to work,—and he drove his tunnel under the Thames for a thousand feet,—but no one thing fell: all were left unfinished. What was wrong with this—Stephenson never lost a friend, and Trevithick never kept one. To the day of his death, Stephenson had among his friends those who had given him a helping hand in early life; and from year to year he went on strengthening the bonds of friendship with them and their sons, and the younger men who grew around him. Then Ravensworths, the Peases, the Bradshaws, Matthew Bell, the Meynells, and others of his earlier friends, will be found with him throughout, standing by him as directors in his great railway undertakings, as they had befriended him in his small beginnings. This was a great strength to him, and though poor he had a mine of wealth in the place of his friends. A many an Englishman, open in speech, steady, straight-forward, and hard-working, he earned their friendship and never lost their trust; and if to others he was known as a great engineer, to them he was better known as an upright man. This made the working-man the rich manufacturer and great mine-owner. This gave him the means of doing what Trevithick and Evans could only talk of.

(To be continued.)

WROUGHT-IRON BOWSTRING GIRDERS FOR BRIDGES.

Some experiments have been lately made at the establishment of Messrs. Fox, Henderson, and Co., at Smethwick, near Birmingham, on a wrought-iron Bowstring Tubular Girder Bridge, of a similar construction to the one designed by Mr. Harrison, and given in our Journal in January. The experiments were made on a wrought-iron rib or girder, 120 feet clear span, in the presence of the Government Inspectors of Railways, and Government Board of Commissioners for inquiring into the Strength of Iron. The girder is constructed entirely of wrought iron, and consists of a wrought iron and angle-iron, tied across the ends by horizontal bars; and the tie-bars are connected with the arch by vertical standards, and by a double system of diagonals, which have the effect of distributing over the whole curve of the arch the action of weights placed on, or pass-
DRAINING MARSHES BY STEAM.

The following paper, "On the application of Steam-power to the Drainage of Marshes and Fea Lands," was read at the recent meeting of the British Association, by Mr. Glynn.

The number of districts in which I have successfully applied the steam-engine to drainage is fifteen, and the quantity of land so drained amounts to more than 1,823,000 acres; the engines employed being 17 in number, and their aggregate power 870 horses, the size of the engines varying from 20 to 80 horse-power. I was also engaged in draining the Hammerbrook District, close by the city of Hamburg; and in another district near to Rotterdam, an engine of machinery with the requisite buildings were erected at my plans by the Chevalier Conrad. In many of the swampy levels of Lincolnshire and Cambridgeshire much had been done to carry off the water by natural means; and many large cuts had been made and embankments formed—especially in the Bedford-level, which contains about 300,000 acres of fen land; and the great level of the Fens contains about 680,000 acres, now rich in corn and cattle. The Dutch engineers who had been engaged in these works had erected a number of windmills to throw off the water when the sluices could not carry it away. By the aid of these machines the land was so far reclaimed as to be brought into pasture and cultivation, producing occasional crops of wheat. The waters from the uplands and higher levels were intercepted by catch-water drains, which carried away as far as might be practicable the highland waters, and prevented them from running down upon the fen; but as it often happened, when there was most rain there was least wind, the engine was useless when their help was most needed, and the crops were lost.

In this state was the fen country when the steam-engine was introduced; and by its aid the farmer may venture to sow wheat upon these rich levels with as much confidence and even more than upon higher ground; for not only can he throw off at pleasure the superfluous water, but in dry weather a supply can be admitted from the rivers—so that farming in such cases is rendered less precarious than in situations originally more favoured by nature. It is, however, to be remarked that the quantity of rain which falls in these levels on the surface and penetrates below the general average of the kingdom, the power required to throw off the superfluous water is small compared with the breadth of land to be drained; the proportion seldom being greater than 10-horse power to 1,000 acres, and in some cases considerably less.

The general plan is to carry away the water coming off the higher grounds, and as far as may be practicable prevent it from running down into the marsh by means of the catch-water drains before-mentioned, leaving the rain water alone to be dealt with by mechanical power. As the quantity of rain falling in the great level of the Fens is estimated at 43 inches, one-third of this quantity is carried off by evaporation and absorption, or the growth of plants, it is only in extreme cases that two inches in depth require to be thrown off by the engines in any one month—which amounts to 14 cubic foot upon every square yard of land, or 7,260 cubic feet of water per acre. The standard pressure of a horse's power is 33,000 lb. raised one foot in a minute, or 3,300 lb. raised ten feet in the same time; and as a cubic foot of water weighs 624 lb. and a gallon of water 10 lb., so a horse's power will raise and discharge at a height of ten feet 350 gallons, or 525 cubic feet of water per minute. Consequently this assumed engine of 7,260 cubic feet of water fallen upon an acre of land will be raised and discharged at an elevation of 10 feet in about two hours and ten minutes.

If the quantity of land be 1,000 acres of fen or marsh, with the upland only to be banked out, the excess of rain, according to the above estimate, will amount to 7,020,000 cubic feet. A steam-engine of 10-horse power will throw off this water in 232 hours, or in less than 20 days, working 18 hours a day; and I have found this calculation fully supported in practice.

Although the rain due to any given month may fall in a few days, yet in such a case the ground will absorb a good deal of it, and the drains must be made of a capacity large enough to receive and contain the rain as it falls;—besides, in cases of necessity, the engine may be made to work 20 hours a day instead of 12, until the water is past. In general, however, the drains and channels should be cut 14 feet deep, and of width sufficient to give them the required capacity to receive the rain water as it falls and bring it down to the engine. In some instances—where the districts are extensive and their length great—it has been found requisite to make them somewhat deeper.

We understand that several girder-bridges of the above construction are to be erected on the Blackwall Extension Railway, under the superintendence of Joseph Locke, Esq.
wheels somewhat resemble the undershot-wheel of a water-mill; but instead of being turned by the impulse of the water, they are set to lift it, and are kept in motion by steam-pressure. They consist of two or more boards, or wheels, of the same size, the axis of each being parallel to the axis of the others, and placed at intervals equal to the diameter of the wheel: the boards of the wheels are made of wood, and fitted to work in a trough or track of masonry; and they are generally made 5 feet in length—that is to say, they are immersed 5 feet in the water—and their width or horizontal dimension varies, with the power of the engine and the head of water to be overcomes, from 2 to 8 feet. In the inside, or hollow, part of the wheels, there is a drain, and the water, in the river being kept out by a pair of pointing doors, like the lock-gates of a canal, which close when the engine ceases to work. The wheels themselves are made of cast-iron, formed in parts, for convenience of transport. The flat wood-boards are connected with the cast-iron part of the wheel by means of oak-sockets, which are stepped into sockets cast in the circumference of the wheel to receive them. There are cast-iron toothed segments fitted to the wheel, into which works a pinion upon the crank-shaft of the engine.

When the head of water in the river or delivering drain does not vary much, it is sufficient to have one speed for the wheel; but when the tide rises in the river, it is desirable to have two speeds or powers of wheel-work—the one to be used at low-water, and the other more powerful combination to act against 6 feet in tide. But, in most cases, it is not requisite to raise the water more than three or four feet higher than the surface of the land intended to be drained—and even that is only necessary when the rivers are full between their banks, from a continuance of wet weather or freezing storms. In the general case, the engine can be so constructed that the river being affected by the tide, the drainage by natural outfall can take place only during the ebb; and here, in case of long-continued rains, the natural drainage requires the assistance of mechanical power.

I have stated that the main drains have generally been made 74 feet deep, or more in larger districts—so that the water may never rise higher than within 18 inches or 2 feet of the surface of the ground, and the lidle or float-board dip 5 feet below the water, leaving a foot below the dip of the wheel, so that the water may run with sufficient speed to alsthr for the current of the main drain—which if it be sufficiently capacious and well-formed, will bring down the water to the engine with a descent of 3 inches in a mile. Suppose, then, that the wheel dip 5 feet below the surface of the water in the main drain, and that the water in the river into which this water must be raised and discharged has its level 5 feet above that in the drain, the wheel in such case will be said to have 10 feet head and dip, and ought to be made 28 or 30 feet in diameter. I am sure that you have seen that the water would rise a foot in a 28- or 30-foot wheel, and would rise above the level of the ground. The quantity of water delivered by one engine is from Deeping Fen, near Spalding. This fen contains 25,000 acres, and is drained by two steam-engines—one of 80 and one of 60-horse power. The 80-horse engine has a wheel of 28 feet in diameter, with float-boards or ladles measuring 54 by 5 feet, and moving with a mean velocity of 6 feet per second. So that the section of the stream, when the engine has its full dip, is 274 feet, and the quantity discharged per second is 165 cubic feet—equal to more than 44 tons of water in a second, or about 16,000 tons of water in an hour. It was in the year 1825 that these two engines were set up, and at that time the section of the cultivated state by the help of 44 windmills—the land at times being wholly under water. It now grows excellent wheat—producing from 4 to 6 quarters to the acre. In many districts land has been purchased at from 10l. to 20l. an acre by persons who foresaw the consequences of these improvements, and which they could now sell at from 20l. to 70l. an acre. This increase in value has arisen not only from the land being cleared from the injurious effects of the water upon it, but from the improved system of cultivation which it has enabled the farmers to adopt.

The fen lands in Cambridgeshire and in part of the neighbouring counties, are formed of rich bottom earth, consisting of decomposed vegetable matter, generally from 6 to 10 feet thick, although in some places much thicker, resting upon a bed of blue gault, containing clay, lime, and sand. When steam-drainage was first introduced, it was the practice to pare away the land and turn it to sod rape-seed, and to feed sheep upon the green crop; after which wheat was sown. The wheat grown upon this land had a long weak straw, easily bent and broken, carrying ears of corn of small size, and having but a weak and uncertain hold by its root in the black soil. Later, however, or when having thrown greater light upon the operations of agriculture, it has been the practice to sink pits, at regular distances, through the black earth, and to bring up the blue gault, which is spread upon the surface as a manure. The straw—by this means taking up an additional supply of nitrogen—becomes firm, strong, and not so easily broken; or if carrying larger and better grains, the nature of clay gives a better hold to the roots, rendering the crops less liable to be laid by the wind and rain; whilst the produce is most luxuriant and abundant."

THE STEAM HAMMER.

JAMES NASMYTH, and HOLBROOK GASKELL, of Manchester, engineers, for "certain improvements in machinery or apparatus for forging, stamping, and cutting iron and other substances."—Granted February 23; Enrolled August 23, 1843.

This patent is for improvements in the steam-hammer, for which invention patents were granted to the same parties in 1842, 1843, and 1844. The principal object of these improvements is to regulate the action of the hammer with greater facility, by working the lifting-cylinder by means of an additional small steam-engine in connection with the primary parts remaining very similar to the hammers now in general use. As is well-understood, the hammer is lifted by admitting the steam below the piston in the cylinder, and, by allowing the steam to escape, the hammer, by its own gravity, falls and gives the required blow. In the present invention, the force of the blow is regulated more conveniently than before. For this purpose, there is a small steam-cylinder for working the main slide-valve. This cylinder is fitted with a piston, connected by means of a rod to the main slide, to which the steam is admitted from the boiler. The small cylinder is furnished with three steam-passages similar to ordinary high-pressure engines, admitting steam alternately above and below the piston, and regulated by the slide-valve. This valve is connected by a rod to the piston of another cylinder, which is subject to the pressure of the steam from the main cylinder on the under-side, and is depressed by steam entering from a tube communicating with the valve-jackets of the slides. Steam having been admitted to the working-cylinder, the piston is elevated, and to regulate the height of the fall, a cock or valve is opened, communicating with an opening in the cylinder. This permits a rush of air into the cylinder, which depresses the under-side of the piston, raising it by the pressure of the steam on the under surface. The effect of this movement is to produce the requisite change in the position of the valve, so as to suffer the steam which entered the small cylinder above the piston, to escape into the atmosphere; the opposite cylinder thus being now driven by the pressure of the valve, so as to cover the steam-passage to the cylinder and the eduction-port, thereby suffering the steam to escape from the main cylinder; consequently the hammer, by its own gravity, will fall from the height to which it has been raised. There are three passages, each furnished with a valve or stop-cock, the levers of which are connected by rods to hand-levers, by which they may be opened or shut at pleasure; therefore, if the hammer is not required to fall from a height greater than the first opening, the valve connected therewith must be closed and the one above it opened. Secondly, the employment of apertures in the main cylinder, for the purpose of working the piston and main slide, thereby effecting the motion of the hammer and regulating the various heights to which is raised.—Thirdly, the use of a vessel, with its plug or cock, so as to regulate the alternate admission and escape of steam to and from the main cylinder. Lastly, the employment of the primary parts of the steam-hammer for the purpose of working the piston and main slide, thereby effecting the motion of the hammer and regulating the various heights to which it is raised.—Fourthly, the application of a valve, placed in the eduction-port of the main cylinder, for actuating the valve,
so as to effect the required change of the piston, and with it the main slide-valve, thereby actuating the hammer, and also for the purpose of obtaining the lapse of the required interval of time for the fall of the hammer.—Fifthly, the application of a latch-lever motion to the moving of the small slide-valve in one direction.—Sixthly, the combination of the latch-lever motion with the arm, and other parts connected therewith, by which motion is also transmitted to the valve, in the reverse direction, instead of employing the small cylinder for that purpose.—Seventhly, the application of the screw, and parts connected therewith, for the purpose of regulating the height to which the hammer is elevated. —And, lastly, providing a means of heating a passing steam or fire through the direct from the piston, and also without the intervention of the main slide.

DECORATIVE ARTS.

MISS ELIZABETH WALLACE, of Laurel-Lodge, Cheltenham, spinster, for "Improvements in facing, figuring, designating, decorating, planning, and otherwise fitting up houses and buildings, parts of which are applicable to articles of furniture."—Granted February 28; Enrolled August 28, 1848.

The improvements in the decorative arts patented by Miss Wallace are divided in the specification into ten kinds, though the distinguishing feature in the invention is the production of the effect of marble, &c., by employing tablets of black, red, or white marble, or of black, red, and white marble, the veins of Parian on to glass, the glass or plaster being coloured or decorated to give the required effect. These tablets are intended to be applied externally and internally, the internal decorations being of course more ornamental than the tablets used to imitate marble, &c., on the exteriors, and the latter are fixed to the walls by cement and long copper nails. Among other parts of the invention is a mode of producing the appearance of gold without employing any metal, and it is thus described:—"To make a flat tablet of this description, I take a plate of figured yellow glass (the nearer the colour of gold the better); to the back of this I attach a plate of plain yellow glass silvered, and I unite the two sides of glass by cementing them at the edges with gutta percha, or any other suitable cement. The result of the combination is, that the figured parts of the upper glass exhibit the appearance of deadened or frosted gold, with ground-work of burnished gold, or vice versa. Sometimes I substitute for the front plate of figured yellow glass, a plate of white glass, figured or ground (the whole of it, or parts only); and sometimes I also dispense with the second sheet of glass altogether, and apply the silvering at once to the back of the figured or ground front plate."

In another part of the specification is described the following process for giving additional brilliancy to painted glass:—"As regards stained, or painted, or other figured glass—t take a sheet of plain white glass, give it a coating of gum, then sprinkle over it a quantity of what are known in the glass trade by the name of "frostings," which are readily laid hold of by the gum; and the glass thus prepared I attach to the stained, or painted, or other figured glass on the inside, or that side which is next to the interior of the house or building, by means of gutta percha solution, or some other suitable cement, applied to the edges. The frostings have on the inside the effect of giving a beautiful lustre to the lighter parts of the design on the stained, or painted, or other figured glass, without impairing in the least the strength of tone of the darker or coloured portions; while they impart to the glass, when viewed from the outside, much the same effect as if a flood of light were streaming through from within."

In all the other different modes proposed for decorating houses by the patentee, the plan of giving a glass surface is adopted so as to produce the effect of a most brilliant polish, and at the same time to serve as a protection against damp and atmospheric corrosion.

ECONOMY OF FUEL IN STEAM-FURNACES.

FELIX DouchET, of Rouen, France, merchant, for "certain means, processes, and apparatus used for saving and applying the lost heat in general, and sometimes direct heat, to many useful purposes." (A communication)—Granted February 19; Enrolled August 10, 1848.

This invention relates, first, to an improvement in the feeding apparatus for supplying the feed-water to steam-boilers, and is constructed as follows. A number of tubes or pipes are placed in a vertical position within a cylindrical vessel, the ends of the tubes being secured to two chambers, one at each of the ends of the tubes, the interior of the tubes forming a communication between the chambers, which have no communication with the exterior of the tube; there are two communicating pipes from the cylindrical vessel, one at the top and the other at the bottom; there are also pipes of communication from the two chambers. The upper pipe of the cylindrical vessel communicates with the upper chamber, and the lower with the feed-pump; thus the supply of feed-water will pass through the cylindrical vessel amongst the tubes, and pass up the heat given off by the waste steam, which is passed through the tubes and chambers for that purpose. The second improvement consists of a slight modification of the above, for the purpose of heating a passing steam or fire through the tubes, the air being in contact with the exterior of the tubes; the patentee gives this apparatus the name of serifor or caloridor. The third improvement relates to a stretching apparatus for stretching the tissues or hemp-strings manufactured by machinery. The fourth improvement consists in allowing the waste steam to flow through a pipe into a large square receiver, where it is condensed. The fifth improvement consists in the application to external surfaces, for the purpose of retaining the heat therein, of envelopes or wrappers.

TURN-TABLES.

WILLIAM THOROLD, of Norwich, engineer, for "Improvements in turn-tables."—Granted January 15; Enrolled July 13, 1848.

This specification is very voluminous, as the patentee claims eleven different improvements in the construction of turn-tables. The first relates to an improved centre-pin, which improvement consists in forming on it a projecting flange or collar, the upper surface of which is an inclined plane, on which the centre of the table rests. The upper part of the pin has a ratchet-wheel attached, which is level with the surface of the table, and fitted with a click or pall attached to the table, which prevents it turning round without the table, while, at the same time, the ratchet and pin may be turned round by inserting a Spanish in two holes in the upper side of the ratchet, the incline plane at the lower end raising the table when such elevation is required. Secondly, the patentee claims a mode of constructing the centre squares of the top frame, having the rails laid thereon, and independent of the other part of the frame-work. Thirdly, different modes of constructing and arranging the working rollers that form the support of the circumference of the turn-tables. Fourthly, a method of diverting the dust, rain, and all extraneous matters, and also for clearing away such extraneous matters from the circumference. Fifthly, a mode of constructing turn-tables without centre-pins, and, consequently, without the usual parts connected with the centre of the other bearings. For this purpose he employs beams or girders of a stronger description than usual, for supporting the rails and platforms of tables of a corresponding size. These girders being attached at each end to the upper bearing-surface of the circumference, which is supported on the lower bearing-surface. The axes of these rollers instead of being attached to a separate frame revolving round the centre-pin, have their axes placed between two concentric belts or rings, which maintain the position of the rollers in a circle equal to the diameter of the bearing-surfaces. The under-bearing-surface has its inner circumference rendered truly circular, and forms a surface on which horizontal guides or friction-rollers travel. These rollers are supported from axes pendent from the under-side of the table, and consequently maintain the position of the table concentric with the bearing-surfaces, and in such a manner that the top frame in several divisions or compartments, and of various kinds of material. The seventh claim is for the exclusive privilege of casting the bearings and all working parts of turn-tables on chills, the same never having been heretofore practised. Eightly, the method of constructing single-line tables in such a manner as to render them more economical than such tables have hitherto been. Ninthly, the constructing larger kinds of turn-tables, with moveable joints in the beams or girders which support the rails; also for the purpose of stopping such tables at the proper point, by effecting a junction with the line of the set by the method of constructing the larger kinds of turn-tables, so that the power of a locomotive can be applied to the turning of such table when it is loaded with the engine and its tender, and when they require reversing on the line of rails. Lastly, the patentee claims a mode of raising and lowering the centre of turn-tables, when they require to be turned.
STEAM-BOILERS.

Horatio Black, of Nottingham, lace-maker, for "Improvements in evaporation."—Granted February 14; Enrolled August 14, 1848.

This invention relates to a mode of supplying water to steam and other boilers, by passing it through a succession of hollow fire-bars, of wrought-iron, brass, copper, or malleable cast-iron, previous to entering the boiler.

The annexed engraving is a plan of a set of fire-bars. a is the supply-pipe, through which the water is forced into the tubular fire-bars, b b b; the water first enters the middle bars b b b, and, after circulating through the whole series of bars, passes, in a highly-heated state, through the pipes c c into the boiler. It is not essential that the water should be divided into two streams, as the whole supply may enter into one bar, and circulate through the series of bars in the same direction; or more than two divisions of bars may be used in large furnaces. d is a cock on the supply-pipe, to regulate the quantity of water admitted. e is a pipe, furnished with a cock f, which is to be opened when the supply of water to the boiler is not going on; as otherwise the heat of the fire would tend to force the water out of the tubular bars; but by the cock f being opened sufficiently to permit the escape of a small quantity of water, such a circulation will be kept up as will prevent the water being driven out of the bars b b, when the supply of water to the boiler is stopped.

The above arrangement is suitable either for high or low pressure boilers; but, generally, for low-pressure, a rising pipe is attached, with a small cistern at the upper part, to the supply-pipe a, near the force-pump; and a valve is placed over the opening through which the water enters the cistern;—the valve preventing the water from flowing from the cistern to the boiler, by the valve being weighted, causes a pressure sufficient to force the water into the pipe a, and thence through the hollow bars b b, into the boiler; the quantity admitted to the boiler being regulated by the cock on the pipe a. By means of this arrangement, the water, forced into the pipe a, will flow into the boiler so long as it is required; but any excess will pass up the rising-pipe into the cistern, which is provided with an overflow-pipe: the boiler will thus work, at all times, subject to the pressure of the column of water in the rising-pipe and cistern. It should be stated that there is a valve in the pipe a, between the rising-pipe and the force-pump; which valve opens towards the boiler, and permits the water to flow in that direction, but closes against any flow of water from the boiler.

REVERBERATORY FURNACES.

James Timmins Chance, and Edward Chance, of Birmingham, for "Improvements in furnaces, and in the manufacture of glass." Granted February 14; Enrolled August 14, 1848.

This invention, as the title imports, relates to improvements in two distinct departments of the manufactures. The first, which refers to reverberatory furnaces, is for its object the greater economy of fuel, by conducting the heated gases to the furnace. In the usual construction of such furnaces, the heat from the fire, after striking against the arch above the furnace, and being reverberated downwards, passes off to the chimney. The patentees, instead of thus passing the heat direct into the chimney, render it further available to heating the furnace by returning the flue and carrying it back over the reverberating arch, and then downwards to the chimney, whereby the heat in passing through the return-flue is reverberated downwards upon the top of the reverberating arch of the furnace itself, and thus assisting in heating that portion of the furnace. The second part of the invention consists in a mode of passing sheets of glass into annealing furnaces or kilns. By the ordinary method the glass to be annealed is pushed into the kiln, and before this can be done the glass must lose a great portion of its heat, to enable it to possess sufficient firmness and solidity to bear the pushing strain to which it is subjected. The patentees make the side walls of the furnace opposite to that where the entrance for the sheets of glass into the furnace is situated, a hole or opening through which the workman passes the instrument by which, passing across the furnace and taking hold of the edge of the sheet of glass, pulls and draws it into the kiln; by this mode the temperature may not be so much reduced as when the old mode of pushing is adopted, inasmuch as the strain attending the pulling is considerably less than that of pushing.

RAILWAY-BREAKS.

Robert Heath, of Heathfield, Manchester, gentleman, for "Certain improvements in the method of applying and working friction brakes to engines and carriages used upon railways."—Granted January 13; Enrolled July 13, 1848.

The object of this invention is to bring a heavy weight, attached to a lever, to bear against the friction break, so as to render the action more certain and regular than when manual force alone is exerted. The lever is placed under the control of the guard, who, by turning a winch placed in the ordinary manner, may bring the weight to bear upon the peripheries of the wheels, or remove it, with very little effort.

Samuel Cunliffe Lister, of Manningham-hall, Bradford, gentleman, for "Improvements in stopping railway trains and other carriages, and generally where a lifting power or pressure is required."—Granted January 18; Enrolled July 18, 1848.

In this railway-break the resisting force is atmospheric pressure, or the pressure of compressed air, by which the breaks, which, as usual, act on the circumferences of the wheels. The apparatus consists of an air-chamber, placed below the framing of the carriage. It is provided with a piston or pistons, to the rods of which are attached the blocks, bearing against the wheels. The air is condensed into the air-chamber by air-pumps, worked by the axles of the carriages; and, by means of the pistons and rods, the pressure is communicated to the wheels. The mode to be adopted when the breaks are required to be thrown into action is, for the guard, by means of suitable connecting apparatus, to open the valve, by which means the air will be admitted to the pumps, a few strokes of which will then compress the air within the receiver as to press the breaks against the wheels. Similar effects are produced by making the pumps act as exhaustors, instead of compressors.

RAILWAY KEYS.

William Henry Barlow, of Derby, civil engineer, for "Improvements in the manufacture of railway keys."—Granted January 27; Enrolled July 27, 1848.

In these improved wooden keys, the inconvenience arising from expansion and contraction is attempted to be obviated, by rendering the wood impervious to moisture. This is done by introducing into the pores of the wood, fatty or other matters that are insoluble in water. The patentee first prepares the keys of the requisite proportions, after which they are subjected to heat for the purpose of expelling the moisture. This he effects by placing them in an oven for 24 hours, which is maintained at a temperature of 212°, after which they are immersed in a solution by preference composed of four gallons of creosote, one gallon of naphtha, 24 lb. of pitch, and half a gallon of boiled linseed oil. The proportion of this mixture used to impregnate the wood is about one gallon to the cubic foot, and the keys should be immersed therein about 24 hours. They are then ready for use, unless it be deemed necessary to subject them to the process of compression. Instead of simple immersion in these insoluble matters, the process may be greatly facilitated by exhausting the air from the wood in a close vessel, and afterwards forcing the fat composition in under pressure.
1. The new steam propeller which forms the leading subject of Mr. Maudslay’s present patent, obviates one of the greatest obstacles that have hitherto stood in the way of steam propelling, whether by means of screw blades or flat blades, or blades of any other description; viz., the difficulty of shipping and unshipping the propeller. Mr. Maudslay affixes the blades of his propeller (which may, he says, be of “any approved or suitable form”) in such a manner to the driving-shaft that the propeller assumes of itself, as it were, the proper angle for propulsion, the instant the driving-shaft is put in motion, and returns as instantly into a neutral or inoperative position when the driving-shaft ceases to rotate.

Fig. 1 represents part of the stern of a vessel fitted with this improved propeller; fig. 2, a front view of the instrument detached from its place in the vessel; and fig. 3, a sectional plan of the propeller, and its connections on the line a b of fig. 1.

A1 A2 are the blades of the propeller, which are inserted at their inner or narrow ends into sockets B1 B2, in the end of the propeller-shaft S, in which sockets they are free to turn to the extent to be presently defined. To the shank of each propeller blade there are two toothed segments C1 C1, C2 C2, attached one at the top of each socket, and the other at the bottom of it; and the two sets of segments work the one into the other within the limits determined by the stops ff, so that the propeller-blades must always move in perfect union, and can only turn round in their sockets to the extent allowed by the stops. E is a sliding clutch, affixed to the driving-shaft inside of the propeller-blades, which may be moved sternwards, so as to lay hold of either of two sets of pins, d d and e e, which project from the back of the wheels of the innermost propeller-blade A2. F is a vertical rod, by means of which the clutch E may be worked from the deck of the vessel; this rod terminating at bottom in a screw, which takes into a screwed nut a, which is attached to one arm of a bell-crank G, the other arm of which is forked so as to embrace the clutch E, when brought down upon it. The mode in which the propeller, as thus fitted, acts, is as follows:—Supposing the clutch to be disengaged, and the driving-shaft to be put in motion, the blades are immediately thrown out into the angular positions proper for propelling, and they will continue in these positions as long as the shaft continues to rotate. Should occasion arise for backing the vessel, the blades are then secured in their extended positions by interlocking the clutch with the pins d d, at the back of the wheels of the innermost blade A2, as represented in fig. 3. When the engine is stopped, and the driving-shaft ceases to rotate, and the clutch is withdrawn, the propeller-blades will, by the action of the water upon them, be turned round in their sockets until they come into a line with the course of the vessel, and present their sharp edges only to the water, as exemplified in fig. 4; and, for greater security, they may be made fast in this position by interlocking the clutch E, with the pins e e, at the back of the wheels of the innermost blade.

From the instantaneousness with which this peculiarly fixed screw propeller can be turned to account, from its never being required to be raised out of the water, and never offering, when in the water and at rest, any material obstruction to the steering or progression of the vessel, it seems to possess so far a great superiority over
all the screw propellers hitherto in use; but it promises to be more especially advantageous in the case of vessels going long voyages, with small store of fuel, and employing steam as an auxiliary power only, when the wind is not fair for the use of sails. With a propeller of this description, not a minute need be lost in changing from sailing to steaming, or from steaming to sailing, and consequently, not a pound more of fuel need be expended than is absolutely required.

2. The peculiar feature of Mr. Maudsley's new furnace consists in the employment of rotating tubular screw bars, and hence the name ("Archimedean") by which we (not Mr. Maudsley) have ventured to distinguish it. Fig. 5 is a longitudinal section of the furnace; and fig. 6 a front view.

H, H, are the fire-bars, which, instead of being as usual solid fixtures, consist of a series of tubes which are free to revolve in their bearings, are open from end to end, screwed-threaded on the outside, and perforated with numerous air-holes. On the front end of each bar there is a broad flange or shoulder F, which projects beyond the general line of the furnace, and has a worm-wheel W, formed upon it. An endless screw-shaft K, which passes across the front of the furnace, and is worked from the engine through the medium of the bevil-wheels N, O, takes into the whole series of worm-wheels W, and causes thereby the constant rotation of the fire-bars. L is a throttle-valve hopper by which the coals are supplied to the furnace. As the coal drops from the hopper they fall upon an inclined shoot M, which projects them upon the front end of the furnace bars, whence they are carried gradually forward to the back, by the rotation of the bars and in consequence of the bars being in this constant state of rotation it is almost impossible that either clinkers or ashes should accumulate on them.

LOCOMOTIVE ENGINES.

Charles Ritchie, of Aberdeen, Scotland, engineer, for "certain Improvements in locomotive engines."—Granted March 2; Enrolled September 1, 1842. [Reported in the Mining Journal.]

This invention consists in, and has reference to, certain improvements in locomotive and other engines, carried into practical effect by the means, or through the agency, of certain new or improved mechanical combinations and arrangements, having for their object the simplification of the construction, and the augmentation of the efficiency of such engines.

The first part consists in the application of a cylinder, or cylinders, with two distinct and separate pistons in each cylinder, to which are affixed piston-rods, for imparting motion to the cranked-axes and driving-wheels fixed thereon, whereby the rocking, or oscillating, motion attending locomotive engines as hitherto constructed, is considerably diminished, and greater steadiness of motion obtained, as, by this arrangement, the momentum of one piston, together with its cranks, and other connections, is at all times exactly balanced, or nearly so, by that of the other, in consequence of the approaching and receding of the pistons to and from each other being always simultaneous. The second part relates to an improved mode of working the slide-valves of locomotive and other engines, by rendering the eccentric, which imparts motion thereto, available for the purpose of reversing the engine. The third part relates to an improved valve for regulating the admission of steam, or other motive power, to the working cylinders of locomotive and other engines, and to improvements in safety-valves, to be applied to the boilers of engines, or other reservoirs of power. The fourth part relates to an improved anti-primer, or steam-collector, to be applied to the boilers of steam-engines. The fifth part relates to an improved self-acting feeding apparatus, for supplying water to the boilers of steam-engines. And the sixth and last part consists in the application to the wheels of locomotive engines of an improved guard, or safety-brake.

The drawing exhibits a side elevation of a locomotive engine, constructed according to this invention. A marks the boiler of the engine; B, the driving-wheels fixed upon the cranked-axes, C; the boss, or nave, D, of each of such wheels serving as the crank, to which one end of the connecting-rod E, is attached by a crank-pin, or stud, α, secured to the said nave, and the opposite end of the rod K, is connected to the piston-rod F, in the usual way of forming such connections. G, G, two pistons, to which are attached the rods F, F—the said pistons working steam-tight in the cylinder H, by means of metallic, or other packing. The cylinders are fixed to each side of the boiler. Instead of having the fixed cylinder and connecting-rods, as above described, oscillating-cylinders may be used, with their piston-rods connected directly with the crank-axe; or where fixed cylinders are used, and space is an object, the connecting-rods E, E, may be dispensed with, by attaching to the piston-rods a cross frame, in which there is a slot formed, into which a crank-pin, or stud, takes. The outer end of the frame works through a guide-hole, fixed to the side of the engine, and thus the rectilinear motion of the piston-rods imparts rotary motion to the crank-axe and driving-wheels fixed thereon. The steam may be admitted through the ports, into the cylinder, by a common slide, in the following manner:—Upon the hindermost driving-axe is fixed an eccentric, upon which is a cam, of the following peculiar construction:—Two rods are fixed to, or formed upon, the said cam; or it may be composed of one double-gabbed rod, one end being employed for effecting the backward, and the other the forward, motion of the slide-valve, through the intervention of a double lever, which has its fulcrum upon a stud, fixed to the side of the boiler, as shown by the drawing; and this lever is connected to the slide-valve by a rod e. The length of this lever, as also the angle of inclination of the parts O, O, should be in accordance with the lead of the valve—the one or other of the inclined parts O, being caused to act upon the lever by a hand lever, connected to the said cam in any convenient manner, so as to enable the engine-driver to start, reverse, and stop the engine readily, by the same eccentric which gives motion to the slide-valve. By making the end of the valve-rod moveable, as in a slot in the lever P, the steam may be worked expansively at pleasure. Improved spring safety-valves are exhibited by other drawings attached to this specification, from which it will appear there are two forms of construction, showing a valve with a conical-shaped seat, being a flat-valve, and constructed with a flange, which the inventor terms a compensation flange—such flange being let into the seat vertically, about one-sixth of the diameter of the steam-
way in the valve-seat. This valve is weighted by a helical spring, of sufficient power; according to the required pressure of the steam; and when it is intended to be used as a reserve safety-valve, the spring is to be placed around that part of the stem below the valve—that is to say, within the boiler. The advantage of this form of construction of valve over the ordinary valve is as follows:—As soon as the pressure of the steam raises the valve from its seat, the flange, being exposed to the action of the steam, presents an increased surface, which compensates for the increasing resistance of the helical spring, until the valve has been raised to a height equal to the area of the steam-way, when it allows the steam, or vapour, to escape freely. When not intended as a reserve safety-valve, this valve may have the spring placed above it. Another valve, which is called an indicator safety-valve, is exhibited, consisting of a piston, which is fitted into a tube, having a spring attached to it—lateral openings being made in the tube, to allow the steam to escape when the piston becomes raised above such openings; and by making the said tube moveable within another one, the “blowing-off” point may be varied at pleasure. An index, like that of a barometer, may then be attached to the stem, or rod, of the piston, and will indicate very slight variations of pressure. A regulating-valve is attached, the construction and arrangement of which is as follows:—There is a short socket-pipe, having two conical valve-seats formed therein, into which the valves fit—such valves being connected together, or formed upon one stem, into which one end of a rod is screwed, or otherwise made fast, and the opposite end of the said rod attached to an eccentric spindle, working through a stuffing-box, by which a hand-lever is fixed—such lever and rod being for the purpose of opening, or closing, the regulator-valve at pleasure.

The anti-primer before-mentioned is formed in the following manner:—Two distinct and separate plates of sheet metal, the outer edges of which are securely fixed to the inside of the boiler, by riveting, or otherwise, the said plates being inclined towards the centre of the boiler, care being taken to leave a space between the inner edges of the two plates, so as to reserve a channel lengthwise of the boiler, for the passage of steam into the steam-chamber thus formed, and, in connection with which the regulating-valve, is situate the steam-pipes which lead to the cylinders being connected thereto. Instead of forming the anti-primer of two separate strips, or pieces, of metal, the same result may be obtained by forming it of one strip, or piece, of metal, of the shape shown—the said plate being pierced with an infinite number of small holes. The construction and arrangement of the feeding apparatus are as follows:—There is a metal cylinder, which should be bored perfectly true and cylindrical, fitted with a piston, the rod of such piston forming the plunger, or ram, of the cold water pump, the barrel of which serves as a compound gland for the stuffing-box of the cylinder and pump-barrel. The slide-valve, which may be made to cover or uncover the ports, or passages, in the cylinder, by the opposite sides of the piston coming into contact with the levers, which are connected to the slide-valve by a rod or rods. There are spherical-valves (the seats of which are knife-edged), fitted within the spherical flange pieces, which have openings for establishing a communication between the ten- der, the pump-barrel, and the steam-boiler, as exhibited. The modus operandi of this feeding-apparatus is as follows:—Upon steam being admitted from the boiler into the cylinder, through the steam-port, or passage, the piston will be acted upon, and the ram, or plunger, be withdrawn, the water from the tenders will raise the valve, and enter the barrel, to supply the space previously occupied by the plunger, or ram; by this time the piston will have acted upon the lever, so as to cause the slide-valve to uncover the port, or passage, and cover the port, or passage, thereby allowing the steam on the other side of the piston to escape through the exhaust-pipe; the piston will now be impelled in a contrary direction, and the plunger, or ram, entering the barrel, will cause the one valve to be closed, and the other to be opened by pressure of the water therein, which as the plunger, or ram, advances, will be forced into the boiler, to supply the deficiency of that water which has been converted into steam. When the steam is formed, the mark wheel-guards, or safety-breaks, which are each composed of a strong band, or strap, of iron, placed like a splasher over the wheel to be protected; the inner surface of the said guard, or break, is formed of the converse shape to that of the cyrcle, and fixed securely to the framing, or boiler, or both, as near to the top of the wheel as the play of the bearing-springs will admit of, and as near to the back of each wheel as possible, without touching it.

To each side of the engine a bar of iron is placed, and securely fixed in a longitudinal direction—such arrangement being intended to preserve such wheels in a vertical position and thereby support the engine, in the event of the axes breaking, and to operate at the same time as a break, to retard the motion of the engine, in the event of any such accident. Another improvement in locomotive engines consists in arranging that part of the boiler known as the fire-box, in such manner that the height of the water in this part of the boiler shall at all times be at a proper level, which is effected by what is called an anti-separator, which is a separate partition-plate across the water space, or an extension of the plate below, when the tubes are fixed as shown; and, by causing the water to be fed to the boiler at that part which surrounds the fire, it will appear evident that the barrel of the boiler can only receive its supply of water from that which overflows the said partition-plate. Having described the nature of his invention, the patentee remarks, that he does not claim the exclusive use of any of the separate parts above-mentioned and referred to, when considered per se and apart from the purposes of the said invention, as hereinbefore set forth and described.

**Improvements in Perforating Glass for Ventilation.**
Patented by Mr. J. Lockhead, of Milton, Gravesend.—In forming plates, sheets, lenses, or other forms of glass, to glass, when in a semi-fluid state, is poured from the pot on to the casting-table—the stream being followed by a pressure-roller, for the purpose of flattening it; and, while the glass is in a plastic state, a metal mould, with teeth or projections on its under-side, according to the pattern required, is applied to the surface, forcibly pressed down, and let in that position until the glass has set; after which it is to be removed, and the glass will be found to be perforated, in corresponding shapes to the projections on the mould. To effect this in the most complete manner, a screw-press, made to the size of the casting-table, is used, very similar to a common copying-press, and different pattern-plates being fixed to the lower end of the screw, and worked by a cross handle.

**Improvements in obtaining Oxide of Zinc from the Ore.**
Patented by M. C. A. P. Roches, of Paris.—By this process, the employment of retorts, as by the old method, is dispensed with, the fuel and labour economised, the operation completely independent of the skill of the workman, and the loss of metal, incidental to the old method, prevented. Ores of lead and zinc may
be operated at on at once. The principal feature consists in the
reduction of the native sulphur of zinc (blende), and of the
carbonates, oxides, and silicates of zinc, and sulphurizes and oxides
of lead, by the action of the reducing gases of a blast-furnace, by
which means the slag, for convenience, is collected, is reduced to a
suitable flux, is introduced into the charging aperture, and, by means of a cover above, and a
sliding plate below, none of the gases are allowed to escape. The
charge thus falls upon a layer of incandescent fuel; a layer of
fuel is then poured upon the ore; then another charge of ore,
until the furnace is full, and it is to be replenished as its volatiles
sink below a certain depth. The zinc is thus volatilised by
heat, and the scoria falls into the lower part of the furnace;
the gases and volatilised zinc pass through proper openings
through a hydraulic main, and then deposit any zinc carried
with them.

BRITISH ASSOCIATION.

REPORTS AND PROGRESS OF THE RAILWAY SYSTEM."

"Facts bearing on the Progress of the Railway System." By Mr. W.
HARRING.

The modern railway system of Europe may be said to date from 1830,
when the construction, by Mr. G. Stephenson, of the Liverpool and Man-
chester Railway, with its locomotive engines, was completed. After that
date we have heard more of such prophecies as the following (from the Quar-
terly Review, vol. 2, 1825), which it is no longer necessary to record as an
omen to us for the future:—"As to those persons who speculate on making
railways generally throughout the kingdom, and superseding all the canals,
all the wagons, mail, and stage-coaches, post-chaises, and, in short, every other
mode of conveying goods and by land, and by water, we deem them and their
visions schemes unworthy of notice. What, for instance, can be more palpably
aburd and ridiculous than the following paragraph," —in which a prospect
is held out of locomotives travelling twice as fast as stage-coaches. "We
should be inclined to think the writer, like the people of Voltaire's time,
should themselves be fired off upon one of Congreve's rocket-shots, as
trust themselves to the mercy of such a machine, going at such a rate."
The modern railway system has, however, not only done this, but it has given
rise to new habits in the present generation, and has proved to be the great
mechanical invention of the nineteenth century, as the steam-engine was of
the eighteenth. As it is still in its infancy, it is especially the province of
statistical inquiry to watch its growth, so that on the one hand timely
remedies may be applied to its defects, and on the other free scope may be
given to its beneficial tendencies. Valuable papers have been contributed by
Mears, Lea, Porter, Graham, and others, analysing the traffic on railways
during the infancy of the system to the year 1843. Shortly before that period
a paper was read in railway companies' meetings, which had been
sanctioned, but the period which has since elapsed comprises the
memorable mail years of 1845 and 1846. Under this excitement intelli-
gence and emulation have been stimulated among the managers of railways
and railway companies, the system has rapidly advanced. The consolidation
of lines under a few great companies, the making of access streets, the
standardisation of cars, and the like, have proceeded;—the atmospheric,
an entirely new system of traction, has been brought forward;—the electric
telegraph, conveying intelligence at the rate of 280,000 miles a second, has been widely introduced,—express trains,
travelling at nearly the highest attainable speeds, have been established,
and the length of railways in operation has been doubled. It therefore
becomes a matter of interest to inquire into what the results of so active
a period point. Have low fares answered.—Has the third-class traffic, the
most neglected to the growth of the penny packet, and has it been
found wise, not only for the users but for the owners of railways, to
encourage it or the reverse?—Has the increase of speed been successful, and are
we likely to travel faster or slower hereafter?—How have the receipts kept
up with the increase of travel?—Has the rate of railway construction and
administration gained, and has it been found wise, not only for the users but for
the owners of railways, to encourage it or the reverse?—Should the experience of the past,
in short, give us confidence in urging on the system at the extraordinary rate
at which we are now doing it, or not? In the following investigation and
collection of facts it has been attempted to throw some light upon these
points—the recent publication of the official railway returns for 1846 and
1847 affording peculiar facilities for the purpose. The following paper refers
to the British Railway companies. The Welsh lines are not included, the
economical condition of Ireland being different from that of this country,
and there being but few railways open in that country:

Comparative Lengths of Railway open in 1843 & 1847 and Receipts thereon.
The lengths of English, Scotch, and Welsh railways open June 1846 were
1,960 miles, an increase of 33% of the length of 1840. The gross receipts returned for the year 1846 were
£474,000. Details, for the year ending June 30, 1847,
3,968,773.

After making the necessary corrections in the above figures, the average
receipts per mile of railways in 1842 were 2,489½; in 1847, 2,556. We therefore arrive at the important fact that, although the mileage of our lines
has been doubled, the receipts have been more than doubled. This must be
regarded as a favourable general feature of the state of railways. There was
much reason to fear that, as the first railways ran between the great towns
or traversed the manufacturing districts, the railways which were next
opened would show a great falling off in receipts. Hitherto, then, we find
this is not the case—this is a further proof that the opening of the great
lengths of railway which has been sanctioned by parliament but which is not
yet open.

Lines sanctioned but not open.—The length of railway sanctioned by
parliamentary trains (assuming it to be applied to open) is 2,110 miles.
A considerable portion of this is in progress, more or less opened. On the 1st
of May 1847, 5,209 miles were returned as in progress, on which 218,792
people were employed, or 42 per mile. These new railways are principally
meant for the accommodation of the agricultural parts of the country.
We will presently refer to the prospects of railways in such districts. When
the railways now in contemplation are completed, and it is probable that the
greater portion will be so in the course of the next five years, we shall have
upwards of 10,000 miles of railway open,—on which, judging from the numbers
employed on lines now open, (viz, 14 per mile), 140,000 persons
will be permanently employed, at good wages,—replacing, at five to a family,
three quarters of a million of the gross population. The importance of this
addition to our internal communications will be appreciated when it is
remembered that there is a considerable number of navigation, and
30,000 miles of turnpike road open for traffic in the country.

Analysis of Traffic.—General Features.—The gross traffic for the year
ending June 30, 1847, was, as we have seen, 8,586,000. There were con-
veyed during that year, from the returns of the Board of Trade, in round
numbers, 7,000,000 tons of merchandise and goods, 8,000,000 tons of coal,
500,000 tons of iron, and 15,000 tons of wood, 100,000 tons.

Of the gross sum, 8,586,000, the passenger receipts were
£8,074,000.

The freight from all other sources—wood, cattle, carriages, parcels,
mails, etc.,
3,343,000.

Total
£8,417,000.

In every 1000 of receipts, the passenger traffic therefore forms 60 per cent.,
the traffic receipt from other sources 40. In 1842 these proportions were
as 64 to 36. The proportions of traffic receipts from other sources than
passengers (being principally goods and cattle traffic) have thus increased
since 1842 as 40 to 36, or 11 per cent. The total number of passengers
carried in the year (ending June 30) 1847 was 47,844,134, as compared with,
in 1842, 28,403,476. The average distance travelled by each passenger was,
in 1842, 15 miles; in 1847 it was 16 miles. The numbers and proportions
of classes were

<table>

</table>

Thus, the third-class passengers (which have increased in number since 1842,
from 6,000,000 annually to 21,000,000) now form nearly half of the whole
number travelling, whereas in 1842 they formed only about one-third.
Only one-third of the third-class passengers have availed themselves of the parlia-
mentary trains (see note on page 372), and the work has been almost entirely
upon railway companies in 1844. The following table, comparing the fares of
the metropolitan railways in the year ending June 1843, with those in the year
ending June 1847, shows the great reduction which has taken place in fares
during the last four years. To make the comparison more complete, the
fares are taken as for 100 miles in pence.

</table>

These reductions in fare, coupled with the increase in the number of trains,
and the speed of travelling, must be regarded as the principal cause of the
great increase of the number of passengers since 1843.

We have already seen that the numbers in 1847 and 1848 are as 47,844,134
to 22,403,478. If we take into account the number of miles opened at these
dates respectively, the annual number per mile was, in 1842, 11,772, and
in 1847, 14,006.

* In this return the number of miles returned as in progress are more than those really
so stated. The number of men employed per mile is less than the truth.

This reduction is not complete; there are some exceptions; and the same
articles are sometimes conveyed over several different lines, and therefore
counted over more than once.
The proportion of third-class passengers has, we have seen, thus satisfactorily increased between 1842 and 1847. The third-class traffic has, however, developed itself very differently on different lines; and it may be well to inquire into this. The statement subjoined shows the third-class traffic of two metropolitan companies (the Eastern Counties and the Great Western)—two North of England companies (the Lancashire and Yorkshire and the Newcastle and Berwick)—and two Scotch companies (the Edinburgh and Glasgow and the Glasgow and Greenock).

**Year ending June 30, 1847.***

</table>

From this it appears that while the Great Western Company, on a line 241 miles long, has only carried 419,063, the Edinburgh and Glasgow Company, on a line 46 miles long, has carried 836,029; the Midland Company, 283 miles long, 2,366,892; and that while on the Great Western 13 out of every 100 third-class passengers, or in the Eastern Counties, out of every 106, and on the Glasgow, Paisley, and Greenock, 83 out of every 100 are third-class passengers. Although it is true that the different character of the population and other circumstances will affect to some extent the number of passengers on different lines, the disparity here is so great that we can come to no other conclusion than that the arrangements of such a line as the Great Western as to third-class passengers must be such as to preclude hundreds of thousands of third-class passengers yearly from using the railway who, with greater facilities, would be glad to use it. I say this with confidence, because as manager of the Glasgow and Greenock Railway, where the third-class system has been more developed than on any line in the country (and where we carried passengers at a profit of one farthing a mile), I have an opportunity of seeing the real advantage and comfort which very cheap travelling is to the working classes. As the results of the working of that line afforded a remarkable instance of the effects of low fares, I have thought that it might be unintertesting to record the fact. The West Clyde line runs beside the Glasgow, Paisley, and Greenock Railway, which is 23 miles long. The steamboats long afforded an excellent mode of transport between Glasgow and Greenock, the fares by boat before the railway opened being from 1s. 2d. and the time occupied was about two hours. Glasgow, with a population of 274,000, was at one end of the line, Greenock, with a population of 36,000, at the other end of the line, and various summer watering places lie at the mouth of the Clyde, below Greenock. On the line were Paisley (population 50,000) and Port Glasgow (population 7,000). Between Glasgow and Paisley was a canal on which the mail, express, and goods were conveyed by horse. The canal is open to horse traffic only 8 months per year. These facilities gave rise to a great traffic before the railway was opened,—the yearly number travelling along the course of the railway being 1,183,340, and the average fare 1s. 4d. Notwithstanding this, after the railways were opened in 1843, the number of passengers travelling by all means of conveyance were found to exceed 2,000,000, or to have increased 100 per cent., the average fare having in the mean time fallen to 1d. This was the gross result; but the fares of the railway (originally 2s. 6d. first-class and 1s. 6d. second-class for 23 miles) were varied from time to time; and as I closely observed the effects of these variations, having caused an account to be taken of the number travelling by steamboat and canal as well as by railway, it may be well to state the results of these variations of fares.

**First alteration.**—In 1843, uncovered, open, third-class carriages, at a fare of 6d. for the 23 miles (or about 4d. per mile), were introduced on the railway between Glasgow and Greenock, whereupon the annual number of railway passengers between those places increased 224,000, being an increase of 22 per cent. of the total number travelling (either by railway or steamboat). The number of first-class fares at the same time, the passengers having transferred themselves from the higher-class carriages into the open third-class carriages, tempted by the difference of fares between 4d. and 4d. per mile. The gross receipts, however, increased only from 15 per cent. of third-class expenses on the other hand, did not appreciably increase, although the average number of passengers per train increased from 72 to 117.—Second alteration. The third-class fares were subsequently (in 1843) raised from 6d. to 1s. with the hope of increasing the revenue. The whole traffic fell off greatly on this change, and steamboats immediately fell off 18 per cent. The first and second class railway passengers increased by 10 per cent., but the gross receipts fell off more than 10 per cent. The effect was also tried of making the third-class carriages more comfortable by filling them in. This was found not to increase the number travelling, but it did reduce the number of first and second-class passengers by 16 per cent., and therefore caused considerable loss to the company. The same experiment was repeated on the second-class carriages: they were made more comfortable by inserting glass windows instead of wooden shutters, and by carrying the interior partition higher. The number of first-class passengers shortly fell off by 12 per cent., but beyond this the second-class passengers did not appreciably increase; this experiment, therefore, also resulted in loss. The results of these experiments were then,—1st. That a reduction of fares to 4d. per mile even for those services which had been reduced to so low a rate as 4d. per mile increased the number travelling nearly by nearly a quarter of a million or by two-thirds of the whole population of the district. As these people were generally of the less affluent classes, it appears that these were wholly drawn out of the market in any case to the North of the Clyde by the temptation of a very low fare, and immediately that the fare was raised they were driven back again into the city. 2nd. That under the circumstances of the line in question, cheap and rapid travelling had the number of passengers from the second-class carriages did, however, appear to act in the same way, but merely tempted passengers from the higher-class carriages—those from the second-class into the third-class carriages, and from the first to the second class—of course it by no means follows that the same causes act on lines in other localities; each case must be determined by its peculiar circumstances. 3rd. That no limit can be assigned to the number of travellers which cheapening and quickening the means of conveyance will create. The introduction of the railway, even where steamboats already afforded a most rapid service, was a great stimulus to the population travelling from 110,000 to 2,000,000—2,000,000 being five times the whole population of the district. I doubt whether either at home or abroad so large a proportion of travellers to the whole population is to be found. The striking contrast between Glasgow and Paisley is probably the most remarkable instance on record of the increase of travelling caused by increased facilities. In 1814 there was only one coach a week between Glasgow and Paisley, conveying about 2,000 persons per annum; if we multiply this by 5 to allow for the number of gig passengers in private vehicles we get by 50,000 persons per annum conveyed between the two places. In 1842 the numbers travelling by public conveyances between Glasgow and Paisley were upwards of 900,000. Now as the population between 1814 and 1842 had only doubled itself, while the traffic, as supplied itself ninety-fold, it follows that the increased facilities of transport had increased the number travelling relatively to the population 45 times: this is to say, that for every journey which an inhabitant of Glasgow or Paisley took in 1814 he took 45 journeys in 1842. These results, I conceive, place it beyond a doubt that we should spare no effort to make railway travelling cheap and within the reach of all classes.

Now, there is only one true way of encouraging cheap travelling, and that is by keeping down the original price, and the expenses of railways. All the other contrivances which the public are inclined to trust such as legislative restriction on profits, and so on, are mere quackery. Even competition is inapplicable to railways, and it is not to be relied on. Mr. E. Stephenson, the engineer, put the whole case into one sentence when he took in 1843 the 45,000 passengers on the 18 stations in his line. The experience of all railway competition shows that this is true; when, therefore, under the plea of competition unnecessary outlay is being incurred, the public may rest assured that they will ultimately suffer for it in the charges they have to pay.

Mr. Hill Williams, the actuary, has compiled some useful tables,32 to show arithmetically how far a remunerative charge for the conveyance of passengers and goods on railways is modified by the original cost5 and other circumstances.

The following is an extract showing the effect of increased cost of construction.

<table>
<thead>
<tr>
<th>Total yearly traffic, number of passengers or tons of goods, 90,000.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Original cost of Construction 15,000 per mile.</strong></td>
</tr>
<tr>
<td>Fixed charge per mile on every passenger and 0.05 on every ton.</td>
</tr>
<tr>
<td>d.</td>
</tr>
<tr>
<td>1.00</td>
</tr>
</tbody>
</table>

We see from this that the fixed charge on every ton of goods or passenger must average 2d. per mile to return common interest on a railway costing 30,000l., whereas if the railway cost 20,000l. 1d. per mile would be sufficient, and if it cost 15,000l. 1d. per mile would be sufficient.

After a series of similar observations, the author concludes as follows:—The result of the preceding inquiry is, it appears to me, on the whole satisfactory. The railway system has doubled itself in the last three years. Fares have been greatly reduced. Third-class passengers have largely increased. The railways have imposed no extra expense on the passenger traffic have become more apparent. The number of trains is greater and the speed of some of the trains has been accelerated; and all this has been effected without any falling off in the average receipts or profit of railway working, but with an increase probably sufficient to meet the increase of the working expense on the increased accommodation now afforded by railways: whatever falling off in dividends

---

32 Evidence Select Committee on Railway Act Knatchula, 1846.  
33 Appendix No. 7, Select Committee on Railway Act Knatchula, 1845.
there may have been, is, therefore, to be attributed in a general view of the
subject to the capitalisation of loans and the creation of fictitious capital by
the purchase of railroads at premiums, and, therefore, as sums beyond what
they actually cost. These being profitable speculations when shares were
high, were pushed to such an extent as now to press severely on the original
subscribers to railway companies. The gross evil of the last three years was
the extravagant outlay of money which has taken place; an outlay which,
instead of being checked by the legislature, has been encouraged to the
utmost by the mode of inquiry adopted. This has inflicted on the railroad
system a burden which it will never be able to throw off, and which the
public will always have to bear with them in a higher degree of charge for
conveyance than would with common prudence have been necessary. It
only remains to stop the extravagance with a strong hand. The very
absurdity of railroad companies depends on the economy they can prac-
tise in making and working their railroads; and nothing which on the face
of it involves increased outlay, be it diversity of gauge and its consequence
the mixed gauge, or the more plausible plea of competition, should be con-
templated by railway companies or by the legislature, if we wish to
secure for ourselves the full fruits of that admirable invention which English
and English engineers who have followed in the steps of George Stephenson
have given to the world.

ANEMOMETRY.

"Report of further progress of Anemometrical Researches." By Pro-

fessor PHILLIPS.

Referring to the report on this subject presented to the Southampton
Meeting, the author recapitulated the steps of the investigation by which
he had been led to propose the evaporation of water as a measure of the
velocity of air-movement. In the former researches, the conclusion which
may be drawn à priori from Dr. Atpjohn's formula for the relation of the
temperature of the dew point to that of evaporating water was verified; and the rate of cooling of air in the open air to be ceased, simply proportional to
I - f (I being the temperature of the air, f that of an evaporating surface).
The air-movement was found to affect the rate of cooling nearly in proportion to the square root of the
velocity; and thus by simply observing the rate of cooling of a wet bulb
exposed to a current of air, and also the values of I - f, the velocity of the
air current becomes easily calculable. But this instrument is only an an-
emoscope, of extreme delicacy and various applicability indeed, but incapable
of being converted to a self-registering anemometer.—It appeared to the
author as probable that the rate of evaporation followed nearly or exactly
the same law as the rate of cooling,—the same reasoning in fact applying to
each case. This was tested by experiment in a great variety of ways, with
instruments of extremely various forms, and with velocities of air-movement
from 400 yards to 27,000 yards in the hour. The velocities of the wind
were measured by a very lightly-posed machine anemometer of Dr. Robin-
son's construction, but without any wheel-work, the revolutions being
counted by the observer.—In the course of these experiments some appar-
taneous anomalies in the rate of evaporation occurred to the author;
but these he hopes to be able to interpret by further careful re-
search, and finally to present in the compass of a few cubic inches an anem-
ometer specially suited to measure and record the low velocities of wind, and
furnish a useful complement to the larger machines already esteemed to be
so important in meteorology.

HEIGHT OF WAVES.

"On the Velocity and Height of Waves," as observed by Capt. STANLEY;
being the result of experiments made on board H.M.S. Rattlernek.

The method adopted for the determination of the length and speed of the
sea was to veer a spar astern by the marked lead line, when the ship was
going dead before the wind and sea, until the spar was on the crest of one
wave; the ship's stern was on the crest of the preceding one. After a
few trials, it was found that when the sea was at all regular, this distance
could be obtained within two or three fathoms, when the length of wave
was 50. In order to ascertain the speed of the sea, the time was noted when
the crest of the advancing wave passed the spar astern, and also the time
when it reached the ship; and by taking a number of observations, there
is every reason to believe results have been obtained not very far from the
truth. The officer noting the time in all these observations having only to
register the indications of the watch when the observer called "Stop," had
no bias to induce him to make the differences more regular. For measuring
the height of the waves, a plan recommended by Mr. Somerville was
adopted—which Capt. Stanley has tried for ten years with great success.
When the ship is in the trough of the sea, the person observing ascends the
rigging on a spar, and just sees the crest of the coming wave on with the hori-
zon, and the height of his eye above the ship's water-line will give a very
fair measure of the difference of level between the crest and hollow of a sea.
Of course, in all these observations, the mean of a great many have been
taken; for even when the sea is most regular, apparently there is a change
in the height of the individual waves. In order to show how closely the
different results came, observations on different days are given from which
they were deduced,—
ATMOSPHERIC WAVES.

"Report on Atmospheric Waves." By Mr. BIRT.

The report consists of three parts:—The first denoting the information we now possess respecting the treatment of the barometric curves which result from the crossing of the north-west and south-west waves, the two principal systems common to Europe—the most prominent subject being that particular curve known by the name of the "gale wave," the third embodying the results that have been obtained during the last year illustrative of the symmetry of the "gale wave," more particularly the locality of greatest symmetry and the departure from symmetry in certain directions. He means to say that the treatment has been thorough, and that the result of his inquiries into the forces presented by the barometric curves at certain stations, and has devoted attention to the symmetrical curve of November as it has been observed at the Observatory at Greenwich in the years 1840 to 1843, and on the curve of the "gale wave," it has been assumed that the symmetrical wave of November consists of two subordinate maxima giving rise to the five maxima which characterise it, the central maximum forming the apex of the symmetrical curve, the remainder being subordinate thereunto. ("Association Reports," 1840, p. 138.) Upon a close inspection of the curves of the "gale wave" as laid down from the Greenwich observations, six subordinate maxima may be traced, three on each side the central apex, which in all the years is by far the most prominent. The mean curve leads to the conclusion that although Greenwich is not the point of greatest symmetry, its closing portion being depressed more than two inches below the commencement. The next feature is the decided rise of the mercurial column during a period of sixty-eight hours, consequent on the crossing of the valley of the rain-clouds, which is 7 inch or about 0.10 inch per hour. The fall is not so precipitous; the barometer appears to be kept up in this locality by the first subordinate maximum succeeding the crest, so that at the epoch of sixty-eight hours after transit the barometer is 7 inch higher than it was six-eight hours before transit. At eighty hours after transit a precipitous fall commences, which continues during the next twenty-three hours, the mercury sinking 7.5 inch; and at 916 per cent. The fall of the times with slight intermissions, answering to the subordinate maxima, until the close of the wave 148 hours after transit. The peculiar features of the mean curve, especially the difference between the initial and terminal readings, 241 inch, combined with certain features exhibited by the European nodal point, towards Ireland and the north-west of Scotland, and is well seen in the series of curves illustrating the author's report in the last volume of the "Association Reports." Three principal maxima, characterise these curves on the 5th, the 9th, and the 15th of November; and the differences of altitude between those of the 5th and 12th have been employed to indicate the deviation from symmetry in the direction already alluded to. The discussion of these differences and the results deduced from them is the third part of the report. The result is shown on a map of the British Isles these differences, and from whom they constructed a chart of the lines of equal deviation from symmetry: these lines range from 100 inch—which passes north-west of the Channel islands, proceeding through the shores of the Irish Sea and Kent, and passes through Ramsgate—to 0 inch, which passes through Limerick, is slightly curved as it crosses Ireland, and proceeds nearly is a straight line across the Scottish Islands to the north-west of Great Britain, the depression of the depression of the maximum of the 5th below that of the 12th. Among these lines the author remarks that the direction of that representing 200 inch as the best determined. It appears to have passed near and to the west of Helstone, this station exhibiting a deviation of 158 inch; it then proceeded along the coast of Cornwall and Devonshire, crossed the Bristol Channel, entered Wales, and continued its course across Glamorganshire towards Brecon, it which it passed over the north-west as it rather abruptly changed its direction and proceeded towards Glasgow, and so the west. It appears to have undergone considerable infection as it traversed the central parts of England, rising again towards Nottingham, which is removed 292 inch from it to the west. It finally left the shores of England at the southern point of the corner of Devon and Cornwall, and the author solicited attention to a feature which characterises all these lines, especially the one just traced, viz., the decided deviation they undergo as they pass over the land. The chart exhibits two systems of infection, one being peculiar to Ireland and England, and the other that occurring on the line undergoing a change as the line of greatest symmetry is approached, the infection being governed apparently by the masses of land; and the other to Scotland, and the very strong depression observed northward of the Frith of Forth. From the single instance discussed, it appears to the author that the symmetry of the barometric curve is departed from in a greater degree at inland stations, a greater difference between the points noticed at the points noticed at the places marked and the places at the coast on either side. The report closed with some remarks on the necessity of the direction of these lines of deviation from symmetry, and on the high probability that they revolve around the nodal point of the two principal systems of atmospheric waves, Brussels.

water of the artesian well, Trafalgar-square, London, contains in each gallon about 50 grains: that at Combe and Delfaford’s Brewery, 12; that at Wolverhampton Railway Station 6; one lately sunk at Southampton, for supplying a private factory, 46. May it not be asked, whether the subject of the disease is of various origins, to which various purposes to which they are applied—be it in manufactories or for steam-engines, domestic purposes or drinking—is not worthy of a greater share of scientific attention than it has hitherto commanded?

GEOLGY OF SOUTH WALES.

The rocks of this district have originated in several distinct ways: some have had a mechanical origin, and consist of detritus of older rocks broken into fragments and tumbled together; others have been deposited from a state of chemical solution, like some of the limestones; and some have been formed almost entirely from the aggregation of organic remains. The materials obtained from this process have been employed over and over again in the formation of those of later date.

1. The most ancient strata of the district have been denominated Cambrian and Silurian. They are the subject of severe dispute, and some of the most important facts in the history of the earth seem to depend on the decision of this question. The Cambro-Silurian series, which has been observed in several parts of this country, has been supposed to contain nearly the same materials as the rocks which have been found in the same strata in North America and South America, and which have been designated as the Carboniferous beds. The most ancient of the Carboniferous series have been designated as the Old Red Sandstone, and are found in the county of Pembroke, in the districts called the Cardigan and Milford. They consist of sandstone, grit, and shale, with bands of coal, and contain the remains of ferns, lycopods, and other plants.

2. The sediments of the Cambrian and Silurian series have been succeeded by the Old Red Sandstone, which consists mostly of detritus, but contains occasional beds of impure limestone (cornstone), and in its upper part there is a great thickness of marl, also coloured red by peroxide of iron, and occasionally streaked with blue and green where the iron has been reduced to a lower state of oxidation by the presence of water. The mass consists of coarse sand and gravel cemented together and forming a hard conglomerate; the multitude of quartz pebbles, derived from granite, indicates an immense destruction of older rocks. No fossils are found in this formation, because sand isyre, and peroxide of iron is fatal to animal life when it exists in excess; but in the cornstones a few remarkable fishes (Cephalaspis, &c.) have been obtained. These rocks appear to have been formed near the coast, at a small distance from Cornwall and Devon, the sea being deep, and the bottom covered with mud, and the shore being low, and the beaches covered with sand.

3. After this another great change took place, and the sea deposited carbonaceous of lime, forming the carboniferous limestone, well shown on the coast of Pembroke. The ledges of these rocks are found in the counties of Pembroke and Cardigan, and extend along the coast for many miles. The limestones form, and are generally of uniform thickness, but contain a great variety of minerals, such as quartz, feldspar, mica, and graphite, and are interbedded with sandstone and shale.

4. The uppermost strata of the Carboniferous series are the coal measures, which consist of sandstone, siltstone, and coal, and contain the remains of plants and animals. The coal measures are of great thickness, and extend throughout the whole of the district.

5. The coal measures are succeeded by the Trias, which consist of sandstone, shale, and页岩, and contain the remains of many animals and plants. The most characteristic of these is the Brachiosaurus, a large fish, which is found in the sandstone of the Trias.

6. The succession of the Rocks, as we have now seen, shows a progressive advance from the lowest to the highest, from the oldest to the youngest, and from the simplest to the most complex, and it is therefore evident that the history of the earth is a gradual and progressive process, and that the earth is a living being, capable of change and development.

7. The coal measures are succeeded by the Tertiary, which consist of sandstone, shale, and页岩, and contain the remains of many animals and plants. The most characteristic of these is the Brachiosaurus, a large fish, which is found in the sandstone of the Trias.

8. The Tertiary are succeeded by the Quaternary, which consist of sandstone, shale, and页岩, and contain the remains of many animals and plants. The most characteristic of these is the Brachiosaurus, a large fish, which is found in the sandstone of the Trias.

9. The Quaternary are succeeded by the Recent, which consist of sandstone, shale, and页岩, and contain the remains of many animals and plants. The most characteristic of these is the Brachiosaurus, a large fish, which is found in the sandstone of the Trias.

10. The Recent are succeeded by the Recent, which consist of sandstone, shale, and页岩, and contain the remains of many animals and plants. The most characteristic of these is the Brachiosaurus, a large fish, which is found in the sandstone of the Trias.

11. The Recent are succeeded by the Recent, which consist of sandstone, shale, and页岩, and contain the remains of many animals and plants. The most characteristic of these is the Brachiosaurus, a large fish, which is found in the sandstone of the Trias.

12. The Recent are succeeded by the Recent, which consist of sandstone, shale, and页岩, and contain the remains of many animals and plants. The most characteristic of these is the Brachiosaurus, a large fish, which is found in the sandstone of the Trias.
they will not be vertical but inclined to the north. If the change in the quality of the coal is attributed to the influence of submarine heat, then the inclination of these lines will serve to point out the direction from which that heat acted, namely, from the north-west of the coal-field.

Mr. Brookes, being called on by the President for some statistical information, stated that in 1563 there were 550,000 tons of iron annually manufactured in the district employed in smelting iron, and that 550,000 tons of iron were annually manufactured. The coal raised in the district was employed as follows:

- 1,000,000 tons annually in the manufacture of iron.
- 200,000 tons in the manufacture of bricks.
- 150,000 tons in the manufacture of cement.
- 100,000 tons in the manufacture of iron, etc.
- 200,000 tons exported.
- 1,260,000 tons employed in domestic purposes and in agriculture.

Total: 4,850,000 tons annually.

At this rate, and supposing the coal to exist only over 100 square miles, there was sufficient for 1,400 years to come. The value of the exports from the district, consisting of iron, &c., in a state of rough manufacture, amounted to 4,000,000L a year.

"On the Submergence of Ancient Land in Wales; the Accumulation of newer Strata above and around it; and the Re-appearance of the same Land by Elevation and Demolition." By Professor A. L. Ramsey.

This communication was illustrated by a section, on a true scale, of the rocks near Buitli, in Radnorshire, where the Wenlock shales rest unconformably on the Llandeilo flags. The lower rocks must have been elevated previously to the formation of the upper, and their upturned edges must have lain close to each other, by the sea which covered them at a former period. No power is known to exist far below the level of the sea, by which this process could have been effected; it must have taken place at the sea's level. Throughout Wales the Lower Silurian rocks appear to have been elevated as a particular period, and to have been heaved up into the district, and formed a coast, around which the succeeding rocks were accumulated. Near Bishop's Castle the upheaval of the Llandeilo flags was followed by the deposition of the Caradoc sandstone, which is full of pebbles of the older rocks. No fossiliferous strata are known to have taken place, the area of the sea was increased, and the Wenlock shale was deposited not only over the Caradoc sandstone, but beyond it, as at Buitli, upon the Llandeilo flags; and in some places the shales rest on greennests rocks and certain pebbles found in being in fact in a gravity bed. This depression of the sea continued also during the deposition of the Ludlow rocks, which are conformable to the Wenlock shales; and there was no marked alteration in the organic remains of the two rocks. The Wenlock shales are 1,500 feet thick, and the Ludlow rocks 3,500 feet; and as it is certain that their organic remains could not have existed at the depth of 5,000 feet, we must suppose a gradual subsidence of the area, such as is believed to be now taking place amongst some of the coral islands, until 5,000 feet of rocks was accumulated over that of the first strata. The old red sandstone, which has a maximum thickness of 8,000 feet, appears also to have extended over this country, judging by the outcusters, at a considerable distance to the north and west. Subsequently, the whole of this series, from the Caradoc sandstone upwards, was removed, and the ancient Silurian strata became the surface of dry land as far back as we can go. The question is, what power of alteration may the Silurian rocks have undergone during the time they were so covered up? If the same laws regulated the ascent of the internal temperature as at present, namely, 1° every 54 feet, then the addition of 54° to the temperature would have raised it to 92°. If by this temperature 25° feet would have added 16°, and with 11,000 of superincumbent strata the Lower Silurian rocks must have endured an increased temperature of 212°. To influences of this kind may, perhaps, be attributed the crystalline or metamorphic condition of some of the more ancient rocks, as suggested by Sir J. Herschel, in a paper communicated years ago to the Geological Society of London.

The Dean of Westminster referred to the Portland rock, in which a bed of vegetable soil occurs, full of trunks of trees, and cycadsites; this bed rests on limestone containing ammonites, and is covered by similar marine deposits. Again in the Weald, fossil forests and beds of fresh-water shells are found above marine accumulations, and followed by the greensand and chalk. At the present time we find peats, and antlers of the red deer, in the bed of the Chert, and inquired off the north coasts, and in the English Channel, are found the bones of the elephant, and fossil wood, disintegrated from former cliffs by the action of the sea. These, with many other circumstances, were quoted as showing that whilst the sea-level was fixed, the land had suffered depressions and elevations at many periods of time.

Professor Phillips pointed out the extent of some of these subsidences of the land; for example, the old red sandstone, 8,000 feet thick, all formed in shallow water, and the coal measures 11,000 feet thick, and added under similar conditions. He asked what condition of the interior of the earth can have admitted of the gradual subsidence of such great masses of strata? According to Mr. Hopkins' statement, it was improbable that the interior would now admit of it. With respect to the augmentation of temperature following on the condition of several of the ancient strata, it should be remembered that the communication of heat from below, through such rocks, was remarkably slow; and the law of the distribution of internal temperature could not be assumed the same in ancient as in modern times. As to the level of the sea remaining unchanged, this was only assumed for security in geological reasoning; there was evidence in the Malvarena of a sea-level 60 feet above the present, but it was impossible to say whether that ancient level was nearer the centre of the earth when formed than now.

"Coast Levels." Lieut.-Col. Portlock communicated some observations on apparent changes in the level of the coast near Portland, and continued that, as these evidences of subsidence could be traced back to the most ancient times, so they had continued up to the present day, and expressed his conviction that a parallel might be found in existing nature to all the phenomena of sea-levels associated with the subsidence of the earth, near Portland, stands on a bank of gravel and sand, and that owing to some new wall made to protect it from the sea, a fresh direction was given to the tide, and a portion of the bank undermined and washed away, in the course of the last 2 or 3 years. A bleak bank was thrown up on the south side of the fort, and this, he thought, had no great antiquity. An artesian well has also been made to supply Blockhouse Fort, which, shows, for the first 60 feet nothing but clean shingle, and then a layer of sandy clay, full of common oyster-shells.

"On the Chemical Character of Steel." By Mr. Nasmyth.

We were to assume, as our standard of the importance of any investigation, the relation which the subject of it bears to the progress of civilization, to the utility of man, and to his capacity to live in comfort and ease, more than that which refers to the subject of steel: seeing that it is to our possession of the art of producing that inestimable material that we owe nearly the whole of the arts. I am desirous of contributing a few ideas on the subject, with a view to our manufactures, and to the distinction of the different varieties of steel, and so lay the true basis for improvement in the process of its manufacture. It may be proper to name that steel is formed by surrounding bars of wrought iron with charcoal placed in fire-brick troughs, from which air is excluded, and keeping the iron bars and charcoal in contact, and at a full red heat for 24 hours, the effect of that heat is to convert the iron into steel. What is the nature of the change which the iron has undergone we have no certain knowledge; the ordinary explanation is, that the iron has absorbed and combined with a portion of the charcoal or carbon, and has in consequence become converted into an alloy of iron. But it has ever been a mystery that to analysis, so very minute and questionable a portion of carbon is exhibited. It appears that the grand error in the above view of the subject consists in not duly understanding the nature of the change which carbon undergoes in its combination with iron in the formation of steel. Those who are familiar with the process of the conversion of iron into steel, must have observed the remarkable change in the outward aspect of the bars of iron, after their conversion—namely, that they are covered with blisters. These blisters indicate the evolution of a very elastic gas, which is set free from the carbon in the act of its combination with the iron. I have the strongest reasons to think that these blisters are the result of the decompositions of the carbon; whose metallic base enters into union with the iron, and leaves with it, as alloy, the other component of the element of the carbon is given forth, and so produces in its escape the blisters in question. On this assumption we come to a very interesting question—What is the nature of this gas? In order to examine this, all that is requisite is to fill a clean glass tube with pure carbon, subject it to a long-continued red heat, and receive the evolved gas over mercury. Having obtained the gas in question, then perform a piece of polished steel to come in contact with this gas, and in all probability we shall then reproduce on the surface of the steel all the phenomena of carbonization of each of the two elements, namely, that of the metallic base of the carbon then existing in the steel, with the, as yet, unknown gas; thus synthetically, as well as by analytic process, eliminating the true nature of steel, and that of the elements or components of carbon.

"On Hydraulic Pressure Engines." By Mr. J. Glyn.

This paper described the mode of employing the power of waterfalls as a most useful and important manner—too long neglected in this country, considering the advantages it affords in hilly districts for the drainage of mines. Mr. Glyn brought under their notice the means of employing high pressure pipes, for the purpose of conveying water to distant places, where there is no other source of power. The pressure-engine acted by the power of a descending column of water upon the piston of a cylinder to give motion to pumps for raising water to a different level, or to produce a reciprocating motion for other purposes. The pressure-engine was calculated to give great mechanical effect in cases where waterfalls may be found of much too great a height and too small a quantity to be practically brought to bear in a sufficient degree on water-wheels within the ordinary limits of diameter. The pressure-engine is the result of the invention of another engine, one of which was constructed about forty years ago in Derbyshire—and which he believed was still at work in Alport Mines, to which it was removed from its original situation. The cylinder was, he believed, 30 inches in diameter, and 10 feet high, and to effect a pressure of 275 feet he produced a pressure of 20 horse-power, and more powerful engine at the Alport Mines, which was made under his (Mr. Glyn's) direction at the Batterley Ironworks in Derbyshire. This was the most powerful engine that had been made. The cylinder was 89 inches in diameter, and 18 feet in height, and he ascertained that it could produce a column of water of 139 feet in height, so that the proportion of power to act on it was as the area of a piston to that of the plunger—namely, 1,958 to 1,385.
or fully 70 per cent. The superintendent of the machinery assured him that the engine never cost them £12 a year since it was erected. Its usual speed was about 5 strokes per minute; but it was capable of working at 7 strokes per minute without any compression in the descending columns, the described action done 183 times a minute, giving a plunger 9’291 feet x 10 feet x 7 strokes = 673.41. 673’4 x 9’291 x 183 = 163 horse-power. The author concluded by remarking that, in this case a large gravity or pressure, those machines do the best work when the water enters the machine without shock or impulse and quits it without velocity. They thereby obtain all the available power that the water will yield with the least loss of effect; and this result is in a great measure accomplished by making the pipes and passages of sufficient and ample size to prevent acceleration of the hydraulic column.

"Analysis of Wrought-Iron produced by Cementation from Cast-Iron." By Professor Miller.

It is to be noticed that considerable change in the specific gravity occurred in the iron after cementation: it was forged, and then found to have increased in density; the brittle iron had a specific gravity of 7.094, the malleable 7.118. The results of analysis were briefly these:—The quantity both of carbon and silicon are materially diminished by the cementation, though still the proportion of both is materially greater than in good bar-iron. It also appears that the portion of carbon which is insoluble in acids is partly the same both before and after the iron has been rendered malleable, the diminution being confined almost to that portion of carbon which was chemically combined with the metal, and which, therefore, would be in state for propagation through the mass more readily by cementation.

The surface of the moss varies from 80 feet to 100 feet above the sea level; its bottom at the deepest part is 100 feet below the sea line. Part of this moss is now being laid dry by means of open drains, and a water which is flowing rapidly; near the main road it is seen perpendicularly 8 ft. 6 in. in nine months, and in one part 2 ft. 6 ins. in a single week.

"Extraction of Silver from some of its Ores by the Wet Way, with a Notice of a Process as a Substitute for that of Liqation." Communicated by Dr. Percy.

This communication proposes to treat silver ores with hyposulphate of lime and chlorine until chloride of silver is the only metal left behind; and if that is, the process is supposed to be a neat process without damage, and to be more economical by regular method. In practice the principle is the same as suggested by Mr. Hunt, proposed from the importance in a practical point of this communication, that it be printed entire in the volume of Transactions. Col. Yorke seconded this proposition; and it was adopted.

"A new Hydrographic Map of the British Isles," by Herr Petermann, was exhibited.

On this map about 1,550 rivers are distinguished by names, 480 lakes and ponds, and the chief towns and the four sea-coasts, and of the rivers and lakes, and the great rivers in the fever districts. It was stated that there were 20 rivers in England, 16 in Scotland, and 10 in Ireland, each draining 500 square miles and upwards. Of these—

- 18 drain as areas each = 500 to 1,000 square miles.
- 1,000
- 2,000
- 8
- 9,000
- 10,000

These last eight are—The

- Thames (including Trent and Ouse) to Surpont Point
- Severn (to Flat Holme)
- Shannon (to Loop Head and Kerry Head)
- Thames (including Medway, to New Light)
- Great Ouse
- Great Ouse
- Ouse
- Ty, as far as Ryhnd

The river Amazon drains a tract of 2,375,000 square miles.

"On a New Element of Mechanism." By Mr. E. Roberts.

The writer explained the construction of a contrivance by which he effected a perfect and simple manner moving for both power and position of the eccentric, which was frequently employed. The model consisted of a steel stock shaft, on which were fitted two brass discs in such a way as to be kept steady. One of the discs had eleven teeth rounded at the top and bottom in its circumference, and was placed on the body of the shaft. The other disc, which was rather the larger, was in the eccentric position of the shaft, with its face to that of the toothed disc. The plain disc had four studs riveted into it at equal distances from each other and at such distances as to be in the middle of being broken, by the eccentric, of the eccentric, to the bottom of the hollows in the toothed disc. The following movements may be effected by this model:—viz., if the shaft is held stationary and the disc to be moved upon it, one of the discs will make 240, or 240 revolutions without any other one makes eleven. Again, if the toothed disc be held whilst the shaft is made to revolve twice, the plain disc will revolve, in the same direction, one revolution only; and if the plain disc be held, the toothed disc will perform one revolution in the contrary direction, for eleven revolutions of the shaft. It would be evident that almost any other number of revolutions may be produced by employing a smaller number of studs, not fewer than three, which will divide the number of teeth in that disc. The idea of this novel object is to be observed by Mr. Roberts, with his usual ingenuity in an American clock.

MINTS.*

The subject of mints is one on which there is little printed, but Major Smith, of Madras, has brought out a considerable book. This will be handed directly to the subject of mints in accounts, but with this object a close investigation is necessary into the processes affecting the condition of the precious metals in the operation of coining, and this may be found of interest. Major Smith's great purpose is to establish that no loss of value of gold or silver can or does take place in coining, and that there is therefore no difficulty, under a proper system of management, of providing an adequate check. He says—

We consider it beyond doubt, judging from the results of actual experience, that there ought to be no loss whatever by the process of coining, in any of the Indian Mints; on the contrary, we have elsewhere explained, there ought to be a small surplus in the out-turn. In the discussion, therefore, of the duties and responsibilities of the different officers of the establishment, we shall consider this as being admitted, because we must determine what is the amount that would be necessary to be properly executed; not what may suffice if it be imperfectly done, or slurred over.

Before proceeding, however, it may be advisable that we should first notice and eradicate a misconception which has been suggested to us in reference to the above assertion, as it strikes at the very root of all the benefit of the important principle involved in it. It has been said, that it is not actually true that our gold or silver, or a slight surplus in the re-delivery of the precious metal entrusted to a Mint, provided it were possible to extract all the particles from the mass of refuse wherein they are buried; that by pushing the recovery to an extreme length, in describing all the metal in the mass of refuse wherein they are buried, that by pushing the recovery to an extreme length, it may be in fact possible to exhibit a trading overplus, though the cost of the extraordinary methods that would be required to make such recovery, would be far exceeded the value of the metal; but that unless this reckless contempt of true economy be systematically persevered in, it is as clear that a certainty of total loss must, of course, be allowed to remain untouched, so as to account for the amount of extraction, a waste must be unavoidable, and that however true in theory, it must be a falsity in practice to say, that there ought to be a net surplus of delivery, and an actual bond fide excess. This argument is, however, based upon a misapprehension of the truth it is intended to oppose, for the assertion is not, that there should be no metal recovered, but that there should be no metal lost whose existence could not be proved, and its value recovered, if necessary. Further, that all that is attempted is to be a net surplus of delivery, including the particles in the drosses, whether they be recovered therefrom or whether they be not, which is totally immaterial to the question; to which it may be added, that this excess ought to be so much larger than the value of all the particles which have been not extracted from the refuse, than even taking the matter in the sense in which it is viewed in the objection, the assertion still remains practically true.

The principle and the practice we contend for is, that the out-turn of a Mint in coins, bullion, and drosses, ought to be exactly estimated, and compared with its receipts; and we affirm that if this be correctly done, and the duties of the Mint have been strictly and faithfully performed throughout, the former ought to exceed the latter, whenever the bullion is debited at the 'trade assay,' which being the case, we are of opinion that, as a matter of system, the comparison ought to be made, and the check thereby established, in preference to the more lax process of omitting the comparison, and writing off all deficiencies to profit and losses and clear profit to do so. In this way it is that the business is carried on in Madras, the refuse, when no longer capable of being recovered on account of Government profit, being sold, and the proceeds carried to account; and it is according to this scheme of practice, that the actual results which have been referred to have produced a nett surplus amounting to 2d per mile.

If, however, there ought to be no deficiency of the precious metals, it does sometimes happen: it seems that coins are sent out of the mints too good. Thus it is said—

We have been informed, that in the year 1846, the issue of MINTS.

* Observations on the Duties and Responsibilities Involved in the Management of MINTS. Reference to the Hon. Richard Mitford, M.P., for his "Researches for their Improvement." By Major J. T. SMITH, R.E.E. Engineers, F.R.S.

A.I.C.E., Master of the Madras Mint. Madras, 1846.
Bombay Mint were so much above Standard, that if they may be assumed as being fairly represented by 50 pyx assays made of them at the Royal Mint, and the value of the cut-surfaces calculated thereof, they would contain about two-thirds of pure silver than they ought to have done; a case in point showing the impossibility of the Mint officers guarding against loss, because if it be assumed that the merchants were partly paid for their bullion, the Mint must have suffered the loss of that sum.

With regard to the probability of loss of metal, the author examines whether it could take place in the melting, and he mentions—

There is a greater probability in this process, that a real loss, an actual diminution of value, shall occur, than in any other part of the process, because the value of silver cannot possibly be effected, except by a literal abstraction of the precious metal, and we can easily understand why such is the case. If a pound of pure silver, for instance, were melted three times, and if copper were added to and subsequently melted by successive portions: at every step of these processes, provided none of the particles of pure silver had been allowed to escape, the result of every true assay of the metal, whether in its coarse or fine condition, ought to be such as to make its value equal to that of a pound of pure silver. There is nothing in mere manipulation to alter value, unless some of the precious particles are disipated; but we might be inclined to suspect that this might occur during fusion. It is not impossible, one would think, that silver might be volatilized, and thus the precious metal be diminished in quantity. It is certain that if any alloy be melted, its weight after fusion is considerably reduced; but it is also equally certain that, practically, no particle of silver escapes from the furnace.

The point on which the smallest doubt could reasonably be entertained, I have given it the most attentive examination. When I was in Calcutta in January, 1849, and visited the Mint there, I made particular inquiries as to the volatilization of silver. The very idea of such a thing seemed to be considered absurd, and I was told that such a thing as volatilisation of silver had ever been experienced. I was not the custom to sweep out the chimneys, because the volatilisation of silver was out of the question, but I was told that when the metal was well heated there was a loss of mass, and particles of the mercury might be evaporated. This is true also in regard to lead, fumes of which escape from silver very frequently. But neither of these would at all change the value of the mass in fusion. The same question has also been practically tested at Madras—and though no such thing as sweeping the chimneys for the purpose of recovering volatilized silver had ever been heard of previously, I determined upon trying it, in order to obtain conclusive evidence on so much important a point. The result was, that the chimneys of a furnace which had been in constant daily use for about 15 years, and in which many crores of rupees worth of bullion must have been melted, there were collected particles of silver which altogether weighed about 70 grains. This experiment taken in connection with the experience of the Calcutta Mint, seems to my mind to be quite conclusive as to the fact that there is no real loss in melting, by any dissipation of the precious metal.

The following is a practical explanation of one of the causes of apparent weight loss. It is notorious, however, that when silver is melted for coinage, the weight after fusion is considerably less than before, even after making this recovery and every allowance. It is admitted also that the metal undergoes refinement, and consequently that it becomes purer in quality than it was before. It is supposed that this value after fusion ought to be precisely equal to the original, and that there is no necessary cause for wastage or loss; and this, because it is simply copper, and nothing besides but copper, or base metal, which is injured by the heat, so as to be separated from the alloy and lost in the refuse, whence it is not worse while to recover it. It is owing to the absence of any means of recognising the minute changes of fineness in the silver alloy, and the consequent adoption of a system of account independent of them, that it has been impracticable to exhibit this truth, or to take advantage of it, in the manner indisputable to avoid waste; and the attention being therefore exclusively paid to that change in the metal which alone is palpable, viz., its fineness, and the causes if any, which influence it, I am induced to detail the means by which this evil has been rectified; in the mean time I must invite attention to another.

When the Mint receives bullion, it is supposed to receive nothing but silver, which is charged to it, according to its weight, without more process, but I found that these supposed conditions did not always exist, and that the bullion was not always made over to the Mint in the solid state. In some cases coins were received, which were always more or less dirty, and were calculated in the accounts by multiplying the gross weight of dirt and silver by the average fineness of a sample melted for assay. The consequence manifestly was an unavoidable loss, corresponding with the amount of dirt which had been reckoned as silver, and the removal of this, taking care to avoid the results incurred in this way one of the principal causes of the previous loss was got rid of.

Another case was more serious to the parties.

We may also cite a case which occurred in Bombay, where there was a deficiency between the produce and valuation of a particular parcel of bullion received into the Mint, to the amount of about 1,200 rupees. A committee being appointed to inquire into the deficiency, stated that the discrepancy was apparent, but as it would never do to doubt the assay, they must consider the loss to be practised by the assayer. The head minter was accordingly ordered to pay the money, and did so; but it was afterwards plain that the valuation had been made without proper precautions against mistake, and that in so far as the evidence of the bullion referred to the least residue to believe that the quantity of bullion for which the minter had been held accountable, had ever been received by him.

In annealing, an apparent increase of weight takes place, which is thus explained. The process of annealing is for the purpose of softening the blanks, and making them more fit to receive the impression of the die. It also serves to eliminate the contraction of the metal, caused by the cold blanks being placed in a reverberatory furnace and brought to a red heat, after which they are cooled, either by immersion in water, or by exposure to the air. The effect of this process is a slight increase of weight, owing to the contraction of the metal by cooling; and as it is entirely superficial, it varies in its proportion according to the form and superficial area of the pieces exposed to its action. We have not made any experiments with minute accuracy on this point, as the pieces after leaving the laminating and adjusting department are counted on transfer, and thus passed from hand to hand by tale, so that trifling variations in the gross weight cease to be of any importance; but from the experiments which we have made, the difference of weight in rupees has been shown to be about 3 annas 72 per quarter, or 4 1/2 per cent. As this increase of weight is occasioned merely by the addition of a foreign substance (oxides) to the metal, it cannot of course, by any possibility, be the cause of any loss of value.

In blanching, a slight difference in the apparent weight takes place, because in some mines grase oil and are used in laminates, which adheres to the metal and is removed by the acid.

Difference of weight may take place, but difference of value cannot; and it is by adopting this latter test that a proper system of accounts can alone be adopted. We may remark, in conclusion, that the author has laboured very hard and conscientiously in establishing the correctness of his views; and, which excites the more admiration, as having been done under the hot sun of Hindostan and in a state of ill-health.

THE PLATE-Glass TRADE.

The statistics of the manufacture of plate-glass in England, just published in a tabular form, with a few remarks appended, on a folio sheet, by Mr. Henry Howard, of Plaistow, in Essex, are very instructive.

In 1819 the excise duty on plate-glass was 96s. per cwt.; none was made in 1821, larger than 34 inches in length; the price when 12 inches square was 13s. 1d. per foot, when 120 inches by 72, it was 160s. per foot.

In 1827 the excise duty was 60s. per cwt.; plate-glass 144 inches by 75, was not manufactured; the price of plate-glass, when 12 inches square, was 5s. 8d. per foot, when 114 inches by 75, it was 50s. per foot.

In 1847 there was no excise duty on plate-glass; plates 144 inches by 75 were manufactured; the price was 5s. per foot; the price of plates 12 inches square was 3s. 4d. per foot; plates 144 inches by 76, cost 3s. 6d. per foot.

In 1819, when the excise duty was 96s. per cwt., the quality of the glass was indifferent, the average price per foot 20s. to 25s., the quantity sold per week about 3,000 feet, and the supply apparently equal to the demand.

In 1827, when the duty was 60s. per cwt., the quality was improved, the average price per foot 19s. to 22s., the quantity sold per week about 5,000, and the supply inadequate to the demand.

In 1847, when the excise duty had been taken off, the quality was very much improved, the average price per foot 4s. 6d., the quantity sold per week about 70,000 feet, and the supply very inadequate to the demand.

In 1836, when the excise duty was 60s. per cwt., the estimated number of husbands directly and indirectly employed in the manufacture, was about 2,500, the capital invested in it about 250,000.

In 1847, when the duty had been taken off, the number of hands was about 12,000, the capital about 1,000,000.

No comment is required on the tendency of these facts to show how much the manufacture was benefited by the reduction of excise duties; how much more it has been benefited by entire emancipation from the trammels of the excise.

Since 1845 foreign plate-glass had been admitted to be imported free of duty. In July 1847, Lord George Bentinck undertook to prove (in Parliament) that the removal of the glass duties had been a failure. He stated that the declared value of glass exported in the first months of 1845 was 215,630f.; in the first five months of 1846, only 131,739f. But
his lordship omitted to state an important explanatory fact pointed out by Mr. Howard:—"It was in the first five months of 1845 that the duty was remitted, and during that particular period the makers and dealers exported enormous quantities of every description, not on account of increased demand from abroad, but for the express purpose of obtaining the large drawbacks (amounting to bounties) which were then, for the last time, allowed by the excise."

The fact is, that an official return, dated May 3, 1845, printed by order of the House of Commons, shows that for the first time English glass was introduced into our commerce for consumption in England, to have been 99,841 feet. This is at the rate of 1,250 feet per week. The number of feet of English make sold per week during that time being 70,000, while in 1845 it was only 23,000.

The importation, instead of causing a displacement of English labour, has, by stimulating competition, improved quality and lowered price, and by thus increasing consumption, caused more English labour to be employed.

The state of the exports, as shown by the return already referred to, is equally satisfactory. The exports of English glass in 1847 exceeded those of 1846, by 14,000 feet, or 20 per cent., in common windows being 44,211; in bottles, by 5; in looking-glasses, by 49; and in plate-glass, by 110 per cent. Well may Mr. Howard remark, "Looking at the unexampled commercial difficulties of 1847, this increase is almost incredible."

Two facts relative to the trade in glass are worthy of note. Mr. Howard, have a bearing upon these several results too important to be omitted. Of two agencies established here, exclusively for the sale of foreign plate-glass, one has been compelled to relinquish the sale of it, simply from inability to withstand British competition. There was no English plate-glass exported to the United States in 1846; while, in 1847, it is equalled in amount the exports to all the world in 1846.

How, then, are we to account for complaints made both in and out of Parliament, that the present state of the British glass duties? Mr. Howard throws some light on this question:—"In 1845, when the excise duty was remitted, the English makers reduced the price of small plates (which foreigners could not afford to send here at all) to a fair and equitable price, viz., as (as before appear, cost less per foot than the small ones) were kept up at the unreasonable rates quoted above. Our neighbours, the French and Belgians, attracted and encouraged by the simplicity which thus invited them here, under cover of our excessive prices, accordingly brought over and sold their larger fabrics at enormous profits, whilst our manufacturers, realizing still greater advantage, and supported by an immense demand, refused to modify this extraordinary tariff, although its manifest injustice to the public, and direct tendency to injure the very interest it was intended to promote, have been almost universally condemned by all."
The Britannia and Conway Bridges.—The report of Mr. Stephenson, presented to the meeting of the Chester and Holyhead Railway, on the 28th ult., stated that the construction of the second tube of the Conway-bridge would be completed this year, and there is every reason to believe that, by the middle of October, the pontoons have been strengthened, the caps re-erected, and every other arrangement in a forward state for its erection. About three-fourths of the masonry of the Britannia-bridge have been completed, and the ironwork is in progress, taking the plan of extensive dimensions that the first tube will be ready for lifting to its place in the course of next March or April. The iron-work at the Britannia-bridge has progressed even more rapidly than was expected, and the four large tubes are just approaching completion. The whole of the central portion of the tube is finished, and the castings at the ends are now being inserted. The scaffolding for the end tubes on the Anglesea side is complete, and a large proportion of the iron is already punched for their immediate commencement. It is probable that the necessary tubular tubes may be erected immediately, to open the line throughout as rapidly as possible. Every arrangement is being made for floating the tubes as soon as the masonry is ready. The works throughout the whole of the line are standing in a satisfactory manner. The daily passage of heavy trains through the Conway tube for four months, together with a series of careful observations as to the effects produced, have completely established the correctness of the views upon which the design was based. The cost of these structures has been very much exceeded what was originally calculated upon; on re-considering, however, the whole subject, Mr. Stephenson is satisfied that the method which has been adopted in the Britannia, though not the only practical one, is the most economical. The following is the account of the Britannia bridge as it stands:

Mode of Extincting Fires of Sea.—The following letter has been addressed by Dr. Reid to a daily morning paper:—"As the danger from fire at sea is attended with so many appalling circumstances (of which we have had a recent instance in the melancholy catastrophe of the 'Oriana), I beg respectfully to submit the public consideration the following plan, as a cheap, simple, and efficient method of preventing the occurrence of such accidents. Flame or combustion cannot go on where there is carbonic acid gas. This is one of the elementary principles of chemistry, and is not the only practical method. By means of tubes proceeding from the upper deck in connection with a cistern containing the dilute sulphuric acid, to the quarters below, where there is most likely danger from fire, or moveable hose (made of gutta percha), which can be introduced into the vessel, the flames may be extinguished. With reference to the destruction of the vessel, I have been requested to state that not more than one or two miles of hose will be sufficient to extinguish any vessel that is burning. The cost of laying the tubes will not exceed 30l. or 40l. sterling. By means of tubes proceeding from the upper deck in connection with a cistern containing the dilute sulphuric acid, to the quarters below, where there is most likely danger from fire, or moveable hose (made of gutta percha), which can be introduced into the vessel, the flames may be extinguished. The cost of laying the tubes will not exceed 30l. or 40l. sterling. By means of tubes proceeding from the upper deck in connection with a cistern containing the dilute sulphuric acid, to the quarters below, where there is most likely danger from fire, or moveable hose (made of gutta percha), which can be introduced into the vessel, the flames may be extinguished."

Great Western Docks, Plymouth.—These docks are being proceeded with rapidly, and, when completed according to the design, will furnish accommodation superior to that afforded by any docks of similar extent in the kingdom. The work is performed with precision, and the building and affording ample wharfage for 12 steamers of the largest size, a number, we believe, equal to that accommodated by the great basin at Portsmouth, recently opened. There will be two entrances to this basin; one will be by the existing channel, and the other by a new one, 120 feet wide, and 30 feet deep. The new channel will be 1 mile in length and 50 feet wide. The wharfage will be nearly 30 acres. If this basin should be deepened to the extent proposed, vessels can enter and be able to sit at all times of the tide without the delay of passing through a lock. This is an advantage not possessed by Liverpool, and many other ports. The entire extent of wharfage will exceed a mile, and the area of ground for stores is adequate to the temporary accommodation of the dock. The docks are now in full operation, and are already serving a large number of vessels.

Birkenhead Docks.—It appears by the Liverpool Times, that the most active preparations are going on in the engineer's department of these works, in the preparation of working drawings, &c., for the recommencement of the work. The dock and the bridge, which have been in progress during the last year, are now in a forward state, and the engineers and workmen are in expectation of an early order to proceed with the works. The dock and bridge are now in a forward state, and the engineers and workmen are in expectation of an early order to proceed with the works.

The Grimsby Docks.—These are mighty works, and are proceeding with most satisfactory rapidity, alike creditable to all concerned. The chief engineer is Mr. Adam Smith, who is very properly called the resident engineer, is always on the works. There is a defect, or rather a sinking, in one portion of the dock, which has, however, been allowed to remain, as it is not deemed necessary to interfere with the ingenuity, and has summed up all by sacrificing to demoniac agency the 'fathomless pit.' Shakespeare was right in putting into Hamlet's soliloquising thoughts, "Oh, what a mighty piece of work is man!" and bad will be the day when mud walls are drawn about our territorial possessions, some other as appropriate exclamation would be by him have been furnished. One hundred and fifty acres taken from the sea, and defences raised to prevent the mighty ocean claiming back 'its own,' and such defences as will resist the wearing rage, let its battering rams and sledge-hammers be hurled against them by the waves, and the defences may be hurled against them by the waves, and the defences may be hurled against them by the waves. The Grimsby Docks are now in a forward state, and the engineers and workmen are in expectation of an early order to proceed with the works.

Clifton Suspension Bridge.—Upwards of £20,000 have already been expended upon this undertaking, and no more money being forthcoming the works are now at a stand-still.

Improvements in Bridge Building.—A fine wooden bridge has recently been built near the river near Dalarnock, to supply the place of the old one, which is now 30 years old, and very much decayed. The new bridge was commenced only five months ago, and was built from a design by Mr. Robson, C.E. The whole length of the bridge is 700 feet, and of its wooden trusses, the king-rails and the ad-rails are laid in 28 feet. There is a footpath on each side, covered with asphalt pavement, and the road-way is composed of a mixture of asphalte and whinstone metal, broken, 7 inches deep, and laid on the top of the planking, which had been previously well caselied with oakum, and coated with pitch and sand, for the purpose of making it water-tight.

Circular Sawing.—An experiment has lately been made at the Saw-mills, Woolwich-dockyard, with the view of testing the efficiency of circular saws in cutting through the centre of rough timber of a diameter nearly equal to that of the saw itself. An elm tree—one end of which was of the full diameter of the saw—was placed upon one of the circular sawing machines, having a saw 4 feet diameter, and a self-feeding motion, in the usual way. By this motion the tree was brought towards the saw, and passed over it; and by a turned motion, and a self-feeding motion, in the tree was passed over the saw, was in dead wood all the way, and fully 20 inches deep. After the tree was run back, it was turned over, and adjusted for a second cut, to line with the first; and in this position it was brought forward, and cut. The whole operation was performed by three men.

Method of Welding Iron, Steel, and Sheet-iron.—In an earthen vase melt borax, and add to it one-tenth of sal-ammoniac. When these ingredients are properly fused and mixed, pour them out upon an iron plate, and allow them to cool, and thus obtained a glassy matter, to which is added an equal quantity of iron. The iron which are to be soldered, are first heated to redness, then this compound, first reduced to powder, is laid upon them; the composition melts and takes a certain shape. The pieces to be replaced in the fire, taking care to heat them at a temperature sufficient to melt the compound, and the joints are then well sanded and hammerad, and the surfaces will be found to be quite perfectly united. The author asserts that this process, may be applied to welding sheet-iron tubes, never fails.—Mechanics' Magazine.
Indian Waterfall.—Among the cliffs of the Eastern Ghats, about mid-way between Bombey and Colombo, runs the river Kukadia, which falls into the Arabian Sea. The bed of the river is one-fourth of a mile in direct breadth; but the edge of the fall is elliptical, with a sweep of half a mile. This body of water rushes at first, for 300 feet, over a slope of 45°, in the form of a cataract, into a lake. It then falls at the depth of 850 feet more into a black abyss, with a thundering noise. It has, therefore, the depth of 1,150 feet! In the rainy season the river appears to be about 80 feet in depth at the fall; in the dry season it is lower, and it is even dry in winter. The beauty and grandeur of the scene, and the depth, are wonderful. Join our full of Genoveses that of the St. Lawrence, and then tumble the two united, and we have the distance of the Shirrawallc cataract. While we allow to Niagara a vast superiority in bulk, yet in respect to the depth of its fall, it is a mountain fall compared with its Indian rival.

—Rockester Democrat.

The American Lakes.—Professor Drake, of Cincinnati, has been making some observations upon these inland seas, and gives the result to the public. The chain of lakes extends over nearly eight and a half degrees of longitude in length. The extent of their surface is estimated at 52,000 square miles; and the area of country drained by them is computed at 400,000 square miles. Their relative sizes are as follows:—Ontario, 5,300 square miles; Erie, 9,000; St. Clair, 2,600; Huron, 20,400; Superior, 22,900. The average depth of water in the different lakes is a question upon which there is no certain information. Authorities differ. Dr. Drake gives it as follows:—St. Clair, 20 feet; Erie, 84; Ontario, 500; Superior, 900; Huron, and Michigan, 1,000. In standard works, Lake Erie is stated to have a depth of 280 feet, but 463 feet have been made in Lake Huron. Of Saginaw Bay, 1,600 feet of line have been sent down without finding the bottom. The altitude of these lakes varies step by step from Ontario to Superior. Lake Ontario is 228 feet above the level of the water of the St. Lawrence, and 115 feet above the tide-water at Albany. St. Clair is 6 feet higher than Erie; Huron and Michigan are 13 feet above St. Clair, and Superior is the same above them. This shows the curious fact that while the surface of Huron is 625 feet above the level of the water at Saginaw Bay, it is, on the same principle, indicated precisely the same temperature,—namely, 56°. His explanation of this fact is: the waters are so pure that the rays of the sun meet with no solid matter in suspension to arrest and retain the heat.

New Cement.—The Buffalo Journal describes a valuable cement, which was first discovered in Sharond, Medina county, Ohio, and, after undergoing the most thorough test, has been pronounced of great value for cementing roofs of buildings, steamboat decks, &c. The mine itself (described in the Cleveland Herald) is one of the most singular depositories to be found. It seems as if poured into a large sand-stone basin, covering some four acres, is found at the depth of 20 feet, presents an even level surface, is about 5 feet thick, and when dug out is as hard as tallow, and is entirely free from dirt and other impurities. An exposure of two weeks to the air changes the cement to stone, so hard, that it is difficult to grind. In preparing it, the cement is first ground when green, and after it has been ground, it is ground again, and mixed with oil for use. When applied to roads, it becomes hard and durable as slate, and is a certain fire-proof, and is in no way affected by the weather. We have been shown a specimen of the cement that has been on the market for a month, is as hard as flint, and has been mixed with oil for use. As it is easy to use, shows pencil marks equally as well, and has the grit of a fine bone. The cost is small, being 3 dollars per cwt., which, with the same amount of oil, is sufficient to cover 1,200 square feet.

A Portrait of Mr. T. C. Bublitt, by Pickergill, has been subscribed for by the Builder's Society.

Salt.—A spring of brine has just been "tapped," by Mr. B. Smith, at Droitwich, Worcestershire, at the depth of 217 feet—being a greater depth than any before discovered; the usual depth being 170 or 180 feet.

On the Occurrence of Vanadium in the Refineries of Staffordshire.—Mr. Deck, in a communication to the Chemical Gazette, says:—Being commissioned by an eminent English railway engineer, who has directed me to make experiments towards the qualification of the iron for this high quality, I have proceeded to examine some refinery slag, which, without any assignable reason, had the property of imparting extraordinary ductility to the iron with which it was mixed. I have succeeded in discovering a large quantity of vanadium, about 5 feet thick, and when dug out is as hard as tallow, and is entirely free from dirt and other impurities. Besides having its expenses defrayed from the public treasury, it is added, that the invention would have been more encouraging had not State expenditures claimed the immediate attention of the emperor. And it is important to mention, that the authenticity of the entire history of Garvy's invention, as published by Gonzales, has been called into question, and that no practical results of any utility followed.

Gutta Percha Boots.—At Seacombe, a No. 1 pilot boat, built of gutta percha has been tested. It is 17½ feet long, and though nearly filled with water, and having four men on its gunwale, kept its buoyancy. It weighs 190 lb. and sustains a pressure of 15 cwt. It not only answers the purpose of a life-boat, but when the weather is bad, the man in charge is able to sleep in it. This substance must make an excellent life-boat; and before we saw the above account, we had thought of calling attention to the feasibility of this application. The toughness, elasticity, and lightness of gutta percha are advantages of the purpose of building life-boats. The price is one dollar per pound, and 50 pounds must make a boat of a moderate size. The old gutta percha can be sold at a reduced price. —Scientific American.
LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM AUGUST 22, TO SEPTEMBER 21, 1848.

Six Months allowed for Enrollment, unless otherwise expressed.

Hugh Lee Pattison, of Washington-house, Gateshead, Durham, chemist manufacturer, for "Improvements in manufacturing a certain compound or certain compounds...for the purpose of..."—August 22.

Alfred Vincent Newton, of Clarkney-lane, Middlesex, mechanical draughtsman, for "Improvements in...construction of..."—August 22.

William Young, plumber, and Henry Burgess Young, engineer, both of Barnet, for their "Improvements in..."—August 22.

Charles Bowley, of Birmingham, Warwick, button-manufacturer, for "Improvements in the manufacture of buttons..."—August 22.

Elizabeth Cheney of Winton, Middlesex, for "Improvements in the manufacture of sealing wax..."—August 22.

Peter Wright, of Dudley, Worcestershire, vice and master manufacturer, for "certain improvements..."—August 22.

George Nasmyth, of Ebury-street, Finsbury, Middlesex, civil engineer, for "certain improvements..."—September 4.

John Lewis Reardon, of Whitechapel, Middlesex, Esq., for "Improvements in..."—September 4.

William Lasor, of Newcastle-upon-Tyne, for "Improvements in steam-engines..."—September 4.

Henry Smith, of Vulcan-works, West Bromwich, for "Improvements in the manufacture of railway wheels..."—September 4.

William Dickinson, of Blacklion Lancaster, machine-maker, for "certain improvements...in, and applicable to, looms for weaving..."—September 11.

Ralph Robert Wilson, of Hulme, Lancashire, manufacturer, and John Wieg, of Wombourne, Staffordshire, aforesaid, a weaver in the employ of the said Robert Wilson Whalley, for "certain improvements in the manufacture of tubes and in the manufacture of certain articles made in part of tubes..."—September 11.

William Sager, of Rochdale, Lancashire, woollen dealer, for "certain improved muslin apparatus for effecting the transit or conveyance of goods, passengers, and correspondents, by land or water, and for other such purposes, on which certain means and apparatus constitute a new and improved method of generating steam, which improvement is..."—September 11.

Joseph Ripple, of Birmingham, manufacturer, for "certain improvements in iron and steel, and other metals..."—September 11.
Candidus's Note-Book, 
Fasciculus LXXVII.

"I must have liberty
What, as a large as a chaste the winds,
To blow on whom I please."

I. I lately called attention to a very feasible improvement, or rather, highly desirable completion, of an important public edifice—namely, Somerset-place; and my remarks appear to have been not entirely thrown away, since upon my return to town, I will now mention another building—a public one, of considerable importance, and admirably situated in many respects, it having among other advantages that of being placed directly at the extremity of a vista from one of the most frequented thoroughfares in the whole of Westminster; a fact, all which, it is itself a most flagitious architectural monstrosity. Can any one, after this, be at a loss to guess what is the building which I allude to? I myself know of no other so situated, precisely at the end of a vista whose sides enclose it. After this, and my calling it a perfect monstrosity, how will you take your time, or take a map of London, and examine it, and then—Oh! you have found it, have you? you that I allude at a glance to the bas-relief on the front of Guildhall! Well, since there is no denying it, I confess it: it is the front of Guildhall that I mean, and both mean and unmeaning enough it is in itself. Civic taste runs more in favour of turtle soup than architecture, or the citizens would abridge the number of their annual expenditures upon it. If we want a fund for a worthy exterior to their banqueting-hall. As far as it goes, their taste is unexceptionable, but it does not go far enough; it is very palatable, but not at all palatial; at least, not externally. The exterior of their Hall of Guild being as tasteless as can well be conceived. Instead of turtle, venison, and champagne, it announces water-gruel and cag-mag; it being the most veritable architectural cag-mag ever produced. Some of the city folks must, I think, have longed to carry off the Victoria porch from the Palace, and not only as a portal before their Guildhall, with such addition as might be found requisite for filling up the entire frontage. What last but may be, I cannot undertake to say—there being no published plan from which measurements can be ascertained. However, that we should there have a front in a perfect duplicate of the Victoria porch at Windsor, is not at all to be desired. We might be very well content with something of similar character in regard to nobleness of idea and grandeur of design. Yet, so long as there is no absolute occasion for doing anything to the building, nothing is likely to be done; whereas a small patch of attention, without the necessity of attempting to unite together, as is there done, two such irreconcilable systems of composition as are those of Columbation and Fenestration. Now, I am not quite so straightforward in my opinions as to object to an order being employed as decoration, but then it should in every case accommodate itself to the structure; while so many, instead of affecting to produce the same expression as a simple open colonnade, where the columns and their entablature alone constitute the exterior of the fabric. When first seen in such a foreshortened view of it that the windows within the intercolumnia are concealed, the front of the Royal Institution suggests the idea of an open colonnade upon a noble scale; but the very next minute we are undeceived, disappointed—even disgusted. Instead of finding anything like nobleness or grandeur, we are shocked at the positive littleness and meanness which prevail in everything but the columns themselves. Not only is there a most violent and offensive contradiction occasioned by the adoption of conflicting modes and ideas, but there is no part of keeping what we call a style. After the columns, there is nothing whatever of Corinthianism in the other features and details. We find the most florid order applied as decoration to what is itself kept most penurious and bare; so that richness and poverty of style—or, I might say, style and no style—coupled together are all that remain. With such a feeling is that pretentious façade treated, that what is meant for its decoration, causes the building itself to appear most insignificant, or even worse. Although both the columns themselves and the front are large enough, the whole is a mass of littleness and incoherence, rather than a mass than a superabundance of windows, the very doors are made to resemble the windows as much as possible: therefore, so far, the design may be said to be all of a piece throughout—yet after so unlookily a fashion, that instead of being a merit, that circumstance becomes a great objection to it.

III. Taste is subject, not only to wholesale revolutions, but to strange fluctuations and relapses. One day we are disposed to think that taste has taken a better direction than before, and is likely to advance in it if allowed to have its free course; when, in the next, we are started and shocked and perplexed, by some architectural monsterism which runs quite counter to, and upsets our calculations. Although such is the fact, it seems hardly credible that two structures which are almost within sight of each other, and were raised in the very same year, should have been set diametrically opposite to each other, by the Water-house and Mr. Hope's new mansion in Piccadilly. The latter is such a vile compound of uncoyness and deformity, as to be nothing less than marvellous. That precious sample of design is said to be by some architect, who is the only thing to be said about it, let whoever may be responsible for it. The design itself, the discreet of adopting it falls upon no other than Mr. Hope himself. Had an ignorant employer—one compelled to trust entirely to the taste and judgment of others, been prevailed upon to make choice of such a piece of studied ugliness, he would have been to be pitied, and our astonishment would have been greatly diminished. But Mr. Hope is not the man to be so imposed upon; he has the reputation—the hereditary reputation at least, of being an authority in matters of art and taste, and among the public, from the most superficial and cursory view of a display of bad taste was to be apprehended. Besides marvelling much, there is also room for fearing that, through the influence of his name, his example may become contagious, and encourage others to perpetuate similar architectural enormities. One comfort is, the building seems to us startled and shocked and condemned; while the evil else to be apprehended from such example will now be greatly counteracted by the very opposite one of Bridgewater-house. What is to be regretted is, that instead of occupying as public a situation as the other, the latter mansion is comparatively concealed; it is very pretty, and not very last, which is somewhat the longer of the two, is where it is almost concealed from public observation,—Cleveland-row being no thoroughfare into the Greenpark, but a mere cul-de-sac.

IV. Bridgewater-house puts its neighbour, "Sutherland," quite out of countenance. The two buildings contrast very strikingly with each other, and afford a very good lesson, and make manifest that decided improvement upon the whole has taken place within the last five-and-twenty years. In point of architectural quality, Sutherland-house is a very ordinary production (by two of the Wyatts); maquin in its ensemble, and impudently flashy at the best. There is nothing about it that can really be called style; it has none of the stamina of the style, but merely feeble, us manière, without a single touch of genuine artistic feeling or taste, or of our own, either. You find there many things which are poor, or even very much worse; to use any language to praise that of it, to such praise Sutherland-house is unequivalently entitled. Such praise, however, is only condemnation in a milder shape; and if the structure in question is not to be called a failure, it is only because nothing more than dull routinier mediocrity seems to have been aimed at—and it has been produced. Apaley-house is another piece of Wyatting, and is such as to make us hope that that time is now departed from among us for ever. In those days, Sansovino seems to have been quite unknown here, or else must have been put into an Index Expurgatorius.
V. In the subjects generally proposed to architectural students in competition for academic medals or other premiums, no very great novelty or originality is necessary; they become invariably of a class altogether out of the sphere of usual practice. Such subjects as royal palaces, senate-houses, cathedrals, and others of a similarly ambitious kind, do not exercise those faculties and abilities which are most of all necessary, because the opportunities for exerting them are of every day and so is the demand for them. Unless the designer can display talent, ingenuity, and taste, on occasions which seem to afford hardly any room for displaying them, will be at no loss for ideas on more important occasions which may require him to put forth his strength, at the same time that they afford a great scope for his imagination. The converse does not hold good: the production of an extravagant chimerical projet as an academical theme, is no pledge for the sort of talent which is really wanted, any more than obtaining a Gold Medal is any pledge for after-distinction. Subjects so are not artistic that they may be ranked among the phenomena of the art, are hardly the very best preparatory themes and exercises. Even granting that they tend to develop and confirm artistic talent of a higher grade, if the talent itself be of a kind that requires extraordinary emergencies and illimitable resources for exerting and displaying it, it becomes, in a manner, a superfluous one. Unless he at the same time has powers more generally available, the possessor of it is likely to prove in the condition of Hercules employed in spinning with a distaff, at which labour his gigantic thews and sinews could have been but a trifle serviceable. The most laid-back sort, no “long yarns” have been preserved as relics; but no doubt they were rather clumsy ones—as clumsy as this fantastical compari-son will perhaps be considered by many. So I drop it, and res-ume with a fresh paragraph.

VI. Such ambitious efforts in architectural design as those above alluded to are no service to call into play what is a most valua-ble species of ability, that which can accommodate itself to un-toward circumstances, and overcome difficulties. Where a carte blanche is offered, all those thwarting and fettering conditions which the architect must expect to meet and contend with, are got rid of; a picture of a sort of ideal comforter, that it is ac-quired where what may be called dreaming will suffice. Were carte blanche matter of course on all occasions, imagination might be left to run riot at will. Though as to imagination, it may be doubted whether even that is much exercised and discip-ling by the kind of subjects proposed for Grande Prix and Gold Medals. They generally show more of high-flying but empty architectural bombast, than of fertile invention. When examined, they may be found to be made up out of the usual stock ideas—some of them rather worn out, or at least the worse for the wear. It requires no great stretch of imagination, or power of fancy, to draw out upon paper mile-long colonnades, or spires that shall pierce the clouds. Between such mere extravagance and the artistic and poetical, there is a wide difference. Moreover, it is very possible to be exceedingly ingenuous and exceedingly dull at the same time. Some of Soane’s architectural “visions,” as it pleased him to call them, partook of that double quality. There was enough of them as to measure and quantity, but the stuff itself of which they were formed was very ordinary and homely—far more prosaic than local in texture. Schemes of such magnitude have ere now been produced upon paper, that Barry’s “Prince of Westmin-ster” would shrink into insignificance in comparison with them; yet, though the things themselves have been of monster size, they have oftener than not been made up of rather dwarfish ideas. Even empty common-place may be inflated to such bulk, as to look not only large, but solid too. But as a monster projet proposed by an Academy is required for producing the inflation, the bladder empties itself, and falls to the ground again. Were colossal monu-mental edifices reared by us every day, there was amply a demand on the part of students; although even then they ought to be accompanied by some sort of conditions, which would have to be observed; but as such is not the case, it would surely be better to direct study with more regard to the ap-plication of it on ordinary occasions, and the things that are displayed in competition,—which is capable of elevating what seems to be a common-place subject into the sphere of art, by happiness of treatment and skillful touch,—is, though it may seem a comparatively humble, an exceedingly rare one. It is one that demands artistic feeling, and a thorough knowledge of artistic character and effect. It works out, as it were intuitively, rules for itself, which unlike ordinary technical ones, do not admit of being formally and clearly expressed in words.

VII. Ordinary rules have, no doubt, their serviceshens, but it is rather of a negative sort: the observance of them will prevent faults, but will not ensure positive beauties, or other merits than those which partake of mere routine, and are therefore equally at every moment of the same. Rules are indispensable, since they constitute the very grammar of the art; but from its grammar to its poetry the distance is pro-digious—at least, so great that ninety-nine out of a hundred never advance beyond the former so as to reach the latter. What is done in one case is not applicable to another; it is not to be learned by one man just as well as by another. It is the something more—the unde-finable and individual non so che, which lying beyond the reach of rules, is not to be overtaken and caught by them. As far as this finer quality of art can be studied and learnt at all, it is what every one must study for himself; for it is not to be learnt from general precepts and rules, but from a careful and diligent examination of examples marked by such felicitous quality. Rules teach much, but they do not teach all. Yet, instead of being frankly acknowl-edged, it is a truth, is often set aside and kept by one eye, which is that ought to be strongly impressed upon every student. Rules and the observance of precedent will suffice for mere mechanical copying, but if architecture need not, or cannot now advance beyond that, it ought to forfeit all pretension to the character and title of Fine Art. And why should it or its follow-ers for it be ambitious of such title, if it cannot support it by acting up to it? If we are content with it in its present condi-tion as a mechanical art, wherefore not confess as much by call-ing it so, instead of claiming for it an empty title, which only re-quests to be filled up to it. As the privileges of certain things seem to be gone; therefore, they and its power being gone, it would lose nothing by being deprived of its nominal rank. This will, no doubt, be considered very harsh and unwelcome advice. Well, then, if its rank must not be given up, let us endeavour to render that dignity which it still retains. The Firma Fine Art, endowed with all those prerogatives and privileges of which in these latter days it has been despoiled and stripped, and forced to subsist upon the remnants of its former treasures.

VIII. Many, it might be supposed, would be really glad, were the idea of architecture being a Fine Art to be altogether renounced, since the practice of it seems in so many ways safer on the dry land—on the honest terra firma of practical routine. Art is a treacherous element to those unprepared for and inexperienced in it. If, according to the opinion which, though not formally expressed, is to be gathered from the remarks of certain writers, we have no further occasion for artistic invention, or any actually op-erating and creative principle in architecture, but may get all the art that is required for it at second-hand, and would therefore do well to confine ourselves exclusively to traditional forms and ideas,—if such be the case, and we can now dispense with art itself, we can dispense with the name of it. Or, if we must still call it art, let us call architecture the art of making new buildings by copying or hatching-up old ones. But to affect to consider and style it a fine art, when we make it in practice just the reverse, partakes too much of the pretentious and exceedingly dull at the same time. Some of Soane’s architectural “visions,” as it pleased him to call them, partook of that double quality. There was enough of them as to measure and quantity, but the stuff itself of which they were formed was very ordinary and homely—far more prosaic than local in texture. Schemes of such magnitude have ere now been produced upon paper, that Barry’s “Prince of Westmin-sters” would shrink into insignificance in comparison with them; yet, though the things themselves have been of monster size, they have oftener than not been made up of rather dwarfish ideas. Even empty common-place may be inflated to such bulk, as to look not only large, but solid too. But as a monster projet proposed by an Academy is required for producing the inflation, the bladder empties itself, and falls to the ground again. Were colossal monumental edifices reared by us every day, there was amply a demand on the part of students; although even then they ought to be accompanied by some sort of conditions, which would have to be observed; but as such is not the case, it would surely be better to direct study with more regard to the application of it on ordinary occasions, and the things that are displayed in competition,—which is capable of elevating what seems to be a common-place subject into the sphere of art, by happiness of treatment and skillful touch,—is, though it may seem a comparatively humble, an exceedingly rare one. It is one that demands artistic feeling, and a thorough knowledge of artistic character and effect. It works out, as it were intuitively, rules for itself, which unlike ordinary technical ones, do not admit of being formally and clearly expressed in words.

IX. Those who admire one style of architecture, are apt to be not merely indifferent to, but intolerant of every other. The lover of pure Greek architecture sees only the corruption of it in the Roman style; and of this latter, the degradation in the Italian. His standard of excellence is the Parthenon; and by that standard he tries everything else, no matter how different may be the principles upon which it is constituted. He would have Greek-Doric temples spring up everywhere throughout the land and language of Europe; and if he found himself even to extend some degree of favour to Ionic, he thought that at all events Grecian; but Corinthian is Roman, and shows a sad falling-off from the manly simplicity of the earlier style. On the other hand, the lover of Roman and Italian design is equally strong towards adorning and improving our towns to be frigidely severe and monotonous, exceedingly bare withal; and Gothic, together with all other medieval styles, to exhibit only the barbarous conceits of the dark ages,—to be utterly devoid of a proportionable, lawless, extravagant, and irreducible to “rules.” Such at least used to be the case. For, as every one knows, such sweeping condemnation and insolent contempt of mediæval architec-ture cannot be expressed with impunity. Tempora mutantur: Gothic may be said to have now the ascendency, and its admirers and devotees repay with compound interest the insults and indig-
nities which it formerly received from the Italian school and its followers. Opposite as they are in their tastes, all these parties are alike in one respect, they being all alike one-sided, prejudiced, and intolerant in their antipathies, and cheating themselves into a much varied enjoyment by limiting the sphere of it to the compass of a narrow style of the art; instead of sympathising with the beautiful and intrinsically esthetic in architecture, whatever may be the particular form under which it presents itself, or the name to which it answers.

STUDY OF MECHANICS.*

Mechanical science is certainly the most ancient branch of natural philosophy. The very commencement of existence is the exercise of force, and of all his physical powers, the first which man puts into operation is his strength: the whole business of his animal life consists in the exercise of it, and from the beginning of the world until now, every human being, from his cradle to his grave, has been making repeated experiments in that knowledge which only modern philosophers profess to teach with perfect accuracy.

Why has a study, of which the study has been universal and uninterrupted, advanced with such slow and uncertain steps? This tardy development is not the history of all other sciences. Geometry—the exact knowledge of forms and dimensions—though its applications to the purposes of life are much fewer, and much later required, became a mathematical science, while mechanics still remains a crude collection of facts. So late as the end of the sixteenth century, the simplest phenomena of falling bodies were in doubt. A heavy body falls to the ground more rapidly than a light body, said the opponents of Galileo. The weight of the bodies makes no difference in their motion, was his counter-assertion. Now, here was a question which the world might be presumed to have settled before Aristotle was born. It was more than six hundred years old. If there be any operation of nature more frequently observed than another, it is this very one of the descent to the ground of unsupported bodies. Yet, notwithstanding the in calculable number of previous observations, it was necessary that Galileo should appeal to direct experiment to support his views. He ascended to the top of the leaning tower of Pisa, with two balls, differing very much in weight, yet both of such a density as not to be much affected by the action of the air. The balls were simultaneously dismissed from his hands, and reached the ground at the same instant, or at least without perceptible interval.

This was conclusive. On the contrary, the discussion gained in veneration what it lost in argumentative reasoning. Galileo’s opponents were not convinced, but merely irritated. From time immemorial, it had been believed that the greater the mass of a body, the greater the acceleration of gravity. As it to be supposed—they asked—that they and all preceding philosophers, from the time of Aristotle, had been mistaken on this fundamental point? Rather than concede that, they chose to disbelieve the evidence of their own senses.

The single moment of mind operates as manifestly as that of matter. The difficulty which Galileo had to combat, arose not from the nature of his subject, but from the necessity of overcoming the previous tendency of men’s minds, and moving them in a contrary direction. This difficulty has existed throughout the history of mechanical science; now, also, it is the greatest obstacle to the student’s progress.

If there were no previous errors and prejudices to be overcome, no previous misconceptions to be unlearned, mechanics would be one of the most easily- acquire branches of human knowledge. If the brain were as an unwritten, unsullied scroll, ready to receive those fair characters which have been traced and perfected by the co-operation of the most stupendous efforts of human intellect—the liability to error and confusion would almost cease to exist. But this can never be the case. The student has been learning mechanics long before he commenced the study of its systematic laws. He has, as was before said, been experimenting on the subject from his infancy; and his experiments have been so crude and irregular, that almost every conclusion derived from them involves a certain amount of error.

Not until a very considerable progress be made in the study of mechanics, is the full extent of this disadvantage perceived. The science may be approached with a perfect willingness to acquiesce in its doctrines, but the perseverance of undigested preconceived prejudices which not the will merely, but great mental strength and long-continued mental habit also, are required to overcome. It becomes, then, a matter of great importance to the student to ascertain beforehand the precise nature of these prejudices and difficulties. To understand these, and to be able to meet and conquer them; some idea must be acquired of the character of the evidence on which the conclusions of the theory of mechanics are founded.

This evidence is of several kinds; that which will most influence the tyro—that which will always be most valid in popular estimation—is the weight of authorities. The testimony, however, of great names, high as it is in itself, is by far the lowest kind of evidence of the truths of mechanics. A sciolist will stop the mouths of those who know as little or less than himself, by quoting the authority of Newton, Leibnitz, Euler, the Bernoullis, Lagrange, Laplace, or Poiseuille. The man of science cannot be so answered. To him—to no one else so much—the ideas of these master-minds are of the highest importance; but they do not work conviction.

Between the effect of Newton’s dictum, and of the greater part of Newton’s reasoning, there exists that immeasurable difference which intervenes between a very high probability and absolute certainty. In the absence of more exact information, the mere knowledge that a certain conclusion is supported by the opinion of one or more of the great founders of the science, will and ought of itself to be a strong argument, but the mere knowledge that the authorities were fallible, is merely to assert that they were human, and that science is progressive.

Another, and a higher, though not the highest, evidence, is that derived from comparing the remote predictions of theory with actual observations. Let us suppose again a system of laws of gravitation, that the earth moves round the sun in an elliptic orbit, if the very small perturbations arising from the influence of other celestial bodies be neglected. This prediction as to the earth’s course is so remote a consequence of theory, that it has only been immediately foreseen—the authorities were fallible, is merely to assert that they were human, and that science is progressive.

If we trace on paper,” says Sir J. Herschel, “an ellipse, ten feet in diameter, to represent the orbit in which the earth is moving about the sun, and if we trace by its side the path actually described by its revolution around the sun, the difference between the two is so inexpressibly slight that the nicest examination with microscopes continued along the outlines of the two curves, would hardly detect any perceptible interval between them.”

Again, it is known that the solar orbit slowly changes from age to age by the mutual attractions of the sun and the planets. Laplace showed to be that the moon’s motion moves more rapidly around the earth now than it did in remote times. This result of theory is exactly verified by observation. It has been ascertained, from the records of ancient lunar eclipses observed by the Chaldean astronomers, and subsequently by the Arabian astronomers in the eighth and ninth centuries, that the moon’s mean motion is increasing by about eleven seconds in a century.

The action of pendulums, the most delicate and refined instruments used for scientific purposes, exemplifies, in a wonderful manner, the precision of mechanical science. The earth’s rotation causes bodies at the equator to be acted upon by a centrifugal force, in the contrary direction to their weight; it is clear, therefore, that their tendency towards the earth is diminished. The value of this diminution, as also of its effects on the vibration of pendulums, is determined by theoretical calculations, which take into account a large number of independent considerations—the earth’s radius, spheroidal attraction, the inertia of the pendulum, the effects of thermodamic expansion, the baromterial pressure, the resistance of the air; etc. By means of these processes, the period is determined in an pendulum which beats seconds in London (that is, vibrates 86,400 times in the twenty-four hours), ought to make fewer vibrations by about 140 at the equator. Also, the number of vibrations which this pendulum ought to make in various other latitudes in Europe and southern England, has been computed; and the results have been confirmed by observation, in a remarkable manner. Pendulums, constructed with the greatest care, have been carried from London to many places on the
earth's surface, and their performances observed with extreme caution. The discrepancies observed between these results and those of previously published observations led the mechanical philosophers to consider them as exceptions to some general law, and to propose mathematical methods for explaining them. Thus, a priori it seems impossible to build upon them a system of a priori truths, such as mathematics. Observations of animal behavior, however, are different from those of mechanics. The properties of living organisms are observed to be generally true, and yet they are not always the same, and can vary depending on the context of observation. This led the mechanical philosophers to question the nature of these observations and to propose mathematical methods for explaining them.

Such results are not possible without the intervention of the mind. The results of observation and the conclusions drawn from them are not always the same, and can vary depending on the context of observation. This led the mechanical philosophers to question the nature of these observations and to propose mathematical methods for explaining them.

The absolute certainty, then, of mechanical science must rest on yet higher grounds. Its supreme authority consists in this—that all its conclusions are rigorous logical inferences from indisputable elementary laws. The philosopher has a right to demand unreserved approbation of his work, and to assert that his conclusions are true. These fundamental principles are the most important of all the principles of nature, and they are the basis of all our knowledge. They are the foundation of all our knowledge, and they are the basis of all our knowledge.

And here it is necessary to establish a distinction between these fundamental laws and their ultimate causes. With the latter, the mechanical philosophers have no concern: they seek only to ascertain and establish these fundamental principles, and to show that they are true. They are, however, not satisfied with this. They are also interested in the cause of the phenomena they observe, and they seek to explain the phenomena observed on each other; but causation or speculation as to the modus operandi, forms no part of his inquiry. That heavy bodies are drawn towards the earth when unsupported, is a fact, of which, notwithstanding its constant occurrence, no explanation has ever yet been given. Were we not so familiar with this phenomenon, it would appear very wonderful, that one body should approach another without any communication between the two, or any visible cause of the motion. To say that it is due to the earth's attraction or gravity, is merely to give a name to, not an explanation of the cause of the motion. Again, we see that the mighty, unseen chain binds this earth to move for ever in a certain orbit round a body ninety-five millions of miles distant! Planets and satellites, apparently isolated in space, separated from all other bodies by distances which the mind is utterly incapable of imagining, move on from age to age in their predetermined courses; yet, so silently, that no mortal ear ever heard the sound of their mighty mechanism. Man, indeed, discerns its minutest operations, and from their regular recurrence learns to predict them with unfailing accuracy; but the secret agency which guides the world, remains an unsearched, an unanswerable, mystery for ever.

The harmonious concord of nature, however—her consistency and never-failing regularity—are questions within the province of mathematical reasoning, and these are the questions upon which the minds of the mechanical philosophers rest. Let it be assumed that the laws of matter are unchangeable and universal, and a system may be founded on those laws, which can never be shaken by speculations as to their ultimate causes.

Such, then, are the premises from which the mechanical philosophers reason. The only remaining question as to evidence is this—which of these premises is the inference? The premises are obtained by induction, the inferences by deduction. The premises, as has just been said, are arrived at by comparing a great number of natural phenomena, and extracting the simple principles common to them all. This is the method of the mechanical philosophers. All the physical sciences derive their origin from this source: thus, by what means are we to contrive a scientific system—that is, how are we to reduce any class of natural phenomena to a regular system—unless by ascertaining, from nature herself, the primary laws, by which she acts? It is clear, that if a man did not look out of himself, into the external world, for this elementary knowledge, his system would be nothing more than an ingenious fiction of his own brain. But the application of the primary laws depends on another kind of logic than that of induction. Now, we no longer reason by analogy—no longer refer to examples—no longer, indeed, draw knowledge from the external world. Nature has furnished the premises; the mind of man depends on itself alone for the inferences. These are deductive from that application of logical syllogisms to abstract propositions, which is no other than the process of commen-sense—the very highest kind of reasoning which the human mind is capable of. It is not within our present scope to discuss the principles on which deductive reasoning depends, further than by explaining, that it may always be immediately recognized. If the primary laws be true, and omni et nullum—what is universally true of a class of things, is true of anything in that class. It is not necessary, however, to examine minutely here this logical, or rather metaphysical, question; it is enough for our purpose that there are common things—truths which are universally true, certain elementary methods of combining them, the validity of which is as certain to every man as his own consciousness, and that on these primary truths and these elementary methods the inferences of mechanical science exclusively depend.

The only remaining question as to evidence is this—which of these considerations can be perceived only in the actual study of the science itself. But we are now in position to explain the difficulties which originally retarded its progress, and which, even now, constitute the greatest obstacles to the student's progress. Geometry, it was mentioned, became a systematic science, while mechanics remained obscure and confused. If the preceding attempt to explain the foundations on which the latter science depends, have been at all successful, the reason of the earlier development of geometry will readily suggest itself. One of the elements of the former is the investigation of truths which are wholly wanting in geometry. It is needless here to inquire whether any of the primary ideas of this science also be derived from experience: we may well be anxious to avoid a discussion of those essential affinities and distinctions between the objective sciences of D'Alembert, Diderot, Locke, Adam Smith, Dugald Stewart, Turgot, &c., have been unable to agree. But this is readily seen, and is of itself quite sufficient to explain the comparatively rapid development of geometry—that its progress was not impeded by difficulties incident to the advancement of mechanics—the necessity of making experiments, and of selecting, from an overwhelming abundance of results, those which, from their universality and precision, might be made the foundations of the new science.

The same difficulties occur to the student now. He approaches the study of geometry with an unprejudiced mind: whatever previous ideas of space, form, and distance he has acquired, may be confused and imperfect, but they cannot refer to any positive element in geometry. Geometry contains no secret principles, detected only by their effects; all its subjects are so obvious and palpable, that any direct mistake respecting them would be certain to soon detect itself. But of mechanics, almost every doctrine is unconsciously prejudiced before the commence ment of its study: here is a secret principle, undetected, except by its effects—such as causas occultas, ruosa, of which the existence is ascertained only by experience of its operations, and of which the ultimate nature is altogether unknown. The great task, then, which the student of mechanics must perform, is to refer every problem to first principles; to refrain from appealing to his own physical notions, acquired accidentally and without method. Not that he is required to give up the right of private judgment, or subject it, uncon-
vinced, to a fixed standard. Thus far only is he called upon to yield to the experience of his predecessors in the same pursuit—to give credence to their assertion that all the knowledge which he requires may be derived from the elementary principles laid down by those who have managed to reduce them to determination of himself by the effort of his own mind, independently of—if he please, in defiance of—the influence of standard authorities.

By adopting the method, here insisted upon as important, of referring every question to a few first principles, his science becomes a connected chain of reasoning, and acquires the two great advantages of method, certainty and facility—certainty of the accuracy of his knowledge, facility in applying it. This, however, is more than can be done at once, as it is necessary to consider several parts of mechanics, and the ultimate dependence of each part upon elements common to them all, is to be acquired only by a long-continued habit. There are certain practical difficulties however in the exercise of it, of which the student ought to be forewarned, and which act as snares upon his judgment; oftentimes inducing him to believe that he traces a logical consequence where none in reality exists.

Of these sources of error in the pursuit of mechanical science, the most important are included among Bacon’s idola fori—idola or fallacies. These are the errors arising from the mistaken course of mankind—the defects of words—the names of non-existencies, or confused names of existencies. Language can never be so perfectly refined as to avoid entirely this disadvantage, for while the subtilties of nature are infinite, the subtilties of words is finite, and, in a great many cases, only to nominal distinctions. In erecting the lofty edifice of science on so narrow a basis as a few elementary definitions and axioms, extreme exactness in the use of words is therefore requisite; and beautifully is it said, that when we attempt to rear a temple to heaven, we must not be unfaithful to the self-evident truths on which he solves. The most trivial incidents of his every-day life—every weight which he moves, every action of his muscles, suggest cases with full instruction respecting the laws of force. There is not a single spot in the material world, free from the influence of force, and in order to avoid absurdities, and to discern innumerable instances in which the actions of their application may be investigated, and the consequences of them predicted. This unintermitted habit of ransacking the source of nature, of tracing the most trivial and the grandest of her operations to first principles, strengthens and confirms the power of investigation, and reduces those effects of the material laws which on a superficial view appear confused and disconnected, to one harmonious and simple system.

On the other class of errors, peculiarly incident to our science, is that arising from incorrect and misleading representations of causes, either from absolute oversight or from an impression that their effect is incomprehensible. The first of these mistakes will seldom be made, except by an inexperienced student; and may altogether avoided by a proper practice and care in conceiving the exact nature of the question before him. Precaution against this difficulty, he should habituate himself to test the accuracy of his conclusions by particular instances, and by varying this test within the widest legitimate limits. If, in any one instance, his general investigations lead to an absurd consequence, they are themselves erroneous; and it will be necessary to re-examine them, and ascertain at what step the error arose.

There are more difficult cases, however, where the neglect of simple and obvious means, not from oversight, but from necessity—where the complexness of the question are such as to render it solution impracticable without hypothetical simplifications. In all such instances, the investigator must remember that he is solving, not a question of real existence, but an artificial case—making the greatest allowance at which his powers of investigation permit. In practical mechanics, this consideration is especially important; and, as a general rule, no such hypothetical simplification should be admitted—or at least acted upon—without some estimate of the limits of the error which it may possibly induce.

Complicated mathematical formulæ are wholly unsuited for the practical application of mechanics, on account of the refine ment and exactness of both workmanship and computation which they require. The only formulæ which the practical artisan or mechanic will trust, are those which he can readily apply, and which afford a margin for all the diversified circumstances of practice, unavoidable and unknown imperfections of materials,
and other irregularities of detail. The method of determining results between certain limits, has the advantage of leaving such a margin, and will therefore be frequently employed in the following pages. Among its incidental recommendations is this,—that it generally gives great simplicity to formulae which otherwise would be exceedingly complicated.

It is not within the compass of the present work, restricted in the rhetorical form of language, to give a systematic development of the whole science of mechanics: its principal aim is to explain those parts of the science which are of the most direct economical importance, and to assume as little previous knowledge as possible on the part of the reader. He must be forewarned, however, that in solving mechanical problems, the difficulty does not wholly consist in determining the nature of the forces supposed to act—but, in a great degree, in ascertaining the position of the several parts of the system at which they are applied. This latter difficulty is, of course, only to be overcome by a competent knowledge of pure geometry. Galileo, the father of modern mechanical philosophy, has explained this point with like accuracy and eloquence. La filosofia—says he, in his Saggiatore—è scritta in questo grandissimo libro, che continuamente ci sta aperto innanzi a gli occhi, ma noi non conosciamo e non conosciamo i caratteri, né quali è scritto. E légì è scritto in lingua matematica, e i caratteri son triangoli, cerchi, ed altre figure geometriche; senza questo è un'aggraviarsi vanamente per un secolo laborioso.

The Elements of Euclid are, and it may be safely assumed always will be, the best foundation of the study of geometry. Unrivalled simplicity and perspicuity recommend this work as an elementary treatise; its method and precision claim for it the highest position among works devoted to the exact sciences. The fourth and sixth books of the sixth century B.C. have been intoned; and, above all, the intelligent student will endeavour to imbue himself with the spirit of Euclid,—to trace the uninterupted current of his reasoning, from the fountain-head (the axioms and definition) to the final conclusions. It is the distinct dependence of all modern research upon, and the equivalence of Euclid, as the authority of the mind into a habit of logical and consecutive reasoning. The beginner will sometimes meet with propositions so simple and obvious, that it appears an idle waste of time to prove them. It is proposed to be a special study: when he has mastered their demonstrations, he will see that Euclid's intention was—not to explain trivial truths, but to show how they might be deduced as necessary consequences of his principles. The familiar study of this ancient work, and sound familiarity at present for two thousand years—will gradually induce a mathematical habit of mind, and a right appreciation of the real nature of proof—of that which not merely does, but ought to, produce conviction.

As the prelude to the study of mechanics, some knowledge of the elements of trigonometry is requisite. The history of mechanical science will also afford important facilities for mastering its principles. The full value of a scientific theorem is not appreciated without some knowledge of the hard struggle by which—so to speak—it has been wrung from nature. The wanderings of the earlier mathematicians, their fruitless labours and controversies, their slow and gradual approximations to right results, reveal the subtle nature of physical truth, the narrow boundaries which separate it from error, and the necessity of maintaining those boundaries inviolate.

Dispute respecting the laws of mechanics is no longer possible. They are demonstrated; and to attempt to make them matters of controversy, is to exhibit ignorance of the processes by which they have been ascertained. We have, therefore, it has well been said, "non secundum partes in mathematicis; but they abound in every other department of human opinion." And again, "in mathematical questions, where relations of quantity alone are concerned, a dispute can be completely terminated; because, from wrong premises, or false reasoning, a contradiction is shown to result.

If, then, the labours which perfected the science of mechanics—for it is now perfect—have been great, if its study now task severely the efforts of the student's mind, are not the results commensurate? The revelations of pure truth in its most attractive forms—its manifestations in the grandest phenomena of nature, and the proudest achievements of art—are the wages of philosophic toil. So vast are the domains of this science, that every year brings tidings of new and rich discoveries within it: while its applications to the practical wants of men are ever receiving fresh and more important developments—ever creating revolutions more extensive, more lasting, and more noble than those of politics or war.

ARE WE TO HAVE AN ARCHITECTURAL EXHIBITION?

Something of the kind seems to be dawning upon us: there is what just at present looks like the prospect of such exhibition, though it may after all turn out into the unsubstantial and deceitful mirage. In proportion as we are anxious that the vision should be realised, we feel apprehensive of its fading away into nothing. We learn from a contemporary, that the "Architectural Association" purpose to "get up an annual architectural exhibition." Between means, and those and no other, there is the chief privilege conferred upon it by the spirit of indulging in indolence and doing nothing. Yet, if it have no charter, a junior and youthful society has, or ought to have, something greatly in its favour; for it may be presumed that it possesses real and energy, of both which much will be required, in order to carry properly into effect the schemes tendered to it, and to meditate. One question for consideration is, how is it likely to be looked upon by the Institute? As to the Royal Academy, that body would, no doubt, be exceedingly well pleased at a separate exhibition for architects and artists being established, since they would thereby be almost entirely relieved from works of that kind, which is evident enough they take in very reluctantly, and treat very slightingly. That the Institute would not take umbrage at that being done by a junior society which they have left undone (although their means are not as great, or much greater), is not quite so certain. Apothetical as it is, the Institute might yet feel something like awkward compunction and shame, were others to bestir themselves diligently, and venture upon an experiment which, should it succeed, would place them before the public more prominently than the Institute itself can boast of being.

The success of the experiment, however, will depend very much upon the manner in which it shall be made. If it be made at all, it is to be hoped that it will not be timidly and feebly.—And it being such that we have possibly been into a misconception, since what the "Architectural Association" contemplates may be something very far short of the kind of exhibition that is needed. If it is to be one confined to that society's own members, instead of being open to contributors generally, and be also upon such a footing as to admit architectural subjects without distinction as to the nature and mode of them—such technical illustrations as plans, sections, and details, as well as those more pictorial representations which are the only ones received by the Royal Academy—if, we say, it is not to do this, it will fall far short of supplying a main desideratum. Resting entirely upon the abilities of the members themselves, without aid from other quarters, the proposed exhibition could hardly have sufficient stamina and substance to come properly before the public, and so as to attract notice and claim support. Neither would anything at all be done towards affording the opportunity of exhibiting these productions to the many who are excluded from the Academy on account of the exceedingly limited accommodation there for architectural designs and models. At present, there is only Hobson's choice for architectural exhibitors,—either the Royal Academy or nowhere. And the accommodation at the Academy for works of this kind is totally inadequate; for while only a comparatively small number of them can be hung up, not above a third of them can be hung so that they can really be looked at. Therefore, what with the chance of being turned away for want of room, or else of being
thrust out of sight, it is not greatly to be wondered at if many are deterred from sending anything at all. To such, other opportunity of exhibiting would be welcome; and their contributions would, it may be presumed, be equally welcome and serviceable to the "Association." Without support of the kind from the extended interest so created for the success of the undertaking, there might not be attraction sufficient to produce extraction—to wit, of shillings from the pockets of the lieges. We speak merely upon our own conjecture, but take for granted that the exhibition in question would require the usual shilling passport for admission to it; because otherwise, the public would be excluded, and the exhibition be merely a private one, open only to the members and their friends, so that any good result as to diffusing a taste for architecture as a branch of design would be frustrated.

What testers so highly desirable that a special exhibition of architectural drawings and models of every class should be established is, that productions of the kind have no chance of obtaining any attention so long as paintings are to be seen at the same place. It would be almost unreasonable to expect that they should, especially at the Academy, where the pictures are so numerous that they alone afford quite occupation enough for several visits. There, the architectural subjects are scarcely looked at at all, except just by those who make them their chief object. Let it then be fair tried, whether, when withdrawn from its eclipse at the Academy, and allowed to display itself in a different orbit, it has really no power of attraction for the many—we do not mean the mob, but those (and they are many) who, if they possess not, affect at least to have a taste for art generally.

Supposing the "Association" now instead to bestow themselves in good earnest, one thing which they ought especially to consider beforehand is, that architectural drawings require proportionately a much greater space for exhibiting them than pictures of the usual kind do,—because they require to be inspected as closely as miniatures or engravings; consequently, little more than the direct line of wall on the level of the eye can be made available for the purpose. It is of no use—a rather a mere mockery—to profess, as the Academy does, to exhibit productions of the kind, and then hang the majority of them where it is only by great effort that their subjects can be made out, and all detail is completely lost. Mr. Billings—who, by-the-bye, at the opening meeting of the present season, signified the Association's intention to get up the exhibition in question,—observed that he himself had no right perhaps to grumble at the Academy, because, of eight drawings which he sent in this year, seven were hung up—but four near the ceiling, and three near the floor. Considering how many subjects of his were admitted, he had reason to look upon himself as highly favoured—if it be any favour or compliment at all to have drawings received merely because their frames happen to be just the size to fit in "very nicely" with others on the same part of the wall. Such must ever be the consequence of the abominable dove-tailing system in hanging pictures and drawings, which frequently renders it necessary to put a good subject or production in an unfavourable situation, or else an inferior one in a good situation merely because no other places where they would so well fit in can be found for them. Possibly, however, our advice may be altogether superfluous, since it is possible that the proper exhibition will turn out to have been a mere flash in the pan.

ON A READY METHOD OF DETERMINING THE WIDTHS OF LAND REQUIRED FOR THE FORMATION OF A RAILWAY.

We will suppose the centre line to be staked out, and the distance from the top of the peg to the intersection of the slopes to be given. Let A be a centre-stake, at which the half-widths are to be determined; B, the intersection of the slopes produced; and r to 1, their ratio. The level must be placed at some point D, and the line of collimation adjusted so as to describe a horizontal plane at a distance a above the point B (fig. 1), for a cutting. B = K; A = h; c = c = K + h — h', the reading of the staff when stationed at c. Then we have,

\[ B = a + c = A + a - a = a = K + h + h', \]

the horizontal distance of c' from a, must also be measured with the chain, and this we will suppose to be y. It is evident, that at the point c', where the slope B'c meets the surface of the ground, the condition \( y = x \) must be satisfied; and for no other point can it be satisfied. This point c' must be found by repeated trials.

In the case of an embankment (fig. 2),

\[ s = r x B = r(K - h' + h) = r(K - h) + r h' = rB + r h' = a'd + r h' \]

This point c' must be found by repeated trials.

Hence, whether there be cutting or embankment, we must determine the half-width (a'c) at the foot of the line of collimation r; and in making repeated trials, we have nothing more to do than multiply the reading of the level-staff (h') for the slope by r, and add the product to a'd for embankments, or subtract it for cuttings, to obtain the value of x, which must be compared with the horizontal distance (y), found by measurement with the chain. Repeated trials must be made until a point is discovered which satisfies the condition \( y = x \).

Take, as an example, fig. 1, which is a cutting.

\[ B = K = 92'0 \text{ ft.}; \quad h = 12'; \quad r = 14' \]

Thus, \( a = r x B = r(K + h) = 14' (92'0 + 12') = 92'8 \text{ ft.} \)

Let the staff be held at f', and suppose the reading to be 6'5 = h'; then r = 97'5, and x = \( df' = a'd - r h' = 49'5 - 97'5 = 38'2'75' \).

By measurement with the chain, y is found = 39'20';

\[ y \neq x \]

Again, suppose the reading c' of the staff at c' to be 10'7 = h'; then r = 10'5; and x = 49'5 - 10'5 = 39'05.

and y is found by measurement to be 39'45'

\[ y = x \]

\[ c' \text{ is the point sought.} \]

Example of an Embankment.—Slope 14 to 1. Let K = 49'36; h = 2'48. Then (K + h) = B = 49'36 - 2'48 = 39'93;

and a'c = r x B = a = \( \frac{1}{2} \times 39'93 = 50'9 \).

Suppose the reading c' of the staff at c' to be 10'05 = h', then r = 15'07;

\[ s = a'c + r h' = 50'9 + 15'07 = 75'97 \]

and suppose that y, found by measurement, is = 75'97 then c' will be the required point.

These necessary calculations are very simple, but they are also very numerous, and I have found it advisable to substitute a kind of sliding rule, which at once performs the multiplication of \( r \) and \( h' \), and adds the product to, or subtracts it from, a'. (See figs. 3 and 4.)
A long scale of equal parts (H) is formed at the edge of a groove, and another (V) slides in contact with this, as shown in the figures. H represents the horizontal measurements commonly taken with the chain, and should extend from 0 to about 150 feet.

Fig. 3.
Slide arranged for determining the Width of a Cutting.

Fig. 4.
Slide arranged for determining the Width of an Embankment.

If the instrument be made of box, H may contain 10 feet to the inch, and each foot be divided into 5 equal parts. The slide V corresponds to, and must at least contain as many feet as are marked on the levelling-staff. The scale on V, as shown in the figures, is for a slope of $1/10$ to 1; for 1 foot on H is equal to 1 foot on V. Other slides will be required for other slopes.

In the example of a cutting previously calculated, we found that $a' = 42$ feet. Bring 0, on slide V, opposite 42' on H (Fig. 3). The staff is set up at $f'$, and the reading is found to be 39.5. Refer to V with 39.5, and opposite this point we find $x = 32/8$ on H, without any calculation.

But the measured distance y is 32.00; therefore $y = x$.

Again, the staff is set up at other points, and the trial repeated till we come to the point $c'$, where the reading of the staff ($k'$) is 10.7 feet. Refer to V with 10.7, and opposite it we find 28.3 on H, which differs only by the 38th of a foot from the result previously given by calculation.

As $28.3$ has to be subtracted from $a'$ in cuttings, it is necessary for the scales V and H to be numbered in opposite directions, as in Fig. 3. But in embankments, $28.3$ must be added to $a'$, and the scales V and H must increase in the same direction, as in Fig. 4. This is the reason why the slide has two scales, differently numbered. Fig. 4 corresponds to the numerical example given above for an embankment: 0 on V being placed opposite 59.0 on H; and 10.03 on V falls opposite 1 on H.

We have hitherto supposed that zero on the scale V is placed opposite $a'$, the horizontal width at the level of the line of collimation. Now, the value of $a'$ is dependent on the accidental position of the level, and must be calculated in the field. Suppose, however, that the half-widths at the levels of the centre-peg have been determined, and registered previously to commencing operations. In the example of a cutting (Fig. 1), we supposed B A to be $K = 96$; therefore the half-width, supposing the ground to be level, is $r = K = 48 \times 96 = 932$; and $a$ was taken $= 213$. And the result is the same, whether we place 9.13 (or $h$) on V opposite 39.3 on H, or 0 on V opposite 42.5 on H.

The first method will be found the best, because all the half-widths at the levels of the stakes may be previously determined in the office. The same may be said of fig. 4.

It will be found convenient to have an index capable of sliding along H, independently of V, and capable of being fixed at pleasure. This may be formed partly of a piece of horn, or other transparent substance, having a line ruled parallel to the divisions of the scales. This will be of great service where the ground is very sloping, and it becomes inconvenient to hold the levelling-staff on every peg.

If, in Figs. 1 and 5, the ground had been so low that the top of the staff $c'$ fell below the line of collimation, it would have been necessary to have shifted the level, and $a'$ would have taken a new position and value. It will, however, be found an easy matter to determine $B a$, and therefore also $a'$, in all cases; and 0 on V must then be placed opposite this every chain, and $a'$ on H.

Or, calculation may be avoided even in this case. Fig. 1. Suppose the first reading at $a$ to be 2.15, and the half-width at the level of $A$, 39.3 feet. Bring 2.15 on V opposite 39.3 on H. Let the staff be held at any point, and take the reading 9.35, suppose. Slide the index along H to point 9.35 on V.

Remove the level to a new position D', and adjust it, and suppose the back sight taken in the ordinary way to be 3.2. Move the scale V, so that the index points to 3.2 on V; and the instrument is adjusted for the cross-section at $A$, so long as the level is not disturbed.

The index will be found very serviceable where it is not convenient to commence levelling from every centre-stake. Suppose the centre-peg to be one chain apart, and that the gradient rises 3 in every chain.

We have seen that the distance $B a$ of the horizontal plane through $a'$ from $B$ is $H + k$ (Fig. 1), as the gradient is supposed to rise 3 feet in a chain, at a point corresponding to B; but a chain from it, the new value of $A B$ becomes $(K + k - h)$; and the new half-width $a' = r (K + k - h) - r k$.

If we take an embankment (Fig. 2), the new value of $A B$ becomes $(K - h - k)$ at the distance of one chain; and the new value of the half-width $a' = r (K - h) + r k$.

Thus, in a rising gradient, $a'$ for cuttings, we must move the slide by the scale V, a distance $r$ upwards for cuttings, and a distance $r$ downwards for embankments.

But $r$ on the scale H is the same in magnitude as $h$ on the scale V, and therefore it will be most convenient to employ the index in moving the slide V upwards or downwards, through a space $h$ for every chain.

It may be useful to remark that for a rising gradient the slide V has to be moved in that direction in which the numbers of the feet on V increase, as denoted by the arrows, whether the case be one of cutting or embankment. If there be a falling gradient, the slide V must be moved in the opposite direction.

It will be found convenient to be provided with the height of each stake above some common datum; the half-width, supposing the ground to be level, is obtained by the numbers and distances of the stakes, with particulars respecting the gradients, slopes, &c. Also, vacant columns must be prepared to receive the half-widths on each side, as they are determined, and the corresponding reading of the level. The point on H to which the zero on V is opposite, ought also to be registered. This last is very useful where a number of consecutive side-stakes are determined without starting from the centre; and doubts might otherwise arise as to whether the proper correction had been made for the gradient in every case.

As this slide-rule has been used where the ground was remarkably uneven, both for determining the widths of cuttings and embankments, and the limits of embankments at the ends of viaducts, I can strongly recommend it to the attention of those practically engaged on such work, as it avoids much trouble and uncertainty, and the result is as accurate as can be desired by the most fastidious. An addition to the widths above found must be made to allow for the ditches and fences.

St. John's College, Cambridge, Oct. 21, 1849.

IV. THE SAFETY LAMP.

Fire-damp is one of the greatest evils happening to coal-mines, and one which is too well known to all having anything to do with them. Thirty or forty years ago, this was so strongly felt that many mines had reached their furthest workings, because the men had no means of going on, for the least flame was enough to set the fire-damp burning, and the steel mill gave little light, and was unsafe.

In 1783, the Academy of Sciences were drawn to look into this matter, several coal-mines at Briannon, in Dauphiny, having fired. All that the Academy did was to recommend a better way of lighting the mines.

Above a hundred years ago, Sir James Lowther had seen that common fire-damp does not catch fire from sparks of flint and steel; and one of his overmen, said to be Mr. Spedding, made a mill for giving light by striking flint and steel. This was worked by a boy, and was used in the English collieries. It is, however, known, that with the steel mill some mines have been set on fire.

In Hainault, amadou, or fungus tinder, was sometimes used; but it gives so little light, that the men could not work by it, and all that they could do was to find their way by it sometimes from one side of the pit to another, where fire-damp was blowing.

In 1796, Humboldt made a lamp for giving light in mines where a common candle would not burn, or would set fire to the mine. It was founded on the plan of keeping the light away from the air, and could only burn a short time—that is, so long as the air within it lasted.

In 1813, Dr. Clanny made a lamp, to which he gave air from the mine, through water, by bellows. This lamp went out of itself in explosive mixtures. It was to be worked by hand or by machinery, but was too heavy to be moved about readily.

From what Dr. Clanny had done, and from a fearful loss of life in the Felling Colliery, whereby 101 men, women, and children died, the minds of many were turned to some way of lessening the fearful evil of fire-damp. At Sunderland a meeting was held, wherein Mr. Biddle, Mr. Dunn, Mr. Cuthbert Ellison, M.P., Bishop Gray, Dr. Clanny, and others, had a share, and who called upon Sir Humphry Davy to search into the whole matter.  

Sir Humphry looked at Dr. Clanny's lamp, but he was told it was too heavy and too costly to be useful. He tried phosphorus and other lights, but at length he found that a lamp could be made air-tight, and to which the air could be sent in through very small pipes or tubes, or from small openings in wire gauze put below the flame, and having a chimney at top of the same kind, for carrying off the foul air. This he afterwards brought to bear in the shape now so well known as the Davy Lamp, or Davy, in which he was greatly helped by Dr. Fawcett.

Meanwhile, others were no less busy: Mr. R. W. Branding, Dr. Murray, and Mr. John Murray made lamps, and so did George Stephenson; and at length there was very great strife between the friends of Davy and Stephenson, as to who was the first. We have here a small book, written by George Stephenson, in his own behalf, and which is the only work of his which is printed, other than reports. Here it is well to say, that it would be worth while to print the reports of George Stephenson, to bind with those of Smestow, for they are written in a very clear, thoughtful, and business way; and are of great worth for the history of engineering, as Stephenson was called upon to do for the locomotive engine and the railway in their childhood, against the world, having few to back him or help him in his hard struggle.

Stephenson's book is called "A Description of the Safety Lamp, invented by George Stephenson, and now in use in Killingworth Colliery; to which is added, an account of the Lamp constructed by Sir Humphry Davy, with Engravings. London: Baldwin, Cradock, and Joy; Archibald Constable and Co., Edinburgh; and E. Charnley, Newcastle, 1817." It is only about sixteen sides, and was desired by S. Hodgson, of Newgate Engravings.

Another very interesting book is the "Report upon the Claims of Mr. George Stephenson relative to the Invention of his Safety Lamp. By the Committee appointed at a meeting held in Newcastle on the 1st Nov., 1817, with an appendix containing the evidence." This was published in Newcastle, and has three plates, which are the same as in Stephenson's book.

Stephenson says: "Several of my friends having expressed a wish that I would lay an engraved plan of my Safety Lamp before the public, with as correct an account of the dates of the invention as I could, I have resolved to do so. I was, at the same time, advised to publish the steps by which I was led to this discovery, and the theory I had formed in my own mind upon the subject, which, with the facts from which I drew my conclusions, were freely communicated to several persons during the time I was engaged in the pursuit. With this I cannot persuade myself to comply; my habits, as a practical mechanic, make me afraid of publishing theories; and I am by no means satisfied that my own reasons, or any of those I have seen published, why hydrogen gas will not explode through small apertures, are the true ones. It is especially for our present purpose that the discovery was arrived at, and that it has been successfully applied in the construction of a lamp that may be carried with perfect safety into the most explosive atmosphere."

"During the four years," Stephenson goes on to say, "that I have been employed upon the engine at Killingworth Colliery, one of the most extensive mines in Northumberland, where there is a considerable quantity of machinery underground, I have had frequent opportunities of employing my leisure hours in making experiments upon hydrogen gas. The result of those experiments has been the discovery of the fact above stated, and the consequent formation of a Safety Lamp, which has been, and is still used, in that concern, and which my friends consider (with what justice the public must decide) as precisely the same in principle with that subsequently presented to their notice by Sir Humphry Davy."

The first thought of the safety lamp had been long in Stephenson's mind; and in August, 1813, he made a drawing of it, which was shown to several people on the works—among others, to Mr. Nicholas Wood, whose name is now, for the first time, seen along with that of Stephenson. He was then a visitor at Killingworth, and seems to have taken a great share and delight in all that Stephenson did, as is shown by the works of both. Stephenson told Wood that he thought a lamp might be made which would burn the fire-damp without blowing-up. The way was this,—to make a lamp in the bottom of which the attraction of the flame upwards would be greater than the force downwards. Wood drew out the plan under Stephenson's eye, and in October, 1815, they went to Mr. Hogg, a timber, at Newcastle, and had a lamp made, which a fortnight after was put into Stephenson's hands. When Stephenson first spoke about it, he asked...
THE CIVIL ENGINEER AND ARCHITECT'S JOURNAL.

[November]

that the tube might be made a quarter of an inch in diameter, but Mr. Hogg having suggested that it probably would not burn, it was made half an inch in diameter, and a slide attached to it in order to lessen it if need were.

This first lamp had an open top and conical shape, and was given to Stephenson on the 21st of October, 1815. This was on a Saturday, and in the dusk, Stephenson, Wood, and Mr. John Moodie, an under writer, were out to try the lamp. Moodie lighted the lamp and went to a blower of fire-damp in the roof, going to it from the windward, and keeping the candle about twenty yards off. By some deals, they made a part of the mine foul, for the purpose of having a trial with the lamp. About an hour afterwards, Moodie went into the part made foul, so that he could smell &c. (of which, from knowledge, he was well assured) that the air was in such a state, that if a candle had been taken in, the place would have caught fire, which would have been very fearful. Moodie told Stephenson it was foul, and hinted at the danger; nevertheless, Stephenson would try the lamp, trusting in its safety. Stephenson took the lamp and went with it to the spot in which Moodie had been, and Nicholas Wood and Moodie, fearful, went further off. Stephenson tried the lamp, and it went out without making any explosion — on which, Stephenson again held forth the safety of his lamp. It has been said, before now, that there is as much bravery in the engineer as in the seaman or the warrior — aye, and as much call for it, too; and often in the common workman — there be as stout and bold a heart in the greatest straits, and in the utmost fear of life and limb, as there is in the leader who storms a breach, or heads the bloodiest fight. Stephenson was not a blusterer, but a sober, careful, and daring when he thought the call was on him; and although death loomed before him, he did not turn back from what he felt to be his duty. Here we have the witness of those who were with him, and we may stand by him in this time of trial, and watch his every step.

"Stephenson," says Moodie, "again lighted the lamp, and Wood, who had now more trust in it, went with him to the former spot, and even held the lamp — they tried it again, and with the same end. When the lamp was put lighted in the gas, there was a great wind of nine times shifting, and there was a flow with bladders filled with air from the blower. The first trial was with the pipe quite open, and the explosion passed downwards. Trials were thereaf arer made with the slide so shifted, that at length the opening was so small, the explosion no longer passed downward, but was got out by the wind. The pipe was then left out by being moved. It was therefore thought, that by making more pipes of this smallness, air enough for burning and for keeping up the light might be let in; and yet the holes or openings be so small, as still to stop the explosion from going downwards.

The lamp was then sent to Matthews, a timberman, in Newcastle, and the three pipes put to it, but outside the burner. On Saturday, the 4th of November, this was tried in the pit, and found to burn better than the other, but still not well. Nevertheless, the explosion passed downwards. A spot in the mine had been again made foul by Moodie, and Stephenson, Nicholas Wood, John Moodie, his son of the same name, an overman, and George Wails, an overman, went down and made further trials, which, as they all thought, turned out better than the first. Moodie here says, that three months before the first lamp was tried, Stephenson was often making trials with a candle near the blowers, for which Moodie, who was fearful, reproved Stephenson. Then Moodie told Stephenson that he thought a lantern could be made so as to be taken in safely amongst the foul air; but Moodie did not think it could be done.

After this, two lamps of the second pattern were made and given to the wasters in Killingworth pit. A few days after — namely, on the 6th of November, a boy was killed in the Pit, at Killingworth, on the spot where the trials were made with the first lamp. Stephenson said, on that day, if the boy had had his lamp, he would not have been burned.

"John McCrie," tells the same tale. He says, that in the summer of 1815, Stephenson was setting up sloping planes underground, and often as he was coming out, he set the blower on fire, and by lighted candles put to windward, put the blower out. Stephenson said that he could make it useful to save men's lives. This he said, when McCrie spoke against what he was doing as hurtful.

Up to this time, Stephenson knew nothing of what Sir Humphry Davy had found out or done, or of what he had written to the coal trade thereupon. He now made his third lamp, which had the same aim, as to get rid of their dreadful nuisance. Afterwards he thought, that if he cut off the middle of the pipes, or made holes in metal plates, set some way from each other, as far as the pipes, that the air would get in better, and that there would be the same safety against explosion. Another lamp was therefore made and tried out.

This third lamp did so well, that it was long used in Killingworth pits, and workmen were bound to it under a fine of half-a-crown for using a candle. This lamp was tried alongside with Davy's, and found to do as well.

The first trimmer was a wire down the chimney of the lamp; but afterwards, Sir Humphry Davy's trimmer was used. Nicholas Wood wrote on this in the Tyne Mercury.

On the 24th of November, 1815, Stephenson showed his lamp to Mr. Robert William Brandling, and to Mr. Murray of Sunderland, both well able to give a judgment upon it. On the 25th, that day, the 26th, and the 27th of November, 1815, Stephenson's lamp was brought before the meeting of the Literary and Philosophical Society of Newcastle, the same evening that Dr. John Murray's paper about his own lamp was read. Trials were made of Stephenson's lamp with bladders, holding the fire-damp, put below, and the fire-damp let into the lamp. The difference between Stephenson's lamp and Sir Humphry Davy's was, that Stephenson used a plate in which holes were cut, and Davy hit upon the happy thought of using a wire gauze screen; but Stephenson seems to have been the first who found that the explosion would not pass downwards, and upon this all depended — for wire gauze instead of a metal plate was a mere change of shape, though for the better.

Whether Stephenson's lamp is still used, we do not know; but, as shown above, it was kept in use till 1818, and very likely till long after, for Stephenson's friends were so steadfast they would not give in to what they said was a copy of their lamp.

V. THE GIFT.

In 1818, those who had called in Sir Humphry Davy, thought it time to give him some present, and therefore called a meeting of coalowners, at Newcastle, on the 31st of October, when Mr. Nathaniel Clayton took the chair. The meeting was to reward Sir Humphry Davy, "for the Invention of the Safety Lamp." By this time, a paper war had arisen, and whilst Bishop Gray and Mr. Boardman had called upon Sir Humphry Davy, a great number held to George Stephenson, and much bitterness of feeling was shown. Neither were there wanting those who upheld Dr. Clancy, Dr. Murray of Edinburgh, Mr. John Murray of Hull, and Mr. Robert William Brandling. Dr. Clancy was the first—Sir Humphry Davy and Stephenson acknowledged this; but the lamps of the two latter had been brought into work, and the struggle lay between them. Dr. Clancy helped Sir Humphry Davy, and Mr. Brandling sided with Stephenson. Davy was so much the stronger than Stephenson, that he was better known, and kept all the merit of his invention on his side, while Stephenson was backed by the Killingworth men, and all those who thought highly of what the self-taught workman had done with the dioxide and the safety lamp. Sir Humphry's friends were angry that one so lowly should be set up against him—Stephenson's, that one so lowly should be put down, and kept out of his fair share of the work, to bolster up a great name. Both sides went great lengths, both went too far, and now it is easy to do right by all.

Perhaps Watt took a part, for he was an early patron of Davy, who was employed in the Pneumatic Institution, at Bristol, under Dr. Beddoes, in which the great man was at this time.

So much was said and done by George Stephenson's friends, they fought so hard for him, and against Davy, that the meeting on the

13 Report, p. 21. 14 Report, p. 16. 15 Witnesses of Mr. Henry Edmonds, Secretary, and of Mr. Henry Atkinson and Mr. Anthony Cripps. Reports, p. 22. 16 The whole of this is well given in the Gateshead Observer, of August 19, 1848, from which the above is taken.

17 Davy, on the Safety Lamp.
31st of August was held over till the 11th of October, when John George Lambton, the late Earl of Durham, took his seat. The meeting was too long, and Mr. Brandling then moved that the meeting should be again put off, that inquiry might be made, whether the "merit of the invention of the Safety Lamp was due to Sir Humphry Davy, or George Stephenson." Mr. Arthur Mowbray likewise stood up for this, but it was set aside by a great number of hands. A purse of one hunstread was offered, but the offer was not accepted.

Stephenson's friends were very wroth at being thus beaten, and Stephenson himself thought that the meeting had dealt very unfairly with him in awarding the medal to Davy. "Whether or not," says Stephenson, in a letter afterwards printed, "Mr. Brandling is justified in the opinion he has expressed [that Stephenson was the inventor], it appears to me may be easily decided; and I shall only add, that if it can be proved that I took advantage, in the formation of the safety lamp, of any suggestions, except the printed opinions of scientific men, I deserve to lose the confidence of my honourable employer and the good opinion of my fellow-men, which I feel an honest pride in, and which even in my humble situation in life is of more value in my estimation than any reward that generous, but indiscriminate influence can bestow."

Davy's friends thought they did not do enough in upholding him, but they must further pull down Stephenson; and instead of choosing the likely path, that both might have gone on without knowing each other, they openly said that Stephenson had taken or stolen the thought from Davy. 5 Here was the sting—and hence the main cause of the sensation. Stephenson himself fully shows what his feelings were—his love of standing well with his fellow-men—his earnestness to be worthy of the trust bestowed upon him. From the time he first set foot in the great world, to the day of his death, these were his strong feelings; and as has been before shown, the key to his life, and lay open to us the springs of his well-doing.

He was quite right in thinking that the good-will of his neighbours, and the trust of his fellow-men, were worth more than any money which could be bestowed; for they were to him as the land which yields a yearly harvest, while the lette is but a crop which is once gathered in, and there is no more of it. The harvest may fall short sometimes, but there is the land to give a better crop in other years, and to give a good income for whatever is laid out upon it: so is it with a good name—it is a lasting mine of wealth to the owner, the yield of which is the greater the longer it is wrought.

The friends of Davy were none the less angry that a common workman was set up against one of his great name, as if it were likely that one of Davy's standing should be behelden for anything to a lowly pitman. They wereadden at the thought of one of the greatest names of the age being set down as having thought or dreamt of the drudge they then looked down upon was to shine upon the world as one less great than Davy—as one of the brightest lights of his day—as one of whom even they now feel proud. Such is the worth of a name, such is it to weigh with and be held in esteem even in the scale of weight. Such a man of to-day soon sinks into the dust—the lowly of yesterday is the mighty of the morrow; but let each be weighed by his deeds, and not by his name; by his own works, and not by the witness of his friends.

The writings which were put forth in Stephenson's name are by one hand; but though they breathe his thoughts, it does not seem likely that they are his. In that last given, the earnestness of thought is his, but it is not his speech. There is too much Latin—there are too many of the chosen words of the schoolman, and too much of classic phrase, to do them equal justice. They are a well-spoken Englishman. In talking, Stephenson always had the homely speech of an Englishman, as indeed it now too often happens that among common men our mother tongue is best spoken. With them, the well of English is bright and strong; whereas bookmen, instead of speaking better English for their greater knowledge, only learn Latin and Greek to bring them into English, as if our English were a worse speech, and the others better; or, as if a word were the better understood by being swaddled in outlandish clothes. Stephenson most often had the pen of another, else we might have had from his hand something worthy of our best writers; for it has been often seen, that those have written the freest who have risen as he did, from among those who know no other tongue but their own. The cot is a better school for speech than the college—there is a greater freshness in its sayings: a strength and earnestness and heartiness which come home to our bosoms; something which breathes sweetly of the heart and home, and its back beyond our school years. Whether in the Bible, or Shakespeare, or the works of the ancient and modern writers, those sayings always delight us most which are most homely; and yet, more care is given to eke out a book with big words, borrowed from every land but our own, than to write such things as every one may readily understand.

If Davy's friends are right, Stephenson's were as steadfast; the war went on, and the Newcastle papers were full of writings, for and against. The Rev. John Hodgson, Mr. Buddle, Mr. Brandling, and the full number of "Friends to Justice," strove together; but neither side would give in, or own that it was in any way right that they were too busy in saddling things on each other to take off one bit from themselves. If Davy had the meeting of coalowners on his side, Stephenson was not to be left barren, and therefore his friends made up their minds that he should have a meeting of his own, and that plate should be given to him again against what had been done for Sir Humphry Davy.

It should, however, be said that, having been beaten in getting an inquiry from the meeting of coalowners, they had a meeting of their own, to look into what Stephenson had done, and which ended in the Report, which has been already named. Stephenson, Nicholas Wood, and the others who had a hand in the business were called together, and gave witness as to what they had seen or done. This was written down and printed at the end of the Report, and it showed the faith the meeting had in the goodness and rightfulness of the side they had taken up. The members were, the Earl of Strathmore, C. J. Brandling, Matthew Bell, Esq., R. W. Grey, Esq., Arthur Mowbray, Esq., James Losh, Esq., T. H. Bigg, Esq., Dr. Headlam, C. N. Wawn, Esq., Anthony Clapham, Esq., and G. Charnley, Esq., Richard Lambert, Esq., was the Treasurer, and Robert William Brandling, Esq., the Secretary.

On the 1st of November, 1817, the further step was taken, and a meeting was held in the Assembly-rooms, Newcastle; at which C. J. Brandling, Esq. took the chair, "for the purpose of remunerating Mr. George Stephenson, for the valuable service he had rendered mankind by the invention of the Safety Lamp.

The first resolution held forth, "that Mr. Stephenson, having discovered the fact that explosion of gas would pass through tubes and apertures of small dimensions, and having been the first to apply that principle in the construction of a Safety Lamp, was entitled to a public reward." A committee, headed by the Earl of Strathmore, was named to carry this out.

Davy's friends were anew stirred up, and they sent to the newspapers a writing, signed by Sir Joseph Banks, President of the Royal Society, William Thomas Brande, Charles Hatchett, H. W. Wood, and Thomas Hodgson, Thomas Hodgson, "in virtue of conviction, that Mr. Stephenson was not the author of the discovery of the fact in question, and was not the first to apply that principle in the construction of the Safety Lamp."

The other committee printed their report and answer, setting forth the plain fact, that it was a matter of history, and "At the same time inquiry into the merits of the case, conducted, as they trusted, in a spirit of fairness and moderation, they could perceive no satisfactory reason for changing their opinion." The dead set made by the men of the learned profession, who stood by their friend, Davy, did not frighten the others, and did not put a stop to their work. Their minds were made up, and the subscriptions set afoot by them went on steadily.

Lord Haversworth (then Sir Thomas Henry Liddell, Bart.) and partners, gave one hundred guineas; C. J. Brandling, and partners, gave the like; 8 Matthew Bell, 9 and partners, gave fifty guineas; and Robert Brandling, gave fifty guineas. A large, greedy purse was filled; and the great gifts of the Liddells, and the other coalowners, are a very good earnest of how Stephenson was looked upon in his own neighbourhood, and the path which lay open before him. It was not hard to tell what he would do with his informed skill.

In January, 1818, a dinner was given to George Stephenson, at

---

5. Thee partner with Stephenson in the patent for the rails and chairs.

6. Afterwards a director of the Newcastle and Carlisle Railway.

8. Matthew Bell, Esq., and partners, gave fifty guineas; and Robert Brandling, gave fifty guineas. The 50 guineas were a modest gift; the large gifts of the Liddells, and the other coalowners, were a very good earnest of how Stephenson was looked upon in his own neighbourhood, and the path which lay open before him. It was not hard to tell what he would do with his informed skill.

the Assembly-rooms, Newcastle, when a silver tankard was put into his hands, together with one thousand guineas.

...I shall ever reflect with pride and gratitude," said he, "that my life has been honourable to the promotion of such a distinguished meeting; and you may rest assured that my time, and any talent I may possess, shall hereafter be employed in such a manner as not to give you, gentlemen, any cause to regret the countenance and support you have so generously afforded me."

This pledge, as is well known, Stephenson fulfilled.

Of the feelings of the committee, the best earnest is the following words, given in their Report:—"When the friends of Mr. Stephenson remembered the humble and laborious station in which he has been born and lived; when they consider the scanty means and opportunities he has had of pursuing his researches in that field of science; and look to the improvements and discoveries which, notwithstanding so many disadvantages, he has been enabled to make, by the judicious and unremitting exercise of the energy and acuteness of his natural understanding, they cannot persuade themselves that they have said anything more than every liberal and feeling mind will most willingly admit."

Thirty years afterwards, a third piece of plate was given to the "Inventor of the Safety Lamp," which this time was Dr. Clancy, who had been named already.

Although so much noise was made at the time, and each said that the other had stolen the thought from him, it is not hard, now that their feelings have softened down, to see the truth. It was held by them that one must be the first finder: but there is no need to believe anything of the kind, for two or three might as readily have invented the lamp with safety to it. Why, indeed, was Sir Humphry Davy called in? Why did Stephenson give his mind to it but from the want of such a thing, the fever of life which had followed from taking candles into fire-damp, and the little good of the steel mill? Many, therefore, set their wits to work to find out a safety lamp. We have named five, and it was in no way odd that two should hit upon the same thing.

Throughout the field of learning, we have found this happen. Was there not the very same thing with Newton and Leibnitz about fluxions? Did not Watt, Cavendish, and Lavoisier each take a share in finding out the composition of water? At the same time, Fulton and Bell were at work on the steamboat,—Trevithick and Oliver Evans on the steam-wagon,—and in our day, there has been a struggle between Le Verrier and Adams, by which the learned world has been torn, as to who found Neptune. There are several put forward as the first lighters of gas. Young and Chapmollion fight over the Rosetta stone; we have not yet added the need to the man who first set railways going; James and Gray (though dead) are still in the field, with many more who strive to wrench from them the name of "Father of Railways." This will ever be, for where there is a want, the ready wit of many men will be ever ready to find out the right way. Is there anything new brought forward that the steam-makers have not already made? Is there much mistake in saying that there were a thousand clever inventors who found out atmospheric railways. The heads of railways unhappily know how many makers there are of new buffers, breaks, links, wheels, rails, and chairs, each good, and each the best. The Gultta Percha Company have before them a list of two hundred hints for making everything of gutta percha, from ear-trumpets to horse-shoes. It is good that it should be so, rather than that we should lag behind, waiting for the slow work of a few minds, when we may bring to bear the fruitfulness of many.

Stephenson seems to have been the first to try a lamp with holes so small that explosion of fire-damp did not pass downward; but Davy had nothing to do with him, and was not far behind, and he made a much better lamp by taking wire-gauze instead of pipes or holes.

The following, from the 9th page of the Report of the Committee, shows what each did:

1815. MR. STEPHENSON. 

Aug. to Oct. 
Busy with those experiments on blowers in Killingworth Colliery, which led to the invention of the safety lamp.

BEGINNING OF OCT. 
Ordered his first lamp, which was tried in the colliery on the 21st of that month.

The following, from the 8th page of the Report of the Committee, shows what each did:

1815. SIR HUMPHRY DAVY.

The subject occupied his attention, as an object of speculation.

BEGINNING OF OCT. 
Commenced his experiments on fire-damp, and before the 18th of that month had discovered certain gases [the facts in question] respecting that inflammable...
This engine was put to work on the Killingworth Railway.

In 1816, Trevithick left England for the West Indies, leaving the locomotive to look after itself, for what he knew. Stephenson, however, looked after it. In this year he took out a patent with Mr. William Losh, a great engineer of Walsall and Newcastle. Among other improvements was that of "sustaining the weight, or a proper part of it, of the weight of the engine upon pistons, moving within the cylinders, into which the steam or water of the boiler is allowed to enter, in order to press upon such pistons, and which pistons are, by the intervention of certain levers and connecting-rods, or by any other effective contrivance, made to bear upon the axles of the wheels of the carriage upon which the engine rests."

The cylinders were open at the bottom and screwed upon the frame of the engine. The piston, which was solid and packed in the common way, was furnished with an inverted rod, the lower end of which passed through a hole in the frame, and supported the engine, and pressed upon the chair, which rested on the axes of the wheels upon which the carriage moved. This chair had motion up and down the piston-rod. The pressure of the steam upon the piston transmitted the weight to the axle, and the reaction took an equal weight from the engine, and the steam served the purpose of an elastic spring.**

Mr. Ritchie objects to this invention, that it aimed at too much, was too complicated, and not precise enough to be of much use.

Messrs. Stephenson and Losh had their patent likewise for a cast-iron rail, which was held to be an improvement on the rails then made. As railways were then laid, the wagon-wheels met with a hindrance at the joints, and a shock was given, and the rails put out and broken. Stephenson therefore wished to fix the rails fast in the chairs. His rails were made with a half-lap joint, having a pin or bolt, which fixed them, so that the end of one rail should not rise above the end of the next one, and so that the rails should not yield if the block sank.

We have seen that in 1817, Stephenson was busy in his struggle with Davy about the safety lamp. In the next year, the dinner was given to him, and he was laying down railway works and making engines.

In that year (1818), and in the next, he gave his time, as Nicholas Wood acknowledges,† to experiments with Wood on railways, which have been printed.

His son had now become an under-viewer, and was a helper to his father.

Perhaps about this time he first came up to London for the patents.

We have followed Stephenson so far until he is upon the eve of starting in a new path, and we find him in a new walk of life, and much better off. We have seen his beginning from his father's cot, his struggles as a workman, his care as a father, and the spreading of his name after making the locomotive and the safety lamp. He had begun to reap some reward from his toil, and instead of being poor and penniless, he had had eleven hundred guineas put to him beyond what he had earned. From being the man, he had become the master; from being the learner, he was to be henceforth a teacher. He had a share in two patents, and there was a call for his work, for besides his old masters at Killingworth, the neighbouring coallowers were now among his friends.

As his rise had been quick, and he was brought at once into the fellowship of the northern gentry, his honours came blushing thick upon him. He did not so fully feel his own weight, but having been kept down so long, he hailed willingly the hands which were stretched forth towards him; taking everything as a kindness, he laid out to him, instead of looking upon it as a right. His greatness had not grown gradually upon him—he did not settle slowly in his seat: he was marked as a new man, and always through life he had a quick feeling of his lowly beginning. It was better, perhaps, that it was so, for he kept up a kindly feeling with all around; whereas, had he taken on him the bearing of a great man, as many do, he might have lorded it over the world. but he would have missed what was dearer to him than this—the love of his fellow-men. He was thankful for everything, and therefore kindly to every one. As he did not look for too much, or stand upon his rights, he was seldom wronged and always happy.

** Ritchie on Railways, p. 275.  
*** Ritchie on Railways, p. 337.  
†† Wood on Railways.
The only return of tiles carried for building or agricultural purposes is that of the Wishaw and Coltness Railway for the year ending June 30, 1846, 502 tons. Receipts £20.

The only return of clay carried for brick-making, pottery, or other purposes, is that of the Wishaw and Coltness Railway, 1846, 344 tons; and 1847, 475 tons. Receipts, 1846 £6, and 1847 £8.

The rates for the carriage of bricks are generally too high, and are exclusive of loading. Twopence per ton per mile would be enough.

The above returns give no means of calculating the quantity of bricks and tiles carried on the whole length of railway.

No. XII.—MISCELLANEOUS MINERAL TRAFFIC.

Besides the articles already enumerated are many others, as lead ores, copper, brass, lead and tin manufactured, salt, sulphur, roman cement, glass, pottery, fuller's-earth, &c., but as to which no information is to be got.

The rates for conveying salt are as follows, per ton per mile:

<table>
<thead>
<tr>
<th>Origin</th>
<th>Rate</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bodmin and Wadebridge</td>
<td>4 00d.</td>
</tr>
<tr>
<td>Newcastle and Carlisle</td>
<td>2 50</td>
</tr>
<tr>
<td>London and Brighton</td>
<td>2 24</td>
</tr>
<tr>
<td>Lancashire and Yorkshire</td>
<td>1 32</td>
</tr>
</tbody>
</table>

The rate for conveying fuller's-earth on the London and Brighton Railway is 2 24d. per ton per mile.

No. XIII.—MINERAL TRAFFIC.

The whole mineral traffic shows the following results in tons:

<table>
<thead>
<tr>
<th>Year</th>
<th>Coal and Coke</th>
<th>Iron</th>
<th>Dross</th>
<th>Copper and Tin</th>
<th>Limestone and Lime</th>
<th>Building Stones</th>
<th>Sand</th>
<th>Ballast</th>
<th>Bricks and Tiles</th>
<th>Miscellaneous</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>1845</td>
<td>7,000,000</td>
<td>400,000</td>
<td>230,000</td>
<td>23,000</td>
<td>200,000</td>
<td>200,000</td>
<td>30,000</td>
<td>30,000</td>
<td>2,000</td>
<td>280,000</td>
<td>11,700</td>
</tr>
<tr>
<td>1846</td>
<td>8,500,000</td>
<td>500,000</td>
<td>230,000</td>
<td>23,000</td>

</table>

Timber is in some returns mixed up with stone traffic, as seen in No. XIU.

On the Cornish and Northern lines, timber is carried for mining purposes; in the agricultural districts, for hop-poles and fences; on all lines for building. Bark is carried on the Southern railways.

In 1845, I estimated the quantity of timber carried at 40,000 tons, and there seems no reason for doubting that this is a safe estimate.

No. XV.—BUILDING TRAFFIC.

On the whole, railways afford great accommodation to the building interests, though not to that extent which they may and will do when the traffic is more developed.

The following is an estimate of the traffic carried on for building purposes under each head:

<table>
<thead>
<tr>
<th>Item</th>
<th>1845</th>
<th>1846</th>
<th>1847</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stone</td>
<td>200,000</td>
<td>400,000</td>

<td>50,000</td>
<td>50,000</td>
<td>50,000</td>
</tr>
<tr>
<td>Sand</td>
<td>10,000</td>
<td>10,000</td>
<td>10,000</td>
</tr>
</tbody>
</table>

| Total | 300,000 | 400,000 | 715,000 |

The rates for the carriage of each of these articles, though below those on roads and canals, are still too high for the development of the traffic. It is a great disadvantage that most of these articles—stone, timber, and bricks—give much trouble in loading and unloading.

No. XVI.—FISH TRAFFIC.

This traffic is of the greater importance, as it gives a positive addition to the supply of food in the country, and is therefore of great national benefit. Railways stimulate the production, or economise the cost of production, of grain, meat, and other article of food; but all fish that can be carried inland, is so much added to the resources of the country. In this respect, railways have done much and can do more, both for the supply of food to the country, and the promotion of the fisheries.

In the beginning of last year, I laid before Mr. Hudson a suggestion for extending the carriage of fish, as a means of relieving the famine, and to which he gave his approval. In the last session, Mr. Wyld, M.P., called the attention of the House of Commons to my plan for increasing the consumption of fish, by adopting it as an article of occasional diet in workhouses and prisons. This would cause an increased consumption of at least 20,000 tons of fish. Sir George Grey said there was no objection to the adoption of this plan, provided enough fish were given.

In consequence of the progress of the railway traffic, there has been a great increase in the consumption of fish inland. A very strong proof of this is given in the case of Birmingham, where they find it necessary greatly to enlarge the fish market.

On the South-Western, Eastern Counties, and other metropolitan railways, great numbers of fish hawkers go down by the early trains.

It is very much to be regretted that there is a great dearth of information on this very important subject; and it is very desirable, in consequence of the absence of definite information, that a parliamentary return should be obtained of the quantities of fish carried by railway. This, however, can only be obtained by approximation, as all the fish is not carried in bulk, but very much is carried as parcel traffic, and some by passengers as luggage.
The only returns are the following:—

---|---|---|---|---
Eastern Counties (Cambridge) | 1,218 | 867 | 5,100 | 
Great North of England, | | | |
Norfolk, | 77 | 1,109 | 2,775 | 7,102 |
Whitby and Pickering, | | | |

The receipts stand as follows:—

1844. | 1845. | 1846. | 1847.
---|---|---|---
Great North of England, £1,378 | £1,020 | £ | £
Norfolk, | 777 | 330 | 7,150 |
Whitby and Pickering, | | | |

* Estimated. † Half-yearly. ‡ Two months.

The rates are high. The following are the rates per ton per mile:

London and Brighton, 6d. per mile.
Great North of England, 6s. 9d. per mile.
Whitby and Pickering, 6d. per mile.
Preston and Wyre, 4d. per mile.
London and South Western, 6d. per mile.
Norfolk, 2d. per mile.

The Great Western are known to carry a great quantity of fish over the South Devon line. The receipts are said to be £500 per week.

The traffic of the lines given above may be estimated as follows:

Eastern Counties (Cambridge) 5,100 tons.
Great North of England, 1,000 tons.
Norfolk, 12,000 tons.
Whitby and Pickering, 1,100 tons.

Total, 19,200 tons.

This is nearly 90,000 tons on four lines of railway, and not including the Eastern Counties (Colchester, Brighton, South-Western, Great Western, South-Eastern, Hull and Selby, Liverpool and Manchester, and Preston and Wyre).

In 1845, I estimated the railway traffic in fish at 13,000 tons, which must have been much below the mark.

The following is an estimate of the amount now conveyed:—

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Scotland</td>
<td>2,000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Northern</td>
<td>4,000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Midland</td>
<td>2,000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Western</td>
<td>2,000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>South Western</td>
<td>4,000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Southern</td>
<td>2,000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Eastern</td>
<td>25,000</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Total, 43,000 tons.

This traffic is very remunerative, and does not bring less than 10s. per ton. If parcels were taken into the account, the gross tonnage of fish carried may be reckoned as 70,000 tons; or, on the lowest computation, the food of as many individuals.

No. XVIII.—GRAIN TRAFFIC.

The conveyance of grain and flour is irregular; for though there is a fixed quantity carried to the local markets, the import of foreign corn is fluctuating.

The returns for the years ending June 30, are as follows:—

---|---|---|---
Great North of England, | 9,901 | | |
Lancashire and Yorkshire, | | | |
Londen and Croydon, | 45 | | |
Manchester and Bolton, | 229 | 2,434 | 120 |
Norfolk, | | | |
Skegness, | | | |
Whitby and Pickering, | 407 | 89 | |
Whitehaven, | | | |
Whitby and Colne, | 1,533 | | |

The amounts received in each of the years are as follows:—

Company. | 1845. | 1846. | 1847.
---|---|---|---
Great North of England, £1,284 | | |
Lancashire and Yorkshire, | | | 4,151 |
Londen and Croydon, | 5 | | |
Manchester and Bolton, | 31 | 97 | 13 |
Norfolk, | | | 1,091 |
Skegness, | | | |
Whitby and Pickering, | 142 | 29 | |
Whitehaven, | | | 2 |
Whitby and Colne, | | 48 |

* Returns for the half-year of grain and provisions.

The rates are as follows, per ton per mile:—

<table>
<thead>
<tr>

<tr>
<td>Norfolk</td>
<td>15</td>
</tr>
</tbody>
</table>

The amount of grain and meal carried by railway is certainly not under a quarter of a million tons, and most probably exceeds three hundred thousand tons.

Through the kindness of Mr. Waddington, I have been favoured with the following return of grain, flour, and seed, carried for the London markets by the Eastern Counties Railway.

<table>
<thead>
<tr>
<th>Half-year ending</th>

</tr>
</tbody>
</table>

Not knowing the average weights of the above, they cannot be reduced into tons.

No. XVIII.—PROVISION TRAFFIC.

There are no means of estimating the provision traffic on railways; but such returns as there are, show that it is very great.

The following are returns of the number of tons of provisions carried in each of the years ending June 30. The Lancashire and Yorkshire, and Norfolk returns, already given, include corn; the Eastern Counties return is from Mr. Moseley, through Mr. Waddington, and includes fish.

---|---|---|---
Eastern Counties, | | | 30,000 |
Lancashire and Yorkshire, | | | 13,367 |
Lancashire and Yorkshire (Preston & Wyre), | 8,251 | 6,412 | 5,220 |
London and Brighton, | | | 3,632 |
London and South Western, | | | 40,655 |
Norfolk, | | | |
South Eastern, | 19,799 | 17,771 | |

* Fruit, meat, and vegetables, half-year, 3,583 tons, besides fish, bacon, hams, &c.
† Half-yearly.

The amounts received are as follows:—

Company. | 1845. | 1846. | 1847.
---|---|---|---
Lancashire and Yorkshire (Preston & Wyre), £22,591 | £23,951 | £17,740 |
London and Brighton, | | | 4,373 |

The rates charged are as follows per ton per mile:—

<table>
<thead>
<tr>
<th>Port</th>
<th>Rate</th>
</tr>
</thead>
<tbody>
<tr>
<td>Londons and Brighton</td>
<td>56d.</td>
</tr>
<tr>
<td>Preston and Wyre</td>
<td>40</td>
</tr>
<tr>
<td>London and South Western</td>
<td>2d.</td>
</tr>
</tbody>
</table>

Ale and beer are carried largely on the South Western, Newcastle and Carlisle, and other lines. The rates on the London and South Western are 18d. per ton per mile, and on the Durham and Sunderland, 10d.

In 1845, I estimated the supply of provisions to the London markets by railway as follows, to which I subjoin a new estimate. This does not include cattle.
Malt is not carried so much by railway as might be expected, because the market gets shaken up, and then measures less on delivery, because it cannot be so well heaped up. As the quality of the malt is not affected, this is only a temporary prejudice on the part of the dealers.

The charges for carrying malt are on the London and South Western Railway 3d. per ton per mile, and on the London and Brighton 2½d.

Bark is carried on most of the Southern lines. The rates are on the London and Brighton, 2½d., and on the London and South Western, 2½d.

Brooms are manufactured near the London and South Western Railway, and are carried at the rate of 2½d. per ton per mile.

Hay is reckoned hazardous from its liability to catch fire from the engine sparks. The quantities carried and amounts received on the Newcastle and Carlisle Railway were:

<table>
<thead>
<tr>
<th>Year</th>
<th>Tons</th>
<th>£</th>
<th>Stgs</th>
</tr>
</thead>
<tbody>
<tr>
<td>1846</td>
<td>1847</td>
<td>1848</td>
<td></td>
</tr>
<tr>
<td>968</td>
<td>963</td>
<td>892</td>
<td>879</td>
</tr>
</tbody>
</table>

The rate of carriage on the above railway is 5d. per ton per mile.

There are no details as to wool traffic, though wool of home and foreign growth is carried. The rate is 3d. per ton per mile.

There is a return of potatoes carried in 1846 on the Wishaw and Coltness Railway, 43 tons at 2½d. per ton per mile, the receipts being £2 only.

The rates for hides are, on the London and South Western 2½d. per ton per mile, and on the London and Brighton, 3½d.

The following are mixed returns of agricultural produce for the years ending June 30:

<table>
<thead>
<tr>
<th>Company</th>
<th>Tons</th>
<th>Tons</th>
<th>Tons</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dublin and Drogheda</td>

</tr>
<tr>
<td>Swine</td>
<td>700,000</td>
</tr>
</tbody>
</table>

Other produce, hides, bams, wool, horses, malt, ale, beer, cider, perry, hay and animal food, timber, bark.

No. XXII.—PARCELS TRAFFIC.

This is a well-paying branch of revenue, connected with the passenger traffic, and has been latterly much improved. The subjoined accounts do not, however, show the full extent of the parcel traffic, as a great portion of it is included in the general account for goods, the carriers making up parcels as goods. The results are therefore minimum results.
The following shows the number of parcels carried in each year ending June 30, so far as they are detailed in the returns:

<table>
<thead>
<tr>
<th>Company</th>
<th>1845</th>
<th>1846</th>
<th>1847</th>
</tr>
</thead>
<tbody>
<tr>
<td>East Lancashire</td>
<td>184,654</td>
<td>135,053</td>
<td>80,920</td>
</tr>
<tr>
<td>Eastern Counties (Co. Chester)</td>
<td>88,571</td>
<td>205,250</td>
<td>89,403</td>
</tr>
<tr>

<td>13,000</td>
<td>40,000</td>
<td>21,000</td>
</tr>
<tr>
<td>Ipwich and Bury</td>
<td>10,900</td>
<td>2,783</td>
<td>6,007</td>
</tr>
<tr>
<td>East Anglian</td>
<td>16,000</td>
<td>24,900</td>
<td>12,389</td>
</tr>
<tr>
<td>Kendal and Windermere</td>
<td>5,974</td>
<td>6,199</td>
<td>2,344</td>
</tr>
<tr>
<td>Lancaster and Preston</td>
<td>2,000</td>
<td>1,597</td>
<td>3,457</td>
</tr>
<tr>
<td>Manchester and Sheffield</td>
<td>1,000</td>
<td>1,568</td>
<td>1,965</td>
</tr>
<tr>
<td>South Devon</td>
<td>20,000</td>
<td>20,000</td>
<td>20,000</td>
</tr>
</tbody>
</table>

The numbers for 1847 may be made out thus:

<table>
<thead>
<tr>
<th>Company</th>
<th>1847</th>
</tr>
</thead>
<tbody>
<tr>
<td>East Lancashire</td>
<td>40,000</td>
</tr>
<tr>
<td>Eastern Counties (Co. Chester)</td>
<td>150,000</td>
</tr>
<tr>
<td>Eastern Union</td>
<td>300,000</td>
</tr>
<tr>
<td>Ipwich and Bury</td>
<td>100,000</td>
</tr>
<tr>
<td>East Anglian</td>
<td>3,000</td>
</tr>
<tr>
<td>Kendal and Windermere</td>
<td>5,000</td>
</tr>
<tr>
<td>Lancaster and Preston</td>
<td>100,000</td>
</tr>
<tr>
<td>Manchester and Sheffield</td>
<td>200,000</td>
</tr>
<tr>
<td>South Devon</td>
<td>20,000</td>
</tr>
</tbody>
</table>

The total receipts in each year are as follows:

<table>
<thead>
<tr>
<th>Year</th>
<th>1845</th>
<th>1846</th>
<th>1847</th>
</tr>
</thead>
<tbody>
<tr>
<td>Value</td>
<td>£182,010</td>
<td>£208,258</td>
<td>£266,048</td>
</tr>
</tbody>
</table>

The returns of parcel traffic are the only returns which show any improvement; the others afford less information in each year.

From the above amounts a correction has to be made for passengers' luggage charged in excess, included in the parcel returns. This is usually about 6 per cent. of the gross returns; but as it is deducted in some cases, 5 per cent. is a sufficient compensation. It must be observed that in some cases parcels are included in the goods returns.

The South Devon return includes receipts for telegraphic messages.

For 1846-7 the number of parcels enumerated was 909,641, and the receipts £6,885, which gives an average of 3.94d. per parcel.

It is questionable, however, whether the average is so low in any of the years, as the London and North Western, which has so large an amount of the parcel traffic, is not taken to form part of the average. It is, however, certain that the average rates for the conveyance of parcels have been much reduced. A fair average will be 18 parcels per pound for 1845-6, 19 for 1846-7, and 20 for 1847-8.

The total number of parcels carried both ways to each town may be reckoned thus:

<table>
<thead>
<tr>
<th>Town</th>
<th>1845</th>
<th>1846</th>
<th>1847</th>
</tr>
</thead>
<tbody>

THEORY OF STEAM-ENGINES.

Account of the experiments to determine the principal laws and numerical data which enter into the calculation of Steam-Engines.
By M. V. Renauvi.

(Continued from page 268.)

FOURTH MEMOIR.—ON THE MEASUREMENT OF TEMPERATURE.

We do not as yet possess any direct means of measuring the quantities of heat absorbed by a body under given circumstances, and we recognise this absorption of heat only by the changes which it produces in the state of the body, or by its dilatation. The name of thermometer is given to the instrument whose object is to indicate the variations in the quantities of heat in any medium. These instruments are generally founded upon the dilatation which bodies undergo by the action of heat, or upon the changes in elastic force with the same bulk of a gas or liquids under the circumstances to which the medium is submitted.

A perfect thermometer would be one whose indications were always proportional to the quantity of heat which it had absorbed, or, in other words, one in which the addition of equal quantities of heat produced always equal dilatations. To fulfil this condition it is necessary, either that the capacity for heat, and the dilatation of the thermometric substance, should remain invariable during the experiment, or that these two elements should vary strictly inversely as each other.

Nor would the perfect thermometer yet indicate the quantity of heat absorbed by the medium under given circumstances, unless this medium presented the same advantages as the thermometric substance—that is, unless it absorbed equal quantities of heat for equal variations of the temperature as noted by the thermometer.

But a comparative study of the dilatations of different substances under the same circumstances, quickly shows that they are far from following the same law; and if we compare together the quantities of heat absorbed by these different bodies when brought successively to different temperatures, the dilatations of one of them, we see that these quantities are variable, and equally variable in each one of them, without our having been able heretofore to show the relations which exist between these variations of capacity and the changes of bulk.

The great precision which can be obtained in the construction of the mercurial thermometer, the facility with which the thermometric liquid may be obtained of the same degree of purity, and the great extent of temperature through which this liquid preserves the same state, have given to the mercurial thermometer the preference over all other instruments of the same kind, and have caused its adoption almost exclusively for all precise experiments.

But there is an essential condition which every apparatus for measurement ought to satisfy; it is, that it should not only reproduce easily and completely its own temperature, but it should also mark the same degree under the same circumstances—but it is moreover necessary that we should be able to reproduce it at will, and obtain always instruments rigorously comparable.

Physical philosophers have thought that they had completely attained this end, by means of the scales of the mercurial thermometers agree at certain normal temperatures which are easily reproduced and always perfectly identical; for this purpose, they have adopted the constant temperature at which ice melts, and that not less constant which saturated steam presents when it exerts an elastic force of 76 millimetres. But I have shown (Annales de Chimie et de Physique, 3rd Series, tome v., pages 100 et seq.) that two mercurial thermometers, adjusted for the same fixed points of melting ice and boiling water under a pressure of 76 mm., may show very considerable differences in their movements beyond these fixed points, if they are not made of glass of the same nature. Even when the glasses of the reservoirs present the same chemical composition, there may still be very sensible differences in their indications according to the way in which the reservoirs have been worked in the glass-blower's lamp, the molecular state of the glass undergoing very notable alterations during this working.

The mercurial thermometer, then, as it has been constructed up to the present time, is defective in one of the most essential conditions which ought to be required of an apparatus for measurements—it cannot be always reproduced in the same state; and the different instruments of the same kind are rarely comparable with each other beyond the fixed points of their scales.

Physical philosophers thought that they had observed that all the gases dilate exactly the same fraction of their volume at 0°, when
they are carried from the temperature 0° to that of 100° (39° to 212° Fahrenheit). This law, so remarkable for its simplicity, naturally led them to think that the dilatation of the gases ought to be in a more simple ratio to the quantities of heat than that of solids or liquids. Since more bold, even concluded that the dilatation of gases must be rigorously proportioned to the quantity of heat, and that the gas thermometer was the true normal thermometer to which all the phenomena of heat ought to be referred.

We now know that this great simplicity in the law of the dilatation of the gases is far from existing. I have shown in the memoir upon the dilatation of gases that not only the different gases, but only the different substances, have not the same coefficient of dilatation, but that even for the same gas this coefficient varies with its density. The indications of thermometers then, can only be considered, like those of other thermometers, as functions more or less complicated of the quantities of heat.

But the gas thermometers present an advantage over the mercurial, and in general over all solid or liquid thermometers, an advantage which arises from the greatness of the dilatation of the thermometric substance. In any thermometer formed by a liquid or gaseous substance, the indications of the instrument depend upon the dilatation of this substance, and of that of the substance in which it is inclosed. Now, the dilatation of mercury is only about seven or eight times that of atmospheric pressure when the reservoir is surrounded by melting ice, we can assume to have instruments rigorously comparable. Nevertheless, if we desire to measure very high temperatures — if for instance the instrument is to be used as an air pyrometer — it is to be feared that the elastic force of the gas will be insufficient, and that the apparatus may experience a permanent change of form under the great interior pressures. This inconvenience may be avoided by introducing into the apparatus, air under an initial pressure less than that of the atmosphere, when the reservoir is at 0°.

The present memoir has for its object the study of the different methods of measuring the temperature in experiments which require great precision. I will divide it into three parts: in the first part, I will treat of the gas thermometer; in the second, of the mercurial thermometer; and in the third, of the measurement of temperatures by means of thermo-electric currents.

**PART I. — OF GAS THERMOMETERS.**

When a gas enclosed in a mathematically-elastic envelope is submitted to an elevation of temperature, its volume increases, and the elastic force of the envelope decreases. The volume may be placed under circumstances such that the pressure which retains it remains constant, and its increase of bulk be observed; or the gas may be compelled to keep the same bulk, and its increase of elastic force be examined.

*First Method.* — In order that a gas should realise the conditions prescribed by this method, which is the simplest, and those found by the mercurial thermometer, it would be requisite that the gas submitted always to the same pressure, should expand freely in a gauged reservoir, kept throughout at the same temperature. But these indications cannot be fulfilled in practice — at least, if the apparatus is to be submitted to high temperatures.

The thermometer must therefore be composed of a reservoir which is to be exposed to the temperature which it is desired to measure, and a gauged tube, united to the reservoir by a capillary tube, which removes the other from the place where the temperature is to be measured. This gauge tube fulfils the purpose of the graduated stem of the mercurial thermometer, and serves to collect the gas which the rising of the temperature drives out of the reservoir. This tube may also be kept at a constant temperature differing but little from that of the surrounding air. At any moment of time the temperature of the gas contained in the tube, the first, contained in the reservoir, is at the temperature to be found, the other in the tube is at the surrounding temperature. These two portions are at the same pressure, which may be brought as nearly as desired of that of the atmosphere. The equations derived from these conditions permit us to calculate the required temperature.

This arrangement is the one adopted by M. Pouillet, in his air pyrometer, and M. Regnault himself employed it in his fifth series of experiments made to determine the dilatation of gases. It presents a very serious inconvenience when the apparatus is to be used for the measurement of high temperatures. In fact, it will be seen that in this case the far greater part of the air will already be in the gauged tube, and but little will remain in the reservoir, so that a further elevation of the temperature will cause but a very small portion to pass over into the tube, and this will with difficulty be able to reach the proper degree of accuracy.

In fact it can be easily shown that, calling a the coefficient of dilatation of the gas a, and the coefficient of dilatation of the gas a, the sensibility of the apparatus will vary very nearly inversely as \((1 + a)^n\). This circumstance led M. Regnault to reject this arrangement for a gas thermometer.

*Second Method.* — In the second method the gas is kept constantly of the same volume, and the elastic force which it presents under different circumstances is measured; then from these, by the law of Mariotte, we may calculate the dilatations which the gas would have undergone if the pressure had been kept constant.

The apparatus founded upon this second method are much more easily managed, and give greater precision than those constructed according to the first method: they have moreover the advantage of presenting the same sensibility at high as at low temperatures. In the true form of the apparatus, in which atmospheric pressure is used, the reservoir is surrounded by melting ice, we can assume to have instruments rigorously comparable. Nevertheless, if we desire to measure very high temperatures — if for instance the instrument is to be used as an air pyrometer — it is to be feared that the elastic force of the gas will be insufficient, and that the apparatus may experience a permanent change of form under the great interior pressures. This inconvenience may be avoided by introducing into the apparatus, air under an initial pressure less than that of the atmosphere, when the reservoir is at 0°. In this way the gas is kept, by the instrument property, and adopt the gas thermometer as a standard, we must study several important questions, so as to fix the conditions under which the instrument will remain comparable.

The present memoir has for its object the study of the different methods of measuring the temperature in experiments which require great precision. I will divide it into three parts: in the first part, I will treat of the gas thermometer; in the second, of the mercurial thermometer; and in the third, of the measurement of temperatures by means of thermo-electric currents.

Each of these thermometers was composed of a globe of flint glass (crystal), of from 400 to 600 cubic centimeters content, terfed by a capillary tube, and a manometric apparatus. The two globes were kept, by copper wires, side by side on a metallic support, consisting of two metallic plates of lozenge form placed, one below, the other above the globes, and united by iron rods; the upper plate was pierced with two holes through which passed the stems of the air thermometers, and with two other holes, situated in a line at right angles to that joining the first, through which passed the stems of two mercurial thermometers.

The capillary tubes of the air reservoir were connected with the capillary tubes of the manometers, by bringing these tubes
A great number of experiments were made by M. Regnaut with the apparatus in which air of ordinary density was compared with that of much less, and with that of much greater density, as well as with hydrogen gas, carbonic and sulphurous acid, and the proportion of the last two which he draws from them are as follows:—

1. The atmospheric air follows the same law of dilution from 0° to 330° (32° to 662° Fahrenheit) of temperature, even when its initial elastic force at 0° varies from 0.14 to 1,353 (1,333 to 4,253 ft.). So that in the construction of an air thermometer, no attention need be paid to the density of the air introduced,—the instruments will be comparable whatever may be the density.

2. Atmospheric air, hydrogen gas, and carbonic acid, follow between 0° and 330°, sensibly the same law of dilution, although their coefficients of dilution are sensibly different. So that the thermometers made with these different gases will accord, provided the temperatures are calculated from their proper coefficients. From this it follows that the coefficients of dilution of these gases present sensibly the same ratio at every temperature.

3. Sulphurous acid gas departs notably from the law of dilution which the preceding gases present. The coefficient of dilution of sulphurous acid diminishes with the temperature as marked by an air thermometer.

It is important to remark that in these experiments the relative dilutions of the gases were not measured directly, but were deduced from the obervations from the other gases which these gases present at the same temperatures, their volume remaining constant. It appears very probable that similar conclusions would be arrived at, by measuring directly the increase in bulk of the different gases for the same temperatures, their elastic force remaining constant, by a method analogous to that of the fifth series of experiments upon the dilution of gases; but these experiments would not be susceptible of equal precision in the measurements, for reasons already given at the commencement of this memoir. (To be continued.)

COPPER SMELTING FURNACE.

A correspondent of the Mining Journal gives the following estimate for the construction of a reverberatory furnace for smelting copper on the Swansea plan. The stack of the furnace was single, 40 feet high, and the furnaces 13 feet by 8. The following are the details:

Making a total of 107 £ 6 s.

To this must be added, about 14l. for the men's labour, and 2l. for that of the smiths', which, added to the cost of the furnace, 107 l. 6s. 6d., will make a total cost of 1,231 l. 6s. 6d. The prices given are those of the period when the furnaces were constructed; of course, at different times they will vary considerably; any one, however, will be able from them to calculate what the present outlay would amount to. By building two furnaces, with a double stack to serve both, and using clay in the sides, instead of bricks, a less consumption of materials would take place, which would necessarily be followed by a commensurate reduction in the expenditure, thereby enabling the contractor to construct his furnaces on a more economical principle than above detailed.
ATMOSPHERIC PILE-DRIVING MACHINE.

PATENTED BY CLARKE AND VARLEY.

This apparatus has been lately used for driving the piles of the cofferdam for Irongate, St. Katherine's Docks. The inventors state that by this machine, piles may be driven at half the expense of driving them by the ordinary machine worked by hand, and in about one-sixth of the time. Mr. Crate, the clerk of the works at the above docks, states that he drove forty-two piles, 16 feet deep, into a bed of very hard compact gravel, at the rate of three piles each tide of about 3½ hours; and to drive one pile only, by the ordinary hand-engine, occupied five tides before it could be finished, and even then was left 2 feet above the height required to be driven. Mr. Harrison, the engineer, also certifies that the Atmospheric Pile-Driven gave him entire satisfaction.

This machine consists of a vacuum cylinder of wrought-iron (A), closed at the bottom and open at the top, having an air-tight piston, and self-acting slide-gear, fixed to any convenient part of the frame of a common pile-engine. The piston-rod is connected to a chain which passes over a fixed pulley (B) on the top of the engine; to the end of this chain is suspended a pulley (C); over this passes a second chain, one end of which is attached to the ram, and the other, passing down under the bottom of the frame, is brought up and affixed to the head of the pile. The power is derived from a small steam-engine, fixed at any convenient spot, which works an air-pump for producing the exhaustion. Communication is made between the air-pump and the Pile-Driving Machine by small wrought-iron tubes, connected together by flexible joints of vulcanised India-rubber. Thus the machine possesses

the incalculable advantage of being worked at any required distance from the steam-engine, and moved about with as much facility as a common crab-engine. The mode of action is as follows: the ram being supposed down on the pile-head, and the piston consequently at the top of the vacuum cylinder, communication is opened by the valve gear with the air-pump, exhaustion then takes place in the cylinder, the piston descends by the external pressure of the atmosphere, and raises the ram; when the piston arrives at the bottom of the cylinder, the valves reverse themselves, communication with the air-pump is then shut off, and the external air admitted under the piston; equilibrium being now restored, the ram falls with the full effect of gravity on the pile; the valves are again reversed, and the same operation is repeated. Thus a succession of short heavy blows is given, rapid of course in proportion to the power of the steam-engine; and, as by the arrangement of the pulleys, the distance between the pile-head and the face of the ram is always the same, a regularity of action is obtained, quite unknown to the old pile-driver, the injurious effect on the head of the pile, and rebound of the ram, consequent upon great height of fall, avoided; and the ram being permanently fastened to the chain, the whole time lost by the re-attachment after every blow is saved. The machine is so constructed, that it may be fixed in a few hours to the frame of a common pile-engine.

Fig. 2 shows an arrangement by which one vacuum cylinder can be made to work two rams, and, consequently, drive two piles at the same time. A pulley (A') is attached to the piston-rod of the
vacuum cylinder; round this passes a chain which goes over the two pulleys (B, B'), having the ends fastened to the two suspended pulleys (C, C'). The arrangement of the second chain is similar to that of the single machine. The two rams, being exactly the same weight, will, of course, rise and fall at the same time with each stroke of the piston. If it should be found that one pile is driving faster than the other, and for this or any other reason it should be desirable to give a shorter blow to one pile than to the other, it can be done in the following simple manner: a small chain or rope is attached to each ram, hanging freely; the man in attendance can at any time, without stopping the machine, fasten the end of this chain or rope so as to check the rise of one ram to any extent—a very small force will do this, as the two rams exactly counterbalance one another; the other ram will, of course, then make a stroke longer in proportion to the shortening of this one. Or the working of one ram may, by the same means, be entirely stopped, the other then making a blow twice the length that it did when both were working equally.

A working model of the machine may be seen at 31, Parliament-street, Westminster.

REGISTER OF NEW PATENTS.

SELF-ACTING GAS APPARATUS.

JOHN WATSON, merchant, and EDWARD CARY, gentleman, both of Hull, for "improvements in the manufacture of gas."—Granted February 11; Enrolled August 14, 1848.

The patentees describe the object of this invention to be the combination of apparatus with an ordinary hot-air stove, for generating gas in proportion to the supply required, and so to arrange the parts that the supply of material to the retort will be cut off by the filling of the gas-holder, so that if the supply of gas from the retort be not consumed, the further feed to the retort will be cut off. The figure represents a section of the apparatus.

c, is an ordinary hot-air stove, with the retort set therein, or the retort may be set in brick-work or masonry, in lieu of the iron stove; f, feed-pipe, to conduct the liquid for gas manufacture from the holder g, to the retort t; g, tap opened and shut at the commencement and conclusion of the process; i, self-acting tap connected with the gas-holder by means of the two rods, m and n, and which are opened together at the joint o. The volume of gas required for combustion being supported by a quantity of the liquid flowing into the retort, the proportion is regulated by the tap t, in exact ratio with the current consumption, and whatever decrease or increase is made in the number of lights during the apparatus being in operation, causes the gas-holder to ascend or descend, until the self-acting tap t, admits only the quantity of liquid to the retort commensurate with the flames burning; p, washer or purifier; q, worm-pipe fixed in a cylindrical vessel containing cold water for condensation. The worm-pipe conveys the gas from the washer or purifier, and terminates with a bend which dips into the water contained in the cylindrical vessel; the gas having forced itself through the surface of this water, rises into the gas-holder, whose sides dip into water contained in the tank surrounding the cylindrical vessel wherein the worm-pipe is fixed; thus it will be perceived that the subsequent cylindrical vessels, one the longer as a tank for the gas-holder, and another the smallest to contain water for condensation only.

The heat used in generating gas may be employed to the ordinary purpose of heating air, in addition to generating gas, or it may be applied to other uses.

STEAM-BOILERS AND ENGINES.

WILLIAM EXALL, of Reading, engineer, for "certain improvements in thrashing machines, and in steam-boilers, engines, and other apparatus for driving the same, which apparatus is applicable to driving other machinery."—Granted March 8; Enrolled September 8, 1848.

This is a very comprehensive specification, and includes nine claims, the enumeration of which will sufficiently explain the nature of the improvements patented. The first and second claims refer to thrashing machines, and to a mode of regulating the distance of the concave from the drum that carries the thrashers. In the third, the patentees claim the employment of two piston-rods to each piston in what are known as the Brunell engine, with a cranked cross-head, and the forming a recess in the top of the cylinders and pistons, thereby obtaining a greater descent of the cross-heads and their connecting-rods. Fourthly, the mode of adjusting the eccentricity of the valves without stopping the engines) by means of a rod, actuated upon a pinion contained within the shaft, this giving motion to another pinion that gears into the toothed ring or arc on the side of the eccentric. Fifthly, in respect to "Her's engine," he claims the introduction of the steam into the arms through a hollow neck of prepared india-rubber, with metal washers, employed to make the revolving joint steam-tight, together with the partial or total closing of the emission apertures, and the reversal of the motion of the engine, by means of valves or slides receiving motion through the hollow axis of the engine. Sixthly, the combining of a vertical cylindrical boiler and fire-box, having radiated horizontal flues, with a flue surrounding the boiler, which is bounded by the external casing of the boiler, and also the placing the surface of the fire-bars somewhat below the bottom of the boiler, for the admission of air on all sides of the fire. The seventh claim refers to an improved horse-gearing for driving machinery. Eighth, the application of compressed wood to the manufacture of the teeth of wheels, so that when the teeth are driven into the recesses or cavities of the periphery of the wheel, the subsequent expansion will retain them securely therein. Ninth, the forming of dovetailed or other suitable shaped grooves extending across the face to receive teeth of a suitable shape formed of wood which has been previously compressed.

HIGH-PRESSURE AND EXPANSIVE STEAM-ENGINES.

JOHN LAWES COLE, of Lucas-street, Middlesex, engineer, for "certain improvements in steam-engines."—Granted March 22; Enrolled September 29, 1848.

This invention has for its object a better arrangement of parts in the combination of high-pressure and expansive steam-engines, wherein two cylinders are used. In the first proposed arrangement of the two cylinders one is placed above the other, and the pistons are fixed to the same piston-rod, the high-pressure cylinder being above, and the larger cylinder for the expanded steam being below. The piston-rod passes through a stuffing-box between the two cylinders which separates them from each other. This stuffing-box is packed by means of two horizontal burnings in the plate forming the stuffing-box, opposite to each other, by which packing is introduced, the packing being forced into contact with the rod by blocks pressing behind by means of screws. In another arrangement, two piston-rods are employed to the piston in the expansion-cylinder, unconnected with the piston-rod of the high-pressure cylinder. These two piston-rods pass up through the cover of the expansion-cylinder and on each side of the high-pressure cylinder to the cross-head or beam above, in which they as well as the piston-rod of the high-pressure cylinder are secured. The other parts of the engine are constructed in the usual manner, or so modified as to be suitable to the present arrangement of the cylinders. Another improvement
is the adaptation to direct-acting steam-engines of high-pressure and expansion cylinders, which are placed side by side upon the sole plate, the two piston-rows of these being attached above to a cross-head, common to both; from the centre of the cross-head a connecting rod extended to the crank placed upon the shaft below. To preserve the parallelism of the piston-rods, a system of levers is placed above, in connection with the cross-head. These levers and rods have also the effect of equalising the strain of the two pistons. Another part of the invention is the substitution of double-acting air-pumps of slide-valves instead of the click-valves, the slide-valves being worked by an eccentric or crank in the manner of the usual slide-valve of steam-cylinders. Expansive slide-valves are formed by placing the cylinder with loose blocks, which are connected to the slide-valve itself by means of two rods, one on each side, upon which are placed nuts for the purpose of adjusting the distance of the blocks from the valve; and thus, by increasing or diminishing that distance, to vary the expansion of the steam in the cylinder. A further improvement consists in the construction of safety-valves for steam-boilers, by combining with the ordinary conical safety-valve, a piston within a cylinder so arranged that whenever, from its ceasing to act, the pressure of steam in the boiler increases beyond the required amount, the rise of the piston will open the valve and thus relieve the pressure.

FURNACES AND BLOWING MACHINES.

George Lloyd, of Stepney, Middlesex, iron-founder, for "certain improvements in furnaces and blowing machines, and in engines and machinery for driving the same; which improvements are also applicable to other purposes where motive power is required."—Granted March 12, 1846; Enrolled September 9, 1846.

This is a multifarious specification, comprising so many separate "improvements," that it is difficult, without occupying more space than we are willing to bestow, to give any description of the whole; we must therefore confine our notice to a few of the leading points. The principal part of the invention relates to furnaces for heating steam-cylinders. The furnace chamber does not pass under the cylinder, but is at the extreme end. The fire-box is placed in a vertical position, about the same situation as usually occupied by the fire-door; while the fuel is inserted at a hopper-mouth at the end of the boiler, which, in this case, is represented as being flat, with the fuel chamber extending partly up the end. This chamber is about the usual width of furnaces; but in its length, it is confined to about the usual depth of fuel by means of a number of fire-brick-lumps, extending from the hearth to the bottom of the boiler, and placed so as to present their edges to the fuel in the manner of bars. The fuel being ignited, is piled within the chamber till quite full, the only covering being the unconsumed fuel which extends in the hopper-mouth above the bars. The products of combustion pass between the fire-lumps, in contact with the bottom of the boiler, and break into a chamber immediately in front of the bridge, where a series of pipes are placed for the admission of air. The great heat attained by the fire-lumps imparts a sufficient degree of heat to the gaseous products to cause them to flash into flame on being mixed with a due proportion of atmospheric air. This flame is conducted over the bridge and through the flues in the ordinary manner. In the construction of the blowing machines, the blades are tamped towards the points, and are placed at angles of 60 degrees backward, by which means the inventor proposes to overcome the disadvantage which blowing machines usually possess of waste of power, by the fumes striking the air within the case that is not expelled. The blades are confined at the sides by discs of metal extending to the point of the blade, and having an opening in the centre, of the same area as the openings in the sides of the case. The air driven off at the periphery is limited by the entire area between the blades being equal to the area of the side inlets, and at the same time attains a superior blast with less power, without that disagreeable beating noise, consequent on a rapid motion being given to the ordinary manner. Another blowing machine, described in the specification, consists of a series of bellows placed within an octagonal case, each of the eight sides forming a base for one bellows. The other boards of the bellows are placed in a radial line, each of the upper or moving boards being attached to a crank in the centre of the case by a suitable connecting-rod; this crank being actuated by a shaft passing out at the sides of the case, which is quite air-tight. On motion being given to the shaft, the bellows will be successively acted upon, as the crank performs its revolution. The air entering from the outside by inlet valves, when the bellows are expanded and discharged inside the case, when collapsed by the motion of the crank, a uniform pressure of air is thus kept up, which may be conducted by suitable pipes or channels from the casing to the point required. The following claim of the patentee set forth the various inventions included in this specification:—First, the construction of a steam-boiler furnace, in so far as regards the combination of vertical fire-bars made in two pieces, together with vertical fire-clay lumps behind the fuel-chamber, and vertical air-tubes behind the fire-lump. Secondly, the employment in furnaces of every description of fire-bars made in two pieces. Thirdly, the mode of applying the vapours arising from the chimneys of cupolas for the heating of boilers. Fourthly, the construction and arrangement of the fan blowing-machine, in so far as regards the employment of an inner casing with openings of small area in its periphery. Fifthly, the general arrangement and combination of parts constituting the bellows blowing-machine. Sixthly, improvements in rotary steam-engines, in so far as regards the employment of two or more chambers, and two or more sets of arms and steam-jets or apertures in such arms of successively increasing area. Seventhly, an improved spindle or shaft-bearing in which the end or journal of the shaft works in a collar or socket of plumbago. Lastly, the construction of strap-riggers of a combination of iron and gutta percha.

ZINC ORES.

Charles André Felix Rochas, of Paris, France, merchant, for "certain improvements in treating zinc ores, and in manufacturing oxide of zinc."—Granted December 23, 1847; Enrolled June 24, 1848. [Reported in Newton's London Journal.]

This invention consists, firstly, in improvements in the treatment of zinc ores; and, secondly, in improvements in manufacturing oxide of zinc.

First, as regards the treatment of the ores of zinc:—This process has usually been effected by first converting them into the state of oxide, by roasting or calcining, and afterwards reducing and distilling the oxide, by mixing them with coal, and submitting them to great heat, in close vessels or retorts. This mode of operation is attended with great disadvantages, for, besides occasioning great consumption of fuel, and rapid destruction of the retorts, the product obtained is by no means proportionate to the quantity of the ores.

By this improved process the employment of retorts is entirely dispensed with, and the fuel and labour are greatly economised; the operation is also completely independent of the skill of the workman or attendant; and, lastly, the loss of metal incidental to the ordinary method is prevented. Besides these advantages, the patentee observes, that ores of lead and zinc may both be operated upon at once by his improved method.

The principal feature of the invention consists in the reduction of roasted blend-ore (native sulphuret of zinc), and of the carbonates, oxides, or silicates of zinc, and also of the sulphurites and oxides of lead, by the action of the reducing gases of a blast fur-
The zinc is volatilised by the heat, and the scoria falls into the lower part of the furnace, and is run out at the places e, e. The volatilised zinc is carried off with the gases arising from combustion, and passes through the opening d, into the receiver c, above. The gases from the fire-place escape through the openings g; and as these latter might carry off particles of zinc with them, and might be allowed to escape into the atmosphere. By this means all solid matter is retained, and the zinc, together with any dust or extraneous particles, is extracted through the openings k. When the fire is to be operated upon in a comminuted state, it is advisable to make it come into a paste, together with the flux, by the addition of water, so that it may be charged in pieces of such size as not to pass through the fuel. Zinc ore is often mixed with sulphuret of lead, and by this mode of operation the zinc is obtained by volatilization, and the lead by fusion (this latter running to the bottom of the furnace below the scoria), if, by previous roasting, a portion of the sulphur has been driven off from the ore.

The second part of the invention consists in a novel construction of apparatus for the manufacture of oxide of zinc. Fig. 4 is a vertical section of the furnace, and of the chamber for the reception of the oxide of zinc; fig. 5 is a horizontal section of the furnace, taken in the line e, d, of fig. 4; and fig. 6 is a vertical section, taken in the line c, a, of fig. 4. A, A, are the retorts or subliming-pots (of which there may be any convenient number), placed in the sole of the furnace; B, B, are the covers of the retorts, which are perforated; C, is the door of the oxidising-chamber; D, D, are upper flues through which the gases and other products of combustion pass from the fire-place to the chimney; E, E, are vessels for receiving the zinc, in case of rupture of the retorts or pots, in which case the liquid metal would run down on the floor a, a, and from thence into these vessels; F, is the flue or chimney of the furnace; M, M, fig. 6, are vertical flues in the wall, for the passage of the waste gases of combustion; N, is a top partition, dividing the oxidising-chamber, R, from the horizontal flue F; M, M, is a chamber for receiving the oxide of zinc; O, a chimney for creating a draught, and thus drawing the oxide of zinc, together with air and gases, through the chamber M, and alternately over and under the upper and lower partitions P, and Q. There may be any number of these partitions, according to the size of the apparatus, and the quantity of oxide to be manufactured. Q', is a wire-cloth, or other suitable fitting partition, at the end of the chamber M, for retaining the oxide of zinc, and, at the same time, allowing the air and gases to pass through to the chimney O. It will be seen that the furnace is divided into three separate chambers or compartments; the lower one, which may properly be called the furnace or heating-flue, contains the retorts A, which are charged with the zinc. The second or oxidising chamber R escapes through the orifices in the cover R, of the retorts, and enters the middle or oxidising-chamber H. The zinc vapour is oxidised and forced through the chamber H, either by means of a blower or by the draught created by the chimney O, at the end of the chamber M. The upper compartment W, is nothing more than a narrow channel or flue, for the passage of the smoke and gases from the fire-place to the chimney L. These gases heat the dome N, and thus keep the oxidising-chamber at a sufficiently high temperature to burn the zinc vapours with facility and rapidity. The partitions P, and Q, in the chamber M, are for the purpose of checking the power of the current and facilitating the deposit of the oxide in the chamber M, from whence it is withdrawn by means of openings at the sides.

The patentee, in conclusion, states that he is aware of oxide of zinc having been heretofore obtained by distillation, and bringing the zinc metal and metallic oxygen in an oxidising-chamber; he does not, therefore, intend to claim, generally, producing oxide of zinc in this manner; but he claims, firstly—obtaining metallic zinc in the manner and by means of the apparatus above set forth and described, or any more modification thereof. And, secondly—producing oxide of zinc by distilling the metal, or matters containing metal, in subliming-pots or vessels, furnished with perforated covers, through which the volatilised metal may issue into an oxidising-chamber, where it is met or brought into contact with the oxygen of the atmosphere, and becomes converted into oxide of zinc.
COUNCIL OF HEALTH OF PARIS.

The most perfectly organised Municipal Board of Health hitherto established is that of the city of Paris. The comprehensive system of the Conseil de Salubrité of Paris, the scientific ability and energy of its members, and their fearlessness and devotion in invading the most dangerous and offensive hiding-places of disease, render invaluable the copious stores of sanitary knowledge contained in the Reports of the Council, and the duties of sanitary surveillance became more and more important, at the same time that they became more and more difficult.

At the close of the last century, these duties were delegated by the Lieutenant of Police to two able physicians, M. Pia and M. Cadet a Vaux, to the latter of whom is due the merit of suppressing the Petit Châtelet, the smelting of pig iron discipline, the suppression of cemeteries in the interior of Paris, and of impurit"ure in churches, in addition to many other salutary reforms.

The year 1805 was the epoch of the creation of the Conseil de Salubrité. At that time, the Prefect, whether he had to give a decision on a subject connected with the public health, took the advice of a physician, surgeon, agriculturist, chemist, or veterinary surgeon, according to the nature of the object which engaged his attention. The inconveniences of this method were such, that in July of the year above-mentioned, the Prefect Durocher instituted the Council, under which he composed of four members, who were to examine the adulterations of liquids, diseases of animals, and noxious manufactures. In 1807, the powers of the Council were extended, and the number of members was increased to seven, who were required to meet regularly twice a month. To them was assigned the control of the regulations of markets, rivers, cemeteries, slaughter-houses, seawerage, public baths, &c., medical statistics, and the tables of mortality, the cleansing of public places, the prevention and reparation of the effects of inundations, the repression of charlatanism, and the lighting of streets. The necessity of particular attention to epidemics, induced the Prefect to add two physicians to the number of the members of the Council; other additions have been made from time to time. In order to add to the authority and importance of this body, it has from its origin had the nomination of its own president and secretary, and the privilege of the Prefect to appoint, and to require from any of the members of the Council to supply any vacancies which may occur in the Council.

Some idea of the importance and number of the investigations undertaken by the Conseil de Salubrité during the first quarter of a century after its establishment, may be obtained from the fact that the number of reports of the Council, expressed in Romans of four thousand three hundred and thirty. The number of these reports averaged, annually, two hundred and twenty-five; and in the years 1818, 1819, and 1829, respectively, exceeded $400, $500, and $600. The beneficial effects which have resulted from the establishment of this institution, are best seen in the reports of similar boards, under different names, in foreign countries; and in France, the Prefects of several departments have created provincial Councils of Health, which, but for the distraction of political events, would now probably exist in every important town in that country.

The functions of the Council are consultative, not administrative; but it assumes the responsibility of measures of government founded on its reports. It was re-organised in 1833, by an ordinance of the Prefect, which directs the reduction of its number to 12 members and one non-stipendiary member. The Prefect is president of the Council, and he the numbers, which are printed.

The number of reports addressed to the government, from the year 1829 to 1888, was four thousand four hundred and thirteen. During the first four years, the number was three thousand and eighty-seven. The augmentation of the annual average is accounted for by the growth of the population, which in 1864 was 1,034,606, showing an increase of 100,000 on the return of the census five years previously. Another consideration, which indicates the importance and difficulty of the duties of the Council of Health of Paris, is, that the metropolis affords facilities for commencing many new manufactures long before they can be successfully introduced into the provinces. Paris is the centre of scientific societies and manufactures, and directing the development of mechanical and chemical arts in the capital, the Council of Health does, in fact, solve problems which affect the health of the whole country.

In the present rapid survey of the recent reports of the Association, the number dealt with is enormous; but it is necessary to confine the selection to a few of the more important subjects. The principal reports relate to the adulteration of food, the analysis of bread, the filtration of water, the escape of waste liquids of manufactories, baths, and wash-houses, the refuse of slaughter-houses, tallow-making, the making of ink, &c., the smoke of kilns and cement works, tanneries, and foundries, the cleansing of cesspools, methods of heating and ventilation, the regulation of baths, the purification of street gas, precautions in the manufacture and conveyance of chemical matches, fuses, and fulminating powders, steam-engines, the sale of100,000, metal-gilding, distilleries, remedies against drowning and suffocation, epidemics, and a large number of questions respecting the medical police.

Salt.—In a single year the Council analysed nearly 5,000 samples of salt, which had been taken from different dealers by the police, and found 2,561 samples to be adulterated, the principal ingredients for the purpose being plaster and potash. After examining other samples taken directly from the salt-pits, the Council reported, that when white salt contains potash, calcareous matter, or sand, it is artificially adulterated; that grey salt appears to contain some quantity of potash and sulphate; but that the foreign substances always exist naturally in very minute quantities.

Water.—In 1841, the Council reported on the different systems of purifying the waters of the Seine; a matter of vast importance in Paris, where a large part of the population use water obtained from the Seine and from the numerous public companies supplied from that river. Two well-known public companies employed Smith's process, with filters of sand and charcoal in open vessels, and under a small pressure. The layer of charcoal is between two layers of sand, which again are between two beds of flints. A third company used the filters of Fouville, which consist of alternate layers of sponge, sand, and charcoal, the whole being subject to a pressure of one atmosphere, for the purpose of increasing the rapidity of filtration. Another process, most extensively used, is that of Souchon's, which consists in filtering the water through a number of layers of a woollen tissue, formed of wool clippings placed on the frames forming the bottom of the filter, and spread, by the action of the water itself, in a compact uniform layer. The water passes through five such layers, at which the two lowest are the thickest and remain unchanged for five or six days; the others are changed two or three times a day. The public conduit of Notre Dame is supplied by five of the above described filters.

On a microscopic examination of water filtered by the three different processes, the Council of Health found the water containing an impurity to be that filtered by the Fouville process; next to which came the water filtered by Souchon's process; but the water of Smith's process is the purer. The quality of the water depends, however, not entirely on the absence of matters held in suspension, but also of dissolved organic substances which after a time give a disagreeable taste to the best filtered water. In this respect, the water filtered by the process first described was found to be far the best, as it remained a much longer time without alterations. This result is attributed to the use of charcoal, which is frequently renewed, washed, and dried. The quantity of water filtered daily by Souchon's process is stated at about 320,000 gallons; by Fouville's process at 85,000 to 110,000 gallons, and the other rapidly. A more detailed report of the council of the Seine water has been addressed.

Steam-Engines.—Numerous memorials have been addressed to the Council respecting the smoke, discharge of waste water, noise, and danger of explosions of steam-engines. With regard to the smoke, the Council have principally confined themselves to prescribing the use of fuel giving comparatively little smoke, such as semi-buminous coal; the improved construction and regulation of furnaces, so as to insure as complete combustion as possible; and, lastly, increased elevation of the furnace chimneys.

Gilding on Metal.—In 1819, the munificent price of 3,000f. (300l.) was offered by the Academy of Sciences to M. D'Arcet, for a most successful method of removing the injuries to health produced by the operation of gilding with mercury. The principal sources of these injuries are the volatilisation of the mercury, the disengagement of hypotoxic acid, and the contact of nitric, sulphuric, and hydrochloric acids, mercury, and nitrate of mercury, with the hands of the workman.
The Council provide against the effect of pernicious vapours, by requiring (according to M. D'Arcey's system) the construction, for all the operations in which vapour is disengaged, of a flue having a strong upward draught, and an opening only just large enough to admit the execution of the work. Air-valves are to be used to prevent the escape of gas in the chimney, and the flues are to be covered with mercurial soot, and often filled with acid or mercurial vapour; and the height of the chimney is required to be sufficient to prevent the deleterious effects of the vapours upon the inhabitants of the neighbourhood of the manufactury.

Street Gas.—The odoriferous street gas is due to hydro-sulphuric acid, free or combined with ammonia or pyrogenous products. When the sulphurated hydrogen and hydro-sulphur of ammonia reach the burner, the combustion converts the sulphur into sulpheric acid, which exercises a deleterious influence on health.

It is curious, that in this respect, the provincial towns of France exhibit an advantage over the capital. In many of the former, gas is delivered to the consumer free from sulphurated hydrogen and ammoniacal gas. By proper management, the process of purification may be rendered complete, and will give, in place of a residue of valueless lime, a product valuable for chemical and agricultural purposes. A commission appointed to examine the process of M. Mallet, which has been successfully employed at Bouloge, Abbeville, and other towns, reports, that his method consists in passing the gas, before it reaches the lime, through chloride of sodium or slaked lime, which is reduced to a state of solution by the pressure of the gas, and leaving others in solution in the liquor in which the gas is washed. The separation of the sulphuric and free carbonic acids is subsequently effected by lime, of which a much smaller quantity is required than in the old method. There are, however, the advantage of utilizing a substance otherwise valueless; for the salts of manganese which he requires are the refuse of numerous kinds of manufactures, where it has been hitherto a useless incumbrance. In localities however, where it cannot be procured, sulphate of ammonia, or potassium sulphate, may be substituted. Moreover, either substance, after being used as the gas-works, furnishes a valuable chemical product—muriate of ammonia, or sulphate of manganese.

Sanitary Police.—At the instance of the Minister of Agriculture and Commerce, the Prefect of Police submitted to the Council the important question whether the bodies of persons deceased in the colonies, of such diseases as plague, typhus, yellow fever, or cholera, could be conveyed to France with safety. The Council replied unanimously in the affirmative; pointing out, at the same time, certain measures of precaution, founded on a singular experiment made by some of its members who had been sent to Egypt upon a commission for the purpose of examining the nature of the plague. All the persons on this commission wore next their skin, for a whole day, without inconvenience, clothes infected by the plague, and impregnated with pus—the only precaution taken being to soak (notes for a certain time) in chloride of sodium with this mixture:

A Report on the effects of the Cholera Morbus in Paris was made by special commission, consisting principally of members of the Council of Health. From this document, published in 1854, and returns made to the commission, the following particulars are deduced:—The cholera appeared nearly simultaneously in Paris and the departments, and its duration was the same in both (March to August, 1832.) The mortality was greater among women than men. The ages which suffered least were those from 6 to 20 years. The total mortality in Paris due to cholera was 16,456 persons, or 252 per 10,000 of the total; and the mortality was most felt during the month of July, and in localities where the population was poor and the air confined. The excesses to which the working population of Paris give themselves up on Sunday, appear to have produced an augmentation of 178 in the number of admissions into the hospitals on Monday. The military throughout the country suffered in the proportion 25:56 to a thousand, which exceeds the corresponding proportion (21:83) of the civil population. In some districts infected by putrid emaciation, the disease was not more destructive than where the air was purer. Up to the 1st of August, the total mortality was 17,072 persons. The city of Paris and the vicinity of the Hôtel de Ville the mortality was truly frightful, and may be readily traced to the filthy condition of those parts of Paris. In many of the houses, the walls were blackened by the damp exhalations of unclosed cesspools; the pipes from these were in odour, and disclosed their contents on the raised staircases. In some cases these pollutions escaped into the living-rooms, and, in many, the only access of air and light was from a court, 3 feet in diameter, the bottom of which was used as a common receptacle. Added to this, a large part of the population of these quarters constitutes the very dregs of society, and subsists on the fruits of dishonesty or debauchery. The retribution which in the case of these persons followed the violation of the laws of society, may be estimated by the fact, that in the lodging-houses of the 7th, 9th, and 12th Arrondissements (the worst parts of Paris), the number of cases of cholera was 1 in 9, and the deaths 1 in 19.

The annual mortality for 10 years previously was 25,300; so that the mortality in 1852, exclusive of cases of cholera, exceeded the annual average. The total duration of the disease was 27 weeks, from the 26th of March to the 30th of September (from one equinox to the other).

The report from which the above particulars are taken, concludes with an earnest appeal on the part of the commission for those sanitary reforms of which their inquiries have revealed the necessity. The statistical returns furnished them with appalling details respecting the filth, indigence, and neglect of a large part of the population. Among the measures specifically recommended are, that no new street should be built less than 40 feet wide (the present average is 22 feet); that the height of the houses should be limited; that public conveniences should be constructed; for open gutters, under-ground pipes communicating with the sewers should be substituted; that there should be an increased supply of gas for public illumination; that the rents of lodgers should be at a rate of 7 litres for each person, the corresponding rate in London being 62 litres; and finally, that as far as possible the centre of Paris should be rendered more open, by new streets and public promenades, sufficiently spacious to be planted with trees.

The following summary of the proceedings of the Council in one particular class of their duties, will give some idea of the extent of their whole labours:

Year. | Manufactories licensed | Including locomotives & steam engines.
--- | --- | ---
1840 | 199 | 64
1841 | 194 | 68
1842 | 361 | 97
1843 | 402 | 95
1844 | 407 | 103
1845 | 387 | 90
1846 | 408 | 95

RAILWAY RESCUE.*

It is a gratifying proof of railway progress, that attention is now more strongly directed to the means of running light trains. The most distinguishing fact in the beginning of the Liverpool and Manchester Railway contest, lightness of the engine was considered the great essential; but for a long time, there was an exigency which demanded all the energies of engineers, and that was—increased speed. When we recollect how very moderate were the expectations of most parties, as to the rate to be run by a locomotive; when we recollect that ten miles an hour was treated as an extravagance, and that superiority over good coaches was doubtful. When railways were started, twelve miles an hour was got by good coaches, and for posting a higher speed; and the locomotive engineer had to get such a velocity for the railway, as should give it a decided superiority over all rivals, and overcome by force the prejudices which were entertained against railway travelling altogether. The engineers put their strength in getting a higher speed, and it must be borne in mind that they were the more pressed to do so, as propositions were then put forward and experiments made, showing that a high speed for passenger travelling could be got on canals, and there were several plans for putting locomotives on the tow-paths of the canals. The steam-carriage was then on the road, and in better favour; and it was necessary to get on the rails that which steam-carriages could not do; but be run on the turnpike roads.

Provided speed was got, whether by an increase of weight or expense, it mattered not: and it was got, and every year has added to the weight; but we are prepared thereby for a new era. By these great exertions, not merely the weight has been increased, but the increasing power, and the economy of working has been greatly promoted.

If the locomotive engineer had his attention absorbed and

---

The total number of deaths in Paris, in 1832, was 44,110, of which 16,456 were due to cholera, leaving 25,717 arising from other causes.
drawn in one direction, so it was with the railway manager. He had to provide for the traffic which first came in his way, and for the demands of the wealthy and commercial classes, for greater accommodation. As yet, this is all that has been done; and although some saving has been made, yet one of the original objects of the railway system—cheap transit—has not yet been accomplished.

A comparatively low speed is the most economical for passengers and goods, but railways have not yet been able to give the accommodation implied by this condition. To suit their general traffic, and to work with safety, they have been obliged to work at a nearly uniform speed—which has, of course, been a high one; but with the resources afforded by the electric telegraph it appears possible to introduce slow and cheap trains. We long since pointed out in this Journal, the plan of running trains at various speeds, which was some years ago advocated by the Railway Chronicle; and we are glad to see that the principle of it has now been more widely adopted.

The pamphlet now before us advocates lighter engines, lighter stock, and lighter works; but it seems that this is to be accompanied by getting rid altogether of the present high speed. There can be no doubt that express trains damage the rails, points, and switches, most seriously; but we cannot now turn back.

The present pamphlet, although it is crude and short-sighted in some of its views, contains a great deal of valuable matter, and in the main point of lighter stock and cheaper trains, is calculated to do very much good. We, therefore, particularly recommend it to our engineering friends.

The following are the author's opinions as to the discrepancy in between rolling stock and rails:

"If there be any doubt expressed as to the discrepancy of strength between the rolling stock and the rails, a very plain answer may be found in the fact of the increasing weight of engines and rolling stock. If the present proportions of the periphery of a locomotive driving-wheel be compared with the rail beneath it. The former weighs upwards of 200 lb. per yard; the latter from 70 lb. to 80 lb. Yet the former is of an arch form, supported by the spokes at intervals of nine inches, while the latter is a solid, flat beam, supported at intervals of thirty-six inches, which wholly deflect beneath the passing load and destroy the continuity of support. To make a perfect railway, the rail-bar should be of sufficient vertical depth to resist all deflection, with the heaviest load passing over it. More than this, it should be sufficiently resistant to the points of the car wheels to prevent them from being so re-inforced as to be entirely inelastic with the solid part of the rail. None of these conditions are yet attained as regards the modern class of engines, and it is a problem whether they can be attained at all. Even as there is a limit to the height of architectural structures relatively to their base, by reason of the friability of the material, so there is a limit to the weight of engines, by reason of the compressibility of iron and the impossibility of increasing surface-bearing; for whether a driving-wheel be of three feet or eight feet diameter, the road can never be wider, or that which geometers call a "bowing point," viz., a line. Iron, according to its density, will bear a given weight without compressing, the point of contact being a line. When iron has done its utmost, steel may be resort to; and, provided there be good, deep, vertical section, of a surface of hard steel three inches in width and three quarters of an inch in depth, supported by cross sleepers at intervals of eighteen inches, might be available to construct a real "permanent way,"—for the modern engines."

"Partial use of cast-iron rails, it is now said, is "permanent maintenance of way" in a practical fact, as shareholders' pockets can testify."

You, gentlemen, will doubtless be startled at the contemplation of the outcry of capital involved in the real permanent way before described. If you will not agree to this proposition, you must "try back." You cannot suit the road to the wheel; you must suit the wheel to the road. Having the fear of "no dividends" before your eyes, you must turn to the practical maxim of the Manchester and Liverpool directors of old, gathered from the experience of the road, and keep down your weights. Light horses for the high speed, for the fast, fast freight. Then build the stations with small waiting rooms, a few policeman and porters, and clerks, a slight increase of drivers and stokers, and a huge decrease of plate-layers, and a reduction in iron invoices, would do more for your dividends and the public accommodation than the present system of electric traction. It will find footing—a power developed and wasted. For it must be obvious that, after expending millions to secure "good gradients," a deflecting rail be laid down, it is equivalent to converting them into bad gradients. In water-transit a steam packet is superior to an electric locomotive. In rail transit, a locomotive drives a wave of rail before her driving-wheels, equivalent to ascending a constant incline, and demanding a far greater expenditure of steam-power to surmount it. The difference in the two cases is, that if it be a question of surmounting a constant incline, the locomotive, whereas in the case of the rail it is a practical surmount the difficulty altogether by proportioning the load on the wheel to the strength of the rail.

The wave line of the rails might fairly be adopted as a standard in estimating the value of a railway; for in proportion to the depth of the wave will be, cataract paribus, the power of steam and the cost of coke. You must be aware that, to ascend a constant hill, requires more horse-power than to surmount a constant incline. You must surmount a constant incline. Should you use a wave line, you would escape the expense of fifty miles of the most expensive part of the line. If your drivers and ostlers and road trustees increase the consumption of coke, the coach will soon be run off the road.

But even wave lines vary. For example, rails laid on longitudinal timbers, as they are in Germany, yield a wave line. If rails laid on chairs and transverse sleepers make unequal waves at their mid-length and at their joints. The result is concussion as well as sinking, and the loss of power is greater. Mechanical men having their living to get by the prevention of faults, and the economy of steam, are, in the great majority of cases, opposed all this, for they carry the safety-valve in their own breeches' pockets but it does not so readily occur to railway directors. Let them maintain a standard gauge—the wave of the rails. Perhaps as an additional stimulus you will take into account the somewhat startling fact that a pair of the largest railway locomotives would furnish power enough to supply pumping stations in works in London. Another pair might achieve the tasks of delivering it into their attics instead of the ground-dwells of the London dwellings. Another pair might pump up all the sewage water south of the Thames, as Mr. Chadwick will inform you.

Smelting Copper Ores.

Description of the process of M.M. Rivot and Phillips, for smelting copper ores. (From a paper read before the Society for the Encouragement of Manufacture. Pa. 1846.)

In a visit to England in 1815, one of us became acquainted with the experiments made in an English copper-works, to extract the metallic copper by means of the action of voltaic electricity, from previously roasted sulphur-ores of copper. The information we obtained was the same as that before the Society as descriptive of the process employed by M. Napier.

The sulphur ores were first well roasted, then smelted in a reverberatory furnace, and the copper brought to a metallic state by passing through the furnace an electric current. We described a very powerful voltaic current; the graphite hearth of the furnace, and a plate of cast-iron kept at the upper part of the melted mass, forming the remaining part of the voltaic current. After several ineffectual attempts, we succeeded in passing more than two hours, a constant current through a crucible containing sulphur of copper at a red heat.

In a common Hessian crucible, we placed two small pieces of compact coke, kept at a little distance by well compressed luting; and in these we plunged two platinum wires communicating with the two poles of the battery. The platinum wires were preserved from the action of the sulphur by the pieces of coke and the luting. We found in these direct experiments, that coke is a good conductor at a red heat, and that the luting conducts but a very little at that temperature.

Tubes, fixed in two notches of the crucible, had for their object the purpose of communicating with the two poles of the battery and the platinum wires, a point of essential importance on two accounts:—First, the burning charcoal would have established a communication between the two poles of the battery outside the crucible, and consequently, a large portion, if not the whole, of the current would have been diverted to the fused mass. Secondly, the alkaline ashes of the wood charcoal would have rapidly attacked the platinum wires, and the current thus has been interrupted. The copper wires closing the circuit communicated with a galvanometer, the needle of which indicated by its deviation the energy of the current. We employed constant batteries with copper and zinc elements, and solutions of sulphate of copper and common salt, of six to twenty-four couples, and sometimes only one Hessian battery of thirty elements.

By employing a Hessian battery of thirty elements, producing a deviation of the needle of the galvanometer of 45 to 50 degrees, we have reduced a notable quantity of copper in a state of fusion; but the largest proportion of the sulphur remained unacted.

After having produced the fusion of twenty-four couples of the voltaic battery, producing a deviation of the needle of the galvanometer of 35 to 40 degrees.

In a vessel containing the water of the battery, the water action of the battery is feeble as regards sulphur of copper, and that the very powerful voltaic current requisite for effecting the decomposition, as well as the difficulty of conveniently disposing the apparatus, would prevent the employment of this process for the production of copper, the proportion for that of pyritic copper, which is the most common ore of copper.

Experiments analogous to the preceding, in which we replaced the two poles of coke by rods of iron, have indicated to us that the action of the battery renders more rapid, but not complete, the reduction of sulphur of copper by the iron. It always forms a mass, rich in copper.
The action of the battery, aided by that of the iron, separates from the sulphuret of copper but a very small proportion of copper.

In the experiments made (melts of lead), this mineral presented the same characters as the sulphuret of copper. We also found always a great loss in the crucible traversed by the voltaic current, due to the volatilisation of the metal. These experiments clearly demonstrate that the action of the battery, even on the poor iron, could not serve as a process for the direct treatment of the sulphurous ores of lead or of copper.

We then repeated the experiments of M. Napié, and endeavoured to reduce the oxides of copper and iron by electrolysis. (3) The direct passage of the electric current was found quite sufficient; and numerous experiments proved to us, that by the action of iron alone, a silicate of copper, containing besides oxides of copper, other bases, such as soda, lime, oxide of iron, &c., gave up in less that half an hour of the fire, the whole of its copper united in a button of complete purity.

It is thus that we have been led to search in the action of iron, the principle of the reduction of oxide of copper. We have made several experiments in crucibles, in order to determine the circumstances most favourable to the action of the iron. The following are the principal results which we obtained.

In our crucible were arranged two or more iron rods, disposed one at the bottom, and of the others in the lining. The material employed was either roasted pyritic copper, or a mixture of oxide of copper, oxide of iron and sand; to these we added fusible, soda, or lime, or even chalk only. By employing soda as the flux, we were able to reduce the oxide of copper one-half of the time. At a quarter of an hour's fusion, the copper obtained was chemically pure. With chalk, the complete reduction required one hour's fusion. The copper produced contained much iron (often 13 per cent.) when the iron was added to the bottom, the crucible and the crucibles, was always very pure when the rods reached but a little way above the bottom. The time necessary for the complete reduction of the oxide of copper, was more or less great in proportion to the number of iron rods employed.

Saturated with these results, we constructed a reverberatory furnace capable of containing about 250 kilogrammes (56 cwt.) of fusible metallic silicates, and presenting no other peculiarity of construction than having six or eight iron tubes bored through the six or eight faces of the furnace. The use of these was to maintain in the fused mass six bars of iron of 8 to 9 centimetres (2 3/4 to 3 1/4 inches) wide, and 70 centimetres (28 inches) long. These bars thus act on a large portion of the melted mass, were not in contact with the copper, were readily put in and removed, and we were able to stir the melted mass between the bars, in such a way as to render it homogeneous, and renew the parts in contact with the iron. We have treated in this furnace, more than three tons of the pyritic ores of Cornwall, Germany, and Spain, all previously carefully roasted. This complete roasting is easy enough when the ore is ground with fine sand; it is done with ordinary precaution, but should be finished with a brisk fire. In the experiment, we were assisted by fusion of the bars to the time and poor slag; and when the furnace complete, we applied six bars of iron, which were allowed to remain during four hours. After this time, we removed the bars and ran out the metal. In operating thus, we have always estimated the consumption of iron from the pressure of the slag, pointed out as sufficient for the reduction of the oxide of copper. The slag retained from 2 to 3 per cent. of copper. We attempted to smelt this slag by itself, and acted upon it with bars of iron for four hours; the result was that we obtained new slag, equally rich in copper with the former; and this, notwithstanding that the bars lost several kilogrammes of weight. This oxidation of the bars of iron could not be attributed to the air of the furnace which had not served for combustion, since the bars were constantly and entirely plunged into the fused material, but was evidently due to the peroxide of iron contained in the metallic silicate, and which would be brought by the iron to the state of protoxide before the oxide of copper could be completely reduced by the iron. This we have verified by the consumption of iron in the absence of copper lost in the slag, by adding to the action of the iron that of charcoal or coal. The carbonaceous material might be employed in two ways. First, mixed with the waste ore, secondly, added after complete fusion, to the compound formed of the fused silicate. In operating in this last manner, we were soon convinced that the charcoal acted but slowly and feebly in the fused silicates, because it floated on the surface of the mass, and could not be kept within it. Nevertheless, its action is of some account. When the mass in its fusion attains the quantity of poor coal, we always observed a rapid augmentation of its fluidity, explained only by the reduction to the state of protoxide of iron, of a considerable quantity of the peroxide. The consumption of iron being very great, we next examined the carbonaceous matter, when mixed with the roasted ore before charging the furnace. After several trials, we have adopted as the most convenient proportion of charcoal, or small coal, that which is required to produce an almost fluid mass, which is accomplished with the oxygen of the oxide of copper, and that combined with the protoxide of iron in the roasted ore. This proportion gave us, without employing the action of iron, a slag containing 21 per cent. of copper. We have proved by several trials (1.) that this proportion of charcoal need not be rigorously adhered to; and that it may be either increased or diminished, without occasioning any considerable increase of copper, or the quality of the copper altered. (2.) That in increasing much the proportion of charcoal mixed with the ore, and in raising the temperature of the furnace to a bright white heat, we could always bring the last demand to such a point, that the metal did not contain more than 2 or 6 per cent. of copper: but then the copper contained 8 to 10 per cent. of iron. By operating at a lower temperature to that strictly necessary for fusion, we obtained a slag rich enough in copper, and still containing 8 to 6 per cent. of iron: a slag containing 2 or 3 per cent. of copper, is powerful and rapid; and that three hours are sufficient to bring the slag to such a state that it shall contain only 2 or 3 per cent. of copper, the copper obtained being at the same time of the quality which we require. In practice, these operations were developed, and the manufacturing process of the furnace so arranged as only to make the changes, the protoxide of iron and the lime, we endeavor to produce a basulicate, containing 13 to 15 per cent. of lime. Experience has pointed out, that a basulicate of protoxide of iron, one base only, melts very quickly and acquires a great fluidity, but readily gives a copper containing much iron.

After charging the furnace, we throw on the surface of the mass one or more bars of iron, and proceed, as above, until the mass is completely free from oxidation by the flames of the furnace. We stir the mass from time to time, in order to enable it to heat more uniformly, and melt quicker. We sometimes succeed in melting completely in four hours. As soon as the mass is fluid, we draw it to the bottom of the crucible, and in the meantime, we have employed a two-pronged rake (very convenient) to clean the surface of the iron-barn immersed in the slag. We then proceed to force the copper into the melted mass, by means of a powerful wooden pole, which, plunged into the slag, gives a considerable disengagement of gas, and produces a strong frothing up. The appearance of the slag furnishes but little indication of the progress of the reduction of the metal; we have however, proved that trials made with a cold rake, plunged for a moment into the fused mass, always presents on contact with the iron, a reddish metallic tint, strongly marked where the slag was rather rich; a tint which, on the contrary, was scarcely discernable when the slag contained more than 3 or 4 per cent. of iron.

We have always examined the slag swimming on the copper at this moment of the operation, after having carefully stirred the mass as soon as to produce slag of a homogeneous quality, and found it to contain 2 to 3 per cent. of copper. When the whole is well melted, we place six bars of iron, weighing altogether from 30 to 45 kilogrammes (84 to 165 lbs.), fixing their ends in the grooves in the side of the furnace opposite to the door, taking care to plunged them entirely into the melted mass. We then proceed to force the copper into the melted mass, to prevent the peroxidation of the protoxide of iron by the flames; then, from half-hour to half-hour, we stir with a two-pronged rake (very convenient) to clean the surface of the iron-barn immersed in the slag. We also employ a powerful wooden pole, which, plunged into the slag, gives a considerable disengagement of gas, and produces a strong frothing up. The appearance of the slag furnishes but little indication of the progress of the reduction of the metal; we have however, proved that trials made with a cold rake, plunged for a moment into the fused mass, always presents on contact with the iron, a reddish metallic tint, strongly marked where the slag was rather rich; a tint which, on the contrary, was scarcely discernable when the slag contained more than 3 or 4 per cent. of iron.

We have always found that three to four hours are sufficient to remove the copper from the slag up to 2 or 3 per cent. After this interval of time we draw out the bars, and run off the metal. The duration of one entire operation depends on the heat of the iron bars, and the number of times they are conducted in one day. The loss in weight of the iron bars varies in our experiments from 1 to 6 kilogrammes (24 to 13 lbs.), for quantities of copper of 12 to 42 kilogrammes (27 to 94 lbs.) obtained from ores of various qualities. This loss is independent of the richness of the ore, and the consumption of the iron is proportionally less for the rich than the poor ores. For the pyritic ores of Spain, containing 21 per cent. of copper, we have consumed 11 parts of iron for 100 of copper obtained. The English ores which we have melted contained 7 per cent. of copper, 4 to 6 per cent. of arsenic, a small portion of antimony, and some traces of tin; from these we have obtained an impure black copper, containing 3 to 5 per cent. of arsenic, 2 to 3 per cent. of tin, and only a few thousandths of sulphur and iron. This result has not surprised us; the arsenic can only be completely driven from the mass by a number of operations of roasting and reduction. Thus, we do not propose the application of our process for the treatment of ores containing much arsenic or antimony,—as, for example, the grey copper ores. With the pyritic ores not containing arsenic we have always obtained a pure black copper, containing only from 2 to 3 per cent. of sulphur and iron.

The roasting has a certain influence on the quality of the copper, and on the consumption of the iron. With well roasted ores we never had a deposit of scales on the copper, and it was always perfectly roasted. The copper contained not the least iron, and less than 1 per cent. of sulphur. The consumption of iron was much less with well roasted ores, and the final slag less rich in copper. The temperature which we have adopted as the most convenient, is that which is strictly that which causes the decomposition of the slag. The carbonaceous matter renders the action of the iron on the silicate of copper more rapid and energetic; but the coal reduces more easily a part of the oxide of iron combined with the silica. In operating in the same manner, on the same mineral, at a well-regulated tempo-
THE CIVIL ENGINEER AND ARCHITECT'S JOURNAL.

The consumption of coal employed in our furnace will not give a great indication as to the quantity which would be required in a large reverberatory furnace kept in constant operation. We can, however, give a calculation of sufficient approximation from the consumption of the large copper furnaces in Wales.

The ores to which our process may be applied with the greatest advantage are the pyritic or pyritic ores and a gangue of pyrites or oxide of iron; they are not, by any means, copper of excellent quality, as at present treated, yield a black copper containing much iron. Our process is also readily applicable to all the ores of copper which do not contain too much arsenic or antimony. The process which we have described offers several marked advantages for the production of this metal in ordinary furnaces. It is rapid and economical, since by one single fusion we obtain a slag sufficiently pure to be rejected, and all the copper in a state of sufficient purity to be sold after one smelting, or at most a short refining. It requires no difficult manipulation, and the workmen can readily understand the way of conducting the operations. The complete roasting of the ore is not a new operation in metallurgy; it is easily accomplished when the ore is ground with sand of sufficient fineness; it requires tact and attention on the part of the workmen, and should be finished by a good stroke of the fire, in order to drive the sulphurates formed at a lower temperature. We have previously pointed out that the principal inconvenience of an incomplete roasting is, in the smelting, a greater consumption of iron, and a less complete removal of the copper from the slag in a given time. A good roasting furnace should contain 25 tons of copper; 11 tons of iron; the slag can be obtained from 13 to 24 hours. For the smelting, the furnaces should be similar to the large reverberatory furnaces of Wales, and contain for a charge 64 cwt. of ore. There should be three smelting furnaces for four roasting furnaces, supposing that the whole of the ore may be conducted in the smelting furnaces daily. The refining of copper of the first smelting may be done in a furnace containing four tons; an operation which does not require more than 12 hours. To give an idea of the principal materials necessary for the construction of a certain quantity of copper, we will suppose that we have to treat a pyritic ore of copper with a gangue of pyrites or quartz, containing at the most 15 per cent. of copper. To produce per annum 100 tons of copper, there will be required two pairs of stamping mills, twelve roasting furnaces, six smelting furnaces, and one refining furnace. We have also added the action of iron on the metallic silicates in fusion to the treatment of sulphate of lead, but less successfully than in the case of copper ores. These trials have been made on a large scale in a reverberatory furnace capable of containing 24 cwt. of material.

To the dry sulphate of lead, we added sand, a little chalk, the slag of a preceding operation, and about three per cent. of charcoal. A larger proportion of charcoal always gave a little sulphur of lead with the metallic lead. We charge the furnace, and heat it so as to affect an entire fusion for the space of 16 hours. We then throw into the fluid mass, at three or four times, iron turnings, which replace to great advantage the bars of iron. The proportion of cast-iron turnings necessary is about one-eighth of the weight of the dry sulphate of lead. We stir the mass very frequently, and after four or five hours' heat, the iron, lead, and copper will be thrown together in this manner, 43 to 48 parts of lead from 100 of sulphate of lead. The loss, therefore, of metal was considerable, which was due in great part to the volatilization of the lead, the fumes of which were evident at the top of the chimney; this volatilization principally took place during the stirring and the charging. We notice this application of our process to the reduction of sulphate of lead, because it proves that iron acts very rapidly on the silicate of lead, and that this action might be employed under certain circumstances.

To complete the description of the process for the metallurgical treatment which we propose, we now proceed to give an estimate of the probable cost of the treatment of copper ores. We base this estimate on the duration of the operations in the reverberatory furnace in which we have treated the ores of copper and the sulphate of lead; on the consumption of coal in the large smelting furnaces in Wales; and on the consumption indicated from our own experiments.

To compare this process with that adopted in the greater number of copper-works in England, we have adopted the figures given by M.M. Dufrenoy, Élie de Beaumont, Costa, and Perdusson, in their "Voyage Métallurgique en Angleterre." We will reckon for the cost of 1 ton of pyritic ore having a gangue of quartz and iron pyrites. For the refining, we calculate the expense for one ton of copper.

**RIVET AND PHILLIPS' PROCESSES.**

First Operation—Grinding of the ore.

For one ton, 1/50. 3. 3d.

Second Operation—Roasting of the ore in furnaces containing 36 cwt.

Duration of roasting process, 18 hours. (We may remark that for the roasting, the lost heat from the smelting furnaces may be very well employed, as is done in some English works.)

Labour, 14 days @ 2 francs... 3 fr.
Coal, 6 cwt. @ 1 fr. 6 cwt. 5.

Total.... 8 fr. 5 c.

Third Operation—Smelting of the roasted ore. Furnaces containing 14 ton of ore (weight of crude ore). Duration of operation, eight hours. Consumption of coal per hour, on an average, 120 kilo = 2 cwt. 1 qr. 16 lb. The iron is put at 25 fr. the 100 kilo = 20s. the 2 cwt.

Labour, 0-87 days @ 2 fr. 11 c.
Coal, 640 kilogrammes @ 1 fr. 6 c.
Iron, &c. 9.

Special expenses... 17 14 = 13s. 8d.

This operation gives all the copper contained in the ore in the state of black copper, containing but a very little iron and sulphur.

The special expenses of the treatment of one ton of copper ore of ordinary quality, 6 to 30 per cent. according to our process,

Grinding... 1 50.
Roasting... 6 00.
Smelting... 17 14.

Total.... 24 64 = 18s. 4d.

Fourth Operation—Refining of the black copper obtained by smelting.

In a furnace containing 4 tons of copper. Duration of the operation, 72 hours. Mean consumption of coal per hour, 3 cwt.

Labour, 1/2 day @ 2 francs... 1 c.
Coal, 14 cwt. @ 1 franc... 1 50.

Total.... 3 0 2 6.

For one ton of copper,

Labour, 600 kilogrammes @ 1 franc... 18 fr.
Labour, &c. 3; c.

Total.... 42 fr. = 33s. 2d.

Difference in favour of our process, 14 francs (11s. 8d.)

For one ton of copper and for the ores ordinarily treated in Wales, the difference in the special expenses of the treatment is 175 francs (7l.).

The Society for the Encouragement of the Arts and Manufactures, and the Academy of Sciences, have both reported favourably on the process of M.M. Rivet and Phillips.

---

**FALL OF RAIN.**

Having been present at a meeting of the Royal Society of London on the evening of the 18th of May last, when a valuable and interesting paper was read, "On the Meteorology of the Lake Districts of Westmoreland and Cumberland," by J. F. Miller, Esq., of Whitehaven, in which paper the following remark occurred:—"It would be premature, from the scanty data before me, to draw any conclusion as to the gradation in the quantity of rain, at these great elevations above the sea. But it seems probable that, in mountainous districts, the amount of rain increases from the valley upwards, to an altitude of about 3,000 feet, where it reaches a maximum; and that above this elevation the quantity rapidly decreases. The table for 1840 exhibits the rain fall of the summer months only; but the additional returns of 1847, obtained in every variety of season, confirm the above deductions in every essential particular, so that we may fairly assume the combined results to be indicative of a physical law, so far as it relates to the particular locality in question."
I am desirous of laying before the Royal Society certain observations made at my own direction, which lead me to differ from the author of that paper in the conclusion he has deduced from his facts.

Mr. Miller kindly furnished me some time since with many, if not all, of the results of his experiments in these districts up to the beginning of March last. I have been convinced that his own observations would bear out the conclusions suggested in the quotation above made, because this conclusion is in direct opposition to the recorded observations of the Honourable Daines Barrington, F.R.S., Dr. Dalton, Professor Dauell, Samuel Marshall, Esq., of Kendal, and John Fleming, Esq., of Manchester, and also to observations made in 1841 by Captain Leofroy, then Director of the Observatory at St. Helena; the results of which observations were published in 1847, by order of Her Majesty's Government, under the supervision of Lieut. Col. Sabine, F.R.S., at the result of "Observations made at the Magntetical and Meteorological Observatory of St. Helena."

The Honourable Daines Barrington, F.R.S., states in the "Philosophical Transactions" for 1771, page 394, that in 1779 he caused a rain gauge to be fixed, which received 6 feet 1 inch more rain than the lowest of all at the bottom of the mountain. It is true that he states, that even when more than 6 inches fell at the bottom of the mountain, the gauge found rain in quantities less than 6 inches at the bottom; but it also appears that the quantity of rain in a low situation is greater than in an elevated situation in the vicinity."

Dr. Dalton, in the "Memorial of the Literary and Philosophical Society of Manchester," vol. iv., New Series, p. 286, states, "It has been ascertained more rain falls at the bottom of a mountain than on its summit. Samuel Marshall, Esq., of Kendal, also states, in a communication published in 1839; in the Transactions of the Meteorological Society, vol. ii., p. 115, that the lowest station established on this mountain, has shown that more rain falls in low situations than in more elevated ones, even when contiguous.

And more recently, John Fleming, Esq., states, in the "Memoirs of the Literary and Philosophical Society of Manchester," vol. ii., Second Series, p. 232, that "On the descent of the hill, and probably about the foot of it, the heaviest rain will fall." In the observation made at the Magntetical and Meteorological Observatory of St. Helena, before alluded to, it is stated, "Rainfall at the surface of the earth made in 1841, Captain Leofroy, then director of the observatory at St. Helena, established rain gauges at three other points of the island, for the purpose of ascertaining a comparative estimate of the quantity of rain. The stations were—1. Near the highest pinnacle of the island, on a very narrow ridge or rock; 2. Lower down on the same ridge of hills; 3. Longwood observatory; 4. James Valley. The three first stations might be comprehended in a circle of one mile radius, and the fourth is but little more distant. The quantities of rain received at these stations, during nine months of 1841, were as follows:

<table>
<thead>
<tr>
<th>Station</th>
<th>Quantity of Rain (inches)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. 1841</td>
<td>foot of the hill, 22.33</td>

<td>43.92</td>
</tr>
<tr>
<td>4. 1782</td>
<td>7.03</td>
</tr>
</tbody>
</table>

This table shows that at 1782 feet elevation, much more rain fell in a given time than at the higher elevation of 1901 feet. The reason why so small a quantity as 7.03 inches only was recorded in the same time at 414 feet elevation, is not very apparent; but it would probably be found, upon examining the local circumstances in the position of the gauge, and not to its elevation—a conclusion to which I am led by an examination of the localities, compared with the quantities of rain collected in Mr. Miller's experiments.

In a Report which I have recently published, "On the Supply of Surplus Water to Manchester, Salford, and Stockport," p. 70, I have shown that, during the past year of 1847, I had four rain gauges fixed, one at the bottom of Todd's Brook Valley, situated in Cheshire, near Whalley, three at the top of the hill hording this valley, 1,500 feet above the level of the sea, and the other at the bottom of the hill, and 58.99 inches in depth was received at the bottom of the hill, and only 28.36 inches at the top of the hill. Since the report just referred to was published, I have been favoured by Thomas Hawkesley, Esq., C.E., with the results of some important unpublished observations made by him for the Corporation of Liverpool, on the amount of the fall of rain at Rivington, and in the Valley of Riddlesworth, near Bradford, in Lancashire. In a year's rain, ground, were fixed in these localities at the beginning of January, 1847, at Rivington, and three in the Valley of Riddlesworth.

The quantities falling per month are shown in the following table, and also the monthly fall for January, February, and March, 1848, all of which proves the same general fact, that more rain falls at the bottom than at the to of the hills in these localities.

The gauge at Comb's Reservoir is a cylindrical gauge, 7 inches diameter, and 15 inches above the level of the ground, and has a float and staff to indicate the amount of rain falling; this gauge probably shows an excess of the amount of rain.

The gauge at Dood's Reservoir is a cylindrical gauge, 7 inches diameter, and 10 inches above the level of the ground, and has a float and staff to indicate the amount of rain falling; this gauge shows an excess of the amount of rain.

The gauge at Todd's Brook, (before referred to), during this period, was 13.03 inches in depth, and at Brink's, the top of the same hill, only 11.51 inches.

The amount of rain received in the rain gauge placed near the bottom of a hill at Todd's Brook, (before referred to), during this period, was 13.03 inches in depth, and at Brink's, the top of the same hill, only 11.51 inches.

The amount of rain received in the rain gauge at the bottom of a hill at Todd's Brook, (before referred to), during this period, was 13.03 inches in depth, and at Brink's, the top of the same hill, only 11.51 inches. The amount of rain received in the rain gauge at the bottom of the hill, was 19.70 inches, and in the gauge at the top of the hill only 10.45 inches, as shown in the monthly report of the observations made with all these gauges which are given in the following table:

Upon examining Mr. Miller's facts, it will be found, from April to December, 1846, both inclusive, that at Whitehaven, 90 feet above the level of the sea, 38-063 inches fell; while at Round Close, 480 feet above the sea, and not far distant only 155-92 inches fell in the same period, chiefly at April, when 42-92 inches are recorded to have fallen at Whitehaven, and only 42-023 at Round Close.

On examining with reference to locality in a similar manner the rain gauges placed in the Valley of Borrowdale, or Derwent Water, in which vale the quantity of rain gathered by Mr. Miller's rain gauges at different altitudes are recorded by Mr. Miller, namely, one at Seatwaite, 242 feet above the sea; one at Sty Head, 1,220 feet high; one at Sesteroller, 1,334 feet high; and one at Sparkling Tarn, 1,906 feet high; it will be found, as shown in the following table, where I have drawn up from a careful analysis of Mr. Miller's experiments as communicated to me by himself, taking the longest period during which he has registered experiments at each of the localities, that from June 1846, to November 1847 inclusive, 193-69 inches fell at a level of 242 feet above the sea, while at the greater elevation of 1,906 feet, a less quantity, or 164-12 inches fell; at the greater elevation still of 1,334 feet, a still smaller quantity, or 155-75 inches. The last example, however, at an elevation of 1,906 feet, shows that 183-47 inches fell in the same time, being, in this instance, less by 10 inches than the quantity which fell at the elevations of 2,190 and 1,334 feet. This last fact I think may be accounted for by referring to the peculiar position of Sparkling Tarn (the mountain on which this last gauge is fixed). This mountain is only 1,906 feet high, but it is in the immediate vicinity, that is, within a mile and a quarter to a mile and a half of the mountains Seatwaite Pike and Bowfell to the south, and within a mile and a quarter of Great Gavel to the north. These mountains vary from 2,500 to 3,166 feet in height, the lowest of them being upwards of 1,000 feet higher than Sparkling Tarn, while the clouds which are exposed to the westerly winds; and the clouds being carried inland by this wind, between the gorge formed by these high mountains, it may be easily conceived that a large portion of rain in the transit of the clouds would be deposited on the top of Sparkling Tarn; so that the large amount of rain falling at this altitude in this locality would appear to be the exception and not the rule.

Dr. Dalton, Professor Daniell, Captain Lefroy, and the other authorities quoted in this paper, confirmed as the observations and recorded experiments of these last-named gentlemen are shown to be by the more recent experiments herein detailed.

NOTES OF THE MONTH.

New Steam or Hydraulic Wheel.—At a meeting of the Royal Cornwall Polytechnic Society, an invention by Mr. James Simonds of Redruth, was explained, the object of which was to carry out simplicity and portability to a greater extent than had hitherto been effected in such engines. It was intended to be worked either by steam or water-power. As a steam-wheel or rotary engine, he conceived, and illustrated all forms of his construction for the purpose of the principle, as the motive power is in the piston and cylinder of the ordinary construction of Boulton and Watt's engines, and the expansive principle of cutting off the steam is carried to a greater extent than in those engines—when the motion of the piston being independent of the motion of the wheel, admitting instantaneous change. In all the rotary or steam-wheels hitherto before the public, he was not aware that any of the inventors had availed themselves of the benefit of working with the ordinary cylinder and piston; they have, therefore, endeavored to carry out the expansive principle and to prevent the leakage of steam. In some cases, packing has been attempted, but here the friction is so great, and the wear so rapid, that not one on this plan has succeeded well. In this engine, on the revolution of the wheel, when the cylinder comes to a perpendicular position, the steam is admitted underneath the piston, at the same time it escapes from the top side, thereby shifting the weight to the top of the wheel, and causing it to revolve by its own power, the force of the engine being the amount of weight moved a certain number of feet in a given time. Regularity of motion being essential, it might be accomplished by a good governor. To make against the buffers is in proportion to the extra quantity of steam admitted, and is on the same principle as the ordinary reciprocating or pumping engine. As an hydraulic engine, it is well adapted for situations where a good height of water can be obtained, but not so for the ordinary mill wheel.

In the valley of West Water, the amount of rain falling at Westdale, 166 feet above the level of the sea, from March 1846, to November 1847, both inclusive, is shown to be 170-55 inches; and at Seatwaite, which borders this valley to the east, 3,166 feet high, only 128-15 inches fell in the same time. In the valley of Ennerdale, at Gilchristwaite, 286 feet above the sea, 133-86 inches fell; while at Great Gavel, 2,925 feet high, during the same time, only 124-68 inches fell.

All the valuable facts here adduced, to supply Mr. Miller with one exception only, prove that the greatest amount of rain falls in the same localities at or near the base of a hill, and not as so great an altitude as 500 feet above the sea. In the observation at Sparkling Tarn, 1,006 feet high, shows that from June 1846, to November 1847 (both inclusive), 183-47 inches fell; while at Seatwaite, the bottom of the valley, bounded by Sparkling Tarn, during the same time, as much as 193-69 inches fell, or 10 inches more at the lower than at the higher locality, thus confirming the conclusion arrived at by my observations, which also fully accord with the meteorological authorities I have quoted.

As the amount or depth of rain falling in a given time in Great Britain, in different localities and under different circumstances, is a matter of very great importance to civil engineers generally, and those engaged in designing works to supply large towns with water, to regulate the flow of rivers, or to drain large tracts of land, independent of their importance in a philosophical point of view, I have been unwilling to allow this valuable collection, which has been made by the Lancashire and Yorkshire mill owners and industry, to pass without a few comments, which, as it appears to me, may tend to make them more generally useful, by explaining their supposed discrepancy with the generally received views, of such accurate observers as...
Geological Discovery.—A correspondent of the *Fife Herald* states that "a section of limestone rock has been lately laid open by the cutting of the Edinburgh and Northern Railway, at the Newburgh station, which believes to be the largest deposit of red sandstone formation. The face exposed is about 100 feet in length, by upwards of 20 feet in thickness, and very distinctly stratified. The beda are broken near the centre, which causes their edges to slip forward and dip in opposite directions, inclining on one side an angle of 20° towards the north-east, and on the other approaching to nearly a vertical position towards the north-west. What adds to the geological importance of the discovery, is the fact that the grey sandstone of the Cambrian tribe is found imbedded in the immediate vicinity of the calcareous deposit. The representative of the Corstone in England, is well known, is extremely rich in fossils, particularly of the genus cephalapex, while not a fragment has as yet been described as being of its kind in Scotland. The colour of the limestone is that of a dark flinty grey, with innumerable white thread-like veins of carbonate of lime, both vertical and longitudinal, and which cause the rock to split up into thin bands of larger and smaller rhombohedral masses. Silt deposits in an extremely hard and cherty texture; it is not nodular or compound, as in so many other places, but of a close, uniform, homogeneous structure."

LIST OF NEW PATENTS.

GRANTED IN ENGLAND FROM SEPTEMBER 28, TO OCTOBER 26, 1948.

Six Months allowed for Enrolment, unless otherwise expressed.

Robert Biriting, Newbail, Gateshead, Durham, for "Improvements in locks and springs, and in the manner of fastening doors and windows."—Sept. 26.

Andrew Paton Halliday, Manchester, manufacturing chemist, for "Certain improvements in the construction of chair, tables, and other articles of furniture for sitting and reclining."—Oct. 5.

William Fitch, of Acton, Gray's Inn Road, civil engineer, for "Improvements in machines for the manufacture of other materials, rendering us the same process."—Sept. 26.

Joseph Gillott and John Morrison, Birmingham, for "Improvements in ornamenting cylindrical and other surfaces of wood and other material."—Sept. 26.

Thomas Meath, High street, Camden Town, Middlesex, gentleman, for "Improvements in the construction of chairs, tables, and other articles of furniture for sitting and reclining."—Oct. 5.

Edward John Luckey, Liverpool, for "Improvements in apparatus for measuring the speed and direction of the winds and storms."—Oct. 12.

Joseph Sharp Bailey, Bradford, York, spinner, for "Certain improvements in preparing, combing, and drawing wool, silk, and other fibrous materials."—Oct. 5.

Samuel, WHith, Camberton,argin, engineer, for "Improvements in generating steam and evaporating liquids."—Oct. 12.

Arthur Dunn, of Delton, chemist, for "Improvements in ascertaining and indicating the temperaure and pressure of soils."—Oct. 12.

John Davie Maries Biriting, of Black Grange, N.B., Esq., for "Improvements in the manufacture of iron and metallic compounds."—Oct. 12.

Edwin Henry Handford, Arthur's Road, Newington, London, and Wildness-Heave, Queen's County, Ireland, Esq., for "Certain improvements in mechanism applicable to impelling and facilitating the propulsion of vessels in the water, which improvements are applicable particularly to those for river and similar uses."—Oct. 12.

John Ashby, of Carseholm, Surrey, miller, for "Certain improvements in machinery applicable for kneading grain and preparing the same for distillation."—Oct. 12.

Daniel Watury, of Wandsworthy, Surrey, distiller, and James John Wentworth, of the same place, for "Improvements in machinery for drilling metals and other substances."—Oct. 12.

William Longmoor, of Bow, London, manufacturer, for "Improvements in treating certain nasses and gasses, or vapours."—Oct. 12.

Robert Angus Smith, of Manchester, for "Improvements in the application and preparation of coal tar."—Oct. 12.

William Brown, of Cambridge Heath, Middlesex, weaver, for "Improvements in machinery and other apparatus applicable to the manufacture of water."—Oct. 26.

Soren Bjorth, of Jeryw-street, Aldefgate, for "Certain improvements in the use of electro magnetism, and its application as a motive power, and other improvements in its application generally, to engines, ships, and railways."—Oct. 26.

James Clark, of Glasgow, Lomond, manufacturer, for "Improvements in the manufacture of fabrics, of all kinds."—Oct. 26.

William Longmoor, of Broomman, Middlesex, gentleman, for "Improvements in treating the cylinder of iron, in and obtaining products therefrom."—Oct. 26.

Joseph Cunningham, civil engineer, of the Lower New Street, both of Birmingham, for "certain improvements in machinery, for use in making legs and playing cards, of all kinds, and other fibrous substances."—Oct. 26.

Emmanuel Wigan, of Lancashire, engineer and draughtsman, and George Molfrey, of Manchester, consulting engineer, for "Certain improvements, in and applicable to steam engines in the machinery of apparatus belonging thereto, in the construction and arrangement of stationary engines, and sluices used in connection therewith; parts of which improvements are also applicable to other similar purposes."—Oct. 26.
THE CENTRAL RAILWAY STATION, NEWCASTLE-UNUPON-TYNE.

John Dobson, Esq., Architect.

(With an Engraving, Plate XIII.)

Railway buildings ought to do much for architecture: being quite a new class of structures, erected for purposes unknown until the present age, or, we may say, the present generation, they suggest, or ought to suggest, a character of their own, and fresh combinations of the old, or some new or old combination strikingly exemplified; and in none more so than at York, Newcastle, and Berwick, in each of which towns the railway station closely adjoins the Castle. The station at Newcastle extends from Westmorland-place, the ancient town-house of the illustrious family of the Nevilles, Earls of Westmorland, situated in Westmorland Street; takes in the site of the convent and garden of the Carmelites or White Friars, known as the Spital, as many years occupied as the Royal Free Grammar School, the alma mater of Lord Stowell, Lord Eldon, and Lord Collingwood; crosses the town-wall and ditch at the Great Tower, and stands on ground formerly in the outskirts of the town, and which was bequeathed by some worthy of former days to the burgesses of Newcastle, "to walk abroad and recreate themselves," a circumstance which has hitherto prevented its being built upon.

The central or principal station is divided into two parts, of 600 feet in length. The style of the building is Roman, and the most striking feature in the design is the portico in the centre, 900 feet in length by 70 feet in width, flanked on each side by an arcade the same length, by 36 feet in width, allowing sufficient room for coaches, and driving in at each, with an attractive view of the whole length and breadth of the station; and at each of the ends of the building, at the entrance to the platform, and the grandeur of the effect produced by an arcade and portico of this length, could not be comprehended, even by the general reader, although no drawing will convey an adequate idea of that effect.

The exterior front of the portico is composed of seven arches, each 24 feet wide, and 21 yards wide, covering an area of 14,426 yards, or about three acres. The roof is composed of iron, divided into three compartments, and supported by columns 33 feet apart, and 25 feet high from the platform to the springing of the roof. The various offices forming a considerable frontage to the platform, with the exception of the booking-office and parcels-offices, which extend the whole width of the building.

The entrance to the shed is, from the centre of the portico, 40 feet wide, with a stone vaulted ceiling, supported by arches of columns, which leads direct to the centre of the platform, about 120 feet square. On the right hand is the booking-office, 70 feet long by 36 feet wide; adjoining which are the two parcels-offices, the telegraph-office, lamp-room, and other rooms and offices extending westward, for the engineers, guards, porters, and other officers of the company. A house for the station-master concludes the front range of buildings to the west.

On the left of the entrance is the station-master's office, first, second, and third class waiting-rooms, (containing separate apartments for ladies and gentlemen), and other offices and apartments of similar kind.
class refreshment-room, 66 feet long by 33 feet wide. At one end is a distinct refreshment-room for ladies, and at the other end a corresponding room for the bar, each 15 feet by 23 feet, divided from the large refreshment-room by columns only, and forming with it one large apartment, 96 feet in length. Adjoining the bar is the second-class refreshment-room, which terminates on the west the range of building facing the platform. The kitchens form the eastern end of the front building, immediately behind the refreshment-rooms, and adjoining the hotel; and are provided with larders, store-rooms, and servants' rooms, on the same floor, with sleeping apartments above.

In addition to the above extensive range of building, it is proposed to erect an hotel, communicating with the station, forming a separate range 190 feet in length by 66 feet in depth; to contain 70 bed-rooms, with a proportionate number of other apartments; and in the basement story, tap-rooms and refreshment-rooms for servants and other persons.

The construction of this building entirely of stone, would, in any other locality, be attended with enormous expense; but the county of Northumberland affords such an abundant supply of the finest freestone, that this material becomes there not only by far the most durable, but really the least expensive.

[We had intended to have given a Perspective View of the building, but the Engraving, which was entrusted to an engraver at Newcastle, has turned out so very defective, that we have been obliged to postpone giving it for another opportunity, that we may do justice to the talents of the architect.—Ed. C.E. & A. Journal.]

CANDIDUS'S NOTE-BOOK.
FASCICULUS LXXVIII.

"I must have liberty
Witul, as large a charter as the wind,
To blow upon whom I please."

I. The organ of De—, as well as that of Con-struencticeness, appears to be possessed by Barry and some other architects. After being taken down and pulled to pieces by critics while living, Nash and Soane are now literally taken down and pulled to pieces by their successors,—by "literally," however, it is not to be understood "personally." The "Board of Trade" of the one, and the Georgian palace of the other, have equally disappeared, although the latter is merely blurred or blurred out. But then, poor Nash has been dismantled of his Quadrant colonnades, which served as a mantle that shielded a good many of his architectural sins; besides which, his Brightonian Pavilion is now a wreck,—whether it is to grow interesting by growing into a ruin, remains to be seen. Nor does the work of destruction stop here, for we are now told by the newspapers that Dover-house is to be taken down, in order to make way for a new Colonial-office, to be erected on its site by Mr. Barry; so we must prepare to bid adieu to its charming screen façade—an architectural gem—not indeed of the first magnitude, but of the first "water,"—picturesque, classic, and elegant, although ignored by those who lavish their state and second-hand extasies on St. Martin's Church. Most unfortunate Holland! thy Drury-lane Theatre expired, like Semele, in flames; thy splendid Carlton-house portico is demolished, and now thy exquisite little composition at Whitehall is doomed to destruction! Were there no other site to be had in the neighbourhood, necessity might excuse the act of vandalism; but excuse for it there is none, while there is a "hoarded-up" gap just by, between Dowey and Fludyer streets,—which gap is apparently not only hoarded-up, but tresured-up, as something infinitely too precious to be parted with. Therefore the gap is likely to remain, and Dover-house to be sacrificed to it,—which is only an exemplification of the feeling and view entertained by Barry himself.

II. I am no bigotted admirer of Holland; if I think that he showed himself a classic and an artist in the portico of Carlton-house, the façade of the ce-devant York, now Dover-house, I freely admit that he showed himself to be no better than an arrant Pecksniff. In that he dictated the Pavilion at Brighton, I gave my vote to Mr. Nash, as his conception and design preserved, most unfortunately for his credit in the "New Vitruvius Britannicus." We look on it with a fit of shuddering, and shudder at the "princely" taste which could adopt anything so vulgar and plebeian,—and not only so vulgar, but so atrociously bad. But George was then "the Prince," and had he taken a fancy to have columns turned upside-down, his taste would have been cried up by his flunky flatterers. That such a truly miserable design,—if design it can be called—should have proceeded from the architect who, in the two other works here mentioned, was so truly a master and a genius, is hardly credible—at all events, quite unaccountable. It ought, however, to teach us something,—namely, to judge of works of art (be they buildings, pictures, or anything else) by their intrinsic merits,—according to what they are in themselves, and not according to the chance classicism or grace or beauty which is so often confused by the prestige of a name is cowardly and worthless. Even Homer sometimes nods, but we are not therefore to nod again when he does so, in affected approbation and delight. Even Raffaello sometimes dawdles, and what would else be called daubing,—but what would he have done off under his breath? In consequence, been admired and extolled for excellences freely imputed to them by the imagination or else by the ears of spectators; whereas, doubts they would have been pronounced to be, had it been known that they proceeded from the so-called (i.e. garret of) some Jack Smith, who lives manufacturing genuine specimens of the Old Masters, and a hungry belly—that great artis magister, as we are assured by most classical authority it is, may be that same Jack's excuse for the deception. But what excuse is there for those who suffer themselves to be deceived? To be in ignorance, and who affect transports which they do not feel? Give me the honest critic, him who is not at all biased by names, but who would as freely condemn either Jones or Wren where they have shown themselves Pecksnifian in taste, as he would Pecksniff himself. "What a stranger man you are, Mr. Candidus! And so you really think, that both Jones and Wren were sometimes Pecksnifian in their taste." Even so: nothing would induce me to praise, or rather, not to condemn and turn away in disgust from some of their dolgones. Few will confess as much, because very few have the moral courage of saying who in his catholic liberality in this room,—who is not only nullius addictus farare in verba magistri, but who animadvert just as freely on a Palladio, a Jones, or a Wren, as on some poor devil of a "Jack Smith!" Let others affect milk-and-water modesty: I am content to be sincere in opinion, and fearless in the expression of it.

III. A most curious accident, and one recorded with singular naiveté, is that which happened to a certain architect in a book of designs published by him; it being expressly stated in the letterpress, that, in one of the elevations, the offices which ought to have been shown, were "omitted by accident." Very much nearer the mark it has been to say, that the omission was occasioned by gross stupidity and unpardonable blundering. "By accident," forsooth! Would "accident," receive as an excuse for a painter sending home your portrait without a nose to your face, he having through sheer forgetfulness omitted the interesting, or at any rate indispensable, feature? Certainly it is that, with regard to the unlucky elevation here alluded to, the omission was discovered before the plate was published, since otherwise, it could not have been apologised for; which being the case, why was the plate in the book at all? But, there is no only valid reason may have been, that the design looked all the better for the accident. If that was not the real reason, the only other imaginable one is, that the expense of altering the plate could not be afforded by the poor devil who published his designs. The reader will agree with me in the latter; another reason being, that that the work here referred to was by Soane! That poor man seems to have been not merely the sport, but the very victim of "accidents"; for, on the very next page of that book, we read, "the archd recesses were semicircular in the drawing, but by a
mistake of the engraver, are made considerably more!" Nor is it that the finest with regard to mistakes, for the printer—or else Soane himself, committed many more, by "omitting by accident" the explanations of the letters of reference in some of the plans. And in his plans, or in what is dependent on and arises out of plans, the chief, or, to speak more correctly, the sole merit of that collection of Soanean designs consists; many of the elevations being little short of the downright ugly and hideous. Soane should have confined himself to plan and contrivance: they were his forte. His ground was that he was well and industriously informed into the literary quite the reverse. The work of Soane's here referred to is remarkable of its kind; for, professing to show only "cottages, villas, and other useful buildings," it includes a design for what is called a very cottage-like nor very utilitarian edifice, to wit, a National School. Soane was a designer for burying people; for the matter of that, he would not have scurried to bury the whole nation alive, so that he had the erecting its mausoleum, or museum, as—terms it; which last, I suppose, means nothing more nor less than a mouse-trap.

IV. Pugin does not at all shine in the parliamentary "blue book" which shows his design for Maynooth College, and those by different architects of some other public buildings that are now in progress in Ireland. "Maynooth" would furnish an illustration for Mr. P.'s own entitled "Contrasts," it being a sufficiently striking sample of pseudo-Gothic, alias modern Gothicizing. It is only fair to put aside the notion of the honour to admire whatever proceeds from him, who can look with complacency on such a dawdy and prosaic design, which possesses neither style, nor quality that atoms for the dereliction of style. Still it may, on that very account, prove not a little satisfactory to some. The almost universal broil of the first half of the year has taken off offence at Welby Pugin's supercilious tone towards them in his "Contrasts" and other writings. Perhaps they will retract upon him, and ask if Maynooth is to be regarded as an example of what can be achieved by those who boast of being inspired by a true understanding of architecture. 

V. Place aus domes! A lady-writer on architecture is so great a phenomenon—such a veritable black swan (applied to one of the finest the simile sounds somewhat antithetical), that Mrs. Tuthill deserves to have a separate article, or at least an entire Fasciculus devoted to her, more especially as she shows herself to be a reader of Candids, and has paid him the compliment of transferring to her own pages one or two of his pithy paragraphs. Still I am not so much indebted to her for the compliment, as she is to me for those little bits of architectural philosophy which sparkle like gems amid the dulness of her book, since she has not had the grace to acknowledge them. Compressed commas mark them for quotations, and that is all; except it be that they are jumbled up with extracts from other writers, without the difference of proprietorship being hinted at. Simum cuique, my good lady, is an honest maxim, and the best policy; for your unscrupulousness is the only character that is embalmed and emblasts me to speak out somewhat freely. Privilege of sex cannot be allowed you: you are of the feminine gender—and so are "man of war" ships; so also are amazons, but their ships did not shield those belligerent ladies from wounds in the breast of battle. I do not deny you the right of wielding that feminine implement the scissors; but I do disapprove of your making use of the paste-pot at the same time; and your book is a notable sample of that species of literary manufacture which goes by the name of "scissors—and paste work." Perhaps you will say that it is genuine patch-work, and, as such, is a very suitable occupation for your sex. That a good deal has been ere now written upon architecture by women I do not dispute; but then, till now they have invariably been old women, and of the man-kind, whereas you are neither the one nor the other. "What then," you will say, "may not ladies, who are not old ones, turn their attention to architecture? Why should they be interdicted from cultivating a taste for that branch of fine art which has so much to do with taste generally?" Why, indeed, should they? Architecture has, as you observe, been strongly recommended in a paper in the "Foreign Quarterly Review" which is perhaps the ablest and most admirable of female accomplishments; and you might also have brought forward Wightwick's opinion to the same effect. Nor do I dissent from them; there certainly is nothing to hinder a woman from understanding architecture—that is, the aesthetics of building, just as well as a man. But, I protest, it is quite another case, since some of them mistake mere building for architecture. Proficiency in the study is quite irrespective of sex: it depends upon the intelligence, the application, and the relish brought to it. Sin-

cerity of study, diligence of reflection, are the sine qua non: whereas you seem to have overlooked some of the most indispensable qualifications for the proper execution of the task which you undertook; and which, in the vastness of your ambition, you seem to have only glanced, as I might say, at the best. Though you get no flattery from me, you may still get plenty of puff from other critics; therefore the acidity of my remarks may be useful to you, by correcting the fulsomeens of theirs. Considering—you understand the ungraciousness of the qualifying expression,—considering, I say, that it is the production of a woman, for a cuisine subject, your book is not so very poor a book after all. At all events, it is something in the bodily shape of a book—a goodly sized octavo volume, with your name on the title-page; which is far more than Candius can boast of having ever sent forth to the public. Yours is, besides, a funny book—funnier perhaps than you intended it to be. One of its drolleries is that of omitting in the list of those who have distinguished themselves in architecture, such recent celebrities as Cagnola, Schinkel, Gartner, and severals, and immortals, such as Inigo, Hawksmoor, Johnson, and John Linnell Bond. Oh! Mrs. Tuthill, Mrs. Tuthill, you are a very rogues creature! To think of your immortalizing—and immortal they now will be in your book—such poor devils in all their littleness, is no doubt very laughable, but partakes too much of a mauveuse plaenierette.

VI. Loudon's "Architectural Magazine," and others of his publications, he has very freely paid a distinguished contribution by Mrs. Tuthill, who has copied several woodcuts from them, but without any acknowledgment of their being copied, and without even mentioning the names of those by whom they were designed. At p. 307, for instance, she has re-produced from the Supplement to Loudon's "Encyclopedia of Gardening," that she very justly calls A beautiful English villa in the Elizabethan style," and recommends as a model for residences of that class in "the northern, middle, and western states;" but very ungraciously withholds from Mr. E. B. Lamb the credit of having designed it, although his name is attached to it in the publication from which she pirated it, or, to speak more prettily—borrowed it. The suppression of its author's name is perhaps less unjust than it otherwise would be, because she exhibits a fac-simile of the original cut, with all the vexatious blunders which Mr. L. complained of and pointed out in the letterpress accompanying his design, observing, that owing to the ignorance of the engraver, "the parapet appears like a Grecian guilloche instead of Gothic perforated panelling; the arches do not present the easy curve of the Gothic four-centred arch, and the scroll label over the projecting bays assumes also a different character. Yet, notwithstanding these provoking defects of design, Mrs. the whole relieved sufficiently pointed out by the author of the design, they are not corrected, neither is there a syllable of caution against them; so that the serious solecisms and errors in the cut may unwittingly be copied together with the real merits of the design. Call you that honesty, Mrs. Tuthill,—or can you fairly call yourself an honest woman?

VII. "Simplicity of style in architecture," says Mrs. Tuthill—Mrs. Tuthill again!—"is in itself a beauty." The dictum requires, however, to be qualified by adding, provided the simplicity itself be aesthetic; otherwise it is but "a Doric temple," as she observes, is such an object of art as is mere imposing and beautiful? No doubt: the Greek Doric temple was worked by refined and truly artistic simplicity, and by perfect consistency and completeness of expression. The difficulty is to infuse an equivalent degree of similarly-refined simplicity into structures very differently constituted, and which, therefore, ought to be stamped by appropriate character of their own. Hardly can Mrs. T. mean to recommend the antique Doric temple as a model at the present day, it being one which it is utterly impossible to adhere to. In fact, Greek temples are the stumblingblocks of English architecture. English ones have a certain simplicity in keeping with the "Grecian" style; English ones I say nothing—have tripped themselves. A mere pastiche is generally made by them their Alpha and Omega of design. They have accordingly showed their classical taste and utter lack of invention, by applying that convenient ready-made feature, the portico, as an unshaken dogma, on all buildings, whether they are least suspicion that they were thereby out-Pecksniffing Pecksniff himself. Mrs. T.'s own book gives us a sample of the kind at page 300, assuring us that "the beautiful portico is copied from the Ereh-
THE CIVIL ENGINEER AND ARCHITECTS JOURNAL

[December]

them." All the more pity then that it should be stuck on to a little smug box-windowed house. It seems, however, that "the front is of white marble." All the more pity again, that white marble should have been wasted upon a design for which lakh and plaster have been quite good enough. The turning Erechtheums and Parthenons into prose is a notable achievement, truly!

VIII. Although she indulges in a good deal of young-lady-like writing and feminine sentimentality, much ready-made enthusiasm (but of a rather threadbare sort) included, Mrs. T. is a very matter-of-fact sort of lady,—a mere materialist in criticism. Artistic idea and design, or the absence of them, are to her as nothing in comparison with the merit derived from such materials as white marble or granite. 

The advertising to the mere circumstance of material, when every other is passed over, does not bespeak much competency to the task in one who professes to instruct others in architecture, and direct their taste. Mrs. T.'s criticism never ventures beyond a poor, solitary, mateless, forlorn old-bachelor, celibatarian epitaph; and even that is not only exceedingly loose and vague, but sometimes quite misapplied also. If we may believe what she says, Yale College Library is a "beautiful edifice," but if we are to believe what she shows, and to trust to our own eyes rather than to her words, it must be truly execrable in every respect. That building and Hartford Athenæum (of which a print is also given) are both by the same architect (H. Austin), and are both meant to be in the Gothic style,—of the Strawberry Hill period, it may be presumed. Which is the most hideous of the two,—which of them the "Democracy" ought to be proud of? It would be quite impossible to decide. Their similarity of merit—or demerit, is so great, that Mrs. T. herself has been forced to employ precisely the same terms for their characterization, calling the one and the other "a symmetrical and effective building,"—a proof that her stock of expressions is but a very infinitesimal one. "they both are, no doubt, and so is: an emetic; and just like an emetic, it is, that they operate; at least, if they resemble the representations of them in the book. Some time ago, an American journal made mention of a fish without eyes; and it would seem that some architects themselves are altogether without eyes (or eye) for Gothic architecture.

IX. It was to be supposed that Mrs. T. would avail herself largely of the opportunity of chronicling for fame some of her own countrymen, in her "Chronological Table of the Principal Architects;" instead of which, she does not there insert the name of a single one, assigning for the omission the following not very logical reason:—"It would be very desirable to add here a list of eminent American architects; but so many of the most distinguished are still living, that we must deny ourselves the pleasure." Oh, Mrs. T.! Mrs. T.! What a woman's reason! You are woman all over:

"In reasoning weak, in espousals so strong."

Dead worthies, it seems, are not to be spoken of, because the race is not extinct, and other worthies are still alive. Very easily might you have helped yourself to some notices of American architects in the Quarterly for the first quarter of the year, under the title of "History of the Arts of Design in the United States;" but you scorn to borrow or pilfer from anybody.

X. At any rate, it cannot be said that Mrs. Tuthill has failed to enrich her volume with a glossary; and a particularly rich treat it is to the lovers of fun and laughter. I, for one, was certainly guilty of mirth-laughter, when I read her definition of "vertical." I would take a thousand bets that no one ever would guess it. She does not indeed actually say that "vertical" means "horizontal;" but she says,—never would you find it out of yourself—that it means "opposite," which being the case, I am quite vertical—"in opinion I mean, and in opinion only—to Mrs. T. How fortunate, or else how unfortunate, it is that the Atlantic is between us!

XI. Among those with whom Mrs. T. has got into debt by her literary borrowings from them, is Mrs. Jameson; of whose description of the Königsbaur, at Munich, she has availed herself, without having the grace to acknowledge its authorship, or the policy to quote it in evidence of the competency of a female pen. However, if she has defrauded some of her literary creditors, she has paid off one of the smallest of them with usurious interest; namely, the gentleman to whom she has thought proper to apply the epithet "learned," as the most characteristic one. She could have borrowed the words which was just the point of her pen,—styling him emphatically "the learned Briton!" Possibly, such epithet may, as a general one, be well merited by the what-shall-I-call-him to whom it is applied; yet hardly appropriate to the actual occasion, since the words she quotes are only a sample of what Sam Slick calls "soft sawder." Go to, Mrs. T.—where you deserve to go, I don't say; but go to, for a very quizzical and roguish woman.

OCCASIONAL NOTES UPON ART.

By Frederick Lewis.

I. Weadmire true art, on account of its ennobling tendency. This has its origin in principles which, founded in the constitution of our nature, are the foundation of excellence. It would not be difficult, through a very interesting task, from the varied and honoured labours of the artists, to show that success demands, upon his part, the exercise of the highest mental faculties. Real art is an evidence of these—a manifestation of skill and manly energy. It proclaims with eloquence its intrinsic dignity. How often, for various instruments and materials which,—having once reared force themselves on our regard, riveting our attention, and commanding our admiration, even when men are intently occupied in the bustling transactions and exciting pursuits of life! When the appeal of art is so powerful, it would be idle to say anything in indirect appreciation of its characteristics, not that these are creatures upon whose minds they seem to make no impression, and who rudely pass them by, or only cast upon them a look of cold indifference. To write, however, on subjects of pure and sublime art is to eulogise them, and at the same time, to give to the world a history of the good they have effected; but not a history of the men who have been felt and acknowledged, from time immemorial, by all persons who have claims to our respect for their quick sensibility to beauty and lofty elevation of intellect; for, to the poet they have ever afforded a congenial and favourable theme; to the wealthy an opportunity of gratifying their own taste in a judicious encouragement of talent; nor has posterity ever forgotten those artists whose services and beautiful emanations have thrown such a glory over their vocation, but have recorded their names on the roll of fame, as benefactors to their race. To these men Homer makes to the works of the skilled Sidonian artists and cunning artificers; with what warm sympathy, but, at the same time, with what propriety he introduces descriptions of various instruments, and the instruments which Homer makes to the architect who built the lofty pile, or the potter who fashioned utensils of domestic use into forms of beauty, each, by the selection of the most durable materials, insured to his work the greatest permanence possible. The lower departments of art received a high degree of artistic value from its refined feeling and knowledge of harmonious composition applied to them; it being an important aim in those decorative and ornamental arts which adorned the palace or the temple to cultivate beauty of design in the fullest extent; so Minerva is represented as watching over and herself occupied in the illustrious labours of the loom; but it was not the stuff of the tapestry, nor the precious stones that composed the floor of rich inlay, but the design that graced it, which was admired and commended. In works of fictive manufacture, where the finer and most delicate skill of the hands was visible, the splendid vase is praised, not because its material was costly, but because it was "figured with art that dignified the gold," and reflected the image of a master-mind. We witness, in all this, a most consummate taste and judgment. So Ovid, in the opening of his glowing description of Phaeton:

"Aepis Solea erat sublimis alta columnarum, Clara mniciumque auro, superque corona nympar; Cujae exo sitidun festissima sunna tegatur; Argenit biformis radiisbus laminas salcis, Materiam usurpat opus."
a wise man, and that he must have acted from precepts delivered
to him by Minerva:—

"Twas a wise artist fram'd, his wisdom taught
By precepts from Minerva."

11. Lord Bacon's definition of art—namely, "a proper disposition of the things of nature, by human thought and experience, so as to lead to the acquisition of truth and perfecting of man's mind"—can be considered as the success with which the mind achieves that desirable end, and the means it adopts for the production of the beautiful, depends upon such high attainments as can be expected only after a long course of observation and experience. Art will exercises, "the influence of beauty, according to the wise and "proper disposition of the things of nature." Herein is pointed out the necessity of a knowledge of first principles, which, when systematized by reasoning and taste, form a sure foundation, wherein the artist may securely sit in all his operations. The amassing together a variety of perceptions requires the perfection and activity of the organ of vision, and the power of combining and representing figures in their most natural and appropriate forms,—is acquired only after a repetition of manual efforts, aided by the co-operation of the mind, and added to much practical wisdom. Such representation of sensible objects—-not, however, strictly copied as they are, but improved to what they should be—portrayed truly, yet poetically, demands a system of various and well-approved precepts, for instruction in which man must look with the cautious and careful eye of observation into the laws which have governed the works of the Divine artist. The words of Paley, when arguing the existence and attributes of God from his works,—"Contrivance proves design, and the predominant tendency of the contrivance indicates the disposition of the designer," apply equally to human productions; and as rectly infer from their elegant beauty or imposing grandeur, the artist's endowments.

111. The well-understanding of the sound principles of art (by which only it can be learnt and appreciated) prevents the commission of fossilisms and barbarisms. Pursued on principles contrary to nature and just reasoning, its results are generally absurdities, and sometimes the one-sided, partial, and imperfect views, which are nothing less than proofs of insanity. Witness Borromini in architecture; or, who was worse, Father Guarini, the specimens of whose architectural achievements in Turin look more like the sugar-and-plaster compositions of a pastry-cook and confectioner; or Bernini, who in sculpture, imitated the style of Rubens; and surely nothing could be so bad in taste as to make the drapery of his sculpture resemble that of painting, or anything it in reality is not; for in the imitative arts, as in morality, the advice esto quod est erisideris, should be recollected. These are examples of an individual capacity to show love of extravagance, and of a spirit so opposed to all truth, that they deserve censure; and the more so, because they are apt to captivate the ignorant and unreflecting. So necessary is it that all should be under the guidance of reason and intention, that he who does not attend to what these governing faculties prescribe not his own and the oration, but acts only from impulse or chance, forfeits all right to the title of artist. But worthy of all admiration is he who exhibits a control over himself and his, perhaps, too ardent imagination; who regulates his enthusiasm by reason; who makes his genius conform to the rules of art; and rising above every particular and partial, represents only the universal truth. For in this, as in other pursuits, it will be best to preserve a medium. Extremes on either side are to be shunned.

"Atilla sperat, coelatis tecta cremabile;
Jferius, terrae; medio tulitamisia tibi."

OVID.

ON THE STABILITY OF FLOATING BODIES.

The doctrine of stability is of much greater importance in the constructive arts than is commonly imagined; it is, moreover, a difficult subject, and when considered in all its generality, it requires a much more extensive knowledge of mathematical investigations, than is possessed by the greater part of that class of individuals engaged in mechanical pursuits; hence the reason why the subject, notwithstanding its importance, is so little understood. The greater part of the observations in the construction of floating bodies are attended with considerable difficulty, yet there are cases of a highly interesting and practical character, in which the difficulties are but slight, and which may consequently be understood by every person moderately acquainted with the elementary departments of science; and it is to those cases which, in the present instance, we intend the more especially our attention of our readers.

The following are the conditions on which the equilibrium of flotation depends. A solid body, floating on a fluid which is specifically heavier than itself, will remain in a state of equilibrium or balanced rest, when it has displaced a volume of fluid equal to its weight, and when the total weight of the floating body is equal to the weight of the displaced fluid, and when the centre of gravity of the whole floating mass, and that of the immersed portion of it, are situated in the same vertical line.

If the floating body be instantaneously removed from the position of equilibrium, the surfaces of the liquid and air, by the action of some external force any how applied, the question of stability consists in determining whether the body, when left to itself under such conditions, will continually recede farther and farther from its position of equilibrium until finally overturned, or whether it will librate about some axis, until it ultimately restores itself to the position which it occupied previously to the action of the disturbing force.

In the following inquiry we shall confine ourselves to that particular case of the problem, in which the first condition of equilibrium is supposed to be satisfied, in whatever position the floating body may be placed; that is, when the weight of the whole floating mass is exactly equal to the weight of the fluid displaced by the immersed portion of it.

Every solid which is generated by the revolution of some plane about a fixed axis, and in general, every solid body having an axis about which the opposite parts are symmetrical, if it is specifically lighter than the fluid on which it floats, and if it is placed in the fluid with its axis perpendicular to the horizon, may sink to a position in the fluid, where it will remain in a state of quiescence or balanced rest. In all such bodies, there are two opposite positions in which the equilibrium obtains; but there is only one position in which a permanence of flotation can take place.

If the floating body be homogeneous, or uniform in density throughout the whole of the mass, the centre of gravity of the body will be situated in the middle of the fluid; or, which is the same thing, that of the displaced fluid; but if the density of that part of the body which is below the plane of flotation* be greater than that of the part above it, the centre of gravity of the whole floating mass may be lower than that of the immersed part, or of the displaced fluid. Indeed, the centre of gravity of the whole floating mass may always be placed below that of the immersed portion of it, by increasing the density of the lower, and diminishing that of the upper portions; and in this way may the stability be augmented in any ratio at pleasure.

If the floating body be heterogeneous, and if there be any cut by a plane, in respect of which the opposite parts are symmetrical, or similarly placed; then, any portion of the body cut off by a plane perpendicular to the former, will also be symmetrical in regard to the same plane; hence, we infer, that if a body, symmetrical with respect to a certain plane, be cut through it, the body remaining at the said plane vertical, the immersed portion of the body will also be symmetrical as regards that plane; and the centre of gravity of the whole floating body, and that of the part below the surface of the fluid will lie in that plane; consequently, for every such plane as that here specified, which can be taken in a floating body, there will be at least one position of equilibrium. These things being premised, we are now in a condition to investigate some of the simpler cases of the instability of flotation.

Problem.—If a uniform prismatic body, whose transverse section is a square, be made to float on a fluid specifically heavier than itself in a given ratio, with one of its angles downwards, it is required to determine the different positions in which it will float in a state of quiescence.

Let A B V, in the annexed engraving, be a transverse section of the prismatic body, floating on the fluid with the angle A V B downwards, and let the straight line C D be the line of common intersection of the plane of the triangle with the surface of the fluid, or that which, by the writers on mechanics, has been called the water-line.

In this case, the specific gravity of the fluid, as well as that of the floating body is known, the area of the triangle C D V is known, being to that of the triangle A B V, as the specific gravity of the floating body is to that of the fluid on which it floats.

Let the floating body be a prism of V, of which the specific

* The plane of flotation, is the horizontal section of the body, coexistent with the surface of the fluid; or it is that horizontal section which separates the immersed and emergent portions of the body.
Then, since the prism is uniform throughout the whole length,
the weights and solidities of the floating body and the
immersed part of it, will be truly represented by the areas
of the triangles \( ABV \) and \( CDV \). Now, by the rules of
measurement and by logarithms, the area of the triangle \( ABV \)
is found as follows.

\[
\text{Area of } ABV = \frac{\text{Area of } AB \times \text{Height of } AB}{2} = \frac{53.4 \times 1}{2} = 13.5 \text{ square inches.}
\]

Since the area of the triangle \( ABV \) is 133 square inches,
and, consequently, the area of the immersed triangle \( CDV \),
being to the whole area as 11 to 20, is

\[
\text{Area of } CDV = \frac{133 \times 11}{20} = 73.8 \text{ square inches.}
\]

The body moves forward with the same velocity, and in lines parallel to
the direction of the impulse communicated. But when the direction
of the impulse does not pass through the centre of gravity,
as in the case in question, the body acquires a rotation
on an axis, and also a progressive motion, by which the centre
of gravity is carried forward in the same straight line, and with
the same velocity, as if the direction of the impulse communicated
had actually passed through the centre of gravity; and it is a
curious mechanical fact, that the rotatory and progressive
totions thus communicated, are wholly independent of one another, each
being the same in itself as if the other did not take place.

This follows from the general mechanical principle or law, that
the quantity of motion in bodies estimated in a given direction, is
not affected or changed by the action of the bodies on one another.
The motion of a body on a given axis is produced by an action of
this kind, and therefore it can neither increase nor diminish
the progressive motion of the whole mass moved. When a single
impulse only is communicated to the body, the axis on which it
begins to revolve is a line drawn through its centre of gravity,
and perpendicular to the plane which passes through that centre
and the direction in which the impulse is communicated.

It is the nature of some floating bodies, when their equilibrium
of flotation has been disturbed, to return to their original position,
after making a few oscillations backwards and forwards, upon an
axis on which they are placed. But other cases, when their
equilibrium of flotation is ever so little disturbed, do not
resume their original position, but continue to revolve on an axis
passing through their centres of gravity, until they attain another
position, when they are again in equilibrium. In the former case,
the equilibrium is said to be stable, and in the latter it is unstable,
and the body overtops.

When the floating body is made to revolve from the position
of equilibrium, by the action of some external force; if the line of
support move, so as to be on the same side of the line of pressure,
as that part of the body, which becomes depressed below the surface
of the fluid in consequence of the inclination from the state of equi-
librium; then, the equilibrium is stable, and the body will restore
itself; that is, it will resume the position which it occupied before
it was submitted to the action of the deflecting force. But if the
line of buoyancy, or the line of support, be on the same side of the
line of pressure, as the emerged or elevated part of the floating
body, then the equilibrium is unstable, and the body will
recede farther and farther from its original position, until it finally
oversteps.

When a body floats upon the surface of a fluid specifically
heavier than itself, the force which tends to make the body revolve
about its centre of gravity, is equal to the weight of the fluid,
acting on a lever, the length of which is equal to the horizontal
distance between the line of pressure and the line of buoyancy;
and when this distance vanishes, that is, when the centres
of gravity of the whole body and the immersed part of it are in the
same vertical line, the force tending to cause the body to revolve
is equal to nothing.

When the floating body is any how inclined or deflected from
the position of equilibrium, and when the line of buoyancy falls
on the same side of the centre of gravity of the whole floating
mass, as that part of the body which becomes depressed below the
surface of the fluid in consequence of the deflection, the lever by
which the force acts is said to be affirmative, and the force tends
to establish the equilibrium, or to restore the body to its original
position. But on the other hand, when the line of buoyancy is on
the same side of the centre of gravity of the whole body, that
part of it which becomes elevated above the surface of the fluid
in consequence of the deflection, the lever by which the force acts,
is said to be negative, and the force tends to overstep the body.

These are the chief principles necessary to be known in taking
a cursory view of the subject; and we shall now proceed to show
in what manner the momentum of stability is to be calculated.

Let the vertical transverse section of the floating body be uniform,
or the same from end to end; then put—

\[
\begin{align*}
\alpha &= \text{area of the transverse section of the immersed part of the body;} \\
\delta &= \text{distance between centre of gravity of the whole and immersed part;} \\
l &= \text{length of the water-line, or the base of the immersed section;} \\
\gamma &= \text{angle of inclination of the axis;} \\
\omega &= \text{whole weight of the floating mass;} \\
\mu &= \text{momentum of stability.}
\end{align*}
\]

* The vertical line which passes through the centre of gravity of the immersed part of the floating body, is called "the line of buoyancy," or "the line of support."

† The vertical line which passes through the centre of gravity of the whole floating mass, is called "the line of pressure."
Then, on the supposition that the angle of deflection is very small, as it must be in all practical cases, the moment of the force tending to restore the equilibrium of flotation is, by the principles of mechanics,

\[ m = \frac{1}{12a} \left( I - d \right) \omega \sin \varphi. \]

This equation is general, whatever may be the form of the floating body; but the subsidiary calculations are more intricate in some cases than in others, and in consequence, the formula in those cases will be more difficult in its application, and the labour will be much more tedious and irksome.

By attentively examining the constitution of the above equation, there are certain inferences that offer themselves, which it may be useful to specify. They are as under:

1. If the first term of the parenthetical expression \( \frac{1}{12a} \) be greater than the second, \( d \), the leverage is affirmative, and the force tends to restore the body to its original state.

2. When the two parenthetical terms are equal, there is no force tending either to restore or destroy the equilibrium; for, in that case, the momentum is nothing.

3. When the first of the parenthetical terms is less than the second, the leverage is negative, and the force tends to destroy the equilibrium and overset the body.

4. When the weight of the body remains constant, the stability is proportional to the expression \( \frac{1}{12a} - d \) \( \sin \varphi \).

5. When the centre of gravity of the whole floating mass is lower than the centre of buoyancy, or that of the part immersed, the term \( d \), or the distance between the centres of gravity, is negative, and the whole parenthetical quantity \( \frac{1}{12a} - d \) becomes affirmative; a circumstance which greatly increases the stability of flotation, as we have already intimated.

If, in the vertical line passing through the centre of gravity of the whole body and that of the immersed portion, there be taken a point distant from the centre of buoyancy, by a quantity equal to \( \frac{1}{12a} \), that point is called the metacentre by naval architects, because it must always be situated above the centre of gravity of the mass, in order that the body may float with stability. These things being premised, we shall now give an example of the method of calculating the momentum of stability, according to the above formula; and if the process be well considered in this particular case, there can be little difficulty in applying the same principles to similar cases, even when the section of the body is of a very different form.

**Example.**—In the prismatic body of fir formerly mentioned, and of which we have given a transverse section, the length of the water-line \( CD \) is 22-8 inches; the vertical distance \( G H \) is 9-3 inches, and the whole weight of the floating body 5,200 lb.; what is the momentum of stability, or what force does the body endeavour to restore itself, when deflected from the equilibrium through an angle of 5 degrees.

By a previous calculation, we have found the area of the immersed triangular section to be 439 square inches, omitting the fraction; hence, by the formula, we have—

\[ \text{Momentum} = \left( \frac{23^3}{12} \times 19 \times 439 \right) \times 5,200 \times \sin 5^\circ. \]

The length of the water-line is 22-8 in.……. log. 1.116197

\[ \frac{23^3}{12} = 17173.502 \] log. 4.2334581

Area of the immersed section = 439 sq. in. ar. co. log. 7.357535

Constant number, 12 …… ar. co. log. 8.9280188

Natural number, 3,2599 …… log. 0.9198134

Consequently, we have \( \frac{1}{12a} = \frac{19}{5,200} = 0.00365 \) and \( \frac{1}{12a} = 3.2599 \), which, being less than the term \( d = 8.5 \) inches, the third inference shows that the leverage at the weight of the body acts negatively, and the force tends to overset it, the momentum of stability being \( \left( -8.5 + 3.2599 \right) \times 5,200 \times 0.00716 = -2374.981 \) pounds.

**FIRE-PROOF BUILDINGS.**

The advantages of building our dwellings fire-proof is so generally acknowledged, that it is needless to say a word in its favour; but the great difficulty in the way has been the expense in constructing the floors and ceilings. To Dr. Fox, of Bristol, are we indebted for the erection of buildings that are fire-proof, and at the same time quite as economical as the ordinary timber-built floors. About 15 years since, Dr. Fox built a private asylum at Northwood, near Bristol, on a large scale, containing no less than 120 rooms. Externally, it is built in the ordinary way with brickwork, but the floors are constructed as shown in the annexed engraving; and in order to make our description practical, we shall describe the weight and size of the beams as adopted to one of the rooms at Northwood. The floor is 19 feet by 13 feet; the joists, which are placed lengthwise, are of cast-iron, of the T shape, and are 3 inches deep at the bearings, and 5 inches deep in the middle; \( 3 \) inches thick at the bottom, and \( 4 \) inch at the top. The depth includes the flange at the bottom, which is 24 inches wide, and 5 inches of an inch thick, on the underside. Each joist weighs 1\( \frac{1}{2} \) lb. per foot, and they are placed 18 inches apart.

Upon the flanges are laid stout fillets of wood, about 1 inch square, close out of short ends of deal, with a space of about half an inch between each slip. Upon these fillets is laid a thickness of coarse mortar, portions of which pass through the spaces, and form a key for the ceiling. Upon the coarse mortar is placed a layer of pugging or concrete, and finally a composition composed of lime, ashes, and sand, well beaten down, and trowelled on the face. After the whole has become tolerably dry, lined earth is rubbed over the surface, which renders the floor perfectly non-absorbent of moisture. The ceiling is then put on below—first a coating of lime and hair, then a floating coat, and at the conclusion the setting coat. When the whole has stood for a few days, the floor forms a solid mass, and is very stiff and strong.

Models, showing the form of construction, may be seen at Messrs. Fox and Barrett’s offices, 46, Leicester-square.

**References to Engraving.**

a. Plate of Ceiling, formed in the ordinary way.—b, b, Cast-Irons Joists. c. Strips of Wood, Slate, or other material, with narrow spaces between each.—d, a coat of coarse Mortar, forming a bed for the concrete above, and a key for the ceiling below.—e, Layer of concrete or pugging.—f, a facing layer of composition, forming a floor of great hardness, toughness, and durability, and perfectly free from absorption.

** Blast Furnaces.**—Remarkable Accident.—At one of our blast-furnaces, blown with heated air, while the blast was shut off, for a few minutes, as is usual after casting, an explosion took place inside the pipes, which, from its effects, we consider extraordinary. In the pipes immediately outside one of the stoves for heating the blast, and at the end of the furnace, is a stop, a disc of cast iron, 14 inches thick, and 12 inches diameter, cutting off the connection between a line of cold-blast pipes and the hot-air pipes. This valve, by the force of the explosion, was literally shattered. Several of the joints in the line of cold-blast pipe, with which the breaking of this valve opened a connection, were blown out, and another stop-valve, in the large main, at a distance of 20 yards, was also broken in pieces; there the explosive mixture escaped in flame at the waste. The furnace, at the same time, belched out a great quantity of the materials in frost. Will any of your scientific correspondents have the kindness to explain the nature of the explosive compound likely to be formed in the hot-air pipes? It appears to have generated in the furnace, and fired by the pipes of the stove being red-hot, which they very soon become (if the fireman is at all careless) when the blast is not passing through them.—An Old Servantman.

HIGH-PRESSURE STEAM GENERATOR.

INVENTED BY J. A. LEON, C.E.

In the beginning of this century the tubular boilers of Woof and Rumford were used for generating steam. Soon after Trevithick's flued-boilers were introduced, it was found that metallic flues surrounded with water were more effectual than tubes filled with water, and surrounded by the products of combustion. Since, the number of flues in a boiler increased successively until they formed the multiflux locomotive boiler.

Flued boilers ought to be used only where they cannot be avoided, as on railways or for navigation. The space occupied by the flues reduces the size of the steam-chamber. The water at its maximum height covering these flues only a few inches, does not permit the use of the float-stone, the best water indicator on stationary boilers. The metallic flues are sometimes left dry, and burst. Boilers of that description are not easily cleaned, free access to the inside being almost impossible; the result of such neglect, if it causes no explosion, it increases greatly the tear and wear, and the expense of extra fuel is very considerable.

The common cylindrical horizontal boiler, being the simplest, the safest, and the most easily cleaned, ought to be preferred as a stationary generator. The only objection against its use was its small area of heating surface; but the greatest part of the waste hot air leaving the boiler can be absorbed before reaching the chimney by an appendix vessel, containing water for feeding the boiler.

To obviate the defective method of cooling the cylinder by injecting cold water in it, Watt condensed the steam in a separate vessel. Here, in place of injecting cold water, mud and all, into the boiler, this compound is primitively received into the heater, where the water, before reaching the boiler, deposits its insoluble matter, and acquires an elevated temperature. The generator receiving by this process a constant supply of hot water, keeping the steam steady, no perturbation is felt, as when injecting cold water.

This heater requires no extra room: its place is below the boiler, and behind the fire-grate bridge, a space commonly filled with rubbish. A great advantage of this heater is, to keep the supply of water in almost a perfect state, which gives the effectual means of obviating the evil of bad water. The sediment accumulates, in one or more heaps, in the front of the heater, where the water happens to be the least agitated. Those deposits are received in some recipient placed near the mud-hole. The generator, fed with water almost clean, is no more liable to burn.

The heater is comparatively of a small size. In the engraving the generator's axis has 26 feet, its diameter 4 feet, while the length of its heater is only 14 feet, its diameter 4 ft. 6 in., and, notwithstanding this, its heating surface is twice as much as the heating surface of the boiler itself, which is here 150 square feet. In reducing the 300 square feet of the inner and outer surface of the heater to 190 square feet of effective heating surface, the whole apparatus has 150 and 120, or 270 square feet of heating surface. This divided by one square yard, or 9 square feet, per horse power, will prove a 30-horse power for the capability of the steam gene-

l l, Safety-valve.

m m', Gauge-cock and pipe-indicator of maximum of steam.

n n', Ditto, of minimum of water.

o o', Discharge-cock and pipe for emptying the water from both vessels, A and B, and for filling them by means of a perpendicular pipe connecting o' with an elevated water-tank.

p p', Passage from the furnace to the fire-grate p.

q q', Movable fire-mouth, in the shape of an arched-top bayed window, placed in the fire doorways, its narrow part inside the furnace, for burning bundles of bagass or dried sugar-cane; each bundle is pressed into the fire-mouth, and acts by burns as a furnace-door. This sort of hopper is removed when wood or coal is used.

r r, Fire-grate.

t t, Moveable plate, when necessary to clear the flues.

u u, Fire-bricks surrounding the sockets a a', not shown in the engraving.

v v, Two fire-brick lamps, on which rests the heater B.

w w, Two return brick flues, joining before reaching the damper d.

x x, Intervened arched bridge.

y y, Partition between upper leading flue u and lower return flues w.

z z, Cast-iron plates, on which are placed the girders f' g'.

*We are indebted for the drawings to a work that Mr. Leon is about publishing, on "Colonial Machinery for Manufacturing and Refining Sugar."*
GEORGE STEPHENSON.

(Continued from page 335.)

VII. STEPHENSON, GRAY, AND JAMES.

The share which Stephenson had in bringing railways to the height at which they now are has been much fought about. He has been named the "Father of Railways" by many of his friends; but there are others who are put forward. By what he did with the locomotive he had made a step towards, and this he followed up by the Stockton and Darlington Railway. These were great works; but no one who fairly looks at it can believe that to George Stephenson only is owing our wide net-work of railways. At Forty, Stephenson was hardly more than a working man, with little weight even among his own friends; and he had no means, had he had the wish of moving the world to the great step, whereby the bounds of neighbourhood were to be widened, the richest shores of England and Scotland brought within a few hours reach, and the householders of London and of Paris, sundered from the beginning of the world, made to know each other as friends and as brothers. He had his share, and a great share, but no more, in this mighty stride towards the fellowship and brotherhood of all mankind, which the wise of old have sighed for and dreamed of, but which they duret never hope should be so nearly brought about.

The earth has this year taken to itself Thomas Gray, as well as Stephenson, so that each can be as fairly brought to doom. Had not the former come forward while living, his name would have never been heard, nor would he have been called the "Railway Pioneer," Bowerman, how many of those who, like Sir Richard Temple, and Stansfield, in his youth, had seen so far beyond his fellows, should be left to starve in the sight of the wonders which he had foretold. There is always a feeling for the seer who is happy in his bodings; more, perhaps, than for the workman who has slowly wrought out the truth that men were able to feel and understand. There was a grey-headed old man, who, in his youth, had seen so far beyond his fellows, should be left to starve in the sight of the wonders which he had foretold.

What Thomas Gray wrote and spoke in 1793, hundreds had said when Trevithick ran his first steam-engine on the Merthyr Railway; to have seen his engine and the Croydon tramway was enough; any man of common daring would forecast the greater speed and might of the iron horse, which would grow with its growth. To map out the railways as Thomas Gray did needed no skill, for they must be made where the trade already flowed, and not in the highlands of Scotland, the wastes of Dartmoor, or the heaths of the North of England. The book no one will gainays, for it awakened others to the worth of railways, so far as it went; but others did the same work, and others did still more. Trevithick, Blenkinsop, Wm. Chapman, Blacker, William, and George Stephenson, set the iron horse going, others laid the tramways, and set down their book, for a great railway from Edinburgh; and later, Wm. James brought forward his great railway undertakings.

On February 11, 1800, Mr. Thomas, of Denton, read before the Literary and Philosophical Society of Newcastle a paper, styled "Observations on the Propriety of the Principal of the Coal Wagon-ways, for the General Carriage of Goods, &c." This is the first proposition that we know of for a general railway system, and nearly twenty years before Gray's.

In 1814, George Stephenson had in his mind's eye a better road, and a greater speed, than that to be had by the others; the book no one yet gainsays, for it awakened others to the worth of railways, so far as it went; and yet, when he spoke of his steam-engine, of which there were but a few, the idea was but a baby, the child of the age. He thought that such an opening, Stephenson would have found unready for it: he had not got his engine in full work; he knew little of railways; and he had not put off his workman's apron. He had neither the strength nor trust in himself; and, though he and Dodg may have talked over what was to be otherwise, yet the mind of Dodg, daring as it was, does not seem to have been awakened fully to what was to do greater wonders, and bring greater wealth than even the steamboat. In taking a share with this, and in viewing railways as a useful and necessary thing, he must have seen its worth, and may have looked forward to its becoming the iron horse, which it has been fondly named; but he did not feel the time come to ask for railways all over the land, as James did, who

47
was a busy railway engineer before he knew Stephenson, when he
helped him to the partnership with Pease, and for which James had
a fortunate effect. 1-3 He was a man of many parts, and others of
his kind; so that he could push railways on;
—there was the time, and there were the men, and the
start was made. It is true, that all which might then have been
done was not done—but there was a beginning: and in
1833 Stephenson had shown his skill, and had greater weight
and power in the world, so that he could push railways on
or rather hinder them from being lost sight of, as they might have
been even then; for there was no want of crookers—the backers of
canals were loud and strong, and the fear of railways eatt
all the old women and wamanish men throughout the

Of the two men who have been mentioned, Trevithick and Dodd—
Trevithick and Dodd—it has never been shown that a strange likeness
there was between them in many things. This went so far, that
each had his tunnel under the Thames, Trevithick at Rotherhithe,
Dodd at Gravesend; each had a patent for the locomotive engine;
each had to meet the same reaper that the other had got from it.
Dodd well knew Trevithick’s works; and, when Stephenson and
he met in 1816, they must have talked about them; but Dodd did
not feel strong enough to set up a great railway-maker.

VIII. STOCKTON AND DARLINGTON RAILWAY.

The Stockton and Darlington Railway was one of our first great
railway works, but it is that as to which the least has been written.
Very little can therefore be said as to George Stephenson’s share
in it; though it is much to be wished we knew more about it, that
we might get the working of his mind in his early undertaking.
Whatever Stephenson had undertaken so far as he could, he
roughly done; and he was always seeking for the best way.
He therefore, in making the Stockton and Darlington Railway,
brought up into use many things which were quite new.

Nicol, says, Dodd, who could best have done it, says nothing
of the Stockton and Darlington Railway in his book, 4 Treadgold
does not seem to have seen it, though he names it. 5 Francis
Whishaw, in the “Analysis of Railways,” 10 often names the Stockton
and Darlington Railway, and speaks about it at length in his
“Railways of Great Britain.” 11 This, however, does not show it
as it first was, and an eye-witness like Nicholas Wood, could
have done much for us.

We have sought in the British Museum, without finding them.
Thomas Gray’s “Observations on a General Iron Railway”; T. C.
Cummings’ “Account of Railways”; Charles Silvester’s “Report,”
and Joseph Sandars’ “Report.” Most of what was written
between 1820 and 1830, on the Stockton and Darlington,
and Liverpool and Manchester Railways, is not to be found in the
British Museum, as such things were not thought of any worth:
they had been a few sheets about a Greek play, they would have
had a good time reading.

In this day we know nothing of the men to whom, less than
thirty years ago, we were beholden for bringing forward our great
railway works. Some, as Joseph Sandars, Robert William Brandling,
and Henry Booth, still live, but many have sunk to the grave,
unknown to the world. Few of these waited pinching
themselves to learn all the truth,—the History of Railways, and the Lives
of Engineers. There are lives of poets, painters, doctors, and lawyers,
but not of engineers, beyond Smeaton, Brindley, Watt, and
Telford. 6 Stuart has done the most in his “Anecdotes of the Steam-engine.”
The Institution of Civil Engineers gives medals for
the lives of Trevithick, and others; but no one asks for them.
George Stephenson will not be forgotten by them; and, before the
Institution of Mechanical Engineers, a life of him was read by
John Saye.

Stephenson was about forty when he was first called on to be
engineer to the Stockton and Darlington Railway. This could
hardly be named as more than a tramway; and, though travellers
were carried by coach, it was only a coal line, made to draw the
coals out of the pits in South Durham. Some of these pits belonged
to Messrs. Pease and Backhouse, members of the Society of
Friends, and powerful bankers.

The Messrs. Pease were partners as bankers with the Liddells,
the owners of Killingworth Pit; and this, perhaps, led to George
Stephenson’s being set out away from his neighbourhood.
The Messrs. Pease thought so highly of Stephenson,
that they afterwards found the money for a locomotive work
shop, now known as that of Robert Stephenson and Co., of
Newcastle. The brothers and their children henceforth took a great
share in railways, not only in the north, but likewise in the mid

but it is not sure what is all the Stockton Med Unusual Railways of the north.
1-15 Whishaw’s Analysis of Railways, p. 579.
The engines are said, by Francis Whishaw, who had seen many of the old ones, to be “ponderous and clumsy, but still powerful.”

Many of the old ones were on the line in 1837. The Lord Brougham was 15 feet long, with six wheels; each being connected by chains to the axle. The engines occurred at a station. About 1836, the steam-whistle came into use for the passenger-engines; but the bell was used for the coal-engines.

Whishaw thought that it was better to have several kinds of signals, rather than the steam-whistle only.

Level road-crossings were then thought to be without any harm; and therefore there were fifteen on the Stockton and Darlington line. This kind of crossing was, as is known, afterwards put to a stop by law; but is now sometimes allowed. In 1839 there were no gates on the line, but merely signal-posts, with the word “Signal.”

In 1825 and 1842, further acts of parliament were got; and the Company were allowed to run locomotives and carry passengers. On the 17th of September, 1825, the line was opened. Stephenson now tried on a large scale, on the Hagger Leases branch of the Stockton and Darlington Railway, his locomotives, which were thought to be very successful. By this time, the Wylam, Killingworth, and Hetton tramways were worked by steam-power.

The gradients on the Stockton and Darlington Railway are mostly steep, 1 in 128, 404, 233, and 427. The line rises from Stockton to Darlington by the agency of engines at stations which are 1 in 30, 32, 33, and 104. The length of the main line is 23 miles, but the whole length is now 55 miles 5 furlongs; and there are eight passenger and goods stations. The whole cost p. in 1825, was 8,000L. 1,064 persons are employed on the line.

Passengers were formerly conveyed as fast as the engines would carry; and it was some time before the locomotive was brought into play, while the speed was low. In 1837, Whishaw found the speed of the passenger-trains only 15 miles per hour. This was as mostly a coal line, it will be seen that the speed of the locomotive would never have been measured out upon it, though its power was fully tried by Stephenson and Nicholas Wood.

Whishaw does not think that the earthworks are heavy, nor does he name any great work. Some of the curves on the main line are sharp, and may be laid under a radius of a quarter of a mile. There are thirteen of this kind, and others of a less degree. The slopes of some of the embankments towards the top of the line are planted with firs. The line is ballasted with small coal.

This is named as the first line on which houses for the workmen were built on both sides of the railway, and Whishaw foresaw that they would be followed elsewhere. The end for which these cots were built was to keep the workmen and other workmen near their work, and away from the ale-house.

In 1839, there were 3,000 coal-wagons at work on the line.

At the time, there were thirty engines, very few of which were the Stephenson’s, some of which were made by the makers of Nicholas Wood’s book on railways, for he made all that belongs to locomotive-engines, and on the Stockton and Darlington Railway, he had set forth the best way of making railways. This is the first great book on railways, and which set Tredgold writing. Wood gives a report by Stephenson, and acknowledges his help in the experiments to discover the precise amount of resistance opposed to the motion of carriages on railways, and the resistance to different forms of carriages. These, undertaken seven years before, show how careful Wood had been in getting his book up. The book was written in 1826, but was not published till 1830. They were written for the Railway Association, and were printed and published at the expense of the Association.

Wood must have been of great help to Stephenson many other times besides this; and his reading and mathematical knowledge must have stood Stephenson in good stead. It is said that the Rev. William Turner, of Newcastle, was a great helper of Stephenson with books, with instruments, and advice.

As an end to this long tale about the Stockton and Darlington Railway, it may be said that the manager is now Mr. George Stephenson, nephew of the engineer, so that the name is still kept up. It is hoped, however, that some more lasting remembrance of the man who first laid down the plan of railways, and its first of his railway works. Mr. Meynell, of Yarm, who laid the first rail at Stockton-on-Tees, is still at a director, and should not let his old friend be forgotten.

IX. LOCOMOTIVE FACTORY.

Before 1825 Stephenson laid down the Stockton and Darlington, Hetton and Springwell Railways, and set the locomotive at work under his name. He had now a young son, Robert, born in 1808, and brought up at Newcastle and Edinburgh; and Joseph Locke, born in 1805, at Attercliffe, near Sheffield, and brought up at Barnsley Grammar School. The latter laid out the Springwell tramway, from Springwell to Jarrow, which is said to have been a good work.

Both Robert Stephenson and Locke are now members of the House of Commons; the former a Knight of Leopold, and the latter of the Legion of Honour. These were the first offspring of what has since been found a great school of engineering. By
George Stephenson were the railways of the north-east, by Robert Stephenson those of the south-east, and by Locke those of the west. The first locomotive of the Liverpool and Manchester Railway, leaving only one great share for Brunel. Therefore, to the three men we owe a great part of our railways. At Birmingham their works meet; and here, some day, will be a fitting seat for some remembrance of the three.

Locke was of great help to George Stephenson, and most in the answer to Mr. W. T. A. of Walker. After the Liverpool and Manchester was done, Locke undertook works of his own, which was not taken well by Stephenson.

In 1834 there were two great things in George Stephenson's life—the setting up of the Locomotive Factory, and his being named as engineer of the Liverpool and Manchester Railway. It has been already seen how he became known to the Messrs. Pease, of Darlington; and they set up the factory at Newcastle, for the building of locomotive engines, of which there was now some want. Messrs. Murray, Fenton, and Wood, seem to have been builders of steam-engines then. Mr. Michael Longridge had a share in the new factory; and afterwards Robert Stephenson.

It was first known as the factory of George Stephenson and Co., and afterwards of Robert Stephenson and Co. It still flourishes, under the care of Mr. Hutchinson.

The first locomotive used on the Stockton and Darlington Railway was built by George Stephenson, and, we believe, at the Newcstle factory. This was the first locomotive used for drawing passengers on a railway, which it did in 1825, and is said to be still in being. In 1846 it was decked out, and brought forth to head the locomotive of the London and Birmingham Railway, so that it has had a busy life for a locomotive. It is a shame to us that there is no English museum for such things, or it might be as proudly kept as we are told that of Cugnot is, in the Conservatoire de l'Arts et Metiers, at Paris.

From the factory they have sent forth engines for the old world and the new; and there is hardly a land on the railways of which Stephenson's locomotives will not be found. From his great name, these locomotives were much sought for on the opening of railways abroad, and from them the French, Flemings, and High Dutch made locomotives.

Up to 1840, above two hundred and fifty of these engines had been sent forth, and as the price was then high, it will be seen how much money must have come into the hands of the makers. Whether in railways or in the factory, the Messrs. Pease had no need to borrow for anything they did with Stephenson; whereas few had anything to do with the other great lights of engineering without making up their minds never to see them again. The lovers of knowledge may overlook the wanderings of great men,—they may look to their heads, and not to their hearts; but when the truth has been once broken it cannot be made whole. The earnings of a good undertaking are a fair ground for doing something greater,—they are looked upon as an earnest; even where there is a loss, it is fairly looked upon; but a breach of trust is never thought of but with sorrow.

The first locomotive used on the Liverpool and Manchester was built at Newcastle, and gave a great name to the factory, so that orders poured in from abroad.

Stephenson most prized himself that Brunel had to make use of his engines. If in anything Stephenson showed a littleness of feeling, it was about Brunel. He was too much given to do as others did about him, to look upon railways and engines as belonging to himself alone, and that no one else had a right to meddle with them. He had so often had to fight for his railways and engines, that he might well have a fondness for them, and think he was made up for his troubles. From 1820 to 1830, to meet the utmost opposition, not only from such men as Mr. B. Thompson and Mr. Francis Giles, but likewise of such as Mr. James Walker, and Mr. J. U. Rastrick. Forgetting that he himself was the follower of Trevithick, Jeesop, and Chapman,—the helpers of James, Birkenhead, Booth, and others, he could not bear to see anything which was not of his school. He never forgave Brunel for taking another gauge, although the narrow gauge was not set up by himself, but found by him already set up. In the speech at Tavestock this soreness broke out strongly, and gave way to very strong words.

He told of the atmospheric railway, that he had never been to look on it, "because I consider it humbug from beginning to end....But it is not the only humbug. The broad gauge is another misconception, as erroneous as the system of the atmospheric railway, only they have got my engines to carry them through." If we wished to draw George Stephenson as anything but what he was in truth, we should be very glad to leave all this, for it shows an utter want of right feeling, and an utter fruitlessness of his own life. The atmospheric railway or the broad gauge were as well worth trying as the two-cylinder locomotive or tubeless boiler; they held forth something which might be done, and it is yet to be seen whether they are so far behind as Stephenson says. The locomotive was twenty years old before Stephenson got it to draw passengers on the Stockton and Darlington; and it has not yet received it all, and after four-and-forty years since it was first set going by Trevithick.

At the Trent Valley opening there was no call for this show of ill-feeling on the behalf of Stephenson, which makes it the worse. He goes on to say, "The Great Western Railway began with an experimental engine of Mr. Buckingham's, and proved so successful that they put the boiler on one carriage and the engine on another; they had the wheels ten feet in diameter, and were determined to go one hundred miles an hour; but what became of these engines? They required porters to help them out of the station, and they were obliged to be built at the North Station, which had sent them from Newcastle, to carry on the train, and though it wanted rest, it was obliged to go out again, and do the duty for which Mr. Brunel's large engine was incapable." George Stephenson had in all likelihood stood by the Wylam tramway when Trevithick's locomotive was helped on by men; and he might have owned, that if Brunel made up his mind to have a speed of one hundred miles an hour, he got it in the end. Whatever Stephenson might choose to say, England owes much to Brunel for spurring on Stephenson; for had it not been for the Great Western, he might have been, which we have now have. Brunel fought against the Stephensons, and against him; and in the end, we have higher speed and cheaper working.

In "Whistam's Railways of Great Britain" will be found a list of all the locomotives in 1839, and in it are many of Stephenson's, some as old as 1830, which were still at work. There was one on the Bolton and Leigh, and two on the Liverpool and Manchester. Of the year 1831, there was one on the Liverpool and Manchester, and some on American railways. Of 1832, three on the Liverpool and Manchester.

(To be continued.)

THE STRENGTH OF HUNGERFORD BRIDGE.

The paper, by Mr. Homersham Cox, on the "Strength of Hungerford Bridge," which appeared in the part of the Civil Engineer and Architect's Journal for October (p. 399), has no doubt been read with interest and with pleasure. The next application of the principles of the dead and moving weights and conditions of the bridge, cannot fail to gratify every professional reader. He gives sound reasons, too, why the subject is at this moment of the highest practical importance. His calculations exhibit the power in the chains of the bridge to support a certain weight, as all necessary, as it may be added, but, as one part of the question,—namely, the load which it is probable will ever be brought upon the structure,—claims a wider consideration than he has given to it, and affects the conclusion he has drawn—that "if 9 tons per square inch be the utmost strain which the metal will safely bear, no margin is left for security against the effects of rapid motion"—it is hoped that some further inquiry into that part may result in advantage.

Mr. Cox computes the greatest gross loads which the suspension chains can support, without exceeding a strain of 9 tons per square inch of iron, as equivalent to a weight of 1,576 tons uniformly distributed, and exerting a tension of 2,664 tons. He adds, that "this is in fact the load to which the bridge is actually liable to be subjected.....The weight of the chains (715 tons), added to that of the platform, parapet, rods, &c., and a crowd covering the platform with a weight of 100 lb. per square foot, gives, according to Mr. Cowper, the maximum load at about 1,500 tons."

The sentence quoted embraces the point which needs examination.

1 In fact, the tension at the lowest point of a catenary is (Polian, in "Barlow on Strength of Materials," p. 363) never greater than the ultimate strength of the suspension rods, platform, and load making the weight, and exerting the angle at the point of suspension, by the horizontal chord with the tangent to the curve.

If the curve is considered as a parabola, this becomes $\frac{y}{w}$, where $x$ being the span or chord line, and the deflection, $y$ expressed in feet, with that given by Mr. Cox. But the suspension chains do not form an exact curve, their figure is a polygon, of which the angles have their foot in a parabola, according to the conditions assumed; and a change in the form of calculation will have consequent, without, however any difference in the result which is worth notice here.
Referring to the *Journal* for June, 1845 (vol. viii., p. 165), there would appear to be an accidental error, in calling the weight of the chains 715 tons: the links of those suspended between the piers, which alone enter into the calculation, are stated by Mr. Cowper to weigh only 392 tons. It is to be regretted that in the extract given, that good before tapings by Mr. Cowper, all mention of the remaining weights which constitute the permanent load, as well as the particulars which would facilitate an approximation, are omitted.

Mr. Cowper appears to exhibit the figures, 296 × 5 = 1480 tons; and those of Mr. Cox, in round numbers, as "about 1,500 tons." But there is this very serious difference between what it seems probable the former meant to convey by them, and the interpretation given to them by the latter—that Mr. Cowper would appear to have calculated upon a tension of 5 tons per square inch as the greatest that could be thrown upon the chains by the heaviest possible accidental load of 100 lb. per square foot of platform, added to the permanent load of chains, rods, &c., which tension would amount in all to 1,480 tons; whereas Mr. Cox has called this the value of the load itself from which the tension arises.

If Mr. Cowper has misinterpreted Mr. Cowper, his conclusion as to the present critical state of Hungerford Bridge fails instantaneously. If Mr. Cowper’s meaning has been mistaken here, what remains to be said will be less forcibly applicable to that great structure as maintaining its sufficiency of strength, but will remain to invite a general notice.

No explanation is given in the *Journal* to show why Mr. Cowper adopted a tension of 5 tons per square inch, as the greatest that would probably arise; and it is desirable to analyse his process of calculation, as far as the imperfect data which are on the instant accessible will permit square foot.

Such an amount of tension would be the effect of a gross load of 878 tons, uniformly distributed, and supported by the chains between the piers. It would be made up of

</tr>
</tbody>
</table>

Total ... 878 tons.

There may be inconceivably in the estimate of the two last items: it cannot, however, be very material, and the mass merely means at command admit of no more certain result.

The principal question now for investigation is, whether it be possible that the bridge is liable to a load of 100 lb. per square foot from the assembly of a crowd of persons on the platform.

This will be answered when we ascertain how many persons can be crowded into a given space, and what the aggregate weight of that number of persons may amount to.

It is well known to military men, that, taking the average of large bodies of infantry when close packed, each man covers with his own person a space of 20 × 15 = 300 square inches. We should therefore find 0'48 men in a square foot.

Mr. James Walker, who, by direction of government, investigated the circumstances connected with the fall of the suspension bridge at Yarmouth, in May, 1843, stated in evidence before the coroner, that he calculated the weight of people, "packed en masse upon the bridge;" at six persons per square yard, consisting chiefly of women, and children under 14 years of age, each person being of the fair average weight of 7 stone; which, he adds, might be a large average, but one adopted by him, partly because it has been frequently employed before. This would give 4 of an individual belonging to such a description of persons, as chiefly women and children under 14 years of age, for each square foot, and, following Mr. Walker's average of weight, it would amount to 65 lb. per square foot.

Herr Von Mitis, who constructed the steel suspension bridge across the Danube at Vienna, computed its probable load as arising from the occupation of a square fathom (of Vienna) by 15 men, each weighing 115 Vienna pounds. Hence, per unit of one square foot English, we should have 0'39 men, and 34'6 lb.

Druy in his work on Suspension Bridges, lays down an arbitrary standard of 2 square feet per man weighing 10 stone. This, per square foot, is equal to 20 × 0'5 = 10'0, a weight of 70 lb. It is familiar information, that in France the conditions imposed by government on the constructors of suspension bridges, require that, before the public is admitted to the use of any such bridge, the chains shall undergo the proof of carrying for 24 hours, an imposed load of 800 kilogrammes per square metre of platform in addition to the weight of chains, rods, platform, &c. This is equal to 41 lb. per square foot. The rigour of this condition is modified, too, in practice, by permitting the use of the bridge, subject to special police regulations, for six months after its completion, if proof to the extent of one-half this weight has been satisfactorily made; but at the end of that time, proof to the full weight of 800 kilogrammes per square metre must take place.

The concessionnaire is required also to maintain the bridge in good order, which shall be done by the authorities, at his expense, in case of neglect. Annual surveys of the works take place; and the Prefect may order a fresh proof to be made whenever any ground for fear arises, as to the stability of the bridge, or as to the safety of using it.

With respect to the average weight of a number of persons assembled accidentally, we may form some precise judgment, with assistance from the researches of Quetelet, published in his "Treatise on Man," in which he gives a table of the average weights and sizes of men and women at different periods of life, sufficient for our purpose being found in the following extract.

To apply this table,—

From military experience, and assuming the age of soldiers to range between 20 and 30, we should get a weight per square foot, arising from a packed crowd, thus—

0'48 × 137'9 = 66'19 lb.

According to Mr. Walker's estimate of the number of persons on the Yarmouth Bridge, there would be a weight per square foot of 49 × 137'9 = 69'33 lb.

Taking the estimate of Herr Von Mitis, as to numbers, the weight per square foot would be 0'39 × 137'9 = 53'78 lb.

And, upon the arbitrary standard of Mr. Drury, that weight would be 0'5 × 137'9 = 68'9 lb.

By bringing all our results together, the conclusion to be derived from them will be more obvious:

Mr. Walker's estimate of weight per square foot is 65 lb.

Herr Von Mitis 55

Drury 70

Proof load by French Government 41

A packed body of infantry 66

From the numbers on Yarmouth Bridge 60

As per Von Mitis 54

As per Drury 69

The average of the whole would be 60

But suppose we adopt that number which is derived from facts actually observed as the best average, 66 lb. per square foot—does it not seem to be inadmissible that an increase of 50 per cent should be made to it when we are about to calculate what margin may be left for contingencies, in the strength of a material member of a suspension bridge? If this be so, let us revise the estimate of strain when shores of so considerable an excess.

The distance between centre and centre of piers being taken at 876'4 feet, the length of platform supported by the chains would appear (from the application of a scale to the plates given in the *Journal* for June, 1845,) to be—

876'4 — 29'4 = 13 = 834 feet.

Hence, straining-weight of platform would be 98 tons

" suspended rods 35 "

" chains would be 392 "

Total ... 737 tons.

Equivalent to a tension of 4'2 tons per square inch on the lowest part of the suspension chains.

Before pronouncing any judgment on the sufficiency of the Hungerford Bridge, it would be requisite to know what weights the suspension rods, the timbers, and the planking of the platform are capable of sustaining. Indeed, it is not impossible that in the latter we might find a limit which would act as a safety-value for other parts of the structure. At all events, we should not forget that dense crowds of persons generate a lateral pressure, such as the parapet railing of a suspension bridge is usually unequal to.
The "Teman."—On Monday, the 13th ult., this iron steamer was launched from the works of Messrs. Robinson and Russell, at Millwall. She is 477 feet long, 26 feet beam, and is to have engines of 180 horse-power. Her lines are by Mr. Ditchburn, and the hull is very smoothly finished. The Telman was also laid under the Run wonderful government, and is to be launched on the Black Sea. She is to be launched by Messrs. Paul. On the next slip is an iron steamer for the Nabob Naizin, one of the mediocrine princes of Indus. She is to go fourteen miles an hour on the Ganges, and is to be used by the nabob in his hunting trips. This shows the progress of European luxury in the East, as the Thames proves that English skill is not yet surpassed on the freezing shores of the Black Sea. The nabob's steamer will make the seventh built by Messrs. Robinson for the Ganges. As iron steamboat for the Humber is to be laid down on the slip of the Thames.

CONTRIBUTIONS TO RAILWAY STATISTICS.

In 1846, 1847, and 1848.—By Hydes Clarke, Esq.

(Concluded from page 338.)

No. XXIV.—MISCELLANEOUS GOODS.

Among other articles enumerated in the returns, are furniture and vitriol.

In the year ending 30th June, 1846, there was carried on the Manchester and Bolton, 356 tons of furniture; on the South-Western, 392 tons (half-year); and on the Brighton, 9,923 tons. The receipts were, Manchester and Bolton 10th; and Brighton 4,907. Total, 16,779 tons. In the year ending 30th June, 1847, there was carried on the Brighton Railway 4,669 tons, the receipts for which were 6,600,600. The carriage of furniture is now considerable, the railway being preferred to the canal for long distances. The rates per ton per mile are high. On the Manchester and Bolton the rate is 12d.; on the London and South-Western, 7d.; and on the London and Brighton 9d.

Vitriol is carried on the Newcastle and Carlisle Railway. In the year ending 30th June, 1846, 17 tons, bringing 11s.; and in 1847, 62 tons, bringing 98.11. Vitriol is classed as dangerous, and the rate for carrying it is 6/- per ton per mile.

No. XXV.—GOODS.

The gross tonnage of goods in the years ending 30th June, 1844, 1845, 1846, and 1847, is as follows, including every description of traffic:

The above letter having been referred to the writer of the "Notes on Engineering," he appended the following note:

The researches of "J. H." seem to prove satisfactorily that the weight of Hungerford Bridge has been over-estimated in the paper (ante p. 292, Oct. 1848) on the strength of that structure. In collecting the data of that paper, considerable pains were taken to reconcile the apparently contradictory accounts of the weight of the bridge, given in the extract (vol. vith., p. 163.) from Mr. Cowper's paper, which contains the following words:—"We have therefore, for the width of the bridge we shall actually bear, 296 x 5,180 tons, while 296 x 5 tons = 1,480 tons is the greatest load that can be actually put upon it."—Was it not natural to infer from this, that Mr. Cowper had ascertained that the weight which the main chains would have to sustain was 1,480 tons?

However, the above letters show that the words just quoted are not the statement of an ascertained fact, but probably the inference from some theoretical computations not given. The main chains of the central span consist of 1,980 links, of which each weighs 5 lbs., and therefore the whole together 3,960. This item, though not included in the weight of the coupling-boxes, pins, and suspension plates:—with respect to these, and the weight of the platform and parapet, which are massive and strengthened by iron steys, we have no data. There are certainly no authentic grounds for objection to the estimate of "J. H.," but in the absence of the weight of the structure, the metal was subject to a tension of 9 tons per square inch. It now, however, appears that the data themselves were incorrect, and that the tension is consequently less; but even the greater amount would by some practical man be deemed within the limits of safety. The error in question, which respecting a point of fact, is not, however, to be regretted, as it has occasioned an inquiry and revision, of which the results are by their near agreement recommended to general confidence. Another benefit of the discussion has been, that it has elicited on one side a display of interesting and extensive research which, it is hoped, will be renewed in other investigations of that important class of which the above letter indicates the familiar study.

The total tonnage in each year was as follows:

1844
1845
1846
1847

9,622,533
12,522,976
15,871,179
16,699,382

The following shows the distribution of the traffic in 1847, in tons:

- Coals and Coke: 8,900,000
- Iron and Ironstone: 600,000
- Coal Dust: 300,000
- Copper and Tin: 110,000
- Limestone and Lime: 300,000
- Building Stones: 600,000
- Sand: 37,000
- Ballast: 36,000
- Bricks and Tiles: 5,000
- Miscellaneous Minerals: 300,000
- Fish: 45,000
- Grain: 300,000
- Provisions: 400,000
- Manure: 40,000
- Goods, Timber, and Sundries: 4,705,352

Total: 16,699,382 tons

To show how small this traffic is relatively to the total carried, the following items in the consumption of the people of this island, in tons, may be noted:

- Corn: 3,000,000
- Potatoes: 3,000,000
- Sugar: 300,000
- Tea, Coffee, and Tobacco: 50,000
- Malt: 400,000
- Spirits: 100,000
- Paper: 40,000
- Soap: 90,000
- Candles: 100,000
- Cotton Goods: 250,000
- Woollens: 100,000
- Linens: 100,000
- Iron: 1,600,000
- Glass: 40,000
- Coals: 30,000,000
- Salt: 650,000
- Timber: 2,000,000

Total: 41,720,000 tons

This enumeration of 41,720,000 tons is under the mark, and only gives the total consumption of this island, reckoning the articles as only carried one way, and not including many articles of agricultural produce.—manures, leather (60,000), fish, stone, lead, copper, earthenware, oil (60,000), fruits, &c.; bark, 50,000; dyestuffs, 70,000; hemp, 50,000; cabinet woods, 50,000; rice, 20,000; tar, 20,000; turpentine, 20,000; &c. The railways at present do not carry more than a fourth of the traffic of the country, if so much.

The largest tonnages in 1847 were the following:

- York and Newcastle: 2,706,529
- Ballachulish: 1,746,339
- London and North-Western: 1,414,925
- Stockton and Darlington: 1,127,058
- Whitby and Colne: 924,421
- Lancashire and Yorkshire: 721,005
- Leeds and Thirsk: 610,353
- North Union: 548,813

The total receipts for minerals and goods in 1847 were 9,600,000l., of which for minerals 750,000l.

No. XXV.—AVERAGE RATE AND MILEAGE.

It is of some importance for engineers to know the average distance that each class of produce is carried, and the average receipt, which are far below what is believed.

No. XXVI.—HORSE TRAFFIC.

The total number of horses carried in 1847 was 59,045, and the total receipts 80,216l.

The greatest horse traffics are the following:

- London and North-Western: 27,715
- Great Western: 11,785
- Eastern Counties: 12,573
- Brighton: 8,155
- York and North Midland: 5,813
- South-Western: 5,447
- South-Eastern: 3,782
- York and Newcastle: 5,455

The charge for horses per mile is, London and North-Western, 3d.; Great Western, 5½d.; Midland, 4½d.; Eastern Counties, 3½d.; Many day-tickets are taken out for horses on the London and North-Western and other lines, by persons going out hunting.

No. XXVIII.—CARRIAGE TRAFFIC.

The total number of carriages in 1847 was 41,133, and the total receipts 51,782l.

The greatest traffics are as follows:

- London and North-Western: 6,790
- Great Western: 5,842
- Midland: 4,757
- Eastern Counties: 3,608
- Brighton: 3,040
- South-Western: 2,504
- South-Eastern: 2,458

The average charge per mile is, on the London and North-Western, 4d.; on the Great Western and Midland, 6d.

No. XXIX.—DOG TRAFFIC.

Dogs are enumerated only in a few returns. The average rate per mile is 4d. The number carried in 1847 on the South Devon line was 1,086, 84l.; on the Maryport and Carlisle 326, 81d.; and on the Whitehaven, 230.

No. XXX.—CARRYING-STOCK.

The following is an enumeration of the carrying-stock of the London and North-Western Railway in 1846, suitable for special traffic—Horse boxes, 210 (horses carried, 27,715); carriage trucks, 217 (carried 8,730); bullion vans, 9; post offices, 8; ditto tenders, 13; milk trucks (north division), 2; convict van, 1; cattle wagons, 40 (cattle, 181,171); sheep wagons, 117 (sheep carried, 399,998); coal wagons, 653 (440,000 tons); timber trucks, 19; powder magazines, 4; iron trolleys, 4.

No. XXXI.—MANCHESTER AND SHEFFIELD.

The following, communicated by the kindness of Mr. Meadows, secretary of the company, gives some particulars as to the traffic of the Manchester, Sheffield, and Lincolnshire Railway:

- See a valuable paper by Mr. Wyndham Harding, read before the British Association, at Swansea, and since re-published.

### REGISTER OF NEW PATENTS.

**GAS-METERS.**

Samuel Clemo, of 24, Regent-square, London, civil engineer, for "certain improvements in gas-meters."—Granted April 20; Enrolled October 20, 1849.

The patentee claims, in this invention, the dividing of the gas which passes through a meter into two or more portions, and ascertaining the whole quantity by measuring a part when under pressure, instead of measuring all the gas which passes through the meter. Another portion of the invention claimed as new, is the making of the inner circle of the drum of a water-meter water-tight, that being in water it may be buoyant, and prevent the weight of the drum from pressing upon the axis. The principle on which the first part of this invention depends, is the well known law, that the discharges of the same fluid through different openings at the same pressure are proportional to the areas of the openings. The arrangement of the apparatus is as follows:—The measuring-drum of a wet meter consists of a hollow concentric ring and cover.

The drum, revolving upon an axis in water, is divided into compartments so arranged that, as the gas enters, it shall in succession fill all the chambers, and be discharged measured. The inner circle c, c, of the drum is made water-tight, so that when the meter is filled to a certain level with water, the drum is buoyed up, and would nearly float if otherwise unsupported; consequently, there is little or no friction upon the axis. The gas from the service enters the meter-case through the pipe k, and after passing a valve,—when, when the meter is sufficiently filled with water, is opened by a float in the usual way,—is divided into two streams, and flows through the pipes c and n', the latter stream being the one measured, and is discharged so measured from the drum-cover by the pipe v, through the opening n. Now this discharge being known, the quantity of gas that passes through the other opening n, is known also, and the sum of the two discharges is marked on the face of an index arranged in the usual way.

To equalize the pressure, the following apparatus is used: z and n, are two hollow vessels connected with one another at their lower parts, open at the bottom, sealed by water, and free to vibrate about a common centre x; v is a slide, covering the two openings k and z, attached to the hood x, in such a manner that, as it rises or falls, it shall move the slide v, and open or close these openings. The pipes k and n, lead into these vessels or hoods, and the gas discharged into them is of the same pressure as that which flows into the meter; so that, if the regulating-hoods were of the same weight, and at equal distances on each side of the centre x, they would balance each other. Over the hood x is fixed immovably another and larger vessel o, open at the bottom and sealed by water, having communication with the drum of the meter, or rather with the drum-cover at p. The openings m and n, closed by the movement of the hood x, are by its descent partially closed, and the pressure of the gas flowing through them is reduced by so much as exists between the gas flowing into the meter-drum through the pipe s', or the initial pressure of that between the interior or exterior surfaces of the hood x, viz., one-tenth; so that the gas now flows through both openings, m and n, with the same relative velocities, the discharges being in proportion to their areas.

Supposing that the measuring-drum required a pressure of two-tenths head of water to work it, and that the initial pressure was four-tenths, the pressure in the cover of the drum and in the fixed hood o, will then be two-tenths. The gas will issue from the opening n, with a pressure also of two-tenths; and the differences of pressure between the interior of the hoods k and n, and the exterior of the hood x, being two-tenths, the hood m, will have a descending power of two-tenths, and thus the velocities with which the gas issues through m and n, will be equalized; and so for any other pressure. The same principle of measurement may be applied to dry meters.

**TUBULAR FLUES.**

Thomas Potts, of Birmingham, brass tube maker, for "improvements in the manufacture of tubular flues of locomotive and other steam-boilers."—Granted April 10; Enrolled October 10, 1848.

The object of this invention is to protect the flues of boilers, by lining them with a composition resembling that used for brazing. In forming this material, ten ounces of refined tin are added to a hundredweight of "bath metal," which is composed of two parts of foreign zinc and three parts of good copper. This compound metal is rolled and formed into a tubular shape of the size required; after which, the tubes are annealed and stretched, so as to straighten them and bring the edges correctly together. On each of these tubes is placed a tube formed of copper or an alloy of copper; and the compound tube is put on to a steel mandril, made with a taper of about one-sixteenth of an inch into its whole length, which not only facilitates the withdrawal of the mandril, but also gives additional thickness to that end of the tubular flue which is to be fixed to the fire-box of the steam-boiler. The compound tubes, each having a mandril within them, are then drawn through draw-plates. It is not necessary to solder together the edges of the inner tube, as it will be sufficiently strong without. The mandril should be made as thin as possible for the outer tube.

The patentee claims the use of a lining of such a preparation of metal, for lining tubular flues of copper and of copper alloyed; the object being to obtain a lining of metal which shall be less prejudicially acted on by the passage of sharp grit from the fire, than if the whole tube were made of copper or of copper alloyed.
AXLE-BOXES AND JOURNALS.

WILLIAM JOHN NORMANVILLE, of Park Village, Middlesex, gentleman, for "certain improvements in railway or other carriages, partly consisting of new modes of constructing the axle-boxes and journals of wheels; also an improved method of lubricating the said journals or other portions of machinery, by the introduction of aqueous, alkaline, oleaginous, or aponevous solutions."—Granted May 2; Enrolled November 2, 1849.

The claims of the patentee do not correspond in length with that of the title of the invention, as they are simply for a peculiar combination of various elastic and other materials with the axle-box and journal, for the purpose of rendering the lubrication of the journals of railway-wheels and other moving parts of machinery more perfect; and, secondly, for arrangements for enclosing the lubricator within a vessel, which shall contain it and exclude the dirt. In carrying into effect the first part of the invention, as regards the axle-boxes of railway-carriages, a shield or collar of vulcanised india-rubber, or other suitable elastic substance, is made of the form shown in the engraving, marked A, A, and attached to the axle-box at its outer edge. This shield is perforated in its centre; such perforation being cut to a perfectly smooth surface, to allow the passage of the journal through it. The perforation is made of less diameter than the diameter of the journal, and by the tendency of the material of which the shield is made to collapse, it presses so closely to the journal, that an air-tight joint is maintained.

The diameter of the perforation in the shield for a four-inch axle should be three inches and five-eighths, the outer diameter of the shield should be one-eighth of an inch less than the disc of the axle-box into which it is to fit, and it will then be found to completely fill it. After having been stretched over the axle, the shield tapers from its centre to its outer edge. For the protection of the elastic shield, and behind it, is placed a thin cast-iron or other metal shield B (secured to the axle-box by four bolts) which being more or less tightened, presses upon the outer periphery of the elastic shield and occasions pressure as required to maintain the joint upon the axle. In adjusting this box upon the journal, no more compression should be put upon the outer diameter of the elastic shield than is necessary to make an air-tight joint, otherwise there would be considerable risk of the air fring, before it could become properly lubricated. When by continued wear the air-tight joint can no longer maintained, a loose ring of india-rubber, of the same diameter as the axle, and about a quarter of an inch in thickness, may be placed upon the axle. The original shield, whose orifice has become enlarged by wear, is then stretched upon this ring, and by its contractile force clamps it so tightly, that a perfect joint is maintained between the two surfaces of the india-rubber, while the axe revolves within the inner or loose ring; and the operation of tightening by the means of the four bolts is repeated. Or by another modification of this arrangement, a metal ring is introduced in contact with the axle, using the contractile force of the india-rubber shield to keep the ring in close contact with the polished axle. These axle-boxes should be filled with a saponaceous grease in a semi-fluid state, so that it may flow towards the shield, and lubricate it without delay. The top of the axle is of a circular form, with a lid furnished with a small air-hole screwed thereon, and effectually closing the box. The grease is introduced through the aperture whenever required.

MANUFACTURE OF WHEELS.

John Askbury, of Openshaw, near Manchester, for "certain improvements in the construction and manufacture of wheels for use upon railways and common roads, and in the methods of preparing and constructing the tyres used thereon."—Granted March, 11; Enrolled September 11, 1848.

Fig. 1, in the annexed woodcuts is a side elevation and a longitudinal section, showing the first part of the patentee's invention.

The nave a is made of cast-iron, and presents the same appearance on each side of the wheel, having six projecting-arms a', a', with sufficient space between them transversely to admit of the insertion of the wooden pieces b, b. They are also divided in the same direction by the radial plates a', a', while the circumferential portions a', a', are of equal breadth and extend transversely between them in the recess thus formed. On each side of the radial plates a', a', are placed one of the wooden pieces b, b, one side of each of which is prepared so as to abut upon the radial plates a', a', and being furnished with a notch, by which the projections of the circumferential plates a' a' are cleared, they impinge upon each other radially, till they reach the periphery of the wheel; all lateral action being prevented by dowels, inserted between them. The opposite sides of the pieces b, b, diverge slightly from the radial line; and between them the wooden wedges d, d, which are prepared to a corresponding angle, are inserted, and driven on towards the nave. The pieces b, b, are brought firmly into contact with the radial plates a', a', their escape outwardly being prevented by the plates a', a'. When these wedges are driven up, they are secured to the nave by the bolts d', d', passing through them transversely, any lateral motion between them and the pieces b, b, being prevented by metal tongues. The wheel then appears like a disc of wood with an iron nave; and in this state it is placed in a lathe, and the periphery trimmed and turned to the required diameter. A wheel thus constructed, although without air, can suffer no injury. The method by which the naves are secured to the wheel by the wedges d is as follows: the convexity of the wheel enables it to assume and retain a more effectual hold upon the wooden portion of the periphery, than if its inner circumference were a flat surface of the ordinary kind. The tyre is secured to the nave a by means of the bolts p, p.

Fig. 2, is a front elevation and longitudinal section, illustrating the method of constructing the wheel according to another improvement. p is the tyre, furnished with two inner flanges p', p', the space between which is equal to the thickness of the spokes r, r, transversely: this tyre, it must be understood, is laid down cold, and the spokes are then arranged in order within it, their motion laterally being prevented by flanges at a short distance from the point of abutment of the spokes. Upon the nave a they converge on each side in lines radiating to the centre of the wheel, or to some centre determined by practice as the most suitable, but in either case sufficiently to admit of the insertion of the wedges t, t, between them. These wedges are driven up by a tapering mandril and by other mandrils of increasing diameter successively until the effectual contact of the spokes with the inner circumference of the tyre and with the wedges is effected. The wheel is then placed in a lathe, and the ends of the spokes and wedges prepared for the reception of the nave, which may be of cast or wrought-iron. The nave is made in two equal parts, consisting of as many arms s, s, as there are wooden spokes to
of the wheel; while the bosses, or that part of each which is inserted in the wheel transversely, is made slightly tapering towards the other: the lugs or projections $a$, $a$, which correspond with the number of the wheel, are made thinner at the head of the wedges being cut away to receive them, and the recesses thus formed in the boss impinging upon the ends of the spokes. Whenever the bolts which secure the two portions of the nave with each other and to the spokes, are screwed up by the nuts, their action upon the surfaces of the boss of each portion of the nave causes the wedges to be driven up further between the spokes $r$, $r$, which are also brought into more effectual contact with the inner circumference of the tyre, as a small space is left between the two portions of the nave in the middle of the wheel. In this wheel the tyne is shown attached by jagged spikes, one of which is driven into each spoke.

The next improvement consists of a cast-iron wheel; the nave from which the arms radiate, and the inner or cast-iron tyre, is formed in the usual manner, the outer tyre being made of wrought-iron. The arms of the wheel have a hollow opening or slot, extending from the inner tyre to the nave; down this opening the bolts which secure the outer tyre to the wheel, pass, and are held by coppers driven transversely through the nave, under the first series of improvements. One great advantage of this method of making the wheel becomes obvious in the manner the tyne is tightened and held fast to the wheel by merely driving up the coppers, without involving the necessity of re-tyring the wheel; and this applies equally to wooden as to iron wheels. The fifth part of the improvements refers to a method of preparing, dressing, and finishing the surface of the tyre for railway wheels, by grinding them with hard stone, instead of dressing them in the lathe in the ordinary manner.

HEATING AND VENTILATION.

John Britten, of Birmingham, machinist, for "certain improvements in heating, lighting, ventilating, and closing and securing the doors of apartments; also in lighting and ventilating carriages; parts of which improvements are applicable to other like purposes."—Granted April 20; Employed October 20, 1848.

This specification is so comprehensive, that we can only notice the principal objects which the invention is intended to accomplish. In the first place, the patentee claims a mode of closing fireplaces or stoves with ground glass, introduced like panels into the iron frame. The door is placed in front of the fire, and is hinged to the frame so as to be adjustable by a ratchet, and the fire can be opened by sliding the frame. The second part of the invention relates to the doors of apartments, in which the patentee proposes to do by closing up the fire-face by a door, and supplying the fire with air by means of a pipe from the top of the room. The pipe conveying the air is divided into two branches, one of which delivers the air above the fire directly into the chimney, and the other delivers it below the fire to aid the combustion of the fuel: it is provided with a valve or damper, by which the intensity of the fire can be regulated as required. Another part of the invention consists of a candle-guard to prevent candles from guttering. It is formed by a cap, which is placed upon the top of the candle, and is adjustable in height to the candle, and thus serves as a candle-guard. Improvements in the windows of carriages are comprised in this specification: the improvements proposed consisting in having the windows to open outward like French windows of houses; and in a projecting roof to the carriage is proposed, for the purpose of avoiding drafts. The hinges and locks of doors come next within the scope of the patentee's improvements. Among other alterations, he proposes to place the common arm-spring on the opposite side of the door, which is hinged at the back, instead of being a fixture to the entrance of the invention relate to the latches and locks of doors. The patentee describes a variety of methods of effecting the lifting of the latch or other fastenings of doors, by simply pulling the door-knob on one side of the door, or by pushing in on the other. The patentee also claims to introduce or other apparatus to the latch or bolt, that any motion given to it will lift the latch. The last part consists in a mode of locking locks without the aid of the opening key. It consists in forming the pins upon the tumblers bevelled on one side, so that by simply pushing forward the bolt, by means of a small lever attached to a handle, the pins will be raised from their respective notches by the pressure of the lever and thus allow the bolt to pass; but the vertical faces of the pins fully lock the bolt, and prevent its being forced back without the key.

ROTORV STEAM-ENGINE.

Isaac Davies, of Birmingham, engineer, for "improvements in steam-engines and locomotives—carriages; parts of which are also applicable to other machinery."—Granted May 9; Employed November 9, 1848.

The improvements in steam-engines comprised in this specification have chiefly reference to rotary-engines, and to a new kind of stuffing-box adapted to the shafts of such engines, for the purpose of keeping them steam-tight, where the shafts pass through the curves, with little friction. The patentee uses a metallic packing, which consists of several segments, the larger set of which are adapted to the size of the box, and are furnished with a flat piece projecting inwards so as to fit the shaft; while the inner set of segments is placed in position, so as to rest on this flange piece, where the piece is prevented turning by the running parallel with the shaft. These segments are cut so as to leave about one-eighth of an inch between the ends, and are placed so as "break joint," as it is technically termed. The whole are forced upon the stuffing-box, placed in recesses cast in the box: the steam has access to the back, and also acts as a spring thereto. Metal discs are placed above and below this packing, and the whole is secured in the usual manner. Another improvement consists in fitting the piston of rotary-engines to the shaft, by means of three feathers let into the piston, instead of keying it fast. This is to prevent the piston turning on the shaft, and at the same time to admit of any slight end-movement consequent on its application as a motive-power, without giving rise to a great amount of friction, which would otherwise be produced in the cylinder. Another part of the invention relates to working the expandable-valves of steam-engines by a double-acting cam, so that by moving a lever, which changes the position of the different connections, the steam is cut off at a different point of the stroke.

The mode of connecting the engine in locomotive-carriages to the driving-wheel forms another part of the patentee's claims. The engine is placed midway between the wheels, within the framing. The axle projecting through has a suitable crank affixed at each end; these being connected by the rods to similar cranks on the driving-axle, describing a circle of the proper radius from the centre. According to the ordinary method of constructing these carriages, the driving-axle is fixed to the framing, and the driving-axle moving vertically in the axle-guards or gabs), the distance of the centres must be increased or diminished, as the points are nearer or farther from a straight line: to prevent which, the patentee constructs the axle-guards in portions of circles, struck from the centre of the engine-shaft and crankpin; consequently the axle-boxes are kept at the same distance, whatever may be the rise and fall of the framing on the driving-axles.

LAYING-DOWN OF RAILS.

Lewis Dunbar Brodie Gordon, of Abingdon-street, Westminster, for "an improvement or improvements in railways."—Granted May 9; Employed November 9, 1848.

The patentee puts in five claims for improvements in the construction of railways. The first is for forming the ends of rails in such manner that the end of one shall rest upon the end of the next. Second, the adaptation of thin malleable plate-iron to form the sleepers for supporting the rails, combined with a mode of fastening the chairs to the sleepers. Third, a mode of supporting the ends of adjoining rails by a trough or girder. Fourth, a mode of fastening the rails in the chairs. And lastly, a mode of preparing the keys of railway-chairs.

The first of these improvements consists in forming the ends of the rails in such manner that the end of one of them shall rest upon the other; the end of one rail being cast so that, when laid in the chair, it shall rest as well upon the end of the rail as upon the chair. In the second improvement, the patentee
states his mode of forming the sleeper as follows. The chair is cast upon the sleeper. A plate of iron of about 15 or 16 inches in width, and of from one-sixth to one-fourth of an inch in thickness, is then to be bent in the direction of its breach into a circular curve, having a radius of from about 30 to 36 inches as most desirable. The moulds for the chairs are placed in the foundry in the exact relative position to each other that they should occupy when permanently laid, and upon that the plate is placed the bent plate, with the convex side downwards to the moulds. The cast-iron is then run into the moulds, and in such manner as to imbibe in the metal of the chair itself a portion of the curved plate; the cast metal being of about the thickness of half an inch upon the upper side of the plate. The chair will be securely cast upon the curved plate, and firmly fixed without any bolts or pins. In carrying into effect the third improvement, upon the sides of the chairs are projecting pieces or ledges, upon which the girders is placed. The one shown by the patentee in his drawings, is of a trough-shape, that is, it passes along beneath the rail to be supported, and also along the sides, so as effectively to support the rail. The mode of fastening the rails to the chair is effected by means of a screwed bolt passing through one of the cheeks of the chair, and through a nut; it is screwed through the nut, and not through the chair, the nut fitting into the recess in the cheek to receive it, and prevent it from turning when the pin is screwed up. In the fifth improvement, for the mode of preparing the wood keys, the patentee proceeds thus. He makes a varnish by combining with any of the drying oils red lead, in the proportion of about 3 parts of the latter to 2 parts of the wood. The latter is to be subjected to heat for several hours, and while at the temperature of about 450° Fahrenheit, the wood keys are immersed therein, and the wood becomes thoroughly impregnated, so as to withstand the tendency of the dryness or moisture of the atmosphere to effect its bulk.

MEASURING WATER.

Edward Hatton, of Wakefield, plumber, and manager of the Wakefield Waterworks Company, has obtained a patent, for measuring water or any other fluid. — Granted May 9; Enrolled November 2, 1848.

This invention for measuring water or other liquids, consists of a wheel or drum, divided vertically by a partition, which contains on each side three measuring chambers. Above the drum is a "preparatory cistern," into which the liquid flows from two feed-pipes, and which is divided into four parts. To the lower end of this cistern in two streams into one of the measuring chambers on either side of the partition alternately; so that while one chamber is filling, the liquid flows through the machine: but the gauge-cocks and other parts of the machine being so nicely adjusted, and its being made to register twice as much as is actually measured, no error is stated can occur. This drum is mounted on a horizontal spindle, and carries at one end a toothed wheel which gears into a toothed pinion, and communicates its revolving motion to an ordinary indicating apparatus as usual. On the periphery of the vertical partition are six projecting pins (equal to the number of measuring chambers), which catch against and rest upon the extremity of a tumbling lever, which is weighted at the other end by a ball; so that when the weight of the water in the measuring chamber exceeds that of the regulator, it gives way, the pins to fall, the chamber to turn, and the water consequently to flow out. The patentee claims — "An apparatus or machine consisting of a 'preparatory cistern' in connection with a drum or wheel containing two sets of measuring chambers, into which the water flows alternately from openings in the 'preparatory cistern,' and being made to rotate by the liquid; and also the employment of the tumbling-lever, or regulator, as before described."

MANUFACTURE OF IRON.

Charles Attwood, of Wolsingham, Durham, Esq., for a "certain improvement or improvements in the manufacture of iron. — Granted April 18; Enrolled October 18, 1848.

The object of this invention is to obtain a better reduction of small pieces of the ore which at present run through the coke, &c. to the bottom of the furnace, without having come sufficiently in contact with the limestone and other substances usually mixed with the ore in blast-furnaces. The small pieces of ore to be operated on are mixed with a bituminous coal, which will assimilate the water of cohesion of the coal. The mass so mixed is afterwards coked in the ordinary way of coking coal for smelting purposes, and the ore becomes involved in the body of the coke, by which it is retained, till freed, by the subsequent process of smelting. Ore so combined with coke will be smelted faster than with coke to which it is combined; it will therefore have abundance of time to combine with carbon to the required extent, before it reaches the bottom of the furnace. With regard to the size of the particles of ore that will be benefited by such treatment, anything of a particle of coke or large walnut, down to the smallest particles of dust, it will be proper to subject to such combination with coal previous to coking; but anything materially larger, it would be unnecessary to subject to such treatment, as it becomes properly reduced in the ordinary method of smelting iron. The patentee finds that coke formed of the kind of coal found in Durham and Northumberland will, after having been coked and combined with one quarter of its weight of ore, bear a burden of ore, in the ordinary manner of charging the blast furnace, equal to the same weight of coke without such combination of degree, independently of the advantage derived from a proper reduction of the smaller particles of ore effected by this process.

SELF-ACTING SAFETY-VALVE.

Edward Walmley, of Heaton Norris, Lancashire, cotton spinner, for "certain improved apparatus for preventing the explosion of steam-boilers." — Granted April 27; Enrolled October 27, 1848.

This invention is chiefly applicable to low-pressure boilers, the safety-valves of which are lifted, when the pressure becomes too great, by a weight of water forced out of the boiler and acting at the end of a lever.

This apparatus consists of a vertical tube, containing a column of water, which may be the ordinary feed-head. In this the water is sustained at a certain height, according to the pressure of the steam. A little higher than the surface of the water is placed a horizontal branch-pipe, leading to a descending-tube, down which the water flows when forced over by any undue pressure in the boiler. Immediately under the descending pipe is placed a small circular pan with a bottom slightly conical, suspended on the end of a long lever. This lever is improved in a very simple degree, independently of the advantage derived from a proper reduction of the smaller particles of ore by this process.

The apparatus consists of a vertical tube, containing a column of water, which may be the ordinary feed-head. In this the water is sustained at a certain height, according to the pressure of the steam. A little higher than the surface of the water is placed a horizontal branch-pipe, leading to a descending-tube, down which the water flows when forced over by any undue pressure in the boiler. Immediately under the descending pipe is placed a small circular pan with a bottom slightly conical, suspended on the end of a long lever. This lever is improved in a very simple degree, independently of the advantage derived from a proper reduction of the smaller particles of ore by this process.
COUPLING IRONS.

DANIEL RICH PRATT, of Worcester, United States of America, for "machinery for connecting railway carriages."—Granted April 27; Enrolled October 27, 1848.

This specification describes a mode of constructing what the patentee calls a self-acting coupling, for connecting together railway carriages. The object to be effected by the use of it is, that when two carriages to which it is applied are brought together, end to end, the coupling connects and secures itself. It is formed of a moveable and peculiarly-shaped hook, to which the draw-link attaches itself. It is represented in the annexed figure, A, A', being the two ends of the draw-bars of two separate carriages. The ends of the draw-bars are provided with the concave buffing-plate B, B'; a hole passes through the centre of each buffing-plate and into the ends of the draw-bars, through which passes the coupling-link C. Hooks D, D', are jointed to the draw-bars by fulcrum-pins, upon which the hooks are at liberty to move. They are of the peculiar shape shown, and the ends so formed, that when the end of the coupling-link passes through the hole into the interior of the draw-bar, it comes against the end hook D', and thereby raises it sufficiently to allow the end of the coupling-link to pass under the end of it; so soon, however, as the end of the link has thus passed, it comes in contact with the other end D" of the hook, and depresses it, and also the other end D' takes hold of the link and retains it fast. The hook may be released by means of a cord or chain attached to the upper part of it being pulled, and thereby raised. The patentee states, his improvement may be attached to all descriptions of railway carriages, whether with or without spring-buffers and draw-rods; and he claims the hook, in conjunction with the coupling-link described.—Patent Journal.

THE BLAST OF ENGINE-FURNACES.

EUGENE ARLOW, of Panton-street, Haymarket, for "improvements in increasing the draft in chimneys of locomotive and other engines."—Granted April 8; Enrolled October 8, 1848.

The object of this invention is to produce a steady draft or blast in the furnaces of locomotive engines more particularly, by causing a quantity of atmospheric air to be drawn into the chimney by the action of the escape-steam. In the annexed cutout, c c c' c represents the form of the pipe by which the air is admitted into the chimney, the mouth d being enlarged for the entrance of the air. The following are the proportions of the pipe, to which considerable importance is attached by the patentee:—The open-
JOINTING CLAMP.

Jointing and Compressing Screw Clamp.—Patented by Mr. James Kimball, of Inge-street, Birmingham.

The accompanying engraving fully explains the nature of an ingenious clamp, to be applied for jointing of floors, &c. Its construction is extremely simple, and its power great, and it can be easily fixed and removed. It is applicable in all cases where two bodies require a fixity and perfect union, and in the laying of floors it compresses the boards very gradually and truly together. It does not require the workman to rise off his knees when using it (as in all former ones) to effect a leverage, one progressive and uninterrupted motion only being wanted; moreover, it can be left, with its full pressure upon its work when necessary, unattended, and with perfect safety. Amongst builders, shipwrights, coach-makers, and others, a cramp to improve upon the ponderous and tedious action of the present kinds in use, has been an object long looked for, and the one described appears to be an invention which will prove a great auxiliary to the working department of every one engaged in the above pursuits,—as multiplying power, reducing labour, and increasing the value of the material used. It is contrived in but few parts, and breakage or derangement appears impossible. The cost of the instrument is two guineas.

NEW LEVER VICE.

The accompanying cut and description will explain the principle of a new lever vice, patented by Messrs. J. Peck and L. Pardee, of the United States. The following qualities it is claimed, give it a decided superiority over all other vices:

- Greater strength than any other vice of equal weight possesses.
- Greater power, and so applied as to save, in work requiring frequent changes, at least one hour in ten, as it is worked entirely by the foot, without the necessity of laying down a file, or other tool, or without any use of the hand, whatever. It can be changed to receive work from one-sixteenth of an inch, to eight or ten inches in width, as easily and as quickly as any other vice can be moved one-fourth of an inch. And heavy work, requiring both hands to lift, can be easily placed in the vice, without calling the assistance of a second man; it will soon pay for itself in saving of time. It is much easier for the labourer, the strain upon the breast in turning up a screw is entirely avoided, and the vice can be closely approached without being obliged to bend the body over the end of the screw, as in other vices. When the vice is forced up, it becomes more firmly attached to the bench than any other vice can be, rendering the whole much more solid, which in chipping, and other heavy work, is very desirable.

- a, sliding jaw. b, jointed, or swinging jaw. c, rail on which the sliding jaw moves. d, click which catches in ratchet on rail e, and holds the sliding jaw firmly where placed. e, jointed lever (elbow joint), which turns on pins &c, and is attached to prong of rail e, and the lower end of the swinging g, foot lever with joint attached to leg of bench, and connected by rod i with jointed lever. a, click which catches in ratchet at the foot of the forward bench leg, and holds the jaws firmly as forced up by the combined levers; it is easily tripped with the foot. f is a spiral spring which lifts the foot-lever, and throws open the jaw.

THE GREAT AMALGAMATION.

The great amalgamation of the three companies, the London and North-Western Railway, the Great Western Railway, and the South-Western Railway, is attracting the attention not only of railway men, but of the public at large. Considered as an amalgamation of fifty millions of capital, it is certainly the largest of the kind yet effected. The capital of the Bank of England is not one-third part of that of the Great Amalgamation; the union of the two East India Companies, which resulted in that which now exists, was not equal in importance; the South Sea Company did not propose to touch so large an amount of capital. Abroad no example is to be found of a private enterprise so great. Yet, considered in its individual features, the measure does not bear that unprecedented character. The annexation of the Great Western to the London and North-Western, is not greater than the annexation of the Grand Junction to the London and Birmingham; and the annexation of the South-Western is of still less importance. It is therefore the aggregate to be constituted which gives character to the measure.

To hold forth any certain views with regard to the course likely to be followed by the managers of this system of policy is so far futile, as it is by no means sure that they have a design of ultimately carrying it out in good faith. When we consider what temporary objects the proposition of such a plan is calculated to serve, regardless of its execution, it is prudent to hesitate before we assume too hastily how it will be carried out. If we recollect that there is no compulsion on one of the chief members of the amalgamated, the Great Western, to participate, we recollect that a purposecontested has been long carried on, and has ended in the achievement of the objects by the party last-named; when we consider the ambition of their views, and the indisposition of the London and North-Western shareholders towards them, we must feel how uncertain is it, so far as the parties themselves are concerned, whether they will persevere,—and still more uncertain, whether they will be allowed by the legislature, in opposition to the public voice and interests, to carry out the measure in the form in which the several boards settle it with each other.

It happens (not unexpectedly to those who know anything of the parties) that the avowed object of this league is to raise fares, and constitute a monopoly; and no time could be more unluckily chosen for the promotion of such designs. Three years ago, the high-fare party were beaten by the conclusive evidence of facts, and forced to give way to a policy which gained neither their conviction nor their sympathies. And as they have ever since been on the look-out for the opportunity of reverting to their old course, the moment a decline took place in railway dividends, it was instantly asserted that it was owing to the lower fares and increased accommodation, and the sympathies of shareholders of their own school, have lost no time in doing away with the day-tickets, raising the fares, and diminishing the number of trains,—and this is but the beginning.

It has not been asked, what were the reasons which led to the adoption of the low-fare system, but that it was the experience of its success which was the cause of its adoption; and some inquiry it would be thought might be made, before its abandonment was determined on. At any rate, while the country was in its
ordinary state, the low-fare system was fully competent to give good dividends; and it is therefore quite groundless to assert that it has ceased to be able to do so, or that it is the cause of lower dividends. No one ever supposed or asserted that that system was competent to give a maximum dividend, irrespective of all other causes; and still less, that it is high-fare. On the contrary, the tax system, could give the same amount of dividend, in defiance of the depression resulting from the greatest financial and political crisis which the world has yet seen,—and (if we take into account the failure of the grain, potatoes, cotton, sugar, and other crops, and the prevalence of cholera (influenza) and the greatest shipping disaster.

If we were to sit down and estimate before-hand what would be the results of such a crisis, we surely could not be surprised at a falling off of dividends from ten to seven per cent.; and if we had a fore-knowledge of such a crisis, we should be able to decide that there must be a falling off in the business of the country, such as would keep the line of railway, and it is perfectly idle to charge the diminution of revenue on the fare system. That there has been a diminution consequent on the opening of a great number of branches, we believe; but that is to a great extent a necessary evil, and is temporary in its operation; at all events, the public are not now paying half the fares they were in 1845, and who pocketed the premiums upon them, are not to turn round in 1848, and make the public pay, because their branches are not yet yielding the full ten per cent. And if the same time is to be considered, as said in the Monthly Herald, "Railway Loans and Railway Administration," that the uniform fares have pressed heavily on some of the branch lines; for with a new and undeveloped traffic, an absolutely low-fare is of no good; because it has no effect on the old traffic, and takes the line of railway, and which time is the chief agent in effecting a reduction in fares will stimulate a traffic already existing, but has not such great effect in diverting traffic from accustomed routes, and in overcoming the prejudices of old men and obstinate men. The remedy proposed for this is a practical one, and that is, to give the Railway Board the power of allowing alterations in the tariffs of fares beneficial to the companies and to the public. The writer just named has pointed out that, so far from fares being raised, they might, if the companies had the power, be beneficially lowered to many of the old and public and private relief; and the question of fares and revenues of the companies would be much increased. A Railway Board, to be good for anything, should have the power of mitigating those regulations which press harshly on the public and the companies: and, as the writer in question has shown, there is great room for the exercise of such a power; especially in the case of amalgamations, loans, new stations, fares, preference shares, and many minor arrangements for which the expense and delay of an act of parliament is now needlessly required.

If, every time there is a commercial panic, the public will find the need of ridding themselves of such oppression; and an additional argument will be furnished for taking railways into the hands of the government.

Altogether, the policy of abridging the public accommodation is as odious as it is unprofitable, but it is held by a certain school who are amongst the worst enemies the railway system has ever had. Mr. Glyn has always advocated monopoly, high fares, and government meddling; and his brother chairmen have much the same views. They have already met severe rebuffs in the narrow policy to which they are attached; but in the present instance failure is sure to attend them, whether successful or unsuccessful in carrying a bill through parliament. The public are fully aware of the motives on which it is founded; and either a bill will be granted, accompanied by such stipulations as permanently to reduce the income of the companies, or free competition in railways will be allowed, the result of which will be, at an early date, a cheap line between London and Birmingham. One railway man already talks of a line at £5,000 per mile; and it is practicable. In either case the expectations of the shareholders will be grievously deceived; and therefore it is a matter of the present difficulties, for it was he who advocated the limitation of dividends to ten per cent., and its enactment by the legislature; a measure uncalled for and injudicious, for while it did not propagate those who objected to railway companies, it must have increased the number of famines and panics, traffic must fluctuate,—and therefore profits must fluctuate. While the object is to declare a maximum dividend of ten per cent., there are no means of forming a reserve to equalize the dividends; but, were there no restriction, profits above ten per cent. would be reserved to keep up the dividends in unfavourable years. This is now rendered impossible, whereby very great hardships are inflicted on railway shareholders. The least possible damage could have been given is an average ten per cent. from the time of opening.

The railway system is yet in its infancy; and nothing can be more unwise than the constant efforts to shake it and to cramp it; and the more directors attempt to do so, the more they peril the existence of the undertakings to which they belong. Interested and prejudiced parties have the choice to assert that nothing can be done; but whoever looks at the history of the last twenty years will never dare to tie himself down to any such conditions. It is the very result of improvement, that it allows further improvements to be made. It would never answer to make a machine for half a dozen pins, but when thousands are wanted machines are set up. A great traffic makes expensive engines cheap; a high speed authorises those means which were before unthought of. After all, dare any one say that engines cannot be made lighter, rails cheaper, bridges and viaducts of reader construction, and gradients of greater inclination? The claimants to effect these things—nay, who are now doing them—are already at the doors; the minds of thousands of ingenious men are at work in inventing new and cheaper modes of traction; the resources of science are daily becoming greater; and, since light and electricity are not the monopoly of any sects of man, a new impulse has been given to the applications of art.

The demand for a monopoly forcibly recalls all the evils of our present system of legislation on public works. The Morisonian and Doctrinaire calls out for a government system of railways, and relies on the Amalgamationists to prove his case: those who advocate freedom in public works equally profit by the same circumstances. Conviction is gaining ground, even among the railway press, who have hitherto been staunch advocates of the old companies, and opposed the introduction of new ones. Herophill's Journal very well points out, that in the district of the Great Western Railway there is a great number of rival and competing lines of railways. And urges that the monopolists will neither make themselves nor allow others to make them. It should be added, neither will the government make them, should it get hold of the railways; and thus the progress of the country in its struggle with manufacturing and commercial rivals may be irretrievably impeded; for if we stand still, other countries will not; and as it is, we are already too much fettered. Nothing short of freedom in the construction of public works can secure us against high charges or inadequate accommodation; and let us have but that freedom, and the Great Western may be the first to be allowed to charge what they like. It is not true that competition in railways cannot exist: the question has never been carefully discussed; for the railway parties who have discussed it have thought themselves bound to monopoly. Till the poorer classes of this country can be conveyed on suitable lines of railway, we shall not have the human accommodation; and we want thousands of miles of railway to do this. In another part of this journal it is shown that the traffic of the existing railways is but a fraction of the whole traffic of the country: indeed, the extension of the means of economical conveyance is most urgent.

When the Amalgamation Bill comes to be discussed in parliament, it is very likely its supporters may be little inclined to go on with it. Their strength in the House of Commons is great; but the exposure of the discussion will of itself be a severe shock, Greenamphionism may be fortunate to discover that the large party in the house a tempting opportunity is offered, of gratifying the people at the expense of the shareholders: cheap travelling will save the members from putting taxation on a fair basis, or giving the people a share in the government. The Cheap Travelling Bill will be the measure of the session; members may look their constituents in the face, and say they have done something; and the character of the Do-nothing Parliament will be retrieved. The temptation to the government is very sure: financial reforms depriving the holders of patronage in the customs, dockyards, and excise of their powers; taking possession of the postal service. The Railway Bill will give them compensation, without alarming the opponents of patronage and prerogative, and to the gratification of those who think that the government should have legitimate means of securing a majority. Neither Whigs nor Tories can withstand such a chance, in which both have an interest,—one contingent, the other immediate.
The catastrophes of a government-purchase Mr. Glyn may anticipate, and may have laid this trap to effect, for he has always been a consistent supporter of such a course; but these are rather dangerous times in which to try such strokes of policy. If a sea be given to the people, railways will be sacred in the problem. He has succeeded in getting the means of coercing the London and North-Western after hard fighting; and he is not likely now to rate so highly as to give up for it the fruits of victory, which offer themselves to him. Has not, that is to be done, with the London and North-Western? After all the service it has done to the public, is it to be set aside? What compensation are the Great Western to get for their varied claims? These are all questions to be solved, and to be solved satisfactorily in a pecuniary sense, or it is very certain amalgamation will not go on. Mr. Saunders has fought to get something, and he will have it.

Mr. Glyn's motives in bringing about the amalgamation are apparent. He effected that with the Grand Junction—he stayed the dissension: and to carry out a further amalgamation, and to appease a most dangerous competition are still greater measures. Can he get the price? His shareholders in a few years, with the most rancorous insinuations by the narrow-gauge advocates; and will they in this day accede to those terms, without which the Great Western will not give up their vantage-ground. The South-Western directors and shareholders are glad to snap at anything; but the Old Grand Junction shareholders, and the shareholders in the Liverpool and Manchester Railways, (who have had their dividends cut down), are not likely to hear calmly any proposition for giving high terms to a company which they have been taught to believe is overcharged with liabilities, paying dividends out of capital, and pursuing a system of management. These falsehoods have been widely propagated, and have been countenanced by those who ought to have known better. Now they reap the fruits of falsehood. The narrow-gauge partisans, editors, and pamphleterists, will find it hard to make the shareholders believe a new tale, after what they have heard for years.

It seems to have been left out of account by most parties, that the amalgamation will result in an increase of income and economy of expenditure; affording a surplus fund which under a liberal system would go partly to extend public accommodation, but which in the present case will be divided between the three parties to the amalgamation. This is the point for negotiation. The Great Western may say, "Without us this amalgamation cannot be carried out, and therefore if fair we should have the larger share;" and as this is true, they are not obliged to accede to a division in proportion to capital, and the greediness of the others must give way.

So far we regard the public interests, we are most heartily glad that this measure has been proposed; for we are convinced that the ultimate result must be for the public benefit, notwithstanding what directors may believe. The latter may plume themselves that they have secured dear fares; but we do not fear that we shall have not only cheap fares, but cheaper fares and greater accommodation. Discussion must do good; and discussion will now take place on a wider and more liberal basis than it has hitherto done.

What the end of the bill will be no one can say; but meanwhile the shareholders will have something to think of, and something to talk of at the meetings; and the directors will have time to look about them. The Times and Punch have got a good cause; the public will get excited; and the bill may be postponed till another session,—or may get into parliament, and the whole basis of railway legislation be upset.

**SHIPS WITHOUT KEELS.**—Captain Jean Napoleon Zerman, of the French navy, has recently taken out a patent in this country for the construction of ships without keels. His ships are to be flat-bottomed; and through the vessel, from stem to stern, there is to be an opening or trough; the size being about the width of one-third the greatest breadth of beam of the vessel, and the breadth of which the lower side of the patentee states his object to be, in adopting this mode of construction, enabling the vessel to draw less water, and take a greater hold of the water. The vessels are so constructed as to go each way, and are to have a rudder at each end.

**REVIEWS.**

We are scarcely in the position to review a book written by Mr. Hann as impartial critics. A pre-disposition in favour of his new work, arising from a strong impression of the merits of those which preceded it, will be admitted by the reader to be, within certain limits, a fair ground for criticism. Moreover, many other sacrifices and tribulations—such as the sacrifice of personal honour, which may sustain each mingled with something like surprise. We are too much accustomed to think that academic discipline is almost indispensable for the attainment of that severe precision of thought and language which is pre-eminently required in mathematical studies. Here, however, those studies have been pursued in far other scenes than the conclusion of a college, and with far other means than the appliances of the professor's lecture, the tutor's private instruction, the discussion with contemporary students, and the powerful stimulus of a university examination.

In Mr. Hann's work we occasionally meet with definitions and expressions which seem to lack the precision of our accustomed books. Our readers in these cases, as it appears to us, uninfluenced by impressions derived from the works of inferior writers,—men who address themselves to practical engineers, and have been too long deemed mathematicians because they use mathematical symbols. But if Mr. Hann and ourselves be at issue respecting the value of the class of authors referred to, this, at least, we concede— that if he sometime borrow from such books their unscientific phrases, he does not borrow their blunders in the conception and application of principles. In turning over English books on engineering and analogous subjects, we usually adopt a rule, derived from practical experience, never to trust to the result of a single investigation till after having worked it over again for ourselves. In looking over the pages of this book we do nothing of the kind; we do not expect to find at every turn an error of principle. On the contrary, we have not yet found but one result which we are disposed to dispute: this occurs at page 205.

"Suppose, by measurement, it be found that a man-of-war, with its ordnance, rigging, and appointments, sink so deep as to displace 1,300 tons of sea-water,—what is the whole weight of the ship, supposing a cubic inch of sea-water to weigh 9949 of a grain? The weight of the water displaced is equal to the weight of the ship. 216 gallons = 1 ton. 1500 x 216 = 250,800 gallons; and if we take 277,278 cubic inches to the gallon, then 260,800 x 277,278 = 77,000,768 cubic inches. Taking 83,04 feet per inch, this becomes 463,180,11,5367 ounces = 1292-35 tons, the weight of the ship."

Surely there is an error in this passage. If the displacement of the ship be 1,300 tons, it will weigh 1,500 tons—not an ounce, not the millionth-part of a grain, more or less. Here, however, without any apparent reason, the displacement is reduced from tons to cubic inches, and then brought back again to tons; and the several multiplications with decimals account for the eight tons lost in this unnecessary process. The error is, however, evidently accidental.

About one-third of Mr. Hann's work is devoted to the theory of statics; and considering the class of readers for whom his work is intended, he has acted judiciously in avoiding, as far as possible, complicated mathematical operations. We wish that it could have been found practicable to substitute arithmetical methods for the somewhat difficult analysis which occurs in the subsequent pages. The chapter upon Revetements (p. 164), for example, consists almost entirely of mathematical symbols, and is, not therefore, likely to have much practical utility. Besides, we have strong doubts whether any system of theoretical computation will express even approximately the pressure of earth upon sustaining walls. Coulomb's idea of the wall, with its external face, is, in a scientific view, extremely beautiful; but in practice many things concern to vitiate all deductions from the theory. In railway cuttings, stratified formations which dip to the horizon will be liable to slide forward where the inclination is towards the face of the cutting; and even in the inclined strata of the same nature, which may sustain each other by their mutual action. In this way it will happen that, in a railway cutting through inclined strata, the
right-hand bank may require the support of a strong revetment wall, while the left-hand bank is able to support itself. Again, the effects of ramming or binding the earth of an embankment, and of impounding drainage, &c., altogether vitiate mathematical formulæ.

We do not insist upon this point to the disadvantage of Mr. Hann’s book, but as a general truth. It might be extended to another important subject—the theory of the Arch. There also we are satisfied that practice and modern theory are widely at variance. Petit and Garidel’s tables (p. 244–5) may be correct abstrackly, but we imagine that it would be difficult to point out one actually existing structure for which they would indicate even approximately correct results. There do not exist any of those “arches with parallel extrados,” and “arches with horizontal extrados,” for which the tables are computed. Real bridges and arches are not the homogeneous uniform structures here supposed: on the contrary, they are composed of materials of very variable specific gravities; the voussoirs may be of granite or Portland stone, the spandrils may be either filled in with solid rubble, or partly occupied by abutting or inverted arches, and the roadway and parapet may be composed of materials still more heterogenous. No general formulæ will meet such cases. If there be any instances where Petit and Garidel’s tables (founded on the assumption that all the materials of the arch are homogeneous, and uniformly distributed throughout) will give anything like accuracy, we at least are not aware of their existence.

In the present treatise, the mathematical theorems of the Arch and Revetements are presented with as much simplicity and analytical elegance as the subjects probably permit, but amongst them we have draughted tables and formulæ in abstruse theoretical calculations, the errors arising from neglect of practical contingencies increase and multiply at every step of the investigation; so that the adoption in practice of remote results of theory is generally inadmissible, and always hazardous. If we were not more interested in these particular extradoses and simple arches, it would not be of more interest, indeed, that, in the case of sound, where two sounds reaching the ear either exalt or destroy the effect, so in light, two rays interfering with each other may produce darkness. But who from this abstract observation, who, thinking of the case, would have imagined that it was a fact? It was a result, a fact, that the light which reached reflecting surfaces at a particular angle was polarised in coming from them; that, for example, much of the light reflected from water is in this condition. Thus, suppose, you look with a binocular in the falls, the common mirror, the moonlight, water, a smooth river, like a lake; by turning round the prism in a certain direction the shadow will disappear, because much of the light is polarised, while the moon seen by common light will remain visible; thus realizing the German fable of the man with a glass and a sheep.

This treatise on the polarisation of light has a time applied to the important purpose of detecting shoals and rocks at sea. It had been long the practice for mariners, when they suspected the existence of shoals, to send a man to the head of the mast to detect them; for the outlook might have been obstructed by the position of the reflected light, which dazzled and obstructed his view. Now, as a great part of this reflected light is polarised, it was obvious that, by looking through a polarising prism from the deck, the depths of the ocean could be scanned without the interruption of the glare, which had formerly rendered this so difficult; and thus, this ancient truth of the alteration of light by reflection became practically applied to the preservation of mariners from the hazards of the sea. Another useful application was now made to salmon fishery, to enable the scavengers to see the fish at considerable depth, where detection was before impossible. The singular insight which polarized light gave into the inner constitution of bodies, was useful employed to discover the laws of tension in beams, thus showing that it might be made to aid in the propulsion of ships. Hence the establishment of the polaroid, a process of light performed with magical quickness the most refined and tedious operations of the analytical chemist, by enabling him to ascertain the amount of sugar in various saccharine substances. He was enabled to follow the increasing richness of sugar in the juck of the sea, as the increase of their supply led to an increase of their consuming power, so as to indicate when they are most fitted to be gathered in for the purposes of the sugar manufacturers; and by the same ray silently performing its quick analysis, he was able to make improvements in the economy of labour. Thus, when best is ready to be gathered, labour is in demand for the harvesting of other crops, and consequently is expensive. It would not do then to take another crop, such as parsnips, inferior in its amount of sugar, as the cost of production would outweigh the returns. But precisely at the time that horseradish and cabbages are discarded, and labor, cheap, parsnips plentiful, and most of their price paid, it is most useful to employ the idle mills in the production of sugar from this plant. Thus a ray of light has produced good also to the farmer, as well as to the seafaring man and the engine. Or to take a case of the use of polarised light to scientific researches, which could not otherwise be obtained, it is clear that they would render it possible, by means of a mineral, to determine such questions as to whether the light of the sun proceeded from a solid mass or from a gaseous canopy, or whether the comets enjoyed light of their own, or not; or to reflect that the sun exhibited transparent substances which would render it possible, by means of a mineral, to determine such questions as to whether the light of the sun proceeded from a solid mass, or from a gaseous canopy, or whether the comets enjoyed light of their own, or not; or to reflect that the sun exhibited transparent substances which would render it possible, by means of a mineral, to determine such questions as to whether the light of the sun proceeded from a solid mass, or from a gaseous canopy, or whether the comets enjoyed light of their own, or not.

There are other applications of polarised light to the telescope for measuring the size of distant objects; but to these I will not at present draw your attention, mentioning only one instance, the recent beautiful discovery of the system of constellations, where a sun exhibits transparent substances which would render it possible, by means of a mineral, to determine such questions as to whether the light of the sun proceeded from a solid mass or from a gaseous canopy, or whether the comets enjoyed light of their own, or not; or to reflect that the sun exhibited transparent substances which would render it possible, by means of a mineral, to determine such questions as to whether the light of the sun proceeded from a solid mass, or from a gaseous canopy, or whether the comets enjoyed light of their own, or not. Wheatstone has adapted a simple and ingenious apparatus, by which the true time may be told within three minutes. This elegant application of the
laws of polarization is only one of others which we may expect from the same philosopher."

The following interests others besides students of the College for Civil Engineers, and in the present dearth of employment at home will meet with attention from many of our readers; and the more so, as it comes from one who has a practical knowledge of what it means.

"It is scarcely necessary to urge on you the desirability of a practical education, such as you will receive at this College. I have said enough to show you that it is indispensable in this country, if you wish to outstrip the competition which now, happily for the world, prevails in all departments of industry, commerce, and the arts here. It is absolutely necessary for the success of the colonial abroad. If not, your future will be a barren field.

The truth is so much in the eyes of all men, that, I doubt not there will be many of you who will try their fortunes in foreign lands. I myself, having been born in a colony, and all my relations and friends having lived and acquired their fortunes in colonies, I naturally know somewhat of the life and the prospects of intelligent emigrants. This I can assure you, that I have never known an instance of failure, where a man went out with a well-grounded scientific knowledge, and with a power of applying it in a special direction. I have many friends in the colonies, who have gone out with no other recommendation than that—a very high one certainly—of being proficient in some one of the sciences. I recall to my mind at the present moment names of men who I am proud to call my friends—men who have all, in the most profitable and lucrative posts abroad, from having gone out, some with a knowledge of geology, others of chemistry, and others of natural history. It is true that scientific men are rare in our colonies; and it is because practical scientific education is wanting, that the colonists have the chance for you who value your youth and your advantages. Look at the treasuries opened in Australia by the discovery of coal and of valuable mineral ores. What a grand field for the minerologist, the metallurgist, the geologist, chemist, and practical engineer! Where we hear of men who have lately made large fortunes in the course of three years, by a happy development of formerly-neglected mineral wealth, is there not here encouragement to those who have a sound knowledge of the applied sciences to devote their lives to the development of our country's industry? But, in attempting to do so, will you not meet with difficulties to overcome, such as cannot occur in this land, where all kinds of professional talent is available. It is for this that we give a general practical education such as we do. To you are for a farmer in the colonies? Then let me understand the principles of agriculture, and the art of making and repairing your implements; learn how to survey; and how to make and repair your agricultural implements; learn how to make repairs, how to cultivate it when procured,—learn to know how the resources of the country are to be economised. Recollect, that in rolling down whole sheaves of sheep for their tallow only, in imitation of your brother farmers, you might at the same time make the most admirable and nutritious portable meat and soup for armies and navies—a process, if carried out, which is, I am sure, destined to become one of the most valuable, though yet untitled manufactures of Australia—and why not? Because there is no science to guide them in a manufacturer involving a knowledge of animal chemistry, as well as of a wise adaptation of machinery, and an acquaintance with what has been done elsewhere in other countries. And you, the mineral surveyor, how invaluable to gain the geological knowledge which you may also here acquire; how indescribably useful your chemical power of detecting and assaying valuable ores and minerals! Are you destined for the army abroad? The best way to gain the appointments or lucrative employment, is to have the power of making yourself useful with your scientific knowledge. I again say, that in this service in our colonies I have never known an instance where a really destined scientific man failed in being speedily advanced to a useful and honourable position.

But do not think that in these days fortunes or honours are easily acquired. It is not mediocrity in your pursuits that will enable you to outstrip the masses struggling to push forward. The age is an age of action, and if you are to succeed in future life, you must now brace and prepare yourself for the struggle. If you fall asleep now while you are young, to vigour, and able to prepare yourself for future life, the world will not know what you have made, and it will be a long and a sad struggle for you to overtake those who were active when you were passive. Recollect, that it is only by study, downright hard study, that you can acquire that mental strength and vigour that will enable you to overcome the increasing difficulties of progress in life."

As there are some remarks on this work in the Fuscicus of "Candidus," we shall not trouble our readers much further as to its critical merits. It was intended for a popular work in the United States, but, unhappily, it gives little definite information as to the buildings there, and is ten years behind hand as to those of Europe, the "Architectural Magazine" having been the chief authority.

It seems from the remarks of the authoress that Gothic and Elizabethan are now the fashions, instead of Greek, but there are few favourable American examples of any style given by the authoress, though there are many American buildings of great merit. We shall try and glean what we can as to buildings in the United States of which examples are given by the writer.

At Boston among the novelties are named—

"Trinity Church," in Summer-street, a Gothic edifice, of granite, built in 1829.

"The Tremont House is a large and beautiful building, of granite, with a fine portico in front. J. Rogers, architect."

Two beautiful Gothic churches, of freestone, were built in 1847. Billings, architect."

At New York—

"The Church in Washington-square, belonging to a congregation of the Dutch Reformed denomination, is said to be one of the most perfect Gothic structures in the United States. Le Parad, architect."

"Trinity Church was commenced in 1841, on the site of the old church in Broadway, and completed in 1846. It is built of a beautiful fine-grained freestone, in the Perpendicular Gothic style. It is 192 feet long, and 84 wide. Its graceful, symmetrical spire is 254 feet high. It is by many considered the finest specimen of ecclesiastical architecture in this country. Mr. Upjohn, architect."

"Grace Church, on Broadway, is built in the form of a cross, in the Gothic style, and is of white marble. The windows are of stained glass, and the carving in bas-relief is of 145,000 dollars ($20,000). It was completed in 1845. Mr. Kenrick, architect."

"The Custom House, in Wall-street, is a beautiful Doric building, 177 feet long, and 59 feet wide. The architects were Ithiel Town and Alexander J. Davis."

"The Episcopal Church of the Holy Trinity, at Brooklyn, New York, is one of the finest specimens of Gothic architecture in this city. A citizen of Brooklyn, with a munificence above commination, has erected this noble edifice, at a cost of about 150,000 dollars ($20,000). Lefevre, architect."

At Philadelphia—

"The United States Bank, now the United States Custom House for the port of Philadelphia, is one of the most beautiful buildings in this city. It is closely copied from a perfect model, the Parthenon. Its length is 161 feet; its breadth 77 feet. The nine massive Doric columns of the portico are on a square platform of 24 feet; the height of the shaft at the top is by a high flight of marble steps. Thus lifted up away from the street it has a very imposing appearance. The banking-room is 81 feet long and 48 feet wide.

The new Bank of Pennsylvania is copied from the Ionic Temple of the Muse, upon the Ilissus; it is built of marble, and is a large and handsome edifice."

"The Girard College,—The main building, which is the subject of this description, is composed in the Corinthian order of Greek architecture; it is 250 feet by 233 feet, and consists of an octastyle peripteral superstructure, resting upon a basement of 8 feet in height, composed entirely of steps extending around the whole edifice; by which a pyramidal appearance is given to the structure, and a means of approach afforded to the students, who enter from every side. The dimensions of the stylobate (or platform on which the columns stand) are 159 feet on the fronts, by 217 feet on the flanks; and the cell, or body of the building, measures 111 feet, by 169 feet. The whole height, from the ground to the apex of the roof, is 106 feet. The columns are 34 in height. The base is 8 feet, and at the bottom of the capital, 5 feet; the height of the capitals, including the abacus, is 9 feet, and the width, from the extreme corners of the abacus, 10 feet; the whole height of the column, including capital and base, is 55 feet. The entablature is 16 feet 3 inches high, and the greatest projection of the cornice, from the face of the frieze, is 4 ft. 9 in.; the elevation of the pediment is 20 ft. 5 in., being one-ninth of the span. The capitals of the columns are proportioned from those of the monument of Lycurgus at Athens, they are of American marble, and were wrought upon the grounds of the college.

The building is three stories in height, each of which is 25 feet from floor to floor: there are four rooms of 50 feet square in each story. Those of the first and second story are vaulted with groin arches, and those of the third story, with domes supported on pendentives, which spring from the corners of the rooms at the floor, and assume the form of a circle on the horizontal section, at the height of 19 feet. These rooms are lighted by means of skylights of 16 feet in diameter. All the domes are terminated below the plane of the roof, and the skylights project but one foot above it, so as not to interfere with the character of the architecture.

The roof is covered with marble tiles, so nicely overlapping each other as to defy the most burning storms. The main edifice, there are four other buildings belonging to the institution, each 52 feet wide, 125 feet long, and four stories high. Thomas U. Walter, architect."

At Washington, among other buildings, are—

"The President's House, of Potomac freestone. It has two fronts with porticoes, and is 180 feet in length by 85 feet in width. The Patent Office is still unfinished; it is designed, when completed, to
surrounded the square on which it stands. It is of the dark freestone of the Potomac. The building already completed has a superabundant portion of the Doric order.

The General Post Office, of white marble, is a magnificent building, ornamented with pilasters, and an entablature of the Corinthian order. The edifice already occupies the front and part of two other sides of a square. It is unfinished, but when completed will be one of the most splendid buildings in the United States.

The Capitol is finely situated, commanding a view of the city, with the surrounding country, and the river Potomac. It is 352 feet long in front, and its greatest height 145 feet. The Hall of the Representatives is of a half-cylinder form. The dome rises above an entablature, supported by 24 Corinthian columns of variegated marble (sometimes called pudding stone), from the banks of the Potomac."

At Baltimore we find—

"The Roman Catholic Cathedral, planned by Latrobe. It is of the Ionic order; 190 feet in length, 117 feet wide, and 127 feet high, to the top of the dome."

For want of something better we shall extract what is said of the public squares and walks of the United States, to which more attention is now paid, a gratifying proof of the progress of taste.

"The citizens of New York have at length become aware of the beauty and salubrity of public squares. St. John's-park, Washington-square, Union-square, and several others in recently-built parts of the city, are tastefully ornamented with walks and shrubs. Here the young and old might meet to drive dull care away, and lose for a few brief moments the calculating money-making plans that almost constantly usurp American thought and feeling."

The Boston Common is the most spacious pleasure ground in the United States. Seventy-five acres were appropriated by the early fathers of the town for this purpose, on the condition that it should ever remain devoted in this way to public convenience and comfort. The same venerable elms which shaded the patriots of the revolution, still wave over the heads of their successors and fresh young trees are planted from year to year by the side of the new gravelled walks, renderd necessary by the rapidly increasing population of the city. The undulating ground of the common gives it a pleasing diversity of hill and vale, and the little lake or pond near the centre adds to its picturesque beauty. The New York Battery, though much smaller, is very delightful, affording a view of the magnificent harbour, graced with its beautiful islands. Convenient seats are placed about the battery, that its numerous visitors may quietly enjoy uninterrupted views from the sea, beneath the gray and white marble of the trees. It is one of the loveliest spots in the world.

The public squares of Philadelphia are incalculably important to the health of the city. Beneath the dense foliage of Washington-square, crowds of merry-makers, joy and delighted, their bursts of laughter, their sports. The public squares of the United States are the centres of several squares are so necessary to the health, as well as the enjoyment of those who are shut up in the close streets of a city, that it should be considered an imperative duty to provide for all classes of the inhabitants.

The following shows the resources available to the architect in the United States:

- Granite, a primary rock, may be called the foundation-stone of the earth. Its constituent parts are quartz, feldspar, and mica. It is a hard and brittle stone, but with much labour may be worked into capitals and other ornamental parts of a building. It abounds in the New England States, especially in New Hampshire and Massachusetts. A beautiful white granite is there quarried, and employed in building at home, and sent to different parts of the Union. The United States Bank is made of white granite; the market house at Boston, some fine dwelling-houses in New York, and many other edifices there and elsewhere. Sienite is often called granite, from its resemblance to it; feldspar and hornblende predominate in its composition, but it is even more difficult to work than granite. The stone of Quincy, near Boston, has given it the name of Quincy stone, by which it is extensively known. The Astor House in New York is built entirely of sienite, and in Boston there are many structures which have now been standing for some years; showing that it bears exposure to the air, without injury to its appearance. The Bunker Hill Monument is of this stone.

- Marble is one of the most durable of stones. The beautiful Pentelic marble of the Parthenon has stood the storms of more than 2,000 years, without injury. Happily for us, this fine material abounds in almost every part of the country. The blocks of these marbles may be purchased throughout the United States. Many marbles are extensively known. Massachusetts furnishes specimens of various kinds. The splendid columns of the Girard College were brought from Sheffield, in Berkshire county, in that State. New Hampshire has several quarries. In Connecticut, near New Haven, green marble abounds, resembling the verdant antique. Many specimens of this marble have been sent to Europe, and been much admired in the cabinets of the curious and scientific. Near them is another great red marble. New York has several quarries. The black marble of Vermont is of the same class as the Conn. The white marble abounds in Pennsylvania. In short, marble is so abundantly supplied, that taste and durability may be combined by the use of this material in elegant edifices.

- Slate, a stone containing a large proportion of mica, splits with ease, and affords a beautiful paving-stone. Slate is found in great abundance in this country; it is used for covering roofs, and should be universally substituted in cities for shingles or other combustible materials.

- Sandstone, usually called freestone, is found in variegated colours, from gray to red, and dark brown. It is easily wrought, and much used in building. Extensive quarries of red freestone are worked at Champaign, in Connecticut. The Potomac freestone is extensively used; the President's House, the Capitol at Washington, and St. Paul's Church, Boston, are built of it. Sometimes it is used in interior decoration, and is thus a durable and economical material for cottages, stables, &c. It is general use for the basement, window-sills, and caps of brick buildings.

- Greenstone, a stone containing a large proportion of mica, splits with ease, and affords a beautiful paving-stone.

- Limestone is found in great abundance in this country; it is used for covering roofs, and should be universally substituted in cities for shingles or other combustible materials.

No country in the world is more abundantly supplied with wood of every variety than the United States.

- The white oak grows to a great height in the Middle States and in Virginia. It is a strong and durable, and although sometimes employed in domestic architecture, is more generally used for ship building. The black oak rises to a still greater height, but is not so large in circumference.

- Maple, of several varieties, is also superior to a fine polish. The curbed and bird's-eye maple are very handsome for interior finishing. Maple grows in almost every part of the Union; they are numerous and luxuriant in the Western States.

- Pine is a soft wood, easily worked, and has for this reason been hitherto quite too much used for building. It is, however, a valuable wood, and will be extensively used in future.同期, durable materials are substituted for the exterior of buildings. From Maine to Florida pines of various kinds abound, and are exported in large quantities to Europe and the West Indies.

- Birch, not much used in building, although it abounds in New England and the Middle States.

- Spruce, a hard, dark-coloured wood, that receives a fine polish, and is very handsome for interior finishing.

- Cypress grows to a great size in the Southern States, and is frequently used for building.

- The white cedar grows abundantly in the Middle and Southern States, and is being a soft light wood is used for shingling and interior finishing. The red cedars is a durable wood, used for posts and fences."

Syllabus of Lectures on Civil Engineering, for the use of the Students at Putney College. By W. Ranger, C.E., lecturer on Civil Engineering and Architecture at Putney College, and on Civil Engineering to the H.E.I. Officers at the Royal Engineering Establishment, Chatham, etc.

This is nothing but what it purports to be—the syllabus of lectures; yet it may be very usefully referred to by the professional man. It seems very easy to put down the heads of lectures; but Mr. Ranger has shown in the arrangement the resources of a logical mind, and his intimate acquaintance with the subject.
which he teaches. It is in these qualities that consists the use for the professional man, who is able practically to supply the detailed information, and may refresh his memory by reading, under each head, the enumeration of the various resources applicable to the work intended.

HYDROGEN GAS AS A MOTIVE POWER.

Among the patents for new inventions in this country specified within the last month, is one (obtained by the widow of a French engineer, at the request of her late husband,) for employing the explosive force of hydrogen gas as a motive power. In the arrangements for effecting this object there is nothing deserving of special notice, the chief novelty being the placing, in two cylinders, wherein the explosions of the gas mixed with atmospheric air take place alternately, either by the agency of electricity or by the flame of a gas-light. To what extent however such an explosive force would be available, supposing it could be regulated to act with uniform pressure, is a question deserving consideration, as the attempt has been previously made, and may be again and again repeated.

There is a peculiarity in the power generated by all explosions, which renders it almost impossible to employ it usefully in working machinery. The power is not concentrated upon the instantaneous or percussive action, which enables it to overcome resistances that would not yield to the same amount of force steadily applied. In the explosion of hydrogen gas there is the further peculiarity, that the resulting product occupies so much less space than the original gases as to result in a partial vacuum; and we have heard a popular lecturer when noticing this result assert, that in such explosions the force is directed altogether inward, and that there is no external force whatever. This assertion, too, was made in defiance of the common experiment of the electrical pistol, with which he must have been familiar. The external force is indeed only momentary, and depends upon the instantaneous expansion of the gases by the heat caused by their ignition; consequently, the difficulty of regulating such a power is greatly increased; but that there is power exerted there can be no doubt. The amount of it we believe to be too small to be ever practically available.

With a view to ascertain the amount of force generated by the explosion of hydrogen gas, we some years since made several experiments, which, if not strictly accurate, were sufficiently so to enable us to conclude that the force generated is much too small to be of use, and amounts only to the expansion of the gases employed into about eight times their original volume; or to the exertion of a momentary pressure of eight atmospheres. The experiments were arranged in two different ways, but the results nearly agreed. In the first, the vessel was filled with water, and above the water, a quantity of gas of hydrogen mixed with atmospheric air. A square tin vessel, open at the bottom, was made to the top of which there was soldered a smaller tin vessel that held one cubic inch. This smaller vessel for holding the gas, was open entirely at the bottom and the top. Insulated wires were introduced into the small gas-holder, for the purpose of causing explosion by means of an electric spark. The vessel being filled with and inverted in water, a cubic inch of an explosive mixture of hydrogen gas and atmospheric air was passed up into the small reservoir. A small trough, into which the tin vessel was inverted, was then filled exactly to the rim; and the tin was held firmly on supports, which raised it several inches above the bottom of the trough. The electric spark was passed through the gases in the gas-holder, and after a certain time, the gas being directed into a receiver. By measuring the water thus displaced, the expansion of the gas by heat during the explosion was ascertained. This experiment was several times repeated with nearly corresponding results: the amount of water displaced being about eight times the volume of the mixed gas.

In the second method the experiments were made in the dry way. Under the impression that the explosive force was very great, a gun barrel was procured; and a piston, attached to a small rod, was loosely fitted into the barrel. The mixed gases were introduced from a bladder through a hole at the breach; the space occupied by the gases being measured by the height to which the piston was drawn up. The explosion of the gases was effected by an electric spark; and the space in the gun-barrel through which the piston was forced was ascertained by a ribbon attached to the piston rod; the ribbon being drawn out with the rod during the explosion, and left loose afterwards. The loose part of the ribbon indicated the extent to which the piston had been forced from its first position, and by measuring and comparing it with the space occupied by the gas, the explosive force of the explosion was determined, and it nearly agreed with the results of the first set of experiments. In the course of these experiments the shell had, unexpectedly, the personal experience of the force exerted by the explosion. The bladder containing the mixed gases, whilst held under his arm, was inadvertently brought near the flame of a candle, and the contents exploded with a loud report and concussion that cleared out the case. He left his hand there unburnt, and indeed, by the force, but without inflicting any injury.

Though these modes of experimenting were certainly not calculated to afford very accurate results, yet they proved that the explosive force of hydrogen gas is very much less than we had anticipated, and that consequently it was useless to pursue an attempt to render it available as a motive power. It is very probable that, by using other proportions of hydrogen gas and atmospheric air than we employed, greater force may be obtained; but it cannot, we feel convinced, be under any circumstances at all comparable to the explosive force of gunpowder. The terrific effects so frequently produced in coal mines by explosions of carburetted hydrogen gas, may probably lead to the supposition that the explosive force is immense; but if the large volumes of gas exploded in producing such disastrous results be taken into consideration, it will be found that the power exerted is insignificant, compared with the explosive force of other agents.

NEW ELECTRIC LIGHT.

An experiment was made on the Great Western Railway, on the 18th ult., to test the power of a new species of light produced by electricity, particularly with a view to its being used in railway trains. The light is produced by an apparatus invented by M. Le Mott, a French gentleman, who has been for several years employed in electrical experiments in Russia, and whose discoveries in that department are well known to the scientific world. At about six o'clock a truck, containing a square wooden box, was turned in the direction of Windsor Castle, not the shape of a sony-box, and having a galvanic battery of some 60 or 70 small jars disposed around it, was attached to the last carriage of the train then about to proceed from Paddington. The light was produced inside the box, and the rays, condensed and heightened by a powerful reflector, were emitted by an aperture contrived for the purpose. The light was produced before the train left Paddington, when a blazing blazed filled the whole of the spacious station, casting the numerous gas lamps through to the windows of the trains. As the train went on its way, the reflection left a long track of clear bright light for the distance of a mile and more behind it, in such a manner as to render it utterly impossible that any train coming up behind should run into it, except as the effect of deliberate intention. The reflection, as seen from the carriages, was very beautiful, the prismatic colours being distinctly and vividly delineated along the outer edge of the circle of radiation; and as these fell upon the dense column of smoke ascending from the engine, the effect was singular and striking. The night was dark, but clear, and so far favourable to the experiment; and objects, such as a bridge, were rendered distinctly visible at the distance of about two miles. The experiment was made as far as Slough, on arriving at which station the train was detached from the train, and continued there for about half-an-hour, till the up-train arrived, with which it returned to Paddington. While at Slough, the light was thrown into the inspection of Windsor Castle, as it was the expectation of M. Le Mott, who accompanied the experiment, that it would be seen from thence. While there a gentleman stationed himself at the distance of 300 yards or so from the apparatus, and read a newspaper by the light produced. It was found that this could be done with perfect ease. The apparatus then returned to town in the same manner, the light being continuously intense during the whole of the journey and return; and we were informed by the ingenious inventor that there could be no difficulty in keeping it up for the whole night. The experiment afforded great satisfaction to all who witnessed it, the only drawback being, that the apparatus, having been in the first instance adapted for stationary experiments, suffered considerably from the jolting inseparable from railway motion—a defect which the inventor considered might be with ease overcome in any future experiment.
PROCEEDINGS OF SCIENTIFIC SOCIETIES.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

Nov. 29.—E. DE GREY, President, in the Chair.

This was the opening meeting. The President, in presenting the Royal Medal which had been awarded to Mr. Cockerell by the Institute, in January last, but which, in consequence of the time required to prepare the dies, made expressly for this purpose, had not been presented at the closing meeting of the last session—complimented that gentleman on his being the first individual selected by his professional brethren to receive the honour which the Sovereign had placed at the disposal of the Institute.

Prof. Donaldson then gave a description of the Cathedral Church of St. Isaac, Petersburg.

SOCIETY OF ARTS, LONDON.

Nov. 29.—J. Walker, Esq., C.E., in the Chair.

A letter from the Royal Society of Edinburgh was read. It was accompanied by a medal bearing the effigy of Napier of Merchiston, and was offered as a mark of respect for the Society of Arts.

The President then addressed the Council, which concluded as follows:—“It is proper, however, that the Council should direct special attention to a new feature in the exhibitions of the present session. It has been complained, that for a couple of years the Society has directed attention too exclusively to the Fine Arts, to the neglect of the Mechanical Arts and Manufactures. This may, perhaps, be in part true. But in reforming the operations of the Society, it was necessary to do one thing at a time. The Council have postponed the mechanics—not lost sight of them; and have allowed themselves of the opinion—no, perhaps, the adoption of larger rooms on the ground floor for the reception at Christmas of an exhibition of the models of large inventions of recent date and of a mechanical nature. This they hope will afford the public the gratification of having laid systematically before them all that is most important in the records of modern invention.”

“On a plan for constructing a Malleable Iron Lever Bridge.” By Mr. T. M. Gladstone.—The advantages which the author considers it to possess over other plans, are that of enabling bridges of any span to be built without a centering, whereby a saving is effected; also enabling a flatter roadway to be obtained while a higher waterway is insured than can be got by any plan in which the arch springing from the pier is made use of. The paper concluded with a detailed account of the comparative cost of constructing bridges on the various plans hitherto used, and also of the weights of metal employed.

INSTITUTION OF MECHANICAL ENGINEERS.

At the last quarter meeting of the members of this institution, held at Birmingham, the recent death of George Stephenson, the lamented President of the Society, and the intimation that a paper relating to his character and life would be read at this meeting, invested the proceedings with an unusual degree of interest.

After the minutes had been read and confirmed, Mr. M'Connell, who occupied the chair, said that in consequence of the absence, from illness, of Mr. Scott Russell, the duty devolved upon him (the chairman) of reading the paper on the character of their late worthy and much lamented President. They had met for the first time since the death of the great man who had lately presided over them—an event which the society greatly deplored, and their grief was shared by all who could appreciate honesty and genius. In his death the world had lost one of its brightest ornaments. He had risen by the force of his own talents from a humble rank in life. He was a kind friend, and not less distinguished as a man than as a great mechanical genius. As long as railways existed, the name of Stephenson would live with them.

The Chairman then proceeded to read Mr. Russell’s memoir, the length of which precludes the possibility of insertion here.

At the conclusion of the paper, Mr. Gach then said he rose under feelings of no ordinary kind to propose that the society should, at this the earliest possible moment, place on their minutes an expression of their deep regret at the loss of their much esteemed friend and President, Mr. George Stephenson. Really when they remembered his last appearance amongst them at the institute, their high spirits, good health, and great strength and activity of mind, it was not easy to realize the full extent of the calamity that had befallen them, nor to speak of the bereavement without feelings of strong emotion. He (Mr. Gach) had not known their late President as many years present; but the peculiarity of Mr. Stephenson’s character was, that one did not require that time should elapse before he was known and loved. It was impossible for any one younger than him to regard him with any other feelings than those of deep affection. There was something in his manner, in the very tone of his voice, which endeared him to all. He was open, honest, manly, and straightforward in all his dealings; sometimes rough, but that peculiarity never could hide the inherent kindness of his disposition. Peculiarities he had, undoubtedly, but in his long battle with the world he had so often found himself right, that he was, as it were, privileged to speak authoritatively; and moreover, what in other men would have been considered bullying, in him it did not at all, only made the better liked. There was another peculiarity that was remarkable: he was never ashamed—why, he was proud of his early life. He never attempted to gloss over his struggles with an unfavourable position; and while he was the most stubborn man, he was the most genial; a man who had been hard pressed, he would have been the first to go back on his early associations with pleasure and pride. And this was almost the only pride he had, for his greatest delight was in meeting with the sons of some early friend who had laboured alongside of him, and gladly acknowledging to them the great debt he had owed to them. He (Mr. Gach) could not refrain from giving these feelings expression; and, in conclusion, he would propose the following resolution:—“That the members of this institution desire to express their deep regret at the decease of their late President, George Stephenson, whose institution has greatly contributed to bring it to its present state of success.”

Mr. FORRERGILL briefly seconded the motion, which was carried unanimously.

Mr. M’Connell remarked, that immediately after the death of Mr. Stephenson, the Council of the institution met at Manchester, and drew up and forwarded a letter of condolence to his widow for the great loss she had experienced. They at the same time thought that the best tribute they could pay to his memory, and the best service they could render the society, would be the selection of Mr. Robert Stephenson as a successor to his father in the chair. Accordingly, Mr. M’Connell endeavoured to get into communication with that gentleman, and the result was, that he had consented to accept the office of President. The announcement was received with loud applause.

Mr. FORRERGILL detailed the steps they had taken to bring about this desirable result.

Mr. M’Connell then formally proposed the election of Mr. Robert Stephenson. A better choice could not have been made, and the active connection of that gentleman with their society would give their proceedings additional lustre.

The motion was seconded by Mr. FORDERGILL, and passed by acclamation.

On the Adaptation of the Cambrian Engine to Locomotive Purposes.”—A paper on this subject, accompanied by drawings, contributed by Mr. John Jones, of Bristol, was then read by the Secretary. The advantages claimed for the engine, constructed on this principle and the obtaining a long stroke in the crank, without the disadvantages of a long-stroked cylinder, where high velocities are required, the arrangement of the levers which balances the balance of the engine, the entire disappearance of any oscillating motion of the engine, and doing away with all centre pressure.—A somewhat lengthy and interesting discussion followed the reading of this paper, in which the Chairman, Mr. Cowper, Mr. Slatie, Mr. Peacock, Mr. Crampton, Mr. Humphries, Mr. Beyer, and others, took part. Considerable difference of opinion existed as to the value of the invention, but the general opinion, which we have no space to follow, was against the presumption that the adaptation would be advantageous; but at the suggestion of the chairman it was proposed to reserve any decision on its merits until there was more information before the meeting.—This suggestion was adopted, and the discussion terminated.

On a Railway Elevator.—Mr. FORDERGILL read a paper contributed by Mr. W. L. Kinmonth, of Glasgow, on an elevator erected for the Glasgow and Ayr Railway Company. Several members stated that they had seen the machine at work, and it was an admirable piece of mechanism. It had been erected in 1840, and had never required repair, except in one instance some years ago.

Brocketton’s Patent India Rubber Joints.—Mr. Cowper brought this subject before the meeting in a brief explanation of the application of vulcanised India rubber to pipe joints, and, if, in his pocket, showed those with those on the shoulder with which he had been encumbered. He apprehended that the practical objection to the adoption of the joints would be the difficulty of repairing them.—Mr. Richards, of Worcester, said he had had more than twelve months’ experience of the joints, and he could speak in confident terms of the great value of the invention. They had withstood the influences of ammonia and other gases, and did not seem to be at all affected by the changes of temperature. He considered that the repairs could be done even more easily with joints such as those than with lead, for there was no lead in the shoulder with which they had been encumbered. He intended to adopt the joints extensively. Mr. FORRERGILL said that Mr. Richard’s explanation had removed the objection stated.

After a few other commendatory remarks, in which the value of the invention was acknowledged, the CHAIRMAN remarked that they seemed to be agreed as to the usefulness of these joints, their durability being the only point on which the society could not give a opinion.
NOTES OF THE MONTH.

Branch Passenger Locomotives.—Several trips were made on Wednesday, 15th ult., by Mr. J. B. Adams, assisted by Mr. W. R. Row, with a charge of 12-ton engine, the Fairfield, which has been constructed for one of the branches of the Bristol and Exeter line. The engine, "tender," and carriage, which have been constructed by Mr. Adams, of Fairfield Works, Row, are connected together in a manner which allows for laying down the present character of permanent way, and supplying the engine with locomotive and carriages as stock. The engine and carriage run upon six wheels. The engine has but two wheels—viz.: the driving-wheels, which are in front. She is fastened to the carriage by longitudinal side-plates, which are screwed together, and also by bolts, in such a manner that when in use the engine is fixed to the carriage, so that when the horse is turned the whole line may be said to run upon one frame. The engine has an upright boiler similar to the little 22 cwt. express engine belonging to Mr. Samuel, the resident engineer of the Eastern Counties Railway. The boiler has 150 tubes of 4 inch diameter outside, and 4 feet long. The fire box is 2 feet 6 inches, by 2 feet. The diameter of the driving wheels, which have about 3 tons upon them, in 4 feet 6 inches; the cylinder 8 inches, and the stroke 12 inches. The engine is to be worked at about 100 lb. pressure, and the consumption of coke is calculated at 10 lb. per hour for each driving wheel of the driving wheels of the tank, which holds 220 gallons of water. The coke is carried in an iron box attached to the carriage. The carriage is a composite one, and will afford sitting-room for 16 first-class and 32 second-class passengers, and with the exception that the carriage is to be made to accommodate 60 persons. The cylinders of the engine communicate with the axle by an intermediate crank shaft. This is connected with the axle by side-rods. The trailing and centre-wheels run loose on their axles; to which there is no escape. With the exception of the driving wheels, the other wheels are fitted with side-plates, and by gearing can be worked under great disadvantages. Being a new engine, her boiler is necessarily dirty, and she runs stiff. It was not till three or four journeys had been made that the pruning could be kept down sufficiently to get anything like an effective working pressure. In the course of the Great Eastern Counties lines. The boiler is to be the common horizontal one. In a few days the Fairfield will, no doubt, be in pretty good working order. We shall then make a few more trips upon her, and be able to offer an opinion upon her speed and power.—Herald.

London and North-Western Railway—Deterioration of Permanent Way.—It is stated a committee has been appointed by the directors of the London and North-Western Railway Company, consisting of Mr. Dockray, the resident engineer; Mr. McConnel, the locomotive superintendent; Mr. Madigan, serving as the secretary of the committee; Mr. Crook, chairman of the line; and Mr. Crompton, C.E.; for the purpose of discussing by what means the comparative deterioration of the permanent way, caused by heavy engines of different classes, may be ascertained.

Certain Prevention of Explosions in Steam Engines.—It is impossible for the foreman of a boiler to keep an eye upon all the engines and reading of boilers that so frequently occur, they are the work of the explosive principle, when disengaged from its combination with steam. Similar is its effects to lighting; it is identical with electricity in its distinctive properties; its velocities are in effect unlimited; it is devoid of weight, and not subject to the laws of gravitation, which are inherent in all matter that has weight, and it is hence evident that it may be conveyed away by similar conductors. It is so extremely certain that the explosive principle is disseminated from steam as it is let into the cavity of the nozzle, or valve chamber, on the opening of the steam valve; the pressure that kept them combined is then in great part taken off, until the cavity is filled with steam. There is no proper escape of the explosive element from the nozzle, which is heated, and in effect insulated, and the accumulation is highly dangerous; but it may be safely carried off by proper conductors—those most convenient are small copper tubes. One end of a tube of proper length is to be fixed in the cavity of the nozzle; the other end to enter the cavity of the nozzle, and have over it a small slit in the end, to allow the explosive element to pass off to the tube by the tubular conductor, the valve to close by the force of steam, and the cavity becomes filled therewith. The conductors of a condensing engine should be carried high enough above the water in which they terminate to preserve the vacuum. The security from explosions and breaking of engines must be complete, the cost and trouble only nominal.—J. Wilson, M. & T. V. J. 1.d.

Testing of Metal at Woolwich Dockyard.—The trial of the large guns supplied to the Board of Ordnance, which has been carried on during the last 18 months, for the purpose of ascertaining the best description of gun, and the best method of manufacture, has been performed by Colonel Dundas, C.B., and Mr. Monk, deserve great credit for the excel- lence of their models. The former 32-pounder gun, of 50 cwt., is now reduced on Colonel Dundas's principle of construction to 23 cwt.; effecting a saving of 14 ton on each gun of that calibre—the average price of the metal being from 101. to 131. per ton. There is also a saving of 6 lb. of powder on each charge, the former charges being 10 lb., and the new ones being reduced to 4 lb. per gun. With this charge of powder cast at the Low Moor Foundry, in Yorkshire, have been found to stand the heaviest charges when fired, and will consequently receive the largest number of shots. The cost of the expense of the trials has been considerable; but the saving which will ultimately be effected, and the saving which will be made by the adoption of the new system, are now to be apprehended from the bursting of guns when placed on board of ships, or mounted for service in the garrisons, must give confidence in the system which is hereby adopted. A trial has also been made of a 12-pounder-high-angle 6-pounder gun, submitted by Mr. Morgan, of Bristol, but it has not as yet been found applicable to the service, in consequence of the great recoil breaking the cap squares, or coverings, of the transition.

Marine Compass.—A new invention, by Captain Sir Samuel Brown, R.N., has been exhibited at the Royal Society in late months at Woolwich Dockyard. It is a compass in a glass box, sustained by a small pillar with telescope slides, by which it can be elevated or lowered to any desired height. It is designed to obviate the local attraction of the ships. The iron that is thrown out is a whole wire. The volume of the compass, and the compass, is estimated to be equal to about 3,000,000 of gallons per day, a quantity considerably exceeding the expectations of the company themselves.

A New Method of Extracting Pure Gold from Alloys and from Ores.—The method of obtaining pure metallic gold in the form of a sponge mass, has been practiced by me for several years, and no account of the process has, to my knowledge, heretofore been published. It is very useful to the chemist and to the manufacturer, and is more economical than any other method that I am acquainted with. After separating the gold from silver, by means of a mixture of nitric and hydrochloric acids, as is usually done, the solution containing gold and copper is to be evaporated to small bulk, and the excess of nitric acid is thus driven off. A little oxalic acid is added, and then a solution of carbonate of potash, sufficient to take up nearly all the gold in the state of aurite of potash is gradually added. A large quantity of crystallized oxalic acid is now added, so as to take up the excess, and the vessel is then boiled, the gold is immediately precipitated in the form of a beautiful yellow sponge, which is absolutely pure metallic gold. All the copper is taken up by the excess of oxalic acid, and may be washed out. Boil the sponge in pure water so long as it contains the copper, then filter the liquid from the sponge, and dry it on filtering-paper. It may be formed into rolls, bars, or this sheets, by pressing it moderately in paper. I have made several useful applications of the gold sponge thus prepared, and had a toothplugged with it in October, 1846, to which purpose it is well adapted. By moderate pressure the sponge gold becomes a solid mass, and burnishes quite brilliantly. The jeweller or goldsmith will find sponge gold to be quite convenient when he requires it for a solder, and it is a convenient form of the metal for making an amalgam for the gilding. I have used it for some years in soldering platin, and prefer it to the filings of gold or foil for that purpose. This method of separating fine gold from coarse is very simple, and cheaper than using any other method. It is applicable in the separation of ores that may be treated by acids, and is vastly preferable to the method commonly used by chemists and assayers. When making oxide of gold for dentist's use, the chemist will find that oxalate of gold in the form of a yellow powder is much more applicable than the oxide that is dissolved in an excess of the alkaline solution. Many other applications of this very simple method will occur to chemists and artisans.—C. T. Jackson: Stillman's Journal.

Extraordinary Block of Granite.—A block of granite, containing upwards of 5000 feet of stone, and weighing upwards of 100 tons, was recently dislodged at the granite quarries of Messrs. Freeman and Co., at Aben. A hole 9 feet deep having been bored, 14 pounds of powder, with which it was charged, produced a slight crack; into this was thrown another charge of 24 lbs., then another charge of 20 lbs., and the block was entirely dislodged. Considering the largeness of some of the stones produced at these quarries, it is astonishing in how comparatively short a time they are prepared for exportation. A few days since, another block of granite, weighing when wrought 180 feet, and in weight 11 tons; the preparing and working of which was performed by a couple of men in a week.
Safety Pressure-Gauge for Gas-Works.—In the manufacture of gas there are many circumstances under which accidents are very likely to occur; for instance, if the pipes which conduct the gas happen to be broken by deposit of crystals of sulphur, or carbonaceous, or other substances, there are great dangers of explosions. Any neglect in the complicated arrangements of the valves will form an obstruction, and by preventing the free flow of the gas generated in the retorts into the gasometers, an explosion is the result. The only means of preserving in its general use to give a distinct indication of the state of the gas in the pipes is the ordinary pressure gauge, which is, under many circumstances, insufficient. M. Magnier communicated at the last sitting of the Paris Academy of Sciences, a plan for an apparatus for giving timely warning of any obstruction to the passage of the gas, which is simple and inexpensive. He terms it a "Safety Pressure-Gauge," which consists of a small bottle-shaped vessel, with two orifices, one of which is attached to the glass tube forming the ordinary pressure-gauge. To this vessel is added an apparatus for giving warning, i.e., any obstruction to the passage of the gas being introduced into the pressure-gauge, which communicates with the gas apparatus, as is the pressure is reproduced, and all the variations of pressure, to several inches of water, can be traced; but if greater than ordinary, the water contained in the pressure-gauge is forced into the bottle, and the gas, escaping through the orifice, acts on the whistle, producing a sound which gives notice of danger, and which sounds becomes so much louder as the pressure increases, thus giving sufficient timely notice to avoid danger.

A Novel Steam Engine.—Practical Application of Water in the Spherical State.—It will be remembered by our readers, that at the meeting of the British Association at Cambridge, a considerable sensation was produced by Mr. Boulton, who brought before the meeting a series of tables concerning what he calls the spherical state of water, and the remarkable phenomenon of freezing water in red-hot crucibles, under the influence of this peculiar condition. At a recent meeting of the Academy of Sciences at Paris, M. Bontinck announced, that by the persevering efforts of a young engineer, M. Testud de Bearegard, a steam-engine had been constructed, which was moved by the vapour of water in its spherical state. This is a horse-power boiler, the boiler of which is so small that it can be easily carried in a pocket. In the manufacture of glass, the machine was in progress, one of two, and the other of four horse-power; and that a third, of four hundred horse-power, was about to be made in England. From a communication to La Presse, we learn that the boiler is placed in a bath of melted lead, and the water is condensed at atmospheric pressure, and collected in a basin beneath the machine.

LIST OF NEW PATENTS.

G RANTED IN ENGLAND FROM OCTOBER 26, TO NOVEMBER 22, 1848.

Six Months allowed for Enrolment, unless otherwise expressed.

Alfred Vincent Newton, of 66, Cheaney-lane, mechanical draughtsman, for "certain Improvements in the manufacture of coal."—Seced Nov. 2.

Charles William Keeslemyer, of Manchester, w h a r e h o u s e m a n , and Thomas Mellowed, of Oldham, for "certain Improvements in the manufacture of velvets, velveteens, and other similar fabrics."—Nov. 2.

Charles Dawson, of Hardinge-street, Islington, professor of music, for "certain Improvements in musical instruments, and in apparatus to be used in connection with musical instruments."—Nov. 2.

Robert Thomson Pattison, of Glasgow, printer, for "an Improved preparation or material for writing or printing, calling, or pigment colours, on cotton, linen, woollen, silk, and other woven fabrics."—Nov. 2.

James Hart, of Bermondsey-square, engineer, for "Improvements in machinery for manufacturing brick, sand, and tiles, parts of which machinery are applicable to moulds in various substances."—Nov. 2.

William Welld, of Manchester, mechanical draughtsman, for "certain Improvements in machinery for spinning cotton and other fibrous substances."—Nov. 2.

Richard Wright, of Huntsman, East Lancashire, for "Improvements in lamps, wicks, and covers for vessels for holding oil and other fluids."—Nov. 2.

Robert Walter Winifred, of Manchester, architect, for "certain Improvements in the construction and manufacture of metallic bedsteads, couches, and arm-chairs."—Nov. 2.

John Harris, of Richard's-terrace, Rotherhithe, Surrey, engineer, for "a mode or modes of constructing, forming, and fixing certain metallic building or other articles."—Nov. 2.

James Roberton, of Liverpool, cooper, for "a mode or modes of consuming smoke and other gaseous products arising from fuel and other substances."—Nov. 2.

Francis Gibbon Sibbaldy, of St. John's Wood, gentleman, for "Improvements in paintings and pigments."—Nov. 2.

Joseph Middie, of Ipswich, engineer, for "Improvements applicable to gas burners."—Nov. 2.

Mayer Jacob, of Spitalfields, Middlesex, gentleman, for "certain Improvements in the manufacture, stamping, and treating generally, of woven fabrics of all kinds."—Nov. 2.

Thomas John Knowles, of Heysham Tower, near Lancaster, gentleman, for "Improvements in the application of finish, such as polish or varnish, to metallic articles."—Nov. 2.

George Henry Barchford, of the Royal Polytechnical Institution, London, for a philosophical, of natural philosophy, for "improved means of transmitting, communicating, or conveying ideas, or information to the brain."—Nov. 2.

Joseph Cooper, of Waltham, tailor, for "Improvements in fastenings for wearing apparel."—Nov. 2.

Charles J. of, of Birmingham, machinist, for "Improvements in the manufacture of certain descriptions of dress fastenings, and in the making up of dress fastenings and other articles."—Nov. 2.

Henry Kempton, of Pentonville, Middlesex, gentleman, for "Improvements in reflectors and apparatus for artificial light."—Nov. 2.

Miss Poole, of the patent bill office, London, gentleman, for "certain Improvements in machinery for making nails." (A communication).—Nov. 2.

James Napier, of Swanses, operative chemist, for "Improvements in the manufacture of copper and other metals, and alloys of metal."—Nov. 2.

Richard Coad, of Kennington, Surrey, chemist, for "Improvements in the construction of blast and other furnaces and fire-places."—Nov. 2.

James Ankers, of High Street, London, manufacturer, for "a certain Improved mode of separating the different qualities of potatoes and other vegetables."—Nov. 2.

Samuel Adamo, of West Bromwich, Stafford, grocer, for "Improvements in mills for grinding."—Nov. 2.

William Williamson, of Farrar, near Gateshead, Durham, coke manufacturer, for "certain Improvements in the construction of coke ovens, and in the manufacture of coke, or coke from coal to be used as fuel."—Nov. 2.

James Birt, of Great Yarmouth, gentleman, for "certain Improvements in apparatus for drawing off liquids; in securing coke or cinders in batteries or other vessels, and in washing and preparing for use in coal and vegetable matter."—Nov. 2.

James Callan, of the city of London, gentleman, for "Improvements in apparatus for steaming ships and other vessels."—Nov. 2.

John Juckes, of Bossmere-cottage, Fathall, gentleman, for "Improvements in furnaces and fire-places."—Nov. 2.

Alexander McDougall, of Longight, Manchester, chemist, and Henry Dawson, of Manchester, agent, for "Improvements in the manufacture of sulphate of soda, nitric acid, caustic soda, chloride, and sulphate."—Nov. 21.

John Oliver York, of 24, Rue de la Mandeliére, Paris, engraver, for "Improvements in the manufacture of metallic tubes."—Nov. 21.

William Hood Clement, of Philadelphia, for "certain Improvements in the manufacture of sugar, part of which improvements are applicable to evaporation generally; also improved apparatus for preparing sugar to be used as fuel."—Nov. 22.

Henry Newson, of Smethwick, near Birmingham, for "Improvements in trusses."—Nov. 22.

Hough Bell, of London, gentleman, for "certain Improvements in aerial machines, and machinery in connection with the buoyant power produced by gaseous matter."—Nov. 23

Edward Robinson, of Manchester, solicitor, for "certain Improvements in the construction of cocks or valves, which improvements are applicable for reducing the pressure of gases, apparatus, journals, leathers, or other rubbing surfaces in machinery in general."—Nov. 23.

Peter Beverley, of Bristol, brass and copper manufacturer, and John Hammoms, of the same place, for "certain Improvements in the manufacture of cocks or valves for drawing off liquids."—Nov. 23.

Henry Ambler, of Great George-street, Westminster, gentleman, for "Improvements in facilitating the division of sheets or pieces of paper, parchment, or other similar substances."—Nov. 23.

Frederick Bramwell, of Millwall, Poplar, printer, and Samuel Cullen Homersham, of the Adelphi, gentlemen, for "Improvements in feeding furnaces with fuel."—Nov. 23.

END OF VOLUME XI.
