SYNOPSIS—The United States Coal & Coke Co. has adopted the motto of the other subsidiaries of the United States Steel Corporation as its own and is doing its best to make the mines safe. The importance of having sufficient power in equipment to do the work demanded of it is emphasized as an item in mine safety.

"Safety the first consideration" is the slogan which has been adopted by the United States Coal & Coke Co. and other subsidiaries of the United States Steel Corporation. This company operates 12 mines around Gary, McDowell county, controls several thousand acres of coal lands and has an average daily output of 15,000 tons. All of the mines are easily reached from Gary, the most remote being No. 12, which is twelve miles from the town. At all the mines the cutting and shooting is done at night and the coal is loaded and hauled out during the day.

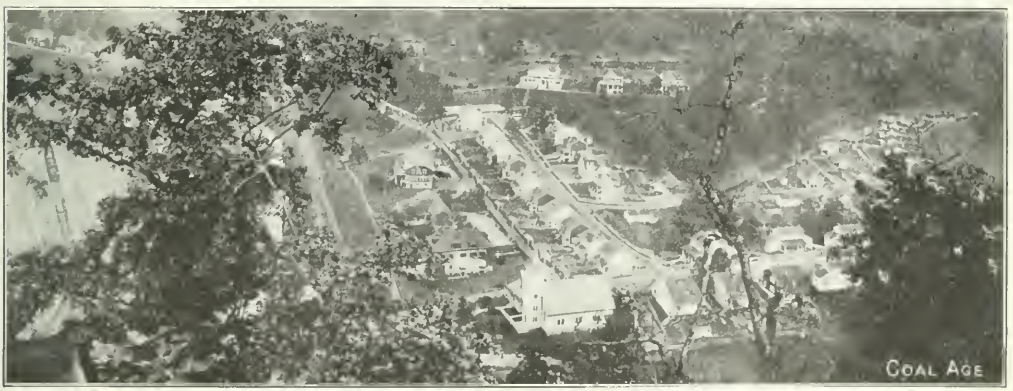
All the mines are drifts with the exception of mine No. 1, which is a shaft and No. 2, which is a slope. The coal seams vary in thickness from 4 ft. in No. 3, to 9 ft. in No. 12. The mines all receive their power from a central power house located in Gary, the power being transmitted by high-tension feeder lines supported in some places by steel towers and in others by wooden poles. At each of the mines is a substation, at which an electrician is constantly in charge and which is frequently visited and inspected by the chief electrician of the company, who also inspects, once each month or six weeks, the entire electrical equipment and any new wiring which may have been done in any part of the mine.

All employees in or about the various mines are required not only to conform to the state mining laws, but also, with the rules and regulations of this company which are more stringent and more exacting than the former. All their employees are urged to report the presence of any unusual danger which they may encounter, rather than begin work under threatening conditions; thus the number of serious injuries has been reduced to a minimum.

Illuminated Warning

At the entrance of each mine, there is placed a large sign, with conspicuous letters, illuminated at night.

THE PREVENTION OF ACCIDENTS AND
INJURIES BY ALL POSSIBLE
MEANS IS A PERSONAL DUTY
WHICH EVERYONE OWES
NOT TO HIMSELF ALONE, BUT
ALSO TO HIS FELLOW WORKMEN



The Village of Gary Seen from the "Camel's Back," Showing Catholic Church, Office and Clubhouse on the Middle Left

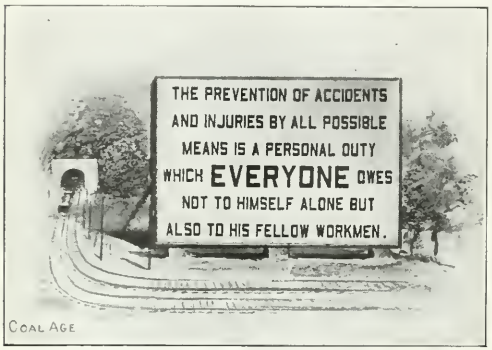
This sign is the last thing the miners see as they enter the mine, and it serves to remind them constantly that the care of their limbs and lives is important and not to be ignored.

The illustration of mine No. 7 shows how conspicuous these signs are and how continually they confront the miners. One is shown directly over the entrance of the mine, another on the side of the foreman's office.

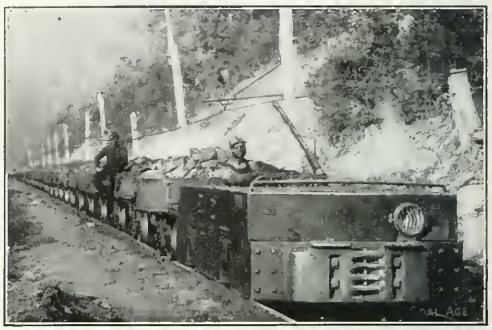
In the actual process of mining the precautions taken by this company are much more stringent than those required by the state mining laws. Crosscuts are driven at such intervals as are considered necessary, regardless of the lesser legal requirement, and the minimum ventilating current is 12,000 cu.ft. per min. in the last breakthrough of every pair of headings, whether working or not. The company requires that props be set within 6 ft. of the working face, although there are but few places where these props are actually necessary.

*Columbus, Ohio.

On all roads where more than one car is hauled at a time the haulageway is driven wide enough to allow 2½ ft. clearance on each side of the mine cars so that a trip may be passed in safety at any point. This applies to all parts of the mine with the exception of the rooms. On main haulage roads where large trips are hauled



THE MOTTO OF THE UNITED STATES COAL & COKE CO., AT GARY, W. VA.



13-TON ARMORPLATE MOTOR HAULING A 212-TON TRIP UP A 1% GRADE

"refuge holes" are provided in addition to the above. These are cut in the coal at stated intervals and kept whitewashed.

GOOD EQUIPMENT AND SAFETY

Every precaution is taken not only in the method of operation, but also in the selection of equipment which has been designed with safety as a prime factor, equipment that will not only give perfect service and afford the maximum output, but will also insure the workmen against the possibility of danger during the operation of the same.

The United States Coal & Coke Co. has adopted the 13-ton "Armorplate" type locomotive as standard haulage equipment, not only because it renders perfect service, but because safety was given careful consideration in its design and construction.

"Safety the first consideration" is also the slogan for the locomotive motorman, as may be seen in the accompanying illustration, showing the motto prominently displayed on the side frame. This legend is repeated on the other side.

Great, powerful locomotives they are, with a frame constructed of solid steel similar to the armorplate used on battleships. This makes the frame absolutely indestructible, and insures the motorman against serious injuries which would ordinarily result from a collision with rolling stock or rib.

The capacity of the motors is such that the locomotives are able to haul heavy trips with great ease, which feature is especially valuable in view of the fact that it permits a schedule to be made for all haulage locomotives.

It is absolutely necessary that they should always be "on time," in order not only to insure the maximum output, but also to prevent personal injuries or serious damage to property, which might result as a failure to heed the importance of this fact. This requires locomotives with a record for reliable service.

The locomotives in operation at this company's mines not only have motors of unusual capacity, but are also designed to control heavy loads on steep grades. This feature itself has averted many accidents.

The power of "Armorplate" type locomotives is shown in the accompanying illustrations, which are reproduced from photographs taken at the mines of the above mentioned company. The illustration of a trip at mine No. 6, south of Gary, shows a 13-ton locomotive approaching the tipple and hauling up a 1 per cent. grade a trip aggregating 212 tons.

A CLEAN AND SANITARY TOWN

The headquarters of the United States Coal & Coke Co. is situated at Gary, McDowell County, on the Norfolk & Western R.R. The offices of the coal company, also their power house and machine shop are located

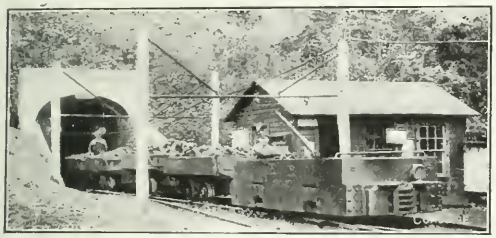
THE SIGN COUNSELING SAFETY DECORATES THE LOCOMOTIVE ON EACH SIDE PLATE. A TRIP AT NO. 3 MINE

there. All are stone buildings, tile roofed and as well constructed and modern throughout as one would find in any city.

The first impression one receives on entering the village is most favorable, as its appearance is far in advance of most mining towns. In fact, it reminds one of a quiet country town, so invisible are the coal mines from most parts of the village. In matter of years the town is as yet in its infancy, but marked improvements are already being made to insure sanitary conditions and nothing is left undone which will promote the health and comfort of its inhabitants, or add to the attractiveness of their homes.

The houses are better equipped than many of those occupied by mechanics in towns and cities. They are all fitted with electric lights and have water in the kitchens, as the company realizes the imposition which is often placed upon the female members of the family in mining communities in having to carry water for long distances and pump it from deep wells. This provision also promotes better sanitary conditions and more cleanliness among the people.

There is also a sanitary committee appointed for each plant, composed of the householders with the resident physician in charge, which makes regular examinations and reports on the sanitary condition of the houses and towns.



No. 7 Mine, United States Coal & Coke Co., with Signs on Drift and Foreman's Office

The houses are built not less than 50 ft. apart, and the yards are all fenced in, giving to each householder ample room for a yard and garden, and a premium at each plant is offered every year by the company to the householder who has the best kept vegetable garden and yard.

Schools and churches of every denomination are found at the plants, and there is now under course of erection at Gary a high-school building which will give parents an opportunity to educate their children at trifling expense.

The rapid advance so readily noticeable is entirely due to the policy of the management of the United States Steel Corporation. That company looks after the welfare of its employees and affords them every convenience possible. The president of the United States Coal & Coke Co., Thomas Lynch, is a man who has had a wide experience in the mining industry, having been in charge of the coal-producing plants of the Carnegie steel companies long before the United States Steel Corporation was formed, and it is entirely due to his untiring efforts that the company has made such rapid advance in the protection of its men from the dangers of the mine and in the development of comfortable villages for its many employees.

Southern Appalachian Coal Operators Association

Special Correspondence

The annual meeting of the Southern Appalachian Coal Operators Association was held in Knoxville on Tuesday, Feb 11. Those who continually harp on the alleged fact that coal men, and especially coal operators, cannot get together should have been present on this occasion. So successful was this meeting, that invited guests who have visited annual meetings of many societies, declared that this association surpassed all others in effective, coöperative work along all lines.

Starting three years ago with a few members who were determined to bring the operators together in a legitimate manner in order to place this field upon a business basis, they increased in numbers and coöperated under the leadership of the president, E. A. Morton, who has been president for these three years, until they developed a strong working body, which has accomplished much for the field.

Upon the refusal of President Morton to stand for re-election, E. C. Mahan, general manager of the sales department of the Southern Coal & Coke Co., was elected to that position. The following operators, all representative men from different districts in the field, make up the official list for 1913:

President, E. C. Mahan, Knoxville; first vice-president, J. L. Boyd, Knoxville; second vice-president, C. S. McManus, Knoxville and Middlesboro; secretary, James E. McCoy, Knoxville; executive board, C. M. Moore, Careyville, Tenn.; E. A. Morton, Knoxville; L. I. Coleman, Knoxville; J. B. Campbell, Atlanta, Ga.; T. I. Stephenson, Knoxville; H. M. La Follette, LaFollette, Tenn.; A. Gatliff, Williamsburg, Ky., James R. Wooldridge, Wooldridge, Tenn.

There are now 80 companies in the association, representing from 80 to 90 per cent. of the tonnage of the field. The report of the secretary showed ample resources to meet all obligations with a handsome surplus on hand, and the financial outlook for 1913 equally bright.

The credit bureau, with a collection department, is much used and acts as a clearing house for credit inquiries and information. The newly elected president, E. C. Mahan, suggested that the association should also act as a clearing house for operating data and that an exchange for ideas and experience in economical operating should be established.

As a number of the large operations in southeastern Kentucky which are just getting into the producing class, produced practically no tonnage in 1912, they will add considerably to the income and importance of the association during the coming year. A traffic bureau, with an expert rate man in charge, is a new feature added during 1912 and it has already shown its value.

A campaign of publicity to create public sentiment in favor of the state abolishing its mine in which convicts are employed, and the placing of them on the roads, is being successfully waged, and it is hoped that some relief will be secured during the legislative session of this year.

A banquet was held at the Hotel Colonial in the evening with James R. Wooldridge as toastmaster. Walter H. Finley spoke on "Scientific Management," and emphasized the point that the human element should be given as careful consideration as the most costly machinery. W. C. Tucker, general manager of the Wisconsin Steel Co., with coal and coke operations at Benham, Ky., spoke on "The Relation of Welfare Work to Production."

C. J. Norwood, chief mine inspector of Kentucky, made "Some Observations Touching Accidents in Coal Mines." J. F. Callbraith, secretary of the American Mining Congress, pleaded for some legislation permitting the operators to combine and arrange prices in a legitimate manner so as to obtain a fair price and profit from their product.

About one hundred and twenty-five members sat down to the banquet table and nearly all were the highest executives in the different departments of their companies.

⁂

Firedamp may be given out from freshly-cut coal, from cracks or fissures in the roof, from the gob or waste, from blowers either in the seam itself or in the strata. In gaseous seams it often escapes with a singing noise and a crackling of the coal. On wet faces small bubbles are often formed by the escaping gas. The presence of firedamp depends in a great measure upon the character of the roof. A soft roof will pack tightly, while a hard roof does not pack so tight, but leaves plenty of space for the collection of gas. Diluted firedamp can be breathed and nothing less than a 50 per cent mixture will affect respiration seriously.

COAL AND COKE NEWS

Washington, D. C.

Developments during the past week indicate that the Federal Government has no intention of abandoning its attack upon the anthracite coal combination, but that it has decided to adopt a new method. As a result of application made by counsel for the Government, the United States Court at Philadelphia, on Feb. 19, dismissed the suit of the Federal Government against the Philadelphia & Reading R.R. Co., in which it was charged that the company was violating the "commodities clause" of the railway rate law.

The Government claimed that the railroad company was violating that section of the law which forbids a line from transporting commodities in which the company has an interest and sought an injunction restraining the road from transporting coal dug from its own mines. In this connection it named as a codefendant the interests allied to the railroad company. The order dismissing the case states that the action taken is without prejudice and will not prevent the Government from bringing another action on the same line.

This dismissal, it is understood, was secured for the purpose of clearing the way for consideration of the position of the road, both under the Sherman law and under the commodities clause of the railroad law. This is the next step in the policy which seems to have been initiated by the civil suit filed a few days ago at Trenton, and charging the Lackawanna R.R. and the Lackawanna Coal Co. with violations both of the Sherman law and the commodities clause. There is no official statement as yet as to how far this policy is likely to be carried.

Bureau of Mines Appropriations

In the Sundry Civil Bill, just reported to the House of Representatives by the Appropriations Committee, the following appropriations are made for the Bureau of Mines for the coming year:

For the general expenses of the Bureau of Mines, including the pay of the director and the necessary assistants, clerks and other employees in the office at Washington, D. C., and in the field, and for every other expense requisite for and incident to the general work of the Bureau of Mines in Washington, D. C., and in the field, to be expended under the direction of the Secretary of the Interior, $70,000.

For the investigation as to the causes of mine explosions, methods of mining, especially in relation to the safety of miners, the appliances best adapted to prevent accidents, the possible improvement of conditions under which mining operations are carried on, the use of explosives and electricity, the prevention of accidents, and other inquiries and technologic investigations pertinent to the mining industry, $347,000.

For the analyzing and testing of the coals, lignites, ores, and other mineral fuel substances belonging to or for the use of the United States, including personal services in the Bureau of Mines at Washington, D. C., not in excess of the number and total compensation of those so employed during the fiscal year nineteen hundred and twelve, $135,000.

For inquiries and investigations into the mining and treatment of ores and other mineral substances, with special reference to safety and waste, $100,000: Provided, that no part thereof may be used for investigation in behalf of any private party, nor shall any part thereof be used for work authorized or required by law to be done by any other branch of the public service.

For one mine inspector for duty in Alaska, $3000.

For per diem, subject to such rules and regulations as the Secretary of the Interior may prescribe, in lieu of subsistence at a rate not exceeding $5 per day when absent on official business from his designated headquarters, and for actual necessary traveling expenses of said inspector, $3500.

For technical and scientific books and publications and books of reference, including payment in advance for subscriptions to publications, $1500.

For the purchase or lease of the necessary land, where and under such conditions as the Secretary of the Interior may direct, for the headquarters of five mine-rescue cars and for the construction of the necessary railway sidings on the same, $2000: Provided, that the Secretary of the Interior is hereby authorized to accept any suitable land or lands that may be donated for said purpose.

In all, for the Bureau of Mines, $662,000.

Concerning the Corporation Tax

After careful inquiry Commissioner of Internal Revenue Cabell has issued the following statement as to the corporation tax:

"There have been several inquiries as to the application of the regulations relative to an allowance for an unearned increment in the ascertainment of net income of mining corporations for the special excise tax on corporations, which indicate that the true intent of the regulations is not understood. The fact has also developed that many corporations, in their attempt to apply the regulations, begin with a current unit valuation of the product concerned instead of the en bloc value as of Jan. 1, 1909, as is required. The manner of entering the ascertained valuation as of record has also been neglected and misunderstood.

In order to make the requirements of this office plainer and to assist corporations in arriving at valuations which shall not be speculative in character nor founded upon the future profits and earnings of the corporations which should belong to the period during which they are earned, and in order that no portion of income which really belongs to any particular year shall be ascribed to or allotted as the earnings of previous years, items Nos. 99, 100, 101 and 103 of T. D. No. 1742 are modified so as to read as follows

"No. 99. The note is amended so that it shall read:

"'Values, as aforesaid, should not be estimated on the basis of the assumed salable value of the output under current operative conditions, less the actual cost of production, because, as hereinbefore stated, the selling price, under such conditions comprehends a profit both for carrying the investment in coals, etc., improvements and working capital, and for conducting operations in respect of production and disposal of product. The value to be determined as stated must be en bloc of the entire deposit of minerals and mineralized property owned, exclusive of improvements and development work, if the same were disposed of in that form.'

"No. 100 is amended to read:

"'The unit value as of Jan. 1, 1909, ascertained as above outlined, would indicate the value to be attached to that date to the capital assets disposed of during any calendar year succeeding. The amount claimed as a deduction from gross income on account of unearned increment shall be shown separately in the deductions from gross income in the return of annual net income.'

"No. 101 is amended to read:

"'The precise detailed manner in which the estimate of value of minerals, etc., as at Jan. 1, 1909, shall be formed, must naturally be determined by each corporation interested. Every corporation claiming and making a deduction for unearned increment as provided in section 100 preceding, shall maintain an official book record of the properties owned by it in connection with which unearned increment is claimed, and which record shall show the general ledger or general balance sheet value thereof, together with the estimated amount of appreciated value in such properties in excess of general balance sheet values, as of Jan. 1, 1909, together with all evidence and information on basis of which such appreciated value was formed. This estimate must be formed on the lines and basis indicated in the 'note,' Section 99, namely, the salable value of the entire deposit considered en bloc. This record should also present clearly and fully the transactions during each year in respect of quantities of minerals disposed of and for which deductions are made, respectively, for depreciation and unearned increment, together with the amount thereof. No deduction for unearned increment will be allowed unless the aforesaid record is kept, nor unless the evidence as to the estimates of quantity of minerals in deposit and the valuation thereof are accepted by the department Values determined and recorded as of Jan. 1, 1909, as aforesaid, should be used in the compilation of all subsequent years' excise tax returns.

"'In case it subsequently develops the property possesses a greater quantity of mineral, etc., reserve than was in the aggregate estimated as of Jan. 1, 1909, only such an amount of aggregate value can be assigned to such excess mineral tonnage as of Jan. 1, 1909, as it was at said date estimated by the company attached to the property and was not assigned by it, as hereinbefore provided, to the specified tonnage in the property.

"No. 103 is amended to read:

"'As the amount to be deducted for depletion of deposits (Regulation No. 101) is to be formed on basis of the estimated reserve of minerals, etc., it follows that if it develops such estimate is understated, the cost investment and estimated unearned increment in the capital asset may be wholly extinguished before all mineral reserves are removed. When this is reached, further deductions for exhaustion of minerals should be discontinued.

"Collectors of internal revenue will make requisition for the necessary number of these amendments and furnish a copy to each corporation interested."

PENNSYLVANIA

Anthracite

Ashland—The Scranton Coal Co. has reported to the Pennsylvania Mine Code Commission that they will allow one-half the value of the property under $3000 if damaged by mine caves. On all properties valued at more than $3000, they will allow half valuation or agree to sell underlying coal subject to royalty agreement.

Archbald—The White Oak colliery of the Delaware & Hudson Co., which resumed operations Feb. 10, after an idleness of eight days, due to a strike, was forced to close down again owing to the burning of the fan house. The company officials arranged to replace the damaged machinery, and an effort was made to operate part of the colliery the following day. There are 800 men and boys employed in the plant. It is supposed that the cause of the fire was a hot journal.

Wilkes-Barre—President White of the United Mine Workers is trying his hand in the anthracite region to stamp out

the petty strike habit. Mr. White says that there has been a tendency to over-step the agreement in the anthracite field by declaring petty strikes. He further states the welfare of the miner's organization depends upon standing firmly by their agreements.

While eight men were being lowered to work in the Alden shaft of the Susquehanna Coal Co., Feb. 13, the drawhead on the mine carriage pulled out and the cage dropped a distance of 200 ft. before the safety devices worked.

The annual summer meeting of the Coal Mining Institute of America will be held in Wilkes-Barre on June 17, 18 and 19. This will mean a gathering of several hundred coal operators, inspectors, engineers, and superintendents from all the soft-coal states, as well as the local men allied with the coal interests. This is the 56th semi-annual meeting of the institute.

Easton—Officials of the Lehigh Valley Coal Co. are canvassing their employees at Mahonoy City for sentiment on a proposition to pay $75 to the widow or dependent of victims of a mine accident, provided the remainder of the men agree to work on the days of funerals.

Bituminous

Mt. Pleasant—Differences between the Brush Run Coal & Coke Co. and their employees have been adjusted and the 40 men who have been idle several days have returned to work. It appears that the men had difficulty with a certain boss whom the company has discharged after a careful investigation of the matter.

Connellsville—Secretary T. B. Dilts, of the State Y. M. C. A. Mining Department, has opened a new Y. M. C. A. building in the mining town of Jerome.

The United Coal Co. has erected the building, a modern two-story structure, 24x100 ft., and has equipped it with bowling alleys, reading rooms and class rooms.

Arcadia—The plant of the Pennsylvania Coal & Coke Corporation at mine No. 41 has been destroyed by fire, entailing a total loss of about $25,000 and throwing 120 men out of work. The company had been making extensive improvements at the plant and intended to abandon that part which the fire destroyed. A new power house, boiler house, and motor barn of brick construction will be completed within a short time.

Pittsburgh—In the recent convention of District No. 5 of the United Mine Workers in the Labor Temple a sympathetic strike of the miners in western Pennsylvania to aid the strikers in West Virginia was urged strongly. The proposal was finally defeated after a stirring debate.

Du Bois—The miners of this region are planning to aid, in a financial way, the strikers of West Virginia fields. Local No. 2722 has decided to assess its members $1 each as a starter for its fund. It is said that $3000 will be sent to the strike zone within the next few weeks.

WEST VIRGINIA

Charleston—Delegate W. W. Wertz has succeeded in forcing his anti-mine guard bill through the house in the face of strong opposition. This measure prohibits the sheriff of any county from appointing deputies to act as mine guards in the pay of private corporations. The measure was carried by a vote of 45 to 31.

It is expected that the Illinois mine workers, in their annual state meeting, will ask President Taft to intervene in the long drawn-out strike in the West Virginia field.

Elk Ridge—A coal tipple of the M. B. Coal Co. was destroyed by fire, Feb. 18, causing a $40,000 loss. There appears to be some doubt about the origin of the fire. The incident at Elk Ridge is the first serious trouble under the present proclamation of martial law.

Military authorities in Paint Creek Junction have announced that, of the 128 prisoners arrested in the strike zone recently, 50 have been released.

ALABAMA

Birmingham—In the effort to enforce the state mining law during the past year, 108 arrests have been made at the instance of the state mine inspector. Certificates of five mine officials have been revoked by the state mining board and certificates of three mine officials are being held, pending the action of the State Board of Examiners.

KENTUCKY

Louisville—An interesting tentative program has been arranged by Prof. H. D. Easton for the annual meeting at Lexington of the Kentucky Mining Institute on May 15, 16 and 17. The first-aid competitions between teams from various mines, which will be one of the most interesting features of the meeting, will probably be held on the first day of the meeting. The second is to be given over to the formal program, and the third to discussions on various questions by mining experts.

OHIO

Bridgeport—The miners employed at the Lansing mine of the Lorain Coal & Dock Co., are on strike because the blacksmith has been discharged. Four hundred men are employed at the mine.

Gallipolis—Three barges of coal belonging to the Campbells Creek Coal Co. were sunk Feb. 13, when the tug boat, Robert T. Gillehan, collided with the cofferdam. Rivermen pronounce the new cofferdam a menace to navigation.

INDIANA

Indianapolis—The shotfirers bill has been passed by the Indiana House by a vote of 84 to 3, and now goes to the Senate. The miners have been trying to get such a bill through for six years. It provides that the shotfirers shall be employed by the operators. The bill provides that the law shall become operative in April, 1914, so that the parties to the next two-year contract between operators and miners, will have full notice of the proposed new law. Under the present shotfirers law, the miners pay the firers, as their appointment is made for the miners' convenience.

Terre Haute—Five hundred cars of coal have been under an embargo on the Big Four road. A complaint was made to the Indiana Railroad Commission and an order was issued for officials of the operating department of the road to appear before the commission and explain why the road had refused to remove the coal. At the offices of the railroad company it is said that the entire tonnage will be removed as soon as possible.

ILLINOIS

Chicago—The Chicago and Northwestern Ry. has awarded a trophy to the rescue team at its mines at Gillespie. This team made the best showing in a contest held recently by the company. The contest is open to all first-aid workers in the state and the winners are declared the champion team of the state of Illinois. Similar contests in the interest of first aid are held by the Superior Coal Co.

Eldarado—Five men were buried by a cave-in caused by an explosion in the Seagraves mine, Feb. 20. Three others were hurt.

Canton—Operations in the mine of the Norris Coal Co. have not yet been resumed, due to the fact that State Mine Inspector Taylor has not completed his investigations to his satisfaction since the time he ordered the mine to be shut down.

MICHIGAN

Grand Rapids—This city is to sell coal at $7.50 per ton to its people. This will afford a saving of $1.60 a ton to the citizens from the price charged by local dealers.

Battle Creek—A rich seam of coal is supposed to be located under a considerable portion of the city and men are attempting to get options on property, beneath which they believe the coal is located. An analysis of this coal has shown it to be of good quality.

KANSAS

Pittsburg—There has been a strike rumor flying over the district for several days to the effect that there is a threatened strike among the coal miners of Cherokee County. It is claimed by those in a position to know that the report is without foundation.

CALIFORNIA

San Francisco—Eight indictments charging criminal conspiracy to defraud the U. S. Government were returned yesterday by a Federal Grand Jury against eight officers and employees of the Western Fuel Co. The investigation disclosed an alleged conspiracy whereby the Government was defrauded out of $450,000 or more in drawing back payments on imported coal resold by the company for use outside the United States.

FOREIGN NEWS

Winnipeg, Can.—It is reported that 72 men have been killed at the Silwash Peak mines at Yale, B. C.

Berlin, Germany—Four miners were killed by an accident Feb. 15 in the Wiecke colliery, near Mulheim, in the Westphallan coalfield.

Vancouver, Can.—The refusal of the Britannia Mining & Smelting Co. to recognize the Western Federation of Miners has resulted in a walk-out in the company's mines. The company employs about 6000 men.

PERSONALS

James F. Thompson, until recently division superintendent of the Colorado Fuel & Iron Co., has been appointed superintendent of the coal mining operations for the Cerrillos Coal Co. at Madrid, N. M.

W. H. Webster has been appointed new traveling coke agent for the Baltimore & Ohio in the Connellsville region, with headquarters at Uniontown. H. C. Tucker, the former representative, has been transferred to Cleveland.

Godwin H. Powel, of Penrallt, Weston-Super-Mare, England, managing director of the Mount Carbon Co., Ltd., arrived in New York on Feb. 18, and is spending the time between the 21st and 27th at the company's operations at Powellton, Fayette County, W. Va. Mr. Powel will sail again for England on Mar. 1.

OBITUARY

William E. Cassidy, aged 54, vice-president of the Cassidy Coal Co. and the Bell-Jellico Coal Co., of Lexington, Ky., died recently at his home in that city from a paralytic stroke sustained ten days before his death. Mr. Cassidy had been engaged in the coal business in Lexington for about 16 years. His wife, who has been seriously ill for about a year, survives him, as well as a daughter and a brother, T. D. Cassidy, of Lexington.

PUBLICATIONS RECEIVED

Goulds Rotary Pumps. Bulletin No. 113. Published by the Goulds Mfg. Co., Seneca Falls, N. Y. The bulletin describes the characteristic features of construction and operation of the Goulds rotary pump. 16 pp.; 7¾x10 in.; ill.

Eighth Biennial Report of the State Mine Inspector of the State of Utah, 1911-1912. 170 pp.: 6x9 in.; ill.

Lightning Arresters. The Electric Service Supplies Co., Philadelphia, Chicago and New York, has issued its 1913 edition of catalog of the Garton-Daniels lightning arresters and other lightning protective apparatus.

In this book is given much information relative to lightning phenomena, installation of lightning arresters, grounding, distribution, inspection and other allied subjects

Its pages illustrate and describe the complete line of Garton-Daniels lighning arresters, a new line of panel-board lightning arresters cataloged for the first time by this company, high- and low-voltage choke coils and disconnecting switches, grounding apparatus, etc.

The last eight pages of this catalog are given over to installation diagrams, through which it is possible at a glance not only to learn the proper method for installing lightning arresters on any circuit, either d.c., a.c. or arc, but also to select exactly the type of arrester which is best suited for the protection of any class of circuit.

The catalog as a whole is well gotten up, intensely interesting, beautifully illustrated and printed, and is a book which every electrical man should have.

CONSTRUCTION NEWS

Kansas City, Mo.—An English syndicate is to begin at once to develop the Christy coal tract in the Waverly-Lexington field.

Morgantown, W. Va.—Three large steel companies are interested in coal in Greene County and extensive developments are expected during the early spring. The Crucible Co. has already begun the operation of its 8 holdings.

Salt Lake City, Utah—Within the next year the Utah Ry. Co., which is building a line between Provo and Mohrland will expend more than $1,500,000 for coal cars. The company is now considering the initial purchase of 500 of these cars at a cost of $500,000.

Pottsville, Penn.—The Philadelphia & Reading Coal & Iron Co. has installed steam heating apparatus at the several bottoms and at each of the shanties of the Locust Gap colliery, where the miners congregate at the end of their day's work, while waiting to be hoisted to the surface.

Harlan, Ky.—A new road is being built in Harlan County, Ky., extending from Harlan several miles up Martin's Fork to the Hall and other large coal holdings, which are among the richest in the county. The right-of-way has been secured, and grading will begin as soon as spring opens.

Baltimore, Md.—The Baltimore & Ohio R.R. Co. has under construction a third track between Rockwood and Garrett, Penn., on the Connellsville division of the road. The completion of this track will give the road additional facilities for the movement of its coal traffic out of the Somerset regions.

Charleston, S. C.—The directors of the Carolina, Clinchfield & Ohio R.R. have approved plans for the construction of modern coal piers at Charleston. The work will be started as soon as the bids have been passed on and it is expected that coal will be shipped from the piers by the end of the year.

Philadelphia, Penn.—The Philadelphia & Reading R.R. Co. is constructing a new coal pier at Port Richmond on the site of old pier No. 18. It will be 765 ft. long by 70 ft. wide, and of concrete construction. It is estimated that the work will be completed and the pier in operation some time during the summer or early fall.

Lexington, Ky.—The Lexington & Eastern R.R. proposes immediately to begin the construction of a 4-mile branch up Yount's Fork, of Boone Creek, in Letcher County, in order to tap the extensive holdings of the Mineral Development Co., a Philadelphia corporation. The branch will be rushed to completion as rapidly as possible.

Martin's Ferry, Ohio—Work is progressing rapidly at the new mine of the George M. Jones Co. at Wegee. The main shaft has been sunk and work is being done on the archways of cement. The shaft will also be of concrete. A temporary wooden tipple will be constructed so that there will be no delay while the material for the steel structure is on the way.

Martin's Ferry, Ohio—The Rail & River Coal Co. is planning extensive improvements in all its properties which will involve an expenditure of $250,000. A new steel tipple is to be built at No. 3 mine, which will more than double the output. Power will be supplied to all openings by a central station. The improvements also include the erection of 100 houses.

Livingston, Ky.—A railroad some 30 miles in length is projected between Livingston and McKee, by the owners of coal lands in Rockcastle and Jackson Counties, in order to open up their properties to development and connect with the Louisville & Nashville at Livingston. The road has been incorporated with a capital stock of $10,000 under the name of the Rockcastle R.R. Co.

Fairmont, W. Va.—The Mineral Fuel Co. has purchased between 4500 and 5000 acres of coal land in Letcher County, Kentucky and is planning an expenditure of approximately $700,000 for opening mines, constructing plants, installing machinery, building houses, etc. The annual output is to be 750,000 tons. The property was purchased from the Mineral Development Co., of Philadelphia.

Fosterburg, Ill.—The Clark Bros. syndicate, of Philadelphia, is projecting a railroad from here to Alton, and contemplating the sinking of several mines here to furnish coal for the several electric lines that they control. They have organized the East Side Coal & Mining Co. as the operating end, and have bought a site for a power house in Alton at a cost of $25,000. The coal land in this vicinity has never been worked, on account of lack of transportation facilities.

NEW INCORPORATIONS

Cleveland, Ohio—The Cleveland Western Coal Co.; capital stock, $250,000; to mine and deal in coal.

Connellsville, Penn.—The Stanton Georges Creek Coal Co.; capital stock, $50,000; to mine coal near Frostburg, Md.

Spokane, Wash.—The Peerless Roundup Coal Co.; capital stock, $500,000. Incorporators, L. G. Nash, M. J. Tait, et al.

Memphis, Tenn.—The National Coal Saving Co.; capital stock, $10,000. Incorporators, S. L. Cockroft, Henry Burkurd, W. D. Beam, G. E. Petty and J. W. Wyatt.

Los Angeles, Calif.—Los Robles Land & Fuel Co.; capital stock, $100,000. Incorporators, E. G. Tilton, G. A. Nehrhood, E. F. Staples, J. O. Horton and C. E. Joslin.

E. Taplin, C. F. Taplin, C. N. Fiscus, W. S. Lister and A. C. Wald.

Morgantown, W. Va.—The Morgan Run Coal & Coke Co.; capital stock, $50,000; to carry on a general mining and coke manufacturing business in the Kingwood district. Incorporators, A. L. Foster, C. W. Zinn, N. C. Steel, A. J. Arnett and J. E. Hamilton.

INDUSTRIAL NEWS

Minonk, Ill.—Webber & Sutton have recently purchased a 120-kw. generator for their coal mine at this place.

Emlenton, Penn.—A $1,000,000 coal deal involving 10,000 acres of high-grade fuel in Somerset County is being closed by the Penn-Quemahoning Coal Co.

Collinsville, Penn.—In the Windber field, during the past year, the Berwind-White Co. has had an output of 4,000,000 tons. Fourteen mines are in operation.

Pittsburgh, Penn.—Ten thousand two hundred and six acres of mineral land in Clearfield County have been sold by A. R. Balcom, of Philadelphia, to the Star Portland Cement Co. for approximately $1,000,000.

Tamaqua, Penn.—The Lehigh Coal & Navigation Co. has made a record output for the month of January, in Panther Creek colliery. The figures reached 330,000 tons, the largest for any single month in the history of the company.

Brazil, Ind.—On account of the poor market for domestic block coal, the Plymouth mine No. 1, of the Coal Bluff Mining Co., northwest of this city, has been closed until next fall. The mild winter has caused a big slump in coal markets.

Connellsville, Penn.—The Buffalo, Rochester & Pittsburgh Ry. has under option about 11,000 acres of coal land belonging to the New York Central. It is predicted that the railway will double-track its Indiana branch in the near future.

Washington, Penn.—It is reported that representatives of some of the big coal companies are trying to take out options on the Pittsburgh seam underlying a few farms near Old Concord. It is said that they are offering about $200 per acre.

Duquoin, Ill.—As a result of the general depression of the coal business a number of the largest mines in southern Illinois have suspended operations indefinitely. Two of the largest mines are the Big Muddy and Chicago and Carterville companies.

Connellsville, Penn.—Announcement has been made of the sale of 206 acres of coal underlying the farm of J. M. Clark, in Jefferson Township, to the Washington Coal & Coke Co., for $412,000. The coal will be operated by the purchasing company from the Star Junction plant.

Pineville, Ky.—Judge M. J. Moss and others have procured a lease on 1800 acres of coal land in the Harlan field and plan to begin development work at once. The land is owned by Judge W. F Hall and lies on Martin's Fork. A 6-ft. seam of coal is to be opened at this time.

McAllister, Okla.—An application has been filed in the Supreme Court requesting the appointment of a receiver for the Choctaw, Newcastle & Western R.R., a small coal road in this section. The petition charges mismanagement and enumerates an alleged indebtedness of about $9000.

Fairmont, W. Va.—The Consolidation Coal Co. has issued its report showing its earnings from all sources for the year, 1912, to be $13,887,410, or an increase of nearly two and one-half million over the preceding year. The surplus for the year was about 10 per cent. of the full capital stock.

Pottsville, Penn.—The St. Clair Coal Co. has purchased a considerable amount of machinery used by the Nolan Bros. in their stripping contract at this place. The coal company will use the material in its own operations. The machinery purchase consists of a steam shovel and a number of locomotives.

Clinton, Ind.—It is reported that the Clinton Coal Co. is using compressed air to pump water from the flooded Crown Hill mine No. 1, west of Clinton. This is said to be the first time the system has been used in the Indiana coalfield. An electric pump hooked up to a 3-in. pipe had failed to reduce the water.

Glenrock, Wyo.—The Fairview Coal Co., which has been operating its mine at this place for the past two years, has recently put in a side track and is now preparing to increase its daily output. The old mines, which have lain idle for several years, have also taken on a new life and one is being operated on a small scale.

Pittsburgh, Penn.—It is reported that the Pennsylvania R.R. is contemplating the extension of its road from Marianna almost directly west to Hackney Station, and to Wheeling, W. Va. This will mean a new and quicker route of transportation from Wheeling to Pittsburgh, than that possessed by the Baltimore & Ohio, its chief competitor.

Whitesburg, Ky.—The Consolidation Coal Co. is now shipping from 20 to 30 cars of coal out from McRoberts per day, an average of from 140 to 175 cars per week. This output will, however, be increased, and it is said that by March 1 they will be shipping about 200 cars per week. They are now shipping more than 500 cars per week from their Jenkins mines.

Shamokin, Penn.—The local engineering department of the Philadelphia & Reading Coal & Iron Co. completed plans today for the sinking of a large new shaft at the Stirling colliery. The new opening will pierce several rich beds of anthracite coal, heretofore untouched or only partly worked. Arrangements were also made to sink a slope at North Franklin colliery.

Jasper, Ala.—The work on the big coal mine, owned by the Jagger Coal Co., is being pushed rapidly and it is expected that the mine will be in operation by the middle of the summer. The mine operates three seams, and each is said to range from 4 to 5 ft. of thickness. The coal is pronounced to be the best grade of steam and domestic coal found in the country.

Ironton, Ohio—The Semet-Solvay Co., of Syracuse, N. Y., is said to be negotiating with the furnace interests of Ironton for the construction of a byproduct coke plant at that place to supply coke in the immediate vicinity. The same interests are now building a plant at Ashland, Ky. It is reported that about $1,000,000 will be involved in the new plant and about 100 byproduct ovens would be included.

Lexington, Ky.—Representatives of 18 bituminous mines in western Kentucky are at Wilmington, Del., in conference with General T. Coleman DuPont, president of the DuPont Powder Co., relative to the consolidation of his large coal interests in that field with their company into one corporation, which will practically control all the large mine properties in that part of the state. The new corporation, if formed will have a capital stock of $15,000,000.

Connellsville, Penn.—Owners of a tract of 6000 acres of coal land lying between Stoyestown and Shanksville have been notified that options which were taken out about three months ago will be listed soon, and that the money, $50 an acre, will be received by the owners within a week. The company making the purchase is not known. The consummation of this deal will mean a transfer of about $300,000. With the exception of a few small mines, the tract of 6000 acres has not been opened; consequently, there is some speculation as to the point from which operations are to be commenced.

Buffalo, N. Y.—The educational force of the Lehigh Valley R.R. Co. has been teaching its firemen how to fire their engines economically. In the face of the fact that the road is running larger and heavier trains than it was a year ago, and that many new firemen were employed in the latter months of 1912, the consumption of coal per ton mile has decreased. In addition to the work of the road foreman of engines, who has the general supervision of this important task, expert firemen are assigned to train the new men and teach them how to economize in the use of coal.

The actual results secured during the last six months of the year 1912, show a net decrease of 5 per cent. in the amount of coal used per ton-mile as compared with the same period of the previous year.

Reading, Penn.—It is said that much money will be spent by coal companies in developing new operations in the Schuylkill district of the anthracite region in 1913.

The prosperous state of the anthracite coal market is inviting the investment of unprecedented amounts of capital in the business. The Philadelphia & Reading Coal & Iron Co., the Lehigh Valley Coal Co., the Lehigh Coal & Navigation Co. and the Pennsylvania Coal Co. are the leaders in developing new fields, but the independent firms are also taking an important part in the work, a feature of which will be the reopening of many collieries whose operation was abandoned as unprofitable.

The Madeira Hill Co. is spending $3,000,000 in opening up new collieries and remodeling old ones. It is suspected that within a year or two they will increase their shipments four fold.

Scranton, Penn.—The old Orangeville mine near Bloomsburg, which has been idle since the civil war, has been reopened and preparations are being made for taking out the coal.

COAL TRADE REVIEWS

GENERAL REVIEW

There is an abundance of individual hard coal being offered at prices well down to the regular Apr. 1 circular and only small tonnages are being placed. Even stove, which was in such heavy demand a short time ago, is now readily obtainable in carload lots. Consumers are keeping their requisitions down to a minimum in order to avoid having any surpluses when the April reduction goes into effect. Orders will gradually contract through the current month, to such an extent, as to force some curtailment in production at the mines.

Bituminous is in good supply, with orders scarce and operators unwilling to make sufficient concessions to move any considerable volume of coal. In the Coastwise trade, contracting is still being confined to inland business, few contracts being closed for water delivery, particularly among the larger consumers. If the high water-freights out of Hampton Roads continue in effect, the Pennsylvania grades all-rail will begin to supersede the West Virginia product at a number of the coastwise points.

The uncertain weather conditions have been such that they would cause a break in the stiffest market. Shipments generally are confined entirely to contracts, although to the north, in Canada, a comparatively heavy local demand has developed, which has tended to steady prices. The railroad movement in that section has also been quite slow and uncertain which has aided the situation materially and is the principal reason for the prices holding so well. There is considerable hesitation over new contracts; consumers are not offering to close and operators are affirming that prices are too low.

There is a fairly good retail demand in the Pittsburgh district, but contract consumers are showing a disposition to hold off because of the prevailing high prices. The trade in Ohio shows little if any improvement. The movement is being seriously restricted, in some instances, and Toledo is badly congested with coal. Ohio operators are eagerly looking forward to the opening of the lake shipping in anticipation of a heavy business the coming season. The Hampton Roads market continues to show a downward tendency and holders of speculative tonnages are in a difficult position. There has been a heavy dumping at the piers, but shipments are mostly on contracts, the demand for snot coal being light.

In the Middlewestern markets, prices were being freely cut in all directions when a drop of temperature and a heavy snowstorm occurred which steadied up the situation materially. The unfavorable conditions in this market were a result of over shipments on speculation and a heavy overproduction.

BOSTON, MASS.

Bituminous is in plentiful supply at all the terminals and orders are scarce. The spot market is lifeless, and the concessions made are not sufficient to move any volume of coal. Contract business has so far been confined for the most part to inland consumers who are supplied from points like Boston and Providence; tide business, especially for the large corporations, has not yet been closed to any extent. Buyers are tempering the situation and in view of the general outlook are likely to be slow coming into the market. Georges Creek is coming down only on orders, and generally there is lack of snap to bituminous in all directions, both all-rail and at tide. Mine prices are down to last year's range for March delivery.

The call for anthracite is spotty. There is an abundance of independent coal being offered at prices well down to the April circular, or 50c. less than the present company figures, but apparently only a small tonnage is being placed. No one wants egg, and the edge is off on the demand for stove and chestnut. Some of the companies, who are equipped with Eastern storage, are sending egg and chestnut to those points and stove coal that only a few weeks ago was next to impossible to get in any but small lots is now being freely offered in straight cargo shipments. Pea is also appearing in increasing quantities, now that the demand is falling off in the large cities.

It is apparent that the distribution business inland is being more and more confined to those agencies that are equipped to make deliveries by the day or by the week. So many of the mills have relatively small storage, as compared with consumption, that the distributor who is in a position to deliver just so much coal at stated intervals has much the advantage. The old method was to rely on rail or barge tonnage to arrive at times that could only be estimated, but now with large steam colliers seldom varying the time in transit or the number of trips in a season, the conditions are much changed. The larger consumers who have large storage facilities will undoubtedly continue to buy a share, at least, of their fuel requirements through the spring and summer, and usually they save a good deal by being in shape to do that.

Current wholesale quotations are about as follows:

Clearfields, f.o.b. mine	$1.25@ 1.40
Clearfields, f.o.b. Philadelphia	2 50@ 2 65
Clearfields, f.o.b. New York	2 80@ 3.00
Cambrias, Somersets, f.o.b. mines	1.35@ 1.60
Cambrias, Somersets, f.o.b. Philadelphia	2.60@ 2.85
Cambrias, Somersets, f.o.b. New York	2.90@ 3.15
Pocahontas, New River, f.o.b. Hampton Roads	2 60@ 2.70
Pocahontas, New River, on cars Boston	3.75@ 3 90
Pocahontas, New River, on cars Providence	3.75@ 3.85

NEW YORK

Bituminous—The bituminous market has shown a tendency to ease off still further during the past week and prices are slightly softer. It is reported in one instance that an indifferent grade of Clearfields has been offered down to $1.05 f.o.b. mine; such cases are, however, more the exception than the rule, and because of the uncertainty in quality, should not be accepted as any accurate criterion of conditions. There are large tonnages on hand at the piers, and rumors state that producers are beginning to curtail production, rather than sell at prevailing low prices.

Little or nothing is being done on next season's contracts, producers and consumers being hopelessly separated on prices. The companies are showing a determined effort to obtain advances over last year's figures of as much as 25c., in exceptional cases. Consumers on the other hand are naturally little interested in these high figures because of the declining spot market and the result is a deadlock. From present indications the buyers will not close contracts until forced to do so, and the ultimate figures will probably be a slight increase, on an average of about 5c. per ton, over last year's figures.

Bituminous prices have experienced a further decline during the week and we quote the nominal local market on both hard and soft coal on the following basis:

	Anthracite		Bituminous
	Circular	Individual	
Broken*	$5 00	4 75	West Virginia, steam	$2.60@2.65
Egg	5.25	4 70	Fair grades, Penna	2.65@2.70
Stove	5 25	5 25	Good grade, Penna	2.75@2 80
Chestnut†	5 50	5 50	Best miller, Penna	3 05@3.15
Pea*	3 50	3 75	Georges Creek	3.25@3.30
Buckwheat**	2.75	2 50		
Buckwheat†	2.45	2 35		
Rice**	2 25	2 25		
Rice†	1 95	1 90		
Barley†	1 75	1 20		

* Scranton and Lehigh. ** Scranton. † Lehigh and Schuykill.

Anthracite—Buying of hard coal is now confined entirely to immediate needs. Consumers are keeping requisitions down to the lowest possible minimum to avoid carrying any tonnages over Apr. 1, when the summer discount goes into effect. The orders will naturally be light from now on until summer stocking begins.

Locally few of the companies appear to be finding it necessary to put any coal in storage as yet. They are, however, already beginning to look forward to an early loading of lake vessels, for shipment into the Northwest. As a rule production at the mines is quite heavy, there being few interruptions. Last week there was some shortage of open cars, but not serious. In view of the reduced circular effective Apr. 1, orders will gradually fall off through this month until operators will be forced to curtail the production.

PHILADELPHIA, PENN.

It is commencing to look now as though the anthracite business, for the winter of 1912-13, was about done. All the dealers here claim to have stocks of coal sufficient to carry them over until the spring or opening prices are announced.

and with the cheap coal offered by the individual operators, there is no reason why they should load themselves up with any more coal at the full circular prices, than is necessary. It would take unusual conditions to bring about any particular active demand. Outside of stove and pea, there does not seem to be any call at all, and there is no waiting in line for stove. Pea coal is still a little short of the demand, although the dealers claim to have no difficulty in keeping up with their current business. It is simply a waiting game and any orders placed now are to piece out, until the usual spring reduction becomes effective.

Bituminous coal still continues in the same apathetic condition. While it is understood that contracts are being renewed at better figures than last year, at the same time current business is far from satisfactory. It is understood that there is a large accumulation of loaded cars at tidewater points, and if demurrage on these grows to any extent, there is likely to be some bargain coal on the market.

PITTSBURGH, PENN.

Bituminous—Retail demand is fairly good, while manufacturing continues rather light. It has been between seasons as to contracts, the next period being the year beginning Apr. 1. Against such contracts there has been only moderate inquiry thus far, consumers showing a disposition to hold off until the last moment, on account of the sizable advance in regular circular prices as compared with those of a year ago. Slack for immediate shipment continues to command a slight premium over the regular contract price of 90c., and is quotable at $1@1.10, while mine-run and screened coal are only moderately firm at regular prices, which we continue to quote as follows: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in., $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—The coke market has continued its stiffening, until $2.50 is the regular asking price for good grades of furnace coke for prompt shipment, and most if not all the operators seem to think they ought to obtain more than this for a contract running to July 1. Curiously enough, there are others, however, who would probably be willing to shade $2.50 for the second half. Demand for prompt coke is light, and the stiffening in the market appears to be due altogether to the recent sales at cut prices which moved a great deal of coke that had been stocked in the region, 25,000 to 35,000 tons, and that production has been somewhat curtailed owing to lessened activity in the production of off grades, chiefly high sulphur coke, which found a ready market during the famine, but which are practically unsalable now. Foundry coke is relatively stiffer than furnace. We quote: Prompt furnace, $2.40@2.50; contract furnace (nominal), $2.50; prompt foundry, $3.25@3.50; contract foundry, $3@3.25, per ton at ovens.

BALTIMORE, MD.

A number of independent operators who work a few mines for a brief period during the season, in order to take advantage of the high prices, have closed down completely, because of the depressed condition of the trade. The elimination of these will tend to benefit the market to a certain extent, as it will decrease the supply of spot coal and enable the other operators to obtain a better supply of men. These intermittent operators offer the miners considerably more than the others can afford to pay, and consequently obtain a better supply of men.

Operators feel that their prices on contracts have been too low, and they are making a determined effort to maintain a higher level and believe they will be successful in doing so. It is generally conceded that it is costing more to produce coal than in previous years and that the profit has of late been exceedingly small. Many of the large consumers believe that there is some justic in the stand taken by the trade, for they registered no complaint against the higher contract prices.

Trade conditions during the week did not undergo any change. Unfavorable reports were heard as to the car situation, and on at least one of the roads, operators stated that conditions were worse than they had been for a month. But little spot business came to the surface, and the only activity apparent was in the contract trade. Low-grade coal was quoted from 90c. to $1 per ton.

There was not much activity at the piers this week, only a few ships loaded here and these were on contract business. Vessel rates for the South were slightly weaker than for weeks previous, owing to the exceptionally favorable weather for sailings. Coke continued strong, the demand for the steel trade holding the market up. Connellsville coke sold around $3.50 and $4. Prices for the West Virginia product also remained firm.

BUFFALO, N. Y.

There was again a weather condition that would flatten out the stiffest coal trade. Still the big demand for bituminous has kept prices much firmer than would be expected, so that some of the leading jobbers are reporting prices about on the level of last week. There is also complaint that the car supply has been down to 40 per cent. of requirements. Many roads have been unable to handle the coal after it had started from the mines. They report all embargoes off, but when urged for prompt delivery of coal in transit it is often found that the cars were so scattered about that it was hard to locate them. Still, as this is the chief reason for coal prices staying up, there may not be much reason for complaint.

Though bituminous prices are weak, they are still based on former quotations and with a return of winter conditions, which may occur any day, the prices would stiffen up and hold indefinitely. Pittsburgh select lump sells at $2.80, three-quarter at $2.63, mine-run at $2.55 and slack at $2.15. Coke hardly holds its own and is not quotable above $5.35 for best Connellsville foundry. When coke goes very high, and then begins to decline, it takes a long time to stop it.

There is still much hesitation over the making of contracts. Consumers are not offering to close and jobbers and operators claim they could not make anything at present figures. They are not often strong enough to resist, though, even if fairly convinced that prices are too low. The demand for anthracite, is, of course, light. Cancelations of orders, made when there was snow on the ground, are common. Buying will hereafter be from hand to mouth.

The coal trade is much steadier than it has been for some time and it promises to remain so if the weather continues seasonable as it has been so far this month. Uncertainties are now confined entirely to the railroads; every day something new comes up to disturb transportation conditions. Sometimes it is a blockade from accidents down the Allegheny Valley or another embargo on the Canadian roads.

If a big snowstorm should appear prices would return to all their former strength, and for this reason the trade is holding tenaciously to old quotations, as it is much harder to restore them when they are off. This is the time when the good salesman earns his salary and the poor one goes to the wall; for quite a long time there has been little for salesmen to do, but they are out again, as the orders are not coming in unsolicited as freely as they were.

COLUMBUS, OHIO

The warmer weather of the past week had the effect of softening the coal trade in Ohio to a certain extent. But the volume of business is still good and the prospects for the future are believed to be fair at least. Prices have not suffered by the warm spell and there is still a fair demand for domestic.

The steam trade continues good as manufacturing is still prosperous. Contracts are expiring now and arrangements are being made to renew at slightly higher figures. Railroads are also taking a large tonnage as the freight movement continues good. The domestic trade is weakening as dealers are not placing orders with operators and shippers as freely as formerly. Stocks on hand are not large and if there should be a spell of cold weather it will be reflected immediately upon the trade.

In the Hocking Valley and in Pomeroy Bend districts the output has been about 80 per cent. of normal. The same is true of other fields with the exception of eastern Ohio where it has been about 75 per cent. Some trouble was reported from a car shortage in eastern Ohio, but other districts appear to have a sufficient supply of equipment.

Quotations in the Ohio fields are as follows.

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1 40		$1 40	$1 40
2-inch	1 30	$1 20	1 35	1 30
Nut	1 30		1 25	
Mine-run	1 15	1.05	1.15	1 15
Nut, pea and slack	1 00		1 05	1 00
Coarse slack	0.90	0.90	0.95	0 90

There is every indication for an active lake business the coming season. The recent cold snap has resulted in the dock stocks being depleted and there is little probability of any coal being carried over. As a result the lake season will be active if sufficient bottoms can be secured, the chances are good for an active ore trade also.

CLEVELAND, OHIO

The Cleveland market shows little, if any, improvement over a week ago. There is an apparent lull in the demand for coal and many consumers have curtailed their shipments to reduce their storage supply.

While the movement to this district has slightly improved, Pennsylvania and Ohio shippers are experiencing great difficulty on coal routed via Toledo. Six hundred cars are delayed, awaiting acceptance by the Detroit & Toledo Shore Line R.R. on account of the congested condition at Toledo. Eastern carriers have placed an embargo restricting the routing of coal via the D. & T. S. L. when destined to points on the Grand Trunk Ry. This has caused no inconsiderable hardship to shippers and they will be forced to discontinue shipments on many large railroad and corporation contracts until the embargo is raised.

Wholesale quotations per short ton, f.o.b. cars at the mines, are as follows:

District	Freight rate	¾-in.lump	Mine-run	Slack
Youghiogheny	$1 00	$1 40	$1.30	$1 10
Pittsburgh No. 8.	0.90	1.20	1.10	1 10
Goshen No. 6.....	0.70	1.35	1.25	1 20
Coshocton.....	0.70	1.55	1.35	1 20

Pocahontas lump and egg is quoted at $1.75, run-of-mine $1.15, and slack $1, f.o.b. mines. Massillon domestic lump is seling at $2.50 and Hocking lump at $1.55, mines. Furnace coke has dropped to $2.25, f.o.b. ovens; about 75c. is added for the foundry grades.

Shippers of coal from the Youghiogheny belt seem to be highly elated over the recent advance in the price of oil. Many of the large gas plants have been making water gas, but the increase in the price of oil will prohibit, to a large degree, the manufacturing of gas from this product. Many large plants have already changed to coal gas, and this will have a stimulating effect on the Youghiogheny market and high premiums will, undoubtedly be paid on coal from this district. This is regarded as the opportune time for the operator of gas coal to insist on getting a good price for his product. He was handicapped by a scarcity of men and cars and is not getting the returns from his miners that he was when labor was plentiful. Certainly better results should be attained from the great tonnage sent out from this field.

HAMPTON ROADS, VA.

Prices of tidewater coals are still showing a downward tendency, with but small prospects of any increase in the near future. Sales of spot, New River and Pocahontas, have been made during the past week at $2.60 f.o.b. and even at this low figure, there have been but few transactions; the holders of surplus tonnages shipped on speculation, have found themselves in a difficult position.

Notwithstanding quite heavy dumping at the coal piers, there are still large accumulations of loaded cars, nearly all of the coal shipped having been on contract business to New England ports. The situation is worse at Newport News, where the dumping has been slow. The Sewalls Point piers did a fair week's business, but nothing to what they could have done, had there been a good supply of ships. Movement of coal from the mines continues to be good.

The export business still shows an increase and rumors are heard of some large contracts to begin on Apr. 1. The local market is still quiet and buyers are slow to make contracts during the present downward tendency; however, there has been as yet, no break in the local contract price, $1.25 per net ton f.o.b. mines.

BIRMINGHAM, ALA.

The volume of the steam business continues to be large with good prospects of unusual prosperity during the next several months. Operators are cheerful over this and also that general business in the South was never as good as it is at present. An immense amount of construction work is under way and there are shortages of labor; neither are there any labor troubles worthy of mention. A slight car shortage is now apparent with two of the larger lines, although, as a rule, all mines have been well supplied with cars since the first of January.

The coke market remains unchanged, although competition with Virginia producers is keen in some districts. The abnormal Virginia coke market during the past several months has enabled the Alabama producers to cover a broader territory and has been a source of strength to the local trade.

LOUISVILLE, KY.

For some unaccountable reason, the steam market has cased up a trifle. Little heating has been required recently, which may be the cause for a slight slackening of the demand. It is possible that the stringency of the market during the past few weeks has resulted in their being forced to curtail operations somewhat, which would have its effect in a considerably lessened demand.

Eastern Kentucky block and lump varies from $1.60 to $2 a ton f.o.b. mines, indicating that coal is being sold at about what it will bring; round is selling at the usual differential below these prices. Mine-run fluctuates between $1 and $1.20, and nut and slack is now selling at from 75 to 90c. for the better grades, and as low as 50c. for lower qualities. Some Indiana nut and slack is reported selling at 65c., the advantage in freight rates making this a favorable price for delivery to this market, in the absence of better coal. Western Kentucky nut and slack can be had at about the same price.

The trade here is still clinging to the possibility of seasonable weather in March, as that month not infrequently brings cold weather and blizzards, but as the whole winter has been one of disappointments, operators are prepared to face an early spring, and a consequent steady slackening off of business. Practically all dealers will, however, have to put in pretty fair stocks, as their conservative attitude at this time indicates that they are taking no chance of going into the summer with a large quantity of coal on hand, bought at winter prices.

INDIANAPOLIS, IND.

Continued mild weather makes the consumption of coal unusually light for February. Mine prices, which have been practically at summer schedule, have not improved any and it is reported there have been some bargain sales to retailers. However, those who bought heavily in the fall, in an effort to take care of their customers, when it looked as if the car shortage was going to cause a coal famine, have not reduced prices. Smaller yards that were unable to place large orders in the fall have had opportunity to take advantage of the mild-weather cut at the mines and are offering Indiana lump as low as $3, Pocahontas lump at $5.75 and furnace anthracite at $8.50. The mines are curtailing their running schedules again. On account of the poor demand for domestic, Plymouth Mine, No. 1, of the Coal Bluff Mining Co., in the Brazil field, has been closed down until next fall. Indiana prices, f.o.b. mill, are as follows:

No. 4 mine-run..	$1 15	Domestic lump 5- and 6-in..	$1 65
Nos. 5 and 6 mine-run.	1 05	Screenings, No. 4.....	0 80
No. 4 steam lump, 1½-in	1 30	Screenings No. 5 and 6.....	0 70
Nut, No. 4.	1 40	Washed coal, Nos. 1 & 2.	$1.75@2.00
Egg.....	1 45	Brazil block.....	2.20
Domestic lump 2½-in....	1 50		

DETROIT, MICH.

Cars are coming through quite promptly, and it is predicted that the D. & T. Shore Line will embargo against the Grand Trunk, because of its inability to handle freight billed over the Grand Trunk. There are few new orders being taken at present owing to the unusually warm weather. However, a considerable number of delayed shipments are coming in and flooding this market with track coal. Domestic is unusually bad. Dealers all over Detroit and immediate vicinity are loaded up so fully that it is impossible for them to take in any more, and they are asking the mines to discontinue shipments on their contracts.

If the present cold weather continues it will give the operators and dealers a chance to bring business up to the record of the previous year at this time. There have been several large contracts let, although operators seem a little reluctant to close owing to the disturbed conditions which exist in West Virginia.

The car situation shows a marked improvement, and there seems to be little trouble in supplying equipment or moving shipments.

The prevailing market prices for today are as follows:

	W.Va. Splint	Gas	Hocking	Cambridge	Ohio No. 8	Pocahontas	Jackson Hill
Domestic lump	$1.40		$1 80		....	$1.60	$2.00
Egg.....	1 40		1 80		....	1 60	2 00
Nut	1 25		1 25				....
¾-in. lump.	1 05	$1 05	1 15	$1 05	$1 15	....	....
Mine-run..	0 90	1 00	0 90	1 00	1 00	1.25	..
Slack. ..	1 10	1 15	1.10	1 10	1.10	1.20	1.10

ST. LOUIS, MO.

In the Carterville field, mine-run costs approximately from $1 to $1.10 per ton to produce. Screenings are selling at 80@85c.; 40% at 85c. means 34c. for screenings, and 60% at $1.10 as a maximum, nets 66c., making $1 per ton for mine-run on a screened basis. These are the minimum producing and the maximum selling prices, so it is easy to see what the situation is. In East Louis there were several hundred cars of coal the past week from the Carterville field, which sold at $1@1.05. In the Standard field it costs from 85@90c. to produce the coal, and mine-run is selling at 80c., with the screened coal going at anything from $2½@90c., and screenings at from 60@65c.

The market condition in St. Louis has not changed any for the better, although the earlier part of the week the weather indications were such that there was hope for improvement.

It would take a period of from a week to ten days before cold weather could affect any change.

	Carterville and Franklin Co.	Trenton and Big Muddy	Mt. Olive	Standard
2-in. lump				$0 90 @ 0 95
3-in. lump			$1.25	
6-in. lump	$1.25		1 35	1.00 @ 1.10
Lump and egg	1.25	$2.25		
No. 1 nut	1 20			
Screenings	0 85			0 60 @ 0 65
Mine-run	1 10			
No. 1 washed nut	1 35			
No. 2 washed nut	1.30			
No. 3 washed nut	1 25			
No. 4 washed nut	1 20			
No. 5 washed nut	1.10			

CHICAGO

With a return of snow and a drop in temperature, Chicago coal dealers are expecting a revival in prices. For several days the market has been demoralized and prices slashed right and left. Unusual production and an exceptionally large volume of shipments are credited with being the chief causes for this condition. The over-shipment was due to a speculative campaign. It has been possible to buy all kinds of Springfield coal at $1 and, in some instances, Springfield egg, on shipments direct from the mine, has been offered at 85c. Some Franklin County coal of the lump and egg variety has been for sale in Chicago at $1 and $1.05.

There has been a reduction of prices for mine-run and steam lump as a result of the fact that a great deal of domestic lump has been sold for steam-making purposes. Prices for screenings also have softened. Furnace and foundry coke are active. A drop of about 25c. a ton has been noted in the prices for domestic sizes of byproduct coke.

Prevailing prices in Chicago are:

	Springfield	Franklin Co.	Clinton	W. Va.
Domestic lump	$2 07@2 22	$2 45@2 55	$2 27	
Egg		2 45@2 55		$3 95
Steam lump	1 92@1 97		2 17	
Mine-run	1 87@1 92	2 20@2 30	1 97	3.30
Screenings	1.57@1.62	1.90@1.95	1 67	

Coke—Connellsville and Wise County, $6@6.25; byproduct, egg, stove and nut, $5.50; gas house, $5.50@5.75.

OGDEN, UTAH

The larger dealers who continue buying during the spring and summer have decreased their orders, and are endeavoring to clean up their yards. This period is the hardest on the operators and probably the dullest time of the year. Later, shipments will adjust themselves to regular summer business, and the mines will be able to work accordingly.

The eastern market is still in bad shape and shipments low; in fact, it has been a number of years since the movement has been so small. Nebraska and Kansas have not been visited by a severe winter and this, in connection with the heavy shipments during January, caused by the railroad routing cars east, has given all dealers a good supply of coal, which must be disposed of before spring.

COAL TRADE NEWS

HAMPTON ROADS, VA.

Lambert Point piers established a new high record during the week ending Feb. 22. Slightly over 150,000 tons were dumped. Between 6 p.m., Sunday, and 6 a.m. Tuesday, the dumping totaled 33,000 tons.

ST. LOUIS, MO.

Local operators are being obliged to close down because of slack business. Those having contracts claim they can buy in the spot market cheaper than they can produce. Hence they are making additional profits by keeping mines idle. Other operations closing down indefinitely has been steadily increasing for several weeks.

BOSTON, MASS.

If water freights from Hampton Roads continue on their present high level there is likely to be a somewhat enlarged market for the better known grades in Pennsylvania. In other words, Pocahontas and New River at $2.85 will lose tonnage to Cambrias and Clearfields that range in price from $2.50@2.75 at Philadelphia, for ordinarily anthracite barge transportation can be had from Philadelphia at less than the going rates from the Virginia ports.

CLEVELAND, OHIO

Too much emphasis cannot be given to the great volume of bituminous and anthracite coal, which will be shipped via the Great Lakes during the coming season of navigation. The demand for Youghiogheny coal for lake shipment, continues to hold out and shippers of coal from the gas belt expect to receive high premiums for their product this year. There has been no change in the lake freight rate to Lake Michigan; so far all contracts have been drawn up on the basis of 35c. per net ton. Coal men look for an early opening of navigation; practically all the coal-carrying vessels will be ready for operation by Apr. 10 at the latest.

PRODUCTION AND TRANSPORTATION STATISTICS

NORFOLK & WESTERN RY.

The following is a comparative statement of the coal and coke shipments over the lines of the N. & W. Ry. for the months of December and January of the last two years, in short tons:

	December		January	
Destination	1911	1912	1912	1913
Coal				
Tidewater, foreign	101,118	84,083	112,204	144,062
Tidewater, coastwise	293,850	258,216	248,219	308,918
Domestic	1,413,644	1,355,189	1,327,525	1,616,894
Coke				
Tidewater, foreign	5,713		4,556	5,055
Domestic	116,988	134,763	127,084	143,196
Total	1,931,313	1,832,251	1,819,588	2,218,125

SOUTHWESTERN TONNAGE

The following is a comparative statement of the Southwestern production for August and September, 1911 and 1912:

	August			September		
State	1911	1912	Change	1911	1912	Change
Missouri	186,852	213,603	+26,751	202,404	242,871	40,467
Kansas	400,820	408,947	+8,127	401,536	424,329	22,793
Arkansas	139,762	172,090	+32,328	133,238	169,325	36,087
Oklahoma	257,773	232,768	—25,005	229,300	249,604	20,304
Totals	985,207	1,027,408	+42,201	966,478	1,086,129	119,651

THE CAR SITUATION

American Ry. Association reports surpluses and shortages of coal equipment for two weeks ended Feb. 15 as follows:

	Surplus	Shortage	Surplus or Shortage
New England Lines	203	250	47
N. Y.; New Jersey, Del.; Maryland; Eastern Penn	5,214	153	**5,061**
Ohio; Indiana; Michigan; Western Pennsylvania	5,563	65	**5,498**
West Virginia, Virginia, North & South Carolina	584	1404	820
Kentucky, Tenn.; Miss.; Alabama, Georgia, Florida	596	517	**79**
Iowa, Illinois, Wisconsin, Minn.; North & South Dakota	1,337	100	**1,231**
Montana, Wyoming, Nebraska	0	11	**47**
Kansas, Colorado, Missouri, Arkansas, Oklahoma	1,068	431	**637**
Texas, Louisiana, New Mexico	416	0	**416**
Oregon, Idaho, California, Arizona	1,117	25	**1,392**
Canadian Lines	0	0	0
Totals	16,398	2986	**13,412**

FOREIGN MARKETS

GREAT BRITAIN

Feb. 11—The market rules quiet. The shortage of ready steamers, caused by this week's dense fog, has depressed conditions for prompt loading. For forward loading sellers are holding for higher figures, and there is a disposition to fix requirements for next month. Smalls remain stationary. Quotations are approximately as follows:

Best Welsh steam	$4 38@4 44	Best Monmouthshires	$4 08@4 14
Best seconds	4 20@4 32	Seconds	3 96@4 02
Seconds	4 14@4 20	Best Cardiff smalls	3.54@3 60
Best dry coals	4 38	Seconds	3.24@3.36

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days—less 2½%.

FINANCIAL DEPARTMENT

Colorado Fuel & Iron Co.

Under date of Oct. 21, President J. F. Welborn issues his report for the fiscal year ended June 30, 1912, from which the following abstract is taken:

Results—Gross earnings from operation were $24,268,452, an increase of $1,333,767, or 6%. Operating expenses absorbed $1,039,835, leaving $293,932 net gain, and making total net from operations $3,772,282, an increase of 8.4%. Adding income from other sources, the net income was $4,448,975. After providing for all fixed charges, sinking funds, etc., there remained a surplus of $1,801,229, out of which a dividend of 5% ($100,000) was declared on the pref. stock, leaving $1,701,229 for profit and loss.

There was a decrease of 195,000 tons in coal output. This is accounted for by a falling off in railroad consumption of somewhat more than that tonnage and an increase in general sales. The result in fuel department earnings was a decrease of $31,092 in gross and an increase of $29,724 in net; as prices of domestic coal were generally lower than in previous years and an advance in miners' wages made effective April, 1912, added at least $20,000 per month to producing cost for three months of the year, this showing is considered particularly favorable.

Charter Renewal—At the stockholders' meeting, Oct. 19, 1912, the charter was renewed for 20 years from Oct. 21, 1912.

STATEMENT OF PRODUCTION FOR YEARS ENDING JUNE 30

Short tons—	1911–12	1910–11	1909–10	1908–09
Coal	4,038,852	4,233,756	4,722,832	4,094,352

⁂

The Lehigh Valley Coal Sales Co.

The Lehigh Valley Coal Sales Co. was incorporated under the date of January 22, 1912, for the purpose of shipping and selling the coal mined and purchased by the parent company. The authorized capital stock of the Sales Co. is $10,000,000, of which $6,060,800, or 121,216 shares, with a par value of $50 each, were full subscribed to and issued. The stockholders of the Lehigh Valley R.R. Co. were given the privilege of subscribing at par to an amount equivalent to 10% of their holdings. After the organization of the company was completed, a contract was executed, effective March 1, 1912, between the parent company and the Sales Co., under the terms of which the latter is now purchasing at the breakers and shipping the coal mined and purchased by the parent company.

COAL SECURITIES

The following table gives the range of various active coal securities and dividends paid during the week ending Feb. 22:

Reading Co.—Regular quarterly on 2d preferred of 1%, payable Apr. 10 to holders of record Mar. 25.

⁂

Burns Bros.—Coal sales of this company increased from 50,000 tons in 1885 to 1,950,000 tons in 1912; the average sales over the last five years were 1,800,000 tons. The company has paid interest on its bonds regularly, redeemed $500,000 of a total of $1,000,000, 5% bonds, and distributed $1,605,000 in dividends on its $1,500,000 common stock.

COAL AGE

Vol. 3 NEW YORK, MARCH 8, 1913 No. 10

"PRECEDENT" forms a comfortable wall for people to lean against. However, the fellow who wants to remain in a standing position needs only to keep his fingers on the railing of "ingenuity" that persistently winds about on the other side of the street.

We make no claim for originality of thought in the above. Sidney Smith hinted the same thing in an essay published in 1824, and, for all we know to the contrary, he may have but voiced the thought of someone who lived a century or two before. Close observation will show that some of our mining folk haven't discovered that there is anything of value above, below or across from the "wall of precedent," even though Smith has been dead "Lo these many years."

For the benefit of all who may be willing to class themselves with the last described, we wish to relate, in part, the experiences of a young fellow who followed the "ingenuity" route regardless of "precedent."

This man was superintendent of a group of mines that supplied coking coal to a blast-furnace plant. The capacity of his mines was such that under normal conditions the requirements of the furnaces were easily met, but during the months of December and January, when the holiday spirit took possession of his men, it was necessary to feed the furnaces largely from stock piles.

Occasionally strikes at the mines compelled the furnaces to draw from the stock piles at other times than Christmas, and during such years the holiday shortage had to be met by buying coke in the open market. Coke bought in this way and at such a time was always high in price and generally inferior in quality. This was especially true following a general strike covering all mines in a district, for in that event the only available source of supply must needs be at a great distance.

Now to return to the fellow who is to furnish the ingenuity lesson. One bright Thanksgiving morn he found himself facing an almost exhausted stock pile of coke and a group of miners longing for a good old-fashioned Christmas drunk. "Precedent" put the responsibility on the shoulders of his manager, since a general strike that affected all mines in the state early in the previous summer was responsible for the meager stock pile.

But the manager was not required to feel the responsibility this time. The superintendent decided that he would try to make his miners forget their annual holiday drunk until Christmas Day at least, and this is how he went about it: He posted a notice stating that all miners who worked every day during the month of December up to the 25th would be presented with a large live turkey on Christmas morning. Of course, he did not know how successful he would be, since "precedent," so far as he could learn, furnished no clue.

As a matter of record here is what happened: His December output exceeded that of any previous month during the year, nearly every man earned a turkey and the company earned the goodwill of the miners. Last, but not least, the meager stock pile remained intact during the holidays, notwithstanding the fact that no coke was purchased from outside companies.

The giving of bonuses or prizes has been successfully employed in many industries for years, but examples in the coal industry are rare. A little ingenuity would suggest numerous possibilities.

There is also a broader aspect to such ingenuity that should appeal to anyone who is ambitious to accomplish things which may be of benefit to the many. *Each innovation carried to a successful conclusion becomes in turn a precedent, which even the most timid may follow unhesitatingly.*

IDEAS AND SUGGESTIONS

Cheer Up

By J. E. Jones*

Centuries upon centuries ago mankind was taught that kind answers would turn away wrath, and a pleasing countenance was better than the possession of gold and silver. And down through the ages, wise men have endeavored to drive these lessons home. But with all of this teaching and our twentieth-century advancement, we are not exceptionally cheerful, nor are we adepts in giving kind answers at critical moments.

Good cheer is not out of place wherever people are associated. Especially is this true in connection with coal mining. The darkness of the mine, the absence of sunlight, the nature of the work and the generally austere bearing of those in authority are a few of the many things that tend to make the average mineworker despondent, cranky and suspicious. But, because of these unfavorable surroundings, the mining industry offers an excellent opportunity for the practice of lessons in "good cheer."

From general manager to trapper boy there is nothing more contagious than cheerfulness. In a brief period of time, it finds its way throughout the mine. Men seem to catch it and their work is lightened, the day made shorter and all go home to enjoy a good night's rest after a prosperous day's work. Even the mules and machinery are benefited, for the work has been accomplished in shorter time and with fewer mishaps when men keep their temper throughout the day.

Good cheer is as essential to the most successful management of a mine as is the good will of the men. To a great extent, these go hand in hand. Other things being equal, a cheerful mine manager will get better results than one who is gruff. Bosses who are able to maintain an earnest, cheerful manner when discussing the faults of men are infinitely more successful than those who are severe in correcting a fault, and leave a bad impression in the minds of workmen in their charge.

The best results are obtained when men perform their work with a hearty good will, and have a pride in the finished job. This sort of workmanship and a cranky boss are seldom found together. Men at best are but grownup children. They are affected nearly if not quite as much by their emotions and the emotions of others. It takes but little more time for a manager or boss to speak cheerfully for a minute or two to men as he travels through the mine. Men often carry to work burdens that a cheerful word will make lighter. It is a simple matter to inquire as to the welfare of a sick child, or speak approvingly of improvements noticed on the house or in the garden at the home of the workman, or ask about the baby and the mother.

Any manager with a little tact and ability to read human nature can, with sincerity and cheerfulness, make a big advancement in the building up of a strong organization. Since the work of the coal producer is at best somewhat unpleasant, the least that men in authority can do is to strive to let in a little of God's sunlight into their lives, and make living for them more worth while, and by so doing the world will be brighter and life happier; therefore, CHEER UP.

*Muleboss, Dering No. 2, Danville, Ill.

Handling Men

By Frank Selbe*

The ability to handle men seems to be one of the chief points in being a successful mine foreman. I have heard this preached since I was a trapper, and while it is undoubtedly true to a certain extent, still I do not believe it to be the most important point. I think, among the qualifications of a successful foreman, the first to be considered is his knowledge of mining operations and methods.

The term "handling men" has more than one meaning. First is the placing of men to obtain the best results from their labor, and to insure their own satisfaction. Next comes the problem of handling them in time of disputes, strikes or other labor troubles. This is a big question in itself and often time can be saved (and time is money) by the exercise of a little judgment and forethought.

A great deal of trouble is often caused over the most trifling matters. For instance, a miner finds some unusual impurities in the seam, something from which it is almost impossible to free the coal and he is then docked. He sends for the mine foreman to examine it and tell him what to do. The foreman sends word that he is well acquainted with conditions and there is nothing for him to do but clean the coal. It may be that the mine foreman has not been in this miner's place for a week, and the latter, feeling that an injustice is being done him, goes with his complaint to the company, with the result that trouble usually follows.

In another instance, one miner sees a fellow-workman bringing his boy, who is under age, according to the state laws, to the mine. He reports the case to the pit-boss, who informs him that: "I am carrying the time-book here and if I need any assistance, I will call on you." It would have been much better had the foreman used a bit of tact and replied: "I will look into the matter—am very glad you mentioned it."

It seems to me that the average mine foreman is too self-important. He quite often resembles Simon Legree—very knowing and important until the superintendent arrives on the scene, when he becomes as meek as a lamb. And not infrequently he is guilty of shifting the blame for mistakes on someone else. The best of men make mistakes and they should have no hesitancy in acknowledging them. It has been wisely said that: "The man who never made a mistake, never made anything."

*Elkridge, W. Va.

Generally, the mine foreman who finds the most fault is the one who ignorantly, but effectively, multiplies the evils, and he often convicts himself while trying to convict someone else. Of course, the foreman has some difficult problems to solve, but if he will use good sense and judgment he will obtain better results.

Frequently he has a man to contend with who is as bullheaded as himself. Such a one, having his own ideas of right and wrong (nearly always wrong), may destroy the peace and contentment of others who are perfectly satisfied. He also has some men who are never satisfied—men who are always on his trail, wanting to change places, extra pay for everything they do, and so on. There is also the man who is always trying to make trouble. He thinks he is the right party to lead the men to victory, when he is simply a black sheep, and the best thing for all concerned is to weed him out.

Modernizing Mine Management

By a Colorado Engineer

The dictionary defines a manager as "One who conducts business or other affairs skillfully and with frugality and economy; an economist." But, in coal mining, many factors complicate the duties of a successful manager. Competition in trade, the increased difficulty in the recovery of coal owing to the exhaustion of the seam, the increasing demand for greater safety and the exacting requirements of large consumers of coal, together with the demand for increased wages and reduction of hours on the part of the miner make it a practical impossibility for *one* man to successfully manage and harmonize these conflicting conditions. The demand is now that every personal unit in the organization be a manager *in fact*, to insure ultimate success.

To bring about this millennium requires an intense desire for the accomplishment of such a purpose, in the mind of the one high in authority, and an ability, on his part, to inspire confidence in his subordinates. Where a subordinate shows a tendency to be stubborn someone must be appointed to take his place, and the choice is preferably of one within the organization. Such change is necessary for proper discipline. The manager must study, standardize, instruct, condemn and reward, using always his best tact and judgment.

Much of the expense of operation, in coal mining, occurs at the working face. Where machines are used in mining the coal, there is great need to study carefully the conditions here, so as to expedite the work of cutting and loading the coal and harmonize the movements of the machine man and his helper, and those whose duty it is to blast and load the coal.

Much delay is often experienced when starting to cut in the morning and when moving the machine from room to room, in the unloading of tools, and setting of anchors or jacks and other details. A careful study is often necessary to determine the exact cause of such delay. The fault may not rest wholly on the man in charge of the machine. The mine electrician may have failed to make the necessary repairs reported the previous day, or the cause may be a faulty installation or equipment.

A careful study of all these conditions should result in ascertaining data by which it is possible to set a standard time for each operation, barring, of course, unforeseen accidents. The coöperation of every man on the job is necessary to do this. In this respect the workmen themselves become undermanagers. They study to conduct their business "with frugality and economy."

The work of the manager is thus, not only lightened, but made more efficient. Difficulty is sometimes met when the work is done on contract; especially if the conditions are such that the man is not interested in increasing his rate of cutting in order to expedite other work in the mine. If he is working at a certain rate per day, he must be assured that an increased rate of cutting will materially increase his wage.

It is, of course, impossible for wages to increase in the same ratio with the increased efficiency of workmen. Men are generally fair as a whole, if they are not as individuals. A workman who increases his efficiency twofold will seldom demand twice his former pay. In this regard experience teaches that a word of encouragement often works wonders that money cannot accomplish.

In seeking to better the management of a coal mine, every improvement in design of equipment, every successful attempt to increase the efficiency of workmen, is a step in the ultimate increase of efficiency.

A growing feature of the new management, in coal mining, is the desire shown to provide for those on whom the industry depends, giving to them comfortable places in which to live, providing suitable amusement and education for them and their families and encouraging thrift in the community of workers. By this means each worker is stimulated to do his best.

The Trapper's Swagger,

By J. R. Allardyce

(Written expressly for Coal Age.)

"When I'm a man," quoth the ancient kid
That sits by the third west door,
"I'll show some guys in this mine, what's what,"
And he spat through his teeth and swore.

"There's Yankem Jones—the son of a gun!—
I'd give that jay a rope."
He swallowed a chew and missed his sprags,
And killed mule Dick on the slope.

"And Balky Pete," says he, as he stuffed
Some "long-cut" into his cheek;
"He cracks his whip like a man, but—huh!—
He couldn't drive cows to the creek."

"And that Red Jack that swipes my oil,
And dopes my dinner tea;
He sleeps on the trip—the roundhead dub,
I'm in training for him," says he.

"And that old guy with the fringe on his chin—
Sam Sears—he thinks he's It;
He bosses me 'round like a blooming slave,
But now he has got to quit."

And he clenched his fist, and he felt his arm
Where the muscle ought to be;
And puffed himself up and smote his chest—
"Oh! I'll soon be a man," says he.

Our Future in the Export Trade—III

By F. R. Wadleigh*

SYNOPSIS—The third and concluding article on this subject. This installment discusses the monetary value of different export coals of the world, and gives a careful analytical comparison. The question of transportation to the loading ports is also discussed in detail.

❖

As already noted in a previous issue, the average railroad haul of Welsh coal is about 20 miles; for this distance the maximum rate chargeable is 1.75c. per ton-mile; a rebate of about 35% is allowed on coal for export. For instance, the rate from mines to Cardiff is 33.3c. for export and 46.3c. for local use. It might also be stated here that both the French and German railroads give special rates on coal for export. The following table shows the market value of the different British coals as of July 1, 1912:

TABLE I COMPARATIVE VALUE OF VARIOUS ENGLISH COALS

South Wales (F.o.b. Cardiff)	
Best Admiralty large	$4 08@4 26
Admiralty seconds	3 65@3 90
Large ordinaries	3 53@3 65
Large best drys	4 02@4 14

Fife steam coals, f.o.b Methil	2 92@3 04
Fife treble nuts, f.o.b. Methil	2 56@2 58

In making any comparison between the coals of the United States and Welsh product, we should first have a clear understanding as to the names and quality of the different grades in question, as well as the coal beds from which they are mined.

The United States fuels considered in this comparison are those known under the trade names of Pocahontas and New River. Both of these come from what is called by the state and U. S. Geological Surveys, the New River-Pocahontas area of West Virginia: both are found in the same geological measures, known as the Pottsville Series, the Pocahontas coal from the Lower Group and the New River from the Middle Group. The estimated total area underlaid by these coals is about 1,648,000 acres, or about 9,888,000,000 tons of available coal.

Pocahontas Coals

About 90 per cent. of the Pocahontas coal is mined from the No. 3 Pocahontas bed, which is generally considered to be the standard. The coal from the upper thin beds is, as a whole, not equal in quality to that from the No. 3 bed, with the exception of the Davy-Sewell bed, which is correlated with the Sewell bed of the New River field proper. There is also a small tonnage of coal from the No. 4 Pocahontas bed that is quite equal in quality to much of that from the No. 3, but the amount is so small as to be negligible in this comparison.

The Pocahontas No. 3 bed has been under development since 1883, since which time to the close of 1910, 101,986,000 tons of coal and 25,000,000 tons of coke have been produced. This coal is probably the best known, especially in foreign countries of all American coals, due largely to its quality and to the intelligent manner in which it was put on the market and advertised by Messrs. Castner & Curran, who for many years were the exclusive sales agents for this coal. The foresight and sagacity of F. J. Kimball, former president of the Norfolk & Western Ry., on which line all of the Pocahontas mines are located, also had much to do with the rapid development of the field.

Area and Thickness—The No. 3 Pocahontas underlies a large area above water level, approximately 300 square miles. The thickness of the bed will run from 4½ to 12 ft., the average for the entire field being about 6½ feet.

Analyses—The following analyses are taken from the various publications of the U. S. Geological Survey, the U. S. Bureau of Mines and the West Virginia State Geological Survey. We also give analysis of a picked sample, made by J. & H. S. Pattinson, Newcastle, England, as showing the purity of the clean coal:

No. 1—Average of 205 mine samples, from 64 mines, U. S. Geological Survey, 1909.

No. 1a—The best single analysis from the ones averaged as No. 1 above.

No. 1b—The worst single analysis from the ones averaged as No. 1 above.

No. 2—Average of five mine samples from three mines, U. S. Geological Survey Bulletin 362.

No. 3—Average of four samples, actual shipment, U. S. Geological Survey Bulletin 362.

No. 4—Average of samples from 15 mines, West Virginia State Survey, 1911, Bulletin 2.

No. 5—Average of samples from 38 mines, West Virginia State Survey, 1908, Vol. II (A).

No. 6—Average of 407,326 tons, shipped to the Panama Canal, 1909-10, Bureau of Mines, Bulletin 41.

No. 6a—Best average of 5021 tons, shipped to the Panama Canal, 1909-10, U. S. Geological Survey.

No. 6b—Worst average of 5530 tons, shipped to the Panama Canal, 1909-10, U. S. Geological Survey.

No. 7—Average of 181,000 tons, shipped to the Panama Canal, 1908-09, U. S. Geological Survey, Bulletin 428.

No. 8—Analysis of samples from 100 tons shipped to the U. S. Navy and made into briquettes, 1907, Bulletin 362.

No. 9—Selected sample. Analysis by J. & H. S. Pattinson, Newcastle, England.

Norfolk & Western Ry.—All Pocahontas coal for ocean shipment is hauled to tidewater at Hampton Roads over this road; the average distance from the mines is 376 miles and the freight rate $1.40 per gross ton, or 3.70 mills per ton-mile; the weight of a coal train hauled to the Lamberts Point terminal and piers with one locomotive is 4200 net tons. There are three piers at Lamberts Point for dumping coal into ships and the best record for one day's dumping was 26,851 tons. During year ending Mar. 31, 1912, 3,827,121 tons of coal were dumped at these piers. A contract has been let and

*Consulting engineer, 1013 Bank of Commerce Building, Norfolk, Va.

work begun on a new steel pier, 1200 ft. long and 90 ft. high, with an estimated capacity of 1700 tons per hour.

New River Coals

There are three beds of coal in the New River field, Sewell, Fire Creek and Beckley, although there are never more than two of these of workable thickness in the same locality; the largest percentage of coal mined comes from the Sewell bed.

The heating value of the coal from each bed is practically the same and no distinction is made between them in shipping.

The field has been under development since 1873, and the coal has been used by the U. S. Navy since 1878; the output last year was 9,298,000 net tons.

TABLE II. TYPICAL ANALYSES OF THE DIFFERENT GRADES OF POCAHONTAS COALS

	1a	1*	1b.	2†	3†	4*	5*	6a**	6**	6b	7†	8	9

* Air dried † Dry ** As received.

Area and Thickness—The New River beds underlie approximately 1600 square miles. Their thickness is as follows: Sewell, from 3½ to 6 ft.; average, 4½ ft. Fire Creek, from 3½ to 6 ft.; average, 4½ ft. Beckley, from 4½ to 11 ft.; average, 5½ ft.

Analyses—The following analyses of New River coals are taken from various bulletins of the U. S. Geological Survey and the U. S. Bureau of Mines, in addition to which are given analyses of coals shipped to the United States Navy in 1911 and 1912. We also give an analysis made by the Babcock & Wilcox Boiler Co., of a sample from a shipment of 100 tons, the gross sample weighing 500 lb. While of no commercial value, but to show the great purity and value of the clean coal, analysis of three different carefully selected samples, *two* made by a well known authority, John W. Hill, of New York, and one by J. & H. S. Pattison, Newcastle, England, are given.

No. 1—Average of 116 samples from 42 mines, U. S. Geological Survey, 1909.

No. 1a—The best of the above analyses.

No. 1b—The worst of the above analyses.

No. 2—Average of 16 samples from eight mines, U. S. Geological Survey, Bulletin 362, 1907.

No. 3—Average of 10 analyses from actual shipments, U. S. Geological Survey, Bulletins 362 and 23.

No. 4—Average of analyses of samples from 60 mines, West Virginia Geological Survey, Bulletin 2, 1911.

No. 5—Average of analyses of samples from 51 mines, West Virginia Geological Survey, Bulletin 2, 1911.

No. 6—Average of 115,000 tons shipped to Panama Canal, 1908-09, sold on a guarantee of 14,850 B.t.u. Reported by U. S. Geological Survey Bulletin 128.

No. 7—Average of 27 cargoes shipped to Panama Canal, sold on a guarantee of 14,850 B.t.u. Reported by U. S. Bureau of Mines.

No. 8—Average of 11 cargoes shipped U. S. Navy in 1911. Samples and analyses by U. S. inspector and chemists.

No. 9—Average of eight cargoes shipped U. S. Navy in 1912. Samples and analyses by U. S. inspector and chemists.

No. 10—Average of samples from 11,700-ton cargo of U. S. Navy Collier "Cyclops," July 27, 1912, five mines represented.

No. 11—Analysis of sample from shipment of 100 tons—Babcock & Wilcox Boiler Co.

No. 12—Selected sample average of five analyses—J. W. Hill.

No. 13—Selected sample average of four analyses—J. W. Hill.

No. 14—Selected sample average of six analyses—J. & H. S. Pattinson.

New River coal is hauled over the Chesapeake & Ohio Ry. to Newport News and over the Virginian Ry. to Sewalls Point.

Chesapeake & Ohio R.R.—The average distance from the mines to tidewater over this road is 418 miles and the freight rate is $1.40 per gross ton or 3.34 mills per ton-mile; the weight of coal trains hauled into the Newport News terminal by one locomotive is 4200 tons. There are four piers or docks at this terminal for loading coal into ships and 31,565 tons is the largest dumping in one day. The quickest loading record was made by the S.S. "Berwindmoor," and was 8612 tons in 10½ hours.

The contract has been let and work begun on a new steel pier, 1200 ft. long, 90 ft. high and 67 ft. wide, with berths for four of the largest steamships and a dumping capacity of 3000 tons per hour.

During the first eight months of 1912, 689,767 tons of coal were shipped to foreign countries from Newport News.

Virginian Ry.—The average distance from the mines to tidewater on this road is 410 miles; the freight rate $1.40 per gross ton or 3.41 mills per ton-mile, while the weight of coal trains hauled by one locomotive into their Sewalls Point terminal is 5000 tons. There is one steel pier for loading ships, 1015 ft. long, with 32 chutes on each side and a handling capacity of one 50-ton car every two minutes.

The largest dumping in one day at this pier was 29,558 tons, the actual working time being 18 hr. 30 min. The largest dumping in one hour was 1721 tons. The quickest loading record was made on the S.S. "Newton," and was 8127 tons in 5 hr. 15 minutes. During the eight months ending Aug. 31, 1912, 181,712 tons of coal were shipped to foreign ports from this terminal.

The Sewalls Point pier, probably the fastest coal dumping pier in the world, is 1015 ft. long, 76 ft. high and 65 ft. wide, with 30 ft. of water at low tide, berth room for four ships and a dumping capacity of one 50-ton car every two minutes.

A Comparison of Foreign and Local Export Fuels

As said elsewhere, it is difficult to make an accurate comparison, based on calorimeter tests between these coals, owing to the fact that many of the tests of British coals, as published, have been made with the Thomson

and Favre & Silbermann calorimeters and comparatively few with the bomb (Mahler) calorimeter, as used in the United States. The Thomson instrument gives uniformly lower results than does the Mahler type, while the Favre & Silbermann determinations are liable to error, owing to the delicacy of the instrument, and the results obtained are usually higher than those obtained from the Mahler.

However, the results, as given elsewhere, show very little difference between the coals under consideration; as regards theoretical heating value, the New River-Pocahontas coals yield slightly higher B.t.u. values.

Ash—The results of analysis show that the ash content of the two kinds of coal is about the same. The United States coals have sometimes shown a greater amount of refuse under boilers, because, where comparative tests have been made the grates were designed for burning the Welsh product and the stokers were accustomed to handling it.

Sulphur—Here the United States coals have a slight advantage, although the amount of sulphur in any of the coals is too small to be of importance.

Volatile Matter—The Welsh coals are uniformly lower in volatile than the local product, which lowers their heating value to some extent (see remarks under Table IV) and causing them to give off slightly less smoke, although this is largely a question of proper combustion conditions and firing.

Clinkers—The writer has been unable to find any actual tests of the ash-fusing point of Welsh coals; a series of tests of a standard New River-Pocahontas coal showed an average of over 2600° F. Actual experience in burning Welsh and New River-Pocahontas coals under boilers has shown, in specific cases, that the latter coals will not clinker any more readily than do Welsh coals, and that the percentage of clinker to total refuse is smaller.

Results Obtained from Actual Trials

When each coal is burned under suitable conditions, the evaporative results obtained from New River-Pocahontas fuels will be quite as high as those yielded by the Welsh coals. Under certain conditions, the former coals will show greater economy and make more steam per pound of coal per hour, owing to their superior coking qualities and higher percentage of volatile matter.

As stated elsewhere, the Welsh export coal is harder and is usually screened at least once, hence reaching the consumer with a larger percentage of lumps, while on the other hand, all of the New River-Pocahontas coals are run-of-mine or "wro't thro'" coals and are not screened at all. This is often the basis for complaints against the American coals, although it is really an advantage, as good run-of-mine, semibituminous coal will yield better results than lump coal; the stoker has less labor on account of the coking qualities and the swelling of the coal into a more or less cellular mass when burning, gives quicker combustion, prevents the coal from falling through grates and makes less smoke.

TABLE III TYPICAL ANALYSES OF DIFFERENT GRADES OF NEW RIVER COALS

*Air dried † Dry.

Oxygen—The researches of Dr. David White have shown that the oxygen content of any coal has a distinct and constant relation to its heating value and that it may be considered as an impurity and as having nearly an equal anti-calorific value with the ash. In this respect the Welsh coals show slightly better, although the combined ash and oxygen will give about the same totals with each kind of coal.

Preparation—The United States coals are not, on the whole, as well prepared as the Welsh. More care is taken with the Welsh coals both in mining and cleaning and they are prepared to suit more nearly the needs of the buyer and consumer.

Large and Small Coal—The slack or small coal in the local run-of-mine product is pure and of higher value than that from the Welsh coals. This is conclusively shown by analyses of briquettes from each, those from the Welsh coal being made from the dock screenings of the large coal, while those from the New River-Pocahontas were made from the run-of-mine smalls.

The following analyses of briquettes will be of interest here:

	New River-Pocahontas					Welsh		
Moisture	1 40	1 06	2 70	1 50		0 92	1 30	1 50
Volatile	19 88	17 30	20 28	16 50	18 50	15 87		
Fixed carbon	73 22	76 13	72 74	73 00		75 52		
Ash	5 50	5 51	4 28	9 00	7 40	7 69	6 60	7 60
Sulphur	0 58	0 65	0 81	0 81			0 90	0 80
Hydrogen	4 32	4 76	4 94				3 90	3 80
Carbon	83 62	85 15	83 75				82 60	83 30
Nitrogen	0 89	1 09	1 45					
Oxygen	5 09	2 90	4 77				4 70	3 00
B t u	14,796	14,836	14,886	...	13,167	14,089	13,740	13,890

Weathering and Storage—The heat value loss under storage may be considered as negligible with both the coals under consideration. Recent exhaustive tests made by the United States Bureau of Mines have proved that, under actual storage conditions, under cover, in the open and under water, in both hot and cold climates, the loss in heating value of the New River-Pocahontas coals is less than 1 per cent. per year.

Firing—The amount of work done by the stoker or fireman, accustomed to handling the New River-Pocahontas coals, will be less, in a day's run, than that done by a Welsh-coal fireman, when burning equal quantities of each coal under similar conditions.

Wear and Corrosion of Heating Surface—The corrosion and wear of heating surfaces, grates and connections and the cleaning of tubes is about the same with both kinds of coal.

Variation in Quality—There will be found less variation in quality in the New River-Pocahontas coals than in the 26 Welsh coals on the British Admiralty list.

Stowage—The New River-Pocahontas coals, being all run-of-mine, will stow more closely and will yield more heat units per cubic foot of space occupied, the specific gravity of the two coals (Welsh and New River-Pocahontas) being practically the same, 1.27 to 1.31.

Spontaneous Combustion—While for obvious reasons, no comparative figures or tests are available, the fact that the U. S. Navy gets its main supplies now, and has done so for years, from the New River-Pocahontas mines and that these same coals are the only ones that the U. S. Government will accept for the Panama Canal work, where thousands of tons are kept in storage, in the open, under the most likely conditions for spontaneous combustion to take place, proves that these are, from actual experience, known to be comparatively free from fires due to spontaneous combustion. There is no bituminous coal that is not liable to fire, under certain conditions and the Welsh coals are not excepted from this liability.

Gas and Locomotive Coals

It must not be thought that New River-Pocahontas coals are the only local ones that can compete in the foreign trade. There are large markets in Europe and South America for coals used in the manufacture of illuminating gas and at least two large gas works in South America have contracted for a year's supply from this country. Our gas coals are quite equal in every way to those from Great Britain and there is no reason why we should not share in this business.

The following laboratory results are the average obtained from eleven mine samples of best Durham (England) gas coal, compared with results obtained from a shipment of 50 tons of West Virginia gas coal in actual practice:

	Durham	West Virginia
Fixed carbon	62 62	61 11
Volatile	30 17	33 16
Moisture	1 26	
Sulphur	1 19	1 18
Ash	4 76	5 73
Coke yield	67 93	74 91
Gas per ton of coal	11,115	10,842
Candlepower	16 65	17 42

In my opinion, there will also be a large market in South America and the West Indies, and possibly in some of the Mediterranean countries, for the medium high-volatile coals of the United States, that are suitable for use as locomotive fuel. There are no better locomotive coals in the world than some of the medium high volatiles (30 to 35 per cent.) mined in West Virginia and Pennsylvania; they will yield the highest evaporation per square foot of heating surface per hour, or, in other words, make the most steam per minute and when properly handled and under suitable conditions will make little smoke; they are also hard and lumpy and will stand transportation well.

As long ago as 1902, a cargo of such West Virginia coal was shipped to Chile and gave excellent results on the State Railways. These same railways are now using large amounts of Australian (116,200 tons) and Chilean (103,000 tons) coals, both of which are high volatile and decidedly inferior in every way to the United States coals mentioned above; they are testing Japanese coal this year, also high volatile. We should secure practically all of this South American railway trade.

Typical analyses of United States locomotive fuels are given below:

Moisture	1 60	1 47	1 47	0 87	1 28	1 54
Fixed carbon	58 92	57 59	62 95	62 19	59 03	58 367
Volatile matter	32 12	34 83	31 87	32 36	33 77	34 985
Ash	7 36	6 11	1 01	4 58	5 92	4 499
Sulphur	0 92	0 89	0 91	0 68	0 68	0 887
B t u	14,153	14,154	14,821	14,776	14 333	

† These analyses are taken from the U. S. Geological Survey Bulletins, 382-348 and represent actual shipments.

Smithing and Coking Coals

There is also quite a large market for smithing coals in South America which we have never made any effort to enter. The coals now used for this purpose come mostly from England (Cardiff and Swansea), the best of which come from the Rhondda No. 3 seam in Wales (analysis given elsewhere). While these are very pure and have been famous for years, they are not in any way superior to the highest grade smithing coals of the United States, such as Piedmont, New River, Valley Forge, Blossburg and Pocahontas. I witnessed a test of ordinary Pocahontas slack from a cargo of steam coal, in a railway shop in Chile, against Swansea smithing coal and the former gave results that were entirely satisfactory, at a lower price for the coal.

The market for coke in South America is also quite extensive; nearly all coke used is imported from England and Germany and Australia. No late consumption figures are obtainable, but it is a business well worth looking into. In 1909 coke was exported from South Wales as follows, in long tons: Chile and Peru, 6258; Argentine, 13,513; Uruguay, 12,543; Brazil, 12,618; Cuba, 2693. The total British exports of coke in 1911 were 1,064,000 long tons.

Exports from the United States during same period were 1,023,839 short tons, most of which went to Mexico and Cuba. Germany also sent 171,000 tons of coke to South America and Mexico during 1911.

Our best Eastern cokes are as good as either the Welsh Durham or German and can be put on ships at a lower price. Present quotations on best Durham foundry coke are $4.76 f.o.b. Tyne ports, while ordinary Cardiff foundry coke is quoted at $5.24@5.20 f.o.b. and Special foundry $7.44@7.67.

Analyses of United States and British cokes are given below:

	Durham Foundry Cokes			Welsh Foundry Cokes		
Fixed carbon	90 30	91 06	93 79	93 234	92 69	90 20
Volatile						0 21
Ash	8 40	7 87	5 17	5 97	5 63	7 75
Sulphur	0 85	0 91	0 66	0 774	1 09	0 51
Moisture	0 45	0 16	0 08		0 59	1 83
Phosphorus			0 003	0 022		0 0041

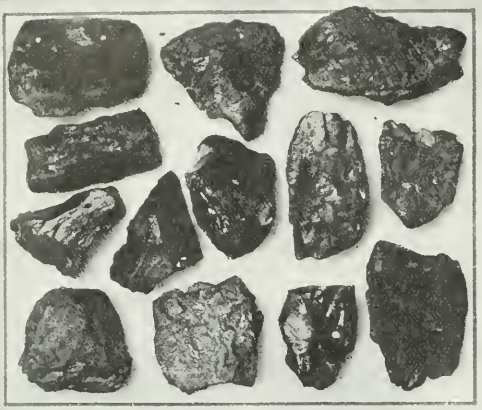
	Pineville, Ky	Pocahontas	New River	Toms Creek, Va	Elkhorn	Best Connellsville
Fixed carbon	91 66	92 691	93 04	91 85	92 74	91 00
Volatile	0 410	0 311	1 34	1 26	1 033	1 70
Ash	3 78	5 822	5 24	6 73	5 63	7 30
Sulphur	0 59	0 738	0 69	0 55	0 451	0 47
Moisture	1 14	0 345	0 39	0 16	0 142	
Phosphorus	0 007	0 006	0 007		0 003	0 012

The above analyses are from the following authorities: U. S. Geological Survey, Bulletins 261, 348 and 290; "Coke," by John Fulton; Greenwell's "British Coals and Cokes."

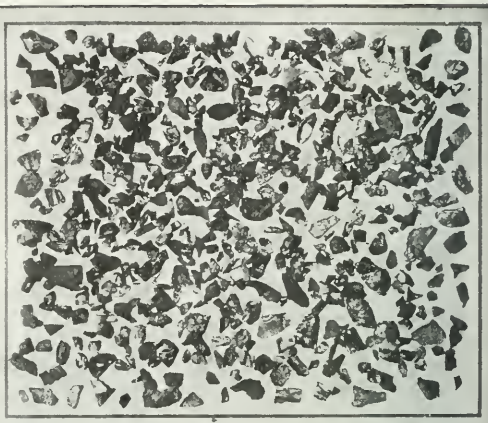
The comparisons given above are based, partly on the heating values of the coals considered, from the best available information, and partly on an experience running through some fifteen years of actual contact with the handling of New River-Pocahontas fuels in foreign markets.

The only solution of the export question for the United States shippers lies in the creation of a consolidated selling agency to handle the sales of all Eastern coal to foreign countries. Such an agency should have not only a single responsible head to direct the whole business, but also a first-class technical department. This department should have charge of the inspection and preparation of the coal, as well as its handling.

Suggested Anthracite Steam Sizes

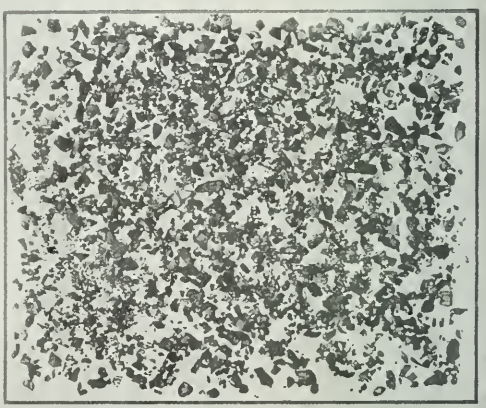


PEA



No 3 - BUCKWHEAT OR BARLEY

No 1 - BUCKWHEAT



No 4 - BUCKWHEAT OR CULM

No 2 - BUCKWHEAT OR RICE

POWER

STANDARDS FOR ANTHRACITE STEAM SIZES, RECOMMENDED BY THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS IN THE SOCIETY'S *Journal*, NOVEMBER, 1912:

Steam Grades	Circular Screen or Opening Through or Over Which Coal Will Pass, Inches: Through	Over
Pea	1	⅝
No. 1 buckwheat	⅝	½
No. 2 buckwheat	½	⅜
No. 3 buckwheat	⅜	⅞
No. 4 buckwheat or culm	⅞	...

Power states that the sizes specified by the New York City Department of Water Supply, Gas and Electricity are practically the same as above except for pea coal, which is specified as coal which will pass through ¾-in. and over ½-in. openings.

Economical Steam Mine Hoists

Special Correspondence

SYNOPSIS—For shafts over 1200 to 1500 ft. deep the first-motion Corliss type of hoist appears to be the most economical, but for shallower depths even the simple slide-valve engine has the advantage. For such locations a valve with a cutoff which is varied automatically has been developed showing satisfactory results.

Operating economy is a subject of rapidly growing interest to all coal-mine owners and managers. A few years ago, many owners did not seem to appreciate that the use of engines and machinery, high in consumption of steam, were profit wasters. Then, too, it was customary to burn run-of-mine or lump coal under the boilers, grades which found a ready market.

At the present time, practically every grade of coal hoisted from the mine has a market value, and managers are realizing that the installation of power equipment of high fuel economy is desirable, if maximum profits are to be obtained.

High Economy Hoists

In the iron and copper fields of northern Michigan and in the precious-metal mines of the West, hoists of high economy have long been favorites. In the Lake Superior country, first-motion hoists with Corliss engines and many refinements, are necessary in order to produce the heavy tonnages from the great depths there encountered.

In ordinary coal-mining work, the depths of the shafts are not sufficient to permit the installation of first-motion Corliss plants, but in mines of over 1200 or 1500 ft. depth, such hoists could be employed with great operating economy. The ordinary Corliss hoisting plants will consume about one-third as much coal in a given space of time as the plain slide-valve engines usually employed.

The photograph, Fig. 1, shows a typical Lake Superior country first-motion hoist. It is equipped with steam reverse and steam brakes and an automatic throttle-closing mechanism, which cuts off the steam from the main throttle at a fixed point in the hoist, so that if the engineer should forget to throw his lever at the proper time, the steam will be shut off automatically and it will be impossible for the skip or cage to come to the landing under steam pressure.

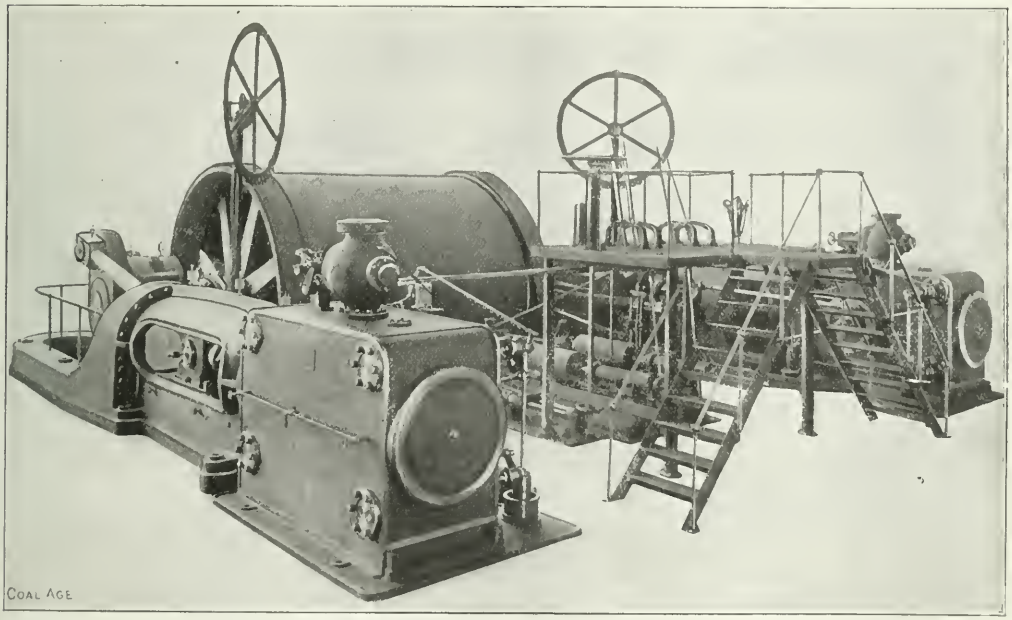


Fig. 1. A 28-60-in. First-motion Corliss Hoist

A further safety device is the automatic brake, which goes into action in a similar manner, in case the brake levers should not be thrown, in time to stop the hoist at the landing.

For mines less than 1000 or 1200 ft. in depth, which are the rule in coal mines in this country, it is out of the question to use first-motion Corliss hoists, as already mentioned, on account of the limitations in speed of the Corliss valve-gear, requiring engines unduly large for the service rendered. In shafts only a few hundred feet in depth, after the load is accelerated, but few revolutions of the engine will be made with the automatic cutoff in action, so that a direct-acting Corliss plant would be needlessly high in first cost, and actually more extravagant in fuel than a slide-valve engine.

Corliss geared hoists have also been tried for shallow mines, but as in the case of first-motion hoists, engines disproportionately large had to be supplied, to keep the number of revolutions as low as possible.

Slide-valve Hoist with Automatic Cutoff

After much study, the Sullivan Machinery Co. has developed an automatic slide-valve type of hoist which has now been in satisfactory use for several years.

In hoisting engines, hand adjustment of the point of cutoff is out of the question. It would require an engineer's constant attention, to give his engine steam for the entire stroke when starting the load, to set the valves at the proper point of cutoff when the load is under full motion, and to lengthen the cutoff again, at the end of the trip. Neither would it be possible for the engineer to set the cutoff at its most economical point each time, owing to variations in steam pressure and load.

The engine of this hoist is of the plain double slide-valve pattern, the valve-gear placing no limit on the speed at which it can be run. The mechanism controlling the automatic cutoff is so arranged that no extra thought or action is required on the part of the engineer.

When the steam-admission lever is pulled, the first two or three inches of its movement opens the main throttles, admitting steam during the entire stroke to start the load from the bottom. As the lever is pulled back, it admits steam to an auxiliary valve mechanism and cylinder. The piston of this cylinder actuates a crank and shaft, which in turn moves a vertical rack at the rear end of each cylinder. These racks engage pinions, one at the outer end of each cutoff-valve stem. The admission of steam to the auxiliary cylinder, therefore, automatically places the main valves in the position of the shortest cutoff. At the end of the trip, the reversal of the lever, to close the main throttles, admits steam to the opposite side of the piston on the auxiliary cylinder, and the cutoff is restored to its first position.

As stated above, no attention to the cutoff mechanism is needed, after the eccentrics have been set, to secure the most economical operation possible with the service factors of steam and load pressure which are prevalent. The slide valves are operated by separate eccentrics, with the usual link motion, a third eccentric being employed for the cutoff. The range of the cutoff is from three-quarters to one-quarter at the latest setting, and from four-tenths to one-tenth at the earliest.

The hoists embody the most modern practice in all details. The engines are reversible, by a standard hand-operated link motion. The drum is keyed to the shaft. The brakes are thrown by steam, with a handwheel for use in emergency or when the plant is not under steam. The gear is of semi-steel, and the pinion is made of cast steel, with cut teeth of the short involute pattern, rendering the action of the hoist smooth and quiet.

While these hoists have been used for the most part in the iron mines of the Lake Superior district, in which they have given excellent service, there are many conditions met with in coal mining wherein they would take care of the required output satisfactorily and result in a tremendous saving in fuel over the plain slide-valve engines in such general use at the present time.

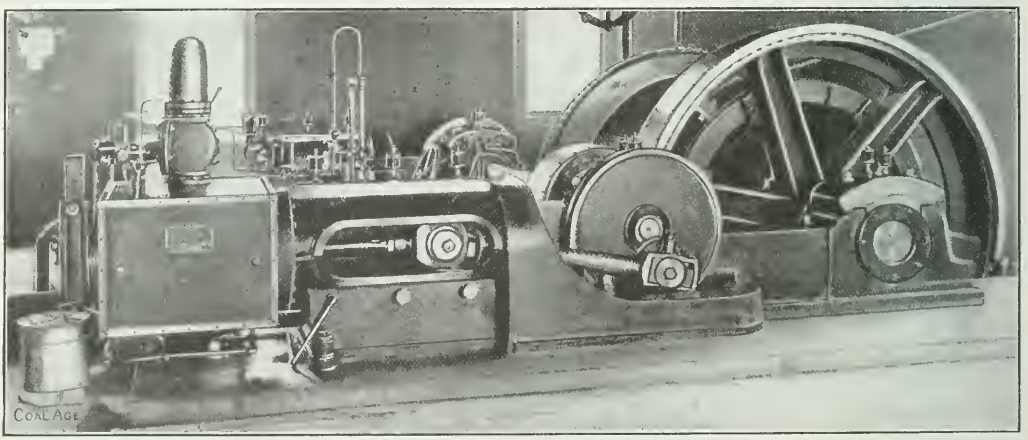

Fig. 2. A Typical, Geared, Automatic Slide-valve Hoist

Difficulties in Indian Mining

In an address before the National Association of Colliery Managers (Yorkshire branch), England, J. R. R. Wilson, a British mine inspector, told the following tale:

In India instead of using canaries or mice as indicators of the presence of carbon monoxide in fighting mine fires they use chickens quite frequently. A gang of men in charge of a Eurasian was building a stopping to close in a mine fire. As a precaution a chicken was placed inby, and the man in charge went frequently to ascertain if it was dead or alive.

The men knew very well that if the chicken died they could be sent out of the mine and moreover would receive their wages in full. Taking advantage of the boss' tendency to doze, a man would slip away from the rest, and after quietly wringing the chicken's neck would return to work. After awhile, they would contrive to make a noise which would waken the boss, who would immediately jump up, go and examine the chicken, only to find it dead. The men, of course, were sent out of the mine without delay.

The Indian's method of work is peculiar. On this subject Mr. Wilson said:

The whole family goes into the mine, father, mother and children, leaving the hut locked up. The males dig the coal and the women carry it, often long distances and 80 lb. to a load. The first mine I visited was a shaft and when the cage came up a woman with a black baby in her arms stepped out of the cage.

Electric Power in Collieries

Special Correspondence

SYNOPSIS—Many operators and mine managers look with more or less justifiable suspicion upon the employment of electricity as a motive power in mines. This article calls attention to some of the common difficulties which occur in the operation of motors underground.

There is no doubt that electric power in collieries has come to stay, and that its introduction has proved a distinct advantage in the processes entailed in the actual mining and transporting of the coal to the surface. It is, however, quite a matter of ordinary experience that a great many mine operatives and even managers have a certain amount of distrust of electric power which is not altogether without foundation in actual experience.

The large number of electrical plants which are working satisfactorily and with good results in economy rather tends to show that where trouble has occurred it may have been more or less preventable. Hence there is justification in bringing forward one or two notes of a minor character concerning incidents which have happened in connection with electro-motive power in mines in order to expose the causes which lead to such difficulties and also to indicate to a certain extent the way in which they might have been avoided.

Little Troubles Which Grow

A great deal of the trouble which occurs in collieries is due to the fact that apparatus is frequently placed in an awkward and ill-lighted position and is moreover not always given the proper amount of attention. The result is that troubles which at first may be insignificant and easily preventable, if allowed to accumulate, develop into quite serious matters.

A very typical case of this nature is to be found in connection with the breakdown of an alternating-current motor which was employed to drive a dip pump. This machine had been in operation for some time, but little attention being bestowed upon it, and, owing to the intrusion of grit into one of the bearings, this bearing ultimately seized. Unfortunately, however, the man in charge of the plant failed to stop the motor, perhaps hardly realizing that anything serious was wrong.

One of two things was, of course bound to occur. Either the seizing would be serious enough to stop the motor and hence by a virtual short-circuit blow the fuse, or the bearing itself would have to give way. The latter actually occurred. The brass bush which seized on the shaft was found to be running round with it, and the amount of heat generated was naturally considerable.

In order to effect a repair the brass had to be knocked off the shaft by means of sets and thoroughly scraped. The shaft was then replaced and the machine was running again in two hours after having been stopped. Taking into account the serious nature of the seizing, this may be reckoned a very quick job, but it was a matter which should not have occurred at all with proper attention.

A great deal of trouble with motor drives in collieries occurs through failure of insulation due to the damp locations in which they are called upon to work. The humid and sometimes hot atmosphere of a mine is extremely trying to an electrical installation and the remarkable fact is not that breakdowns occur, but that they are not far more common. Their infrequency points to the excellence of the work which is now being turned out by motor manufacturers.

It will often be found, also, that the cause of trouble with an electric drive is traceable not to the motor itself but to the apparatus controlling it. Here, again, although occasionally the fault may lie with the manufacturer, it is frequently caused through insufficient attention to the needs of the equipment.

It was found in connection with the motor driving a main and tail haulage that it started up very sluggishly and was therefore difficult to control. The trouble gradually became so bad that at last it was quite often the case that the rope was broken. Eventually a thorough overhaul and investigation was made not only of the motor itself, but also of the controlling apparatus.

It was then discovered that the liquid starter which was being used had not been cleaned out for months, but as the water evaporated a fresh supply had simply been added. As these replenishments had been obtained from the mine itself, it can be readily understood that when the tank was emptied a considerable quantity of mud and other impurities was removed.

After clean water had been provided and the requisite amount of salt added, it was found that the machine which had been giving so much trouble worked in a perfectly satisfactory manner. In this instance the mine management learned a valuable lesson on the importance of a thorough periodic overhaul.

The Maker Must Consider the Exacting Conditions

As was mentioned above, it sometimes occurs that the manufacturer has not thoroughly grasped the peculiar conditions attendant on mine operation. The result is that apparatus which may perform its work satisfactorily above ground, fails in mining service. This often applies to the auxiliaries.

The temperature of a mine is frequently in excess of that common in a factory and in addition to this there is a large amount of moisture contained in the atmosphere. These causes sometimes lead to breakdown.

In one installation, for example, the no-voltage coils on some oil switches repeatedly burned out. Sometimes the failure occurred twice in one week. The instruments could not be used without these coils, unless the switch was fastened in, and as this was a dangerous proceeding, a considerable number of stoppages took place.

After various methods to obviate the difficulty had been tried without success, it was decided that the root of the matter lay in the fact, that, considering the temperature and humidity of the air, the coils were of too small a cross-section for the current density they carried, and as a result they were rewound with a slightly larger wire, provided with a better class of insulation. After this had been done the trouble entirely ceased.

This is a very useful instance of the extra care and attention which has to be paid by manufacturers of electrical mining equipment in order to safeguard against the extremely severe conditions of operation which prevail.

Railroad Coaling Plants in England

British Correspondence

Description of one of the newest railroad coaling stations in Great Britain. Provision is made for cleaning the smoke-box and tubes, dropping the fire, filling tank and coaling the locomotive, all of which operations are accomplished in 24 min., as compared with 1¼ to 1¾ hr. by the method previously in use. The plant operates at a high speed and is designed to reduce breakage and labor costs to a minimum.

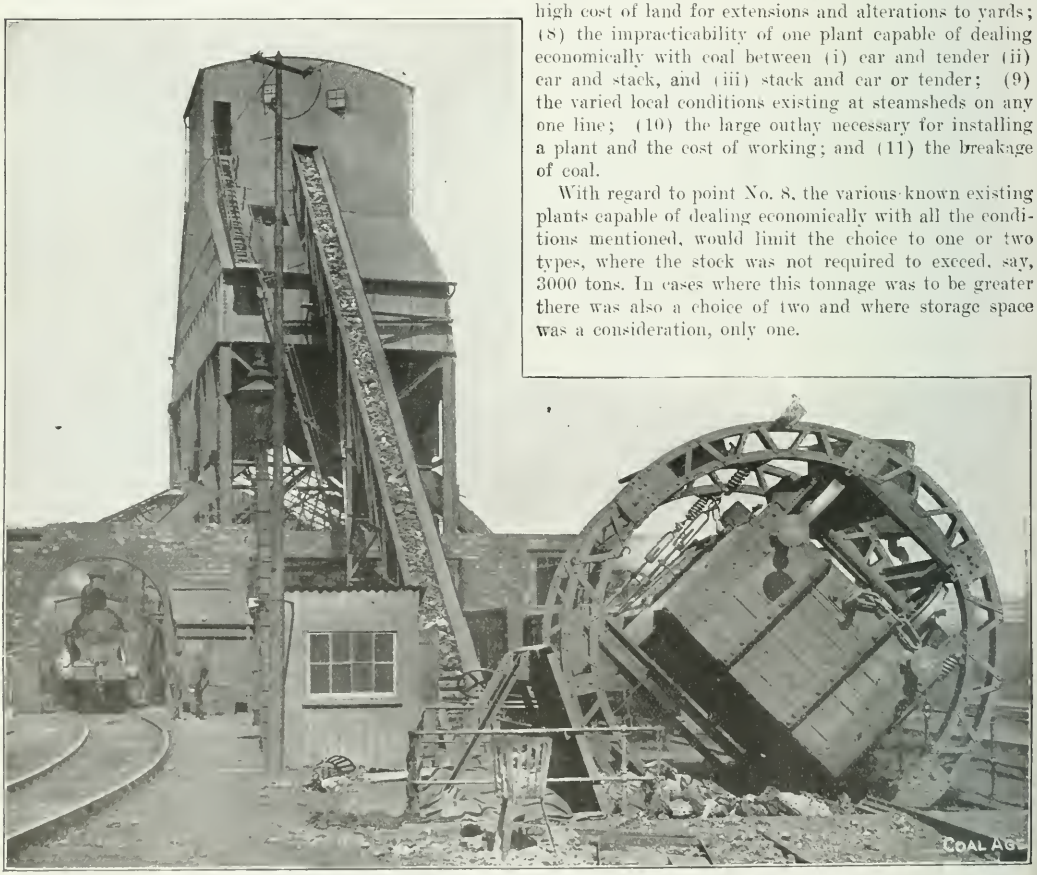
An interesting description of the mechanical coal handling plant recently installed by the London & North-Western Ry. Co. is contained in a paper read before the British Institution of Civil Engineers at the end of November by C. J. Bowen Cooke, Chief Mechanical Engineer of the company. This plant removes the coal automatically from the car, conveys it to the overhead bunkers, measures it, and places it on the tender without hand shoveling of any description. This is the first of its kind in the country, it is the joint design of Mr. Cooke and the builders of the machines.

The increasing consumption of coal at the Crewe depot, and other causes, made the cost of transferring it from the cars, amount to 7.38c. per ton. This high price, and the fact that the tonnage dealt with is the largest on the London & North-Western system, were two of the principal factors leading to the adoption of a mechanical coaling plant.

Considerations Affecting Design

In designing the new plant it was necessary to consider the following points: (1) The cheap rate at which coal was now dealt with by hand; (2) the impossibility of obtaining reliable statistics of a plant suitable for British requirements; (3) the large size of coal mined in England; (4) the class and size of coal cars in use; (5) the restricted area available in most railroad yards; (6) the regular and adequate supply of coal; (7) the high cost of land for extensions and alterations to yards; (8) the impracticability of one plant capable of dealing economically with coal between (i) car and tender (ii) car and stack, and (iii) stack and car or tender; (9) the varied local conditions existing at steamsheds on any one line; (10) the large outlay necessary for installing a plant and the cost of working; and (11) the breakage of coal.

With regard to point No. 8, the various known existing plants capable of dealing economically with all the conditions mentioned, would limit the choice to one or two types, where the stock was not required to exceed, say, 3000 tons. In cases where this tonnage was to be greater there was also a choice of two and where storage space was a consideration, only one.



View of Railroad Coaling Plant, at Crewe, England, Showing Car in Process of Dumping

In case (i) the two types were: (a) one adopted by certain railways abroad, in which the handling of stock and current coal by gravity, bucket, or conveyor was combined; and (b) some form of power driven crane and grab bucket.

With plants of type (a) the stock rarely exceeded 3000 tons and was stored in bunkers, either underground immediately below the coaling stage, or above ground and forming part of the coaling stage. In the latter case the coal was handled no less than six times between the colliery and locomotive tender, with consequent breakage at each stage. It had been argued that, owing to the deterioration of coal when left in stock out of doors for several years, it was more economical to handle it in this manner; but actual experiments had shown that a hard Yorkshire coal, after being in stock out of doors for eleven years, had deteriorated only 2.5 per cent., which is equivalent to a loss in value of 9.6c. per ton, or in the case of a 30,000-ton stack $262 per annum.

With a soft Blaenavon coal the deterioration after seven years was, 2 per cent. which is equivalent to a loss in value of 7.2c. per ton or in the case of a 30,000 ton stack, $309 per annum. Adding even $309 to the $750 for the taking up and putting down, the resultant figure—$1059 per annum—did not leave much margin for profit on a mechanical plant, after allowing for all capital charges and for the cost of working the plant, even if one of such capacity could be designed. Further at nearly all depots in England where the annual consumption was sufficient to warrant the installation of mechanical handling, the stock coal greatly exceeded 3000 tons; so that this type of plant appeared to be undesirable.

Regarding type (b) the crane might be of the revolving derrick class travelling on rails or the bucket might be supported from a traveller running on the overhead guide of a crane of goliath type. The grab-bucket, however, was limited in size by the receptacle from which it picked its load; when, therefore, it was compelled to work out of railway cars such as those used in England it became anything but the most economical form of appliance.

In case (ii) where the stock exceeded 30,000 tons, choice could be made between the bow string girder type of conveyor and the crane and grab-bucket. Where the former arrangement was installed it was apparently used only for handling coal much smaller than that generally mined in Great Britain, and therefore, in Mr. Cooke's opinion, it was not suitable for British conditions. In case (iii) the crane and grab-bucket type appeared to be the only one available, and further comment was unnecessary.

Type Finally Adopted

It appeared, therefore, that so far as Great Britain was concerned, the existing types of apparatus, capable of putting coal from cars to stock, stock to cars or tender, and cars to tender, were not suitable, owing to the peculiar conditions. The problem of coaling engines direct from cars would therefore alone be considered.

With regard to point No. 10 consideration of seven different types of plant showed that a suitable one could not be erected for less than $25,000 to $30,000 capital expenditure. Further, that where electric current was available at about 2c. per unit, the total cost per ton of coal when handling 110,000 tons per annum would be about 1c. per ton including interest on capital, depreciation, maintenance, and working charges. Such an expenditure, with such a result might lead locomotive engineers to the conclusion that, in their case, the experiment was not worth trying, owing to the smaller tonnage dealt with.

The consideration of certain inducements might, however, be studied before condemning such a proposition. For instance, (1), a mechanical plant, whilst occupying less ground than an old fashioned coal stage, could deal with nearly double the quantity of coal per annum; (2) there was an economical advantage in coaling as many engines as possible at a point adjacent to the collieries (where coal was cheapest) and in the shortest time possible; (3) the rapidity of coaling might enable a railway company to dispense with an engine or two, or even to refrain from building a similar number, with consequent economy of capital; (4) the release of cars would probably take place in less than half the time required at present, with consequent increase in earning capacity, and a possible reduction in the cost of shunting in the yards.

The large amount of slack created by the present manual handling was perhaps not generally realized, and the following statement might come somewhat as a surprise. After a tender had been loaded in the ordinary manner, and the coal broken by the fireman to a suitable size, the proportion of slack ranged from 13 per cent. in the case of Welsh coal to 2.3 per cent. in the case of North Staffordshire coal, although particular care had been taken to start the experiment with cars from which all slack had been removed by hand. When the slack which was in the car when it arrived at the coal stage was added to this—in this case 10.2 per cent. in soft coal and 2.9 per cent. in hard coal—the total was sufficient to make one pause to consider how this waste might be avoided. In this test "slack" meant all the small coal which was passed by a screen with ½-in. mesh.

Description of the Plant

The new plant was installed at the Crewe, north steamshed where about 130 engines were permanently stabled, and where the quantity of coal transferred from truck to locomotive every 21 hr. was about 150 tons or 110,000 tons per annum.

As the coal cars belonging to the railway company had neither side nor end doors, a "tippler" capable of dealing with cars of up to ten tons capacity, became the initial part of the apparatus. It was driven by a 660 volt, direct current, electric motor of 5 h.p. and was capable of emptying a car in about five minutes inclusive of the time taken to cramp down and release the wagon.

The hopper—of mild steel plates and angles—held about 20 tons and was carried by cross girders in a brick-lined pit. The coal was fed from this hopper by a jigging-tray, through an adjustable door, and into a two-roll breaker, where the large lumps were reduced to 8 in. This breaker, was belt-driven by an independent direct-current electric-motor of 10 h.p. which also operated the jigging-tray. The coal passed, with the large lumps broken, through the breaker to the conveyor trays, which carried it to the overhead storage. At the back of the jigging-tray was fitted a chute which delivered any powdered coal that tended to work out between the bottom of the hopper and the jigging-tray.

The conveyor was of the "tipping-tray" type, running at a speed of 70 ft. per minute and capable of lifting about 60 tons an hour. The driving gear consisted of a 660-volt, direct-current electric motor of 9 hp. driving through a belt, a train of machine-cut gear-wheels the effect of which was to give a very quiet drive. The coal was delivered over the end of the conveyor-track but, in order to prevent any breakage at this point, a special form of balance-plate retained it on the trays until the return journey, when it had a fall of only about one foot to the inclined chute which delivered it to the requisite division of the bunker.

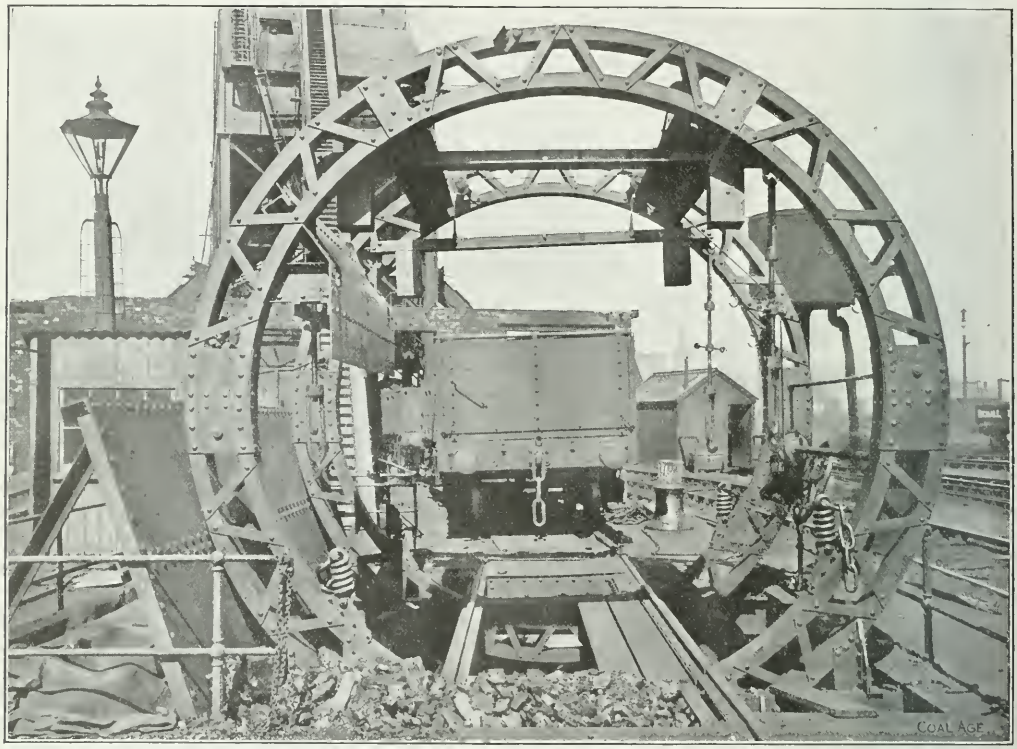
Owing to a large number of the main-line engines being loaded with two classes of coal—namely, Welsh and "hard"—it was necessary to provide separate bins for each class. The bunker was therefore divided into two parts, so as to store 100 tons of Welsh and 200 tons of "hard", with the floors, of course, built to suit. There was an outlet on each side of each division of the bunker, four in all, so that the tenders could be coaled on both sides at the same time.

Result Obtained

In conjunction with the coaling plant, an ash-conveyor had been installed close to the coal bunkers. There was also a compressed air, tube-cleaning apparatus consisting of a special form of pipe that could be held against the smoke-box end of the tube, and through which a jet of air at 100 lb. per sq.in. pressure, could be blown down.

The average daily quantity of coal placed on tenders is now about 450 tons and the new plant performs this task with a staff of three men by day and one by night, the conveyor being at work approximately ten hours a day. At present between 140 and 150 engines are coaled per 24 hours, and the coal should be placed on the tenders at the rate of two tons per minute, though the rate at which engines pass through the coaling plant is governed by factors other than that at which coal could actually be put on the tenders.

Under the new condition of things, an engine coming off the turntable proceeds in the following way, and is detained for the time stated for each process: Cleaning smoke-box of ashes, 4 min.; filling tank at water-column, 3½ min.; cleaning tubes, 4½ min.; coaling engine, 4 min.; and dropping fire, 8 min.; or a total of 24 min. These are the actual times taken by the several operations, and as they are only a few feet apart, little additional time was occupied in moving from one to the other. Under the old conditions the time taken was 1¼ to 1¾ hours.



Railroad Coal-car Dumping Arrangement, Showing Anti-breakage Device

✲

England's new coal-mines bill states that all newly opened coal mines shall have two main intake airways, affording means of ingress and egress to the mine, one of which shall not be used for haulage purposes. Mines employing less than 100 men, are exempt from this provision.

Diamond Crossovers for Shaft Bottoms

By H. D. Easton

SYNOPSIS—The article describes a neat graphical method of designing a diamond crossover to fit given conditions at the foot of the shaft.

Track arrangements at shaft bottoms must be in first-class condition if caging is to be done expeditiously and the maximum output of coal is to be obtained. In cases where the caging is done from one side of the shaft only, the most rapid handling of cars is made possible. The loads bump the empty cars off the cages and allow them to run by gravity into a kick-back and thence into the empty hole. This permits the tracks on the caging side to have a gentle down grade to the shaft, and allows the loaded car to bump the empty car off from the cage almost at the instant it lands. Such an arrangement requires few bottom men.

There are many mines in which the caging is done from both sides of the shaft where it would be an inexpensive improvement to alter the arrangements so as to take advantage of natural grades and do all the caging from one side. This is true of many mines operating in pitching coals. In other cases, especially in flat beds of coal, it would be necessary to install an automatic empty car lift to run the empties into a kick-back. This would prove advantageous in cases where mines have reached the maximum capacity of caging from both sides.

The Diamond Crossover

In mines where all of the caging is done from one side of the shaft, a diamond crossover is needed on the caging side. When the caging is done from both sides of the shaft, two of these crossovers are necessary. It is rather common to find these diamond crossovers constructed in the crudest manner possible. Often they are built by a blacksmith, who has no design to follow, but is left to his own resources. Much time is lost in caging over such tracks and the shaft bottom is always littered with coal spilled from the well-topped cars because of the abrupt turns and sudden jars. Besides this, wrecks and derails are especially expensive at the shaft bottom since they always impose a forced idleness upon the top men.

How to Design a Satisfactory Diamond Crossover

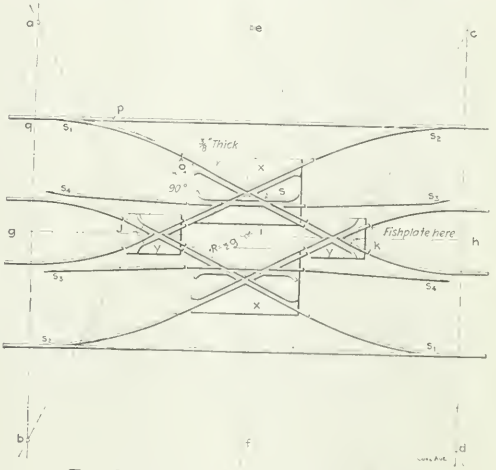
The distance between the track centers is determined by the size of the shaft compartments. The track gage is known, and the weight and size of rail used. The clearance is taken to accommodate the wheels used. In addition to the above data, it will be necessary to know one of two things before proceeding with the design. First, the frog angle must be known. To most people, however, the frog angle means little, and its use would require several trials in order to find the best angle to be used. If the angle selected is too great, the crossover will be too short and abrupt; while, if too small, the crossover will be too long and occupy too much of the shaft-bottom space besides causing the cagers to travel a long way to get a loaded car, since the trips cannot be kept up close to the shaft. Second, instead of determining the frog angle, it is a very easy matter to determine how much length can be allotted to the crossover and then to design the best one for the given length.

Our proposition, then, is to design the best diamond crossover with the following data given:

1. Track gage.
2. Size of rail to be used.
3. Distance between track centers.
4. Clearance.
5. Length of shaft bottom to be given up to the diamond crossover, bearing in mind that the longer it is the greater the ease of pushing loaded cars over it.

Procedure

The sketch shows a purely graphic method of designing a diamond crossover with the above data. Draw the tracks accurately to scale at the given distance apart. Erect the perpendiculars *ab* and *cd* so that the distance



The Layout of a Diamond Crossover

ac equals the allotted length for the crossover. Erect the perpendicular *ef* midway between *ab* and *cd*, also draw *gh* midway between the center lines of the two tracks. Establish points *j* and *k* so that $ji = ik = \frac{1}{4}\ ac$. With *i* as center and a radius of ½ track gage, draw a circle.

Now place a 90-deg. triangle at *o*, so that one side will be tangent to the circle at *s*, with the other side cutting through the point *j*; shift about until a position is found, such that the distance $op = pq$. This can best be done by using a second triangle, or a straight-edge, against the first one so as to produce the line *so* to *p* and comparing the distances *op* with *pq* by means of a pair of dividers. With the triangle in the right position, draw the line *oj* and extend it to *c* and to *b*.

Now, locate point *f*; $ie = if$. Draw *fja*, *fkc* and *ekd*, thus locating the four points *a*, *b*, *c* and *d*. With these four points, *a*, *b*, *c* and *d*, as centers, use a beam compass and draw the curved portions of the diamond crossover and then fill in the remainder, as shown, using any desired clearance.

*Professor of mining engineering, Kentucky State University, Lexington, Ky.

A special drawing of the steel plate *X*, with its pieces of track, can now be given to the blacksmith with instructions to make two of these; similarly for plate *Y*, two of which will be needed. All pieces of track and guards should be riveted solidly to the plates so there will be little danger of the track being torn up by a run-a-way or wreck. These plates can be spiked solidly to the ties.

If the shop has the machinery available, the points S_1, S_2, S_3 and S_4 can be planed to fit accurately to the sides of the rails. There will be two of each of these. Each pair of points can then be connected to a rod and the switch thrown as on a railroad, allowing the play to come at the fishplates. In the absence of a planer, to fit the points to the side of the rail, the usual mine points can be substituted for the planed ones.

Being made in sections, as shown by the plates *X* and *Y*, this diamond crossover can be taken into the mine without difficulty, readily assembled and, in case a wreck tears a portion of it up, it can easily be taken to the shop for repair.

Some Foreign Coke Oven Improvements

By Alfred Gobiet*

SYNOPSIS—Description of some unique departures in established coke-oven practice. These consist of two unusual door-lifters and two new methods of quenching coke. The last installations are more elaborate than would ordinarily be considered good practice in this country, but they are not without their advantages.

The following are two methods of lifting and moving aside coke-oven doors, the first being that of H. Grono, Oberhausen, Germany:

The winch frame *A*, Fig. 1, balanced by the counterweight *B*, carries a roll-guided, horizontal slide rack *C* moved by a pinion *D* geared to a crank. The rack is connected with the lever *E* by the shaft *F*, and *E* in turn

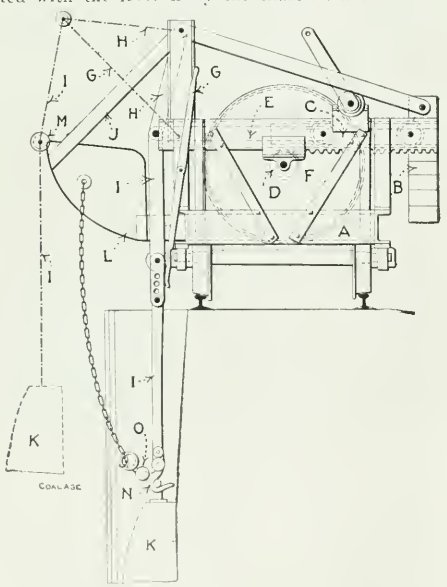


Fig. 1. Grono Door Lifter

with the lever *H*, so as to form a toggle joint. The coke-oven door *K* is suspended by means of strong, adjustable, jointed rods *I*. The movement of the rack in the direction of the arrow brings the door into the position indicated by the dotted lines, raising it obliquely 20 to 24 in. high, out of its socket, so that it can readily be moved sidewise.

Fastened to the rope windlass by the braces *J* are the guide shields *L*, the curved edges of which serve as tracks for the rolls *M*, from which the door is hung. The rod *I* is connected with the door *K* by a hook *N*, with a balance weight *O*. As the apparatus, with the door swinging from it is moved aside, the lever *G* may be used to push forward the rod *I* and keep the suspended door from striking against the front of the ovens. For use with doors that have to be lifted straight up before removal from the oven, the shields *L* may be shaped as vertical guides.

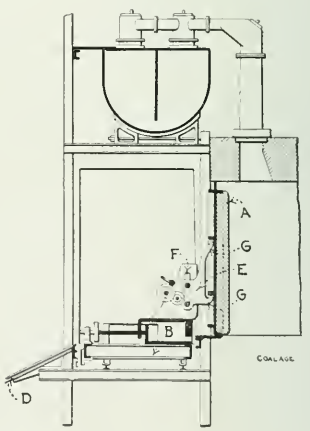

Fig. 2. Coke-oven Door Lifter

The H. Koppers door lifter, Fig. 2, is a car *B* moved in front of the oven and carrying a mechanism for raising the door *X*. A bracket with a horizontal cross movement by the screw *C* supports the lifter proper *E*, which slides on a vertical guide *F*. It is elevated by the aid of a rack, and other gearing, and can be held in any desired position. Two fingers *G* of this lifter enter corresponding hollows of the oven-door frame which may thus be raised, drawn back by means of the horizontal slide, and rolled aside by moving the car. In the construction shown in the figure, there is a bridge on the same car which, when the door is moved aside, forms a connection

*Engineer, the Witkowitzer Mines, Ostrau, Moravia, Austria.

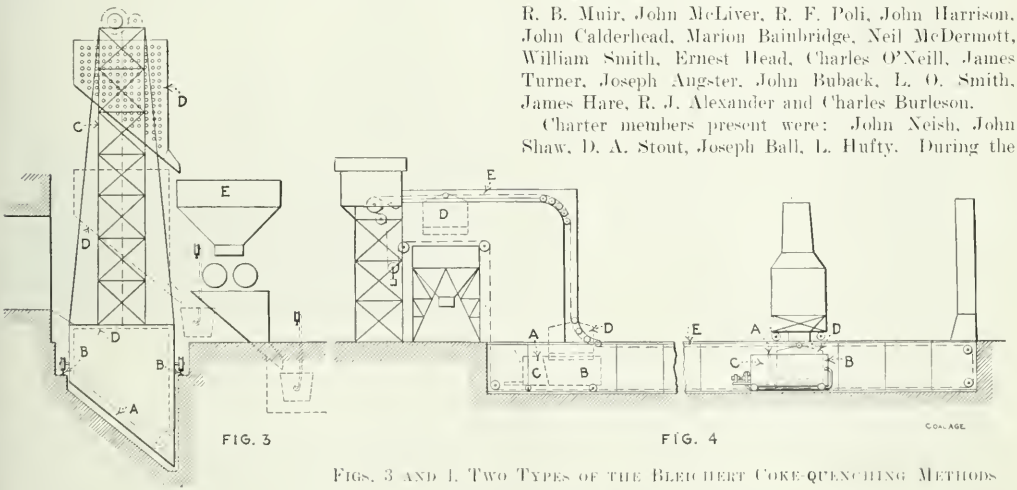
Note—Abstract of paper appearing in "Montanistische Rundschau" (Vienna), Oct. 1, 1912.

between the oven floor and the inclined coke dump *D*. Moreover, the car carries two side shields which prevent an untimely dumping of the coke that is drawn out.

Bleichert Coke Quenching Apparatus

The following quenching apparatus are patented by Adolf Bleichert & Co., of Leipzig and Vienna. The type illustrated in Fig. 3 consists of a water tank *A* of the peculiar shape shown, which runs on rails *B* in front of the oven battery; a perforated bucket *D* is let down into this tank. After the coke has been quenched, the bucket is lifted out of the water by a hoist on the frame *C*, and is thus drained. The bucket may then be placed on a car and transported to the storage yard, or the tank and bucket together may be rolled to a hopper *E* and there the coke dumped out, as shown by full lines in the drawing. Instead, the bucket may be raised to the dotted position and dumped into cableway buckets.

At the Tegal gas works, near Berlin, is installed a Bleichert quenching system on this general principle. There the coke is drawn into the bucket standing over the tank and during the operation the tank is slowly elevated so that the water gradually rises in the bucket. Afterward the tank is let down again and the bucket moved aside for emptying.



Figs. 3 and 4. Two Types of the Bleichert Coke-quenching Methods

Another patented Bleichert quenching system is shown in Fig. 4. Here the water tank, and in it the bucket, are rolled on rails in front of the ovens, and after the quenching are run to a particular place at a distance, where the bucket is lifted out of the water and its contents disposed of. The tank *A* is partitioned, so that it contains the reservoir *C* and the compartment *B*, which receives the perforated bucket *D*. These two compartments are connected by piping with a pump. The bucket is fastened to an endless cable chain *E* by which both it and the tank are moved.

The quenching process is as follows: The tank is moved in front of the oven and after the charge has been drawn into the bucket *D*, the pump is set in operation to force the water from the reservoir *C* into the bucket compartment *B*. At the same time the endless rope is started, and during transportation the coke becomes sufficiently quenched.

At a certain point beyond the oven battery the cable bends upward and elevates the bucket *D* out of the tank and carries it to a bunker or storage yard. At the bend, guide rails are provided for it. When the bucket has been dumped the movement of the cable is reversed, the bucket restored to the tank at the bend, where it is rolled to the oven to be drawn next.

The Huerfano Chapter of the Rocky Mountain Coal Mining Institute

The election of permanent officers for the chapter took place in the County Court House and resulted as follows: President, Joseph Ball; vice-president, D. A. Stout; secretary-treasurer, L. Hufty; executive committee, John McDowell, Martin Brennan, James Turner, James Tyson, R. Poli.

The ones who joined as new members are: M. Brennan, John McDowell, James McDowell, T. J. Stone, R. B. Muir, John McLiver, R. F. Poli, John Harrison, John Calderhead, Marion Bainbridge, Neil McDermott, William Smith, Ernest Head, Charles O'Neill, James Turner, Joseph Angster, John Buback, L. O. Smith, James Hare, R. J. Alexander and Charles Burleson.

Charter members present were: John Neish, John Shaw, D. A. Stout, Joseph Ball, L. Hufty. During the meeting, Mr. Stout gave a very interesting talk. Regular meetings will be held the third Sundays of each month at 2 p.m.

Briquette Binders

The best binder for briquetting depends upon the locality, the character of the coal, and the purpose for which the briquettes are intended. If the mines are near an oil field, the cheapest and best binder is asphalt; the best results are obtained with about 4 per cent., which costs 50 or 60c. per ton of briquettes. Five or six per cent. of water-gas pitch is a good binder and costs about the same as asphalt; 6.5 to 8 per cent. of coal-tar pitch is probably one of the most widely available binders and the cost is from 65 to 90c. per ton. Wood-distilled tars and asphalts form good binders but, with the exception of a few localities, they are too high in cost to be generally used. Producer-gas tar gives the best of results and calls for a low percentage of binder.

Belgian Methods of Coal Working

SPECIAL CORRESPONDENCE

Owing to the difficulties under which the Belgian coal industry is operated, the margin between the cost of production and the selling price is much smaller than in other European mining countries where circumstances are more favorable.

The method of working generally used is that of continuous headings, which are pushed forward from the shaft toward the limit of the field. The room-and-pillar system has occasionally been adopted in some thick beds in the districts of the Center and of Liége, while steeply inclined seams are worked in reverse steps, and the flatter measures either by rising or forward stalls.*

PRIMITIVE METHODS OF MINING

Coal cutting is nearly always performed by hand and it is preceded by cutting, in the unproductive parts of the seam. Blasting in coal is restricted to mines containing little or no firedamp and is specially used in the hard seams of coal near Charleroi. The consumption of explosives for the getting of coal in these latter seams varies from 40 to 96 lb. per 100 tons extracted, but in other mines where the use of explosives is allowed their average consumption does not exceed 28 lb. per 100 tons.

Compressed air is applied to drilling machines and small fans. Haulage is mostly done by horses; mechanical traction is restricted to the main roads, and is less developed than in the other coal fields where the output is greater and more concentrated. Locomotives are preferred in Belgium to the endless rope or chain systems. In the colliery of Amercoeur at Jumet, the underground haulage is effected by accumulator locomotives, but of late in a number of collieries preference has been given to benzine-propelled locomotives.

The underground applications of electricity for drilling, lighting, and especially pumping, hoisting and haulage, are already numerous, but have hitherto been confined to downcast shafts and intake airways except in non-fiery mines. In most cases continuous current at a moderate voltage has been employed, but three-phase current is used in some important installations.

At present more than 50 per cent. of the companies have no underground power, except for the dumping of cars. But since the application of the new law limiting the hours of work in coal mines, the adoption of mechanical appliances has been considered by a number of companies as a matter of necessity.

THIN AND CONTORTED BEDS MAKE COAL COSTLY AND METHODS PRIMITIVE

Three circumstances have a preponderating influence on the cost of production of the Belgium mines—the thinness and contortion of the seams, the occurrence of firedamp, and the depth of the workings. The seams are split and folded everywhere. These folds and wrinkles are most numerous in the southern portions of the coal-bearing area, but while they are still well marked in the center, they become less noticeable toward the north, in the lower part of the country.

The average thickness of the workable seams is only 27 in. with 10½ in. as low limit; in several collieries of the Hainaut province the average available thickness of all the seams is from 16 to 20 in. These conditions present obstacles to the use of coal-cutting machines, which in that part of the Belgian coal field known as the "Couchant de Mons" (Borinage district) will be impracticable on account of the folded character of the beds.

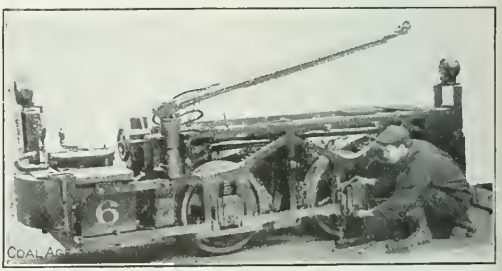
*Narrow rooms usually with large pillars and frequent crosscuts dividing the ribs into large rectangular pillars.—Editor

⁂

A New Type of Locomotive

The accompanying illustration shows a type of mine locomotive which has recently been placed on the market by the Baldwin Locomotive Works and the Westinghouse Electric & Manufacturing Co., which it is claimed will operate satisfactorily under the worst conditions with minimum attention and maintenance expense.

The motors, brake rigging, brake shoes and sand boxes are easily accessible. The upper parts of the motor and armature-bearing housings can be removed without disturbing the suspension, so that each part of the motor is exposed for inspection. The only work necessary to remove the grid resistors is to take off the locomotive covers and loosen the bolts and terminals that hold the resistor frames in place.



REMOVING A JOURNAL BOX ON AN OUTSIDE-FRAME LOCOMOTIVE

The Vauclain removable jib is introduced on locomotives with outside frames. To remove a journal box with this jib it is only necessary to drop the binder and take the weight off the box, which may then be slipped out from the side. On locomotives with inside frames the journal-box cellars are arranged to be easily dropped out for repacking. The frames of the motors are made of cast steel, and are split diagonally. The axle bearings and suspension nose are on the lower half, so that the upper half, the armature and bearing housings can be removed without disturbing the suspension or axle brackets.

The armature core is mounted on a spider to which it is keyed, making it possible to remove the shaft without disturbing the windings, and also reinforcing the shaft against bending. Large openings are provided in the spider and through the core to give sufficient ventilation.

⁂

When designing an underground stable the character of the floor to be decided upon requires special consideration. So long as the mules are shod, it does not make any difference to the foot itself what the shoe rests upon. The material used for flooring should be such as will keep the stalls and mules clean, with the least amount of work. Cement, properly corrugated, gives the best results in stable construction. Drainage should be so arranged that the slant and the direct sewer conection will remove all fluids.

EDITORIALS

A Bad Name

The mining industry has a malodorous name. Everywhere we go we are informed that the mines are the largest graves in the country, that nothing is being done to remedy the evil, for nobody cares about the countless sacrifices but the general public.

Really the populace is to be thanked for its keen continued interest in our deliquencies. It would be well, however, if it did not inquire into *our* conduct alone. Congress is willing to spend thirty times as much for agriculture as for mining, but it is not desirous of discovering how many agriculturists yearly succumb to the perils of farming. An investigation pursued with diligence would probably show that the number of fatalities among farmers exceeds, as in Germany, the accidental deaths of any other class of operatives.

Since 1909, no investigations have been made regarding the deaths of railroad trainmen. The Interstate Commerce Commission no longer gives publicity to such losses, but during the last year in which the record was kept, the death rate among trainmen was 4.87 per thousand.

These men were killed mainly one by one. There were no sudden reapings of men by tens and hundreds, which in years of gloom swell the death rate in mines. The record represents a far greater number of separate accidents than would be indicated by a similar figure in coal mining. Nevertheless, though this proportion has been exceeded in France and Canada, it has only once been reached in the mining records of the United States. That was during the year 1907, which is generally conceded to have been abnormal.

There are many industries more dangerous than mining, and it would be well if all were investigated. We do not advocate ceasing the good work of inquiring into the fatalities of mining. By all means let the investigation proceed as a continued prod to the industry to do better and to prove to the world that progress is being made.

The loss of life is not great, though larger than it should be. The City of New York often records as many deaths from all causes in ten days as are collected by the Bureau of Mines in a whole year. Of course, the population of the city is about seven times as great as that of the mines, and it is not just to compare accidental deaths with mortalities of all kinds.

But we need a base, a norm to control the public mind. It is easy to condemn and to rant whether the losses be few or many. The man on the street will shudder as readily when told that 1000 men died in the mines last year, as he would if you increased the number to 10,000. He has no basis for judgment and readily believes the purchased press.

For the press is venal. It may be free from the constraint and control of the multi-millionaire, but it is usually slavish before the man who pays pennies and dimes for its circulation. This press should be given a chance to learn related facts from other bodies beside the Bureau of Mines; should be presented with an opportunity for fulminations against other persons than those who chance to be producing coal and should be afforded an opportunity to do justice to an industry which deserves to stand well in the judgment of the public.

⁂

The Efficiencies of Large and Small Turbines

Ever since the conversion of the steam turbine from a scientific toy to a commercial prime mover, there has been a steady increase in the size and power of these machines. Simultaneously also they have been developed both in capacity and efficiency.

There is a marked difference in the performance of large and small turbines as they exist commercially today. The average overall efficiency of a 1000-kw. unit is in the vicinity of 57 per cent., while that of a 10,000-kw. machine may easily reach 70 per cent.

There are two principal reasons why the small machine is less efficient than the larger one. The first of these is simple and readily understood. In low-capacity turbines, a far greater percentage of the entire cost is taken up by those parts (governor, oiling system, pipes, etc.), which do not directly contribute to the internal efficiency of the unit. In a 500-kw. machine, the cost of these parts may easily reach 15 per cent. of the total, while in one of 10,000-kw. capacity, this item is only about 30 per cent. From this it may be readily appreciated that small turbines of high efficiency cannot be commercially produced unless exceptional prices are obtainable.

The second reason is more obscure, and is strictly technical. Each pound of steam contains a certain definite amount of potential energy, which, through expansion, is converted into kinetic energy, in which form it may be absorbed by the moving blading. The wide range or difference in pressure between intake and exhaust on a modern turbine, renders available a considrable amount of heat for each pound of steam, and the machine's efficiency depends upon how and in what manner this heat is distributed.

To obtain a maximum absorption of the heat energy made available by a given pressure drop, the velocity of the steam must bear a certain ratio to that of the blades. This ratio, however, varies according to the type of blading employed.

With a given speed of rotation, number of stages, and total pressure range, the radius of application or mean diameter of blading must remain constant, and the output of the machine is dependent directly upon the length of the blades. The more stages there are employed, the greater, within limits dependent upon the type of the turbine and the speed, will be the overall efficiency.

As to reliability, which is an extremely important factor in mining service, there can be but little question

but that the steam turbine is the equal, if not the superior, of any prime mover now in use. It has the further advantage that wear is confined to but a few surfaces, practically all of which may be subjected to forced lubrication, so that the maintenance charges on even the largest of units may, and under ordinary circumstances should be, so small as to be almost entirely negligible.

❖

The Committee on Gas Wells

We hope the mining inspectors of the United States will be well represented on the committee on gas wells and oil wells passing through coal. Unless the mine departments of the states do their part, there will be an imperfectly balanced council, for the gas and oil industries both have their representatives, and the coal men have no more than either of these interests.

Someone jokingly remarked at the conference that the separating of two industries, so unified in their purposes as those pertaining to gas and oil, would justify the coal men in demanding a representation both for their point of view and for that of the producers of lignite. However, if the inspectors do their part, the unfairness in representation will be met.

The Pennsylvania inspectors were represented by one man only and he came late for the third part of the conference. It seemed to bode no coöperation on the part of the inspectional service of that state where the Bureau of Mines finds its home. The sentiment of the mining public, we believe, hardly justifies that abstention.

Unfortunately, the whole question has sprung upon us before the problem of roof action has been thrashed out to a universally satisfactory conclusion. We still have many adhering to a belief in shear as an explanation of all difficulties. The Belgian bureau seems to favor this hypothesis, others believe that the roof bends but oppose the idea that the strata act as a unit, and, of course, there are others whose ideas are contradicted by every evidence, but their theories are not worthy of serious consideration. That being the case, the various departments of mining in the states should be willing to meet in conference and contribute to the consideration of the subject.

❖

Red Tape in the Geological Survey

The government printing office in Washington assumes prerogatives that are, at times, exasperating in the extreme. For instance, when one orders a series of topographic maps, he is apt to receive a notice with them to the effect that a certain sheet is out of stock, for which another one has been substituted. What firm of publishers would reply to a request for a certain issue of their magazine by sending the number immediately preceding or following the one asked for? Engineers generally know what they want and resent this apparently indifferent attention to their requests.

The procrastination (common to all government departments) in filling these orders is also prolific cause of annoyance. It is difficult to understand, for instance, why it should take eight days to get certain topographic and geologic sheets ordered from New York City. Few engineers have either the means or the facilities for filing anything like a complete set of the Geological Survey publications now in print, and it frequently happens that one of these may be required on short notice. Unless one has connections in Washington to whom he can wire he is sure to be disappointed, for the government would not trust the greatest engineer in the country for a 10c. map.

The high excellence of the government publications, and particularly its maps, are too well known to require comment. But it is to be deplored that the distribution of these cannot be effected in a more businesslike manner. If certain maps are out of stock, the question naturally presents itself as to when they will be in again, or reprints be made. Questions as to when certain reports will be issued are ignored, and there are numerous ways in which the survey could enlarge the scope of its usefulness had it the facilities for getting in closer touch with the public. Surely it would not strain the resources of the department to install a force of correspondents, well posted on the Survey's publications and competent to act promptly and effectively on all communications received.

❖

Sand Filling

The new bulletin of N. H. Darton on the "Sand Available for Filling Mine Workings" is painstaking and complete. In fact, Mr. Darton is a most unwearied investigator. The monograph frankly acknowledges the main difficulties in the sand-filling problem, the fineness of the silts and the possibility of their running like a quicksand, if not restrained by pillars. This difficulty we pointed out in an editorial, of identical name with the present, published Nov. 25, 1911.

We then urged, and still continue to insist, that experiments on cementation should be made, and though we know Mr. Darton has been extremely busy along other valuable lines of investigation, we think it would have been well had the Bureau of Mines taken up the problem from the first.

The bureau is acting in an open way with the public. The parting and thus the most prominent words in the bulletin draw attention to the inadequacy of the available supply of sand to fill the workings. "The quantity necessary to replace all the coal which can be shipped in the future, under present conditions, is about 10,000,000 tons, or sufficient to cover to a depth of 25 ft. the whole area of the coal basin, 176 square miles. This is more than twice as much material as is contained in the buried valley of the Susquehanna River, but is about the same quantity as the contents of that valley, together with all the till and terrace deposits."

Excluding areas, now occupied by towns, and which can hardly be removed for the obtaining of the sand, it will be seen that the supply is inadequate. Still there is sufficient to do a greater part of the flushing needed, and to support and control completely those parts of the workings under permanent buildings. With such a large body of sand placed almost providentially to hand, and with the crying need for some release from the severity of the present situation, it seems that some effort should be made to guarantee a continued life to the otherwise permanent beauties of the city of Scranton.

Nevertheless, prudence compels us to declare that the removal of much of the sand in the Wyoming buried valley would involve engineering difficulties as great or greater than it would solve.

SOCIOLOGICAL DEPARTMENT

Pure Milk for a Colliery Village

Special Correspondence

SYNOPSIS—The Heilwood Co., composed of persons forming the corporation which operates the Penn-Mary coal mines, has started a model dairy farm. The company hopes to make money on the project, but is still more anxious to assure a good milk supply for the miners, thus preventing such diseases as might result from contaminated milk. The daily expense is $16, the income $14.80; so in due time both health and profit may be attained.

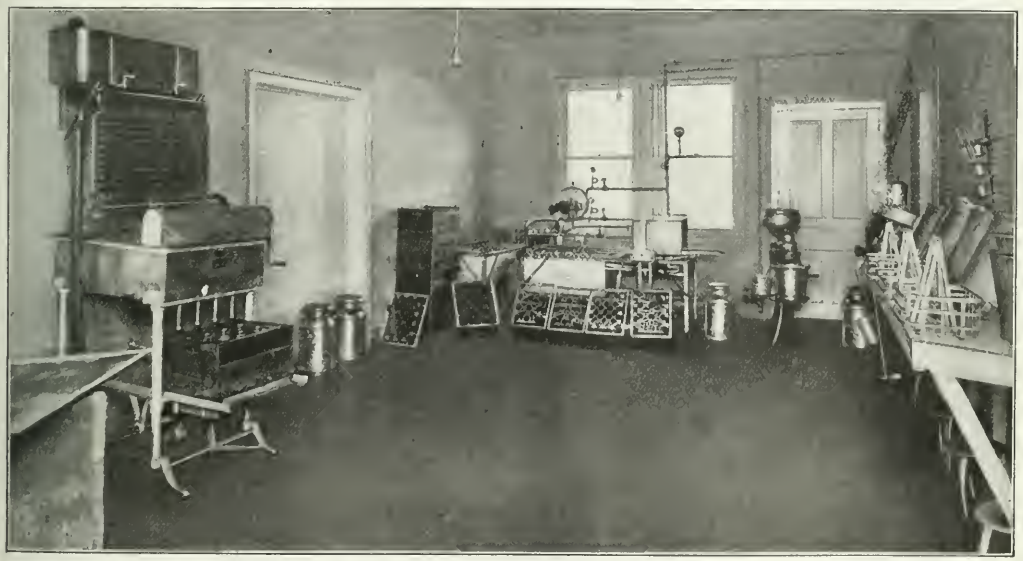
The Heilwood Co. is a corporation running a store at Heilwood, Penn. It is believed to be controlled by the stockholders of the Penn-Mary Coal Co., a subsidiary of the Maryland Steel Co., which has its offices and houses in that village. The store company does not, however, make any collections on the coal company's rolls and the miners buy where they will. As prices are reasonable and the line of goods of a high order, the Penn-Mary employees do not avail themselves of their opportunity to purchase elsewhere, and being men of a good class, they are appreciative of the innovations in merchandising which the Heilwood Co. has developed for their advantage.

I make this statement regarding the personnel because the experiment has been tried elsewhere without success, at the suggestion of a well known Philadelphia philanthropist, owning stock in another coal company. The project, in that instance, has been conducted, I understand, at a considerable loss because the miners prefer to buy their milk from other and less desirable sources.

A $15,000 Plant

The Heilwood Co. has signed a 20-year lease with the Penn-Mary Coal Co. for some 400 acres of farm land. It has erected the modern dairy plant shown on the front cover and is now prepared to supply milk to all the miners. The plant, when entirely complete, will cost about $15,000.

The cowbarn measures 40x130 ft., and is finished with floors and feeding troughs of concrete. Drinking water can be turned into these troughs when needed. The stalls are built of steel pipe, as are also the stanchions by which the cattle are secured. Each stanchion consists of two pipes about 5 ft. long, set just far enough apart to hold the head of a cow. These pipes approach each other at either end and are arranged with swivels above and below. The cow's head can slide up and down in the stanchion and the animal can turn her head through a large angle without restraint and yet is absolutely secured by the framework. She can lie down or rise at will. In fact, the method of securing the animal's head is sanitary, safe and humanitarian, and probably would be equally available for use in mule stables.



Interior of the Milk Room at the Dairy of the Heilwood Company

Holstein-Friesian Stock

In the foreground of the picture illustrating the cowbarn are the box stalls for the calves and bull. In the

rear are single stalls for the grown cattle. There are 32 milch cows at present; 19 of which are giving milk and there is room in all for 50 cows. All but one of the present herd are of Holstein-Friesian stock, and it is altogether probable that after the weeding-out process has been completed and the herd is well balanced, the milk production will gradually increase.

The second floor of the barn is divided into two compartments; one for hay and the other for a feed room. On the one side of the main building are twin silos, two large towers which can be seen in the picture of the exterior of the building. Each holds 150 tons of ensilage. They are connected by an entryway to the barn proper. Between the main barn and milk house, to the left of the silos, a passage 8x14 contains a room in which milkers change clothes and another with a milk scale and a lavatory.

The Cow Hospital

The smaller barn is an emergency building. It contains six box stalls for sick cattle. It is almost entirely empty at present, having only one cow in it, and that is only in the hospital because she is about to become fresh. There are diseases among cows like cow-pox, which are exceedingly infectious, but which cannot be transmitted to human beings except by inoculation. It is necessary to have an emergency building for such cases, if any should occur. The cows having tuberculosis will, of course, be killed. In this same building are the boiler room and coal bins. The entire plant is lighted by electricity.

Sanitary Milk at Eight Cents a Quart

The production of certified milk is a comparatively small industry and it is still only in its infancy, for it is certain that before long such milk will be the only kind sold in the larger cities. The retail price of certified milk in Philadelphia and Pittsburgh is 15c. per quart, while commercial milk sells at 8c. The Heilwood Co. is marketing its product at the lower figure, so it will be seen that only a narrow margin is left for profit.

Absolute cleanliness at every stage marks the production of the Heilwood milk. First of all the cows must be free from disease. They are tuberculin-tested and passed as perfectly healthy animals by official veterinarians, recommended by the dairy division of the Department of Agriculture, at Harrisburg, Penn. Any cow found to be diseased is immediately isolated and if the malady is found to be in an advanced stage, the animal is killed at once.

Barns must be sanitary in construction, well ventilated and clean. Cleanliness in this connection means the daily removal of any contaminating filth. It also involves the employment of expensive and responsible labor. Pure running water must be accessible at all times and only persons of good health and clean habits should be allowed to work in the milk room. All milkers are required to wear clean white duck suits when milking.

How the Milk Is Kept Free from Pollution of Cow and Air

When a cow freshens, all the long hairs are clipped from the udder, inside of the hind legs and part of the tail. Before milking, the udders are washed clean with warm water and all milking is done into sanitary pails, having two layers of strainer cloth over the top. Each cow's milk is weighed as soon as it is drawn and is emptied into a large funnel, which conveys it through the wall to the cooling tank. In this funnel is a large mass of absorbent cotton, through which the milk filters into the cooler.

Through the pipes in this tank passes a continuous stream of fresh water at a temperature of 45 deg. F. This eliminates the animal heat from the milk and prevents the multiplication of bacteria, some of which would be harmful to life. As the milk cools it is allowed to drip slowly through two or more layers of gauze or strainer cloth and goes into the bottling machine through a wire cloth strainer and is fed into sterilized bottles. It is then put in a cooling room, kept at an even temperature by the ammonia system of refrigeration, and delivered to the consumer in a condition such that it will be maintained sweet and pure for twice the length of time that common milk can be kept.

High Percentage of Butter Fats

Tests prove that the milk averages 4.4 per cent. of butter fats, which shows that it is of a very fair quality. In the village of Montclair, N. J., just outside New York, where a most diligent campaign for good milk has been conducted for many years, only one firm out of the dozen doing business in 1911 had as good a record for richness of milk as the Heilwood Co.' Certified milk is required to have over 3.5 per cent. of butter fats.'

It must be free from any disease germs and should contain only the harmless bacteria found in all milk. All these germs multiply very rapidly when the animal heat is retained in the milk, and when it is exposed in open vessels. It is owing to their presence that milk sours quickly. It is known that commercial milk contains ten times as many germs as are found in the certified product.

All pails and utensils used in the handling of the milk are sterilized daily in live steam, even to the milking stools. Ventilation is secured by the King system. Each cow stands on a cork-brick floor covered with sawdust. Once a day, all the cows are curried and brushed, litter and bedding being removed every morning. Eventually the floor will be covered daily with a sprinkling of land plaster or cheap lime as a deodorizer and disinfectant. This will be removed with the litter.

Milk for Babies and Invalids

The Heilwood Co. is selling milk especially for babies. This milk is supplied by cows which are fed on simple food, excluding oil cake and like heating foods. Two cows, whose milk runs low in butter fats, have been selected, and their milk is marketed especially for babies and invalids. For this a charge of 10c. per quart is made. The babies which have been fed on this milk have shown remarkable improvement.

It is the purpose of the company to keep a detailed account of the cost of running the dairy, though the large amount of work involved hitherto in starting the plant has caused all attention to be directed to building, sanitation and marketing. In the coming year, the company expects to run truck and stock farms. The cost of living is increased throughout the country by the fact that many coal companies hold idle large acreages of land, which they could make generously productive, but

which they either keep idle or rent at rates which barely pay the taxes, to tenants who try to extract the last vestige of nitrogen from the soil without regard to the future. The action of the Heilwood Co. is therefore to be welcomed.

The manager of the store company is J. M. Thompson, who is also in charge of the farm. E. E. Blackburn, a graduate of State College (1912) is in immediate charge of the dairy project. Two men deliver the milk through the town of about 3000 inhabitants, and one man does the rough chores around the plant.

The Nova Scotia Steel and Coal Co.'s Car

SPECIAL CORRESPONDENCE

The death rate in Canada has not been enlarged by any great fatality in the Nova Scotia mines, but this has not prevented the Nova Scotia Steel & Coal Co. and other nearby corporations from providing a complete system of protection for their mines. In fact, no other company in Canada except its neighbor, the Dominion Coal Co., is so well fitted for fighting mine fires and for rescue work after an explosion, as is this Nova Scotia company.

The Rescue Car

It formerly kept its apparatus in a room in the general office building, but the equipment is now transferred to a railroad car, which is always ready to go to any col-

FIG. 1. THE MIDDLE SECTION OF THE NOVA SCOTIA STEEL & COAL CO.'S RESCUE CAR

lieries in the province with which railroad connections can be made. The car is a remodeled passenger coach divided into three sections. Two of these are illustrated in this article; the third, at one end of the car, is for the use of the rescue corps during travel. It is fitted with seven seats and a lavatory.

The middle section is shown in Fig. 1. On the left, in the foreground, is a long closet with two doors for the accommodation of Draeger apparatus and clothing for the rescuers. On the floor at the rear left is an oxygen pump and still further back a switch board and table for charging the hand electric lamps. Above the closet, the plans of the mines and of the various water systems are kept ready for use.

Above the rear door leading to the third section are a row of electric lamps and three oil safety lamps for gas observation. In the rear on the right is the surgical case with the pulmotor at its foot. Several Draeger helmets are hung on the right wall of the car with oxygen tanks adjacent. Below this are the regenerating apparatus which are carried on the backs of the rescuers. In the foreground on the same side is a desk with a telephone.

Surface Fire-fighting Equipment

The second illustration shows the section equipped for fire fighting. The large doors on the right and left are hinged at their lower edges so that when let down they furnish a suitable runway for the hose reel in the rear. It will be noted that these doors are slatted horizon-

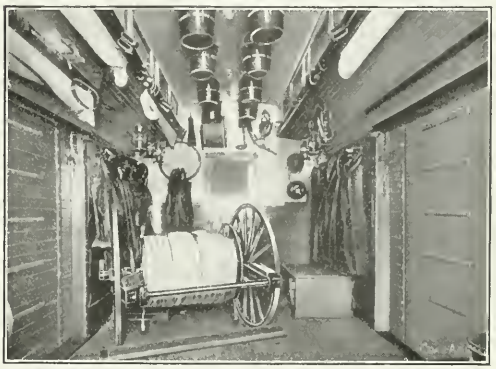


FIG. 2. THE END OF FIRE-FIGHTING SECTION OF THE NOVA SCOTIA CAR

tally so as to make it possible to travel up them when they are on a steep slant. At the same time the slats are so short that the hose cart clears the ends of the strips.

The walls wherever available carry firemen's coats, boots and fire helmets. The roof is hung with stretchers, lanterns, wire, rope and fire buckets. On the floor to the right are a tool box and a "three-hole" oil stove, the latter not being visible in the photograph.

The Equipment

In all there are 15 sets of Draeger-helmet rescue apparatus, and one of the Ever-Ready mouthpiece type, 24 oxygen cylinders, 2 oxygen-refill pumps, 1 pulmotor, 2 dozen electric safety lamps, 1 electric charging device for the electric-lamp batteries, 1 Draeger oxygen reviving box, 6 ordinary respirators, 1 set of portable telephones and some canaries. Of the 24 oxygen cylinders only seven are carried in the car, the others being stored as an emergency supply. These cylinders contain 100 cu.ft. of oxygen at a pressure of 125 atmospheres.

A smoke house has been constructed in a central location. It is so built that the head trainer can observe the men from outside as they perform their evolutions. At present there are about 40 men, including the officials of the collieries, who are trained in the use of rescue apparatus. In addition to this number, 24 of the officials hold certificates of proficiency in first aid.

There are ambulances, stretchers and blankets at each colliery, and in the rescue car there is a first-class ambulance for the conveyance of injured men from the car to the hospital or to their homes.

DISCUSSION BY READERS

Timbering at the Working Face

Letter No. 1—This subject is of the greatest importance with respect to the safety of the miner, the conservation of the coal, cost of production and economy of time and labor; although the timbering of the working face is primarily for the protection of the workman. For the most part, post timbering is employed. The province of a mine post is twofold: First, to give support to loose pieces of overhanging slate or rock; and second, to give suitable warning of any movement of the roof and the danger that is imminent. In post timbering, the time and place of setting posts are items of more importance than the number of timbers set. There must be no delay in setting a post under a loose piece of roof slate; or, better still, the loose piece should be pulled down at once. The manner of setting posts or style of timbering adopted will depend on many conditions, such as the character of roof and floor, thickness and character of coal, size of opening and length of time the place must be kept open.

A strong slate or shale roof will generally have a good bending factor. In my opinion, such roof requires a systematic method of timbering, which should be rigidly maintained. The posts should be set a constant distance apart every way. This will enable a large percentage of the posts to be recovered when the room is finished and the pillars are being drawn back. In all cases, it is important to keep the timbering within as short a distance of the working face as practicable.

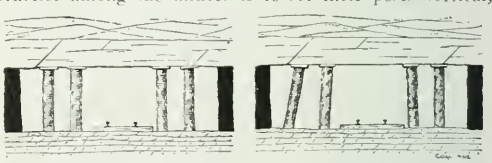
Since a good, strong slate or shale is generally considered the safest kind of roof, in coal mining, its proper support is too frequently neglected by the miner, and this neglect is not regarded as serious by most mine foremen. An experience of 20 years in the superintendence of mines has convinced me that this is one of our greatest dangers in coal mining; and the reports of mine accidents, both fatal and nonfatal, in all states, bear out this conclusion. Many times I have seen a space 20x30 ft. left wholly unsupported, under a strong roof slate, while miners still continue to advance the face of the coal. Frequently, such neglect will result in a fall of roof sufficient to close the place before it has been driven 30 yd., causing both a loss of coal to the company and loss of time and labor to the miner.

A soft, friable roof, or a drawslate that disintegrates by exposure to the air or by reason of the increasing roof pressure, or a roof containing slips or faults, or one of a fireclay nature is always more or less dangerous. An example of such roof is found in the Pittsburgh seam. This seam, in West Virginia, is soft and friable; and, in the mines of the lower Kanawha region, must have careful attention to insure safety and economy in mining. I think this fact is clearly shown by the state inspectors' reports of these mines.

Mine roof of the character just mentioned requires a practical system of timbering adapted to the special conditions of the roof and coal and the pressure exerted by the overburden. In the mines of the Kanawha region, there are few if any foreign miners employed. The mine officials are careful; a good system of inspection is maintained; and any failure to properly timber the face results in "stopping the turn" of the miner. As a result, under this treacherous roof, there are comparatively few nonfatal accidents, while the fatal accidents, which are mostly unavoidable, do not exceed the general average for the state.

In my opinion, a large percentage of accidents due to falls of roof and coal can be ascribed to what may be called the "personal equation." It is stated with some truth that probably 50 per cent. of the falls at the working face may be ascribed to the neglect of mine foremen in seeing that their orders, in respect to timbering, are properly obeyed. It has been my duty, frequently, to take mine foremen to task for their lack of discipline in this respect: but the excuse is always, the "scarcity of men" and the "demand for coal."

I want to refer to a peculiarity of the roof in this region, which I have found requires special treatment. Frequent slips occur in the roof slate here, and the general practice among the miners is to set their posts vertical,



A Suggestion in Timbering Roof Slips over Roads

on each side of the road in the rooms, as shown on the left, in the accompanying figure. This invariably causes the slate to break over the roads, which gives no end of trouble. I have found that this difficulty may be largely avoided by setting the first post, next to the road, slightly inclined toward the roadway, and the post behind this, more inclined in the same direction, as shown on the right of the same figure. The advantage is twofold; namely, a break in the roof is resisted by the full thickness of the slate and the inclination of the post tends to arch the weight over the roadway.

Many miners and a large number of foremen know of but one way of setting a mine post, and that is in a vertical position, without regard to the conditions existing in the roof or the seam. I am proud to say, however, that the majority of our good foremen know that the proper position of a mine post is in line with the pressure.

The fireclay formation overlying much of the coal, in the Connellsville coke region and in various parts of the United States and Canada, is a hard roof to handle, except where the coal is thick enough to leave a top bench for roof when driving the rooms up to the limit or, as we say, in the "first working." This top coal forms a good roof and can be taken down when the pillars are drawn back. In a thin seam having no top bench, it is often necessary to resort to crossbar timbering.

A sandstone roof is likewise a dangerous roof. The roof stone often contains joints and irregular fractures that give no warning of their presence. Mine posts are of little use under such a roof, except for giving some slight warning of danger, which, however, often comes too late. This roof breaks in massive pieces, which, when they once start to move, cannot be held except by building substantial cribs. I have seen hundreds of cases where the attempt has been made to hold up a large roof rock that required constant retimbering and was still a constant menace to safety. Time, labor and material are generally saved by allowing such a rock to fall and finding a way around it. When this cannot be done, it should be cribbed and crossbarred in such a manner that cars cannot knock out the timbers and cause an accident.

My experience has taught me that this class of accidents, in the past, has been largely the result of a lack of proper supervision. What has already been accomplished in this direction, proves that perhaps 90 per cent. of these accidents could have been avoided by a system of careful inspection of the roof. Operators now very generally realize the importance of regarding *safety first* and *profits second*. This was the experience, formerly, in England. The district where I worked (1872) was notorious for accidents from roof falls. When the Coal Mines Regulation Act became a law, in that year, roof inspection was made compulsory, with the result that, in five years, this class of accidents was reduced 50 per cent.; and, if my memory serves me right, this reduction gradually increased to 80 per cent.

While it is true that the neglect of miners to properly examine their own working place before going to work and to promptly set any timbers that may be required and, likewise, the neglect of mine officials and bosses to give sufficient time for a thorough inspection of each working place, will account for many accidents, the larger responsibility rests upon the operator for the maintenance of proper discipline in the mine. This responsibility is shared in part by the mine foreman. The discussion of this question in COAL AGE cannot fail to impress the responsibility for proper roof inspection upon every mine worker, foreman, superintendent and operator.

JOSEPH VIRGIN.

Bancroft, W. Va.

Ventilating Breasts in the Mammoth Seam (Penn.)

Referring to the article of Mr. Crankshaw, COAL AGE, Feb. 15, p. 263, in which he describes the method of ventilating the breasts in the Mammoth seam, by separate air splits, I was surprised that no crossheadings are shown connecting the breasts.

The system of mining described is what is known as "rock chute mining." The system of ventilating by splits is good, with the exception that crossheadings should be driven between the chambers or chutes every 60 ft., or less if the conditions require. In the first split to the left, the air current taken up chute No. 5 should not be made to return by that chute to the airway; but should be conducted through the upper crosshead-ing to the face No. 4, from which it should pass through another crosshead-ing to No. 3 and so on, returning to the airway through No. 1 chute.

In the same manner, each air split should be conducted along the faces of the several chutes or breasts, by passing through the crossheadings connecting the chutes near the face, and only returning to the airway by the last chute in that split. To course the air up one side of the chute and down the other, ventilating in this way several breasts without crossheadings, is not in accordance with the best accepted laws of ventilation. Experience has taught us that seams of any considerable inclination should be ventilated, as far as practicable, so that the course of the air will be generally toward the rise; in other words, the ventilation should be *ascensional*. This system should be adopted in all mine ventilation whenever practicable.

By driving crossheadings every 60 ft. or less, between adjoining chutes, the course of the air is much shortened and the mine resistance reduced, which will increase the circulation of air, for the same power. Again, it would be impracticable to drive breasts any considerable distance, either in flat or pitching seams, without crossheadings connecting them, and it would be difficult to remove any accumulation of gas from such breasts and much time and labor would be lost, besides running a risk of gas or dust explosions.

The statement that "if one breast makes gas freely it can be isolated from the other breasts on that split without shutting down the whole gangway" is true; but, in the majority of cases, this would not be necessary if the circulation in each split was properly arranged and the air current conducted through the crossheadings as explained.

Good ventilation at the working face is one of the important factors in the economical operation of a mine; as, thereby, many long delays are avoided, which would otherwise greatly reduce the output and increase the operating expense.

DANIEL J. BOYLE.

Fern Glen, Penn.

Danger of Powder Smoke

The danger from powder smoke is greater than miners commonly suppose. In one of the recent letters discussing the reducing of the ventilation when firing, I was glad to see a reference to the explosibility of powder smoke. (COAL AGE, Feb. 1, p. 196.)

In some mines, the miners have a practice of rushing back to the face immediately after a shot has been fired, so as to light the smoke behind the standing shot before this smoke has mixed with the air to such an extent that it will not ignite. I have often thought the practice should be stopped, as the miner not only runs the risk of being burned, but the shot may have knocked out a prop, leaving a loose piece of slate that is ready to fall at any moment.

Firedamp is not the only danger in mines and I believe it is a great mistake that one or more firebosses are not employed, in every mine, whether gas is generated or not. There are many accidents of this class that a competent fireboss could prevent, in a large mine where it is a practical impossibility for the mine foreman to give proper attention to many of these matters.

WILLIAM ROTHWELL,
Fireboss.

Castle Gate, Utah.

Seven Shifts a Week

I have noticed recently the discussion of the question of working seven shifts a week and want to say that, while we cannot altogether avoid Sunday work at a coal mine, I have never advocated the practice of working seven days in the week. I think there are many jobs set aside for Sunday that could be done as well during the week. I presume I have been "on the job" as many hours as Mine Foreman, COAL AGE, Feb. 15, p. 272; but I have never regarded it as "living on the job."

When a man has worked for me two shifts running, I would not give him 50c. for a third shift. Many men want to work extra time, but it is more the *time*, on the pay sheet, they are after, than the work they assay to accomplish. More and better work is always done by observing regular hours; begin on time and quit on time is generally good doctrine. Men should be allowed to make extra time, only when this is necessary for the continuous operation of the mine. When the work requires, it is all right to put in an extra shift on Sunday or any idle day, although this may cause unexpected trouble.

I have known men to be so anxious to make extra time, that they have called the attention of the mine committee to the fact that they were not employed on certain extra shifts, disregarding the right of the boss to employ such men on an extra job as he considers most capable of doing the work.

While I consider it necessary that any man in charge of the work should be ready to respond to a call at any time, I do not think it is necessary for him to eat and sleep with the job. Extra time is often made at the expense of efficiency and with loss to the company.

AN INDIANA FIREBOSS.

West Terre Haute, Ind.

High Fan Efficiency

Referring to your editorial "Too High an Efficiency," COAL AGE, Feb. 22, p. 306, I infer you do not fully understand the methods that were employed to determine the amount of air exhausted by the fan during the test.

The measurements taken by the Hydro recording gage were not relied upon solely in calculating the results, but the amount of air passing was measured simultaneously by three methods as follows:

(A) By Hydro recording gage; the pitot tubes attached to this instrument being fixed permanently in the main airway, at a point in the cross-section, where the average velocity was obtained.

(B) By an anemometer in the main airway.

(C) By an anemometer in each of the three airways leading to the main airway.

It is, of course, well known that the velocity of the air is not the same in all parts of the airway; that the points where the average velocity occurs remains unchanged for different velocities, has also been established. To determine the point of average velocity, the main airway was divided by wires into sixteen sections and repeated readings taken in each section with pitot tubes attached to a portable recording gage, the dial of which was graduated to read velocities in feet per second. The pitot tubes of the Hydro gage, used during the test, were fixed permanently at the point of average velocity thus determined, and readings taken on both instruments were found to check very closely.

The three splits were sectioned and readings taken consecutively in adjacent squares. In the main airway, the anemometer was moved crosswise at the same height as the pitot tubes. These airways are concrete lined; during the test they were lighted by electric lamps and the time was announced by electric bells, offering the best possible facilities for accurate work. A deduction of six square feet for each operator was made from the sectional area of the airways. The water gage shown by the Hydro recording gage was also checked by two water manometers on opposite sides of the fan drifts. By this method of taking measurements, the volumes of air measured in the main airway should check with each other and also with the total volumes measured in the three splits.

The results of an average test were as follows:

Volume in cubic feet per minute: (A) 322,410. (B) 306,620. (C) 302,550. The water gage was 4.89 and the calculated mechanical efficiencies of the fan 83%, 77.6% and 76.6%, respectively.

The above results are typical and, considering the difficulty and the chance of error in taking anemometer readings in large airways, are probably as close as could be expected.

With the above facts understood, I think it must be admitted that the results of the test are reasonably near the truth, or that all the instruments were inaccurate in the same direction, which is hardly probable.

Good efficiency would naturally be expected of this fan, with its long evasé chimney and low inlet velocities and, granting that all the observers were deceived a reasonable amount, the efficiency would yet be in excess of that obtained in the laboratory experiments mentioned in your first editorial, Feb. 1, p. 193.

U. U. CARR.

California, Penn.

[As all fan engineers know, there are fan tests and fan tests. An important feature in every practical fan test, that is to say, in every test of a fan under working conditions at the mine, is to eliminate other factors acting to assist or oppose the general circulation of air through the fan and in the airways, of which the fan-ducts must be considered a part. This is one of the most troublesome features of such a test, and one that is often unconsciously overlooked, and for which the high efficiencies obtained are often responsible.

Because a certain fan shows a high efficiency, say 80 per cent., or even higher, it does not follow that these troublesome features have not been fully considered and eliminated by the engineers in charge of the test. The writer has made tests in which such high efficiencies were obtained, and is, therefore, of the opinion that they are possible.

In speaking of fan efficiency, it is generally recognized by engineers that such efficiency includes the efficiency of the engine driving the fan, and is the ratio of the power on the air, as measured in the fan drift, to the indicated horsepower of the engine card. The attempt is seldom made to separate these factors, while at the same time it is recognized that an engine of poor design and low efficiency may seriously handicap the ventilator and reduce the efficiency that should be obtained.

The letter of Mr. Carr shows clearly that the test to which he refers was carefully conducted, and the efficiency claimed for the fan is a proper one, barring the unsuspected operation of air columns in the mine.—EDITOR.]

EXAMINATION QUESTIONS

Mine Gases and Ventilation

Ques.—If a water gage of 2 in. produces a velocity of 500 ft. per min., in an air course 4000 ft. long, what water gage will be required to produce a velocity of 800 ft. per min., in the same airway extended to a length of 8000 ft.?

Ans.—In this case, the sectional area and the perimeter of the airway remain unchanged, while the length of the airway is doubled. Since the pressure per square foot varies as the length of the airway and the square of the velocity, the *pressure ratio* will be equal to the *length ratio* multiplied by the square of the *velocity ratio*. Therefore, calling the required water gage x, we have

$$\frac{x}{2} = \frac{8000}{4000}\left(\frac{800}{500}\right)^2 = 2\left(\frac{8}{5}\right)^2 = \frac{2 \times 64}{25} = 5.12 \text{ in.}$$

Ques.—If a water gage of 1.2 in. produces a velocity of 500 ft. per min., in an airway 6x8 ft., 1 mile long; what water gage will be required to produce a velocity of 750 ft. per min. when the length of this airway is increased to 2 miles?

Ans.—As in the previous example, the sectional area and the perimeter of the airway remain unchanged while the length of the airway is doubled and the velocity increased from 500 to 750 ft. per min. The area and perimeter of the airway being constant, the *water-gage ratio* varies as the *length ratio* times the square of the *velocity ratio*. Therefore, calling the required water gage, in this case x, we have

$$\frac{x}{1.2} = \frac{2}{1}\left(\frac{750}{500}\right)^2 = 2\left(\frac{3}{2}\right)^2 = \frac{2 \times 9}{4} = 4.5 \text{ in.}$$

Ques.—If a certain pressure produces 20,000 cu.ft. of air per minute, in an airway 6 ft. in diameter; what quantity of air will the same pressure produce in an airway 12 ft. in diameter, assuming the airways have equal lengths?

Ans.—In this case, the pressure and the length of the airways are constant. Since both these airways are circular, they are similar and the square of the quantity of air passing varies as the fifth power of the diameter of the airway. In other words, the square of the *quantity ratio* is equal to the fifth power of the *diameter ratio*. Therefore, calling the required quantity of air x, we have

$$\left(\frac{x}{20{,}000}\right)^2 = \left(\frac{12}{6}\right)^5 = 2^5 = 32$$

$$x = 20{,}000\sqrt{32} = \textit{say } 113{,}000 \textit{ cu.ft. per min.}$$

Ques.—The total rubbing surface of a square airway being 160,000 sq.ft., the length of the airway, 5000 ft., and the quantity of air passing, 80,000 cu.ft. per min.; find the velocity of the air current, in feet per minute.

Ans.—First find the perimeter of the airway by dividing the rubbing surface by the length of airway; thus, $160{,}000 \div 5000 = 32$ ft. But the airway being square, each side is $32 \div 4 = 8$ ft.; and the sectional area of the airway is then $8 \times 8 = 64$ sq.ft. Now, find the velocity of the air current by dividing the quantity of air in circulation by the sectional area of the airway; thus, $80{,}000 \div 64 = 1250$ ft. per minute.

Ques.—Would you recommend a fan of furnace for a new shaft mine 500 ft. deep? Give reasons for your recommendation.

Ans.—If the seam is generating explosive gas, a furnace could not be used with any degree of safety. If the mine generates no gas, however, a furnace can be used to good advantage in the early development of the mine, as the depth of the mine below the surface would give an air column that would insure ample ventilation, for a considerable time to come.

As the development of the mine increased, however, a ventilating fan would be found to give better satisfaction and be more economical in the end. A furnace should not be used in any mine liable to dust explosion; for the reason that, in the event of an explosion, the circulation in the mine is under better control and the means of ventilation immediately accessible when a fan is employed.

Ques.—Find the entire rubbing surface of three airways each 6000 ft. long, and each having a sectional area of 15 sq.ft. The first airway is rectangular, its width being three times its height; the second airway is square, and the third airway is circular.

Ans.—The first step is to find the perimeter of each separate airway. Calling the height of the first airway h, its width is $3h$, and the sectional area is then $h \times 3h = 3h^2 = 15$ sq.ft. Then, $h = \sqrt{\frac{15}{3}} = \sqrt{5} = 2.$ The first airway is, however, 5×15 ft., in section, and its perimeter is $2(5 + 15) = 40$ ft.

The second airway being square, one side is $\sqrt{15} = 8.66$ ft.; and its perimeter is then $4 \times 8.66 = 34.64$ ft.

The third airway being circular, its diameter is

$$d = \sqrt{\frac{15}{0.7854}} = 4.37 \textit{ ft.}$$

and its perimeter or circumference is then $3.1416 \times 4.37 = 13.7$ ft., nearly.

Since the length of each airway is 6000 ft., the entire rubbing surface is

$s = 6000\ (40 + 34.64 + 13.7) =$ *say* 632,000 *sq.ft.*

Ques.—A volume of 10,000 cu.ft. of air and marsh gas is at its most explosive point; how many cubic feet of marsh gas does the mixture contain?

Ans.—A mixture of marsh gas and air, at its maximum explosive point, contains 9.46 per cent. of the gas. Therefore, a volume of 10,000 cu.ft. of this mixture will contain $10{,}000 \times 0.0946 = 946$ cu.ft. of marsh gas.

Ques.—Under what conditions may afterdamp become explosive?

Ans.—Afterdamp may contain unburned marsh gas (CH_4) or carbon monoxide (CO), either of which gases becomes explosive when mixed with a sufficient quantity of fresh air. Such an atmosphere may have a temperature sufficiently high to ignite these gases, should fresh air have access to the place where they are found.

COAL AND COKE NEWS

Washington, D. C.

Secretary Nagel just at the close of Congress has rendered a report covering the much discussed question, what was the effect of the advance in prices on anthracite coal and how far it was warranted. His investigators have reached the conclusion that the advance of prices took about $9,000,000 out of the consumers in 1912, but that there was no good warrant for the action taken. This is the net result of the so called Difenderfer resolution which was presented and passed about nine months ago.

With reference to wages the conclusion is arrived at that the advance represented about 8 or 10c. per ton and was necessary in order to avoid strike conditions and insure a supply. This cost the companies about $4,000,000. On the average, however, there was an advance of over 31c. per ton. Wholesale prices were increased on the average only about 26c. a ton, but when the advance in price is considered in connection with the change in sizes of coal it figures out at more than 31c. per ton.

The sources of profit to the companies were not, however, exhausted in a mere advance in price, but considerable gain was made by cutting off the discounts of 40 and 50c. per ton usually granted to consumers on purchases made in April and May. Altogether the total excess gathered in from the community was about $13,450,000 more than would have been obtained had the same tonnage been sold at the old prices. Nearly $11,000,000 of this sum came from the advance in prices and about $2,500,000 from the suspension of the discount. There were also some profits made by sales of coal at famine prices in certain instances.

The report goes on to charge the existence of a trust including the mines and the railroads with which they are affiliated. As a result of this community of interest it is claimed that there is nothing in the mere fact that production costs somewhat more to warrant an increase of price to the consumer unless there is some very large advance to bring it about. "The capital invested in coal mining," says the report, "derives its income both from the mining and the transportation of the coal, and a failure to realize profits in the mines may be and often is compensated by the profit in the operation of the railroad on account of coal tonnage. The purpose is simply to operate the coal mines and the railroad so as to produce the maximum profit from both together and not simply to secure profitable results from each source of income separately."

Secretary Nagel is quite severe in his strictures on the retailers, as he asserts that they took large advantage of the increase in cost and were often responsible for the suspension of the discounts. He cites New York, Philadelphia and Washington as places where the retailer shifted the full amount of the increase demanded by the operators, and perhaps something more, to the shoulders of the consumer. He adds that in each of the cities mentioned the increase in retail prices was very similar to the advance in the circular prices quoted by the operator.

This report, of course, comes too late to serve as a basis of any legislation by Congress at the session which closes Mar. 4, but it is expected that the subject will promptly come up again during the special session which has been called for the present month. Specifically, it is believed that the showing made will lead to the removal of the tariff on coal as has already frequently been predicted.

Winston-Salem Rate Decision

In a decision issued by the Interstate Commerce Commission on Feb. 25, it was ordered that the case of the Board of Trade of Winston-Salem against the Norfolk & Western R.R. should be dismissed. The Commission held that the rate of $2.10 per ton on coal from the Pocahontas fields in Virginia and West Virginia to Winston-Salem is not unreasonable. The Commission, however, concluded that the rate of $2 per ton from the same point of origin to Martinsville, Virginia, is excessive to the extent that it exceeds $1.80. The roads were ordered to put the latter rate into effect by Apr. 15.

The Commission further held that the Chicago, Milwaukee & St. Paul and other railways had failed to justify the proposed advances in the rates on coal in carloads from mines in Iowa to stations in South Dakota, North Dakota and Montana. The tariffs were ordered withdrawn. A similar decision was reached with respect to the proposed advances on the rates for soft coal in carloads from Illinois mines to Clinton, Ia., and other points on the Chicago, Burlington & Quincy R.R. The Chicago & Alton and other roads were ordered to withdraw their suspended tariffs not later than Apr. 15.

PENNSYLVANIA

Anthracite

Scranton—At a conference with the officials of the Scranton Coal Co., Feb. 20, the 300 striking miners from the lower seams of the Capouse colliery agreed to go back to work. Instead of returning, however, they not only stayed out, but induced 300 additional men to quit. As a result the whole colliery is idle.

Wilkes-Barre—A cave in the Pine Ridge mine of the Delaware & Hudson Co. at Miner's Mills, Feb. 20, caused the cellar of a house belonging to James Flynn to sink. The house was immediately vacated.

An attempt to call a strike at the Avondale Colliery of the D., L. & W. Coal Co., in Plymouth Township, has resulted in the mine being closed indefinitely, while repairs are being made to the breaker and the mine workings. The subject of disagreement was the price for standing timber, the men claiming that the price had been reduced, and the foreman showing his books to prove that no reduction had been made. The evidence of the books was satisfactory to the members of the committee, and they announced their readiness to return to work the next day, only to be met with the statement by the superintendent that inasmuch as they had quit and thrown the colliery idle contrary to their agreement, work would not be resumed until the long contemplated repairs had been made.

Pottsville—The miners who were entombed, Feb. 25, in a colliery near Mahanoy City were rescued early Feb. 28. Two of them were completely exhausted and had to be dragged through a small aperture, which had been made during the last 10 ft. of digging in the wall. The men were without food for 58 hours, and their clothing was soaked with icy water.

Bituminous

New Kensington—While trapped in a fiery mine of the Valley Camp Coal Co. at Valley Camp, a searching party narrowly escaped death. Four of the party of 10 were badly burned by an explosion and three of these are now in the hospital. Three hundred men employed on the day shift were warned in time to escape, but it is feared that there may be others in the workings.

Dubois—Nearly 700 men employed at the Eriton shaft of the Northwestern Mining & Exchange Co. have gone on strike. It is said that the weighing methods employed at the colliery are the cause of the trouble.

California—Three men were seriously injured Feb. 25, in the mines of the Vesta Coal Co. Two were caught in a fall of slate while a third had his right arm torn off by an electric cutting machine.

WEST VIRGINIA

Charleston—General Elliott, commanding the troops in the martial law district has reported to Governor Glasscock that the mines in and out of the country covered by the National Guard resumed operations Feb. 18. This is taken to indicate that the crisis has passed and that peace will soon be restored. No arrests have been made as yet in connection with the burning of the tipple of the M. B. Coal Co.

Fairmont—Karl F. Schoew, state mine inspector for the first district, is an applicant for the position of chief of the department of mines of the state of West Virginia, to succeed John Laing, whose term expires June 30.

OHIO

Columbus—One of the most important events in coal circles during the past week was the enactment by the Ohio legislature of the Green compulsory workmen's compensation bill, which will apply to every coal mine in the Buckeye State. Effective after Jan. 1, 1914, every individual, firm or corporation which employs more than five people must pay into the state board of awards a premium based on the yearly pay roll,

which is calculated to take the place of liability insurance and to compensate all workmen for injury or their dependants for loss of life. The law provides for a schedule of compensation to be paid to workmen injured by the loss of members. For partial disability, the injured laborer is to receive two-thirds of his weekly wage, providing it does not exceed $12 weekly for a term of six weeks. For permanent disability he is to receive two-thirds of his average weekly wages for life, providing it does not exceed $12 weekly. Employees of less than five persons can come in but are not required to do so. The law will make quite a change in the system of operating mines in Ohio.

The Ohio legislature has also passed a bill giving heirs instead of lineal descendants the right to recover damages caused by death in the mines of Ohio.

KENTUCKY

Louisville—Recent rains throughout the Ohio Valley have resulted in a rise in the river, which is expected to bring a stage of water from Pittsburgh down that will enable the coal fleets to get out with the biggest tonnage in years. Tows are now being made up at Louisville for several of the steamers, which have recently returned from the South with empties, the quantities of river coal now available at this port being ample for this purpose.

The decision of the Interstate Commerce Commission makes permanent the recent suspension of the Louisville & Nashville's advances in rates on coal from mines on the Stony Fork branch to various destinations. The decision upholds also the contention of the coal men that the L. & N. is legally the initial carrier, and is, therefore, responsible for the furnishing of cars.

ILLINOIS

Edwardsville—The Henrietta Mine, owned by the Federal Trust Co. of St. Louis and leased by W. S. Walker, was shut down by action of the miners filing claim for wages. The management claims that the mine was unable to work, because the people of Edwardsville bought outside coal instead of patronizing the local mines.

Cherry—The last death claim against the St. Paul Coal Co. arising out of the mine disaster at Cherry in 1909 has just been settled in the circuit court at Princeton. It is estimated that the company has paid out over half a million dollars in settlements to date.

Peoria—The Illinois miners in state convention Feb. 25, voted to give the striking miners of West Virginia $900,000 to aid them in their struggle. The gift not only means a levy of $100,000 upon the members of the union in this state, but it authorizes the state executive board to spend every cent of the reserve fund of $800,000 if necessary.

PERSONALS

Dr. J. H. Hughes, of Nanticoke, has received an appointment as first-aid advisor for the Susquehanna Coal Co. in Nanticoke and Glen Lyon to fill the vacancy caused by the death of Dr. F. L. McKee, of Wilkes-Barre.

Hiram Smith, general foreman at the Dorrnce colliery of the Lehigh Valley Coal Co., has resigned, and his place has been taken by Hugh Price, foreman at Mineral Spring colliery. James Weston, assistant foreman at the Dorrance, has been promoted to foreman at Mineral Spring.

N. W. Campbell, C. H. Peacock and S. L. Kinzer have resigned from their positions with the Pennsylvania Coal & Coke Corporation at the Philadelphia office. Their places will be filled for the present by E. S. Lawrence, assisted by N. C. Ashcom, G. A. Brown, H. G. Mettlach and W. J. Ryan.

The annual meeting of the stockholders of the Goulds Mfg. Co. was held at Seneca Falls, N. Y., Feb. 24. No change was made in the board of directors, and the following officers were reëlected: President, N. J. Gould; vice-presidents, D. V. Colby, W. D. Pomeroy, W. E. Davis, W. E. Dickey; secretary, H. S. Fredenburg; treasurer, B. R. Wells; assistant treasurer, E. W. Medden.

RECENT COAL AND COKE PATENTS

Mine Door—N. Jacho, Allentown, Penn., 1,052,147, Feb. 4, 1913. Filed June 7, 1912. Serial No. 702,257

Coke Oven—W. Felchs, Bethlehem, Penn., 1,051,875, Feb. 4, 1913. Filed Oct. 12, 1910. Serial No. 586,630.

Coaling Apparatus—F. E. Davis, Payette, Idaho, 1,051,699, Jan. 28, 1913. Filed May 11, 1912. Serial No. 696,796.

Mine Car Wheel—I. W. Jones, Birmingham, Ala., 1,051,892, Feb. 4, 1913. Filed Sept. 18, 1911. Serial No. 649,831.

Mining Machine—P. J. & J. S. Kelley, Pana, Ill., 1,051,417, January 28, 1913. Filed Feb. 8, 1911. Serial No. 607,598.

Steam Boiler Furnace—E. Buckley, Philadelphia, Penn., 1,051,546, Jan. 28, 1913. Filed May 27, 1912. Serial No. 699,914.

Mine Car Couplings—O. & C. Anderson, Bitumen, Penn., 1,051,536 Jan. 28, 1913. Filed April 5, 1909. Serial No. 487,852.

Conveyor—G. C. Horst, assignor to J. A. Jeffrey, Columbus, O., 1,052,253, Feb. 4, 1913. Filed May 14, 1903. Serial No. 157,160.

Mining Machine—J. McDonald, New Philadelphia, Penn., 1,052,359, Feb. 4, 1913. Filed March 14, 1911. Serial No. 614,417.

Loading and Unloading Apparatus—O. N. Gardner, Jamestown, N. Y., 1,051,994, Feb. 4, 1913. Filed March 15, 1912. Serial No. 683,972.

Process of Briquetting and Pressing Fuels—A. Ronay, Berlin, Germany, 1,052,093, Feb. 4, 1913. Filed July 21, 1909. Serial No. 508,784.

Superheater Boiler—J. E. Beel, Assignor to Babcock and Wilcox Co., New York, N. Y., 1,051,829, Jan. 28, 1913. Filed May 21, 1906. Serial No. 317,856.

Water Tube Boiler—D. S. Jacobus, assignor to Babcock and Wilcox Co., New York, N. Y., 1,051,890, Feb. 4, 1913. Filed Sept. 21, 1912. Serial No. 721,531. Also 1,051,891, Feb. 4, 1913. Filed Sept. 21, 1912. Serial No. 721,532.

Water Tube Boiler—A. D. Pratt, assignor to Babcock & Wilcox Co., New York, N. Y., 1,051,912, Feb. 4, 1913. Filed July 3, 1912. Serial No. 707,419. Also 1,051,913, Feb. 4, 1913. Filed July 3, 1912. Serial No. 707,420.

CONSTRUCTION NEWS

Middlesboro, Tenn.—The Mary Moose Mining Co. is preparing to sink a shaft at its mines, four miles below town.

Mt. Union, Penn.—The Lehigh Coal and Navigation Co. intends to erect 100 new houses at Summit Hill next summer instead of only 50.

Shamokin, Penn.—The local engineering department of the Philadelphia & Reading Coal & Iron Co. have completed plans for the sinking of a new shaft at the Sterling colliery.

Friedens, Penn.—A gigantic electric power plant has just been completed here for the Stauffer Coal Co. Many other improvements are being planned and will be carried out in the spring.

Coshocton, Ohio—The stockholders of the Ohio Cannel Coal Co., of Coshocton, Ohio, met recently to discuss plans for building a large number of houses and generally improving its property. The mines are located near Warsaw.

Birmingham, Ala.—A new crusher of 200 tons capacity, a new tipple and other machinery is being installed at the mines operated by the North Alabama Coal Iron and Railroad Co. Another slope soon will be started to tap another ore vein. Improvements will cost $10,000.

Montreal, Can.—The Albert coal branch of the Grand Trunk Pacific R.R. has been completed and the work on another branch line to the Yellowhead Coke Co.'s mine is now well under way and will probably be finished by the end of the month. On a line to the Mountain Park mines, steel has been laid five miles west of Edson.

Columbus, Ohio—Reports from Bellaire say that extensive improvements are being planned on the property of the Ball & River Coal Co., recently purchased by the Grand Trunk R.R. The program announced will involve the expenditure of $250,000 in the three mines of the company. When the proposed improvements are completed it is expected that 1500 more men will be employed.

Kansas City, Mo.—An English syndicate, headed by Col. L. B. Drage, of London is to begin at once to develop the Christie coal tract in the Waverly-Lexington field. They propose to extend one mine that is now a small producer and to sink other shafts. They expect to be able to offer Kansas City several thousand tons of coal daily. Christie Tract, formerly the property of C. C. Christie, of Kansas City, is 2500 acres in extent.

Whitesburg, Ky.—It is reported that R. E. Echols and associates, of Huntington, W. Va., have been purchasing numerous tracts of coal lands in the Carr's Fork Creek section of Knott County, where their holdings will aggregate from 10,000 to 12,000 acres when deals now pending are completed. It is the intention of the purchasers to start development work during this year, which will involve the construction of a twelve-mile branch from the Lexington & Eastern's new extension.

Pottsville, Penn.—The Philadelphia & Reading Coal and Iron Co. is paying considerable attention to the improvement of its mines in the Shamokin region. The four-way shaft of the Reliance colliery at Beaverdale is being sunk, and when finished, will be 620 feet in depth. The Dolan Bros., of Pottsville have taken charge of the sinking and will push the work as rapidly as possible.

The Reading Co. expects to have this shaft completed within ten months.

The P. & R. C. & I. Co. will spare no expense to make this shaft one of the finest in the anthracite coal fields. It also intends in the very near future to have Reliance, Alaska, Locust Springs and Potts collieries equipped with electricity, motor cars, electric hoist and light. They will all receive the power from the electric plant at Locust Spring. The company expects to enlarge this plant and will ship in a few days a Corliss engine of 700 horsepower and one of the largest in that section. When completed this plant will be able to furnish power for all the collieries in that district and Potts colliery at Locustdale. At the Locust Spring colliery the work on the electric hoist at the new rock slope has been started.

Bluefield, W. Va.—The Virginian R.R. is making a survey along the water course of New River for a direct line from its present connection at Rich Creek, Va., to its subsidiary line, the Piney Creek R.R. The latter road was one of the several lines recently acquired by the Virginian. The cutoff extension will probably be seventy-five miles in length. Engineers are at present engaged in making estimates on this proposition and preparations will probably be made for actual work by the latter part of the summer.

Ft. Worth, Texas—The development of coal fields in the northern part of Stevens County containing estimated deposits of 100,000,000 tons of coal and the construction of a railroad from Knox City on the Orient Ry. to this city will begin within a few weeks. The line will pass through oil lands aggregating 20,000 acres and located between Bomarton and Crystal Falls. The estimated cost of its construction is $1,650,000. Six towns, Knox City, Munday, Goree, Bomarton, Throckmorton and Woodson have agreed to furnish the right-of-way for the railroad and land for stations, and to purchase coal from the newly discovered deposits to the value of $750,000.

Connellsville, Penn—Preparations are under way to increase the capacity of the Provident Coke & Mining Co.'s plant at the Kelly station, in the Allegheny Valley. The present output of the mine is 500 tons a day. This will be increased to 2000 tons as rapidly as possible. The company owns 3250 acres of land under which run three seams, the Upper and Lower Freeport and the Middle Kittanning. About 50,000,000 tons are contained in the tract and the coal is of excellent quality.

The plant is being electrically equipped. The West Penn Co. will furnish curent for the haulage system, the cutting machines and other equipment.

NEW INCORPORATIONS

Hazleton, Penn—The Cranberry Creek Coal Co.; capital stock, $10,000.

Helena, Mont.—The Lock Bluff Coal Co.; capital stock, $15,000. Incorporators: J. L. Wester, Jens Rivenes and Harry Wold.

Louisville, Ky.—The Schwind Coal Co.; capital stock, $10,000. Incorporators: Ernest E. Schwind, John C. Schwind, Jr., and George Miller, Jr.

Hazard, Ky.—The Hazard Dean Coal Co.; capital stock, $50,000. Incorporators: C. R. Luttrell, J. R. Jones, W. R. Marsee and Hiram H. Owens.

Wheeling, W. Va.—The Warren Coal Co.; to mine coal; capital stock, $25,000. Incorporators: Johnson C. McKinley, Harry O. Wills, M. B. Mather and John C. Beury.

Wheeling, W. Va.—Warwood Coal Co., $25,000. Incorporators, Johnson C. McKinley, W. R. Warwood, Harry O. Wells W. B. Mathes and John C. Berry, all of Wheeling.

Indianapolis, Ind.—The Warren Coal Co.; to operate mines; capital stock, $100,000. Directors: William P. Ijams, Thomas H. Gill, Albert L. Pfau, Clem J. Richards, J. W. Ijams.

Charleston, W. Va.—The Claybrook Coal Mining Co.; to mine coal; capital stock, $100,000. Incorporators: J. E. Chilton, John A. Thayer, S. B. Chilton, S. Hess and T. S. Clark.

Chicago, Ill.—The Lignite Products Co.; to mine lignite, coal, metals and other natural minerals; capital stock, $5000. Incorporators: Charles Martin, T. A. Sheehan and H. M. Byall.

Chicago, Ill.—The Harkes Coal Co.; to mine and sell coal and clay and their products; capital stock, $6000. Incorporators: Arthur Connor, Thomas J. Luney, Christopher Walen.

St. John, N. B.—New Brunswick Coal, Iron & Clay Co. is asking incorporation, with $275,000 capital, to develop coal, iron and clay deposits and carry on business incidental thereto.

Fairmont, W. Va.—The Ross Coal Co.; chief works in Logan County; capital stock, $75,000. Incorporators: C. E. Hutchinson, C. H. Jenkins, E. C. Curry, R. A. Johnson and H M. Piermont, all of Fairmont.

Wilmington, Del.—The Octave Mines Co.; capital stock, $1,000,000; to acquire mining rights of all kinds; acquire mining sites. Incorporators, George Steigler, W. M. Pyle, Edmund S. Hellings, all of Wilmington, Del.

Oklahoma City, Okla.—A charter has been granted to the Hillock Oil & Coal Co., of Welcetka; capital, $100,000. Incorporators, Robt. F. Turner and J. H. Bynum, of Indianola, Okla., and M. H. Sharp, of Mena, Ark.

Hazard, Ky.—The Mabel Hill Coal Co. is a recent entry into the field around Hazard, Ky., the capital stock being $100,000. The company has taken over the properties formerly owned by the Gaddie Coal Co., and has engineers on the ground making surveys for additional improvements. A daily output of 500 tons is aimed at.

Salt Lake City, Utah—The Utah Coal Sales Agency has been organized under the laws of the State of Utah and after Mar. 1 will handle the output of the Consolidated Fuel Co., Black Hawk Coal Co., Castle Valley Coal Co., and Castle Gate Coal Co. The officers of the company are: W. D. McLean, president and manager; W. O. Bridgman, vice-president; G. E. Forrister, secretary-treasurer; J. H. Mays, director; H. R. Macmillan, director. This is a departure from the established method of handling the sales department of the mines in the Intermountain territory and will be closely watched by the other operators.

INDUSTRIAL NEWS

Dalfax, Penn.—The Pett Mountain Coal Co., near Matamoras, has installed a new 10-hp. hoist and engine and a new pump.

Punxsutawney, Penn.—Annie M. Guthrie, of Center Township, sold 174 acres of coal land to the Tide Coal Mining Co. for $17,500.

Scranton, Penn.—The various collieries of the D., L. & W. Coal Co. were idle Feb. 22, to give their men a holiday on Washington's birthday.

Waynesburg, Penn.—The Enterprise Realty Co. has transferred 600 acres of coal land in Springhill Township to Robert Norris, of Connellsville.

Ravenna, Ohio—The Hudson Coal Co. has recently purchased a 400-acre tract of coal land at Hopedale. The removal of mine No. 8 will soon commence.

Indiana, Penn.—F. L. Neff and E. I. Berry are opening a coal mine on the John Lydick farm in Cherryhill township, where they own 30 acres of high-grade coal.

Gadsen, Ala.—The North Alabama Iron, Coal & R.R. Co. has received a 200-ton ore crusher. The capacity of the mine will be brought up from 75 to 200 tons a day.

Klee, Ohio—The Klee coal mine, known as the Brutchey & Eberling Coal Co., will hereafter be known as the Eberling Coal Co. Mr. Eberling has bought out his partner's interest.

Washington, Penn.—A. B. Kirsch, of Nicktown, is optioning many hundreds of acres of coal lands in the vicinity of Bradley. For whom Kirsch is acting no one has any information.

Altoona, Penn.—The mine operated until three years ago by the Ashville Coal & Coke Co., at Ashville, has been reopened under the direction of Clair P. Burtner, with offices in the Altoona Trust Building.

Connellsville, Penn.—Jas. M. Clark has sold to the Washington Coal & Coke Co. 206 acres of coal underlying his farm in Jefferson Township. The price will be about $200 an acre. The coal is the 9-ft. seam of Pittsburgh coal.

Gary, W. Va.—The United States Coal & Coke Co., a subsidiary of the United States Steel Corporation, has announced a general advance in wages to its employees averaging about 8 per cent., effective Mar. 1. Three thousand men are affected.

Columbus, Ohio—Columbus capitalists headed by Attorney E. D. Howard are negotiating for the purchase of extensive coal rights in Lawrence County, Ohio. The tract comprises about 12,000 acres, and will be developed during the summer if the deal is closed.

Charlestown, W. Va.—Announcement has been made that the coal holdings of the Dixon Pocahontas Fuel Co., together with all the property of the company, has passed by purchase into the hands of the Lake Superior Coal Co. The price paid is said to exceed $500,000.

Bellefonte, Penn.—The Pennsylvania Coal & Coke Corporation have fired up some 400 coke ovens at its No. 10 mine at Gallitzin. They have been idle for the past week or more for repairs, and these have been finished and all will be put into operation as quickly as possible.

Reynoldsville, Penn.—A coal deal involving over 5000 acres of land was consumated in Perry Township when the Buffalo company bought the Adam Eyler Farm and opened negotiations to secure the surrounding territory. It is believed that an opening will be made in the spring.

Lester, Ark.—The Camden Coal & Clay Co., of Camden, has acquired and will develop 10,000 acres of lignite coal land, and also the clay. The clay will be ground and washed at the mines and shipped to Pittsburgh, Penn., for pottery use. The lignite is a somewhat unmatured deposit.

Connellsville, Penn.—The Indian Head Coal & Mining Co. began operations Feb. 24 at the two mines just opened at Indian Head. The number will be increased as the workings are developed. Lloyd Reese, of Indian Head, president and general manager of the company, is in charge.

Connellsville, Penn.—The possibilities of large coal deposits as yet untouched in the Ozark regions will be investigated by Eastern capitalists headed by A. D. Vance, of Pittsburgh, who will go to Taney County, Mo., and begin prospecting in the country near Gretna, Branson and Hollister.

Connellsville, Penn.—The Operators' Coal Co., composed of Johnstown men, has taken over the holdings of the Pennsylvania Smokeless Coal Co. in Somerset County. More than 1000 acres near Holsopple changes hands. Two mines, with an output of 1000 tons a day, are being operated.

Columbus, Ohio—Announcements were received here recently that a special meeting of stockholders of the Provident Coal Co. will be held Mar. 20, to vote on increasing the capital stock from $300,000 to $600,000, to finance improvements made at the company's property in Belmont County.

Birmingham, Ala.—The Alabama Coal & Coke Co. have sold their mine and coal lands at Waverly, Union County, Ky., on the Illinois Central R.R., to the Drury Coal Co., of Morganfield, Ky., and it is now being operated by A. Maben Hobson, of Birmingham, Ala., as trustee for the purchaser.

Charleroi, Penn.—The Carnegie Coal Co. is surveying the block of 1400 acres of coal near Hickory, recently bought by them. The work is under the supervision of Engineer Thomas. This is the company that bought the Charleroi Coal Works at Charleroi, which it will operate as soon as a new tipple is built.

Huntington, W. Va.—The management of the Chesapeake & Ohio R.R. expects soon to let a contract for the construction of 3000 seventy-ton coal cars. Half of the 50 locomotives which the company ordered last year have been completed and delivered. The remainder will be finished and delivered within the next two months.

Morgantown, W. Va.—J. A. Comley has sold a tract of Pittsburgh coal along the Buckhannon & Northern R.R. to Pennsylvania men with the understanding that it is to be operated on a royalty basis. The purchasers must mine at least 10,000 tons per acre. The deal involves $70,000. The mines will be opened at once.

Georgetown, Colo.—The Blue Ridge Mining Co., operating the Millington group of mines on Columbia Mountain, promises to soon have one of the heaviest producing properties in the upper Clear Creek district. A big force of men is being employed, and as fast as ground has been placed in condition more miners will be given work.

Rockwood, Penn.—A syndicate composed of Baltimore capitalists have taken options on about 8000 acres of mineral land lying along the Baltimore & Ohio R.R., one mile west of Rockwood. The operations will then at once be commenced on a large scale and the mined products will be shipped to the Eastern markets as soon as the syndicate takes over the land.

Indiana, Penn.—What promises to be the biggest coal deal made in this county for 10 years, may be closed on May 1, when a block of 6000 acres of Greene township, which is now under option, may be bought by Philadelphia capitalists. Elmer E. Davis, of Johnstown, representing Philadelphia capitalists, is securing the options. The entire tract lies along Twolick Creek.

St. Louis, Mo.—Interest was aroused in Alton by the announcement that the Clark Brothers syndicate, owning the East Side electric lines and systems in East St. Louis, Alton, Belleville, Edwardsville, Collinsville and Granite City, has organized the East Side Coal Mining Co., and that a site for a power house has been bought by the company from Mrs. Janet Watson at Alton for $25,000.

Pittsburgh, Penn.—A Pittsburgh coal land broker has sold to the Welsh combine, headed by David Andrew Thomas, 227,000 acres in West Virginia and Kentucky at a price aggregating $10,000,000. Of this land 175,000 acres are represented as being in the Gauley River district, of West Virginia and 52,000 acres in Belle, Whitely and Knox Counties, Kentucky. The report, as yet, lacks confirmation.

Fairmont, W. Va.—The Mineral Fuel Co. announces that it has purchased between 4500 and 5000 acres of coal land in Letcher County, Ky., and is planning an expenditure of $500,000 to $700,000 for development work, including the opening of mines, machinery installation, building houses, and the like, for a modern coal operation with an annual output of something like 750,000 tons. The property was purchased of the Mineral Development Co., and adjoins the 100,000-acre holdings of the Consolidation Coal Co.

Huntington, W. Va.—J. W. Parshall, an agent for Eastern capitalists, who has been inspecting coal and oil lands in West Virginia and Kentucky, expected to close a deal by Mar. 1 for a 50,000-acre tract on New River. It is the intention of this syndicate to build and open up six new collieries on New River before next winter. An expenditure of $7,000,000 is planed. This sale will mean the opening up of three new towns. Over four thousand workmen and officials will be brought into the state to help in the developing of the first big tract which it is decided to open up.

Barbourville, Ky.—The recently-organized Raccoon Coal Co. has acquired 1200 acres of rich coal land near Hazard, Ky., and will proceed to develop it at once, the daily capacity being estimated at 500 tons. The company intends to install sufficient electrical generating machinery to operate four six-ton motors, four fans and eight machines, as well as four electric rock drills. Machinery bids will be opened about May 1. It is probable that an electric-lighting franchise will be asked for, in order that the company may sell its surplus current.

Wilkes-Barre, Penn.—The Buttertub coal property, in the borough of West Wyoming, has been sold by Messrs. Stark and Kintz to J. D. Davis, of Kingston. No announcement is made as to what company is to acquire possession of the tract. The property consists of about 15 acres, which, according to the account of the mining engineer, carry six veins of coal. The property is bounded on one side by the Mt. Lookout Colliery of the Temple Coal & Iron Co., and on the other side by the Lehigh Valley Coal Co. An opening was made on the property about 25 years ago, but no mining operations have ever been conducted.

Corbin, Ky.—The Louisville & Nashville is planning to double-track that portion of the Cumberland Valley division between Varilla and Corbin, Ky., the latter point being the juncture with the Knoxville division, and the former being the point a which the new Harlan County extension joins the Cumberland Valley division. The cause for the decision to make the improvement is the crowding of the present single track by the increase in coal traffic during the past few years, and the increasing development along the extensions will naturally increase this condition. Work on the additional track, which will be about 35 miles in length, will begin early in the spring.

Louisville, Ky.—At a recent special meeting of the stockholders of the Tennessee-Jellico Coal Corporation, held at the company's office in the Equitable building, in Louisville, it was unanimously decided to increase the capital stock from $300,000 to $400,000, for the purpose of providing capital to develop a large tract of coal land recently acquired by the company near Hazard, in the rapidly developing Perry County field. Most of the stockholders are residents of Louisville, the officers being Robert Wedekind, president; L. I. Coleman, vice-president and general manager; John P. Gorman, general superintendent of mines, and W. P. Polk, secretary and treasurer.

COAL TRADE REVIEWS

GENERAL REVIEW

All kinds of prices are being quoted on individual hard coal in anticipation of the April reduction in the company's circular. Few sales are being made, however, only a small volume of coal moving into consumption and this only for the purpose of carrying the consumers over until the reduction goes into effect. The dealers in particular are quite active, endeavoring to dispose of their stocks, but indications are that there will be considerable on hand the first of the month. April, May and June will no doubt see heavy buying for storage purposes, in order to take advantage of the reduced prices in effect and the present inactivity is giving the companies a welcomed opportunity to accumulate surpluses against this impending demand.

The most striking feature in the bituminous market is the evident determination on the part of the larger companies to obtain an advance on next season's contracts, and this, in the face of an unusually adverse market. With the contract season now at hand, the operators are making every effort to get control of the market. Ordinarily prices are high at this season of the year, but now spot quotations are firmly established well below contract asking prices, and as a result consumers are reluctant to close and will not do so until forced.

In the Eastern Coastwise trade concessions are becoming more frequent and there appear to be too large accumulations to permit of any great stability to the market. Comparatively high water-freights are making spot buying slow at some points, and the more competitive contract business has not yet developed. The Pennsylvania grades are dull, but firm. Buyers generally believe there is an abundance of coal and are showing a disposition to buy only as they require the product. In the Pittsburgh district there is some irregularity as to prices due to concessions on the part of the small operators, but the uncertainty about obtaining shipments of these, in time of a heavy demand, makes the buyer hesitate to close with them.

The volume of trade in Ohio is considerably restricted by the higher temperatures, but the price list shows little change. The manufacturing demand is good, but buyers are anticipating cheaper coal in the near future and are confining their orders to immediate requirements. Contracts are being renewed on the same basis as last year. Domestic prices in the Southern market have been advanced 25c. over last year's circular.

The Middle Western mines are running on a still shorter schedule and the demand is so light that there is not even any incentive to reduce prices further. Quotations have, in any event, about reached an irreducable minimum and even, on occasions, run off to below the cost of production. February proved a good month for the Rocky Mountain operators and the higher temperatures prevailing over the first part of the current month indicate a continuance of these favorable conditions.

BOSTON, MASS.

Only a rigid curtailment can improve the present situation on Pocahontas and New River, and it is understood that such a move is in prospect. The $2.85 price is going hard; the accumulation of coal at Hampton Roads is too great to give any stability to the market. Concessions have been made perhaps more freely the past week than at any time so far this year and if there really is to be a restriction it will be interesting to see how it works. There is apparently little doing on contract; the more competitive business has not yet come into the market to any extent. There is no activity at the distributing points and Southern coals are dull in every quarter. Strike rumors in the New River field will be followed closely in this section and for the spring outlook much will depend on the news that comes from the seat of the threatened troubles.

The high range of water freights, particularly from Hampton Roads, has interfered with the ready absorption of spot coal and will likely make the movement slower still if there is a concerted move to realize the $2.85 price f.o.b. The Georges Creek shippers seem well supplied with orders. An influx of government steamers at Baltimore has taken up whatever slackness there was.

The Pennsylvania grades are dull but with a fairly firm attitude on the part of most of the operators to net higher prices than in 1912. There is only a scattering business at tide, and all-rail there are no new features. Buyers feel there is to be an abundance of coal and they are following a hand-to-mouth policy of ordering.

It is "between seasons" on anthracite and all kinds of prices are current on independent coals. As low as $5, $5.25 and $5.50 alongside for egg, stove and chestnut, respectively, have been quoted; in other words the individual shippers are anticipating the expected 50c. reduction in the companies' circular, Apr. 1. Few sales are reported, however, for the dealers are generally loyal to the companies who saw them through the hard season and what cargoes they are taking are largely of the sizes on which there will be no reduction. Individual operators are having difficulty in moving the steam sizes as well as egg and chestnut. This is where the companies with their storage depots here and there have a distinct advantage in dull periods.

The retail price in Boston for bituminous was reduced Mar. 1 from $5 to $4.75 per net ton delivered in teams.

Current quotations at wholesale are about as follows:

Clearfields, f.o.b. mine	$1.25@ 1.50
Clearfields, f.o.b. Philadelphia	2.50@ 2.75
Clearfields, f.o.b. New York	2.80@ 3.05
Cambrias, Somersets, f.o.b. mines	1.35@ 1.60
Pocahontas, New River, f.o.b. Hampton Roads	2.65@ 2.70
Pocahontas, New River, on cars Boston	3.85@ 4.00
Pocahontas, New River, on cars Providence	3.75@ 3.85

NEW YORK

Bituminous—The soft-coal consumers are still holding off on contracts and the weather has been such that the domestic consumption has been reduced to a minimum with the result that there is little or no demand. Only a small proportion of the contract business has been closed so far this year, but such is not unusual; last year it is believed most of the larger companies closed as many contracts during April as in March.

However, conditions for contracting are particularly unfavorable this season. Last year at this time there was a strong spot market, with prices ruling well above contract asking prices, with the result that consumers were eager to get under cover by closing business. During the current season, the conditions are almost reversed, the spot market being substantially less than contract asking prices, so that consumers will hold off closing until they are absolutely forced to do so. The prospects for obtaining higher prices for next year's contracts are looking more favorable, consumers appearing to have accepted the advance as inevitable particularly on the higher grades.

The larger companies are still curtailing production preferring not to sell at the prevailing low prices in the spot market. The supplies at tide are a trifle low and the car supply is fairly good and much better than last week.

The New York soft-coal market is not quotably changed from last week and continues dull and quiet on the following basis: West Virginia steam, $2.60@2.65; fair grades, Pennsylvanias, $2.65@2.70; good grades of Pennsylvanias, $2.75@2.80; best Miller, Pennsylvania, $3.05@3.15; Georges Creek, $3.25@3.30.

Anthracite—While there is some hard coal still moving, the volume is relatively small and confined entirely to the small tonnages required to carry some of the consumers over until the spring discount goes into effect Apr. 1. Shipments of any grades can be had promptly and individuals are offering discounts well down to the spring circular. Such conditions, of course, makes it difficult for the larger companies to maintain circular prices with the result that much of their coal is now being diverted into storage. The operators are now looking forward to a great activity after the first of the month. Consumers of all kinds are working their supplies off down to the lowest possible point in anticipation of the reduced prices, and will be in the market for large tonnages.

We quote the New York market on the following basis:

	Circular	Lehigh	Individual — Scranton	Individual — Schuylkill
Broken	$5.00	$5.00		
Egg	5.25	4.55		
Stove	5.25	4.85		
Chestnut	5.50			$4.90
Pea	3.50	3.60		
Buckwheat	2.75		$2.50	2.15
Rice	2.25		2.25	1.80
Barley	1.75	....	....	1.15

PHILADELPHIA, PENN.

A long continued spell of unseasonable weather, broke here and there by a cold snap, has reduced the market to almost a standstill. There is actually no size at the present time which cannot be furnished at a moment's notice, and orders are promised prompt delivery, without hesitation. Some coal is moving, of course, but the tonnage is comparatively small, and is only to piece out, until the opportunity is presented of buying at the spring or opening prices. The dealers are trying to get rid of what coal they have, so as to carry as little as possible of the high-priced product over into spring; judging from the number of idle men and teams many of them complain about, there may, however, be considerable coal on hand Apr. 1. Some of the most severe snowstorms in this vicinity have occurred during this month, in former years, and the dealers are living in hopes that such will be the case this year.

The demand for the steam sizes, however, continues good, and furnishes the only firm feature of the market. The individual operators are already in the market with April coal, that is, 50c. off the prevailing circular prices, and even less than this it is said. Taking their mid-winter prices of $5.25@5.50 at the mines, this represents at least as much as $1.75@2 shrinkage in the value of individual coal. The large companies are still adhering to their circular prices of $3.75 for egg, $4 for stove and $4.15 for chestnut, and what they cannot dispose of at this figure is going into stock, to provide against the heavy demand that is likely to prevail during the months of April, May and June.

Production still continues at top notch, none of the collieries having suspended operations owing to the unfavorable market, and the prevailing dull condition really comes in the shape of a blessing, as it will give them an opportunity to place some coal in stock, which a winter of even normal temperature would have rendered impossible. When it is recalled that most if not all of the companies went into last June with no coal in stock at all, and have had no opportunity until the present to divert any to their storage places, it will place the companies in a much more comfortable position to take care of their spring and summer business.

The bituminous market shows no improvement whatever. Constant production has thrown large quantities of coal on the market, which has to be disposed of, and in most cases, at ruinous prices.

PITTSBURGH, PENN.

Bituminous—It continues to be between seasons as to contract coal, buyers having contracts expiring Apr. 1, being slow to close. There is some irregularity in prices quoted on contracts, due to cutting by small operators, but the large producers are adhering strictly to the regular prices and as supplies are usually somewhat uncertain from the smaller companies, in the event of high prices for prompt coal, the cut prices named are not readily accepted, though occasional sales are made. Demand for prompt coal is not heavy, as the weather has been unusually open for winter, and retail demand is rather light. Slack for early shipment usually brings a premium of 10c., occasionally more, and can be quoted at $1@1.05. Regular prices are: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in., $1.55.

Connellsville Coke—The improved prices noted a week ago as having been reached through the stiffening which followed the unloading of considerable stock coke, have been maintained without difficulty, and the present outlook seems to indicate further increases rather than a recession. Demand for prompt furnace coke has not been particularly heavy, but shipments have been larger on contracts and it seems evident that the recession, which began late in January was, as suggested at the time, due simply to a few furnaces working badly temporarily, and to some furnaces starting to consume portions of stock piles accumulated late in the year against the irregularities in shipment, which are usually experienced in the winter, but which were absent this time.

Prompt furnace coke has been held at a minimum of $2.50, and while demand has been rather small in point of tonnage, the figure has been well maintained. For contract coke, operators have held to higher figures than expected, and in one instance a moderate tonnage was placed at $2.65, for regular shipments to July 1. There are few operators quoting as low as $2.50, but the price could probably be done either to July 1 or for second-half. Foundry coke has undergone considerable stiffening. Transactions are now based on standard foundry coke, the foundries no longer purchasing the indifferent grade they were glad to get around holiday time. We quote: Prompt furnace, $2.50; contract furnace, largely nominal, $2.50; prompt foundry, $3@3.25; contract foundry, $3@3.25, per ton at ovens.

BALTIMORE, MD.

The market underwent no change whatever during the week. The low grades of coal are still being quoted around $1, but the car situation improved slightly. Operators are still quoting contract prices for the better grades at 10c. to 15c. above last year's level. About two weeks ago, a number of contracts were closed on this basis, but the buyers are inclined to hold off for a while, and are talking of seeking other fields, if the trade insists on the higher prices. The coal men claim that they are entitled to the advance, owing to the increased operating cost.

West Virginia operators were in Baltimore during the week to confer with Baltimore & Ohio officials relative to the suggested change in the car-distribution system prevailing on that system. Many complaints have been made regarding the present distribution, and the railway company is endeavoring to satisfy its shippers. It is thought that some plan will be evolved which will be satisfactory to all concerned. There is some talk of this road building another coal pier at Curtis Bay.

BUFFALO, N. Y.

The weather has spoiled anthracite so completely that it will require a more severe freeze than March is likely to develop, to restore it to its former activity. Sometimes the semiwinter season continues so persistently that there is a fairly good market all through April, but that does not appear to be expected now. February was only a winter month for about two-thirds of the time, and spring is too near for much return of the demand.

Bituminous naturally suffers less from the unseasonable weather than anthracite, but even it is now standing still because of the increased efficiency on the part of the railroads. During the first half of February the roads became badly demoralized and prices were strong in consequence, but now the delayed shipments are coming forward freely and there is plenty of coal being offered. But the soft-coal market is not so weak as the small sales would seem to indicate. The large operators are holding firm, and if the surplus coal on track can be worked off in a short time it is possible that no break of consequence will take place. Still the tendency is to mine more coal than is needed, and if the railroads can move a full output, it is going to be difficult to hold the quotations.

Jobbers, as a rule, refuse to concede of any lower quotations, saying that the extra quietness of the bituminous market does not necessarily indicate weakness. Pittsburgh select lump continues at $2.80; three-quarter, $2.65; mine-run, $2.55, and slack, $2.15, with Reynoldsville and Allegheny Valley 15c. to 25c. lower. Coke continues to decline. It went too high and, now on the decline, it does not seem to know where to stop. Jobbers find no other reason for its present weakness. Quotations are on the basis of $5.20 for best Connellsville foundry, with very little stock coke yet to be had. The consumption remains good, or stock piles would mount up.

Anthracite premiums are a thing of the past, and Buffalo has three Lake cargoes made up of surplus large sizes, with more to be loaded right along. So far only the Lehigh Valley company has done any water loading, though the D., L. & W. would begin soon but for the seizure of the water trestle by the government on a charge of trespass.

COLUMBUS, OHIO

During the past week the temperature rose and the demand for domestic grades became less, although the general price list showed only a slight change from the previous week. The volume of trade is considerably restricted and operators believe that there is not much in store for them in the future, unless weather conditions become more favorable.

Operations in most of the Ohio fields have been curtailed because of the weak demand. In the Hocking Valley district it is estimated that the output was only 65 per cent. of the average and the same is reported from Pomeroy Bend district. In Eastern Ohio where the steam trade is more active, the output was about 75 per cent. of normal. In the strictly domestic fields the production was below 50 per cent.

Steam business is as active as could be expected under the circumstances. Manufacturing plants are still taking a fairly large tonnage although they are not stocking up any, believing that cheaper coal will prevail in the future. Quite a few of the steam contracts are expiring about this time and they are being renewed generally at the same figures that prevailed during the past twelve months. In eastern Ohio practically all of the larger fuel contracts are being entered into at a slightly higher figure than last year. Re-

tail stocks are fairly large and as a result orders are not coming in fast from that source. Dealers have not been having much business and they are inclined to pull in and prepare for the summer season.

Quotations in the Ohio Field are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1.50		$1 50	$1 45
2-inch	1.35	$1 20	1 35	1 30
Nut	1.30		1 30	
Mine-run	1 15	1 05	1 15	1 15
Nut, pea and slack	0 90		0 90	0.90
Coarse slack	0 80	0 85	0.80	0.80

CLEVELAND, OHIO

The demand for soft coal continues light and conditions indicate that the production exceeds the consumption. The reduction on slack is most noticeable and prices fell off from 10c. to 15c. per ton.

Wholesale quotations per short ton f.o.b. cars at the mines are as follows:

District.	Freight rate	4-in. lump	Mine-run	Slack
Youghiogheny	$1.00	$1 40	$1 30	$1 00
Pittsburgh No. 8	0.90	1 20	1 10	1 00
Goshen No. 6	0.70	1 35	1 25	1 10
Coshocton	0.70	1 55	1 35	1 15

Pocahontas lump and egg is quoted at $1.70, run-of-mine $1.10, slack $1 f.o.b. mines. Hocking is going at $1.55; Massillon domestic lump at $2.50 mines. Furnace coke is quoted at $2.25 f.o.b. ovens with about 75c. added for the foundry grade.

LOUISVILLE, KY.

The market is swamped with fuel and prices are nearly at an irreducible minimum, yet fail to move the coal. It is said that the quantity of fuel in the principal markets of the South was never before so great at this season of year. The best grades of lump and block are going begging at prices as much as a dollar below normal, and even the steam market is exhibiting astonishing weakness.

Good Eastern Kentucky lump and block has been sold during the past few days as low as $1.50 a ton; and round can be had at $1.15 or thereabouts. The better grades of nut and slack are held at 75@85c., with a weak demand, which may presage still lower prices, unless manufacturers realize their opportunity and take advantage of it to lay in a supply against the almost certain scarcity which must follow a dead domestic market. Western Kentucky nut and slack is selling at about 60c., and pea and slack ranges from 40@55c.

HAMPTON ROADS, VA.

The past week has been a quiet one in the tidewater market and there has been no change in the price of contract or spot coal, which remain around $2.60 f.o.b. Hampton Roads, for standard New River and Pocahontas coals. The inferior grades are selling as low as $2.50, while high-volatile coals, of which there is always a small supply on hand, are bringing about $2.40 to $2.45. The movement continues good and the coal roads are all receiving new equipment, and placing further orders for still more. Contracts are being made on the basis of $2.85 f.o.b., but buyers are slow, apparently expecting a break in prices before April, but this is hardly justified by the present outlook.

Considerable talk is heard of the likelihood of a general strike in the West Virginia coal fields, based on the evident intention of the Miners Union to make a determined effort to effect an organizatiion of the miners in these fields, especially in the New River-Pocahontas section; it is quite likely that these efforts will be more successful than ever before, if persisted in.

There are still quite heavy accumulations of coal at the piers and the congested conditions at Newport News continue, although slightly improved, as is shown by the increased dumping. Dumping at Lamberts Point pier for January was 484,343 tons as compared with 482,102 for February; Sewalls Point handled 260,544 tons in January and 258,183 in February; Newport News, 243,571 and 284,706 respectively.

BIRMINGHAM, ALA.

Orders are now being booked by the domestic producers at the new schedule of prices, as follows:

Month	Fancy Lump	3x6-in. Lump
April	$2 50	$2 00
May	2 60	2 10
June	2 70	2 20
July	2 80	2 30
August	2 90	2 40
September	3 00	2 50
October		
November		
February	3 25	2 75

Protests are being made by some of the dealers at paying 25c. per ton more than for last season's coal, but this increase is necessary to take care of the advance in miners' wages and operating costs in general. It is a well known fact that the quantity of high-grade domestic coals in Alabama are more limited than are the steam and coking grades. Many of the domestic mines are already working to a great depth, which accounts for the high cost of mining this grade.

The steam market is approaching the season of the year when a natural decline takes place all along the line and it is not believed that the high prices ruling at this time can be maintained over a long period. Producers of blacksmith coal are enjoying an unusual era of prosperity and prevailing prices are higher than for many years past. Foundry cokes are in good demand and quotations firm. Virginia ovens, however, are shading prices to some extent and a sympathetic weakness may develop in the local market at any time.

INDIANAPOLIS, IND.

The coal situation remains unchanged, with the exception that the mines have been on shorter schedule. The report from Terre Haute is that 3000 miners have been idle and are trusting to a little colder weather that ushered March in, to improve conditions. But the cold spells this winter have, as a rule, been too short to get in good action before mild weather ensued. Prices both at the mines and in the retail yards hold steady, the former being at the bottom. The demand is so poor that there is no incentive for retailers to reduce quotations, so they are holding them at the high level that came in with the beginning of winter. There are some bargains to be picked up by them, but most of them had their winter supply contracted and have had enough trouble to dispose of that, without looking for more.

Steam coal is almost all sold on contract, but those who depend on the open market have had opportunity to get some cheap fuel. Operators are now concerning themselves with renewals for next season. Whether the experiences of retailers the past season will make them backward in entering into similar agreements for the future remains to be seen.

DETROIT, MICH.

Bituminous—With all the large users of steam coal well stocked, and the dealers with a large supply of domestic on hands, both the steam and the domestic markets bring the situation to a standstill. Slack is not strong but should be with the larger sizes as they are; however, the demand is not worrying shippers. The price is slightly affected, but it is predicted it will advance to normal.

Current quotations are as follows:

	W Va Splint	Gas	Hocking	Cambridge	Ohio No. 8	Pocahontas	Jackson Hill
Domestic lump	$1.50		$1 60	...	....	$1 75	$2 00
Egg	1.40	..	1 40	.. ..	...	1 75	2 00
1½-in. lump	1 25					....	....
¾-in. lump	1.10	$1.10	1.10	$1 10	$1 10	....	...
Mine-run	1 00	1 00	1 00	1 00	1 00	1 25	
Slack	1.00	1.00	1 00	1 00	1 00		

Anthracite—Demand for anthracite has been falling off until it is down to circular. However the bulk of hard coal for this vicinity is going at $5.75, for egg and stove and chestnut, $6 f.o.b. Suspension Bridge.

Coke—There seems to be an increase in demand for this product just at the present time. Connellsville is quoted at $3.50, Semet Solvay $4 and gashouse, $3.75 f.o.b. ovens.

CHICAGO

Dullness prevails in the Chicago coal market; prices, in a measure at least, are at the same level that usually obtains during the summer months. Some operators are selling coal at a loss of 5c. a ton or more.

Six-inch egg has been offered on the local market for shipment direct from the mines on the basis of 85c. and many of the Illinois operators seem willing to dispose of their coal at almost any price. Mines in Franklin County are being operated on about a half-time basis. While the Franklin County operators are adhering to reasonable figures, other companies are slashing prices right and left. The latter have been accepting $1.25 for high-grade domestic lump, egg and nut and in some instances have scaled the price to $1.10.

Springfield operators are selling domestic lump for $1.25 to $1.35. There has been a good demand for Hocking Valley coal, the price being firm at $1.50. Smokeless lump and egg ranges in price between $1.50 and $1.75. There is little activity in the coke trade.

Prevailing prices in Chicago are:

	Sullivan Co.	Springfield	Clinton	W Va
Domestic lump	$2 47	$2 07 @ 2 22	$2.27	
Egg	2 47			$3 95
Steam lump	$2 12 @ 2 37	1 92 @ 1 97	2 17	
Mine-run		1 87 @ 1 92	1 97	3 30
Screenings	1.67 @ 1 72	1.57 @ 1.62	1 67	

Prevailing prices for coke are: Connellsville and Wise County, $5.75@6; byproduct, egg, stove and nut, $5.50; gashouse, $5.50.

ST. LOUIS, MO.

Weather conditions have been more favorable to the coal men the past week than for over a month, but it was not of sufficient strength to create any market. Movement of coal for Northern points picked up some, but the local demand showed but a slight increase. The operators have settled down with the knowledge that there will be nothing more doing now until next fall, and many of the mines are making arrangements to shut down for several months.

For the last week or ten days coke has been a drug on the market, and the demand for smokeless coal has dropped off wonderfully. It has been actually hard to give away, at the circular or under, the different sizes of anthracite. The St. Louis coal market was perhaps never in a more deplorable condition at this season of the year than it is at the present time.

The circular prices are:

	Carterville and Franklin Co.	Trenton and Big Muddy	Mt. Olive	Standard
2-in. lump				$0 85 @ 0 90
3-in. lump			$1 15	
6-in. lump	$1 20 @ 1 25		1 25	1.00 @ 1.10
Lump and egg	1 25	$2 25		
No. 1 nut	1 10 @ 1 20			
Screenings	0 85 @ 0 90			0 60 @ 0 65
Mine-run	1 05 @ 1 20			0 80
No. 1 washed nut	1 35 @ 1 40			
No. 2 washed nut	1 25 @ 1 30			
No. 3 washed nut	1 20 @ 1 25			
No. 4 washed nut	1 15 @ 1 20			
No. 5 washed nut	1 00 @ 1.05			

MINNEAPOLIS—ST. PAUL

There are no new phases in the Northwestern trade at the present time. While the weather of the past two weeks has stimulated a few orders they have been few and far between. There has been so much free coal on track in this territory that few orders go direct to the mines. The Twin Cities during the past two months have been made a regular dumping ground for surplus tonnages and this has had a demoralizing effect on the market; in many cases such coal has been sold for the freight.

OGDEN, UTAH

February has been a good month both for the operator and dealers. In the early part of the month shipments were decreased slightly, due probably to the fact that most dealers anticipated warmer weather, but this condition did not prevail and orders were freely placed for additional shipments the month finishing quite strong. Conditions in Nebraska and Kansas have not improved and consignments to that territoty are at a low point. A general storm with lowering temperatures is now visiting these two states and if of any duration, should relieve the situation to some extent.

California is experiencing some wet weather and the Utah mines report good shipments to that territory; however, the prices for that market have been lowered to: Lump and nut, $2.50, effective Mar. 1.

Quotations throughout the balance of the territory remain unchanged as follows: Wyoming lump, $2.75; nut, $2.25; mine-run, $1.85; slack, $1; Utah lump, $2.75; mine-run, $1.85; slack, $1.25.

PORTLAND, ORE.

The cold weather is practically over for the winter and signs of spring have already appeared in the Pacific Northwest, particularly along the coast where the weather is seldom severe, although the temperature is low enough to create a good demand for fuel. Coal dealers here expect no changes in the market situation till next July when summer prices will undoubtedly be made upon the strength of concessions from the mines.

PRODUCTION AND TRANSPORTATION STATISTICS

PENNSYLVANIA RAILROAD

Statement of coal and coke carried on the P. R.R Co.'s lines east of Pittsburgh and Erie during last December and January, with the increase or decrease over the same period last year, in short tons:

	December	Difference	January	Difference
Anthracite	1,036,717	— 178,088	1,014,259	— 26,276
Bituminous	4,271,702	+ 290,216	4,210,196	+ 628,831
Coke	1,242,882	+ 331,911	1,288,514	+ 347,583
Total	6,551,301	+ 444,039	6,512,969	+ 950,138

VIRGINIAN RAILWAY

Total shipments of coal over this road for January of the current year were 453,886 tons as compared with 317,405 tons for the month previous.

BALTIMORE & OHIO R.R.

Coal tonnage moved over the B. & O. and affiliated lines during January of the current year was 3,003,404, as compared with 2,443,528, for the same month last year; coke tonnages for the same months were 439,176 and 329,556, respectively, making gross of 3,442,580 tons for 1913, as compared with 2,773,084 in 1912.

IMPORTS AND EXPORTS

The following is a comparative statement of imports and exports in the United States for the years 1910-11-12, and for December of 1911-12 in long tons:

	Year			December	
Imports from:	1910	1911	1912	1911	1912
United Kingdom	13,124	9,278	8,697	988	2,403
Canada	1,675,692	980,174	1,404,139	106,969	109,723
Japan	56,278	16,031	30,621	4,658	4,958
Japan	240,899	232,969	162,671	25,024	10,743
Australia & Tasmania					
Other countries	5,950	356	2,222	1	20
Total	1,991,943	1,238,808	1,608,350	137,580	127,847
Exports:					
Anthracite	3,021,627	3,553,969	3,688,789	241,244	283,831
Bituminous,					
Canada	7,567,297	10,609,587	10,433,010	691,847	594,309
Mexico	197,316	496,830	462,659	45,087	39,332
Cuba	675,980	470,674	302,487	21,003	33,480
West Indies	858,776	1,053,703	1,152,004	112,199	118,784
Canada	487,519	565,882	650,617	54,214	48,211
Other countries	697,351	682,138	1,459,201	74,062	76,109
Total	10,784,239	13,878,754	14,459,978	998,412	910,225
Bunker coal	6,445,593	6,667,338	7,340,100	548,844	578,667

FOREIGN MARKETS

GREAT BRITAIN

Feb. 21—Prompt business is difficult to arrange, owing to congestion at the docks. Colliery owners are adopting a very firm attitude forward, in anticipation of high pressure being maintained until after Easter. Small coals are very scarce and dear. Prices are approximately as follows:

Best Welsh steam	$4 44@4 56	Best Monmouthshires	$4 14@4 20
Best seconds	4 32@4 38	Seconds	3 96@4 02
Seconds	4 20@4 32	Best Cardiff smalls	3 72@3 84
Best dry coals	4 20@4 44	Seconds	3 36@3 60

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days—less 2½%.

British Exports The following is a comparative statement of British exports for December and January of the last two years, in long tons:

	December		January	
	1911	1912	1912	1913
Anthracite	221,359	230,803	241,924	298,308
Steam	4,255,304	4,210,302	3,945,278	4,417,993
Gas	910,950	829,435	827,198	901,364
Household	166,491	141,763	139,679	145,726
Other sorts	240,710	284,447	267,096	306,927
Total	5,793,911	5,697,368	5,421,175	6,070,318
Coke	115,956	97,409	113,871	107,095
Manufactured fuel	103,912	171,400	148,932	196,739
Grand total	6,010,770	5,966,177	5,683,978	6,374,152

BELGIUM IMPORTS AND EXPORTS

The following is a comparative statement of the imports and exports from Belgium for January, 1912-13.

	Imports		Exports	
	1912	1913	1912	1913
Coal	722,495	693,923	304,161	390,386
Coke	73,963	114,188	75,509	8,4080
Briquettes	31,756	10,146	38,228	40,641

FRENCH PRODUCTION IN 1912

Coal production of the Pas-de-Calais and Nord basins for the year 1912 was 29,888,015 tons, as compared with 28,152,993 in 1911. Coke production for the same periods was 2,443,142 and 2,328,715 tons, respectively.

FINANCIAL DEPARTMENT

Monongahela River Consolidated Coal and Coke Co.

President John A. Donaldson, under date of Jan. 15, reports, in part, for the fiscal year ended Oct. 31, 1912, as follows:

Trade improvement in the fiscal year balanced the special difficulties. The river was frozen up for 48 days during January and February, no loading being done at the river tipples, and there was an entire suspension of all operations during April in negotiating a labor wage scale, which together materially decreased production and lessened profits from the transportation department; but both were offset by an unusual demand during the lake shipping season and a betterment in prices.

Four steamers and one tug being out of commission, entirely dismantled, and valued on the books at $142,452, with a depreciation fund of only $50,753 to the credit of the account, left a balance of $91,699 unprovided for. It was decided as an equitable disposition of such balance to charge one-half, or $45,849, against the profits of the fiscal year just ended, and the other half against undivided earnings account, for the reason that some of these boats have been out of commission for several years. Adjustment of the active river craft equipment net book value to its present trade worth is being considered.

COAL ACREAGE PURCHASED TO DATE, MINED OUT AND SOLD—REMAINDER

	Orig. Purchased	Since 1899	Total	Mined Out	Balance
Pennsylvania	33,075	6,551	39,626	22,754	16,872
Kentucky	2,119	558	2,677	242	2,435

[A reserve fund of $100,000 each has been created to provide for future loss by fire and sinkage.

Bonds have been redeemed and canceled during the year amounting to $214,000. Certificates of indebtedness have been redeemed during the year amounting to $145,000.]

Total	42,410,700	43,142,466	Total	42,410,700	43,142,466

There was an increase of 14% in tonnage sales of steel, yet as most of the smaller products, representing about 30% of total output, were sold at generally lower prices, there was not a corresponding gain in steel department earnings, though the ratio of increase in gross was maintained in the net earnings.

COAL SECURITIES

The following table gives the range of various active coal securities and dividends paid during the week ending March 1:

Stocks	Week's Range High	Week's Range Low	Week's Range Last	Year's Range High	Year's Range Low

No Important Dividends were announced during the week.

⁂

The Rock Island R.R. Co.—This corporation owns stock in coal companies as follows: Coal Valley Mining Co., $50,000; Consolidated Indiana Coal Co., $2,400,600; Crawford County Mining Co., $100,000; Dering Coal Co., $1,700,000.

Burns Bros.—The recently formed consolidation under this name will have net tangible assets after depreciation allowance of $2,407,309. This figure includes only the salvage value of equipment carried at $269,000, and which is appraised at $1,029,100, the difference, $760,000, having been transferred to the item good will, leases and contracts.

Pittsburgh Coal Co.—This company was incorporated in New Jersey, September, 1899. It owns about 150 coal mines and 100,000 acres of coal land in or within a radius of 40 miles of Pittsburgh, together with 5000 coal cars, operating over railroads radiating from Pittsburgh. Dividends paid were: On preferred, 1900 to April, 1905, 7% yearly; 1906 to 1909, none; 1910, 1911 and 1912, 5 per cent.

Reading Co.—In 1896 this corporation was bankrupt, but in the past decade it has expended from income, on additions and betterments, an amount equal to 45% of its $70,000,000 common stock. This is at the rate of $3,150,000, or 4½% per annum. For the fiscal year ended June 30, 1912, this expenditure was $3,469,482, and had this not been charged to income, the common dividend would have amounted to 12½% for the fiscal year.

Jefferson & Clearfield Coal & Iron Co.—This company was organized under the laws of Pennsylvania in May, 1896. The maximum production per year so far was 2,595,161 tons. The $1,500,000 common and $300,000 of the $1,500,000 of 5 per cent. noncumulative preferred stock is owned by the Rochester & Pittsburg Coal & Iron Co. On the common stock 5 per cent. was paid in 1900, nothing in 1901, 5 per cent. per annum during 1902 to 1905, since which date nothing further has been paid. On the preferred stock 5 per cent. per annum has been paid regularly since August, 1897.

PRICES OF MINING SUPPLIES

MARKETS IN GENERAL

Business did not improve during February, either in the volume of orders, or in sentiment. The distinct feeling of unrest which was discernible a month ago continues, and the most disquieting thing about it is that it is as prevalent in the agricultural region as in eastern cities. Business men seem to be afraid of a number of different things, which in all probability will pass away without leaving any mark on affairs.

The continual drawing of gold from the United States to Europe must soon have a serious effect on interest rates and money conditions here. The continent of Europe has been hoarding currency, and in as large amount as was laid away in the United States during the money panic of 1907.

The continued unrest in the Balkan States and an outbreak of a revolution in Mexico have not been favorable factors in business.

The steel market is barely holding its own. Prices have shown practically no change, but the demand is falling off. This is not at all serious, and the unfilled orders of the U. S. Steel Corporation decreased less than 2% in the month of January. Since that time, too, there has been an almost unheard of amount of buying by the railways of cars, locomotives and all kinds of materials. Those conversant with the situation appear to think that the railways will secure their desired increase in rates some time this year.

Labor conditions are not especially unsatisfactory, although there are a number of strikes reported, including a rather serious one among the carbuilders on the railways. The fact that the firemen on the railroads and the railway managers have reached an agreement regarding the arbitration removes this danger, and at one time it was a serious question whether or not a strike could be averted.

Continued activity is noted in shipbuilding work. Several new vessels have been laid down, or plans prepared during the last month, and the activity continues as great as ever.

LABOR

The defeat of the attempt to pass the Immigration Bill over the veto of the President is one of the most important topics which has confronted the labor world for some time. While it may be granted that a strieter supervision is needed of some of the immigrants coming into the country, it does not mean, by any stretch of imagination, that we are to put up barriers against all comers except those who can pass an elaborate educational test. What the country needs is the best kind of workers it can obtain, workers who are capable of wielding a pick and shovel, without any pretension as to educational fitness.

The threatened strike of the firemen on the railways was averted at, almost the last moment. Some hold the opinion that it would have been better to have had a strike at this time, fighting it out once and for all, and thrashing the matter out regarding higher freight rates and the like, even if it did stop business, and cause discomfort to thousands of disinterested people. It is a test of the Erdman Act which may go a long way toward its further use in industrial dissensions, or result in a modification of the bill to make it more applicable to all kinds of disputes. As the railway managers claim, it does put an enormous responsibility on the third arbitrator.

Unrest continues among the garment workers in New York, one result of which has been the establishment of factories outside of New York City. On the Lehigh Valley, men employed in the car building and repair shops are striking in Buffalo, and there is a threat to carry the trouble all along the line.

IRON AND STEEL PRODUCTS

Continued activity in the purchase of rolling stock, rails and track fastenings by the railroads, has been the interesting feature of the market during the month. The railroads have been just as active buyers as they were during the last month of 1912, and, had general mercantile consumers purchased as freely as they did then, the tonnage disposed of would have been as large, if not larger, than at any other time in the last year. As it was, the early estimates regarding the total booking of steel orders during February were revised more than once during the month, and while it is probable that some diminution will be shown in the volume of orders on the books of the leading steel company, these will be by no means as large as was first expected. The fact that orders fell off less than 2% in January, is sufficient reason to believe that the present activities in steel production will continue for the next six months, at least.

Building operations were larger in January than last year, and, outside of New York, indications are that they will continue just as large as during 1912. Manufacturing concerns are making some additions and extensions to plants, but these are by no means as numerous as they were last year.

The decline in coke has affected sentiment, and a further weakening in the price of foundry iron in Birmingham has had a depressing effect on eonsumers who ordinarily purchased in that market. There has been very little pig iron sold for forward delivery during the last month.

Iron trade conditions in Europe are not as satisfactory as they were, and, in Germany especially, prices are only maintained through the operation of a strong syndicate. It is probable that there will be more active competition for export orders this year than last.

The scrap market shows an improvement in the West, but in the Pittsburgh district there is a continued falling off in the number of new orders, and prices have likewise declined.

Rails—A significant feature of the buying of rails this month has been the comparatively large number of orders, all of them for small lots. Big railway companies have purchased freely, and these purchases are much earlier than usual. More activity is noted in light rails than in any other branch of trade, and there is considerable delay in making shipments.

Quotations continue unchanged as follows: Standard sections, 50 to 100 lb. per yd., 1.25c. per lb.; 40 to 50 lb., 1.21c.; 12 lb., 1.25c. Relaying rails in Chicago of standard sections are held at $24 per ton.

Track Supplies—Specifications on contracts are heavy for all kinds of track supplies, but spikes seem to be in especially large requisition. The Great Northern recently ordered 15,000 kegs of spikes; the Pennsylvania is taking as many spikes as can be sent it by the two mills making special kinds used by this railroad, and other railroads are having difficulty in securing the materials needed.

Prices of spikes are $1.90 to $2 for small lots, but for prompt delivery, as high as $2.25 has been paid in Pittsburgh. In Chicago, prices are $1.95 to $2.05; track bolts with square nuts, $2.30 to $2.40; angle bars, $1.50. These quotations are per 100 lb. An especially heavy demand is noted for tie plates, and probably more have been sold this year than ever before. Quotations are from $32 to $34.50 per net ton.

Structural Materials—The market is considerably better than for several weeks past, and quite a little new work is cropping up, especially in the West. Most of this is for small jobs, although an order for 15,000 tons of merchant shapes for the Newport News Shipbuilding Co. has been taken and some enormous orders have been placed for cars. There is a prospect that contracts for the operation of the new subways in New York will be signed this week which will call for a great deal of structural material. The trade has been expecting these contracts for a long time.

Much plate work is being taken for water supply, as well as for cars and shipbuilding work. Prices for structural shapes are unchanged at 1.50 to 1.55c. Pittsburgh, for future delivery, and 1.75 for prompt. In Chicago, quotations for future shipment are made at 1.58 to 1.78c., while prompt delivery commands 1.88 to 1.93c. Plates are held at 1.55 to 1.60c. Pittsburgh, for future delivery, and 1.75 to 1.80c. for fairly prompt. In Chicago, plates are 1.68 to 1.73c. on contract, and 1.88 to 1.93c. for nearby shipments. These are base prices, and small sizes are held at advances above this quotation. All quotations are per 100 lb.

Pipe—Business continued just as heavy during February as in January. Some large orders have been received from Canada where a great deal of work is going on in natural gas fields. For the smaller sizes of pipe, the demand is not quite as active as a month ago.

Discounts continue unchanged as follows: Steel pipe, 1½-in., in large lots from mill, black, 77%; galvanized, 66%; ¾ to 2-in. black, 80%; galvanized, 70½%; 2½- to 6-in. black, 79%; galvanized, 70½%.

Based on these discounts, the net prices of pipe are as follows in carload lots, f.o.b. Pittsburgh:

Size, inches	Cents: Black	Cents: Galvanized
¾	2.30	3.40
1	3.40	4.85
1¼	4.60	6.55
1½	5.50	7.70
2	7.40	10.30
2½	11.50	16.70
3	15.40	21.75

Sheets—Business offered the mills for third-quarter delivery at present prices has been refused, and many jobbers would be willing to place orders for such shipments, provided they would be accepted at these quotations. Activity continues, and many orders are being received for delivery during the first half of the year, yet there are only a few mills that can spare any tonnage for delivery before July. On the ordinary grade of black and galvanized sheets, mills are from twelve to fourteen weeks behind in shipments.

Should the general steel business improve, there seems to be little doubt that prices will be advanced from $1 to $2 per ton later in the year. The following table gives the price of sheets in Pittsburgh, and likewise in Chicago:

	Cents per pound: Pittsburgh Black	Pittsburgh Galv.	Chicago Black	Chicago Galv.
Nos. 22 to 24	2.20	2.90	2.65	3.60
Nos. 25 and 26	2.25	3.10	2.70	3.65
No. 27	2.70	3.25	2.75	3.90
No. 28	2.85	3.40	2.90	4.15

WIRE PRODUCTS

Wire—Business continues active, with more orders being received than is usual at this time of year. One mill has advanced its quotation on wire nails, but other mills have not followed. Quotations are unchanged, painted barbed wire in Pittsburgh being held at $1.75, and galvanized at $2.15. Annealed fence wire in carload lots is $1.55 and galvanized in $1.05. In Chicago, annealed fence wire is $1.73; galvanized, $2.13, while barbed wire in that market is $1.93 and galvanized $2.33. All of these quotations are per 100 lb.

Wire Rope—Prices are without change, 2-in. rope being held in Pittsburgh at 57c. per ft.; 1¼-in., 23c.; ¾-in., 10c. These quotations are the minimum for large lots, and for the better grades, higher quotations are demanded.

Telegraph Wire—Prices are without change for lots of fair size. Measured in Birmingham Wire Gage, the prices in cents per lb. are as follows: "Extra Best," Nos. 6 to 9, 4⅝c.; Nos. 10 to 11, 4½c.; No. 1, 4⅝c.; No. 14, 5⅛c.; "Best," Nos. 6 to 9, 3½c.; Nos. 10 and 11, 3⅝c.; No. 12, 3½c.; No. 14, 4c. Actual freight is allowed from Trenton, N. J., where it does not exceed 25c. per 100 lb.

Copper Wire—As a result of the steady decline in copper metal, the prices of wire declined, almost, day by day. The base price now quoted is 16c.

MISCELLANEOUS

Bar Iron and Steel—Prices are unchanged from last month, and quotations from jobber's store, either New York or Chicago, are as follows:

	Per lb.
Refined iron:	
1 to 1⅞ in., round and square	2.15c.
1½ to 4 in. x ¾ to 1 in.	2.15c.
1½ to 4 in. x ¼ in. to ½ in.	2.35c.
Norway bars	3.60c.
Soft steel:	
¾ to 3 in., round and square	2.10c.
1 to 6 in. x ⅜ to 1 in.	2.10c.
1 to 6 in. x ¼ and ⅝ in.	2.25c.
Rods—⅝ and ½ in.	2.20c.
Bands—1½ to 6 x 1/16 in. to No. 8	2.40c.
Beams and channels—3 to 15 in.	2.25c.

Nails—The demand is not as heavy as a month ago, but is as large as usual for this time of year. Stocks are not large, as manufacturers of nails who make other wire products are devoting as much raw material as possible to other lines which are more profitable. Quotations are unchanged as follows: Large lots of carloads and over are $1.75 Pittsburgh. In Chicago, carload lots are $1.98; less than carload lots $2.03. In New York, wire nails from store are $2.05. Cut nails are $1.70 to 1.75, Pittsburgh, and $2.05, New York. All of these quotations are per 100 lb.

Packing—There is more demand for packing than a month ago, and quotations are as follows: Asbestos wick and rope, 13c.; sheet rubber, 11 to 13c.; pure gum rubber, 40 to 45c.; red sheet packing, 40 to 50; cotton packing 16 to 25c.; Russian packing, 9 to 10c.

Brattice Cloth—Prices are higher than last month and no relief appears to be in sight before the end of the summer at least. The mills are now quoting on April, May and June shipments which, of course, means late arrivals. The deliveries are still delayed. Despite the usual February dullness, the volume of business seems normal.

Chain—Prices of chain are firm, but the buying has not been especially large. Ruling quotations per 100 lb., f.o.b. Pittsburgh, are as follows:

1/4 in.	$7.50
5/16 in.	4.95
3/8 in.	3.95
7/16 in.	3.40
½ in.	3.20
½ and 9/16 in.	3.00
5/8 and 11/16 in.	2.90
¾ and 13/16 in.	2.80
7/8 and 15/16 in.	2.70
1 to 1¼ in.	2.60
Extras for BB	
¼ in.	1.50
5/16 in.	1.50
⅜ in. and larger	1.25
Extras for BBB	
¼ and 5/16 in.	2c.
⅜ and larger	1.75c.

Portland Cement—The market is especially firm, [illegible] manufacturers in New York State are securing as much as $1.10 per bbl. in bulk at the mills. The greater part of the business transacted for mills in the Lehigh Valley district is at 90c. per bbl., but some few sales have been made around 95c. Quotations in Pittsburgh and New York delivered are $1.58 per bbl. with an allowance of 40c. for the bags returned. These are for shipments in cloth bags.

Manufacturers of cement are especially optimistic over the situation, and believe that the present year will be make a new record in the matter of shipments and are also of the opinion that prices may work somewhat higher as the season advances.

Bars, Concrete Reinforcing—The demand has not been as active in the last month as previously, and some of the largest interests are refusing to sell bars beyond July 1, at the quotation of $1.50 Pittsburgh. The supply from warehouse stock is somewhat better than a month ago, and likewise mill shipments are being made a trifle more promptly.

PITTSBURGH PRICES IN CENTS PER POUND

	Mill Shipments	Warehouse Stock
¾-in.	1.50@1.55	2.00@2.10
⅝-in.	1.55@1.60	2.05@2.15
½-in.	1.60@1.70	2.10@2.20
⅜-in.	1.70@1.80	2.25@2.35

Triangular Mesh—Business is active, but producers are able to ship promptly on receipt of orders. Stocks are very fair, and a large production is looked for this year.

From mill in De Kalb, Ill., quotations are 18c. per 100 lb. higher. Prices are as follows per 100 sq.ft., f.o.b. Pittsburgh district, for less than carload lots and lots of more than 10,000 sq.ft.:

No. 3	$1.23	No. 32	$2.62
No. 23	2.05	No. 36	1.05
No. 26	1.42	No. 40	3.25
No. 28	1.97	No. 41	2.48

THE MULE MARKET

Mules—The demand for mules in Kentucky and Tennessee is reported to be active. Two-year-olds have sold recently at Danville, Ky., at from $120 to $150 per head. Buyers in the Lancaster, Ky., market have paid from $175 to $215, while several excellent pairs have sold at $550. Four hundred mules were sold at Mt. Sterling, Ky., recently, at from $200 to $350 per head. A large lot of three-year-old mules sold in Danville recently brought $160 per head. Prices in the Paris, Ky., market range from $200 to $225. Five hundred mules disposed of at a recent sale at Franklin, Ky., brought prices ranging from $125 to $250. Fancy prices are being quoted in some of the Tennessee markets. At Lawrenceburg, pairs are selling at as high as $600. Lynchburg, which, with Columbia, takes rank as the leading mule market of Tennessee, has shipped over 1800 mules this season. Some unusually high prices have been paid for the fancy stock offered there, the record price of $900 being paid for a single pair recently. The average is about $275 per head. Two pairs of two-year-olds sold recently for $1025. A Louisville, Ky., mule firm recently purchased three carloads of mules in Hardin County, Ky., at $250 a head.

COAL AGE

Vol. 3 NEW YORK, MARCH 15, 1913 No. 11

Payday at the Mine

By Berton Braley

Written expressly for Coal Age

I

Say Jimmie, git the whiskey out
An' order up the gin,
We want the boys to go the route
When they come rollin' in,
It's booze that starts 'em in to spend
An' gits 'em feelin' fine,
Till each guy's treatin' of his friend
—It's payday at the mine.

II

They stops fer just one little drink
To wash their throats of coal,
We'll keep 'em blowin' in their chink
Until we git their roll,
An' if it gits 'em wild an' rough
Or lyin' round like swine,
Aw, we don't care, we got the stuff
—It's payday at the mine.

III

If, full of booze, they row an' fight
An' bruise an' smash an' maim,
Aw well, we got our cash all right
An' they—they gits the blame,
It's they that has to go to jail
Or pay the court their fine,
An' we're the boys that gits the kale
—It's payday at the mine.

IV

They risks their lives an' sweats to make
Their little wad of pay,
But we're the wise ones—an' we take
The most of it away,
So let their women weep an' cry
An' let their children whine,
We're coinin' dough an' livin' high
—It's payday at the mine!

Coal Mining in Carbon County, Utah

By A. C. Watts*

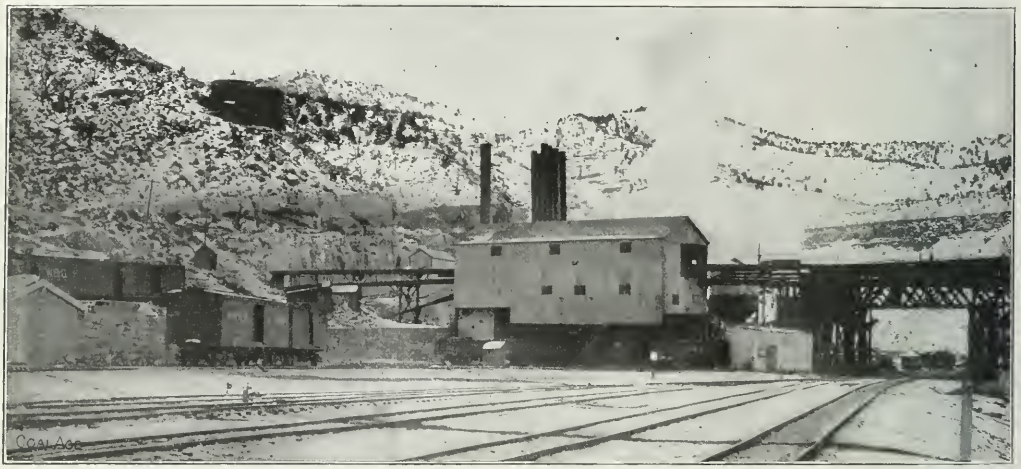
SYNOPSIS—Description of one of the most important of the Western coal fields. Relatively thick seams prevail and mining conditions are generally favorable. The district is subject to those peculiar freaks, which have on occasions proved so disastrous, termed "bounces." Dikes and faults are encountered and the crop coal has been found burned for a distance of 1500 ft. from the surface.

The advent of railroads in Utah marked the dawn of coal mining in this state. Soon after the completion of the Union Pacific R.R. in 1869, mines began to be opened, and in 1871 the Summit County R.R. began operations between Echo on the Union Pacific R.R. and the mines at Coalville, a distance of nine miles. In 1880 a line was in operation between the Coalville mines and the rich silver and lead mines at Park City, which required a cheaper fuel for their operations than the timber found on the mountains. In 1876 the Utah and Pleasant Valley R.R. commenced operations between the coal fields of Pleasant Valley at Scofield and the town of Springville.

This date probably marked the first coal mining on a commercial scale in Carbon County. In 1881 the Rio Grande Western Ry. began construction between Salt Lake City, Utah, and Grand Junction, Colo., connecting with the Denver & Rio Grande R.R. at the latter point. In 1889 the coal deposits at Castle Gate on the main line of the Rio Grande Western were opened and the second mine for commercial business in Carbon County came into being. This date has some significance not only in the history of coal mining in Utah, but in the United States as well, for it was at this mine, at about this date, that the dangers of coal dust were fully recognized and sprinkling by hose, the turning of exhaust steam into the mine, the use of electricity in the coal mines of the state and the practice of shooting from the outside of the mine with electricity, after all the men were out, were first introduced.

Although the coal measures of Utah embrace a wide territory and mining is being carried on in many places, by far the greater part of the coal produced, approximately 90 per cent., comes from Carbon County, so that a description of the methods employed by the companies operating there will cover the best practices in the state.

Carbon County lies approximately in the center of the state. The county seat, Price, a town of about 2000 inhabitants, is situated 121 miles east of Salt Lake City on the D. & R. G. R.R., and lies in the center of the agricultural district of the county. It is also an outfitting point for freighters to the Uintah Reservation.



Utah Fuel Co.s Steel Tipple and Screening Plant at Castle Gate

The principal drainage stream of this county is the Price River which heads in the Wasatch Mountains at Soldier Summit and also near the Scofield coal-mining district. The waters from this drainage area flow east in the Price River to the Green River, thence south in the Green to the Grand River, and south and southwest in the Grand to the Colorado, which empties into the Gulf of California.

Outside of the coal-mining towns of Castle Gate, Clear Creek, Winter Quarters, Sunnyside, Kenilworth, Black Hawk and Hiawatha, the principal towns of the county are Price, Helper (a D. & R. G. R.R. division point) Scofield and Wellington. The D. & R. G. R.R. is the only trunk line passing through this territory and Castle Gate is the only coal-mining town on the main line of the railroad. All other camps are reached by branch lines of the D. & R. G., or by railroads under the control of the mining companies.

The coal production of the county in 1912 was 2,750,265 short tons, an increase of 504,210 tons over 1911. Practically two-thirds of the total production of the state is consumed within its boundaries, the amount be-

*Chief engineer, Utah Fuel Co., 722 Judge Bldg., Salt Lake City, Utah.

ing almost equal to the total output of Carbon County. The balance of the production goes to Idaho and the Northwest, Nevada and the Southwest, and to California.

The coal of the various seams is a good bituminous variety, and, although there are many grades having a coking tendency, none but that from Sunnyside field make a good coke. The coal as a rule is hard and clean and stands storage and shipment well. The analyses will vary generally between the two following:

Moisture	3.49	1.87
Volatile matter	43.35	39.22
Fixed carbon	47.23	54.78
Ash	5.93	4.13
	100.00	100.00
Sulphur	0.67	1.022

A good ultimate analysis is about as follows:

Hydrogen	5.07
Carbon	79.06
Nitrogen	1.09
Sulphur	0.76
Oxygen	10.03
Ash	3.99
Calories	7720

of the Cretaceous period. There are three formations, locally known as the Upper, Main and Sub, coal horizons.

On top of the Upper horizon is a massive gray sandstone from 200 to 700 ft. thick, called the Castle Gate Reef. This forms the high vertical cliffs seen from the train in the Price Valley Cañon in the vicinity of Castle Gate, and near the bottom of the formation are some shale and thin coal seams.

The Upper Coal Horizon is from 200 to 500 ft. thick and consists of thin beds of sandstones and shales with thin seams of coal, occasionally 5 ft. thick, occurring locally. At present these seams have no commercial value.

The Main Coal Horizon is from 200 to 500 ft. thick and consists of alternating beds of sandstones and shales. The latter are often arenaceous and the sandstones, massive. In this horizon are all the workable coal seams at present known in this field with the exception of the Sub coal seam in Spring Cañon between Castle Gate and

General View of the Town of Kenilworth in Carbon County, Utah

Average analysis of the coke is as follows:

Moisture at 115° C.	0.15
Com. volatile matter	1.05
Fixed carbon	88.61
Ash	10.19
Total sulphur	1.25

The roof and floor as a rule consist of hard, unyielding sandstones, although in some places there will be a few feet of shale on top of the coal. When two seams come to within a few feet of each other the parting is often a shale. The roof is generally so good that it is misleading and operators are sometimes led to trust too much to it. After extensive areas have been opened up, and the extraction of pillars begun, roof troubles often start and "bounces," which do much damage to pillars and are a serious menace to life, occur. The amount of cover over the coal varies, of course, a great deal; some mining is being done under 1500 to 2000 ft. of cover.

Geology

The coal measures in Carbon County occur in the Laramie, or as some call it, the Mesa Verde formation

Helper. There are two, and sometimes three, workable seams varying in thickness from 5 to 20 ft. The Castle Gate seam is the most important one in the district, and, although it pinches out in places, it is generally between 5 and 18 ft. in thickness. This seam rests on what is known locally as the Castle Gate coal floor, a massive, grayish white sandstone from 60 to 80 ft. thick, which serves to identify the seam and the workable horizon.

The Sub Coal Horizon is from 100 to 160 ft. thick and lies directly under the Castle Gate coal floor. One seam of this horizon, though usually thin, occasionally attains a workable thickness as noted above. This seam rests on a sandstone floor of from 10 to 60 ft. in thickness which lies on the Montana Shales.

The pitch of the seams varies in different localities from practically level to 10 or 12 per cent., and the two extremes may be found within a few miles of each other. The Scofield district, or Pleasant Valley coal fields, is traversed with north and south faults having throws ranging from a few feet to 1500, and with many cross faults, which add considerably to the difficulties and ex-

pense of mining. Dikes are encountered as thick as 50 ft. The width of these dikes does not seem to have any influence on the amount of coking of the coal; the smallest dikes sometimes have the greatest amount of coked coal adjoining them. These dikes, as encountered in the mines, run approximately east and west.

From the Castle Gate district east, great areas of burnt coal are encountered. In many places the burning has penetrated a distance of 1500 ft. from the outcrop. It is usually the case that the upper seams have been burnt the most; the lower ones are often found to be good for a considerable distance under a burned area of the upper seams. This burning must have occurred many years ago, as evidenced by the growth of trees over some parts of the burnt area.

rock from weathering, minimizes the amount of timber required, and affords an easy way of recovering a large percentage of the coal.

Entries as a rule are driven on sights as well as rooms, as experience has shown that water-level entries make the maintenance of proper pillars for safe mining difficult because the seams are so irregular. The seams are so thick, as a rule, that the grading of entries is comparatively easy and inexpensive. The pillars between entries will vary between 30 and 60 ft. with barrier pillars between the rooms below of from 50 to 150 ft. Main slopes and haulageways have thick pillars, from 100 to 250 ft. on each side. The general heavy cover requires substantial pillars and careful work in drawing them. All mines thus far opened are slopes or drifts. The pos-

Inspection Party at the Kenilworth Mine. Note the Great Thickness of the Seam

System of Mining

The room-and-pillar system of mining is generally practiced. Rooms vary from 18 to 30 ft. wide, according to mining conditions. Where mining machines are used in low coal, the rooms are 30 ft. wide and have two tracks, one on each side. Pillars between are from 30 to 50 ft. thick, depending upon the nature of the coal, roof and floor and depth of cover. The length of rooms will average 350 ft. Those in pitching seams are turned off level entries at such angles as will permit them being worked on, or quartering to, the face cleavages of the coal and not have the grade too steep for animal haulage. In large seams, from 11 to 18 ft. thick, a roof of coal varying generally from 3 to 8 ft. is left up until retreating is started. This method gives additional safety to the miners, as the coal forms a good roof and protects the

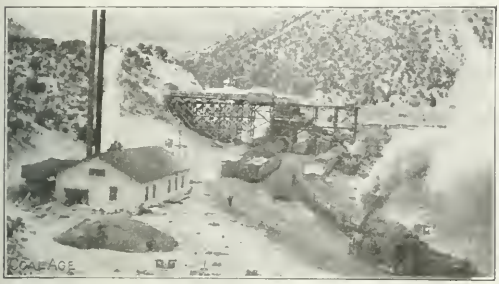
sibilities of shaft mining are limited as the mountains are precipitous and high.

Undercutting the coal by hand is followed at many of the mines, and in some places where conditions demand, overcutting is practiced. The undercutting by chain-mining machines is being introduced and will probably be followed to a greater extent in the future. The continuous cutter, short-wall machine seems to be the best adapted to the work. In several mines shooting off the solid is still in vogue. Black powder is still used at some mines, but the use of permissible explosives is becoming more general.

Shotfiring and Sprinkling

In some mines shotfiring is done by the miners, usually at stated periods during the day. Shotfirers or in-

spectors are employed, whose duty it is to continually inspect the preparation and firing of shots. Rigid inspection is the general practice, as the explosive nature of the coal dust has taught operators to be careful. At two of the mines of the Utah Fuel Co., Castle Gate and Sunnyside, shotfiring by electricity from the outside, after all men and animals are out of the mine, has been prac-



Surface Plant at the Hiawatha Mine

ticed with excellent results for years, and this is looked upon with favor by most people. This method of firing was adopted at Castle Gate about 1889, and as far as is known this was the first time this commendable safeguard was tried. It was the outgrowth of a series of experiments to reduce the number of dust explosions and was used in conjunction with sprinkling and exhaust steam. With electric shotfiring both dynamite and permissible explosives are used, with wet wood pulp or clay tamping.

The state mine law requires all mines not naturally damp to be thoroughly wet down by some sprinkling device, although the moistening by turning in live or exhaust steam is recognized when shown to be efficient, and this method is used in many dry mines. Not only is the floor sprinkled, but the sides, roof, timbers, overcasts, brattices, doors and in fact all places in the open parts of the mines where dust can lodge. The dust must be so wet that it can be easily pressed into a ball by the hand. The mines are laid with pipe and the places sprinkled by hand through hose carried by regularly employed sprinklers.

Water is pumped into the mines in most cases, although in some mines the pumps are so connected as to be used in part for this purpose. Pipes are laid in the return airways when there is any danger from freezing in the cold weather. In the intakes where the water freezes, salt is used. While sprinkling has been compulsory since about 1900, it was adopted at the Castle Gate mine of the Utah Fuel Co. as early as 1889, and sprays, operated by steam in connection with the water, were placed at regular intervals along the main intake. That the system has proved its worth can be shown in many ways as, for instance: Samples of dust have been taken from abandoned places where there was no water, and which had not been sprinkled for four years, and have been found to contain 50 per cent. moisture, and were of about the consistency of mud. The objections that dust cannot be successfully moistened; that moisture injuriously affects the roof and the health of the men; that it forms wet places which seriously inconvenience the men, have been proved not to apply in this region.

Gases and Methods of Ventilating

Explosive gas is found in some mines, although in but one is it in sufficient quantities to make the use of safety lamps imperative. These are, however, used in other mines in the pillar workings where bounces sometimes occur. This is found to be necessary, because the dust generated by the bounces crushing the pillars, can be readily fired by open lights.

Ventilation is accomplished entirely by mechanical means and there are various types of fans. The older installations were large, slow-speed fans, but of late the adoption of the smaller, high-speed type is coming more into vogue. Most of the fans are situated near the power houses so that steam is used to run them, but when the workings are at some distance, electricity is used. Almost all fans are run exhausting and are equipped with reversing doors; they are generally so located that they have not been destroyed by the explosions in the past. Some booster fans of the Stine variety are used and have given excellent results. The split system of ventilation is used almost entirely, the state law requiring that not more than 75 persons shall work at the same time in one split.

Consolidated Fuel Co.'s Upper Camp and the Hiawatha Mine Opening

The law also requires 100 cu.ft. of air per min. for each person and 300 cu.ft. for each animal. Stoppings and overcasts of concrete are becoming more popular.

Haulage and Hoisting

As a general rule all gathering from rooms to partings is done by animals, heavy horses being used a great deal. In pitching seams the coal is taken to partings in level entries and either let down or raised to the main haulage-roads where locomotives take it to the tipple. Few steam

hoists are used, electricity being the general practice. At some mines it is necessary to have long outside rope tramways to lower the coal to the tipples.

Cars are generally made of wood with a capacity of from one to three tons and track gages from 36 to 42 in. Gathering locomotives are used in some mines where the coal seams are flat. Main haulage locomotives vary in weight from 6 to 15 tons. Sixteen-pound rails are used in rooms and from 30 to 60 lb. for main haulage roads.

All mines have their own steam-power plants using run-of-mine, slack and sometimes dust under the boilers. The majority of boilers used are the horizontal, return-tubular type of from 125 to 150 hp., although there are some internal furnace boilers used, having steam pressures of between 100 and 150 lb. At some mines American Automatic stokers are used. Of late there is a tendency toward central power plants for mines of the same company, situated within a few miles of each other.

Almost every mine is using electricity for hoisting, haulage and lighting. Reciprocating engines, direct connected to the generators, have been the usual installations up to the last year when turbo-generators appeared in the field. Direct current, of voltage varying from 250 to 500 is used in the mines, while alternating current of from 2200 to 4000 volts is used for transmission lines outside the mines. This is converted to direct current by motor-generator sets at the mines.

Preparation of Coal

All mines where commercial coal is mined are equipped with shaking-screen plants, making four principal sizes, as follows:

Lump over 4½ in. round perforations
Nut through 4½ in. and over 1¼ in. round
Slack through 1¼ in. and over ¾ in. round
Dust through ¾ in. round

These sizes will vary a little, owing to the nature of the coal, as some break into more angular and slabby shapes than others. At mines where the coal is wet, rescreening of the smaller sizes, by means of revolving screens, is resorted to. At the Winter Quarters mine of the Utah Fuel Co., in the Pleasant Valley district, the first steel tipple and screening plant was built in the winter of 1909-10. At the Castle Gate mine of the same company the second steel tipple and screening plant was built in the summer of 1912, while the third installation of this kind is being erected by the Spring Cañon Coal Co.

The general practice is to dump the coal by Phillips or Wilson cross-over, or rotary dumps, after having been weighed with registering scales, into receiving hoppers, from which it is fed to the shakers by reciprocating feeders. As the seams mined are, as a general rule, clean throughout, picking is not resorted to, to any extent, and washing is unnecessary. Picking can be done at some plants which use conveyors for carrying the coal from the receiving hoppers to the screens. The boxcar loaders, used for loading run-of-mine, lump and nut into box-cars, are the Ottumwa and Christy types.

Railroad Yards

Railroad yards at the mines are laid out to suit conditions and no general plan is or could be adopted. At some plants there are tracks for each grade of coal, with scales under the tipple on each track. At others, one track may be used to serve for two and sometimes three different sizes of coal. Another plan is to have but one track scale, with deal rails, on which all cars, empties and loads are weighed with a locomotive. At the Castle Gate mine of the Utah Fuel Co., two railroad track-scales are used, one above the tipple for weighing empties and one below for the loads. As all the mines are located in mountain cañons, the grades of the yards must conform in most cases to those of the cañons and as high as 4 per cent. is found.

The only coking is done by the Utah Fuel Co. at its Sunnyside mine, where it has 650 beehive ovens. The production of coke in 1912 was 347,356 tons, an increase of 134,988 tons over 1911. The coal for coking is crushed to pass through a ⅜-in. square opening.

Tipple and Incline at the Kenilworth Operation

Nationalities Represented and Sociological Conditions

Of a total of 4063 men employed at the mines Americans comprise 35 per cent., Greeks 30, Italians 16, Austrians 11, Japanese 3 and Negroes, French, Scandinavians, Swedes and Germans make up the balance, or 5 per cent. During 1912 the larger producers averaged 280 working days and the average tonnage per man was 770.

As most of the mines are situated in mountain cañons, the laying out of towns in a regular manner is a difficult proposition, and as water is a rather expensive luxury, the possibilities of having attractive homes with lawns and gardens are limited. The altitude of some of the camps adds to the difficulties of garden making, and none but the hardiest and quick growing variety of flowers can be raised in these places where heavy frosts often occur in midsummer.

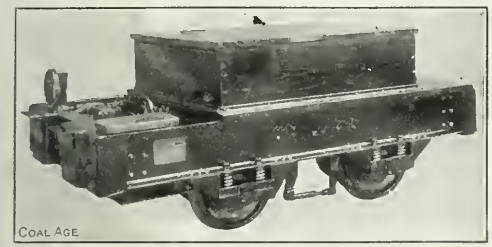
Mines are equipped with Draeger helmets, and have regularly trained men ready for emergencies. The motto, "Safety is the First Consideration," is evidenced by the methods adopted at all mines.

A Storage Battery Gathering Motor

Special Correspondence

SYNOPSIS—One of the latest application of the storage-battery electric-haulage locomotive is for gathering work in coal mines. One of these machines, manufactured by the General Electric Co., was recently installed in the Glendower colliery of the Philadelphia & Reading Coal & Iron Co. The locomotive is designed specially for the service and built for hauling six cars.

Electric locomotives, of both the storage battery and overhead-trolley types, have been employed advantageously for industrial service. Comparatively recently a number of motors of this type were also introduced and have operated successfully in the work of excavating the



Motor Assembled Ready for Work

Catskill Aqueduct Tunnel in New York. In general, locomotives of this kind are designed specifically for short-distance hauls, at moderate speeds, where it is not feasible to install the overhead-trolley system. Under these conditions, the storage-battery machine has proved to be both economical and well adapted for the purpose.

Description of the Motor

The locomotive for service in the Glendower colliery is equipped with two, 85-volt motors and controller. The batteries are Type A-8, Edison, 70-cell and have a 300-ampere-hour capacity with a discharge rate of 60 amperes for five hours. They provide, at the full rated drawbar pull and speed, for a mileage of nine miles with one charge of the batteries. Under an assumed car and track friction of 30 lb. per ton on level track, this rating is equivalent to 300 ton-miles on one charge. The machine is fitted with the usual ampere-hour meter, indicating the amount of charge and discharge, headlight and gong.

The locomotive is built to conform to the following specifications:

Total weight	8000 lb.
Length overall	8-ft. 9-in.
Width overall	5-ft. 3-in.
Height over platform	2-ft. 4-in.
Height over battery compartment	3-ft. 9-in.
Wheel base	4-in.
Diameter wheels	20-in.
Track gage	44-in.
Rated drawbar pull	1000-lb.
Speed at rated drawbar pull	3½ m.p.hr.

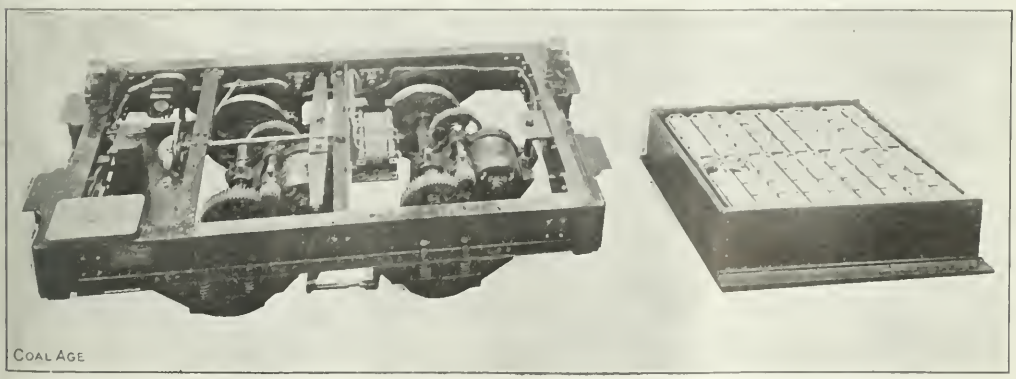
The batteries are designed for the particular service, and are of rugged construction; the plates are made specially to give the high service efficiency. The cells are grouped in 18 trays and are mounted on top the locomotive frame in a wooden case.

The mechanical design of the machine is in accordance with the latest modern practice. The frame consists of steel channel sides and steel plate ends carefully fitted at the joints and held together rigidly by bolts and steel angles. The end plates are faced with wooden bumpers, to which suitable couplers are attached. A seat for the operator is provided in the rear. The cast-steel pedestal jaws, which carry the journal boxes, are securely bolted to the lower web of the channel side-frames.

Details of Construction

The cast-steel journal boxes are of special design and fitted with roller bearings, which assures efficient mechanical transmission of power and consequent economy in battery current consumption. The weight of the car is supported from the journal boxes by two coiled springs. The wheels are of chilled iron, and are pressed on and securely keyed to the axles, which are made from a special grade of steel, case-hardened at the journals. Thus the wear on either the roller bearings or the axles is practically negligible.

Brake tension is effected by means of a square, threaded, brake-spindle. A square-threaded nut travels



View of Motor Truck with Battery Removed and Showing Driving Mechanism

on the spindle and carries an equalizing bar, to the ends of which are connected chains leading from the brake levers. This device admits of locking the brakes automatically, without the use of pawls or ratchets, in any position left by the operator. The controller is of the drum type and built for this particular class of work.

The motors are series wound, totally inclosed and of the familiar automobile type. They are designed especially to operate from batteries and have characteristics that develop the maximum possible economy in the use of battery current. They have high efficiency, large overload capacity and operate with practically sparkless commutation. The high efficiency is obtained by designing them with a small air-gap and running the iron at low densities. By reason of the latter provision, the speed and torque characteristics are steeper than in the ordinary series motor, thereby tending to limit the overload which can be thrown on the batteries.

The motors drive the axles through double reduction gearing, an intermediate shaft, supported in the bearing housing integral with the suspension cradle, carrying the intermediate gearing. As slow-speed service is ordinarily required of a storage-battery locomotive, the use of double reduction gearing affords such speeds with minimum rheostatic losses; and due to the large gear ratio from armature shaft to wheel tread, high tractive efforts are obtained at comparatively small current inputs to the motors.

Stripping Operations, at Pittsburg, Kansas

All the steam shovels used in the coal stripping operations in the Pittsburg district are working continually, and four new ones are being erected. It is expected that by the end of February there will be 20 in active operation. A noteworthy fact is that all have been installed within the past two years, thus demonstrating the greater advantage and economy in strip mining as compared with underground shaft mining. The coal in this field averages 3 ft. in thickness, or 3000 tons to the acre, and it is claimed that a depth of 10 to 30 ft. of overburden can be removed with the new type of revolving steam shovel, at a low cost per ton of coal mined.

There are many thousand acres of good coal land available for stripping, with an overburden varying from 10 ft. to 25 ft. in depth. This land can be bought or leased and operated at a good profit; in fact, the Kansas coal fields offer as great inducements for stripping as any other section of the country. The coal is of a good quality and is quite free from sulphur. It burns freely, with but little clinker.

The increased demand for soft coal is largely due to the withdrawal of crude oil from the market and the failure of the natural-gas supply.

Two large 175-ton Bucyrus shovels have been erected for Smith, Scott & White, contractors on the Weir fields, two miles east of Chicaope, and a third is being installed. The Pittsburg-Scammon Coal Co. is also using a Bucyrus shovel of 150-tons capacity, on their field two miles south of Scammon.

The E. H. Markham Coal Co. is operating a 150-ton Bucyrus steam shovel of the revolving type, which is capable of handling 2000 cu.yd. of overburden and soft shale a day. The Markham Co.'s Workings are located at Curranville, about 10 miles north of Pittsburg. The coal in this locality is of good quality, about 3 ft. thick, and the overburden varies from 15 to 22 ft. in depth.

Another 150-ton Bucyrus shovel has been purchased by the Roy Millner Coal Co., of Weir City, and is now being installed. This shovel carries a 60-ft. boom, 2½-yd. dipper, and will handle 2000 cu.yd. of earth per 10-hr. day.

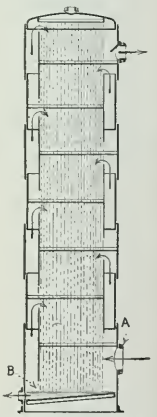
A Marion steam shovel, model 270, has been installed at the Ellsworth-Klaner Co., two miles east of Chicaope. This shovel is likewise of the revolving type, with a 90-ft. boom, a 5-yd. dipper, and will handle 2000 cu.yd. a day. This long boom enables a 40-ft. depth of overburden to be removed.

The Sternberg Construction Co., who have been stripping coal with a Marion steam shovel, model 250, have recently sold their plant three miles north of Weir City, to the J. R. Crowe Coal Co. They have purchased a tract of 400 acres near Minden, Mo., and will proceed to develop it at once.

Kubierschky's Gas Cooler and Washer

By Alfred Gobiet*

A frequent fault of coolers and washers, such as are used for coke-oven gas, results from the unequal temperatures of the different strata of the gases. As they enter at the bottom they are cooled and tend to remain there while the hot gases following them, which lack the velocity needed to sweep them up and overcome the resistance of the falling water, seek short cuts of less resistance to the upper regions. Moreover, gases that have been washed and cooled will sink to the bottom. Thus the efficiency of the apparatus is seriously affected.



Kubierschky's Gas Cooler and Washer

To obviate this difficulty, Dr. Kubierschky has patented the washer shown herewith.

It is divided into vertical compartments, with sieve bottoms which let the water drip through in a fine rain from one to another, but are so clogged by the liquid that they obstruct currents of gas from passing through. The gas enters *A* and as it is cooled, sinks. The light gas following it floats over it like oil upon water, during which time it is well exposed to the streams.

As it cools, it presses downward and crowds the lower layer through the outlet *B* into the compartment next above, where the same process is repeated. Finally the heaviest, coolest and best washed gas escapes from the top chamber. The gases have no liquid resistance to overcome in ascending, and the water flow harmonizes with that of the gas instead of opposing it. This device is said to effect a perfect washing and cooling.

Note—Abstract of paper appearing in "Montanische Rundschau" (Vienna), Oct. 1, 1912.

*Engineer, the Witkowitzer Mines Ostrau, Moravia, Austria.

CURRENT COAL LITERATURE

A British Byproduct Coking Plant

Until quite recently the beehive coke oven held undisputed sway in Cumberland, England. Indeed, to go no further back than 1910, out of the total of 582 ovens which were then in operation, no less than 502 were of the beehive and square types, the remaining 80 being Koppers regenerative byproduct ovens installed at Watergate Colliery, at Flimby and at St. Helens No. 3 mine, at Siddick. Naturally other coke makers in the district paid close attention to the operation of these new ovens, which proved from the first a marked success, perhaps the best testimony to this being that the whole of the Allerdale Coal Co., Ltd., was making coke in beehive ovens at both their Buckhill and Clifton collieries. A few of these are still in operation at Buckhill, where the waste heat is used for raising steam for the colliery. The plant installed at the Clifton collieries—with a capacity of 7000 tons of coke per month—is designed to deal with the smalls from the whole of the company's properties. Of the coal required at the ovens, the Clifton colliery supplies about a half and Buckhill and Brayton collieries each about a quarter, only a little outside coal being bought. The coal from Buckhill is delivered in a washed condition, while that from Brayton Knowe is washed, together with the Clifton smalls, in a Shep-

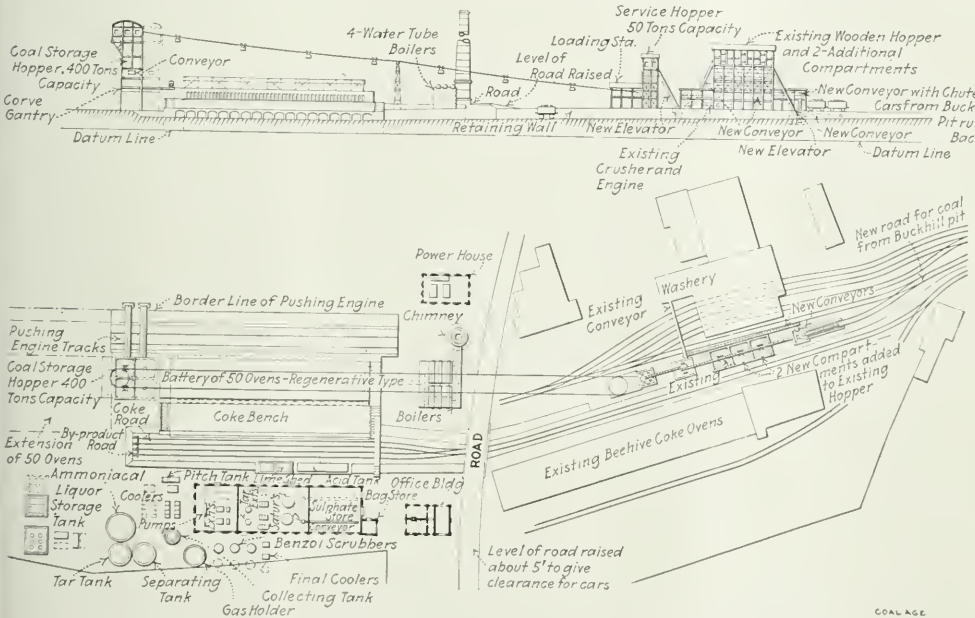


FIG. 1. GENERAL PLAN AND ELEVATION OF BYPRODUCT PLANT AT THE CLIFTON COLLIERY

pard washery, adjacent to which is the drainage bunker, which serves the disintegrator.

The new installation comprises a battery of 50 Koppers latest regenerative coke ovens, with recovery plant designed on the makers' patent direct-recovery principle for the extraction of tar and benzol. Provision is also made for the manufacture of sulphate of ammonia, together with auxiliary plant, comprising machinery for elevating and conveying the washed coal to the drainage bunker of 300 tons capacity, an aërial ropeway with a feed hopper of 560 tons capacity, and a combined coal-compressing and coke-discharging machine. In addition, four Stirling boilers and an electric generating plant for power and lighting are erected. The contract for

byproduct ovens in Cumberland, both in operation and under construction, are of the same type.

Though the introduction of the regenerative oven into Cumberland was somewhat belated, its development has since been rapid, for while in 1910 there were only 80 such ovens installed, there are today 230 in regular service, and a further 100 in course of construction. These last comprise an additional 10 to the existing battery of 50 for the Moresby Coal Co., Ltd., a battery of 50 for the Harrington Coke Ovens, Ltd., and an initial installation of 40 ovens for the Oughterside Coal Co., Limited.

Prior to starting the plant with which this article deals,

Note—From "Iron and Coal Trade Review," London, England, Jan. 17, 1913.

the whole of the work was placed with the Koppers' Coke Oven & Byproduct Co., Sheffield.

The general arrangement of the plant will be seen in our illustration, Fig. 1. The whole of the washed coal is delivered to the drainage bunker, that from Buckhill colliery, which is delivered washed, being raised by a bucket elevator, and the locally washed coal, treated in the Sheppard washery, delivered by conveyor. The coal is allowed to drain until the moisture does not exceed 8 per cent. From the drainage bunker the coal passes to the disintegrator, which at present is driven by a high-speed engine. This, however, will shortly give place to a Siemens motor of 100 hp. From the disintegrator the crushed coal is elevated to a 50-ton feed hopper, which serves an aërial ropeway of the Pohlig type, in connection with which an Avery automatic weigher and totalizer will shortly be installed. The ropeway buckets have a holding capacity of 9½ cwts., and are automatically discharged into the crushed-coal storage hopper at the ovens, which has a capacity of 560 tons. The ropeway is equal to handling 800 tons of coal in 12 hours.

From the storage bunker the coal is discharged through openings in the bottom onto a conveyor and thence into the receiving hoppers fitted to a combined coal-compressing and coke-discharging machine. The hoppers on this machine have a capacity equal to two full charges, thus enabling two ovens to be charged for each visit of the machine to the coal bunker. The stamps for compress-

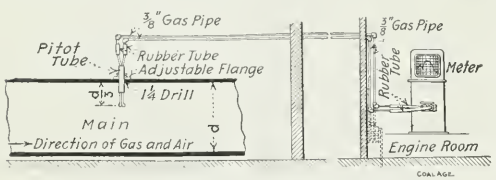

Fig. 2. The "Factum" Gas and Air Meter

ing the charge are driven by a Brush motor of 8-10 hp. The combined ram and charger, which travels upon a double set of rails, is operated from a 50-hp. motor taking current from bare overhead wires. Any coal which may be split during charging operations is tipped down a chute at the end of the battery nearest the storage bunker, to which it is raised by means of a bucket elevator.

The Koppers Ovens

Most of our readers will, no doubt, be familiar with the general principles of the Koppers ovens, in which the gas and air for combustion are separately distributed on each side and along the whole length of the oven. Each oven wall is formed of about 30 vertical flues with a gas jet in each, so that the ovens are heated from 60 points. The means of regulation are simple and effective, and absolutely uniform heating from end to end is rendered easily possible. This uniformity is, of course, the salient point of success in a coking plant, as not only is it essential to the production of a homogeneous coke and enables the charge to be burnt off more quickly, but it effects a considerable economy in gas, thus giving a larger available surplus.

The ovens, as previously stated, are of the regenerative type, the advantages claimed over those of the waste-heat type being important, though that does not seem to be so fully appreciated in England as upon the Continent and in America. It may not, therefore, be out of place to point out that the chief advantage to be derived from regenerative ovens is that the surplus heat in the coal (i.e., the heat over and above that which is required for heating the ovens) is produced wholly in the form of a combustible gas, while the surplus heat from waste-heat ovens is produced mainly in the form of a hot waste gas, which can only be used for firing boilers and must be consumed on the spot directly it is produced. Gas in a combustible form, such as is obtainable from regenerative ovens, on the other hand, can be employed for illuminating purposes, for raising power in gas engines, or for firing steam boilers. This last is, of course, by no means an economical application, as the gas engine would probably yield from two and one-half to three times the power produced from the steam raised with an equal quantity of gas.

The distinctive feature of the Koppers regenerative oven lies in the employment of separate regenerative chambers for each oven, so that each is an independent unit; thus the air for combustion and the chimney draft can be separately regulated. The average charge for each oven is 9½ tons of wet coal. The coke is discharged through a quencher onto a sloping bench, covered with cast-iron plates, from which it is loaded by gripes into the trucks, the coke being of exceptionally good quality and homogeneous character and little breeze being made.

As already stated, the byproduct recovery is on the direct-recovery system, or what is perhaps better known as Koppers low-temperature principle. The hot gases from the ovens pass by way of a common main to a series of multitubular water coolers, where the temperature is reduced and the condensation of tar and aqueous vapor brought about. The gas is then drawn by a turbo-blower, and driven forward to the tar extractors, where the last remaining traces of the tar are effectually removed, an operation which cannot be successfully performed without cooling the gases.

The turbo-blowers referred to (which, like all the important apparatus and engines in the plant, are in duplicate) work at 25-in. water gage. Their normal speed is 3400 r.p.m., but this is governed by the pressure in the main. The governor is a simple and ingenious arrangement which can best be described as a miniature gasometer, the top of whose gas tank is connected by levers to the stop valve of the turbine. After being freed from the tar the gas is superheated to such a degree that it may be passed directly into the saturator without condensation taking place. The salt produced is of excellent quality, being white in color and containing no trace of tar.

The sulphate factory adjoins the exhauster and pump house. The exhaust steam from the blowers provides the necessary heat for the superheaters, and the surplus exhaust, together with the exhaust steam from the pumps, is used for distilling the gas liquor without the addition of live steam. The benzol plant is arranged in a parallel line with the sulphate factory. After passing through the saturators, the gases are conducted to final coolers, where the temperature is reduced to the degree required for the efficient extraction of the benzol, which is washed out in the usual manner. From the scrubbers the gases pass in part back to the ovens and in part to the boilers, while a considerable portion is at present going to waste.

As a matter of fact, of the total gas evolved from the coal, approximately 70 per cent. is available for purposes other than heating the ovens.

The Benzol Recovery

The Koppers method of benzol recovery is as follows: The rich oil containing the benzol is run into a collecting tank, where its temperature is about 20 deg. C., whence it is pumped into a preliminary heater, where the temperature is raised to about 40 deg. C. It then goes to the superheater and finally to the still proper, where it is subjected to distillation by means of live steam at a temperature of about 105 deg. C.

In this way the whole of the benzol is removed from the washing oil, and the benzol vapor, together with the steam, passes away into coolers, where the two liquids separate, owing to the difference in their densities, the washing oil, from which the benzol has been removed, passing out at the bottom of the still, through a series of water coolers, into the storage tanks to be used again. Water for condensing the gases is drawn from the River Derwent, which is distant about a quarter of a mile and is 145 ft. below the works' level. For this purpose Worthington centrifugal pumps are installed in duplicate. Each pump is driven direct by a 62-hp. motor, and is capable of delivering 822 gal. per minute.

The power-house equipment comprises two Browett-Lindley combined sets, each of 120 kw., generating three-phase current at 500 volts, and a small lighting set, consisting of a Robey high-speed engine coupled to a continuous-current dynamo generating at 230 volts.

Steam is raised in four Stirling boilers at 150 lb., fired entirely by waste gases. The power units exhaust to a Wright feed-water heater. In addition to firing these boilers, three of the Lancashire boilers at the colliery have a gas-burner fitted to each of the flues.

As previously stated, the results obtained at the Clifton colliery plant are of a remarkable character. We are indebted to the coke-works manager for the following figures, indicating the yield of the various products, as also for diagrams showing the gas yield and consumption.

Records of the gases are taken on a "Factum" meter (Fig. 9), which is installed in the manager's office. One reads: Coke, 72.5 per cent. of coal carbonized; tar, 5.25 per cent. of coal carbonized; sulphate of ammonia, 1.62 per cent. of coal carbonized; crude benzol, 3 gal. per ton of coal carbonized; surplus gas, 60 per cent. of total quantity evolved from coal. The surplus gas would certainly appear to be an abnormally high percentage; but the manager is satisfied as to its accuracy.

Requirements of British Electrical Rules

In the course of his presidential address to the British Association of Mining Electrical Engineers, at Sheffield, on Sept. 21, 1912, W. C. Mountain referred to the new Home Office rules for the installation of electricity in Mines. Claiming an intimate knowledge of what the rules demand, he briefly stated the requirements as follows:

Armoring Compulsory, Voltage Unspecified

1. All cables in future must be armored, the conductivity of the armoring being 50 per cent. of that of the cables inclosed if three-core, and if single armored cables are used for continuous current, then the armoring must be 25 per cent. of the conductivity of the cable inclosed and this armoring must be bonded every 50 feet.

2. No restriction is placed upon the voltages used underground (within, of course, reasonable limits), except that motors below 20 hp. must not be supplied at a pressure higher than 650 volts.

Leakage Detectors and Grounding Required

3. Leakage detectors are required, and all systems must be grounded to the surface, preferably through the armoring or the outer sheath.

4. Direct-current electric lighting circuits which exceed 250 volts must be grounded. Similar alternating-current circuits must be grounded if the pressure exceeds 125 volts.

5. The method of grounding portable machinery, such as coal cutters and conveyors is described in the memorandum and the grounding arrangements must be such that the earth connection is made before the live connection. The live circuit must also be broken before the earth connection.

In brief, the main object of the new rules is to make armoring compulsory in the future; and there is no question but that armoring affords a good mechanical protection and is also convenient for grounding. Grounding may seem to be a simple matter but it is sometimes difficult to secure satisfactory results.

In a recent case, although the installation complied in all details with the new requirements, it was found that the resistance measured from the earthplate on the surface to the armor at the inby terminal was nearly 12 ohms, which is much more than it should be.

The Difficulty in Grounding

Insulating strata exist in many mines. It is extremely difficult to bond the armoring to the junction boxes, and there is also the risk of the armoring being damaged, or the joints broken by falls and by corrosion. Therefore it is questionable whether a grounding system consisting of as many earthplates as possible is safer underground than an installation where grounding is avoided.

In every case it is necessary to consider the local circumstances, and only those experienced in this particular work can satisfactorily determine the right method of obtaining a good grounding system. There can be no question but that grounding in some form or another is desirable and in fact necessary.

Our Front Cover This Week

The illustration on the front cover of this week's issue shows the 550-ft. Link-Belt chain-retarding conveyor and tipple, designed and built for the E. E. White Coal Co., Stotesbury, W. Va., by the Link Belt Co. of Philadelphia. The capacity of this equipment is 300 tons per hour over two dumps. A 60-in. wide Link-Belt picking table in the head house delivers the coal to the retarder. The storage bin is shown at the bottom of the incline. This is one of the most modern and efficient tipple equipments in the West Virginia field.

Some Notes on Diamond Drill Prospecting

By J. B. Dilworth*

SYNOPSIS—An interesting review of the current practice in prospecting large undeveloped coal fields with the diamond drill. A number of useful hints are given with regard to the location of the holes, subterfuges of unscrupulous contractors and size of holes. The author regards $1.75 per foot as an average price for work of this character, although this cost often amounts to $2 or $2.50 in some districts. The article is confined more particularly to the drilling of relatively shallow and horizontal seams.

The following article treats of the method of laying out a field for drilling; the character of drill employed; the form of contract; the supervision of drilling; the instrumental location of holes and the compilation of data obtained, which have proved most satisfactory in testing extensive areas of shaft coal in the Appalachian and Interior coal fields With the rapid exhaustion of the more accessible areas of crop coal in the older bituminous fields within recent years, the attention of operators and capitalists has naturally been drawn to those localities where coal seams, known to be of commercial thickness and quality in neighboring fields, are buried beneath a few hundred feet of rock measures.

The seams are frequently as thick and pure in those areas as elsewhere and, when operated on a large scale, can be mined almost as cheaply as in drift or slope mining. The chief obstacle to their earlier development has been the difficulty of obtaining accurate information concerning the structure, bed section and quality of the seams, conditions which can be disclosed most satisfactorily by judicious prospecting with the diamond drill.

Preliminary Examination

The engineer's first duty upon undertaking the prospecting of such a field is to familiarize himself with general geologic conditions in adjoining areas. There the seams, to be sought by the drills in the locality under consideration, will frequently be found to outcrop, and valuable data as to the structure of the region, its geologic section and the characteristics of the principal coal beds can be secured, which will prove a great help in interpreting the drill records obtained.

In determining the number of holes to be drilled, consideration must be given first, to the object of the drilling, whether a knowledge merely of the general value of the field is sought—to determine its desirability for purchase as a whole, for instance—or whether such detailed information is wanted as will closely define the best mining areas, determine the most suitable shaft sites, etc. And, second, the regional character of the principal coal seam, as regards persistency and uniformity of bed section. Thus one good core would "prove" a much larger area of the regular Pittsburgh seam in southwestern Pennsylvania than of the Freeport or Kittanning in the Alleghany Mountain district of that state.

As a rule, where the object of the drilling is to ascertain the general commercial value of the field as a basis for purchase and where the coal beds are fairly regular, as those of the Lower Productive Measures in the northern Appalachian field, one hole for each square mile of area is sufficient. If the property tested is in a comparatively solid block this will place the holes about one mile apart. This rule will usually be found quite satisfactory, though at times a bed in one portion of the field will prove so variable that closer drilling in that particular area will be required. After tentatively locating the drill-holes on a map, the points selected should be visited on the ground, where it will frequently be found desirable to shift them somewhat that the drill may be readily set up, on firm ground and near water.

In a hilly region the location will naturally be selected in valley bottoms, if possible, to avoid needlessly deep holes. A local prejudice against such locations will sometimes be found, based on a belief that the underlying coal seams have been disturbed by the streams. Generally speaking, there can, of course be no relation between a valley and the character of the much older strata in, and over which it courses. If the coal seam has not been actually reached by erosion, or, in other words, if the natural, stratified roof is found above the coal, it is safe to assume that a core from under a valley is as typical as one from beneath a hill. It rarely happens that erosion has extended more than 50 ft. below the present surface even in a flat valley, so if the coal bed sought lies at a greater depth than that it will usually be found intact.

Character of Drill

The most satisfactory machine for the work under consideration is the light, easily moved diamond drill of a type similar to that generally used in the coal fields east of the Mississippi River. It consists essentially of a hollow stem about 6 ft. long, held in either a vertical or inclined position and moved upward or downward by two hydraulic pistons. The drill rod passes through this stem, in which it is clamped by a chuck at the lower end and the whole is rotated by two small steam engines. This apparatus, together with a small boiler, a steam windlass for lowering and withdrawing the drill rod and a pump, for forcing the water down the drill rod, and supplying the boiler, are all mounted together on a wheeled truck. The whole weighs about three tons and can be hauled to any ordinary location by two teams.

The main accessories are derrick poles, drill-rod sections, core barrels, hand tools and, where the location is more than a few feet from the water supply, a mounted pump and boiler with 1-in. water pipe and a small tank. The entire outfit can be moved over fair roads by seven teams and set up by three men in 10 hr., or dismantled in half that time. The best results in coring bituminous coal have been obtained in using an eight- or ten-diamond bit attached to a double core barrel and cutting a core 2¼ in. in diameter. A careful driller thus equipped will usually secure a perfect core even of the soft, low-volatile coals; indeed it is customary for him to guarantee such a core when drilling in fields with which he is familiar.

The speed of drilling with such an equipment naturally varies with the character of the strata penetrated and the skill of the driller. In the ordinary Carboniferous shales

*Associate of Edward V. d'Invilliers, geologist and mining engineer, 506 Walnut St., Philadelphia, Penn.

and sandstones 50 ft. per 10-hr. day of steady running is a good average, though occasionally more than twice that speed will be maintained for a single shift. In estimating the *total* time required to drill a field one should allow a shift of 10 hr. for each 20 ft. of hole to be drilled by one machine. This is generally sufficient to cover the time consumed in moving to new locations, laying water lines, maintaining bits and machine, and redrilling an occasional hole where a core has been lost.

The amount of fuel required for such drilling may be roughly estimated at one-third bushel of coal per foot of hole, or a long ton per one hundred feet. If a separate pump boiler is used, the fuel allowance must be increased somewhat, probably to one and one-half tons per hundred feet of hole. The water requirement of a drill in full operation is about two-thirds of a barrel per minute. Considerably less will suffice in an emergency if the discharge from the hole can be repeatedly pumped back into it; but this is not always possible, owing to rock fissures, through which the water sent down the rod escapes. As already stated, an auxiliary pump and boiler are necessary if the location is more than a few feet from water. The type generally used will force sufficient water for drilling for about a mile against a moderate head.

Form of Contract

Most drill prospecting in the Eastern coal fields is done, under supervision, by special contracting firms. Under the contract usually in force the drilling company agrees to furnish a certain number of machines with all necessary appliances and men for their proper operation; to transport the equipment into the field; to move it to the various locations assigned; to supply all fuel and water; to drill holes of a specified size to the depths desired by the engineer in charge, and, usually, to furnish perfect cores of the coal seams penetrated. The maximum and minimum depths to which any hole may be carried is usually specified; also the minimum total amount of drilling to be done.

The contract price for such work in the Pennsylvania coal fields, when several thousand feet of drilling is to be done and the maximum depth of hole is approximately 600 ft., averages about $1.75 per foot for a hole yielding a 2¼-in. core. In less accessible localities, farther from the base of supplies, as in many portions of West Virginia, Kentucky, Illinois and the Middle West, the contract price ranges from $2 to $2.50 per foot, or even more if an exceptionally hard formation—such as the Raleigh Sandstone of the New River field in West Virginia—has to be penetrated.

Supervision of Drilling

Usually the engineer in charge of drilling operations is responsible for the accuracy of the reported records rather than the drill contractor or his machine runner, and very properly so. As large expenditures of money for purchase and mining development are frequently based wholly upon the records of a few holes, it is essential that the supervising engineer know, beyond all reasonable doubt, that the coal cores secured, represent the full thickness of the beds, and not be dependent on the word of the driller, who is sometimes tempted to overlook a few inches of ground-up core—especially when his contract calls for the hole to be redrilled unless complete coal cores are obtained.

To secure these results it is not necessary that the engineer remain constantly at the drill, but only while the coal and a foot or so of strata immediately below are being cut. His free time can be advantageously utilized in safeguarding his employers' interests by familiarizing himself with all the local conditions and in general surveying as a basis for his complete graphic records.

The time of striking a given seam can usually be predetermined with some accuracy if the structure and geologic section of the field are at all regular. When the driller reaches the coal, which can be readily told by the action of the machine, he at once stops and sends for the engineer. After the latter marks the position of the drill rod the coal is cored and the point at which the floor is struck is noted. Measuring between these two points gives the total thickness of the seam. When the drill has gone a foot or so into the floor, to give a hold for the key piece, the rod is drawn and the contents of the core barrel carefully pushed out. Detailed measurement of the coal core can then be checked with the rod measurement, from which it should not vary more than an inch.

There might be raised the objection to this method that an unscrupulous driller, fearing he would grind up and lose part of the core, would run some distance into the bed before calling the engineer and thus have less core to account for than should properly be present. But this is most improbable, for no driller could tell just how much of the core he would grind up, and if he should produce more than the rod readings called for his deception would be at once apparent.

It is well to have a long, narrow box in which the coal core will fit snugly when pushed from the core barrel, as it is sometimes very tender and difficult to measure accurately unless prevented from falling to pieces. Usually it is best to let the core dry before it is finally measured in detail and broken up for chemical analysis, as bony coal and small partings of bone or black slate are apt to be overlooked in a wet core.

Instrumental Surveys and Office Records

To properly interpret the results of drilling a series of holes it is essential that both the position and elevation of each be known. Neighboring mines or outcrop openings should also be located for the light they may throw on structural and other conditions in the field, and all referred to a definite bench mark in the district. A stadia survey is usually sufficiently accurate for the purposes involved in the examination. If so, it is particularly desirable because of the rapidity with which the surveyor can obtain, not only the locations and elevations of the drill holes and coal exposures, but also a wealth of topographic and cultural data useful in preparing a general map of the field.

The common method is to measure the distances by stadia on a self-reading rod, the horizontal angles by compass and the vertical angles, from which elevations are calculated, by reading the vertical arc on a carefully leveled transit. When running a continuous line the transitman and rodman occupy alternate stations, the transit pointing first back then ahead. In a fairly open country two men can readily average four miles of line a day.

Drill records are usually most intelligible when seen in graphic form where the character of the various strata

penetrated, the relative position and thickness of the coal seams, and the variations of these features in different parts of the field can be comprehended at a glance. A scale of 40 ft. to 1 in. has been found suitable for plotting the drill logs, though it is usually desirable to supplement these records with magnified sections of the coal seams plotted on a scale about ten times as large.

The map accompanying the plate of drill records should show the location and elevation of each hole and coal opening; the lines of the property tested; the drainage and important culture and geographical features of the field and, by contours based on survey elevations, the structure of the principal coal seam. With such data at hand the engineer is able to discuss intelligently and with a fair degree of accuracy the geologic conditions of a field; to determine its economic value, and to outline a general plan for future development. The cost of such methods of investigation amounts to such a trifling sum per acre of coal involved that, viewed as a tentative or permanent record, there can be little doubt of its value and expediency, particularly so with the advancing prices of good coal lands and the greater security vouchsafed to any professional opinion which may be rendered in the premises.

A New Rotary Dump

The rotary dump here illustrated is a type used by the Rheinischen A. G. für Braunkohlenbergbau und Briquettfabrikation, Cologne, Germany. It is described by Christian Steg in "Glückauf," Oct. 12, 1912.

From the central switching station the cars are distributed to the several dumps, run upon them by gravity and after dumping pass on to a chain road for the empty cars.

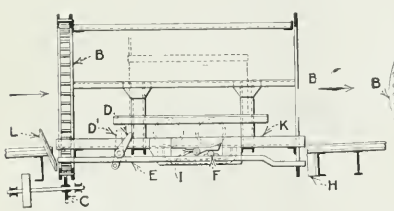

Fig. 1. Side View

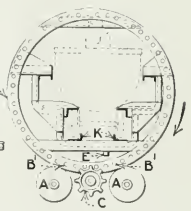

Fig. 2. End View

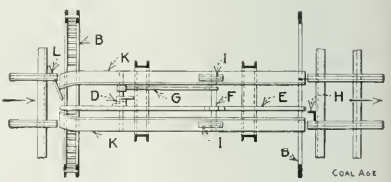

Fig. 3. Top View

The dump is adapted to the form of the car, and it is mounted in the usual manner on four rollers *A* which support its two end rings *B*. It is inclined as is the approach track. The double ring *B* at the front is provided with pins to form a lantern gear meshing with the driving pinion C. The pins of this lantern gear are lacking, however, for a distance of about 20 inches, between the points *B'* and *B''*, Fig. 2, which interval corresponds to the initial and final position of the dump rotation. Thus the pinion C, which keeps on turning, has no further effect upon the lantern gear when this open space is reached.

The axle of the car, in running upon the dump pushes down and passes over the lever *D*, which moves the longitudinal bar *E* away from the catch *H*. The weight of the car upon the rails (which are not in the exact center), then starts the dump in its revolution.

As soon as the open space above referred to in the lantern gear has been passed, the pinion *C* meshes therewith and causes the dump to turn completely over. Upon nearing its initial position, the guide *L* forces the locking bar *E* back into its former place, thus locking the dump upright, in which position it remains until the next car is run upon it ready to be emptied.

Coal Mining in Holland

Special Correspondence

From a return dealing specially with the Limburg (Holland) coal industry, it appears that in 1911 the coal raised from the seven mines working amounted to a total of 1,654,240 short tons against 1,447,040 tons in 1910 and 1,255,520 tons in 1909. The total number of workmen was 7477 of whom 5499 were below the surface and 1978 above. They included 6122 Hollander, 1397 Germans, 200 Belgians and 244 Austrians.

Dealing specially with the state-owned mines, the report states that a fair tendency is noticeable toward the nationalization of the Dutch Limburg basin, the determining reasons being on the one hand, the increasing competition in Holland of the German-Westphalian Coal Syndicate and, on the other, the apprehension that concessions granted to Dutch firms may pass into foreign hands.

The state-owned area extends over 62,600 acres, containing an estimated total of a billion tons, of which 593,000 lie at a depth of less than 3281 ft. or 1000 m., as compared with an area of 17,291 acres in the hands of private firms. The only state-owned mine in regular exploitation is the Wilhelmina, which was responsible for a total of 275,555 tons in 1911. About 65 per cent. of the state output was sold abroad.

Work is still in progress for completing the two shafts of the Emma Colliery, sunk by the freezing process. These in 1911 produced 662 tons. The coal formation was reached at a depth of only 650 ft., and four workable seams from 27½ in. to 47 in. thick were intersected at between 650 and 912 ft. At the third state-owned mine, Hendrik, a depth of 722 ft. of cap rock had to be passed through before the coal formation was reached.

It is estimated that when completed the Emma and Hendrik Collieries will yield 3400 tons daily. The probable production of the state collieries is put at 672,000 tons in 1915 and 3,920,000 tons in 1930, the number of workmen occupied being estimated at 3000 in 1915 and 17,000 in 1930, and the capital invested at $12,000,000 in 1930, against $3,200,000 at present.

It is claimed that the increasing invasion of the Dutch market by German coal is attributable to the reduced railway tariffs and the low freight rates on the Rhine.

Switch Gear for Collieries

The development of switch-gear design has of late years received a considerable impetus owing to the remarkably rapid way in which electric power has been adopted for use in collieries and other mines. The problems attending the use of power in such situations make electric mining machinery a class by itself, since not only is the danger of coal dust and gas to be contended with, but the necessity of placing machinery in dark and damp situations under the control of inexperienced workmen have introduced difficulties which it has taken a considerable amount of careful design to overcome.

Two New Pieces of Apparatus

Among the firms who have carefully investigated the problems of mining machinery is the Morely Electrical Engineering Co., Ltd., of Stanningley, near Leeds, and two of their latest productions in mining switch gear are worth attention. It is therefore proposed to describe briefly, first an oil-immersed drum type starter and controller, which is shown photographically in Fig. 1.

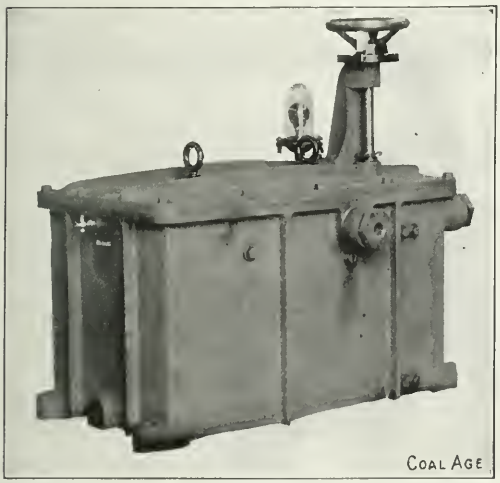

Fig. 1. Oil-immersed Starter and Controller

Those who have had experience in the manipulation of colliery switch gear for direct current, know that although there is a great advantage in having the switch resistance and joint boxes combined in one self-contained, transportable or semi-transportable box. Many designs which have been previously attempted on these lines have not been entirely successful on account of the fact that the work of inspection, always difficult in collieries, has been impeded by the way in which the parts of the gear have been arranged with relation to one another inside the case.

Where bad lighting is the rule rather than the exception, it is extremely desirable that the utmost facilities for inspection of the working parts should be given, and it is in this feature that several of the previous designs have to some extent failed.

This disadvantage, in the present instance, has been avoided. By means of hinging the two drums and also by a suitable arrangement of the plugs, a few minutes will suffice to dismantle the whole of the switch gear and thoroughly inspect the same.

It is hardly necessary to describe this device to any great length, but it may be said that the general specifications conform in all particulars to the British Home Office regulations for apparatus used generally in mines. The design allows of a certain flexibility of arrangement and as no two collieries are alike in desiring the same class of apparatus, the manufacturers are able to vary the position of the component parts in order to suit individual requirements.

A Double-pole Mining Switch

The second piece of apparatus of interest which this firm has recently placed on the market is the double-pole mining switch of the oil immersed type, with patent fuses and joint boxes, shown in Fig. 2. When the switch is placed in the off position, there can be no possibility of its being turned back again unless the man in charge of the machine which it controls unlocks the switch frame.

This voluntary act prevents any unauthorized person from tampering with the fuse or putting larger sizes of conductor into the fuse holders than the current of the machine warrants. That this is important will be readily granted, inasmuch as considerable damage has before now been done in mines, owing to unauthorized tampering with fuses.

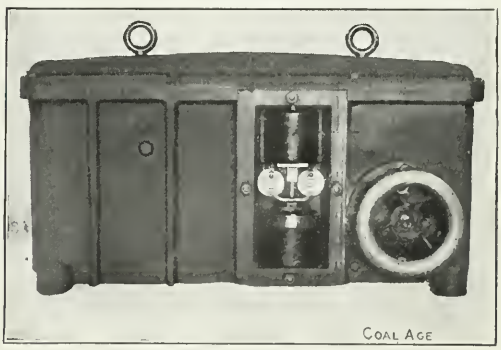

Fig. 2. Double-pole Mining Switch

These switches have been standardized and made in various sizes from 25 to 250 amp. capacities, and have been found especially suitable for controlling coal cutters, drills and similar mining machinery. It will be seen also that this type of switch gear lends itself equally to use in such situations as flour mills, powder factories, or other dangerous places, and therefore possesses a wide range of technical interest.

The U. S. Geological Survey classifies land as coal land only when the coal lies at what is now considered a minable depth in this country. The character of the coal determines the depth to a certain extent. The higher-grade coals are allowed a maximum depth of 3000 ft.; less is allowed for poorer grades. Lands underlaid with coal at a depth of 3500 or 4000 ft. are classed as "non-coal" lands. The amount of coal below 3000 ft. has not yet been estimated, but it is without doubt large. The coal above this depth is estimated by the Survey to be 2000 billion tons. Less than 11 billion tons have been mined. A large part of the estimated 2000 billion tons consists of the comparatively low grades of lignite.

Loading Coal for the Retail Trade

Mechanical loaders for loading coal wagons from storage have fairly jumped into prominence. A year and a half ago there were probably not over half a dozen in use the country over, while now hundreds are in successful operation. This method of loading wagons is such a decided improvement over the hand-shoveling, that manufacturers are finding it difficult to build enough machines to meet the heavy demand.

The accompanying illustration shows the Link-Belt Wagon Loader in the yards of the Scranton & Lehigh Coal Co., of Brooklyn, N. Y. This is the company's standard Type "D" bituminous loader, which will load a 2-ton wagon with bituminous or small anthracite coal in about two minutes, or a 5-ton truck in five minutes. It fills a

THE WAGON LOADER AT WORK

wagon so quickly that it hardly pays the driver to leave his seat, if the loader can be fed without his help. Where considerable coal is handled and rapidity of loading is essential in order to avoid delaying teams, greater capacity is secured by using another yard man to feed the machine, in addition to the operator. The driver then stays on the wagon and simply trims the load. Operating in this way an average of 40 or 50 tons an hour, or 400 to 500 tons in ten hours can be loaded.

The Link-Belt Co. has recently published a 16-page book which describes the method of operating the machine and the results to be expected with it.

⁂

Acetylene Lamps Permitted in Ohio Mines

Section 974 of the Ohio General Code has recently been amended by the General Assembly. One item of revision provides that it shall be lawful to use acetylene gas in lamps in mines subject to the following conditions and restrictions:

First, no person shall take into a mine a greater quantity of calcium carbide than will be a reasonable supply for his own lamp for one day's work.

Second, no person shall deposit, or keep in his possession, in a mine any calcium carbide, or refuse therefrom, in anything except air-tight containers These containers must be taken out of the mine at the end of each day's work.

Third, no person shall be allowed to use acetylene gas in lamps where there are old or abandoned workings, where large quantities of blackdamp or other poisonous gases are liable to accumulate, until such places have been examined by a competent person and pronounced free from a foul or poisonous atmosphere.

Up to the present time all efforts to introduce acetylene lamps in Ohio mines have proved unavailing. The Ohio Mining Law as amended June 11, 1910 (Section 974), it may seem, was drastic in respect to the use of acetylene or carbide lamps in the mines. The position taken by the commission appointed to revise the mining law at that time was that, owing to the many dangerous conditions incident to the use of calcium carbide for the generation of acetylene gas, in the mines, the use of this lamp should be prohibited by law.

This ruling of the commission, it may be supposed, was not wholly acceptable to all classes of mining men and efforts have been made from time to time to overcome the prejudice that existed in the Department of Mines of Ohio against the use of the lamp.

Under the new administration these efforts have been successful, and Section 974 of the mining law was revised Feb. 13, by action of the Ohio Assembly. The revised law was approved by the governor, Feb. 24. In justification of the previous action of the Mining Commission in this regard, it may be stated that the section as now amended provides certain restrictions, which cover all of the objections raised against the use of the lamp in mines.

BY THE WAY

Many people see a glow-worm and think it a conflagration.

⁂

The man who holds the bag sins as much as the one who puts into it.

⁂

A mining camp weekly says: "Apparently we were erroneously informed as to the nationality of Joseph Remas, as in our account of the burglary at the A. C. M. Co. store, we stated that he was a Finn. Later we were waited upon by a delegation of that nationality whose sensibilities were highly outraged by the statement. We apologized for the error and were informed that he was a Lithuanian. If this is a mistake, we are prepared with another apology," which goes to show that the way of the editor is hard.

⁂

When we are in the valley we should act in such a way that we need not fear those who stand on the hill.

⁂

Mine Inspector James Taylor, 4th District, Peoria, Ill., has issued a neat booklet presenting the Compliments of the Season, 1913, and extending "greetings" to the coal operators and all employees in and about the mines. He reports but one fatal accident having occurred in his district during the first six months of the fiscal year. To everybody Mr. Taylor says: "Don't fail to brighten the usual gray of life with a bit of the rosegold of kindness." He then gives a series of "Don'ts" for operators and superintendents, mine managers, miners, mine examiners, shotfirers, hoisting engineers and drivers. The ground of necessary precautions in coal mining is pretty fully covered by these worth-while suggestions.

EDITORIALS

Storage of Powder

A few years ago the coal industry began to realize that an urgent campaign must be made to protect the miner at his work, but more recently operators have begun to take the larger view that workmen should also be taken care of at their homes.

Unfortunately when laws were made restricting the amount of powder which might be taken into the mines at one time, the ordinance made it necessary that each miner should either buy powder in small quantities, which was an extravagant practice, or store a broken keg of powder at home. At one mine, a genial clerk of the commissary, on his own responsibility, agreed to keep the partly used powder supplies of the miners in his "general supply house" and dole out the powder to each man as he desired it, supplying every individual from his own keg until that receptacle was empty.

The mine inspector arrived and condemned this practice, which, of course, was dangerous, as the miners persisted in calling for powder with lighted lamps in their hats, and, it being winter, there was an open fire not far distant. So the miners reverted to the old practice which was at least as bad. They took the powder home and left it often where the children could play with it, subject to fires should the house burn, a danger to neighboring houses and a terror to the local fire department.

Powder cannot well be sold like milk, of which a certain amount is purchased each day, the consumption always being regulated by the consumer to equal the quantity ordered. The men use part of a canister of powder one day and on the day following have less on hand than will serve them for a full day's run. Consequently, they desire to purchase a quantity running to a certain number of odd pounds or even ounces, only to be determined by weighing the can from which the powder is transferred both before and after depletion. This involves excessive clerical work, which it seems reasonable to add to the price of the powder.

Every coal company should have, in addition to the regular storehouse, a safety magazine where the miners may store their powder and where their cans may be filled every night. They should never be permitted to enter the magazine and no stove should be allowed within its walls. The men should be obliged to leave their depleted kegs at this place of storage and on quitting the mine at night should deposit their numbered canisters for storage and replenishment.

This will not only serve the purpose of safety, but should also lower insurance risks. In Great Britain the men are required to bring out their canisters nightly.

The Coal Mines Order of 1911 reads:

> No explosive substance shall be stored underground in a mine. The owner, agent or manager of the mine shall provide a suitable place or places of storage above ground for all explosives intended to be used in the mine and shall make suitable provision conveniently near the entrance of the mine for the storage of surplus explosive brought out of the mine at the end of each shift.
>
> If any explosive remains in the possession of a workman at the end of his shift, either he shall bring it with him, out of the mine and return it at once to the place of storage provided for the purpose or if the explosive is required for a shift immediately following, he shall deliver it personally to the workman succeeding him in his working place.

In view of the possibility that explosions may occur from the falling of rock on canisters of powder, it seems desirable that the American operators should require here what the law demands in Great Britain, that every man bring the remnants of his day's supply of powder to the surface when his shift is done and deposit it in a magazine.

In places where cartridges of permissible explosives are sold, there is less difficulty in arranging the sale of the powder in small units, but the need for a place for storage over night and idle days should be carefully considered in this case also.

⁂

The Need of Efficient Mining Legislation

Much confusion is liable to exist in the minds of legislators, in relation to what is needed or desired in mining legislation. The confusion arises from the variety of mining bills that are being presented for the consideration of the legislature now in session at Harrisburg. While some of the proposed bills that have been brought to our attention contain commendable features and are based upon a practical knowledge of mining conditions and requirements, there are others that have seemingly been drawn more for the purpose of defeating good and needed legislation than to supply a recognized need or to meet certain known dangerous conditions existing in mines. An example of this is to be found in House File No. 592, which is a bill introduced by Representative J. Wilfred Donahoe and referred to the committee on Mines and Mining, Feb. 12.

Mr. Donahoe is a native of Schuylkill County, having been born at Ashland, Nov., 1880, and educated in the public schools of that place. At the time of his election to the House of Representatives, Nov., 1910, Mr. Donahoe was engaged in clerking at a stationery store.

What the author of the bill knows of mining may be judged better by some of the features of the bill. For example, one of its first provisions is that "the Board of Examiners for Inspectors of Mines and the examinations provided for in Art. 2 of the Act approved June 2, '891, be and are hereby abolished."

The bill further provides for "two chief officers of the Department of Mines, one to be known as chief of the bituminous mining district and the other chief of the anthracite mining district." By the provision of the bill, both of these officers of the Department are to be "elected by the qualified electors of the counties" of their respective districts, "for a term of four years or until their successors are duly qualified."

Under the present law, approved April 11, 1903, estab-

lishing the Department of Mines in Pennsylvania, the chief of the Department is *appointed by the governor.* Under the provision of the bituminous mining law (1911), Art. 19, the bituminous mine inspectors are *appointed and commissioned by the governor,* from a list of names certified to him by the Examining Board. In the anthracite district, under the Act approved June 8, 1901, and amended May 3, 1909, the mine inspectors are *elected by the qualified voters in the counties of the district.* If the proposed bill should become law, the *elective system* would control the Department of Mines as well as the anthracite mine inspectors, leaving the bituminous inspectors to be appointed by the governor.

In abolishing the requirement of the examination of candidates for the office of inspector of mines, the proposed bill provides that

> Any person shall be eligible for election to the office of inspector of mines in the anthracite mining district who shall be a citizen of the State of Pennsylvania, not less than 30 years nor more than 60 years of age at the time of his election, shall have not less than ten years' practical experience as a miner in mines where noxious and explosive gases are evolved and shall have a mine foreman's certificate, granted to him in accordance with the provisions of Art. 8 of the Act approved June 2, 1891, and who has been employed in or about a coal mine within five years prior to his first election to the office of inspector of mines.

By the proposed bill the expenses of the Department of Mines would be increased from the present $19,500 per annum to $21,800, or an increase of $2300 per annum. Instead of the present force of one chief, one deputy, six clerks, three stenographers and one messenger; the working force, under the new bill, would be two chiefs, two assistants, four clerks, two stenographers and two messengers. The clerical force, including messenger, would be reduced from ten persons to eight, with a reduction of $4400 for the expense in the clerical department of the work, while the force of supervision is doubled, with an increase of $6700 in expense for supervision.

No argument is required to show that the work so efficiently done under the present system, would be greatly hampered and its efficiency impaired by the proposed division of the Department. The questions presented are: 1. Is there any existing need for such division in the Department of Mines? 2. Would the work of the Department be conducted harmoniously under two heads?

While the conditions in the two districts, in Pennsylvania, are recognized as substantially different and are regulated by a separate code of laws, the anthracite mine inspectors and the bituminous mine inspectors report to the same head, and we predict greater advantage and harmony in the working of the present system than would exist if the interests in these two districts were completely divorced.

We believe that the committee on Mines and Mining, that must pass on this and other bills before they can be presented to the legislature, will be too wise to handicap the work of the committee appointed some time ago to revise the anthracite mining law. That committee has given much time and study to the conditions existing in the state and the anthracite district, and the report will be presented in due form for such action as the Assembly deems fit. In view of the extended work of the committee and the time it has consumed in the codification of suitable laws to govern the mining of anthracite coal in the state, the introduction of similar bills at this time, would seem to have no other purpose than to block legislation in this regard, by confusing the true estimate of the situation and conditions.

The Downsitting and the Uprising

With what deliberate purpose we sit down between the arms of our office chair to think on the whys and wherefores of our tonnage cost, our output and our sales.

It would be well if we would often compel ourselves to re-sit, with the same, earnest, knitted brow, and view awhile in anticipation that unforseen, because unlooked for, group, or it might be even a succession of groups, proceeding slowly, with frequent stops, carrying the injured on stretchers from our mine.

If a stranger were to travel unbidden, without carping spirit or the hope of journalistic reward, the length and breadth of coaldom, we cannot but think he would be impressed that many were the provisions of safety resulting from such downsittings.

But most of these provisions have not come as the result of such deliberation. Too many carry the blood mark on them. It would be well; it would be worthy of this our new century, and this our modern outlook, if we did not wait for misfortune, for maiming, for death, for hecatombs even, before we roll that chair into position and deliberately sit down and review, and again review, the question of safety.

And having sat down and considered, let us go around and explore. It is not here can be written down all the thoughts we will think and the places we will visit.

Let us hark back to our first visit in some large city, recall with what difficulty we found our way around, stopping here and there a man and plying him with the endless question, the way to reach the object of our visit. Remember our strictures on that city for omitted, defaced and misplaced signs and on the pioneers for crooked, happy-go-lucky twisting of the streets.

Cherish that memory; it will help us to understand the predicament of strangers, of that foreigner, newly arrived, who barely learns the way to work and may never learn the way to safety, to whom the maps of our labyrinth are inexplicable puzzles, to whom the general principles on which our mine is based are unknown, who is not enlightened by converse with his more competent fellows.

In semi-darkness, in complete darkness, in terror, facing the eye of death, after cavings have destroyed landmarks, through roadways rarely traveled, he must thread his way to safety. Have we explored that roadway which he will travel if he has the knowledge to choose and the power to reach it, and which he must strive to pass before we, following time-honored precedent, restart the fan driving the afterdamp on him.

Is that roadway free of water? Is it likely to be after the shock has jarred down the slate in the heading? Is it reasonably straight? Can a man in the dark, groping, wandering, ignorant, unerringly follow it? Is it low and narrow? It will be lower and narrower after a fall.

And now let us uprise and make our mine in this and all other ways a compliance with the law, with the spirit of the enactment, nay more, a reflection of this present age of altruism, even more, a foreshadowing of that age of psycho-sympathy which is yet to come.

SOCIOLOGICAL DEPARTMENT

How the H. C. Frick Coke Co. Takes Care of Its Men

By Thomas W. Dawson*

SYNOPSIS—The company realizes that safety is promoted as much by preparedness and discipline as by the introduction of mere devices for protection. The personal aspect of safety is as important as the material.

The H. C. Frick Coke Co. has carefully considered the risks of mine and village fires. For the illumination of the mines and mine buildings, only the best and safest oils are used. Open lights are prohibited in all buildings around the mine. No oils and explosives must be stored in the underground workings.

Stables, pump rooms, haulage-engine rooms, shaft bottoms, underground offices, and all such places where men might congregate, are of fireproof construction and are kept clean and neat.

All mine rooms, as well as those on the surface, must be well ventilated and kept both neat and clean. Cans are provided for the reception of oily waste, grease, small quantities of oil, etc.

Hay and straw are taken into the mines in bales, not loose. All electric wiring, either for lighting or power, is carefully installed and properly examined at stated intervals. All stoppings and overcasts along main airways are of fireproof construction. In the newer shafts, concrete linings have been provided.

Village Fire Departments

At every mine there is an organized fire-fighting force. The equipment is standard for all plants and interchangeable. Scattered throughout the towns, as well as at the mine, are hose, reels and drying towers. Fire signals are printed on cards and posted at the convenient points, as is customary in the larger well-ordered towns. Water systems are laid, having sufficient water head for fighting fire. On about every fifth or sixth house in the town you will note a ladder and water buckets ready for immediate use.

All bare power lines underground and on the surface are properly guarded for their entire length by a neat wooden guard, so as to prevent the workman or his tools from coming in contact with the same. To insure the same security, trolley wires for coke-drawing machines are placed at a sufficient height to make contact with tools unlikely.

An improved system for checking men in and out of the workings is maintained at all the mines. This shows *HOW MANY* men and *WHO* are underground at all times.

The Personnel

Article No. 5 of the general rules provides for the employing of only steady, reliable and sober men as mine foremen, firebosses, master mechanics, hoisting engineers, boiler and fan tenders and stable bosses. The use of intoxicating liquors by any employee on duty is absolutely forbidden.

Article No. 16 of the general rules says: "No one will be permitted to interfere with the religious or political opinions of the workmen, and no superintendent, boss or clerk will be allowed to solicit money or make collections from the workmen for any church, society or association." Employees must have permission to be absent from duty.

A Spring Stretcher for Use in a Mine Car

The company employs four mine inspectors, one of them acting as chief. It is the duty of these men to visit each and every mine, and thoroughly inspect it at least once every 60 days, reporting the result of his inspection in writing to the general superintendent. When an accident does occur in or about the mine, the chief mine inspector of the company promptly visits the scene of the accident, gathers all the data he can relative thereto, and makes a sketch of the surroundings.

Immediately this sketch is put into permanent form, blueprinted and sent to each mine with a circular letter giving a full account of the accident, and making suggestions for preventing a similar one. This circular and plan is discussed at a meeting of the local officials at each and every plant and methods are devised for preventing similar accidents at their mines.

The Weekly Council

Once each week the superintendents of every mine and their subordinates meet and discuss mine conditions and

*Assistant chief engineer H. C. Frick Coke Co. Scottdale, Penn.

Note—Abstract from paper entitled "Welfare, H. C. Frick Coke Co." read before the winter meeting of the Coal Mining Institute of America

operations generally, and especially matters pertaining to the protection of the lives and health of the employees, and the care and safety of the property. The discussions at these meetings are reported to the general superintendent each week. Then there are general meetings at stated intervals held at the main offices; these are attended by the superintendents of all the plants, and the heads of departments.

There is a separate and distinct plan for the future working of each mine. This plan provides a layout which will assure the best results. Specifications are written for each mine, stating where and how the mining is to be done. These are signed by the company's chief engineer, mine inspector, division engineer, superintendent and mine foreman, to show that they are all familiar with the plan for working each mine.

Projections are made for the workings far in advance of the actual work, and the haulage and ventilating problems planned so that when the mine is developed the best systems are in use.

The officials of the company periodically make a detailed inspection of each and every mine, insuring that their instructions, and the best methods are actually followed at all mines.

The Committee of Safety

In addition to these precautions there is appointed at each mine a committee known as a "Safety Committee." It is composed of three or four men chosen from the various occupations in and about the mine, and it is their duty to inspect periodically the working places, roadways, ventilation and any other things which in their opinion might be the cause of an accident.

They report their findings in writing to the superintendent of the mine, who forwards the same to the general office. These suggestions are immediately acted upon, and any and all dangers, should there be any reported, are removed as quickly as possible. Thus there is a frequent check on the general condition of the mine, and a stimulus to mine officials to keep everything in first-class condition.

All "new" or "green" men are conducted to and from their work underground, and this is continued as long as it is necessary to acquaint them with the traveling way to and from the surface. Should an employee not return from the mine in due time, after the day's work is done, a search is at once made for him.

Reports are made daily by the firebosses, shotfirers and mine foreman. These reports eventually get in the general superintendent's office, so that he is in close touch with existing conditions in detail.

Central Stations for First-aid and Rescue

This company established the first rescue and first-aid station in the bituminous-coal fields of the United States, aside from those which were established by the government. Three stations are now maintained, one at Leisenring No. 1, one at Buffington, and one at Hecla No. 2. They are fully equipped with the best apparatus and accessories obtainable.

There are 36 trained corps of five men each which practice quarterly, and twice that number of men are fully trained and qualified in both rescue and first-aid work. A certificate is issued to each man on completion of the course, and a card is given him which is his credential, permitting him to use the oxygen helmet at the time of an accident.

The company has spent $20,000 on this work in one year, about one-half of which went as wages to the men who attended practice. Before a man is allowed to practice rescue work, he must possess a doctor's certificate showing that he is physically fit to train and perform the labor incident to that work. Every corps elects its own captain or leader, and consequently a man is chosen in whom they have confidence. Printed regulations for rescue-corps men are freely circulated.

Local First-aid Stations

To supplement these rescue stations, pulmotors or resuscitating apparatus are kept at many of the mines throughout the region. By their prompt application a number of employees have been resuscitated after severe electrical shocks and similar accidents.

There are 180 first-aid teams fully organized and qualified to render first aid to the injured. For the purpose of increasing proficiency, local contests are held from time to time. Much interest is manifested by these first-aid men, and in the miners' contest held by the Ninth International Red Cross Conference, in Washington, D. C., the team from Phillips mine won first prize, a silver loving cup.

Emergency hospitals fully equipped have been provided at a number of the larger mines, and the company is contemplating erecting one at each of its operating mines. Underground, in close proximity to the various working sections, can be found first-aid rooms, in which are stored stretchers, blankets and such accessories as may be needed immediately in case of accident. Hospital wagons are used at some of the mines. A device having springs and straps to be applied to the ordinary mine wagon is on hand at each mine. On this the stretcher can be placed and the injured conveyed to the shaft bottom or the surface, without the least shock due to transportation.

(*To be continued in an early issue*)

A Traveling Hospital

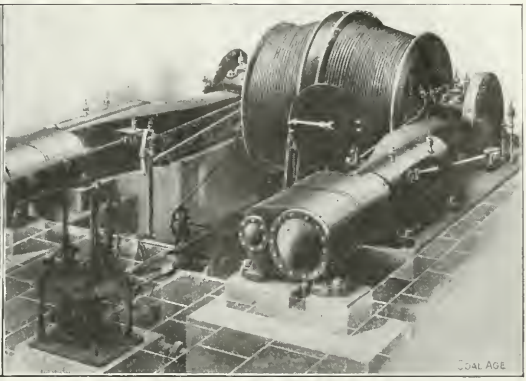
In addition to the elaborate provisions for rescue and first-aid work now in force in the anthracite-coal mines, the Lehigh Valley Coal Co. is just putting into service a mine-rescue car which can be rushed at a moment's notice to any colliery in case of accident. This car consists of a remodelled passenger car equipped with oxygen-breathing apparatus and every kind of first-aid equipment.

It has six complete Draeger oxygen-helmet outfits, by means of which the wearer can breathe for two hours in a gas-filled chamber, with the necessary auxiliary equipment, resuscitating apparatus consisting of pulmotors, stretchers, blankets, splints, antiseptic cotton and provisions for setting up a small commissary in the field.

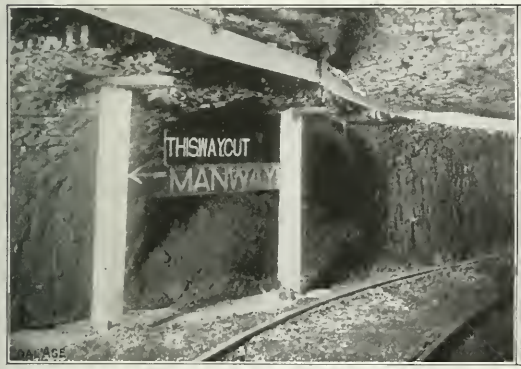
It will be used as a hospital and ambulance car combined, and rushed on call by special train service to any colliery where an accident has occurred, and will be manned by a crew of thoroughly trained helmet men. As there is already a corps in every mine, specially trained in first-aid work and a small hospital with similar first-aid facilities at the foot of all the working shafts, this additional service will complete the provisions for the comfort and safety of the injured mine workers.

Safety Provisions of H. C. Frick Coke Co.

Steel Doors to Drop over Shaft Mouth in Case of Fire



All Hoists Are Provided with Overwind Devices



Trolley-wire Protection and Sign Pointing the Way Out

Stile over Rope Sheaves to Protect Traveling Men

Fireproof Overcast of Concrete with Steel and Tile Roof

All Man Trips Are Secured with Double Safety Chains

S[illegible]ions for Mine Safety

By J. V. Rhodes*

[illegible]ally arise from persons stepping be[illegible]n [illegible]k-back rails at the tipple. Safety [illegible] be placed at this point, so that employees c[illegible] their feet caught and possibly mashed by the op[illegible]he dump.

[illegible]hts should be provided at all switches on ha[illegible]ge roads, and the throws for partings should be put on the opposite side from the trolley wire, to keep brakemen from coming in contact with the charged wire.

No motormen should be permitted to make flying switches, as such a practice is dangerous and is prohibited on all first-class railroads. A practice which is dangerous with heavy equipment on a good rail is even more to be feared with light cars on a mine track underground, where in case of a derailment there is no opportunity for escape. The pushing of trips of cars, either loaded or empty, is also very dangerous and should be prohibited.

On delivering empty cars to miners, the driver should ride inside the car at the brake end, and should see that the wagon is properly provided with a "dead block" to keep it from running away from the face. In some cases the miners depend upon the brake to hold the car, and when they start to load coal, the brake is knocked loose by a lump and the car may run on the miner or in the opposite direction, causing an accident either to some employee or to property.

I would recommend that the assistant mine foreman, when hiring a new miner, put the brake on and then pick up a shovel and throw some coal into the car so that it will knock the brake loose. This will show the miner the danger arising from relying upon the brake. Mere explanation may fail to produce the required result, as the miner may not understand what the foreman is endeavoring to tell him.

Many people fail to understand the importance of keeping cars in good condition. One wagon which does not run truly on the track, or which has some other defect, is apt to derail a whole trip and seriously cripple or kill the motorman or brakeman. It is also important that all the bolts on the car shall be thoroughly tightened and the ends cut off flush with the top of the bolt. Otherwise the clothes of men on traveling ways may be caught by passing motor trips.

*Mine foreman, No. 2 plant, U. S. Coal & Coke Co., Gary, W. Va.

Note—Abstract from a paper read at the "Safety Boosting" banquet of the U. S. Coal & Coke Co., Jan. 4.

The Canteen at the Coal Camp

In view of the discouraging results arising from the privately owned saloon in mining towns, the Sunnyside Coal Co. has taken a leaf from the past history of the army and established a canteen at Sunnyside, Colo.

W. P. Oakes, vice-president of the corporation, makes the following statement relative to this novel attempt to meet the situation:

"One of the acknowledged handicaps in every mining camp is the character of the saloons maintained there. These bar rooms are generally of a low order; the liquor sold in them is the vilest of the vile, and trouble of one sort or another is always impending. It is useless to argue against the existence of a saloon of one sort or another in or about a mining-camp. If the men cannot get their beer, or whatever they want to drink, they will buy it from bootleggers, who are even less scrupulous than the owners of groggeries. Either they will get their liquid refreshment from this source, or they will go to some other camp where they can obtain it.

"We had our share of trouble because of the existence of a cheap saloon at our camp. Finally seeing that something drastic had to be done, I called some of the men together and we talked it over. The outcome was that we organized a social club and furnished a club house.

"The members appointed an experienced manager, fitted up their club with all necessary conveniences and comforts, ordered only the best brands of beers and liquors, and were ready for business. They decided at the outset that only bottled beer would be handled, and that all drinks would be served at just about a price which would pay running expenses.

"One of the first rules laid down was that the club bar should be open only from 4:30 to 10:30 p.m. This has been strictly enforced. This regulation has resulted in the men retiring early every night, being fresh for work the next day, and starting in with a clear head because drinking is discouraged in the evening, and the club is closed until after working hours the next day.

"To date the plan has worked to the satisfaction of the men and the company, and I believe the system will eventually be adopted in all the big camps in the state.

"The Sunnyside club is fitted with barber chairs and necessary tonsorial equipment, a pool table, several card tables for social games, in which gambling is barred, easy chairs, a library table and other attractive furnishings, including pictures."

Fatality Reduction in Anthracite Mines

The number of deaths from accidents in and about the mines of the anthracite region of Pennsylvania decreased from 699 in 1911 to 593 in 1912, according to the annual report of the Department of Mines. This is an improvement of approximately 15.2 per cent. The actual improvement will not be ascertained till it is possible to obtain the number of days worked. It must be remembered, moreover, that one of the two largest mine disasters which have occurred in the anthracite region of Pennsylvania happened in 1911, so that comparisons with that year are misleading.

The number of fatal accidents per 1000 employees decreased from 4.03 in 1911 to 2.86 in 1912. The production of coal per fatal accident rose from 130,067 tons in 1911 to 136,902 tons in 1912. The number of fatal accidents per million tons produced decreased, therefore, from 7.69 to 7.42.

FATALITY TABLE OF ANTHRACITE MINES

Yearly Average	Employees	Fatalities	Fatalities per 1000 Employees	Output per Fatal Accident	Fatalities per million tons
1869-1879	55,953	225	4 02	93,288	10 72
1879-1889	97,716	311	3 18	122,572	8 16
1889-1899	137,790	434	3 15	121,185	8 23
1899-1909	160,167	549	3 42	130,256	7 68
1912.	175,964	593	2 86	136,902	7 42

This is a gratifying result to the anthracite operators who have spent much money, time and thought in securing safety.

DISCUSSION BY READERS

Post Timbering at the Working Face

Letter No. 2—It would be useless to attempt to be original in the discussion of such a subject as mine timbering; but I have in mind a suggestion that I believe, if carried out, would have a greater tendency to reduce accidents from falls of roof and coal than can possibly result from the closest vigilance of mine officials.

In Great Britain and on the Continent, the mining laws specify clearly what is called the maximum distance that mine timbers may be set apart and the distance such timbers may be set from the face of the coal. Any violation of this law on the part of the miner, if discovered, is followed by prosecution. It is needless to say that this kind of legislation has had the effect of greatly reducing the rate of accidents from this cause. If good legislation and the enforcement of such laws have been good for Great Britain and Germany, surely it would be worth while to try the effect of the same in this country.

Information on which to base such legislation could be best obtained from the mine inspectors who have good opportunities to know the nature of the various seams in their districts. I believe it would be possible for the mine inspectors, in most mining districts, to determine what should be considered a maximum distance apart for setting post timbers and the maximum distance such timbers should stand from the face of the coal, for different depths of seam and for different kinds of roof, leaving, perhaps, to the mine inspector of the district, the particular classification of the mine in this respect.

Having settled upon the details of such a classification of mines and the maximum distance of timbers apart, for the several conditions, it would be up to the chief mine inspector in each state to urge suitable legislation that would enable the mine inspectors to enforce compliance with such requirements, in their districts. A good law is the first requisite and this should be followed with a thorough discipline in the mine, without which it is impossible to secure the greatest efficiency, safety and economy in mining.

Another suggestion is in regard to the size of timbers sent into the mine, for use in certain places. The ordinary miner does not give any attention to the diameter of the posts that are sent in to him. To most miners, a post is a post, and its length is of the first importance; the diameter concerns him less. I have seen props taken into a mine that were 10 ft. long and only 4 in. in diameter at the small end. Every miner should know that a prop of this kind is out of proportion and totally inadequate to support any reasonable amount of weight.

In post timber, some specified diameter should be determined by those who have the matter in charge. It is also important that all miners should be required to have suitable tools for setting timbers; and, as a further precaution, every miner should be required to demonstrate his method of testing roof and setting a mine post.

I have tried to make these suggestions [illegible]d such as I believe should form a basis for our work [illegible] reducing the number of accidents from falls of roof and coal.

WILLIAM CROOKS,
Mine Foreman.

Quinton, Ala.

Letter No. 3—The question of timbering at the working face is one that needs careful thought and study. In the first place, the work of timbering should not be planned for the present only but also for the future. What is the working face today will soon be left behind for a road or haulway, and the weight on the timbers will not be less but greater, if anything, as the face is advanced. The timbering, good or bad, will affect the expense of keeping the place open and maintaining the road in good, safe condition.

Mine timbers should be set so that they will conform to the rules and regulations of the mine, and in such a manner and where they will do the most good. In my opinion and experience as a miner, however, there can be no set rule for the placing of props. This is particularly true in the anthracite region.

To avoid accidents due to falls of roof and coal, it is necessary to consider carefully the condition of the roof, having regard to whether it is a hard or soft stone, or a slate or bony roof; as the size of the timbers needed will vary accordingly, from 6 to 12 or 16 in.; although such heavy timbers are seldom sent to the face.

In most anthracite mines, no timber less than 10 in. in diameter should be used. In general, the strata have been very much disturbed and broken. The nature and condition of the roof play a large part and, in fact, are the chief factors to be considered, in timbering. Study the roof and consider whether a large or small prop is needed. Many times a small prop is stood where a large one would be better; and, again, a large one is used where a smaller one would answer the purpose. Props should be stood so that they will give the necessary support and take the weight properly.

The strength of mine timber is important and largely determines its value. The best timber is needed and should be used, as the weight it is required to support cannot always be estimated and varies with different kinds of roof. When the character of the roof and overlying strata are known the style of timbering best adapted to the conditions can be determined; but without that knowledge one is mostly playing a game of chance.

Timbers should be set as soon as possible after a slant slab or other condition that requires special attention has been discovered. Observing this rule carefully will prevent many accidents that occur from falls of roof at the face. A good plan is to always protect the timber supporting the roof, by leaving some coal around the props that will prevent them from being knocked out by the flying coal when a shot is fired. It is always more dangerous to reset a prop that has been once stood and then knocked out, under a bad roof.

The wedging of a post is important. The wedge should cover the whole top of the post and not just a few inches. Proper wedging is necessary to give the post greater resisting power against flying coal to avoid, as far as possible, its being knocked out when a shot is fired.

The life of post timber differs with the kind of wood and the manner and time it is cut, as well as the conditions to which it is subjected in the mine. Props cut when the sap is out of them will last longer than the same timber cut when it is green.

There are good reasons why miners should stand their own timber. This practice will make each miner, to a large degree, responsible for his own safety. If a miner does not understand the roof where he is working, he should be instructed by someone who is competent to instruct him. In many cases, it would be better to take down a bad piece of roof than to attempt to prop it up and hold it in place. There would be fewer accidents at the working face if this was done.

A MINER.

Scranton, Penn.

Posting a Drawslate

Some time since, notice was sent by the bituminous-mine inspectors to the different superintendents, mine foremen, assistant mine foremen and firebosses, in their several districts, describing in detail the manner suggested for the posting of drawslate (COAL AGE, Vol. 2, p. 258). I would like to draw special attention to a dangerous feature and one that is often overlooked in posting roof slate, at the face of a room. I refer to the possible existence of a clay vein or spar, or a slip in the slate, at the back end of the cut, which is, as yet, hidden from sight, so that it is not detected.

Having this matter in mind, I prepared, a while ago, the following instructions, which were sent to the several mines in my district, asking for the kindly aid and cooperation of all the general superintendents and superintendents in the district, to assist in reducing accidents at the working face, by again directing all mine officials in their charge to urge that every precaution be taken by the workmen to avoid danger from this cause.

In sending out this notice, I was anxious to urge that it is not sufficient for the mine foreman, assistant foreman or fireboss to draw attention to the notice as posted and think that his responsibility ends when he has told the men to set the needed posts. It is important that he should see that his orders are carried out to the letter, as this is the only way to reduce the number of accidents from falls of roof and coal.

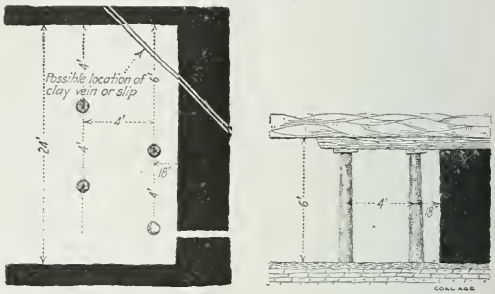
The reduction of fatal accidents during 1912 has been largely due to the carrying out of Art. 4, Sec. 10, and Art. 5, Sec. 3, of the new bituminous-mine law (1911). I wish to express my satisfaction in the generous assistance the operators have given their mine foremen, aiding them to carry out this part of the law. I feel that what remains to be done is to impress upon all mine officials the absolute necessity of seeing that their instructions *are carried out or enforced*.

In this connection, also, I want to call attention to the fact that all coal should be spragged while being undermined, especially in pillar and stump workings, in accordance with Art. 4, Sec. 9. I would also refer to the high percentage of accidents by mine cars and draw attention to the need of widening all old entries where hauling is done, as required by the law, Art. 4, Sec. 8; and where electricity is used I would urge that due attention be given to paragraphs 40 and 41, of Art. 11. In asking this coöperation of the mine officials in the district, I desire to express my satisfaction in the work they have already done in this direction, and my confidence in them that it will still be carried vigorously forward.

CHARLES P. MCGREGOR,
State Mine Inspector, 7th Bit. Dist.

Carnegie, Penn.

Following is a copy of the instructions:



SHOWING POSSIBLE LOCATION OF SLIP IN ROOF SLATE

INSTRUCTIONS TO MACHINE LOADERS AND MINERS AS TO POSTING DRAWSLATE WHILE LOADING OUT A CUT OF COAL.

To Mine Foreman of.....Mine.

.....

The common method of posting along the front of the slate is not safe, as there may be a false slip, clay vein, or spar, at back end of cut of coal, which will throw the posts and slate forward. In order to avoid this, as far as possible, the mine foreman, assistant mine foreman and fireboss should each instruct the men under their charge to put from four to five posts at a point halfway back or near the face of coal, under all slate, in the form of a triangle, the mine foreman to use his own judgment as to the distance these posts should be set apart, as shown on blue print. It would be a good thing to insist on the machine cutters putting a piece of pit rail about 8 or 10 ft. from the rib or pillar, under the coal, as a sprag, which would keep the coal from settling down and allowing the drawslate to sag. All projecting drawslate, both in rooms and entries, to be taken down, also on haulage and travelingways.

The writer would urge the manager, general superintendent, mine superintendent, mine foreman, assistant mine foreman and firebosses to give this matter their most careful consideration. I feel certain that the number of fatal and nonfatal accidents can be reduced.

The mine foreman is referred to Art. 20, Sec. 1, Rule 1 of the mining laws, which reads as follows: "The mine foreman shall attend to his duties in the mine and carry out all the instructions set forth in this act and see that the regulations prescribed for each class of workmen under his charge are carried out in the strictest manner possible." Post this up in a conspicuous place at mine, as provided for in Art. 10, Sec. 12, of the mining laws.

CHAS. P. MCGREGOR,
State Mine Inspector, 19th Penn. District.

Engineers Meeting

The New York section of the American Institute of Mining Engineers will hold its next meeting at the Engineering Societies' Building, 29 West Thirty-ninth St., New York City, on Friday, Mar. 21, at 8:30 p.m. G. S. Rice, chief mining engineer of the U. S. Bureau of Mines, will present a paper on "Notes on European Mining Practice, especially the Methods of the Hydraulic Filling or Flushing of Mines."

Taxation of Coal Lands

Your editorial on the Tax Valuation of Coal Property, Coal Age, Feb. 15, 1913, p. 267, advocating a royalty basis of valuation, was evidently written without considering in full the present laws of the state of Pennsylvania. The assessment of lands for taxation in Pennsylvania is made under the Acts of the Legislature of 1841 and 1842, under which all properties must be assessed at the actual value and at such rates and prices as the property would bring at a bona fide sale, after due notice."

In the long, tax litigation that has taken place over the 1907 anthracite assessment, in the Pennsylvania courts, the matter has been five times brought to the Supreme Court on appeal, and the decisions made in these cases must be followed in making any legal assessment. The question of valuation on a royalty basis was brought up in two of these appeals, and the Pennsylvania Supreme Court says, referring to such a royalty basis, (Penn. Supreme Court Report No. 299, page 470):

> Its market value is its fair selling value for cash, not payable as royalty strung out through a long series of years, but payable at the time or as soon thereafter as the value could be determined. Such a method does not make allowance in undeveloped territory for the length of time coal may lie in the ground unmined, undeveloped and unprofitable. It is impossible to reduce to a scientific basis and to mathematical precision the elements of value entering into the present selling price of a tract of coal land. The question is not what earning power coal lands may develop in the future, but what they are actually worth in the market at present.

Further, in the opinion of Judge Fuller, President Judge of Luzerne County, Pennsylvania, No. 614, October term, 1907, sustained by the Supreme Court, it is stated, page 21,

> The law does not sanction a valuation upon coal in place specifically determined by the royalties which it may yield or its availability for market.

Under these decisions, which form the law of the state, it is necessary to assess coal land at its sale value not on a royalty basis, nor on the foot-acre basis, as was previously done; for, in Pennsylvania Supreme Court Report No. 229, page 465, Reading appeal, the Court says,

> * * * * that the foot-acre rule for ascertaining valuation of coal lands of the appellant for the purpose of taxation is not the proper measure of their value * * * *.

Further, it may be pointed out that, under the Pennsylvania law, assessment on similar properties must be equal and, if not so made, may be equalized by the County commissioners. On a royalty basis, the time of mining would be the deciding factor in the value of any property. Calculating the present value on a six-per cent. basis, less the taxes, which must be paid as an annuity and which amount to about 2¼ per cent. of the assessed valuation in Luzerne County at the present time, coal land of a value of $100 per acre if mined now, would be reduced in value to about $42 per acre if it were not to be mined for ten years, or to $11 per acre if standing idle twenty years, and beyond 23 yr., 8 mos. such lands would have a present minus value amounting, at thirty years, to minus $20 per acre, and at forty years, to minus $40 per acre.

Then, on a royalty basis, two adjacent and similar tracts, one opened and in operation and to be mined out in ten years; and the other not to be opened for thirty years, would show radically different values though containing similar amounts of coal of identical value in the market; and further, a mere extension of ownership to include the reserved with the opened tract would change the value of the reserved tract from zero to a very large cash value, which is certainly neither legal under the state laws, nor apparently just to the communities involved.

It seems to me that all taxation of coal or other minerals in the ground is logically wrong. The coal has no value until it has been mined and prepared for market.* The amount of mineral, its availability, and the duration and cost of working are all undetermined and undeterminable factors, which, used as a basis for assessment only lead to dissatisfaction and litigation. The proper method of taxation of all minerals would be a tax on the value of each year's output, at the rate assessed for that particular year, including taxation of surface improvements and machinery the value of which is readily ascertainable, but not including any valuation for mine openings, which are incidental to the mining of the mineral and which on its exhaustion are no longer of any value.

Thus, a colliery producing 1,000,000 tons of anthracite in 1912, with a value at the breaker of $2,500,000, should pay taxes in 1913, at the regular rate for that year, on a valuation of $2,500,000, regardless of the area of coal land tributary to such a colliery. This method is clearly unlawful under the present Pennsylvania law, and would require special legislation to put it in force. However, such a system if legalized would possess the advantage of doing away with all uncertainty and litigation as to the assessed valuations, and would result in the payment of taxes in greatest amount, at the times and in the localities of greatest production and consequent greatest population and greatest need for money; and, by concentrating taxation on the land being most actively worked and relieving reserve land from its present almost insupportable burdens not only of taxation but of litigation, it would tend to the conservation of the unreplaceable coal resources of the community by encouraging the complete mining of lands once opened, including all workable beds large or small, rather than the opening of the best beds on all lands, to obtain immediate earnings even at the cost of injury or destruction to interstratified, smaller and less profitable beds.

R. V. Norris,
Consulting Engineer.

Wilkes-Barre, Penn.

[The arguments of Mr. Norris are familiar to us, as are also the Supreme Court decisions. The main question is concerned with the methods of determining actual present value. How does a competent well informed engineer arrive at such value? Naturally, by the method suggested in our editorial, which is the method used by such authorities as Joseph H. Harris, and the late W. A. Lathrop in determining the value of coal lands as the security for issues of bonds, etc. *The statement that coal has no value till mined and prepared for market does not agree with the Supreme Court decisions quoted.

If no common-sense method of valuing property exists under present judicial interpretation of the laws, is it not time to devise such a method, and if necessary to revise the laws for that purpose? We would like to hear from other engineers who have ideas in this matter.—Editor.]

INQUIRIES OF GENERAL INTEREST

Blowing vs. Exhausting in Fan Ventilation

Will you kindly inform me whether there is any difference in the pressure that a fan will produce at a given mine when blowing or exhausting, under the same conditions and at the same speed.

For example, suppose a reversible fan, at a certain mine, produces 60,000 cu.ft. of air at a given speed, under a water gage of one inch; and suppose it is desired to reverse the air current by shifting the doors in the fan drift so as to make the fan blow the air into the mine instead of exhausting the same from the mine. For the same quantity of air in circulation, will there be any difference in the water gage and, if so, why?

J. A. McD.

Reserve Mines, C. B., Nova Scotia.

For the same quantity of air in circulation in the mine, there will be no change in the ventilating pressure or water gage, unless there are natural or secondary air columns in the mine that act for or against the circulation, or some other obstruction exists that makes the flow of air in one direction easier than the flow in the opposite direction. Either of these conditions would change the observed water gage, for the same circulation of air.

A secondary air column might easily exist in a shaft mine or in a seam of steep inclination, owing to the heat radiated from steam pipes in the shaft or slope. This air column would act to assist the general circulation when such shaft or slope was the upcast, but would oppose the circulation when the air current was changed so as to make the same shaft or slope the downcast. Without knowing these conditions it would be impossible to state what change of pressure would take place when the fan was reversed.

In this connection, it is necessary to remember that it is the resistance of the mine airways, including the shafts, both downcast and upcast, that produces the ventilating pressure or water gage. Without this resistance there would be no pressure, but the power of the fan would be wholly exerted to produce a high velocity of the air current. There are still other conditions affecting this question besides those we have mentioned.

When the fan is exhausting, it is filled with the mine air, which may be warmer or colder than the outside air and may contain gases that are lighter or heavier than pure air. When the fan is working on heavier air, a greater power is required to produce the same speed of revolution of the fan and, *vice versa*, when the fan is filled with lighter air, a less power is required to produce the same speed. It may be stated that the power applied to the fan shaft varies as the *square* of the efficiency of the fan, the *fourth power* of the speed and the *square* of the density of the air passing through the fan; and *inversely* as the resistance of the mine, the latter being measured by the product of the unit pressure and the sectional area of the fan drift. It is readily seen from this statement and the foregoing explanation that the question of how the reversing of the air current in a mine will affect the water gage, cannot be determined, except with a full knowledge of the conditions.

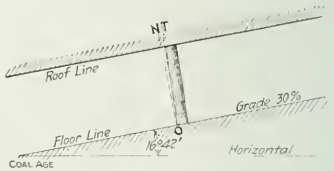
Setting Post Timber in an Inclined Seam

How much pitch should be given to a post in a seam having an inclination of 18 deg.? Explain the manner of setting a post in an inclined seam. What is the purpose of the cap-piece above the post?

A MINER.

Crosby, Wyo.

When setting a post in an inclined seam, the post must be *underset;* that is to say, it must be inclined up the pitch a slight angle from the normal, as shown in the accompanying figure. The angle *NOT* at which the post



SHOWING HOW A POST SHOULD BE SET IN AN INCLINED SEAM

is inclined up the pitch, will vary from 1 to 9 deg., according to the amount of inclination of the seam. The purpose of undersetting a post, in an inclined seam, is to prevent its being loosened by the slipping of the roof downhill, as the coal is extracted. It is evident from the figure that any movement of the roof, in a direction down the pitch, will tend to tighten the post when it is thus underset.

When setting a post in an inclined seam, a slight foothold is first cut in the floor of the seam sufficient to hold the foot of the post in place while setting. The small end of the post is then placed over this foothold with the large end up the pitch. In this position, the head of the post is raised, the cap-piece being inserted between the top of the post and the roof. Both the head of the post and the cap are then driven forward from the upper side, until the post assumes its proper position.

The purpose of the cap-piece is twofold: First, the cap-piece serves to distribute the resistance of the post over a greater surface of the roof and tends to prevent the post from cutting into the roof as would otherwise often be the case. Second, the cap-piece should be of soft wood and of sufficient size to completely cover the head of the post. As the roof "weights," the head of the post is forced into the soft wood of the cap, which binds it together and prevents the "furring" of the post. By *furring* is meant the crushing over of the fibers, at the head of the post.

EXAMINATION QUESTIONS

Miscellaneous

Answered by Request

Ques.—What precaution would you take in a gaseous mine, where coal is cut by electric machines and what method of blasting the same would you adopt?

Ans.—The use of electric machines in gaseous mines is attended with danger and should only be permitted when the working face can be kept free from any accumulation of gas and an ample current of air continually sweeps the face of the coal. In a gaseous mine, it is better to use some other type of machine for undercutting the coal. If electric machines are used, every precaution must be taken to prevent sparking or short-circuiting of the electric current, as well as to maintain an ample ventilating current sufficient to carry off the gases as they are generated.

In blasting down the coal, after the face has been undercut, care should be taken to avoid heavy shots and to see that the coal is not cracked or broken in the vicinity of the shot. The fine machine cuttings must be cleaned up and removed and the place carefully tested for gas before a shot is fired. Permissible powder should be used in blasting. If the mine is dusty, the working face should be thoroughly sprinkled, and also the road and ribs for a distance of about 20 yd. from the face.

Ques.—Give the composition of monobel powder and state what gases are generated when this powder is exploded.

Ans.—Monobel is a permissible powder of the ammonium-nitrate class, containing nitroglycerin. The principal constituents of the powder are nitroglycerin, wood pulp, ammonium nitrate and moisture. The proportions of these constituents are such as to produce complete combustion. The gases produced are carbon dioxide, nitrogen and water vapor.

Ques.—At the same temperature and pressure, which is the heavier, dry air or the same volume of air fully saturated with moisture?

Ans.—At the same temperature and pressure, dry air is heavier than air saturated with moisture, volume for volume. The reason for this is that the water vapor or moisture occupying a portion of the space is lighter than the air that it displaces. The specific gravity of water vapor is 0.6235.

Ques.—(a) With a barometric pressure of 30 in. and a temperature of 60 deg. F., what effect would be produced on a given volume of air if the barometer should fall to 29.5 in.? (b) What change in temperature would be required to maintain a constant volume of air, under this fall of barometer?

Ans.—(a) For a constant temperature, the volume of air or gas varies inversely as the barometric pressure; in other words, the *volume* ratio is equal to the *inverse pressure ratio* or *barometer ratio*. For example,

$$\frac{V_2}{V_1} = \frac{B_1}{B_2} = \frac{30}{29.5} = 1.017, \text{ nearly}$$

Therefore, the temperature remaining the same, a fall of barometer from 30 to 29.5 in. expands the air volume 1.017 times; or, 10,000 cu.ft. of air would then become 10,170 cu.ft.

(b) For a constant volume, the absolute temperature varies as the barometer; or, in other words, the *absolute-temperature ratio* is equal to the *barometer ratio*. In this case, calling x the temperature required to maintain the volume of air constant when the barometer falls from 30 to 29.5 in., we have

$$\frac{460 + x}{460 + 60}; \text{ or } \frac{460 + x}{520} = \frac{29.5}{30} = 0.9833$$

$$460 + x = 0.9833 \times 520 = 511.3$$

$$x = 511.3 - 460 = 51.3^\circ \text{ F.}$$

Therefore, if the temperature falls from 60 to 51.3 deg. F, when the barometer falls from 30 to 29.5 in., the volume of air will remain unchanged.

Ques.—What determines the number of posts that must be set in a room 24 ft. wide?

Ans.—The number of posts that must be set at the face of a room will depend on the character of the roof and floor, the depth of the seam below the surface and, to some extent, on the thickness of the seam. Assuming a 5-ft. seam and timbers 5 ft. long and 5 in. in diameter at the small end, the end area of each post would be $0.7854 \times 5^2 = 19.635$ sq.in. Then, taking the safe crushing strength of the timber as, say, 3500 lb. per sq.in., and the load each post will carry without crushing is

$$\frac{19.635 \times 3500}{2000} = 34.36, \text{ say } 35 \text{ tons}$$

Under a fair roof, the height of the loose material resting on the props may be taken as one-half of the width of the opening. Then taking the weight of the roof material as 160 lb. per cu.ft., the pressure per square foot resting on the props is

$$\frac{24 \times 160}{2} = 1920 \textit{ lb.}, \text{ say } 1 \text{ ton}$$

In this case, therefore, each post will safely support 35 sq.ft. of roof; or the posts may be set $\sqrt{35}$ = say, 6 ft. apart. This is what may be called the maximum distance apart of the posts, under the conditions assumed. With a frail roof, the timbers must be set closer together.

Ques.—Find the inclination of a seam of coal outcropping on a level surface. A vertical borehole is sunk at a point 500 ft. from the line of outcrop and penetrates the seam at a depth of 350 ft. below the surface.

Ans.—The tangent of the angle of inclination of the seam or the tangent of the angle the seam makes with the horizontal plane is equal to the depth of the hole divided by the horizontal distance from the bore hole to the outcrop of the seam as measured on the surface. Thus, in this case,

$$\tan A = \frac{350}{500} = 0.7$$

The angle of inclination, as found in the table of tangents is, therefore, 35 deg.

COAL AND COKE NEWS

Washington, D. C.

Investigations which have been ordered by the Interstate Commerce Commission during the past few weeks have developed, it is now understood, a condition which, it is believed, can be corrected only through a searching inquiry and orders issued as a result thereof. The case in question relates to the use of private cars in a way that tends to produce abuse and to give what amounts to rebates to those who are disposed to avail themselves of the opportunities in this regard that are offered under the situation said to be in existence today.

In order to get at the facts in the matter, inquiries have been sent out to a large number of concerns throughout the United States that the commission may ascertain, if possible, whether these concerns have shared in any degree in the supposed profits of the private car system. Among those who are understood to have made serious complaints to the commission within the recent past, are many coal-mine owners who assert that they have been unable to get the facilities they desire, and that, as a result, they have had to witness advantages given to others who are not especially entitled to them and whose preference over the complainants has resulted in decided damage to the latter.

The private-car question has formed the basis of a good many inquiries and hearings before the commission for some time past, and there has apparently been no way of correcting the abuses said to have sprung up, under existing laws. Mr. Marble, the newly appointed member of the commission, is particularly close to the private car situation, as he has devoted himself largely to the study of the conditions growing out of the widespread use of the cars in question.

Commissioner McCord has been given general authority over this investigation and has designated George P. Boyle as chief examiner to collect the information and direct the work of special examiners. In communicating with the public, the commission says officially: "It is the desire of the commission that all shippers or associations interested in this investigation communicate to it not later than Mar. 31 such information as may be in their possession and which they consider pertinent to the inquiry."

It is stated that in all probably about 1200 private car companies exist, and the series of questions has been mailed to them, preceded by a statement setting forth that it is the intention of the Commission to hold hearings at various places throughout the country and informing the recipients that the answers sent in will be used as the basis of the hearings.

It is believed that one important phase of the answers to the interrogatories will be found in the question whether in the judgment of the shippers and the car companies a carrier ought to own enough equipment to take care of all of the commodities of every kind originating on its line and which it is likely to be asked to handle.

Judging from present appearances, the investigation is likely to be protracted for a good many months. Much of it will probably be carried on in the mining regions.

Proposed Rate Advances

Definite plans have been made, according to information received here by the domestic interests, to urge upon President Wilson's administration what is considered by railway men the necessity of an advance in the rates on bulk commodities generally and on coal and a few others in particular.

The roads are feeling keenly the movement for the increase of wages which, they assert, has put them in position to suffer severely unless they are enabled to raise their rates in a corresponding degree. Up to date, as is well known, the attitude of the Interstate Commerce Commission has been hostile to any advance in rates, and proposed increases have been almost uniformly turned down on the ground that they were not required and were not in harmony with the policy enunciated in the so called "advanced rate decisions" of a couple of years ago.

The action of the administration in appointing Franklin K. Lane as its Secretary of the Interior and in nominating John H. Marble, who has been in general sympathy with the policy of Mr. Lane as his successor, is not considered to show much sympathy with the plan to advance charges on the roads. Nevertheless, the railroad men are preparing to present their case in a strong and effective manner in order that Mr. Wilson himself may be persuaded to take a definite attitude regarding it.

It is felt that, while the powers of the administration with respect to rates are far smaller than they were at the opening of the Taft administration, owing to the transfer of so much power to the commission, the point of view of the President would be exceptionally influential with the commission as the policy to be followed on rates has always been considered a semipolitical, if not a wholly political, issue.

PENNSYLVANIA

Anthracite

Wilkes-Barre—No. 4 colliery of the Kingston Coal Co. was totally destroyed by a fire which broke out in a tower over the engine house. The loss to the company will amount to $100,000, which is partially covered by insurance. More than 2000 men and boys will be thrown out of employment for a time at least. The cause of the fire is supposed to have been a crossed wire in the tower of the breaker.

Hazleton—The Government mine-rescue car which has been stationed at the collieries of the Hazleton district for the past seven weeks has been removed to Wilkes-Barre.

Plymouth—According to the decision of the officials of the Avondale colliery of the D., L. & W. Coal Co. that colliery will probably be closed down for some time. The company is having trouble with its men over the prices paid for setting timber.

Bituminous

Adrian—The large company store of the Jefferson & Clearfield Co. has been totally destroyed by fire. The building was a three-story structure, with a warehouse annex.

Harrisburg—Governor Tener has named the members of the mine-examining board for the bituminous district for the next four years. The board consists of A. W. Callaway, Indiana; Robert Morris, Greensburg; H. C. Drum, Coal Center; R. M. Pollock, Star Junction, and C. B. Maxwell, Morrisdale. All appointments have been confirmed.

California—William Matthews and son were seriously injured by a fall of slate in the Vesta Coal Co.'s mine at California.

Altoona—Mine-rescue car No. 6, in charge of Mine Foreman D. D. Davis, has left Cardiff and is now located at Vintondale.

Du Bois—Superintendent John H. Fulford, of the Eriton shaft, announced, Mar. 6, that that operation would close down for the purpose of repairing the pan on the tipple.

Mr. Fulford stated that it would require three weeks to repair the work, and that the mines would be idle all of that time. He stated that in the 40 hours that have been worked at the shaft since the men resumed work under the new system, the company has lost 257 tons of coal, which is the chief cause for stopping work at this time.

It is planned to raise the rear of the pan so that it will clean itself.

WEST VIRGINIA

Wheeling—Seventy-five miners at the mine of the Fairpoint Coal & Coke Co. are out on strike. Subdistrict officials are investigating the trouble with a view to an early settlement.

Moundsville—The jury has granted a judgment of $6000 in favor of the widow of one of the eight men who lost their lives in the Panama disaster last July. This case is the first of the eight to be tried. Incompetency on the part of the fireboss was alleged.

INDIANA

Princeton—The Jackson coal mine at Fort Branch has been closed down by the state inspectors. The inspectors insist that black powder shall not be used in the mine, while the company declares they see no reason for a change, since the mining law does not prohibit it. The trouble is the outcome of a recent accident in which two shotfirers were killed and the mine partly wrecked. It is probable that the owners

of the mine will bring action to restrain the state mine inspector from enforcing this order.

KANSAS

Pittsburg—Two hundred miners employed at the mine No. 14 of the Fleming Coal Co. have been ordered to remove their coal and tools from the mine by the district mine officials. The men say they quit work because the operators refused to raise the wages of the mine motormen according to an alleged agreement.

Coal has been struck in Grant Township on the land which has been optioned by the Misouri, Kansas & Texas Ry. Co. The seam is 10 in. thick and lies at a depth of 84 ft.

NORTH DAKOTA

Makoti—A 6-ft. bed of high-grade coal is said to have been discovered on the B. Rosenberg farm by well diggers. It is believed that the fuel is of the highest quality ever found in the state. It is extremely hard and apparently not of the ordinary lignite type.

FOREIGN NEWS

Hobart, Tasmania—The bodies of 18 miners were brought to the surface of the North Mount Lyell mine Mar. 1, after a search which has lasted nearly five months. Forty-five bodies have now been recovered, and a further search has been abandoned. A fierce fire, started by the explosion in which the men were killed last October, has made it unsafe to explore the mine further.

PERSONALS

F. R. Lyon has been appointed general manager of the Consolidation Coal Co. Mr. Lyon will be in charge of the operations in all the coalfields of the company.

Daniel C. McAlpine, formerly superintendent for the Brewer Coal Co., at Brewer, Okla., has taken the position of superintendent for the Folson Morris Coal Co., at Lehigh, Okla.

John Markle, for over thirty years a prominent factor in the anthracite mining industry, is about to retire to private life, and his brother, Alvin Markle, will assume charge of the Markle mining interests on Apr. 1.

H. M. Wilson, engineer in charge of the government experiment station at Pittsburgh, has been made chairman of the executive committee of the American Mine Safety Association. This organization has been formed to work for a reduction in the number of deaths in the mines and quarries through the country.

Fred R. W. Thomas, formerly superintendent of mines for the Northern Pacific Ry. Co., at Roslyn and Cle-Elum, Wash., was recently promoted to take charge of the company's mines in King County, where the mining conditions are much more complex. His headquarters are at Ravensdale on the main line of the Northern Pacific, about 30 miles from Seattle.

Herman Bacharach, until recently located at 722 Lewis Block, Pittsburgh, Penn., has moved into larger quarters at 1009 Hartje Building. He has enlarged the number of his specialties in scientific and industrial instruments. Besides indicating and recording steam and gas apparatus, he has taken up some new lines of instruments. Among others, smoke and dust recorders, specific gravity meters for gas and liquid, carbon dioxide recorders and engine indicators with automatic efficiency reckoner, etc.

Device for Propping Mines. F. Nellen. Essen-on-the-Ruhr, Germany. 1,049,135, Dec. 31, 1912. Filed July 29, 1908. Serial No. 445,964.

Handle Fastening for Picks and Other Tools. E. L. Ray, Agency, Iowa. 1,048,096, Dec. 24, 1912. Filed Mar. 12, 1912. Serial No. 683,281.

System of Feeding Treated Water to Boilers. J. H. Cooper, Paola, Kan. 1,050,616, Jan. 14, 1913. Filed Mar. 13, 1911. Serial No. 614,198.

Centrifugal Pump. J. A. Yeatman, assignor to United Iron Works, Oakland, Calif. 1,050,588, Jan. 14, 1913. Filed Dec. 26, 1911. Serial No. 667,758.

Valve Gear. T. Hall, assignor to Ridgway Dynamo & Engine Co., Ridgway, Penn. 1,050,213, Jan. 14, 1913. Filed Dec. 8, 1912. Serial No. 531,938.

Gas Producer. W. B. Chapman, assignor to Chapman Engineering Co., New York, N. Y. 1,049,994, Jan. 7, 1913. Filed Mar. 5, 1910. Serial No. 547,514.

Stoker. H. E. Stover, assignor to Baldwin Locomotive Works, Philadelphia, Penn. 1,048,756, Dec. 31, 1912. Filed May 21, 1912. Serial No. 698,680.

System for Utilizing Waste Heat from Furnaces for Heating Boilers. J. W. and Herman Hegeler, Danville, Ill. 1,050,134, Jan. 14, 1913. Filed Jan. 25, 1912. Serial No. 673,428.

Apparatus for Watering Coke in Coke Ovens. C. E. Taylor, Pittsburgh, Penn., and A. C. Wolfe, Alicia, Penn. 1,049,006, Dec. 31, 1912. Filed Oct. 11, 1911. Serial No. 654,152.

Coke Oven Steam Generator. J. H. Morgan, assignor to Titlow Waste Heat Power Co., Uniontown, Penn. 1,050,679, Jan. 14, 1913. Filed July 28, 1909. Serial No. 510,091.

Apparatus for Removing Ashes from Gas Producers. W. H. Bradley, assignor to Duff Patents Co., Pittsburgh, Penn. 1,049,561, Jan. 7, 1913. Filed Feb. 8, 1912. Serial No. 676,461.

Endless Movable Grate for Furnaces. F. Girtanner, assignor to Laclede-Christy Clay Products Co., St. Louis, Mo. 1,050,531, Jan. 14, 1913. Filed July 8, 1911. Serial No. 637,464.

Shield for Detonators which are used in Shot-firing in Mines of all kinds and in Quarries. A. Price and W. Pryse, both of Treorky, Pontypridd, Eng. 1,049,143, Dec. 31, 1912. Filed Dec. 12, 1911. Serial No. 665,343.

CONSTRUCTION NEWS

Scalp Level, Penn.—The Scalp Level Coal Mining Co. is erecting an extensive tipple east of Rummel.

Tamaqua, Penn.—Work on a shaft to be 750 ft. deep and requiring one year's time to complete was started recently by the Lehigh Coal & Navigation Co. at No. 11 colliery.

Shenandoah, Penn.—Work was commenced Mar. 1, on the construction of a colliery to prepare for market the coal which will be mined from the recently discovered coal beds in Locust Mountain.

Wheeling, W. Va.—Work has been started on general repairs of the machinery which operates the cables at the Big Bull coal mine. A new 150-hp. boiler is being installed and the work will be completed about the middle of the week.

Baltimore, Md.—The Alabama & New Orleans Transporta-

tion Co. is having built at its shipyard 16 self-propelling barges of 1000 tons each, to cost altogether $416,000. One barge is ready for launching and the others will be ready at the rate of about one every six weeks.

Little Rock, Ark.—Electric mining machines have been installed in Central Mine No. 4 and are declared to be an unqualified success. It is said by their use the output of coal is made 80 per cent. lump and the quantity of explosives used and the danger therefrom is reduced one half.

Ashland, Penn.—The G. B. Markle Co. is completing a fine wash house for the employees at No. 5 Highland, which will be ready for use in a few days. The building was formerly the old elctric-light station, the interior of which has been remodeled and fitted with all modern conveniences.

Connellsville, Penn.—Charles Pore and H. N. Odbert, of Monessen, said to represent Pittsburgh and Charleroi capitalists, are putting a force of men to work opening a mine to develop a tract of 540 acres of coal at Rogers Mill, in the Indian Creek valley. It is reported a coke plant will be constructed.

Fairpoint, Ohio—The Provident Coal Co. is planning to construct another mammoth reservoir which will furnish water for the use of the new mine of the company at Fairpoint. It is not known whether the reservoir will be constructed this year or not. The cost of construction is estimated at about $30,000.

Peoria, Ill.—The Newsam Bros. are sinking a shaft on the Frank Bateman farm, one mile south of Glasford. They expect to have a greater output of coal than that afforded by their mine at Kingston, and hope to be able to hoist coal by the latter part of the summer. One hundred and seventy-five men will be employed.

Huntington, W. Va.—Thirty miles of railroad is to be built by the Chesapeake & Ohio Ry. Co., near Beaver Creek, Ky. The work will be begun Apr. 1. A number of capitalists owning valuable coal and timber lands adjacent to the Beaver Creek territory, are preparing to begin work at once on building tipples and locating mine openings.

Scranton, Penn.—It is estimated that the Laurel line will be able to reclaim approximately from fifteen to twenty thousand tons of coal out of the basin of the old Roaring Brook boom that it owns along its right-of-way and preparations have been made to double the capacity of its pumping plant. The addition to the plant will probably commence operations Apr. 1.

Pottsville, Penn.—The Reading Co. is developing plans for greatly adding to the output of coal within the next few years. Many new openings will be made. The largest proposition which is now in hand is the sinking of a four-compartment shaft at the Reliance Colliery at Beaverdale. This will probably be dropped to a depth of 620 ft.

Pittsburgh, Penn.—The Pennsylvania R.R. is arranging to enlarge the coaling stations along its lines, especially at larger terminals. In the improvement contemplated the Pennsylvania will probably carry out the new plan adopted by the Wabash. This road has erected at different points along its territory modern steel structures, which store about 300,000 tons of coal, which are arranged so that they can deliver the coal to the engine either on the main tract or on passing tracts.

Brownsville, Penn.—The plant of the Luzerne Coke & Coal Co. is expected to be in operation by May 1. When completed it will consist of 35 ovens and in addition it is expected to mine about 400 tons of coal per day for shipment. The Belle Vernon plant is now in full operation with a battery of 32 ovens. The W. Moreland Co. plant of the concern, heretofore known as the Marion Coke & Coal Co., has increased in size by 40 ovens.

NEW INCORPORATIONS

McKeesport, Penn.—The Meyers Coal Co.; capital stock, $5000.

Pineville, Ky.—The Pineville Coal Mining Co. ;to develop coal land; capital stock, $50,000.

Harrisburg, Penn.—The Hudson Coal Co. has increased its capital stock from $2,500,000 to $3,500,000.

Harrisburg, Penn.—The Locust Mountain Coal Co. has increased its capital stock from $10,000 to $350,000.

Dallas, Tex.—The McKay Lignite Mining Co.; capital stock, $7500. Incorporators: J. C. McKay, H. C. McKay and F. R. McKay.

Hartlesville, Tex.—The Interstate Oil & Gas Co.; capital stock, $100,000. ncorporators: A. H. Garges, John Melcher, C. S. Whitlow.

Charleston, W. Va.—The Claybrook Coal Mining Co.; to mine coal; capital stock, $100,000. Incorporators: J. E. Chilton, S. Hess and T. S. Clark.

Hamilton, Mont.—The Darby Coal Mining Co.; to engage in mining. Incorporators: R. B. Nicholson, D. D. Nicholson, Thomas Padden and W. R. Gibford.

Little Rock, Ark.—A number of Pine Bluff capitalists have organized a company for developing the coal and clay resources of the county; capital stock, $1,000,000.

Wheeling, W. Va.—The Warewood Coal Co.; to mine coal; capital stock, $25,000. Incorporators: Johnson C. McKinley, Harry D. Wells, M. B. Marther and John C. Beury.

Louisville, Ky.—The Tennessee Jellico Coal Corporation has increased its capital stock from $300,000 to $400,000 for the purpose of developing a large tract of coal land at Hazard, Ky.

Chicago, Ill.—The Harkes Coal Co.; to mine and sell coal and clay and their products; capital stock, $6000. Incorporators: Arthur Conno, Thomas J. Dunney and Christopher Whalen.

East St. Louis, Ill.—The Southern Coal, Coke & Mining Co.; to mine coal and manufacture coke; capital stock, $1,000,000. Incorporators: W. K. Kavanaugh, James Y. Lockwood and John B. Kennard.

Kingston, N. Y.—The Silver Bell Mining Co.; acquire mining rights of all kinds and to develop mineral lands; capital stock, $1,000,000. Incorporators: Walter H. Clark, John M. Lester, Guillermo M. Bingham.

Cumberland, Md.—The Proctor Slate Mfg. Co.; to quarry and mine for slate and all byproducts; capital stock, $1,200,000. Incorporators: Theodore Thimmel, G. Harry Bevard, M. C. Alwine Roberts, H. Rea Engle, D. H. Silver and W. J. Maloney.

INDUSTRIAL NEWS

Canton, Ill.—Star Mine No. 2 has shut down indefinitely owing to the poor market for coal.

Lethbridge, Alta.—The city contemplates purchase of 240 additional acres for an industrial site and another municipal coal mine.

Hickton Station, Penn.—J. H. Sanford Coal Co. will soon install a 13-ton electric mining locomotive recently ordered from the General Electric Co.

Pottsville, Penn.—The Gilberton colliery has resumed operations. The colliery has been idle since Feb. 25, when the waters of Mahanoy Creek broke into the workings.

Johnson City, Tenn.—The auditor's department of the Clinchfield Coal Corporation has been removed to Dante, Va., where the mines and headquarters of the company are located.

Pittsburgh, Penn.—Reports are heard of the formation of a company whose purpose will be to install retort coke ovens in the region surrounding Oakmont, to utilize the coal of the twin Freeport seams.

Georgetown, Ill.—The Bunsen Coal Co. will place a 13-ton electric locomotive in service in connection with its colliery at Georgetown. The order for the machine has been placed with the General Electric Co.

Pittsburgh, Penn.—The Pittsburgh Coal Co. will shortly install in its power plants, nineteen 150-kw., two-unit, three-bearing, synchronous motor-generator sets recently ordered from the General Electric Co.

Pottsville, Penn.—The anthracite region is again handicapped by a shortage of cars. So pronounced is this deficiency that collieries in the Shenandoah district have reduced their working day to seven hours.

Fairmont, W. Va.—The Consolidation Coal Co. will add to the equipment of its mines at Jenkins, Ky., four 10-ton and four 6-ton electric mining locomotives. The machines have been ordered from the General Electric Co.

Carrolltown, Penn.—No. 33 Mine, the biggest of the Pennsylvania Coal & Coke Corporation, at Patton, was closed on Wednesday of last week, because, it is said, of a fault in the coal. Between 300 and 400 men were employed there.

Ashland, Penn.—The Midvalley collieries Nos. 1 and 2 of the Midvalley Coal Co. are tied up by a strike which was caused by the alleged refusal of the company to discharge nonunion workmen. About 900 men and boys are idle.

Green Bay, Wis.—The C. Reiss Coal Co. closed a deal by which it becomes owner of the Waukegan Coal & Dock Co., at Waukegan, Ill. The new property has the capacity of 150,000 tons of coal, and is equipped with three loading towers.

Scranton, Penn.—The Reading company is developing plans which will add greatly to its output of coal within the next few years. The contemplated improvements consist of many new openings, besides the breaking in of a tract of virgin territory.

Russellville, Ark.—The store at the Russelville anthracite mines, which has been closed since the mines shut down two years ago, is to be reopened. The mining property is being put in shape for operation again, and will start work early in March.

Greensburg, Penn.—Rockwell Marietta, of Connellsville, purchased for the Marietta-Connellsville Coke Co. 225 acres of coal land in the Ligonier Valley from Judge John B. Steele, of Greensburg. The consideration was in the neighborhood of $200 per acre.

McAlester, Okla.—Osage mine No. 8 at Krebs and No. 7 at Richville have been shut down by the operators, and the miners have removed their tools from the pit. The mild weather has caused a falling off of orders, which has resulted in the shutdown.

Wilkes-Barre, Penn.—The Lehigh Valley Coal Co. is pumping the water out of the old Tomhicken Colliery, which has been idle for years. The company intends to retimber the workings and resume operations, as considerable unmined coal remains in the colliery.

Birmingham, Ala.—The Maryland Coal & Coke Co. will equip its plant at Sipsey, Ala., with two 150-kw. generators, 18 motors, ranging from 6.75 to 40 hp., switchboard and three 7-ton electric locomotives. All the equipment will be supplied by the General Electric Co.

Philadelphia, Penn.—The Berwind-White Coal Mining Co. will add to the electrical equipment in its collieries at Windber, Penn., a 400-hp. two-unit two-bearing motor frequency changer set and switchboard apparatus, which has been ordered from the General Electric Co.

Du Pont, Ill.—It is generally understood that the new Du Pont Coal Co. will combine the Central Coal & Iron Co., Caldwell Coal Co., Duncan Coal Co., Wickliffe Coal Co., Broadway Coal Co., and others on the Illinois Central and Louisville & Nashville railways in Kentucky.

Scranton, Penn.—Five collieries have been shut down temporarily by the Delaware, Lackawanna & Western R.R. Co. These are the Sloan and Central shafts of the Avondale, the Dodge, the Diamond and the Pyne. It is understood that operations have been discontinued because of the need for repairs.

Big Stone Gap, Va.—The Stonega Coke & Coal Co. is arranging to install a 200-kw. generator and switchboard in its power plant, and will add to its mine equipment six 4-ton and two 13-ton electric mining locomotives. The order for all this new apparatus has been placed with the General Electric Co.

Russelville, Ark.—The Southern Anthracite Coal Co. mines closed the season's run Saturday, and will shut down for a short time to make necessary repairs and clean up for the coming season. It is reported that the mines will start again not later than Mar. 15. They have had practically a 12-months' run.

Connellsville, Penn.—The No. 4 mine of the Vesta Coal Co., a subsidiary of the Jones & Laughlin Steel Co., has during the past 10½ years produced 13,337,599 tons of coal. The mine employs 1050 men inside. The property originally covered four square miles. The mined-out area would make a tunnel 6 ft. wide and 1263 miles long.

Connellsville, Penn.—Further development of the Indian Creek valley coal field is to be undertaken shortly near Rogers Mill. Preparations are under way for opening a mine on a tract of 540 acres. Charles Pore, of Monessen, who, with H. N. Odbert, of that place some time ago purchased the tract, is on the ground employing men for the initial work.

Bluefield, W. Va.—The U. S. Coal & Coke Co. has inaugurated an educational department for its employees. The principal subjects treated in the instruction are arithmetic and the properties of gases. So far there has been considerable interest manifested by the employees, and it is understood that the meetings are largely attended. The school is open to all.

New Bethlehem, Penn.—It is rumored that the Pennsylvania R.R. has an option on the Buffalo & Susquehanna R.R., and that there is a probability of its taking that road over in the near future. The B. & S. road has been in the hands of a receiver for several years. The purpose of its construction was to tap some of the best mining territory in the soft-coal region.

Charleston, S. C.—The action of the directors of the Carolina, Clinchfield & Ohio in approving plans for the construction of large coal piers at Charleston has been warmly indorsed by business interests. By improved machinery, vessels of 8000 tons will be loaded with coal in four or five hours. Much double-tracking has been done over the Coast Line road entering Charleston.

Morgantown, W. Va.—A deal for the sale of 500 acres of coal in Union district was consummated Mar. 2. The sale included two tracts, one of 201 acres, the other of 250 acres. The surface and the Pittsburg, Sewickley, and other beds of coal were sold to W. H. Seymour, of Pittsburgh. The price was $200 an acre. It is said that the purchaser expects to develop it without delay.

Columbus, Ohio—Attorney E. D. Howard is negotiating for a tract of 12,000 acres of coal land in Lawrence County for interests here. A 30-day option on the tract known as the McGugin coal and iron fields has been authorized by Judge Corn. The price mentioned in the option is $200,000. It is understood that a new mining company is to be organized here to operate the property.

Terre Haute, Ind.—The Grant Coal Mining Co. of Vigo County executed to the Continental & Commercial Trust & Savings Bank, of Chicago, Ill., a mortgage on its holdings in this county for $100,000, to cover a bond issue of 100 gold bonds of the par value of $1000 each. The bonds are to bring 6 per cent. interest, and the money so realized is to be used in improving the property of the company.

Hutchinson, Kan.—The Columbus Coal Co. has leased about 800 acres southwest and west of here, with the guarantee that work will begin on prospecting within 90 days, and that if coal is found, that shafts will be sunk at once. That the fuel will be discovered in paying quantities is almost a foregone conclusion as prospects were made there several years ago, and it was declared then that good deposits existed.

Grafton, W. Va.—Unless unforeseen difficulties arise it is practically certain that the coal holdings of Col. J. M. Guffey will soon be taken up by the Morgan interests. The tract lies in Preston, Barbour and Taylor Counties, and comprises something like 100,000 acres. The price is said to exceed $100 an acre. It is understood that the deal will be closed in anticipation that the New York Central will push the completion of its line from Fairmont to Belington.

Red Bank, Penn.—In a few days active work will start on the Pennsylvania R.R. tunnel at the junction of Red Bank Creek and the Allegheny River. This tunnel cuts off several miles of a bend, and was to have been constructed many decades ago, when the road was built. East Brady parties, however, paid part of the construction cost of diverting the railroad several miles. The tunnel is half a mile through and will save several miles between Pittsburgh and Buffalo.

Scranton, Penn.—Producing a million tons of coal without a fatal accident is the record to which the Lackawanna coal officials are pointing on behalf of the National Colliery, at Scranton. The last fatal accident at this place was in the fall of 1910. The inside foreman at the National is John Owens, and the outside foreman is Fred Peters. The Manville Colliery, of the same company, has had a perfect record for the past two years, but is not so large a colliery as the National.

Pottsville, Penn.—The increase of the capital stock of the Delaware & Hudson Coal Co. from $2,500,000 to $3,500,000, and the increase of capital stock of the Locust Mountain Coal Co. from $10,000 to $550,000, are indications that the former company will develop the coal lands in Schuylkill Valley soon. The Locust Mountain Co. came into possession recently of rich coal lands north of Shenandoah belonging to the Girard estate, which will be opened during the year and great producing facilities will be established.

Pottsville, Penn.—The Philadelphia & Reading Coal & Iron Co. has arranged for installing considerable electrical equipment, consisting of a 150-kw., two-unit, three-bearing, motor-generator set, switchboard, and an 8-ton, 48-in. gage electric mining locomotive in the Suffolk Colliery near St. Nicholas, Penn.; a 600-kv.a. generator with 30-kw. exciter, 20-kw. motor-generator set and switchboards in the Bear Valley Colliery, near Shamokin, Penn.; a 600-kv.a. generator with 30-kw. exciter and switchboard in the Locust Gap Colliery; a 100-hp. induction motor and controller in the Mahanoy Colliery; a 600-kv.a. generator with 30-kw exciter and switchboard in the Pine Knob Colliery, near Minersville, Penn.; and a 375 kv.a. generator, 20-kw. exciter and switchboard in the Silver Creek Colliery near Pigila, Penn. All this various apparatus has been recently ordered from the General Electric Co.

COAL TRADE REVIEWS

GENERAL REVIEW

Orders for hard coal are so scarce that companies have finally been forced to curtail production. Such a condition at this period of the year has never been known to exist in the recent history of the industry, and it is even more remarkable in view of the fact that there was a shortage of over 6,000,000 tons in last year's production. The individuals are making every effort to sell at the April discount, but with only indifferent success. The movement now is restricted almost entirely to the steam grades, in which there is some little activity particularly on pea, which is the strongest of any size. Indications are that considerable winter coal will be carried over into April, and there is not a very favorable feeling over the outlook for that month.

The attempt of the Eastern bituminous operators to gain some control over the market is apparently meeting with partial success. It is obvious that production is being restricted, while accumulations are slowly disappearing, and if this continues the weak points in the market will be eliminated shortly. The movement is light, although steady, and only on specific orders, while the general tone is firmer and concessions less frequent. It is noticeable that contracts for the new year are generally for a larger tonnage.

Shipments in the Pittsburgh district are almost entirely on contract, but are quite heavy. It is evident that the consumers are accumulating as much of a surplus as possible before the higher contract prices go into effect. The market is not particularly good, and operators are now looking forward to the opening of navigation on the Lakes, which will be somewhat earlier than usual according to present indications. In Buffalo and vicinity the railroads have not yet caught up, and there is considerable coal on track. Some colder weather caused a slight temporary increase in the demand, but dealers generally are well stocked and new sales are limited.

There has been a small increase in the demand in Ohio, as the result of the colder weather, but the trade is by no means active; however, this change in conditions served to check the rapid decline. Operations are fairly good ,contracts are being closed, at a slight advance, and the producers are looking forward to a heavy Lake business. The smokeless operators in the West Virginia fields are said to have agreed to suspend operations for one week, in order to work off surplus tonnages; dumping at the piers continues relatively slow. There have been some vigorous protests at the advance in retail prices in the Southern market, but the trade has been active as a result of the recent cold snap.

There are no new features in the Middle Western market, and operators are concentrating their attention on the new contracts. There has been a curtailment of shipments in Chicago, which has resuted in an increased demand, but dealers are holding off buying, believing they have enough to carry them over into the summer. The St. Louis trade is still badly demoralized, and some operators are going into bankruptcy.

BOSTON, MASS.

There is a firmer tone to Pocahontas and New River. Most of the agencies are holding to the $2.85 price and concessions are less frequent. The accumulation at the Hampton Roads piers seems materially reduced and delivered prices at this end are up somewhat from a week ago. It is early for any restriction to be effective but if that said to have been determined upon last week, is carried out it is likely that soft places will disappear for the next month or two. That prices will be firm throughout the summer at a range from 15@35c. higher than last year seems too much to expect. Coal is to plentiful and there are too many shippers to permit such a general advance in an off year; $2.70 is still more nearly the actual price for spot coal.

Georges Creek is in rather short supply and orders have to be taken up in turn. The price for next season has not yet been announced but it is likely the f.o.b. basis at Baltimore will closely follow the Hampton Roads price. The Pennsylvania grades continue on about the same range. Clearfields are in light demand and, with other grades, are coming down only on orders. Prices are still from 5@10c. higher than the summer basis last year.

The all-rail movement is fairly steady but with only a light volume of coal running. Contract business is being closed slowly; buyers generally are showing only a lukewarm interest. Water freights are firm at 95c.@$1 for large vessels, Hampton Roads to Boston. Tonnage is in fair demand.

Anthracite is marking time, pending the first of April. Orders are being filed for spring shipment and a normal season is looked for. March so far has been good for coal-burning and stocks are going to be low when April shipments start coming in. Representatives of the independent operators are making desperate efforts to move March coal at April prices but so far they have had little success. Shipments for March are confined almost entirely to sizes like pea and broken on which the price does not change. There was some apprehension over spring ,orders calling for large proportions of stove but they turn out to be well assorted as to sizes.

Current wholesale prices are about as follows:

Clearfields, f.o.b. mine	$1.25@ 1.50
Clearfields, f.o.b. Philadelphia	2.50@ 2.75
Clearfields, f.o.b. New York	2.80@ 3.10
Cambrias, Somersets, f.o.b. mines	1.30@ 1.60
Cambrias, Somersets, f.o.b. Philadelphia	2.55@ 2.85
Pocahontas, New River, f.o.b. Hampton Roads	2.70@ 2.85
Pocahontas, New River, on cars Boston	3.85@ 4.00
Pocahontas, New River, on cars Providence	3.75@ 3.85

NEW YORK

Bituminous—The soft-coal market is comparatively firm on the better grades, which are in sufficient demand to make it necessary for consumers to await their turn in having orders filled. The off-grades are not so active, and as a rule are rather hard to move. There is still little or nothing doing in contracting, and operators are not showing any disposition to recede from their avowed intention of obtaining higher prices for the new year's business. The demand on current contracts is quite heavy, it being evident that consumers intend taking all the tonnage they can accommodate before these expire.

Stocks of soft coal at tide are about normal. Mines as a rule are working fairly good, and while there has been a slight shortage of equipment on the Pennsylvania R.R., the New York Central has been furnishing a full supply. Quotations are probably somewhat easier, and small lots of the lower grades can no doubt be picked up at less than $2.60. However, operators continue holding the nominal market at last week's level as follows: West Virginia steam, $2.60@2.65; fair grades, Pennsylvanias, $2.65@2.70; good grades of Pennsylvanias, $2.75@2.80; best Miller, Pennsylvania, $3.05@3.15; Georges Creek, $3.25@3.30.

Anthracite—The condition of the hard-coal market is such that nearly all companies have been forced to suspend operations because of the insufficiency of orders. This is probably the first time in the recent history of the industry that the operators have been forced to restrict their output so early in the season; it is a rather remarkable condition in view of the fact that production last year was over six million tons less than in 1911.

Of course, grades of all kinds are now accumulating in storage with the exception of the steam sizes, which still continue in fairly good demand, particularly pea, which is the strongest grade in the market. The large companies are still adhering rigidly to their circular, but individuals are readily quoting at the April discount, and even lower; individuals are also being forced to close down, and they are not making any further shipments on consignment. There is a feeling on the part of some of the conservative members of the trade, that if there is not a better buying movement, and a more pronounced disposition on the part of the consumers to stock, conditions this year will be a repetition of last year.

The market has shown slight fluctuations during the week, and is now quotable on about the following basis:

		Individual	
	Circular	Lehigh	Scranton
Broken	$5.00	$4.50 @ $4.75	$4.50 @ $4.75
Egg	5.25	4.55 @ 5.20	4.60 @ 5.25
Stove	5.25	4.95 @ 5.20	4.95 @ 5.25
Chestnut	5.50	4.70 @ 5.45	5.00 @ 5.50
Pea	3.50	3.45 @ 3.55	3.50 @ 3.60
Buckwheat	2.75	2.00 @ 2.45	2.50 @ 2.75
Rice	2.25	1.80 @ 1.95	2.25 @ 2.35
Barley	1.75	1.25 @ 1.70	1.55 @ 1.80

PHILADELPHIA, PENN.

The element of curtailment has been introduced into the anthracite coal situation and the time has passed when the current output can be disposed of at the ruling circular prices; this does not refer to the quotations made by the individuals, which are hard to keep track of during the present period of inactivity. Half time is now the rule with many of the important companies, and a large proportion of the coal mined is going into stock.

The retail trade is in no sense active. The occasional cold snaps cause a monetary liveliness, but stagnation is likely to mark this branch of the trade until Apr. 1. There is no report of any of the dealers reducing their prices, which might be possible, considering that many of them are taking advantage of the low offerings by the individual operators. Perhaps they regard this as a recompense for some of the premium coal bought during the strenuous times a couple of months ago.

Stocks are not dwindling to the extent that the dealers would like, and if the present weather conditions continue, there are good prospects that some of them will carry over considerable coal into April, for which they have paid top-notch prices. Some of them are even complaining of premium coal still on hands, and their only salvation is to secure bargain coal now to mix with it, and get out with as little loss as possible. As a matter of fact, there does not seem to be an altogether favorable feeling as regards April business.

The bituminous market seems to have reached a process of elimination. Good coals are being offered at low prices, and as a consequence, inferior grades cannot find any outlet at all. Everything seems to be uncertain, and while contracts are being talked over, nothing definite seems to take place. Buyers are prospecting, looking to get the best for their money, and shippers indicate that they will expect anywhere from 10c. to 15c. advance over the figures prevailing last year.

PITTSBURGH, PENN.

Bituminous—Mines are running at slightly greater output than formerly, and shipments are heavy, with a good car supply. There has been no difficulty as to the labor supply for some time. Operators notice a strong tendency on the part of many consumers having contracts expiring Apr. 1, to take extra tonnages at this time in order to create a surplus, in view of the fact that prices are on a higher level than those of expiring contracts. While it is claimed efforts are being made to prevent such accumulations, and to restrict shipments to actual needs, it is doubtful whether these efforts are made with any energy. The market has not been particularly good and the average operator is probably satisfied to obtain shipping instructions, irrespective of whether or not the consumer is trying to "beat the market." Prompt coal is bringing approximately contract prices, with slack at $1@1.05, or a premium of 10 to 15c. a ton. Regular prices remain: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in., $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—The market has been dull as to both prompt and contract. Strictly standard grades of coke are well held, but grades slightly off in sulphur or ash are offered at concessions, down to $2.15 or $2.20 for prompt furnace, such coke being better than much that was freely taken during the famine which suddenly terminated nearly two months ago. There have been no serious negotiations on contract furnace coke. Prices for standard grades, which are partly nominal, can be quoted as follows: Prompt furnace, $2.50; contract furnace, $2.50; prompt foundry, $3@3.50; contract foundry, $3@3.25, per ton at ovens.

BALTIMORE, MD.

Failing to get relief from the continued open-weather conditions, the local trade is now looking to the future expansion of business to force the large industries to enter the market. This is the only hope the trade has for any real profitable business. Many of the largest consumers, expecting severe weather in January and February, stocked up heavily, and because of the mild weather, the depletion of this supply was slow, and not a few of them have remained completely out of the market for the first two months of the year. There are now rumors that the concerns are about to the end of supplies, and will again be in the market shortly. There are also reports to the effect that there are inquiries for American coal on the part of English operators, who claim that they can find markets for the local product, among foreign consumers who prefer American, to English, coal.

While the date for the opening of the lakes has not yet been set, it is believed that it will be earlier this year, on account of the mild winter. The movement of coal from the West Virginia and Pennsylvania mining districts is increasing each year, and Western business always proves highly profitable to the trade. A few eastern contracts were closed during the week, but many consumers prefer to wait until the latter part of the month.

Practically the only fuel moving at this time, is on under contract. There is little or no spot business in sight. The week brought about no change in prices and the low grades are still being marketed around $1. Vessel rates continue easy, owing to prevailing good sailing weather. Train movements are all that could be desired, although there is still some complaint about a lack of cars. The local coke market remains firm, and there appears to be a fairly good demand for the product.

BUFFALO, N. Y.

There has been plenty of winter lately, but it has come too late to help the coal trade. There has been some return of the demand and if March continues wintry, which is doubtful, the situation will be farly good. The amount of both anthracite or bituminous sold lately, has been much less as the consumer appears to have had a large amount bought that had not been delivered.

On account of the uncertainty of the demand, the jobbers have not known how to take the market. Sometimes it would look as if prices were going to smash and then there would be an increased firmness; at present the word is that contract prices will be better than they were last year. There are more dealers staying out of the contract market this year than usual and if they continue to hold aloof there will be an added solidity to everything on that account. There will also be a further effort to shut down if coal again drops down to cost, as some who did that last summer made a paying venture of it.

There is report of considerable bituminous on track at various points, as the railroads have not entirely caught up with bituminous, though there are no more reports of embargoes. Allegheny Valley operators now say there is no shortage of cars at the mines and everything is progressing smoothly. From that it must be taken as a certainty that the consumption of bituminous is heavy, for the output is probably larger now than it has been in a long time.

In spite of all this the bituminous trade is rather quiet and there is some cheap coal on the market. Prices are fairly steady and may go lower before long, but at present are quotable as follows: $2.80 for Pittsburgh select lump, $2.65 for three-quarter, $2.55 for mine-run and $2.15 for slack, with Reynoldsville and Allegheny Valley 15 to 25c. lower, chiefly on account of the difference in freight rates. Coke still sags a little, the best Connellsville foundry being quoted at $5.15.

There is a small spurt in anthracite on account of some final heavy winter weather, but it is now too late for any great activity. Besides the local dealers as a rule had bought heavily and are taking advantage of the severe turn, but they will see their stocks run pretty low before they buy much more. It sometimes happens that March and even April are good coal-burning months, but they cannot be depended upon for it.

COLUMBUS, OHIO

While the colder weather during the past week caused a small increase in domestic business, the coal trade in Ohio has been anything but active. It is between seasons and everyone is apparently waiting for the Lake trade to open. Orders from retailers are slightly larger and more numerous and this had the effect of bracing up what was a rapidly declining market. Prices have not reached lower levels than prevailed a week ago excepting in fine coal which is weak.

Steam business is fairly active although some decline is noted in the tonnage. The falling off is not sufficient, however, to demoralize the trade to any great extent and prices are about as strong as formerly for mine-run. Iron and steel concerns are not quiet as good purchasers as they have been during the past few months. Other lines of industry apparently buy as much as formerly. There is no movement among factories to stock up and many plants will purchase their fuel supply on the open market. Many of the contracts will be renewed at a slightly higher figure than prevailed the previous year.

Indications are bright for an active Lake demand. Reports from the Northwest indicate the consumption of most of the dock coal and as a result the movement will be large. It is expected that bottoms will be chartered earlier than usual. Plans are being laid for some development work in Ohio during the coming season. The greater part will be in the eastern Ohio district where there are thousands of acres of coal which has not been touched.

Operations in Ohio fields during the past week have been

fairly active. Operators from the Hocking Valley district report about 75 per cent. of normal and the same percentage is reported from the Pomeroy Bend district. In Eastern Ohio the output has been fairly large and the production is estimated at about 70 per cent. This section is busy renewing fuel contracts which expire about Apr. 1. In the strictly domestic sections, the output has been below 50 per cent. of the average.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1.50	.....	$1.50	$1.45
3-inch	1.35	$1.20	1 35	1.30
Nut	1.30	.....	1.30	. ..
Mine-run	1.15	1.05	1.15	1.15
Nut, pea and slack	0.85	....	0 85	0.85
Coarse slack	0 75	0.85	0 75	0.75

CLEVELAND, OHIO

Ohio carriers still hold an iron-clad embargo restricting the routing of coal via the Detroit & Toledo Shoreline Railroad, when destined to points on the Grand Trunk. Conditions at Toledo are acute and transportation people report an accumulation of 700 cars at that point. Many shippers have diverted their coal to the Ann Arbor and other Western connections to avoid the blockade.

Lake shippers have already started to load Lake coal at the mines and several large companies in the Youghiogheny district are forwarding Lake fuel to Cleveland via the Erie R.R. This coal will be loaded abroad vessels for forwarding via the Great Lakes at the opening of navigation. It has just been announced that the loading charge on fuel coal for coal carrying vessels will be reduced from 11c. to 8c. per ton. This change will be effective on all coal loaded on and after Apr. 15. Three hundred and fifty thousand tons of coal has been contracted for shipment via the Lakes at rates previously mentioned.

HAMPTON ROADS, VA.

There has been comparatively slow dumping and heavy accumulations of coal during the past week, with prices remaining at the same low level, around $2.60 per gross ton f.o.b. There are approximately 5000 loaded cars at the three terminals or on nearby sidings and this, notwithstanding lighter loading at the mines. It is said that a curtailment for a week during the current month was agreed upon by the smokeless coal operators, but this has not been effective so far. What looks more promising, is the expected arrival of heavy vessel tonnage which, with the light loading, should aid materially in reducing the surplus stocks at the piers.

Movement of coal by the Norfolk & Western and Virginian Railways continues good, but the Chesapeake & Ohio is still badly congested and the tieup is especially bad at Richmond, where tidewater trains are being seriously delayed going through the yards.

It is said, on good authority, that the tidewater coal of the McKell Coal & Coke Co., some 500,000 tons annually, which has been handled by the Chesapeake & Ohio Coal & Coke Co. for a number of years, will, after Apr. 1, be sold by the Geo. E. Warren Co., of Boston. It has already been announced that the C. G. Blake Co. will handle the McKell inland coal.

BIRMINGHAM, ALA.

The weather seems to have made a final effort to aid the retail dealers as winter of a severe nature has been prevailing during the current week. Although it is usually spring by this time, the cold wave in March has partially offset the unusually mild winter. Some additional protests are being made by retailers because of the 25c. increase in Cahaba domestic prices and many of them are slow in placing orders for their requirements.

All Alabama mines are working at a high production rate, and unless interfered with by car shortages or adverse business conditions the output for this year should be well above the 1912 figures, which were approximately 17 million short tons. The coke market is somewhat weaker, due possibly to the gradual decline which has been taking place in the local pig-iron market for the past several weeks.

LOUISVILLE, KY.

In contracting, it is interesting to note that the Southern Ry., which, with the Louisville & Nashville, is taking a good deal of coal from company mines just now, recently made an arrangement with the Middlesboro operators by which it will take washed 4-in. round for steam purposes at $1 a ton, whereas the prices for straight run-of-mine, unwashed, have been 95c. a ton. Naturally, this has been a source of considerable satisfaction among these operators who have installed washing equipment, as it enables them to dispose of this grade at a profit, and get a higher average price for their coal than on mine-run basis. The railroad is said to have found that it gets better results from the smaller coal, owing to the quantity of impurities found in the mine-run.

Price for even the better grades of block and lump are uncertain, running from a maximum of $2 down to $1.60 or $1.75 as the lower levels at which sales are being made. The market on screenings is easier at present, the better grades of nut and slack selling around 75c., and 50 to 60c. for second grades from the Eastern field. Western Kentucky nut, pea and slack is being handled also at 60 to 75c., with domestic nut at about $1 and lump $1.25 to $1.35. A shortage in steam coal is looked for soon, however, on account of the condition of the domestic market.

INDIANAPOLIS, IND.

The coal situation here presents no new features. The operators are concerning themselves chiefly in making new contracts over the next season and say they are asking what have been their standard prices.

Retailers are busy disposing of the coal they contracted for in the fall, with as little loss as possible. The daily newspapers have been carrying front-page articles, pointing out that consumers got no benefit from the mild winter: the price of coal has been as high this winter as it ever was, but the papers do not intimate that dealers have made any fortunes because such is the case. It is generally understood that the only thing that saved them from losses is that there was no price cutting in an effort to stimulate business.

A feature of the retail trade this season has been the larger sales of soft coals, especially Indiana's, caused by the difficulty in getting anthracite and coke in the earlier part of the winter and their unusually high price. Mine prices remain unchanged, with the mines running three and four days a week.

DETROIT, MICH.

It is believed that many large steam contracts will be signed shortly and that the open-market buying this year will be fully as large if not larger than 1912. As to the domestic outlook, the cold weather of February, coupled with the fact that March has started in rather threatening, has started cleaning out the stock of high-priced coal, so that one may look for spring buying on the part of the retailers to a satisfactory extent. The operators in this branch predict also that higher prices will be obtained for this kind of fuel.

CHICAGO

Notwithstanding the fact that there has been no material increase in the consumption of domestic coal, the wholesale demand has shown improvement during the week. This is attributed to the curtailment of shipments and to retail dealers having disposed of their storage supply. The steam market also showed some improvement as far as its technical position is concerned. The continued accumulation of egg and nut coal has resulted in its being moved into the domestic or steam trade, although the former met with a limited market and as a result was substituted for steam lump, mine-run, or even screenings. In consequence of the Chicago dealers curtailing their buying for the last two weeks, believing they had sufficient Western domestic coal to last through the season, many have been obliged to make unusually large inroads on their storage piles while fresh supplies were being withheld.

Prevailing prices in Chicago are:

	Springfield	Franklin Co.	Clinton	W. Va.
Domestic lump	$2.07@2.22	$2 45@2.55	$2.27	
Egg		2 45@2.55		$3.95
Steam lump	1.92@1 97		2 17	
Mine-run	1.87@1.92	2.20@2.30	1 97	3 30
Screenings	1.57@1 62	1.90@1.95	1.67	

Coke—Connellsville and Wise County, $5.75@6; byproduct, egg, stove and nut, $5.50; gas house, $5.50.

MINNEAPOLIS—ST. PAUL

About all the hard coal there is at the Head of the Lakes is a little egg size. Nut, stove and pea have been cleaned up for some time. Early this year wholesalers began ordering direct from Pennsylvania mines, but arrivals are slow. There is considerable pressure for the prepared sizes of hard coal; householders are ordering their second installments and find they cannot get what they want.

The situation on hard coal in the country is peculiar. Last fall many dealers ordered more coal than they actually needed and had to throw some on the ground, having their storage bins full. While in other towns, dealers did not get enough, and are now clamoring for shipments, and are even willing to pay premium prices.

Dock prices are holding firm at circular. Quotations on Illinois and smokeless coal are uncertain and buyers in most cases set the price. Some Smokeless from the east has been known to have sold on the basis of less than a dollar at the mines

ST. LOUIS, MO.

Continued spring weather and the action of the operators in producing and selling coal below cost, is keeping the market in the same condition that has prevailed for the past four or five weeks. There is absolutely no change and nothing to indicate that there will be any change.

As was to be expected, a few of the producers have reached their limit and have sought refuge under the bankruptcy laws, and it will not be surprising to have a few more follow suit. Several St. Louis offices have also been ordered to close up in order to curtail expenses.

Anthracite and coke, such as is coming in, are a drug on the market. A small volume of smokeless is moving in, but there is practically no demand. The circular on other coals is:

	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard
2-in. lump				$0 85 @ 0.90
3-in. lump			$1 25	
6-in. lump	$1 20 @ 1 25		1.35	1.10
Lump and egg	1 25	$2 25		
No. 1 nut	1 10 @ 1.15			
Screenings	0.90 @ 0.95			0.65
Mine-run	1 05 @ 1 15			0.85
No. 1 washed nut	1 40 @ 1 50			
No. 2 washed nut	1 35 @ 1.45			
No. 3 washed nut	1 25 @ 1.30			
No. 4 washed nut	1 15 @ 1.20			
No. 5 washed nut	1.00 @ 1 05			

OGDEN, UTAH

All during the month of February the mines have been long on slack and nut coal. The slack can be handled by unloading at the mines, but none of the operators have had the courage to unload the nut as it would, no doubt, be a total loss; however, the operators are face to face with a large over-production of this grade of coal. A little latter in the spring and during the summer months there will be a fair demand for this, but at present it is a drag on the market. The operators are endeavoring to hold the market price on all grades, but there is a tendency to weaken in several localities, especially on slack and nut coal.

The Colorado operators have announced their spring quotations for April and May shipments to the Nebraska market, as follows, f.o.b. mines: Lump, $2.25; nut, $1.75. Wyoming and Utah quotations remain unchanged, except nut coal, which has been selling below circular, due to the surplus.

PORTLAND, ORE.

It is expected that consideraole development work will be done this summer in the mines at Coos Bay, Ore., and in Washington; in the former district because of the fact that Coos Bay will have railroad facilities by the end of the summer, upon the completion of the Southern Pacific line from Eugene to Marshfield. It is said that there is little probability of much coal, if any, being imported here next summer and fall from Australia, on account of the high rates on vessels. Tonnage is fully as scarce now as last year and importations here were light

PRODUCTION AND TRANSPORTATION STATISTICS

ANTHRACITE SHIPMENTS

The following is comparative statement of the anthracite shipments for February and the first two months, of the years 1912-13, in long tons:

	February		2 Months	
	1913	1912	1913	1912
Phila. & Reading	1,165,449	1,202,536	2,422,581	2,389,070
Lehigh Valley	1,062,129	1,083,925	2,237,280	2,104,372
Cent. R. R. N. J.	761,070	785,000	1,574,437	1,545,035
Del. Lack. & West	763,571	782,699	1,685,670	1,574,397
Del. & Hudson	567,371	572,021	1,220,548	1,139,300
Pennsylvania	491,062	523,539	1,067,614	1,066,358
Erie	655,919	710,263	1,373,154	1,393,108
Ont. & Western	207,598	215,985	429,304	428,024
Total	5,674,169	5,875,968	12,010,588	11,639,664

ANTHRACITE STOCKS AT TIDE

Stocks at tidewater Mar. 1, were 484,270 tons, as compared with 375,566 tons on Feb. 1.

THE CAR SITUATION

American Ry. Association reports surpluses and shortages of coal equipment for two weeks ended Mar. 1 as follows:

	Surplus	Shortage	Surplus or Shortage
New England Lines	33	110	77
N. Y.; New Jersey, Del.; Maryland; Eastern Penn	1,196	1939	733
Ohio; Indiana; Michigan; Western Pennsylvania	4,240	134	**4,106**
West Virginia, Virginia, North & South Carolina	952	560	**392**
Kentucky, Tenn.; Miss.; Alabama, Georgia, Florida	1,561	382	**1,179**
Iowa, Illinois, Wis., Minn.; North & South Dakota	3,163	193	**2,970**
Montana, Wyoming, Nebraska	623	82	**541**
Kansas, Colorado, Missouri, Arkansas, Oklahoma	2,645	13	**2,632**
Texas, Louisiana, New Mexico	477	0	**477**
Oregon, Idaho, California, Arizona	3,149	30	**3,119**
Totals	18,039	3355	**14,681**
Greatest surplus in 1912 (Apr. 25)	94,692	2,144	**92,5064**
Greatest shortage in 1912 (Oct. 10)	6,491	14,897	**8,48**

FOREIGN MARKETS

GREAT BRITAIN

Feb. 28—Tonnage continues in heavy supply, and great activity prevails at the various docks. The inquiry for March delivery is brisk, and sellers are holding firm. Small coals particularly are scarce and dear.

Today's quotations are approximately as follows:

Best Welsh steam	$4.56@4.62	Best Monmouthshires	$4.14@4 20
Best seconds	4.38@4 50	Seconds	3.84@4.08
Seconds	4 26@4 38	Best Cardiff smalls	3.84@3 96
Best dry coals	4 38@4.44	Seconds	3.72@3.84

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days—less 2½%.

FRENCH IMPORTS AND EXPORTS

The following is a comparative statement of the French imports and exports for 1911 and 1912:

Imports	Coal		Coke		Briquettes	
From	1911	1912	1911	1912	1911	1912
Great Britain	9,099,345	9,022,411	211,909	122,797	482,655	426,124
Belgium	3,910,825	3,506,767	790,957	664,230	1,787,853	2,299,093
Germany	2,994,208	3,182,160	189,391	218,381	49,005	63,748
Other countries	227,319	255,430	86,982	117,336	49,005	63,748
Totals	16,231,787	15,966,768	1,189,239	1,122,744	2,319,513	2,788,965

Exports	1910	1911	1912
Coal	1,278,698	1,336,014	1,911,697
Coke	168,977	184,522	217,537
Briquettes	131,457	114,467	191,69

COAL SECURITIES

The following table gives the range of various active coal securities and dividends paid during the week ending March 8:

Stocks	Week's Range—High	Low	Last	Year's Range—High	Low
American Coal Products	87	87	87	87	87

III—MINING TECHNOLOGY

Systematic Handling of Machinery. Fr. Helbig. (Systematische Maschinenbehandlung.) "Braunkohle." vol. 11, 1912. 17, p. 257-9.

Tests of Pick-Quick Electric Coal Cutters on the Petite Pleuse Coal Seam of 380 meters depth in the Monceau-Fontaine Colliery. Vogel & Losseau. (Essais de havage mechanique.) "Annales d. Mines Belgiq." 1912, vol. 17, 4. p. 1099.

Colliery Practice in Concreting. E. E. Seelye and Shurick, A. T. "Coal Age." vol. 2, 23, p. 822-5; 6 fig.

IV—WORKING OF MINERALS

Protection Against Dangers of Mining. W. Heckmann. (Schutz gegen die Gefahren des Bergbaues.) "Bergbau," 1912, 46, p. 646-8, 1 fig. 50c.

High Grade Bituminous Coals—Their Mining and Preparation. A. Haenig. (Die Steinkohle, ihre Gewinnung und Verwertung.) Leipzig, 1912.

Machine Mining of Thin Coal Seam Using Face Conveyors; Ruhr. Dist. Germany. Bolesta-Malewski. (Abbau mit hohem Stoss unter Verwendung von Abbaufordereinrichtungen.) "Gluckauf." Oct. 26, p. 1749-58. Nov. 2. 75c.

Machine Mining in Oklahoma. J. S. Cameron. Coal Tr. Bull. 1912, p. 29.

Coal Mines in Arkansas. A. A. Steel. Vol. I. "Geol. Survey Report." 1912, 632 p.

V—BORING, SHAFT SINKING AND TUNNELING

Concrete Mining Shafts. C. R. Fletcher. "Los Angeles Min. Rev." 1912. Nov. 1, p. 7.

Notes on Shotfiring by Electricity. F. H. Gunsolus. Coal Age. Vol. 2, 23, p. 787-8. (Prescribes remedies for the common failings in electric firing.)

VI—TIMBERING, PACKING, ETC.

The Hydraulic Stowing of Goaves. Knox G. "Colliery Guard." vol. 104, 2711, p. 1195-6; 2712, p. 1240-1. (Special notes on the relation between subsidence and packing. The careful attention to the packing of the goaf is as important as the timbering.

Square Set Timbering. E. T. Rice. "Min. Eng. World." vol. 37, 24, p. 1079-82. 5 fig.

Mine Supports in Germany. "Min. Min." vol. 33. 5, p. 240-2, 16 fig. (Timber, steel and concrete rails, pipes and angle iron.)

Insect Damage to Mine Props and Its Prevention. T. E. Snyder. "Min. Eng. World," vol. 37, 23. p. 1043.

VII—WINDING AND HAULAGE

Three-Phase Hoists at Bantjes Con. Mines, Transvaal. J. Askew. "Min. Eng. World." vol. 37. 22, p. 993-5, 2 fig. 2 tab.

New Arrangement in Mine Hoisting. H. K. English. "Coal Age." Vol. 2, 23, p. 791-2, 2 fig. (The electric hoist employing herringbone gears is placed on the ground, the operator is in the scale house and can watch the discharge of the car, but no signals are dispensed with.)

Cage Fence Gates. W. G. Peasegood. "Colliery Guard." Vol. 104, 2712. p. 1245. (The gates cannot be opened inward into the shaft.)

Skip Accidents on the East Rand. Suggestions for Safety Catch Inventors. S. African Min. Jl. 1912, p. 38. 50c.

Requirements for a Model Mine Track. McIntyre, J. B. "Coal Tr. Bull." Oct. 15, p. 35.

VIII—SIGNALING

Modern Practice in Mine Telephony. G. Brown. "Coal Age," vol. 2, 23, p. 789-91. 6 fig.

IX—LIGHTING

Some Fundamental Principles of Safety Lamp Construction Wm. Clifford. "Coal & Coke Op." 1912, p. 276.

X—VENTILATION

C. F. & T. Co.'s Rockvale Mine, Fremont, Colo. J. B. Marks and G. Alley. "Coal Age," vol. 2, p. 744-6, 7 fig.

XI—MINE GASES, TESTING

A Portable Electric Instrument for the Detection of Combustible Gases and Vapors in Air. L. J. Steele. "Jl. Inst. El. Eng." vol. 49, 214. p. 289-96. 2 fig. 3 Ill. (The Philpp & Steel detector.)

XII—COAL DUST

Prevention of Coal Dust Explosions. S. Dean. "Coal Age," vol. 2, 22, p. 756-8. 5 fig. 2 tabl.

The Production of Coal Dust in Mines. T. J. Matthews. "Min. Eng." p. 182. (Reviews the various means of producing dust underground.) 15c.

Dust Explosions. Young C. M. "Mines Min." vol. 33, 5, p. 258-60. (The influence of the composition and fineness of dust, and the presence of gas on the liability of ignition.

Wet Mines Not Necessarily Safe from Coal Dust Explosions. S. Dean. "Mines Min." vol. 33, 5, p. 245-8. 6 fig. 3 tab.

The French Experiments Made with Coal Dust at Lievin. M. Ryback. (Die franzoesischen Versuche mit Kohlenstaub in Lievin.) "Oesterr. Z. Berg-Huettenwes." 1912. 8. p. 99-103; 9. p. 113-7 50c.

Humidifying Mine Air to Avoid Explosion. "Black Diamond," 1912. p. 15.

U. S. Bureau of Mines Type of Air Humidifier. "Black Diamond." 1912, p. 19. "Eng. World." 1912, p. 852.

XIII—EXPLOSIONS

Discussion of the Ignition of Coal Gas and Methane by Momentary Electric Arcs. W. M. Thornton. "Colliery Guard." vol. 104, 2712, p. 1242, 15c.

Official Report of the Mining Disaster at Lothringen. (Der amtliche Bericht ueber das Grubenunglueck auf Lothringen.) "Bergbau," 1912, 45, p. 629-31. 50c.

XIV—MINE FIRES

Experience with Gob Fires in Leicestershire. T. Stubbs. "Colliery Guard." vol. 104, 2711, p. 1192-4. 15c.

Mine Fires, a Preliminary Study. G. S. Rice. "U. S. Bureau of Mines." Tech. Paper No. 24. 51 p.

XV—RESCUE AND AMBULANCE

Mine Rescue Appliances. Dr. J. Cadman. "Colliery Guard." vol. 104, 2712, p. 1243-4. 2 fig. (Indicates a danger occurring in the use of an apparatus in which an injector is employed.) 15c.

On the Organization of Rescue Work in Mines. Josef Popper. (Ueber die Organisation des Rettungswesens im Bergbau.) "Montan. Rdsch." 1912, Special Number, p. 959. 30c.

XVI—DRAINAGE, PUMPING, ETC.

The Inundation of the Victoria and Habsburg Pits near Bruex, in February 1909. Wolfgang Kummer. (Die Inundation der Viktoria-und Habsburgschaechte bei Bruex in Februar, 1909.) "Montan Rdsch." 1912, 11, p. 521-6, 4 fig. 30c.

Turbo Compressors. Ernst Blau. (Turbokompressoren.) "Kohle-Erz." 1912, 37, p. 921-4. 50c.

XVII—PREPARATION

Improvements in Coal Preparation. A. J. Reef. "Coal Age," vol. 2, 24, p. 829-30, 4 fig. (Particular attention is given to defects in shaking screens and coal chutes of adjustable pitch, and the principal defects in other appliances.)

XVIII—BRIQUETTES

The Briquetting of Pit Coal with Addition of Napthaline. Grahn. Steinkohlenbrikettierung mit Napthalinzusatz "Gluckauf," 1912. 38. p. 1536-7. 2 fig. 75c.

Advantages of Driving Briquetting Presses by Steam. A. Eckardt. (Vorteile des Dampfantriebes von Brikettpressen.) "Braunkohle," vol. 11, 1912. 32. p. 507-9. 20c.

XIX—COKE OVENS

The Coking of Coals at Low Temperatures, with a Preliminary Study of the Byproducts. S. W. Parr and H. L. Olin. Univ. of Illinois, Eng. Experiment Station Bull. No. 60.

Automatic Indicating Devices at Coke Tar Plants, with Special Reference to Gas Metering. A. Thau. (Selbsttaetige Betriebsueberwachung auf Teer-Kokerien mit besonderer Berueecksichtigung der Gasabsaugung.) "Gluckauf," 1912, p. 1706-19, p. 1858-64. 75c.

Byproduct Coke Ovens. "Metall. Chem. Eng." vol. 10, 12, p. 806-11. 2 fig.

Coking Practice in the South Wales District. Greaves, R. H. G. "Foundry Tr. Jl." vol. 14. 130. p. 618-23. 3 fig. 3 tab.

The Coking of Coal at Low Temperatures. "Power," vol. 36. 19. p. 697. (Considers the possibility of modifying the composition of raw coal in order that a different type of fuel may be produced in coking.)

The Coking of Coal at Low Temperatures. S. W. Parr, and H. L. Olin. "Colliery Guard." vol. 104. 2708. p. 1039-42. 1 fig. 3 tab. 15c.

The Manufacture of Coke. F. E. Lucas. "Am. Inst. Min. Eng." Bull. 71. p. 1315-26. (Deals exclusiveiy with the by-product oven and its economy of working.)

The Manufacture of Coke. W. H. Blauvelt. "Am. Inst. Min Eng." Bull. 71. p. 1299-1314. 1 fig. (The qualities of the by-product oven and some of its advantages over the beehive oven.)

Progress in Byproduct Coke Manufacture. F. E. Lucas and others. "Iron Age." vol. 90. 20. p. 1161-5. 5 fig.

Significance of the Counter Current. J. Verner. "Coal Age." vol. 2. 20. p. 677-9. 2 fig. (The flame of an explosion feeds on the rear of the dust column, so there must be fresh air behind the dust! The air is supplied by the return draft. The coke dust on the leeward side of projections is deposited also by the counter current.)

Electric Smelting in Norway. J. L. Vogt and others. "Min. Jl." vol. 99. 4031. p. 1145-7. (The employment of coke as a reduction material in electric iron smelting is considered to make a poorer and more sulphur-containig pig iron.) 25c.

XX—FUEL TESTING

Shortcomings of the B. T. U. System. G. D. C. Coal & Coke Op." 1912, p. 225.

Testing Texas Lump Lignite. Earnest, D. C. "Min. Min." Nov. p. 180.

Determining Coal Values, Chemical and Calorific. Bailey, E. G. "Min. Meth." Nov. p. 191.

Decomposition of Coal in Storage and Upon Exposure. (Ueber die Zersetzung von aufgestapelter Kohle.) "Kali Erz & Kohle," Oct. 25, p. 1072.

New Calorimetric Bomb, System Fery. (Nouvelle bombe calorimetrique "Ind. Nat." 1912, vol. 118. 2 sem. 1. p. 30-6. 2 fig. (Thermo-electric bomb.)

Determination of Heating Value of Solid Fuels by Calculation from the Proximate Analysis. H. H. Clark. "Progress Age." vol. 30, 22. p. 881. 3 tab. (Formula applied to anthracite, bituminous and lignite coal and coke.)

Spontaneous Combustion of Coal. S. F. Walker. "Gas World." vol. 57. 1480. p. 725-8. 5 fig. (Some methods of prevention are discussed.) 30c.

Coal Stacking and Coal Firing. H. Kendrick. "Gas World." vol. 57. 1481. p. 762-7. (Special consideration is given to gas works storage of coal in anticipation of strikes.) 30c.

XXI—STEAM ENGINES AND BOILERS

Selling Energy instead of Slack. "Coal Age," vol. 2, 23, p. 781-4, 9 fig. 1 tab. (Electric energy generated from slack and sold in nearby towns.)

Boiler Practice and Fuel Economy. Dales. J. H., "Eng. Rev." vol. 26. 5. p. 166-8. (The estimated preventable loss of fuel is 10%, which is valued at £8,000,000 per annum.)

How and Why Coal Smoke Is Injurious. B. C. Benner. "Metall. Chem. Eng." vol. 10. 11. p. 735-7. 3 fig. 3 tab. (Some specific instances from the town of Pittsburgh.)

Laws in Force in Europe against the Emission of Black Smoke. J. B. C. Kershaw. "Metall. Chem. Eng." vol. 10. 11. p. 756-9. (American laws differ greatly in various States, European laws have greater uniformity.)

Smoke Abatement as Related to Steam Railroads. W. A. Hoffman. "Boiler Maker." vol. 12, 11. p. 325-7. 5 fig.

XXII—ELECTRICITY

Electricity Applied to Coal Mining. J. T. Jennings. Coal Age," vol. 2, 23, p. 779-80.

Electrical Equipment of the Shelton Iron Steel & Coal Co.'s Works, Stoke-on-Trent. "Colliery Guard." vol. 104, 2711, p. 1187, 6 fig.

Application of Electric Power for Coal Mining. S. R. Stone. "Min. Eng. World," vol. 37, 24, p. 1085-8, 3 fig.

Emergency Treatments of Mine Electrical Troubles. E. Clemens. "Coal Age," vol. 2, 23, p. 783-5, 10 fig.

Central Stations Service in Mining Operations. E. T. Spence. "El. World." vol. 60. 5. p. 260-1. (Interest of the central station in the use of electricity, in coal mines within reach of its circuits; electric cutting of coal, haulage, draining and pumping, hoisting of coal, ventilating, lighting.)

A German Electrical Colliery Installation. J. B. Van Brussel. "Coal Age." vol. 2. 19. p. 635-7. 4 fig. 2 tab. (A typical plant of six unusually complete electrical plants which total 20,000 hp.; the important units are all duplicated.)

Mine No. 9 of the Penn. Coal and Coke Corp. R. D. Meinwaring. "Coal Age." vol. 2. 18. p. 600-3. 6 fig. (The electrical equipment is exceptionally complete and extensive, also a large amount of water is handled.)

Electrical Regulations in Belgian Coal Mines. "Coll. Guard." vol. 104, 2706. p. 939-40. 15c.

Underground Mine Switches. D. W. Jessup. "Eng. Min. Jl." vol. 94. 22. p. 1031-4. 17 fig.

The Wireless Motor in Mining. S. McMahon. "Coal Age." vol. 2. 20. p. 671-2.

Alternating Current Motors for Mines and Mills. S. R. Stone. "Min. Eng. World." vol. 37. 19. p. 839-43. 7 fig.

XXIII—SURFACE TRANSPORTATION

Mechanical Handling of Coal for British Locomotives. C. J. B. Cooke. "Colliery Guard." vol. 104, 2712, p. 1239-40. 1 fig. 15c.

An Electric Elevated Tramroad Installation. "Coal Age," vol. 2, 24, p. 831-2, 3 fig. (It employs no third rail nor overhead trolley, no cross-ties nor sleepers are used; the cars dump automatically in all weathers.)

Lake Docks May Determine Success at Panama. "Black Diamond," 1912, p. 18. (Coal handling methods at lake docks.)

Mechanical Handling of Coal for British Locomotives. J. C. B. Cooke. "Inst. Civ. Eng." No. 2. 27. Nov. 1912. p. 1-5.

The Adair Face Conveyor. "Coll. Guard." vol. 104, 2708, p. 1035-6, 11 fig. (A coal conveyor which is designed to take as little space as possible in a verticle direction when discharging.) 15c.

Gantry Coal Handling Crane. A. D. Williams. "Power." vol. 36. 20. p. 703-4.

The World's First Coal Port. M. Meredith. "Cassier's Mag." vol. 42. 5. p. 379-88. 9 fig. (The Bute Docks, Cardiff, of the Cardiff Railway Co.) 40c.

XXIV—SANITATION DISEASES

Compulsory Reporting by Physicians of Industrial Diseases. L. W. Hotch. "Am. Labor Legisl. Rev." vol. 2, p. 263-72.

Miners' Baths. W. B. Wilson. "Coal Age." vol. 2. 18. p. 619-20. 10. 656-8. 4 fig. (Notes upon provision made in different mines and the building constructions for from 650 to 1000 men.)

Miners' Baths. H. F. Bulman. "Coal Age." vol. 2. 18. p. 619-20. 6 fig. (Method of running the bath and some mechanical appliances for suspending clothes, the locked hoists being under owners' control.)

Town Planning on the South Yorkshire Coalfield. P. H. Boulnois. "Colliery Guard," vol. 104. 2709. p. 1092-3. 15c.

COAL AGE

Vol. 3 NEW YORK, MARCH 22, 1913 No. 12

A few years ago an ingenious advertising man popularized a poster that pictured a large hand with the fore-finger pointing straight at the passerby and underneath, in flaming red letters, was the word *YOU*.

It was so designed that no matter from what angle you viewed it, the finger seemed always to point at you.

This man realized that the average human being is prone to accept any statement as true, so long as it affects mankind in general, but if you hope to make the human being in question realize that you are talking to *him*, and for *him*, you must stop him long enough to get his mind off mankind in general.

If, after pondering over this statement for a moment, you are inclined to agree with it, you'll be in position to understand why it is that so much of the welfare work carried on around our mining camps seems to bear so little fruit.

Take the "safety first" campaign as an illustration: Just now it generally begins (and very often ends) with placards. Now a large part of the placards used are so worded that no one can dispute the truth of the statements and yet they fail to make each man realize that the message is intended primarily for *him*.

If we hark back to the old, old proverb that tells us to remember that a chain is no stronger than its weakest link, the necessity of the personal note as suggested by the advertising man's pointing forefinger becomes apparent

For example, *Mr. Superintendent*, you're one of the links! The next time you are inside the mine and decide that you will ride the haulage trip out, to save time, even though none of your men are allowed to ride, under penalty of discharge; think of that invisible but fearfully real finger pointing at *you* from a "Safety first" placard.

Mr. Mine Foreman, you're one of the links! When you are tempted to urge your motormen to make up time they have lost, even though it be contrary to speed rules; think of that haunting finger pointing at you.

Mr. Fireboss, you're one of the links! The next time you skip a room on your rounds, just because you are tired and know that it is safe; think of that ominous finger pointing your way.

Mr. Trackman, you're also one of the links! When you put two spikes in a rail that requires five, just because you are out of spikes and don't feel like going after more; think of that tell-tale finger pointing at you.

No need to get personal with you, *Mr. Miner*: every one knows that you must be careful and every one tells you so. Perhaps, however, if some of the bosses acted as if they understood, you might manifest interest enough to inquire from your neighbor as to just what all the fuss was about.

We are not attempting to take sides with the miner; we are simply trying to follow the example set by the advertising man—we want to get you, Mr. Superintendent and Mr. Mine Foreman and Mr. Fireboss and Mr. Trackman and Mr. every other man, into an argument with your thoughtless self.

Ralph Waldo Emerson, who knew a few things about human nature, *partially* covered the ground when he said: "If you would lift me, you must be on higher ground." We say partially because this isn't a case of lifting me; it's something far more difficult; its a case of lifting *you*.

MORAL: Don't forget that you and I and every other body must realize our individual responsibility if we would be linked in a chain of safety.

Scientific Principles in Use of Dynamite

Special Correspondence

SYNOPSIS—The use of explosives has been scientifically considered but no one seems desirous of using the results of the determinations. The writer shows that safety and efficiency both depend on the methods employed in the use of dynamite. The action of the detonator should be directed toward the main body of the charge and so arranged that the maximum shock will be at the end of the hole.

It is said that there is a right and a wrong way of performing even the most ordinary and commonplace act, and it is interesting to note that the unerring instinct of so many is to do it the wrong way, especially those people who "know it all." Any user of dynamite and every blaster will tell you that he knows all about dynamite and has been shooting holes ever since dynamite was invented, and some of them claim to have blasted with dynamite even before that time.

It is no exaggeration to say that there is hardly a line of manufactured articles which is used with such

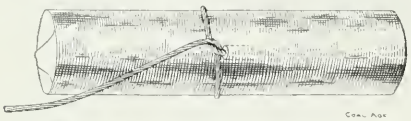

Fig. 1. A Method of Priming by Which Short-circuits and Misfires Result. Avoid Half Hitches

utter disregard of the manufacturer's directions as high explosives. Manufacturers print directions, which are placed in every box of dynamite; they distribute thousands of booklets and catalogs and issue carloads of warning cards of various descriptions indicating how their goods should be used. Notwithstanding all this, there is probably not more than one consumer in five hundred who thinks it necessary or desirable to follow these directions. He considers himself an expert on the subject and knows more than the manufacturer about the product.

There are two requisites which consumers fail to observe, and because of their neglect they get lessened efficiency from the dynamite; (1) they do not thaw the explosive correctly and (2) they fail to make the primer in the proper manner. The question of thawing will not be dealt with in this article. Correct priming involves two precautions: correctly locating the connecting medium, that is, fuse or electric fuse wire, and placing the detonator in the proper position in relation to the charge.

Beware of Sharp Bends in the Electric Fuse

Taking up electric blasting first, 99 out of 100 blasters insert the electric fuse in the side of the dynamite cartridge and take a half hitch with the wires around the cartridge, giving them a smart pull to tighten them, as in Fig. 1.

Of those who do not use this method, 99 out of 100 insert the detonator in the end of the dynamite cartridge, double it over, and stick the cartridge exploder end first into the borehole. The trouble with the half-hitch method is that it is liable to cause misfires by a short circuit, where the wires are pulled against each other at the hitch. Of course, if the current goes across this point, it will not fire the detonator.

Fig. 2. Wrong Method of Priming, Giving Greatest Intensity of Detonation near the Tamping

The detonator when stuck in the end of the cartridge and pointing out toward the mouth of the borehole, does not realize the full power of the explosive for the reason that the direction of the greatest detonating force of an electric fuse or blasting cap is out of the "business end,"

Fig. 3. A Well Planned Shot. The "Business End" of the Primer Faces Larger Part of Charge

that is the opposite end from that into which the fuse is put or from which the fuse wires protrude.

The Detonator Should Have the Open End Facing the Bulk of the Charge

When the primer is placed, as shown in Fig. 2, the dynamite at the point indicated by *A* gets the maximum strength of the explosion, and in actual practice it has been found that there is a liability of unexploded powder being found at *B*.

Fig. 3 shows the proper way of placing the detonator where only one is used in each hole.

Fig. 4 shows even a better method with two detonators,

Fig. 4. A Well Arranged Shot with Two Centers of Detonation and with Primers Rightly Located

one set not far from the tamping in the second cartridge and the other running to a cartridge in the end of the hole. Practically every particle of strength of the explosive is used and there is almost no chance for a misfire or of having unexploded dynamite in the débris.

Avoid the Possibility of Striking the Cartridge with Tamper

The few blasters who do not use either of the two methods of priming condemned above, open up one end

The shots here illustrated are for the most part arranged for vertical holes, as frequently appears in the text. In many cases, it will be seen that the holes, being in soft material, have been enlarged at the ends by untamped shots. The principles enuntiated apply equally to all forms of dynamite shooting.—Editor.

of the paper wrapper and stick the blasting cap or electric fuse in the end and either tie or crimp the paper down to hold the detonator in place. Once this is loaded in the hole, it makes an ideal blast, as the detonator is in the center of the borehole and pointed towards the end. It has the disadvantages, however, of bending the fuse wire or fuse sharply when the tamping stick is pushed against it and of bringing the detonator itself nearly in contact with the tamping stick, and on this account is a little less safe than the method whereby the detonator is placed in the middle of the cartridge, as shown in Fig. 5.

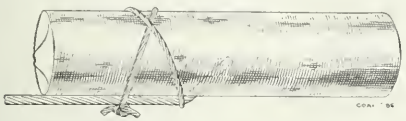

FIG. 5. TYING FUSE BY LOOP AROUND THE PERIPHERY OF THE CARTRIDGE KEEPS IT SECURELY IN PLACE

The fuse or fuse wires may be tied with a string to the cartridge, or the fuse wires may be laced through the cartridge (see Fig. 6), thus avoiding the wires crossing and so making a short circuit.

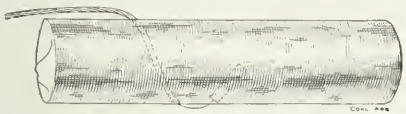

FIG. 6. A METHOD OF ARRANGING ELECTRIC FUSE WIRES SO THAT THERE IS NO RISK OF A SHORT-CIRCUIT

COMMON FUSE SHOULD BE RUN TO LAST CARTRIDGE, ELECTRIC FUSE TO LAST BUT ONE

Fuse, of course, should not be laced through dynamite cartridges, as it is liable to ignite them from its side spit, and for the same reason, charges fired with blasting cap and fuse should have the primer in the last cartridge loaded in the hole, especially in charges where the cartridges are slit or taken out of their paper wrappers. With electric exploders it is usually best to allow one cartridge to be above the primer, i.e., have the primer next to the last cartridge loaded in the hole so that in case of a misfire, if the tamping is to be removed, there

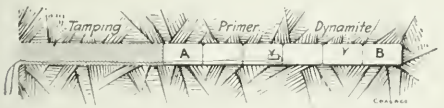

FIG. 7. PRIMER WITH ITS "BUSINESS END" FACING *A*, WILL DETONATE MORE VIOLENTLY THERE THAN AT *B*

is one cartridge between the tamping and the primer, which is the most dangerous point in the charge.

There are two reasons why better execution is obtained from the priming method shown in Fig. 3, than from that exemplified in Fig. 2. One reason is that the maximum effect of the detonator is at its "business end" in a hole loaded as shown thus.

With the primer in the middle (see Fig. 7) and an equal amount of dynamite at each end, the charge at *A* would explode with greater force than that at *B*, where it is most desired. With very sensitive explosives and those most dangerous to handle, this difference in the effect of the direction of the detonator would not be as noticeable as with more insensitive explosives, such as the gelatines and ammonia powders.

DYNAMITE DETONATION GAINS SPEED WITH TRAVEL UP TO A CERTAIN LIMIT

In a hole loaded like this, you will not get as much work out of the dynamite as if the primer were placed as in Fig. 3, because the power of an explosive depends on two things—the volume of gas liberated and the quickness with which this is done. It takes a certain well-defined distance in the dynamite for its detonation to pick up its full speed, just as it takes a certain time for a railroad train to get under way.

It takes about a foot, sometimes more for modern, safe, insensitive dynamites to reach their maximum speed of propagation. This is not theory; it has been positively and accurately determined by firing charges with different explosives in a tube, through which wires are passed at intervals, which are connected electrically with an instrument called a chronograph. In this way, it has been determined that a detonating wave will travel

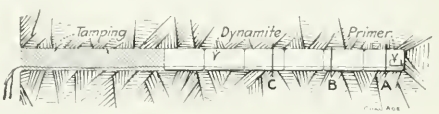

FIG. 8. A GOOD SHOT WIRED TO SHOW THAT DETONATION TIME IS SHORTER FROM *B* TO *C* THAN FROM *A* TO *B*

through dynamite quite slowly, comparatively speaking, for the first 6 or 8 in., and about a foot from the place where the detonator was located it acquires its full velocity and goes on at that speed for the rest of the distance.

It has been often observed in firing horizontal shots in a comparatively shallow hole, say 10 or 12 in. deep, that after the blast the rock shows a perfectly smooth surface up at the top, where the detonator was located, and for 6 in. from that point, but after that and at the bottom of the hole, the rock is burned and shattered. In Fig. 8 if wires are placed across the charge at equal distances at the points indicated by *A*, *B* and *C*, it will be found that it takes much longer for wire *B* to break after *A* has broken than it does for *C* to break after *B* has broken.

This point has been proven on a large scale in practical quarry work by priming half the holes in a uniform ledge of 28 holes as shown in Fig. 2—the detonator being at the top and pointing towards the mouth of the hole. The other holes were loaded as shown in Fig. 3, with the detonator at the top and pointing toward the bulk of the charge. The ledge in which the detonator pointed outward was thrown off to within 2 ft. of the bottom of the hole. There the rock was broken in places but was not thrown out. In the other half of the ledge where the detonator pointed towards the bulk of the charge, the rock was thrown off clear and clean and nearly 2 ft. below the bottom line of the hole, taking off about 30 per cent. more material than the same charge did with the detonator pointed the wrong way.

Naphthalene as a Briquette Binder

SYNOPSIS—Exhaustive experiments have been conducted by both the government and private individuals in the effort to obtain a substitute for pitch as a binder in briquetting. These have, in the main, been unproductive of results. The accompanying article describes the use of naphthalene for this purpose and it is said to give satisfaction when used as a partial substitute.

A new method of mixing naphthalene with briquettes as a substance for part of the pitch binder is described in *Glückhauf*, Essen, Germany, Sept. 21, and Oct. 26, 1912, by Mine Assessor Grahn, instructor at the Bochum Mining School. We translate in abstract as follows:

The binder generally used for briquetting coal is pitch, the price of which is therefore an important consideration. It is quite an expensive binder and if, at a cost of $10 per ton, 7 per cent. by weight is added to the briquettes, this means an item of 70c. per ton of the product. Search has been made for a cheaper substance with which to replace some at least of the pitch. An important material for this purpose is naphthalene.

The Buss-Fohr System

There has been introduced in Germany the Buss-Fohr patent system for briquetting coal, lignite, peat, etc., using superheated steam and naphthalene. This apparatus is successfully operated in Kray, Germany, at the Bonifacius mine of the Gelsengirchener Bergswerks-A. G.; it is shown in the accompanying figures.

Crude naphthalene is first led into an iron pressure tank in the briquette factory cellar and there melted by steam. It is then forced, by compressed air, through a sieve filter, and into a reservoir above the mixer, the reservoir being likewise heated by steam coils. Formerly the naphthalene simply flowed from this reservoir into the mixer, but it was found that on mixing with the fine coal it formed into lumps which adhered to the briquetting press.

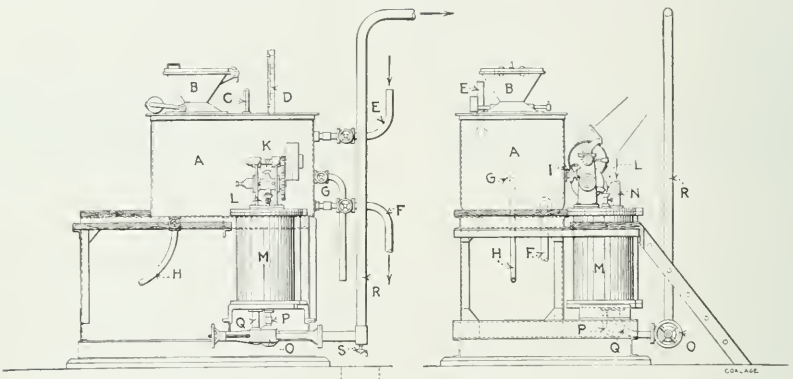
This difficulty has been remedied by introducing a spraying nozzle or injector in the top of the mixer. The liquid naphthalene is now blown by steam and thus distributed as evenly as possible upon the fine coal, which is kneaded by a stirring device in the mixer. Into the mixer is led superheated steam at about 660 deg. F., which keeps the temperature at about 480 deg. In contrast to the Schüring apparatus, to be described later, the naphthalene is not vaporized until it reaches the mixer.

The Importance of Vaporizing.

It is important that all the naphthalene shall vaporize and be distributed in the gaseous state between the particles of coal. That it does effectually vaporize, and not remain in liquid form, is proved by the fact that when more steam is led into the mixer, or when same is at a considerably higher temperature than usual, naphalene in vapor form escapes above and precipitates outside of the mixer in white flakes. This visible deposit is a guide for regulating the temperature and quantity of steam supplied.

From the mixer, the pasty mass of fine coal, melted pitch and naphthalene is conveyed to the presses. At the Bonifacius mine two Tigler presses of new design are used for making large industrial briquettes weighing 22 lb. The average pitch consumption, without naphthalene, is 6 per cent. of the coal supplied, but this is reduced to 5 per cent. when replaced by about 2 per cent. of naphthalene. It is stated by the inventor, however, that the spray nozzle which has been mentioned, renders possible a further reduction in the pitch of about 1 per cent., for which is substituted 1 per cent. more of naphthalene. The results at the Bonifacius mine were attained in making briquettes of very fine coal of a sort requiring more pitch than some other kinds.

Briquettes, containing naphthalene, from this mine have proved satisfactory for marine use after more than two years storage. The manufacturers prefer the briquettes with naphthalene; they come from the press softer but harden on cooling.



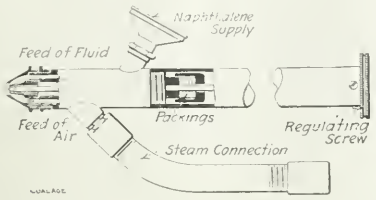
Schüring's Naphthalene Vaporizer for Briquetting

Schüring System

Another process it that of Schüring, also patented in Germany. The naphthalene, melted outside of the mixer, is next vaporized in a carburetor heated by superheated

steam and afterward forced into the material by superheated steam in the mixer. The apparatus is illustrated in the accompanying figures.

The naphthalene is first fed through a hopper *B* into a pot *A*, where, by means of live steam from the superheater coil *E*, it is heated to about 212 deg. F. and so melted. The cocks *G* and *H* allow the melting pot to

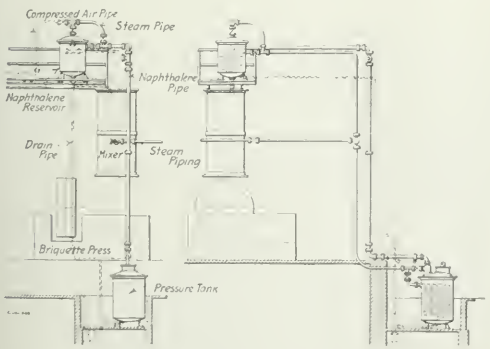


Nozzle for Spraying Naphthalene

be emptied of naphthalene and naphthalene sediment for cleaning. The condensed steam is led off through the pipe *F*.

In general, the melted naphthalene passes automatically through the outlet cock *I* into the measuring apparatus *K*, which is surrounded by a jacket that can be heated, and thence in definite quantities, through the feed funnel *L*, into the vaporizing coil in the heating cylinder *M*. Through the pipe *N*, superheated steam at perhaps 480 to 660 deg. F. enters the heating cylinder, surrounds the vaporizer coil and emerges through the pipe *Q* in order to serve the steam-jet apparatus or injector *O*.

The napthalene is vaporized in the heating cylinder and flows through the outlet connection *P* also to the injector *O*. Here the steam pressure should be at least four atmospheres absolute, with a temperature of 480 deg. The naphthalene, in a practically gaseous state, is blown through it and along the pipe *R* to the steam kneader or mixer. A drainage cock *S* permits the re-



Front and Side View of Buss-Fohr System

moval of any condensed naphthalene that may have collected. It must always be opened when the entire apparatus ceases operation.

The thermometer *C* and a pyrometer are provided for observing the temperatures of melting pot and vaporizer respectively. A float gage *D* shows the level of the naphthalene in the melting pot.

Some Practical Applications

The coal, together with the required proportion of the pitch binder, is heated in the ordinary manner. It is then well impregnated by passing the naphthalene and steam mixture through it from the bottom to top, yet so that no naphthalene vapor escapes at the upper end. The briquetting press is connected with the vapor mixer.

The Schüring system has been tried at the Blankenburg mine in the Dortmund Upper District. It was found there that by the addition of 3 per cent. naphthalene the percentage of pitch could be reduced from 6¼ or 6½ per cent. to 4½ or 5 per cent., while maintaining a satisfactory quality of the product; it was found impracticable to use over 3 per cent. naphthalene, as the briquettes stuck in the press and also showed less strength. The average quantity of pitch per ton of briquettes without naphthalene, as employed in the district, is said to be slightly larger than that at the Blankenburg mine, which will indicate a still greater possibility of saving.

While the percentages of saving in pitch, as here stated, are too rough and fragmentary for close comparisons, it is proper to point out a slight difference in the bases of computation, the percentage at the Bonifacius mine apparently being reckoned upon the weight of coal used and at the Blankenburg colliery upon the weight of briquettes produced.

A Large Coal Bill

The coal bill of a big trans-Atlantic liner is sufficiently great under ordinary circumstances, but when strike conditions prevail, with consequent high prices, the sum paid for sufficient fuel for a single voyage may amount almost to a small fortune.

The White Star liner "Olympic" for her last trip to this country was compelled to pay $5 per ton for her bunker coal, and had difficulty in securing enough to supply her needs at even this price. Her total expense for coal alone upon this voyage was $25,000.

Upon this trip the vessel carried 1586 passengers of all classes, and the expense for fuel for each passenger amounted in round numbers to $15.70, and as the voyage was completed in 5 days, 18 hours and 16 min., the coal bill amounted to very slightly over $3 per minute.

In reckoning fuel costs, all figures should be regarded as relative. Because one steamer burns a greater weight or value of coal than another, does not necessarily signify that her freight cost per ton-mile is any higher. It is probable that other vessels plying between the same ports at about the same time as the Olympic were compelled to pay equal rates per ton in order to fill their bunkers. It is doubtful, however, if any other steamer paid such an enormous sum for fuel enough for a single voyage.

The advantages of electric mine lights, as compared with ordinary mine lights, are:

(1) The absence of oil permits tilting at any angle without injury to the light, thus affording a good illumination for the examination of roofs. (2) Regular and constant radiance. (3) Safety in explosive gas unless the bulb is broken. (4) Light not extinguished by the presence of gas or by small blasts of air. (5) No loss of time from being accidentally extinguished. (7) Periodical examinations unnecessary. (8) No smoke. (9) No gauze being used. It cannot become heated by the tilting of the lamp with a consequent explosion of gas.

Mine Explosions Caused by Gas Wells

By A. W. Hesse*

SYNOPSIS—The writer shows that gas wells have been the cause of three severe explosions. The upward pressure of the gas at the coal may be greater than the downward pressure of the roof. It is easy, therefore, to see how leakage through crevices takes place. A mine separated from a well by 1500 ft. of unbroken strata caused a violent explosion in a mine just opened. A one-inch pipe inserted in the coal gave 17,600 cu.ft. of gas.

On Nov. 21, 1912, an explosion occurred in a small country coal mine located about three miles west of Shinnston, W. Va. Two small boys were killed and the father was fatally burned while attempting to rescue them. Later examination showed the cause to be the escape of gas from a well located about three or four hundred feet away. This well had been drilled to the gas about 6 years previously and about 1910 it was cleaned out and tubed; after which a casing head was placed so as to enclose the gas within the outside casings. In all probability no packers were placed at the bottom of the hole to prevent leakage around the casings.

Attention has been called to Judge Doty's decision against the Penn. Gas Coal Co., which corporation sought to restrain the Greensboro Gas Co. from drilling a well through their coal without fulfilling a previous agreement to protect their operations.[1]

Explosion at a Consolidation Mine

The explosion which occurred in two mines of The Consolidation Coal Co., in the Fairmount region in 1910, was proved to be directly caused by a capped gas well.[2]

This well was started with a 13-in. bit and drilled to a depth of about 246 ft., or about 82 ft. below the Pittsburgh coal seam. An 8¼-in. casing was then "run in" and a cement mixture poured around it, up to some point above the coal. The cover at this point is about 176 ft. thick. When the well reached the gas, a casing head was placed on the 8¼-in. casing. After standing for some time, the pressure reached about 850 lb. per sq.in.

The Downward Pressure of the Measures Compared with the Upward Pressure of the Gas

According to investigations made at Lehigh University a vertical column of coal-measure rock, 176 ft. high and one foot square, will produce, approximately, a compression of 13.3 tons net or about 185 lb. per sq.in. The gas pressure of the aforementioned well was over four and a half times this amount, and as most of the coal in this neighborhood was extracted, the chances for the leaking of the gas were highly favorable.

In June of 1911, the Hutchinson Coal Co. made an opening into the Pittsburgh coal, about 8 miles west of Clarksburg, on the Parkersburg branch of the Baltimore & Ohio R.R. After the entries had advanced about 80 ft. a gas explosion blew mine cars and tools out of the opening. Upon investigation, the odor of natural gas could be easily detected and a 1-in pipe inserted into the coal showed a pressure of two-tenths inch water gage or a flow of about 17,600 cu.ft. of gas per day. It is easy to imagine how large a quantity of gas must have been escaping from the entire face of the entry.

Explosion Caused by a Well 1500 Feet Away

A gas well about 450 ft. distant from this opening, and near the outcrop, was uncapped but this had no effect upon the flow of gas. Another well located about 1500 ft. south was then opened and the flow of gas immediately stopped. No indication of gas has since been found in this mine.

Any gas well of long standing may be considered a menace to coal operations, especially if the gas is confined in the outer casings. The reason follows, reference being made to the sands penetrated in this locality.

A well is drilled at the commencement with a 13- or 16-in. bit and goes to some point between the surface and the Dunkard Sand, depending on the location of water. Ten-inch casing is run in the hole to this depth; but no packer is placed on the bottom to prevent any possible escape of gas.

The hole may be drilled on down to the Big Lime and 8-in. casing run in to this point. It is probable that the driller will fail to place a packer on the bottom. The size of the bit and drill is then reduced and the hole extended down to the Big Injun Sand, where a sufficient quantity of gas to warrant immediate piping may be found. But we will suppose that a fair quantity is obtained. The 6-in. casing is immediately run in the hole and the packer placed in some rock just above the point where gas is found. This confines the gas to the 6-in. casing.

The driller continues down to the Thirty Foot, Fifty Foot, or the Fifth and Sixth Sands, depending on the gas indications and the location. Perhaps 5-in. casing is run in to some point below the Injun Sand to confine this gas between the 5- and 6-in. casings. Then if the flow of gas is not exceptional from the lower sand, 3-in tubing is run in to the gas-producing sand and the anchor packer placed in some solid rock above.

If Packers Deteriorate, the Casings Cease to Protect

Should this well stand for a number of years, there is little doubt but that the rubber on the various packers may deteriorate to such an extent as to allow the escape of gas around the bottom of the casings to which the packers are attached. It is difficult to say just where this gas will appear—on the surface or in the mine.

Therefore, a coal operator should know, and has the right to know, as much regarding the conditions and methods, of a well being drilled through the seam of coal he is working as the person, party or company drilling such a well. Otherwise, he is negligent and, unless he takes sufficient interest in his own property to call attention to these dangers, how can he expect the gas or oil man to care for his interests.

Original Impurities of Bering Coals

By W. R. Crane*

SYNOPSIS—Had the Bering field coals never been folded, faulted, pulverized, devolatilized and streaked with dikes and sills, they would still have been intensely interesting to economic geologists. Dr. Crane in this, the third of his series of papers, shows that the partings rise and wane incontinently, and that pyrite boulders are found of an abnormal size. Bituminous shale "horses" and "bells" of argillaceous material add to the risks of mining and to the difficulties experienced in preparing clean coal.

The coals of the Bering River field occur in Tertiary rocks, as do many other coals in Alaska. The beds are given a number of local names, but the enumeration of

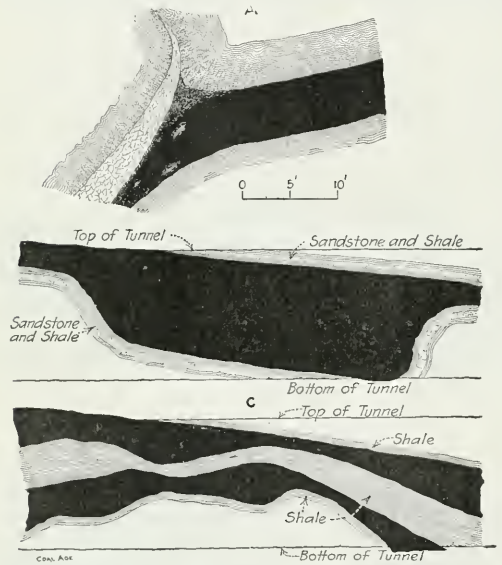

Fig. 1. Sections in Tunnel on Carbon Mountain, Showing Variations in Coal and Shale

these would be of no particular interest, and I therefore omit all reference to them.

How Upheaval, Erosion, Subsidence, Folding, Intrusion and Glaciation Have Modified the Coal

The geological history of this region is one of many and diversified changes; it has been subjected to periods of upheaval, alternating with periods of inactivity, during which time erosion acted, cutting out valleys which, at present, are filled with alluvium. Later, subsidence brought the land to practically its present position. Folding and faulting, accompanied by intrusions of igneous materials in the form of dikes and sills, were probably subsequent actions.

Glaciers have played no small part in the production of the present topography of the region and further have left behind in their retreat vast accumulations of débris, which are still choking the rivers and bays with silt. Bering River, which would otherwise have been of great assistance in the opening up and development of the coal field has, by such accumulations, been rendered unnavigable to all vessels except canoes and rowboats.

The condition of the rock strata is an index of the condition and character of the coals found associated with them. The folding and faulting observed in this region and the occurrence of igneous intrusions as dikes and sills, are evidence of extensive rock movements, and the coal beds being soft and friable have been disturbed even in undue proportion to what might possibly be expected from the conditions of the rock formations.

The character of the coal both physically and chemically has also undergone marked changes, as the whole

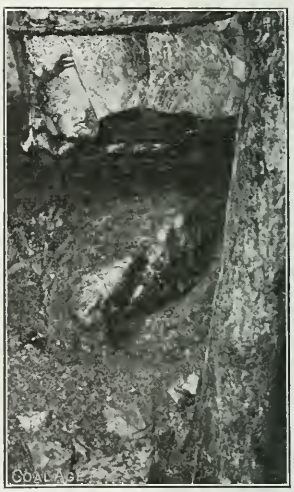

Fig. 2. A Nodule of Pyrite Occurring Close to the Top Rock

range from bituminous coal to anthracite is to be found in the limited area of this field. Reference has already been made on pages 212 and 298 to certain badly disturbed areas, and some sections were given showing the forms assumed.

The characters of the coal beds result from the conditions existing either (1) during formation or deposition, or (2) during subsequent periods. In this paper only the nature of the coal, as determined by the first conditions, will be discussed. In the first case may be considered such characters as, variations in thickness of deposit, occurrence of shale partings, nodules of shale, clay and pyrites, horses of shale (not clay veins) and bells, which occur in the deposits or extend into them from the top or bottom formations; in the second case, such occurrences as clay veins, igneous intrusions as dikes and sills, and a wide range of irregularities resulting from folding and faulting of the formations.

*Professor of mining, Pennsylvania State College, State College, Penn.

Occasionally it is found extremely difficult to explain the occurrence of an irregularity without considering both causes as contributing to its formation. There will be occasion to refer to one or more such occurrences in connection with this discussion.

Interstratifications of Foreign Material

Probably the most common form of irregularity is the occurrence of foreign material interstratified with the coal. Few coals are free from such interstratifications or partings and those of this field are no exception to the rule. These partings, in some instances, vary greatly in thickness at points not far removed from each other, and they are often far from parallel with the coal beds. See Fig. 1. Further, both partings and coal may assume lenticular forms varying in width in a most surprising manner. Again a parting may become abnormally thick, assuming the form of a roll and wholly or in part pinching out the coal. It is not an easy matter to consider that such irregularities are produced alone by conditions affecting depositions of the coal and rock materials, but

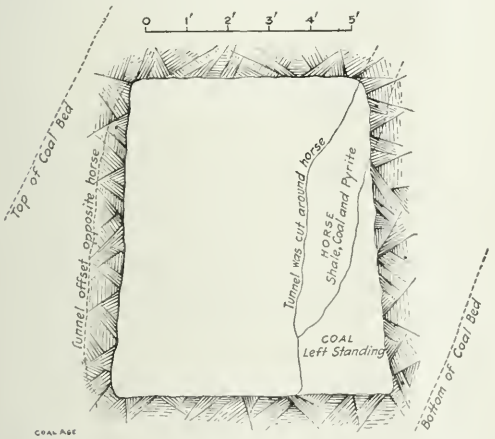

Fig. 3. Horse Next to Bottom Rock as Exposed in Tunnel, Showing How Latter Was Turned to Avoid Excavation of Waste Rock

when the lines of stratification conform with the irregularities, such a conclusion can hardly be denied. See Fig. 2, *B* and *C*.

Pyrite Occurs in Phenomenal Masses

Considerable pyrite, regularly termed "sulphur," occurs in the coal beds of certain portions of the field. Such occurrences are locally known, as nigger heads; they are nodules, oval or disk-like in form, and they vary in size from a fraction of an inch to several feet in diameter. In fact, in certain coal beds masses lenticular in form, have been observed to extend for 6 or 8 ft., forming in reality horses. They usually follow close to the top or bottom of the bed, although occasionally they protrude into it. See Fig. 2.

These nodules, having no connection or bond with either the coal or rock, present an element of danger which, in many cases, is formidable. Further, nodules of moderate size are apt to fall from the faces and ribs of coal and do considerable damage. In any case, large or small, they must be separated from the coal, the difficulty of handling increasing with the size.

Horses and Bells Make Mining Dangerous

Masses of clay and shale, so bituminous in character as to have every appearance of coal, not excepting the luster, are of frequent occurrence, often making an extremely treacherous top or even bad walls if the bed stands at a high angle, as is frequently the case. See Fig. 3. Aside from difficulties of support, much coal is often of necessity left around such masses or horses, the idea

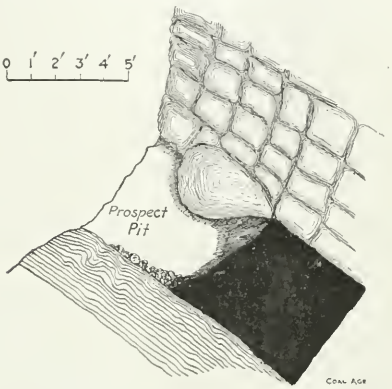

Fig. 4. Bell and Weathering of Shale Top Rock along Joint Planes

being to prevent their fall rather than go to the trouble and expense of removing them. Such irregularities are usually designated as "horses."

Large rounded masses of clay and shale occurring in the top formations of the coal beds and having practically no connection with them, are usually known as "bells." As a general rule they are of limited size, seldom exceeding 6 or 8 ft. in diameter, but occasionally they assume such proportions locally as to be in the nature of beds, and they may even pinch out the coal entirely. See Fig. 4.

The Deepest Borehole in the World?

Near Czuchow, in Silesia, according to *The Mining Journal*, a borehole has been sunk to a depth of 7349 ft., the time required for its completion being 982 days. The first 174 ft. were bored by auger, the next 1715 ft. by churn drill, and the rest by diamond drill. More than 700 carats of diamond were used up. The total cost of the bore was about $72,900. It was expected that the coal measure would be struck at 1920 ft. and the original diameter of the hole was made to accord with that assumption, but when that depth was exceeded, the hole had to be enlarged, thus much increasing the cost and the working time. Other deep boreholes have been sunk in Germany at from $4.35 to $5.80 per foot. The rods were constructed of Mannesmann tubes, the 6560 ft. running length of the tubes weighing 31,305 lb. At 1640-ft. depth, the temperature was 79 deg. F.; at 3280 ft., 104 deg. F.; at 1920 ft., 156 deg. F.; and at 7287 ft., 182.1 deg. Fahrenheit.

The Psychology of the Illegal Strike

By E. L. Cole

SYNOPSIS—A review of the recent "button" strikes in the anthracite-coal field. The author presents some thoughts and brings out a number of points not generally known to the public at large. According to his version the miners have repeatedly violated their agreement.

A survey of the industrial world reveals the fact that the labor unions are not rigidly adhering to their contract agreements signed by employers and their employees who are members of labor organizations. And this is true notwithstanding that it was organized labor that initiated the contract form of agreement in the hope that by means of periodical conferences between labor and capital, more amicable relations would thus be maintained, and the wasteful strikes relegated to oblivion. The labor organizations, alone, are guilty of violating the agreements that have been thus legally made. This illegal attitude on the part of organized labor is not confined to any particular industry or country. The dock laborers of England, the miners of Great Britain, the railway workers of France, and many others have in times past been found guilty of violating their contracts.

The numerous violations of the agreement entered into by the anthracite operators and the U. M. W. of A. has given much cause for comment in the press. The executive officers of the coal companies seem to be at a loss how to account for the irresponsible attitude of the miners, and more than one manager has despaired of being able to operate his collieries continuously.

Causes of the "Illegal Strikes"

An investigation of the causes of these "illegal" strikes brings to light a number of interesting points. Since the present contract between the anthracite operators and miners was signed, the U. M. W. of A. have posted at the collieries an alleged remark of G. F. Baer, who is reported to have said to the union officials: "When you succeed in enrolling the employees of our companies in your union, we will recognize your organization."

Furthermore, while the miners realize that they are now working under better conditions than have ever before been obtained, they are, nevertheless, far from being satisfied. At the recent district conventions, when the officers were interrogated by the radical element of the organization, as to why they did not insist on further concessions from the operators, they have replied that the concessions secured were all that could logically be expected in view of the numerical strength of the organization. This reply of the union officers shows that they believe that it is only necessary for the miners to join the union and whatsoever concessions they may desire at the termination of the present agreement will be theirs for the asking.

Here then we have the real reason for the so called "button" strikes. Most of the miners have been persuaded to join the U. M. W. of A. in hope that the next conference will find them not only numerically strong, but also with substantial resources with which to carry on the fight. One of the means employed to increase the membership of the miners union is the work of the "button committee" at each colliery. This committee is usually made up of aggressive union men; they do not mince words when engaged in seeking additional members, and in more than one instance men have refused to join, or to continue paying dues, because of the insolent and domineering attitude of its members. No one cares to do what is compulsory, and it may not be amiss to suggest that a more diplomatic course would result in less friction.

When the miners call a "button" strike they state that they are not on strike, but have simply stopped working with nonunion men, for whom they have secured an advance in wages. Therefore, they reason, it should be compulsory for these men to pay tribute to the U. M. W. of A. They further aver, that the responsibility for the stoppage of operations, should be laid at the door of these nonunion men. That this is illogical is readily apparent to any thinking man, and the organization will undoubtedly find their "illegal" strikes an obstacle in their path when they seek to secure further concessions.

The Radical Element

In justice to the national officers it must be said that they have placed themselves on record as being opposed to what they are pleased to term these "petty" strikes. No strike is "petty" that causes a loss of even one day's production of a product for which there is a ready market; and surely, a strike is not "petty" when a cessation of work causes a loss of hundreds of thousands of dollars in wages, and thousands of tons of coal. The men do not seem to realize that the permanent success of their organization rests on the strict adherence to the orders of their officers. Ever since President White has been in office a large number of miners have boldly disregarded his instructions, and their illegal acts have caused their executive officers considerable embarrassment.

Since the resumption of operations after the Tri-district Convention of May, there has been circulated through the coal fields, statements that boldly denounce the agreements. One radical magazine states that the men have been handed over to their employers, bound hand and foot, for four years; furthermore, the miners are advised that they are morally right in refusing to mine coal whenever they think that a stoppage of work will injure their employer financially. As the operators cannot recover any losses sustained, it can readily be seen that they are helpless, unless they should do the same as the miners and violate their agreements; it is only fair to say that they have so far scrupulously observed the letter and spirit of their contract.

The recent Panther Valley strike was probably the largest of the "button" strikes, in point of tonnage lost. It occurred while the Seventh District convention, of which the Panther Valley is a part, was held. Toward the close of the meeting, the men were addressed by James Mauer, of Reading, the lone Socialist member of the Pennsylvania Legislature, (but who has since been defeated in the recent election). The result of his fervent appeal to class-hatred was that within a few hours every colliery in the Panther Creek Valley was closed down and remained closed until the Conciliation Board found a way out of the difficulty.

Too often the officers are prone to pay undue attention to the enhancing of their personal fortunes within the organization, instead of discharging the duties for which they are well paid.

The Duty of the Mine Officials

There is strenuous work ahead for the officers of the U. M. W. of A. Theirs is the task of combating the schools of radical thought, both politically and industrially. On the other hand, should the work of the opponents of present-day organized labor be permitted to go unchallenged, we shall soon see two labor organizations in the coal fields. As a matter of fact, it is an open secret that representatives of the radical element among the miners, have recently succeeded in organizing more than one branch of their school of thought in the very heart of the anthracite field, and it is their boast that April, 1916, will find the U. M. W. of A. fighting for its life. They further contend that in the meantime they will so thoroughly inoculate the miners with their conception of the moral and statutory law that there will be an entirely new method of industrial warfare inaugurated.

It will be readily acknowledged that, through the U. M. W. of A., the coal miners of this country are better recompensed for their labor than ever before. All who have the well-being of the present-day society at heart should do all that can be done to keep organized labor on a high plane of honor so that its existence will result in a permanent industrial peace.

When the district officers of the U. M. W. of A. were recently interviewed, they averred that inasmuch as the "check off" is not in effect they cannot be held responsible for illegal strikes. They have said: "If we had the 'check off' and the miners should cease working without just cause, we would at once suspend the guilty locals and immediately end the strikes." The question arises: If all the miners could be suspended when the "check off" is in effect, why can't the union miners be suspended by their officers today? What answer will the miners' leaders make to the operators in 1916, should they be refused recognition because they have given such little evidence of their ability to control the miners?

The responsibility for the numerous illegal strikes rests squarely on the shoulders of the union officers. They have failed so far to maintain the production of coal, which is one of the foremost reasons they always advance when seeking recognition at the hands of the operators.

The usefulness of the U. M. W. of A. in the anthracite field will be limited unless there is a peaceful adherence to the legal and advantageous wage agreement entered into last May.

Guarding Coal Mines against Fuel Wells

SYNOPSIS—At its meeting on Mar. 11, the national fuel-well committee prepared an act to regulate the drilling of oil and gas wells through coal. The text of this measure is here given in full. The recommendations of the Bureau of Mines required that there should be two casings, the diameters of which varied 4 in., and that the drillhole should be 4 in. larger than the outer casing. The committee dispenses with this exterior pipe altogether and requires that the single casing which is retained shall have an internal diameter 6 in. less than that of the hole. The annular space between the casing and the walls of the hole may be filled with either cement mortar or puddled clay. The bureau's recommendation proposed only the latter. The thickness of the casing is not specified though this was a feature of the original draft.

An act to provide for the location, drilling, casing, protecting, operating, abandoning, plugging and filling of natural gas and petroleum wells, and for the protection and preservation of life and property, especially in and about coal mines in gas and oil regions, creating the office of chief inspector of natural gas and petroleum wells, and providing penalties for the violation of this act.

ARTICLE 1—Definitions

Section 1. Be it enacted, etc., that for the purposes of this act, the terms and definitions contained therein shall be as follows:

Well—A borehole drilled for the purpose of developing natural gas or petroleum, or a borehole producing natural gas or petroleum.

Well Operator—Any person, persons, firm, partnership, corporation, company, or association, who drills, operates or abandons, or purposes to drill, operate or abandon such well as hereinbefore defined.

Coal Operator—Any person, persons, firm, partnership, corporation, company, or association, owning, leasing or operating coal mines, or coal properties, but excluding coal stripping operations.

Plat—A map, drawing, or print, made in accordance with the provisions of this act, as hereinafter contained.

Casing—The pipe commonly used within wells drilled for natural gas and petroleum. The sizes of casing refer to nominal commercial dimensions.

Cement Mortar—Cement mortar shall consist of one part of portland cement and two parts clean sand, mixed with sufficient water.

Coal Bed—A workable bed or seam of coal that may be mined during the reasonable life of a well, proposed to be drilled through it.

Well Inspector—The chief inspector of natural gas and petroleum wells, or his duly authorized deputy.

ARTICLE 2—Location of Well

License—Section 1. When a location for a well has been made, the well operator shall make application in writing to the chief well inspector, for a license to drill, and send therewith a description and plat in duplicate of the proposed location.

Survey—Section 2. The location shall be determined by survey, and the description and plat shall give the courses and distances from two permanent points on the boundaries of the tract of land upon which the well is located, together with the name of the tract of land, names of adjoining tracts, township or district and county.

Copies of Plat—Section 3. The well operator shall send to the coal operator, if known, and to the state coal-mine inspector, a copy of the description and plat filed with the chief well inspector.

Verify Location—Section 4. Immediately on the receipt of the plat the coal operator shall verify the well location and mail, to the well operator, a plat showing the present and proposed mine workings under the tract of land on which the proposed well is located.

Time Limit of Complaint—Section 5. The license to drill shall issue immediately on the expiration of five days (excluding legal holidays) after the application and the plat of location have been received by the well inspector unless he makes or shall have received notice of complaint during that time.

Time Limit to Issue License—Section 6. If notice of complaint is made by or served on the well inspector within the said five days, then it shall be the duty of the well inspector to confer with the several interests, including the state mine inspector, coal operator, well operator, and where possible the owner of the land and of the royalty interest, and designate, within 10 days of the receipt of the application for license, a suitable location for the well, or if no well can

be drilled on the premises because of conditions hereinafter specified, refuse to issue a license to drill.

Resurvey—Section 7. If the well is relocated, a resurvey shall be made by the well operator, and corrected description and plat mailed as previously required.

Mine Plats—Section 8. Each coal operator shall furnish annually to the inspector a plat of all of his present and immediate projected mining operations within the state showing the location of all known wells. The coal operator shall also furnish, if requested, to any well operator, a plat of the mine under the leases or property owned or operated by the said well operator.

Distance from Buildings, Etc.—Section 9. No well shall be located within 300 ft. of a hoisting or air shaft, slope or drift into an artificially ventilated coal mine when not definitely abandoned or sealed, nor shall such well be located within 300 ft. of any mine shaft house, boiler house, engine house, power house, mine fan, or mine tipple, unless such structure has been abandoned.

Distance from Mine Ways—Section 10. No well shall be drilled within 15 ft. of any underground haulage way, traveling way, drainage way or air way.

Display of License—Section 11. It shall be the duty of the chief well inspector to issue the license in duplicate, and the well operator shall display at the location, one copy of the license properly protected from injury, and in such place and manner that it may be easily seen.

Duration of License—Section 12. The license shall expire at the end of one year from the date of issue unless drilling operations are actually in progress.

ARTICLE 3—Manner of Drilling and Protecting Well

Through Workable Beds—Section 1. Each well passing through a workable bed of coal shall be drilled, cased and protected in the manner hereinafter provided:

(a) Where the coal is in place.

A hole of a diameter 6 in. greater than the inside diameter of the outside casing to be put through the coal shall be drilled at least 30 ft. below the bottom of said coal bed.

Within this hole shall be placed the casing, and the space between the outside of said casing and the wall of the hole shall be filled with cement mortar, or puddled clay, to a height of at least 30 ft. above the top of said coal bed, to exclude water from the coal bed.

(b) Where the coal is removed and the mine excavation is inaccessible.

A hole of a diameter sufficiently large to permit the setting in of a liner 4 in. larger in diameter than the inside diameter of the casing to be put through the coal, shall be drilled at least 30 ft. below the bottom of said coal bed.

Within this hole shall be placed a liner 4 in. larger than the inside diameter of the said casing and extending from the bottom of said hole to at least 30 ft. above the mine roof.

A string of casing centrally guided by shoes or winged guides shall be placed within the said liner and the space between the liner and the casing shall be filled with cement mortar or puddled clay to the top of the liner.

To exclude water, the space between the said casing and the wall of the hole and immediately above the top of the liner, shall be filled for a distance of at least 10 ft. with cement mortar or puddled clay.

(c) Where the coal is removed and the mine excavation is accessible.

The method may be either as provided in the case of inaccessible mine excavations or as where the coal is in place, provided that if the latter method is chosen the well operator shall at his own expense provide a suitable retaining wall laid in cement mortar to retain the cement mortar or puddled clay about the casing. This wall shall extend from 2 ft. below the mine floor to the roof of the mine, and be of such size as to retain at least 2 in. of puddled clay or cement mortar about the said casing.

Affidavit as to Casing—Section 2. The well operator shall upon completion of the work of casing through a coal bed make an affidavit signed by two men having at least three years' experience in casing wells as to the method of casing and protecting the well; said affidavit to be filed with the chief well inspector

Vent—Section 3. Under any of the above provisions the work of casing and protecting from gas and water through the coal bed shall be completed before the well is drilled to a greater depth; and in the event of any well being productive of oil or gas, the space between the said outside casing and the next string of such other casing as may be left in, shall remain open, the top being provided with a suitable device to permit ventilation and at the same time to prevent dirt or débris from falling in, or being thrown in, or the ventilating opening from being readily closed.

ARTICLE 4—Abandonment of Well

Notice—Section 1. The well operator when he purposes to abandon any well, shall send a written notice of his intention to the chief well inspector, and the work of plugging the hole or pulling the casing shall not proceed until the well inspector is present to see that said plugging is done as prescribed by this act, except as hereinafter provided.

In Absence of Inspector—Section 2. In case the well inspector fails to be present within three days from receipt of notice, then the work may proceed provided that two men having experience of at least three years in the plugging of wells be present, and make affidavit in duplicate that the work was done in accordance with the provisions of this act, said affidavits to be filed with the chief well inspector, and made a record of his office.

Copy of License—Section 3. The well operator shall send to the chief well inspector with the notice of abandonment, a legally certified copy of the license to drill, provided the well was drilled under the provisions of this act.

Locating Old Wells—Section 4. If the well was drilled prior to the passage of this act, the well operator shall send to the chief well inspector, with the notice of abandonment, a description and plat showing the location of the well as herein provided for in the application for license to drill.

Method of Plugging—Section 5. Every well upon abandonment must be plugged and filled solidly and tightly from the bottom to the top as follows:

The hole must be filled with rock sediment, sand, clay, or other suitable material from the bottom of the well to a hard and firm stratum below the last string of casing set in above the producing oil or gas sands. When the well inspector declares that it is impracticable to fill the cavity in the lowest producing sand then he shall permit the well operator to place plugs at the top of the lowest producing sand and fill as hereafter specified.

In this firm, hard stratum three seasoned wood plugs of a diameter equal to the diameter of the hole, and each of a length of at least 3 ft., shall be driven into place. Above the third plug 10 ft. of clay must be placed and thoroughly tamped down so as to prevent the passage of oil, gas or water.

Immediately below the seat of each and every string of casing there shall be driven a seasoned wood plug as described, and all spaces between wood plugs shall be filled solidly and tightly with rock sediment, clay, sand or other suitable material as the casing is withdrawn length by length. All plugs shall be driven in place with proper drilling tools.

In the case of a well in which the outside casing has been cemented as herebefore provided, said outer casing may be cut off at a point not less than 50 ft. above the coal bed and removed, but in any event the hole shall be filled to the surface.

The location of the plugs herein provided for are made with reference to the relative positions of the workable coal beds and the gas and oil sands, for the purpose of preventing the passage of oil or gas into the workable coal beds and of water into the oil and gas sands, and if any well presents a variation in such relative positions of the said strata, such additional wood plugs as the well inspector may deem necessary shall be driven into place by the well operator.

Report of Plugging—Section 6. When the work of plugging and filling from bottom to top has been completed, the well operator, or his authorized agent, shall make a report in duplicate to the chief well inspector, upon forms to be furnished by the well inspector, showing the date of completion of the well, the depths to the coal beds, the names of, and depths to, all productive oil or gas measures, the total depth of the well, and the location and kind of all plugs and filling used, and the method followed in placing the same.

Section 7. If the well inspector has been present during the performance of this work, he also shall sign the report to the chief well inspector.

Section 8. If the well inspector has not been present, this report shall be joined in by two men employed on the work as provided for in this act.

Protection of Casing by Coal Operator—Section 9. When the coal is removed from around a well casing or liner, the coal operator shall protect the same from corrosion and mechanical injury by a wall of suitable material to retain 2 in. of cement mortar between the said wall and the said casing or liner; this protection shall extend from 2 ft. below the mine floor to the roof of the mine, except in the case of an abandoned well, which has been plugged and filled as prescribed in this act.

ARTICLE 5—Chief Inspector of Natural Gas and Petroleum Wells

Office—Section 1. There is hereby created the office of chief inspector of natural gas and petroleum wells.

Appointment—Section 2. A chief inspector of natural gas and petroleum wells shall be appointed by the governor, or by a commission provided for the purpose, from an eligible list of men who have passed a satisfactory examination showing their technical and practical fitness for the position.

Salary—Section 3. The salary and necessary travel expenses of the chief well inspector shall be borne by the state, and an office provided and equipped with suitable filing arrangements.

Bond—Section 4. The chief well inspector shall, before entering upon the discharge of his duties, give bond in the sum of $———— with approved sureties for the faithful discharge of his duties; and shall take oath that he will discharge his duties with impartiality and fidelity to the best of his knowledge and ability. But no person who is acting as manager or agent of any oil or gas company, or any coal company, or who is interested in operating any oil or gas well or any coal mine, shall at the same time act as chief well inspector under this Act.

Assistants—Section 5. The chief well inspector shall be authorized to appoint field and office assistants whose salaries and expenses shall be borne by the state.

Appeal—Section 6. An appeal from the decisions of any assistant may be made to the chief well inspector.

Duties—Section 7. It shall be the duty of the chief well inspector to carry out all of the provisions of this act, and keep a complete record and prepare for publication, a yearly report of the wells drilled in the state, together with their location, date of completion, depth, character of product, date of abandonment, and name of owner, and other information.

The well inspector shall receive and investigate all complaints as to injury, present or impending, due to lack of precaution on the part of any well operator or coal operator. If he finds the complaints against the coal operator, well founded, he shall lay the facts before the mine inspector.

In case of failure of the well operator to plug an abandoned well, in accordance with the provisions of this act, it shall be the duty of the well inspector to have the work performed by contract, and to assess the cost against the well operator.

If the well inspector discovers any well being drilled, operated or plugged, contrary to the requirements of this act, he shall order the workmen engaged upon such well to cease work at once, and shall not permit the work to be resumed until he is satisfied that the law is complied with.

The well inspector shall determine the sufficiency of plats for the purpose of accurately locating wells, and shall cause a new survey of such location in case the available plat and descriptions are unsatisfactory. This survey shall be paid for by the applicant unless it is shown that the original plat is correct in which case the cost of the new survey is to be borne by the state.

It shall be the duty of the chief well inspector to transmit to the proper county recorder, the duplicate of plats, descriptions, applications and reports sent to him by well operators, and these shall be recorded in a book kept specially for this purpose by the county recorder.

Height of Entry—Section 8. To enable the well inspector to perform the duties imposed upon him by this act, he shall have the right at all times to approach and examine any well in his district and with the authority of the state mine inspector, to enter any mine affected, and upon discovery of any violation of this act or upon being informed of such violation, he shall institute proceedings against the person or persons at fault, under the provisions of the law provided for such cases.

When a well is so located that it passes through a mine or near a mine, the well operator may appoint as his representative a mining engineer or other competent person experienced in mining operations, who shall, with the written permission of the chief or district state mine inspector have the right to enter the mine at such times as will not interfere with the operation of the mine.

ARTICLE 6—Miscellaneous

Penalties—Section 1. Any coal operator or well operator who neglects or refuses to comply with the provisions of this act, or who violates any of the provisions or requirements thereof, shall be deemed guilty of a misdemeanor, and shall, upon conviction thereof in the court of the county in which the misdemeanor was committed, be punished by a fine or imprisonment at the discretion of the Court.

Constitutionality—Section 2. Each section of this Act and every part thereof is hereby declared to be an independent section or part of a section and if any section or sub-section shall for any reason be held unconstitutional the validity of the remaining sub-section and sections shall not be affected thereby.

Repeal of Conflicting Legislation—Section 3. All acts or parts of acts inconsistent herewith are hereby repealed.

Coal Mining Institute of America

The Coal Mining Institute of America expects to make its summer visit to the anthracite-coal regions. The program is not yet completed, but it is roughly as follows: Members will leave the bituminous field from Pittsburgh at 8:50 p.m., Monday evening, June 16, special sleeping cars being attached. The train will take up passengers between Pittsburgh and Tyrone and will arrive at Wilkes-Barre at 8.59 on Tuesday morning, June 17. Those who desire to make the interesting trip during the day may leave Pittsburgh at 7:50 a.m. on Monday morning, and arrive at Wilkes-Barre at 7:50 p.m.

The meeting for organization purposes will be held in Wilkes-Barre at 10:30 a.m., June 17. Luncheon will be at 12 o'clock. In the afternoon, a trip will be made to near-by collieries, and in the evening, after the institute banquet, H. G. Davis, district superintendent of the Delaware, Lackawanna & Western R.R. Coal Department, will deliver a lecture on anthracite methods of mining and will detail the sociological work which has been done by the company. The address will be illustrated by stereoptican slides.

The following Wednesday, the 18th, the visitors will pass over the scenic Wilkes-Barre & Hazelton third-rail system to the latter town and view the anthracite strippings and collieries in that district. In the evening, the institute will invite the members of the local District Mining Institutes to meet them at Wilkes-Barre. Addresses will be delivered on soft-coal methods of mining and sociological work in the bituminous region, illustrated by the stereoptican and possibly moving pictures.

On Thursday, the 19th, a trip will be made to the anthracite collieries in the Wyoming Valley. From 3 to 5 o'clock a session will be held at Wilkes-Barre for a discussion on the impressions received while visiting the anthracite operations.

At 6:20 the train will leave Wilkes-Barre for Pittsburgh and other points in the bituminous-coal field. It may be added that the members are invited to bring their wives with them if they so desire. Several of the leading anthracite companies have, by their executives, expressed themselves much pleased to have an opportunity to show their hospitality to the members of the visiting institute.

⁂

A Special Pump Number

Our issue of Apr. 5 will be devoted entirely to the question of pumping at coal-mining properties. The various problems encountered in actual practice will be discussed in detail, while several modern types of pumps will be described. All readers of COAL AGE are invited to send us photos and data concerning interesting pump installations with which they are familiar. Copy should be in our hands within a week.

⁂

Entombed in a Kentucky Mine

It is reported that 130 miners were imprisoned Mar. 18 in a colliery at Basketts, Henderson County, Ky., by a cave-in, which clogged the mouth of the shaft. Though it is stated that the men had not escaped when the report arrived, it was said that there were no fatalities. It was expected that the men would soon be released by way of the air shaft.

CURRENT COAL LITERATURE

A Benzine Incandescent Safety Lamp

By Emmanuel Lemaire*

SYNOPSIS—M. Goulet has introduced a safety lamp which utilizes an incandescent mantle to intensify the light. The oil is vaporized and mixed with air in a carburetor resting on the top of the lamp. The illuminating power is from 1 to 3 cp.

Improvement of the illuminating power of safety lamps is a great desideratum. Imperfect light is prejudical to the safety of the miner, reduces his output and causes him to do poor work. To it is also attributed, in part at least, that occupational disease of the miner known as nystagmus.

It is true that there are many mining lamps which offer a high degree of security as regards gas, but their average illuminating power in practice is low and hardly reaches one unit Hefner[1]. Now that the question of safety is, in large part, solved, attention should be paid to improvement in lighting power.

A Light with a Mantle Which Gives 3.2 C.P.

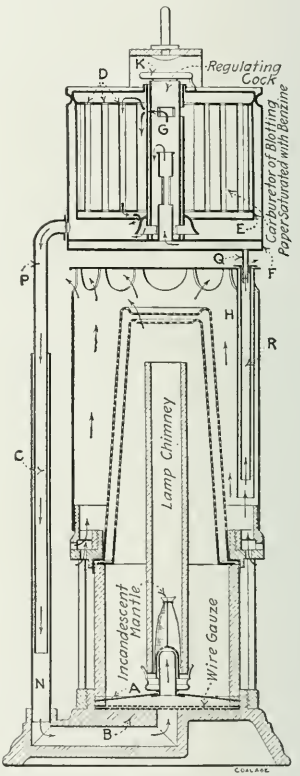
During the year 1910, a new lamp giving a better light than any of its predecessors was subjected to safety tests at the Belgian Experimental Station in Frameries. The inventor of this lamp, M. Goulet, applies the principle of incandescence, which has been so much developed since the appearance of the Auer mantle. Thus he has obtained a lighting power which may reach 3.5 Hefner units. The mantle is brought to incandescence by combustion of the mixture of air and benzine vapor obtained by using a carburetor.

As shown in the accompanying figure, the Goulet is in general arranged, like an ordinary safety lamp, with two gauzes and a bonnet. The oil reservoir, formed by the carburetor, instead of being below the burner, is on the top of the lamp above the bonnet. This position favors the flow of the combustible gas to the burner, since a mixture of air and benzine vapor has a density greater than that of air alone.

To Improve the Draft a Chimney Is Provided

The burner is a simple copper tube, the bottom being inserted in an immovable metal disk *A*, resting by asbestos washers on a copper socket base *B*, which closes the lamp at the bottom. It is connected with the carburetor on the outside by a tube *C* and a conduit in the base *B*. The two gauzes placed below the disc *A*, as well as the double gauze which closes the burner at the top, checks any return of flame toward the carburetor.

The lamp is supplied with a glass and a chimney. The former is cushioned on the disk *A* by an asbestos washer. An inside chimney covers the burner and the draft it occasions favors the circulation of the air in the carburetor. The metal fixture or guard which protects the outside chimney, surrounding the lower part



The Goulet Lamp with a Lamp Chimney, Incandescent Mantle and Carburetor

of the lamp, and which supports the bonnet, screws upon the base *B*.

The Benzine Is Not Free but Absorbed by Blotting Paper

An absorbent mass formed of blotting paper in layers, keeps the benzine in the carburetor quiet and is lodged in a sheet-metal cylindrical tank *E*, from the ends and side walls of which it is held free by supports. The mass is pierced with cylindrical vertical channels *D* for the passage of the air to the carburetor.

The tank *E* is placed within another cylinder *F*, which has a double bottom. The joint between the two,

*Chief Engineer of the Mining Corps attached to the Mining and Gas Accident Service, Belgium (Frameries Government Experimental Station). Professor at the University of Louvain.

Note—Translated from the French by E. F. Buffet for Coal Age.

[1]One Hefner candle is nine-tenths of an international candle.—Editor.

completely closes the outer cylinder at the top, the inner tank extending only part of the way down to the bottom of the outer, forming a false bottom.

A cylindrical sheet-metal cock, set vertically in the center of the double bottom, passes through the carburetor and provides a way for regulating the admission of air to that vessel. It puts the inside of the carburetor in communication with the space between the two bottoms of cylinder *F*, a space into which air enters through the tube *H** placed inside the bonnet of the lamp. The aforesaid cock is composed of two tubes, one outside the other, the inner tube being movable. This inner tube turns with light friction in the former, and is manipulated by a knurled head *K*.

These two tubes are pierced near each end with two apertures diametrically opposite each other. The lower openings of the movable tube are placed at right angles to its upper openings and the rotation of the tube is limited to a half turn by two stops.

Regulation of Gas Mixture for Burner

The extreme positions of the movable tubes correspond respectively to a complete closing of the upper and lower apertures or to an uncovering of the lower openings with a closing of the upper apertures. The mean position is a complete uncovering of the upper openings with a closing of the lower ones.

For this position of the movable tube, the air enters tank *E* by the upper openings, becomes charged with benzine vapors by circulating around the absorbent mass and through the canals by which it is pierced, and passes to the burner by tube *C*. When the air enters by the upper openings, the proportion of benzine vapor contained in the gas reaches a maximum.

When the movable tube is turned to the extreme position, which gives the complete opening of the lower openings with closing of the upper, the air passes through these lower apertures into space comprised between the bottom of tank *E* and the double bottom of the cylindrical vessel *F*, and goes to the burner without coming in contact with the absorbent mass.

It merely mixes with the benzine vapors which issue from tank *E* through the space between the edge of the central orifice of the lower end of this cylinder and the cock. In this case the gas which reaches the burner is but feebly charged with benzine vapors.

Carburetion of Air Fed to Flame May Be Closely Adjusted

For other positions of the movable tube, the lower and upper apertures are partly uncovered. A portion of the air comes in contact with the absorbent mass and the rest of it goes directly to the burner. The degree of carburetion of the air varies with the amount of opening of the upper apertures and this carburetion is so regulated that the mantle is brought to maximum incandescence.

To extinguish the lamp, we simultaneously close the upper and lower openings in the cock. Nevertheless the benzine vapors produced in the carburetor continue to reach the burner, so that the extinction is not always complete, but in this case a light blow on the side of the lamp will extinguish it.

*The tube H is simply described as a tubulure; but from the illustration the tube is double.

The mixture which passes out of the carburetor contains a quantity of air too small to insure complete combustion; admission of supplementary air is therefore necessary. This enters the lamp through the double gauze which surmounts the lamp glass and reaches the burner by openings in the bottom of the ring, or fixture, which supports the chimney.

The Lamp Locking Mechanism

The outside tube *C*, which leads the combustible gas to the burner, is formed by two tubes, one sliding in the other. The outside tube *N* is soldered to the base *B* and the inside tube *P* to the carburetor. The open tube *H* through which the air enters the carburetor comprises an inside tube *Q* soldered to that tank and an outside tube *R* fixed to the inside of the bonnet.

When the carburetor is in place, the tubes *P* and *Q*, which engage in the tubes *N* and *R*, oppose the unscrewing of the fixture or guard which supports the bonnet, and in consequence the opening of the lamp. Thus, until the carburetor is removed, it is impossible to unscrew the lamp. The carburetor is held by a sort of yoke, the ends of which are attached to the bonnet at two diametrically opposite points. These ends engage in two eyes on the bonnet and are held by two magnetically controlled bolts. The yoke carries the hook for the suspension of the lamp.

Points of support fixed under the carburetor prevent it from resting directly upon the top of the bonnet, and thus keep it from becoming excessively heated.

The lighting power of a Goulet lamp has been found to be 3.2 Hefner units, after having been burned for a half hour and 1.25 Hefner units after nine hours of lighting. It is important that the mantle be well adapted to the burner, otherwise the lighting power is much less.

Lamp Showed Good Results in Gas Tests

The safety tests have given the following results:

The Goulet lamp resisted a current of air containing 8 per cent. of methane, and traveling at a speed of 15 m. (49.2 ft.) per sec. The gas mixture was caused to travel in 5 different directions, namely, horizontal, descending and rising at 45 deg., ascending and descending vertically.

The gauze became heated to redness when the air traveled at the following speeds and under the conditions specified.

8 m. (26.2 ft.) per sec. or 1575 ft. per min. in a horizontal current;

6 m. (19.7 ft.) per sec. or 1181 ft. per min. in a current descending at 45 deg.;

9 m. (29.5 ft.) per sec. or 1772 ft. per min. in a current rising at 45 deg.;

13 m. (42.7 ft.) per sec. or 2559 ft. per min. in a vertical ascending or descending current;

The outside chimney was broken at the speed of 14 m (45.9 ft.) per sec. or 2756 ft. per min. in a current descending at 45 deg.; it resisted in the other currents. The inside chimney was not broken in any of the tests, but several times it softened to a point of bending and even of closing partially or completely at the top.

The Carburetor Does Not Explode When Heated

When placed in an atmosphere at rest, the Goulet lamp becomes considerably heated. In order to make sure that an excessive heating of the lamp would not create

a dangerous pressure in the carburetor, the latter was heated directly by a bunsen burner so intensely that the solder was fused. This did not lead to an explosion of the carburetor; when the solder melted, the benzine vapors were simply ignited by contact with the bunsen flame. As has already been said, the opening in the base of the sheet-metal casing, which contains the absorbent blotter is larger than is needed to permit the regulating cock to pass through, thus the benzine vapor produced in the carburetor can always escape through the burner.

In the preceding experiment it was found that some benzine was condensed in the conduit at the base of the lamp. The presence in such a place of liquid benzine not retained by an absorbing substance, could not be otherwise than objectionable if the lamp were reversed. It seems, however, that there is no need of worrying about this cause of danger, since it has never been found that benzine vapors produced in the carburetor by normal heating of the lamp, even in an atmosphere at rest, become condensed in the conduit of the base.

When the tank with its absorbing substance is put into place immediately after having been dipped and before it has been allowed to drip, the benzine in excess falls into the base of the lamp. Although this benzine rapidly evaporates, it is better to wait a few moments before putting the tank in place after filling. The porous substance absorbs 65 grams of benzine (0.143 lb.).

No Risk of Back Firing of Carburetor

With a view to determining the degree of explosiveness of the gas produced in the carburetor, the gas was lighted several times as it issued from the burner. Although the wire gauzes, which are intended to prevent a return of flame, were removed, the fire was never transmitted as far as the carburetor.

The Goulet lamp seems to be reasonably safe in gas. It is an interesting attempt to improve the lighting power of mining lamps and for this reason it deserves notice. It is, however, too early as yet to judge of its practical availability in the mines.

Gleanings from British Experience

Special Correspondence

SYNOPSIS—A digest of the worth-while coal news from the British Islands. The reports from the institutes illustrate the trend of the mining industry and the efforts put forth to increase safety.

❖

The English practice seems strongly in favor of the use of armored cables. The British electrical inspector of mines, Robert Nelson[1], advocates covering all insulating material with a grounded metallic cover, as a protection from leakage even when using low-pressure currents, by which he means those not exceeding 250 volts. That being his advice, we are somewhat surprised that he finds it necessary to add that those who fail to armor and ground cables carrying more than a medium pressure (over 650 volts) are inviting accident.

He points out that fuses and circuit breakers (or "maximum cutouts," as our British friends term the latter) are called into action only in the event of the strength of the electrical current exceeding a certain predetermined value, namely, that at which the fuse is set to melt or the circuit breaker to operate. The protection is, therefore, in no manner sensitive, and in a current so protected a mere overload may cause the current to be cut off.

Importance of Leakage Cutouts

On the other hand, leakage cutouts do not operate on an overload, temporary or permanent, so long as the flow of current is confined to the conductors. They only act when some portion of the current elects to leave the path provided for it and returns to the generator by some other way, possibly by the earth. When that occurs there is a "fault" on the circuit, and the balance which normally exists at every instant between the current which enters and that which leaves the conductors of a healthy circuit, is disturbed at every point. Leakage cutouts are operated by disturbances only; that is, they act only in case of a fault. A break in the line, caused possibly by the fall of a rock, puts the cutout into action and thus the sparking is immediately stopped.

Bare Signal Wires May Cause an Explosion

As Mr. Nelson recalled, an explosion in South Wales was attributed to bare signal wires. Men were engaged removing a fall when the electric bell was heard to ring, though there was nobody at the other end to operate it. There was a second ring, and almost at the same time an explosion occurred which burned five or six of the men. Those who investigated the accident agreed that something had brought the two bare wires into contact.

An extensive knowledge of the theory of electricity is not necessary to enable a colliery manager to take an active interest in the electrical plant under his charge. What he needs to learn is easy of attainment, but if soundly applied, he should be able to supervise the electrician effectively, to the advantage of that official and of the plant under his care, and in the interests of safety and efficiency.

Will the Byproduct Market Fail?

In a recent paper, J. E. Christopher[2] stated that in 1900 the world's output of sulphate of ammonia was under half a million tons. Now it is more than doubled, but the price has been well maintained. There is plenty of scope for the use of sulphate of ammonia, and the outlets for tar also appear promising, with the increased demand for use in surfacing roads.

The main outlet for benzol is for use in automobiles. Assuming an average yield of one gallon of automobile benzol per ton of coal, Mr. Christopher estimates the coke

[1]In an address before the North Staffordshire Institute of Mining and Mechanical Engineers.

[2]Paper read before the Manchester section of the Society of Chemical Industry.

works of Great Britain can turn out 19,000,000 gal. per annum, without overstocking the market, so that the field for the exploitation of benzol is extensive.

The production of gas for purposes of illumination as a byproduct of the coke industry has lately made considerable headway. In the period 1903-1910, the amount of gas produced in Germany in this way has increased from 13,350,000 cu.ft. to 1,472,000,000. It is not suggested that gas manufacture in coke ovens will ever displace the modern vertical retort, with its advantages of continuous carbonization; but an attempt has been made to show that coke-oven gas is nevertheless a valuable byproduct which cannot be overlooked.

Controllers for Hoisting Engines

James Black[3] recently stated that with the passing of the British Coal Mines Act, 1911, numerous controllers have been placed on the market, which prevent an excessive hoisting speed.

It is his opinion that the speed of an engine should be controlled throughout the whole length of the hoist, because: (1) Complete control is accompanied by no disadvantage whatever, as it can be adjusted to permit any margin above the normal hoisting speed, and consequently does not interfere in any way with the output of the shaft; (2) the controller will not come into operation at any point during the hoist unless the engine is running faster than the predetermined safe speed at that point; (3) the engine speed, and, therefore, also the speed of the cage when it comes into operation, is likely to be less with complete than with partial control. Controllers are also so constructed that they act instantly if the engine is started in the wrong direction.

Relics of Early Mining

Mines of the Glengarnock Iron & Steel Co., near Stevenston, in Ayrshire, date back to the 17th century. The coal was drawn from the working faces to the main roads by children, the coal being placed on small sledges to make the transference less difficult.

A part of one of these sleds is all which has survived from that remote time. The coal was reloaded at the main roads into creel-like baskets and carried by women up a staircase in the shaft to the surface.

Toward the end of the eighteenth century, the coal was hauled to the shaft landing on large sleds and hoisted to the surface probably by a horse gin. Simple methods for draining mines were also introduced and implements for this purpose have been discovered in the mine, including a wooden shovel, coal picks, a wooden bowl for ladling water and a number of tallies or pins similar to those used today by miners in Scotland for marking coal wagons before sending them to the surface. These relics are deposited in the Scottish National Museum, the gift of Robert Main, general manager of the iron company owning the mine.

Prime Mover of the Future

In his lecture on "Prime Movers," before the Greenock Philosophical Society, S. Z. de Ferranti declared that the electric motor, actuated by electricity from central power stations, is displacing all forms of small engines. He thinks it probable that in future small prime movers will be required only to propel cars and boats, and that all stationary power generators will be electric. Reciprocating engines will be used, no doubt, for a long time, but they can only be regarded as makeshifts, and as soon as an equally efficient machine for any particular purpose is developed, it will replace the reciprocating prime mover.

It is difficult to predict the form of the prime mover of the future, but in search of the highest economy, and with the limitations of temperature imposed by known materials, Mr. Ferranti is inclined to look to electricity, converting the energy of the fuel at low temperature and giving its power in rotary form, as the most likely eventual solution.

Peat Coke

The Peat Coke & Oil Syndicate, of Doncaster, in Yorkshire, is developing a new invention for treating special dried black peat and converting it into a hard foundry coke, byproducts being tar and tar liquor, from which can be distilled fuel and automobile oils. It is not claimed that all kinds of peat can be profitably utilized, but it is said that thousands of acres, containing millions of tons of peat, by this process can yield results satisfactory as a commercial undertaking.

The bottom or black layer of the peat is most suitable for the manufacture of coke. This is freed from an excess of moisture and subjected to a carbonizing process by which the byproducts are recovered, the residue being a soft, friable coke. Although peat coke contains a lower percentage of sulphur than other fuel, a difficulty hitherto has been to produce a coke from it hard and strong enough to hold up in the smelting furnace. This, it is said, has now been overcome, a hard, strong, clean coke being the result. Analysis by a German chemist, based on 1000 tons of air-dried peat, show that the following results can be obtained: Coke, 400 tons; tar, 40 tons; tar water, 400 tons. The tar can be further distilled, yielding 18 tons of crude oil, 2 tons of creosote oil, 2 tons of pitch, 8 tons of paraffin. The tar water will yield 4 tons sulphate of ammonia, 6 tons acetate of lime, 2 tons methylic alcohol. It is estimated there will be a profit of 90c. on every ton of prepared peat so treated.

A Hoisting Accident

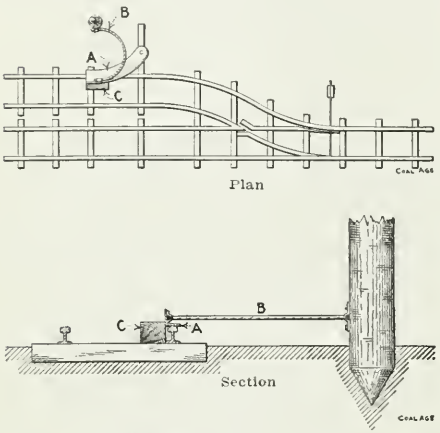
The *Colliery Guardian* says: "An accident in which 11 men were killed and four others injured, occurred on Feb. 7, at the Rufford shaft of the Bolsover Colliery Co., Rainworth, near Mansfield, close to the Nottinghamshire and Derbyshire line, England. A large barrel, containing about 900 gal. of water, fell a distance of 480 ft., and struck a platform in the shaft on which were 18 sinkers, who were engaged in tubbing. The barrel was being hoisted when the rope was overwound and thus broken. In falling, the barrel broke the scaffolding, and all the men, dead and living alike, were thrown into the water beneath them. The five survivors clung to the wreckage and were ultimately rescued.

The overwinding was caused in a peculiar way. While the engineman, Sidney Brown, was working the controlling levers, a horsecloth which had been placed beneath the roof of the engine house to keep out the rain, fell upon him, and at the same time some wooden laths used to support it dropped between the levers. Momentarily blinded by the canvas, Brown was unable to pull the laths from between the handles and to stop the hoisting engine.

[3]Paper read before the Scottish members of the National Association of Colliery Managers.

Automatic Car Latch for Siding

To prevent cars underground when run upon an incline from sliding back and doing mischief, there is installed in the Sterkrade mine, Oberhausen, Germany, a sort of latch or chock, which lets the car pass freely forward upon the incline, but bars its return.



An Automatic Car Latch

This device is shown in Figs. 1 and 2. The latch consists of an angle iron *A*, bent in a circular arc, pivoted beside one rail and resting upon it. A spring *B* made of old wire cable, presses this angle iron against a stop *C*, thus holding it in place. If a car runs forward on the track its wheels push the angle iron aside against the force of the spring. When the car has passed, the spring restores the angle iron to its position against the stop and thus blocks the rail.

Note—Translated from "Glückauf," Feb. 22, 1913.

Seventh Bituminous District (Penn.), 1912

The advance report of C. P. McGregor, mine inspector of the seventh bituminous district in Pennsylvania, for 1912, shows 30 mines in operation, 15 gaseous, 13 nongaseous and two new mines opened; total production of coal, 5,740,099 tons, of which the Pittsburgh Coal Co. produced nearly one-half, or 2,777,404 tons. The number of persons employed in the mines was 6402; the number of fatal accidents inside the mines, 15; nonfatal accidents, inside, 54; outside, two.

The death rate shows 426 persons employed inside the mines and 382,673 tons of coal produced, per fatal accident inside. The causes of fatal accidents showed the following percentages: Falls of roof, slate and coal, 40 per cent.; mine cars, 40 per cent.; electricity, 13.3 per cent.; drawing timber (one accident), 6.7 per cent. The causes of nonfatal accidents, inside the mines, showed the following percentages: Falls of roof, slate and coal, 70.38 per cent.; mine cars, 7.41 per cent.; explosions of gas and dust, 5.55 per cent.; blasting, 3.70 per cent.; machinery, 3.70 per cent.; electricity, 1.85 per cent.; miscellaneous, 7.41 per cent.

Waste

By Berton Braley

Written expressly for "Coal Age"

If only our fathers had faced
The problems we face in our mining,
If *they* were less given to waste,
We might be less prone to repining;
They worked with a carelessness vast
And they left us a burden unpleasant,
For the Waste of a bounteous past
Is the Coal of a close-fisted Present.

We are saving the culm which they lost,
We are working the gobs that they filled,
And we seek to recover the cost
Of the coal they left standing—or spilled;
For somehow they never caught on
To this item of sane information,
That the culm of the days that are gone
Is the Coal of a new generation.

Now they probably thought they were wise
And we think we are careful and tasteful,
Yet our sons, without doubt, will devise
New methods which make US seem wasteful;
For this we must learn—or we pay
In trouble and money and sorrow—
That the Waste of a Careless Today
Is the Coal of a Careful Tomorrow!

BY THE WAY

In skating over thin ice our safety is in our speed.

A single breaker may recede even though the tide is coming in.

Paint Creek miners are showing up fast on the initiative, but are lacking in control on the referendum.

The difference between landscape and landscape is small, but there is great difference between the beholders.

Never judge a coal camp by the mine whistle—some of them have to shut down the works when they blow.

The United States imported 32 million dollars worth of diamonds in 1912. However, we sold foreign countries 59 million dollars worth of "black diamonds"—so we got "ours."

Thespian talents are a failure when applied to coal mining, according to a suit recently filed in Chicago by Mrs. Richard Harding Davis (née Bessie McCoy), the well known actress. She and others of her company were induced to invest in an Indiana coal property for which they are said to have advanced the necessary funds to meet the last pay-roll before the concern became defunct.

A special cable to the New York Times states: "An official notice has been issued to the effect that six large spiders have been added to the Canal forces. They are to be used for spinning threads for use in the engineers' transits." It is said the new spider department is being double shifted, which speaks bad for the carelessness of the engineering corps in the matter of handling their instruments. Too bad to waste good money cabling the "discovery" of a new method long ago abandoned.

EDITORIALS

The Eight Hour Day

There are certain labor agitators at work at the present time to influence opinion and secure the passage, by the Legislature now in session, of a bill to reduce the time of labor for all minors, or persons under 21 years of age, from the present nine hours to eight hours a day.

This action is being promulgated under an assumed sympathy and consideration for the young who work underground. Such a purpose, at any other time, would be accepted as just and humane. Consideration for the young is a noble trait; but when such assumed consideration is clearly only a guise under which the work of mining coal is being performed at the present time in the anthracite mines of Pennsylvania, and upon which the price of labor, including monthly and shift rates, is based, the attempt appears in its true light.

The miners and their representatives must show as high a regard for their agreement with the operators, as consideration for the young. They should be reminded here of the old saying—"Consistency, thou art a jewel." Be honest, stand fast to the agreement, and when that expires it will be the proper time to show *consideration for the young,* which is made the pretext for the present action. It would, indeed, have been more honorable on the part of the miners, and their desire would have been received with greater favor by the general public, had they sought this as a concession from the operators, instead of attempting to force a bill through the Pennsylvania Assembly that practically abrogates the miners' agreement now in force.

Mining Legislation

It is reported that the so called Schaeffer bill that has been before the Pennsylvania Legislature during the present session, has passed the House by a practically unanimous vote and now goes to the Senate.

The bill provides that all persons holding certificates of competency to act as mine foremen are, by virtue of such certificate, eligible for election to the higher office of mine inspector, in the anthracite district.

The promoters of this bill made an unsuccessful attempt to have its provisions adopted and made a part of the new law recently codified and recommended by the Anthracite Code Commission. Its rejection by the commission, whose prolonged and careful study of anthracite conditions render their conclusions worthy of the utmost regard, makes it difficult to understand the action of the House in this matter.

The present anthracite mining law provides that all candidates for election to the office of mine inspector must pass an examination before the mine inspectors' examining board, which is differently constituted from the mine foremen's examining boards.

The office of state mine inspector is a higher and more responsible office than that of mine foreman; and the examination of candidates for the former has always been of a higher grade than that required to qualify for the latter position. The questions that are made the test of qualification for mine inspectors are not only more difficult, but many of them are of a widely different character, as required by the greater scope of the work.

It is not expected that the upper branch of the Legislature will lend themselves to endorsing the unwise and hasty action of the lower House. The bill passed by the House is a first step in the lowering of the present high standard of the work of the mine inspectors in Pennsylvania. It is an entering wedge to make men eligible for the high office of inspector, who possess only a limited knowledge of the theory and principles on which modern economical mining is based.

The work of mine inspection is one in which theory and practice go hand in hand. The one is as essential as the other. No man, however successful he may have proved as a mine foreman, can make an efficient inspector of mines unless he possesses a thorough knowledge of the theory and principles of mining that he can apply to all conditions.

It would be a miserable mistake to pass such a bill through the Pennsylvania Legislature, and virtually begin to tear down the work of the past twenty years in that state. Education is the recognized leading feature in every branch of industry today, and the examination of all candidates for positions of responsibility is the one sure means of securing the highest efficiency in office, and safeguarding hazardous occupations.

The Fuel Well Menace

The fuel-well committee has made its report, but the controversy relative to gas and oil wells in the coal regions is by no means settled. The discussion should continue till more is known relative to earth movements and about the placing of cement mortar or plastic clay in deep and narrow spaces and until careful investigation has confirmed or corrected current notions.

We regarded the suggestions of the Bureau of Mines as marking the minimum requirements of the mining profession. They should have been conceded in full without any abatement or quibbling. Unfortunately the committee undertook to increase the Bureau's concessions to the fuel industry; where the Bureau asked for two casings, the committee concedes but one; where an annular space of four inches was required around the inner casing, the committee reduces it to less than three.

We feel we must warn the fuel-well interests that the public will make unreasonable restrictions on their business in return for their unreason, if any accident occurs. The safest position for any industry to take is that which promises most safety for the public. The pendulum which is held out of perpendicularity on the right is apt to be destructive on the left if once let loose.

The exterior of the couplings in a line of 10-in. casing

exceeds the interior diameter by 1.3 in. so that the clear annular space around the single liner, which the committee provides, is only $2\frac{1}{3}$ in. instead of 3 in.

If the gage of the bit is reduced by wear, the hole will be narrowed and the clearance reduced. It will be contended that the driller will not permit such a reduction, that if he allows the hole to be reduced, it will be impossible to get the full sized bit in later. But as a matter of fact as the width of the hole is not to be tested by the entry of casing couplings of equal diameter, there is nothing to prevent the driller from reducing the size of the hole at will, except careful inspection, which is not likely to be exercised.

The contracted character of this annular space increases the probability of air being shut up in the filling material, whether the latter be of clay or of cement mortar. There is nothing to prevent the borehole caving in such a manner, before completion, that the cement or clay will be rendered incapable of implacement by bodies of broken stone made impermeable at their upper surfaces by bodies of clay.

We are sorry that the use of clay is merely an option, and are surprised that the person to whom that choice is left is not anywhere specified. If clay is desirable, caving of the walls of the hole will result in having masses of hard material which will prevent a lateral movement of the pipe to compensate for the motion of the measures. If concrete is desirable, any caving will replace concrete with clay. We are afraid there is little option provided; the failure to provide an outer casing assures the parties interested that the filling will be of a hybrid nature, partly caved, and partly filled material with some of the faults and few of the virtues of either.

It is regrettable that the committee's bill is more liberal to the oil-well interests than the decision of Judge Van Swearinger in the Greensboro Gas Co. case. He required two casings and a hole full 6 in. larger in diameter than the outer diameter of the inner casing.

Argue, contrive and use diplomacy as we will, the last word is never said till safety is secured.

A Good Suggestion

The following letter lends support to the arguments so often advanced by COAL AGE, that mining examining boards should give to candidates, in certain sessions of the examination, the privilege of the free use of such textbooks as they see fit to bring with them.

The best material in mining, the strongest and most practical men, are men whose minds have never been trained to remember formulas, constants and other data to be found in all mining handbooks.

It goes without saying that these *handbooks are the necessary tools of every intelligent mine official,* and of none more so than of mine foremen, firebosses and hoisting engineers, who are daily called upon to make calculations, many of which are impossible for anyone, other than a born mathematician, to make without a textbook containing the necessary formulas and data.

Some of our best colleges now allow the use of textbooks, in certain examinations, and this by students with trained minds. The reason for it is educators recognize that in the growing demands and the ever expanding spheres of knowledge much valuable time is lost in students attempting to memorize anything but the most commonly used rules and data. Few college men can extract cube root, today, without their table of logarithms. Why, then, ask practical hard-working men, compelled to pass competitive examinations in order to show their fitness for filling positions of responsibility, to sit in examination under conditions more arduous than those that govern in daily practice?

Here is the letter:

> Please find inclosed 3 units of the great and only "Long Green," for which you will please credit me with one (Great Sun) year's subscription to the Public Forum or that book of yours called "Coal Age." My time is up tonight. Am sorry I did not come across before, but the ghost did not walk till the 28th; so blame it on the company.
>
> Now say, Old Cotton, there is just one favor I would like to ask—could you find a little space to put in your book a few formulas, what you think I would need for the examination for mine foreman (anthracite) next month? I can work the problems all right if I can think of the formulas. I mean just a small space, so that a fellow could tuck it in his vest pocket to look at frequently and memorize. If you can do this I shall be much obliged, but if you can't, why it's all right anyway.
>
> The book is all O. K. Keep the good work going, and we will all get there—I don't know where, but we are on our way.

On another page of this issue will be found a brief outline of a plan we have had in contemplation for some time past. Its aim and purpose is twofold: (1) To simplify the calculation of mining problems and provide a practical Study Course for mining students and those preparing for examination. (2) To provide a handy reference book of formulas, data, rules and principles that are constantly needed by mining engineers, mine superintendents, foremen, firebosses, timbermen, trackmen and mine mechanics and electricians.

We hope this handbook, which will be published later as "The Coal Age Pocketbook," will simplify and advance the study of coal mining.

Photography in Coal Mining

Some of the larger coal companies having come to realize the importance of visual records in coal mining, have installed complete photographic apparatus at each of their plants.

In case of serious injury to any of their employees, corporations so equipped can immediately secure a view of the particular place where the accident happened so as to verify the engineer's report on the casualty. The plan of having a camera handy makes it easy to show the condition of anything when an explanation regarding it is desired.

In the case of one large company in the Middlewest, the railroad serving the mines asked the coal officials to fill a number of new cars, and load into each as much coal as could be piled on and carried safely to destination without wastage. The desire of the railroad company was to determine the exact capacity of the cars. After the latter were loaded to a safe height, photographs were taken and endorsed on the back with the gross, tare and net weight. It was thus possible for anyone to see exactly how the cars looked when loaded to capacity, and to judge whether they were suitably piled for safe carriage.

It is also a fact that photographs furnish the best means of conveying to anyone the general appearance of coal-company yards as to whether they are dirty or clean. They tell the story better than can be described in writing by an inspector.

DISCUSSION BY READERS

Post Timbering at the Working Face

Letter No. 4—In regard to timbering the working face in our mines, I do not believe it would be well to have a fixed law or system that would specify exactly how such timber should be set, as the conditions vary constantly. Neither do I think it advisable to have men appointed to visit the working places and timber the same, as this would mean much loss of time to the miners in waiting for the timbermen to reach their places. Every miner ought to be compelled to timber his own place and he should be responsible for keeping his place in safe condition.

In my opinion a law should be passed requiring that all post timber at the working face should have a certain minimum diameter, say 12 in. This would be a heavy timber to handle; but my reason for suggesting it is that a heavy timber will stand more of a blow and will not be knocked out so easily by a shot. Where light timber, say from 6 to 8 in. in diameter is used, the miner will often set up such a post under a stone that he should have taken down. Then, when he fires a blast the stick is knocked out by the flying coal, and when the miner goes back in the smoke he will probably be caught by the loose rock falling on him. The advantage gained, if the law required the use of heavy timber, would be that it would often be easier to take down the stone than to set the heavy timber, and greater safety would result.

When I started to mine coal 35 years ago, we were required to take down any loose rock that was liable to fall. At times we had to take down rock 6 ft. thick and we were allowed so much a ton for it. I believe some such regulation in the anthracite mines would greatly reduce the number of accidents from this cause.

Timber should be cut in the fall when the sap is in the roots. Such timber will not rot as quickly, in the mine, as green timber. To preserve timber, I think a thin solution of well-slacked lime is better than any solution of creosote or other chemical that has a bad odor, as the odor taints the air and is unpleasant to breathe.

When shooting under bad roof, the miner can often drill the hole so that the shot will not be apt to knock out the timber. A miner should be just as careful under a good roof, when the firehoss orders him to stand a prop, to attend to it at once, as delay is often fatal. I believe it would be better for the company to pay a miner for taking down a bad section of roof instead of attempting to prop the same.

THOMAS R. PIERCE, Miner.

Scranton, Penn.

Letter No. 5—The matter of timbering the working face should have first attention. The miner should set his posts before starting to load out his coal. Post timber should be set plumb with a heavy cap-piece over the post so as to cross any slips in the roof. The large end of the prop should be up. In my experience, I have found that a post stood with its large end up will bear a greater load than one stood with the small end up.

It is important that the cap-piece should be of softer wood than the post itself, so that when the weight comes on, the cap will bind the head of the post together. When both a cap and a wedge are used the wedge should be driven between the cap and the head of the post, and not between the roof and the cap. In this case, the cap may be of hard wood and the wedge of softer wood.

I have had six years' experience as mine foreman in the No. 8 Pittsburgh seam, and during that time have had but one man hurt by accident other than by a fall of slate at the face. In No. 8 seam, there is a drawslate averaging from 12 to 15 in. thick, which the miner tries to hold up for three or four yards at the face, to give him an opportunity to load out his coal before dropping the slate. In this way we have had more men hurt in the mine, than from any other cause.

The best plan, in No. 8 seam, in posting this drawslate, is to set the posts 4 ft. apart each way so that they will form a triangle. Large caps, say 3 ft. long, if necessary, should be used, pointing toward the face. The caps should always point toward the face, unless it is necessary to point them in another direction in order to cross the slips in the roof. Too small a wedge or cap-piece will often cause a post to "trip" and they do not give the proper support across the slips or breaks, which makes their use dangerous. If miners would be more careful to use good wedges and long caps under a roof stone or slate, at the face, it would greatly reduce the number of accidents.

It is always important that a post should be set so that the weight comes directly over the post; otherwise, the post may "trip" and the cap be broken. Where the bottom is soft, a mudsill should be used; and this should not be less than 10 in. wide, 18 in. long and 4 to 6 in. thick. In some cases, a larger and heavier sill will be required to give a suitable foundation to the post. The system of timbering will necessarily depend on the conditions at the working face. In many cases, it is necessary to set the posts in rows parallel to the face. Sometimes, four rows of posts will be necessary, the rows being only 2 ft. apart, while the posts are 4 ft. apart in each row. This method throws an equal weight on each post and greatly strengthens the roof.

MICHAEL FREEMAN, Mine Foreman.
Glendale Coal Co.

Glendale, W. Va.

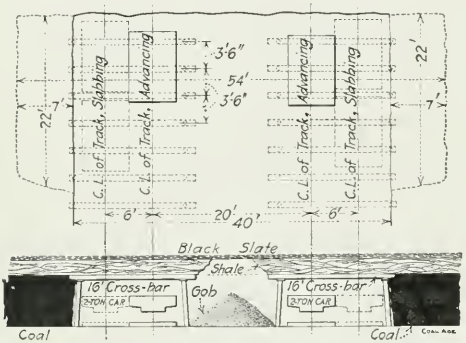
Letter No. 6—The following brief description, together with the inclosed drawing, shows a new method of working I have inaugurated in this district. The whole plan depends on the special style of timbering adopted, which, therefore, will be of interest in this discussion.

The method of timbering I am about to describe is used to mine a 6- or 7-ft. seam of coal, overlaid by a bench of shale varying in thickness from a few inches up to 3 ft. The cover above the shale is nowhere thicker than 80 ft. and often less than 25 ft. The stratum immediately above the shale is a hard black slate that breaks

easily. The roof shale, if not supported, will stay in place but a few days, a couple of weeks at the most, after the coal has been removed. It weathers rapidly when exposed to the air, detaching itself in large slabs measuring sometimes 3 or 4 sq.yd. and only 5 or 6 in. thick.

The rooms are driven 40 ft. wide, with two loading tracks spaced 20-ft. centers. The roof is supported by crossbars spaced 3½-ft. centers. One end of each crossbar is "hitched" into the coal, while the other end rests on a prop so placed as to clear the mine cars by at least 8 in. This has been found amply sufficient to hold the roof. The coal is undercut 7 ft. deep by electric-chain machines. After the room is driven up to the assigned limit, the miner starts what is called "slabbing"; a 7-ft. slice being taken off each rib.

Starting at the face, the machine makes a cut extending outward under six crossbars. This is plain sailing, as there are no props in the way. But, as soon as the cut is done, the timbermen set a prop under each crossbar, leaving a space of not less than 8 in. between the rib and



Plan and Cross-section of a 40-ft. Room, Showing Method of Removing Pillars by "Slabbing"

the prop. The timbermen then shift that part of the track which is opposite the newly made cut, 6 ft. toward the rib. The work is done in a very short time with ordinary crowbars and without disconnecting any rail joint. The slab is then bored and shot by special men before the loaders come to work.

The shooting seldom knocks down a prop, so accustomed to the work have the men become. If, however, a prop is either knocked down or moved, it is immediately reset. When the loaders come to work, in the early morning, they at once set themselves to dislodging and shoveling the coal. It would seem, and for a time, it certainly did seem to me, that the distance between the props was too short to permit of quick work on the loaders' part. But, after the men got accustomed to the work, the thing proved a great deal easier than was at first anticipated.

The first slab cut is started at the face of the room and consequently, both ends of it are fast. This is the case shown in the figure. But the next cut will have one loose end—the upper or inside one. The lower or outside end of the cuts will, of course, always be fast; but it is a matter of only 30 min. work for two men to make an opening there. When this has been done, the work progresses rapidly. In slab work, four men work together, and two mine cars are set out for them every time a change of cars is made. After a slab-cut is loaded out and before another cut is started by the machine, the timbermen remove all props and crossbars they can take out without exposing themselves, always stopping at the last set of timber, above the lower end of the cut where the coal has just been loaded. This set they leave for the present. The timbermen are careful to remove also the upper end of the track that has now become useless.

It has been found practicable to save six props out of ten, and about the same proportion of crossbars. It has always proved easy to knock down any standing props that it was thought too risky to attempt to save. This allows the falls to take place more easily. The space left open is only 54 ft. wide, but it falls nicely, in a few days. The caves appearing on the surface are so neatly and definitely cut, that a map of the workings could be made from them without the surveyors going underground.

F. C. Cornet,
Mining Engineer.

Charleston, W. Va.

Letter No. 7—Timbering at the working face is, I believe, one of the most important subjects connected with mining, and, at the same time, the work most neglected by the miners. The disregard of miners for their own safety is the most serious problem with which mine officials have to contend. Many mine officials fail in their duty by not requiring of each miner the proper timbering of his working face, at the proper time. As a consequence, we are losing more lives from falls of roof slate and coal than from all other causes combined.

The question is, what can we do to reduce the number of accidents from this cause? I am a firm believer in *systematic timbering*. Any kind of a *system* is better than none. I am also convinced that the miner is the proper person to do the timbering, except in some special cases that require the skill of experienced timbermen, employed for that purpose.

The miner should understand the necessity of setting a post, at the proper place and time; if he does not, he should be instructed along these lines. On the other hand, if he had to wait till men employed to do the posting arrived, he would too frequently take chances and load an extra car of coal, which, in past experience, has often proved to be the fatal car. Accidents from this cause will continue as long as the negligence of the miner is allowed to prevail.

In my experience, the best results have been obtained by adopting and enforcing a certain system of posting, more or less adapted to the conditions. Then, satisfy yourself that the miner thoroughly understands it and hold him directly responsible for the proper performance of the work. I am of the opinion that systematic timbering, in one form or another, will cover most of the conditions in coal mines. It may be, of course, necessary to have different systems to cover different conditions, in different mines, or in different sections of the same mine. In the various systems that I have recommended, I have only given the *minimum* amount of posting required or, in other words, the *maximum* distance apart of the timbers, which would not prevent intermediate posting should the case require. By so doing the miner or the official will always have to keep within this limit in setting posts. In case the rule is violated by setting post timber farther apart, an example should be made of the person or persons at fault.

My remarks and rules are particularly adapted to the Pittsburgh coal seam; but the same rules can be modified so as to apply to similar seams and conditions in other mining districts. The accidents from falls seem to be on the increase, so that about twelve of the bituminous-mine inspectors, I being one of the number, met early in 1910, and after several meetings and much discussion, adopted a system of posting the drawslate in the Pittsburgh coal seam, which posting is temporary while the miner or loader is loading out the coal from under the slate. This system was shown and fully described in COAL AGE, Vol. 2, p. 258.

We also adopted seven rules for timbering, which are particularly adapted to the Connellsville coke region, but will meet the requirements in seams of coal where conditions are similar. I give them here for the benefit of the reader:

Rule No. 1—In all rooms, entries, cut-throughs and chutes, exceeding 10 ft. in width, posts must be set nearly at right angles to the pitch of the seam, with good cap-pieces and in a straight line as near the center of the place as practicable. The distance between centers must not exceed 4 ft. 6 in., and the distance between the last post and the working face must not exceed 6 ft., except in places being undercut by machine, when the distance between the last post and the face may be such as the mine foreman, using sound judgment, may deem necessary for the safety of the workmen.

Rule No. 2—Where roof conditions necessitate the use of crossbars, no room, entry, cut-through, or chute shall exceed 10 ft. in width, except where special requirements render a greater width necessary. All crossbars must be properly and securely set, the distance between centers not exceeding 4 ft. and the distance from the last crossbar to the working face must not exceed 5 ft. We advise the use of temporary center posts, with good cap-pieces, to be set between the last crossbar and the working face, until another crossbar has been set, or until the loose coal or slate is taken down, as the case may be.

Rule No. 3—In all places after a blast has been fired, the roof and timber must be carefully examined by the workmen before they start to work, and any displaced timber must be promptly placed in position.

Rule No. 4—In the removal of pillars, the timbering should be done in a systematic manner. The distance between posts and between rows of posts must not exceed 4 ft. 6 in., and they must be set nearly at right angles to the pitch of the seam, with good cap-pieces and in parallel lines as close to the working face as practicable, maintaining a sufficient number of rows to insure the roof being kept in a safe condition until the posts are withdrawn.

Rule No. 5—In cutting across ribs or pillars where their thickness requires track across the working face, posts should be set on each side of the track, in the manner described in Rule No. 1 or Rule No. 2, according to the nature and condition of the roof.

Rule No. 6—In all cases when the coal is removed and the gob exposed, a line of posts shall be set near its edge. The distance between such posts or between the posts and the coal must not exceed 4 ft. 6 in.

Rule No. 7—In the removal of posts or timber while making rib-falls, none but competent workmen shall be permitted to perform the work.

You will understand that the system described in the above rules gives but the minimum amount of posting required and is not to be understood as forbidding intermediate posting or the adoption of additional precautions that circumstances may render advisable; nor as permitting you to omit such additional precautions if circumstances should render them reasonably necessary; nor does it permit you to neglect the rigid enforcement of any of the provisions of the mining laws pertaining to the prevention of accidents.

In order that these rules may be fully and carefully carried out and in order that the desired results may be secured—the prevention of accidents from falls—we would respectfully recommend a more rigid and frequent inspection, by mine officials, of all working places, roadways, etc.; because we are decidedly of the opinion that by exercising good judgment and strict discipline in the enforcement of these rules, there will be a very material decrease in the number of both fatal and nonfatal accidents from falls in the mines under consideration.

In mines where the coal is undercut, in wide rooms, by mining machines, the coal should not be blasted until the roof is posted within 6 ft. of the face. The blast many times causes a sag in the roof, and a number of accidents have resulted therefrom, that could have been avoided by setting timbers to prevent this sag.

In timbering, in pillar work, the cap-piece should be directed toward the fall or gob, and wedged in the same direction, so that when rock presses against the post from the side of the gob, it will tend to tighten the post instead of knocking it out. Accidents, both fatal and nonfatal, have resulted from the failure of properly wedging a post, on pillar-work.

The ordinary posting of a room should be carried out on a system best adapted to the particular locality in which the mine is located, and which past experience has proved adequate.

F. W. CUNNINGHAM.
Mine Inspector, 21st Bituminous District.
Charleroi, Penn.

Self Education of Miners

To become a fireboss is the ambition of many miners. It is the stepping stone to something higher. The general run of miners and men employed in and around the mine began work at an early age and, as a result, many have considerable less than a common-school education.

When a man has attained his first position as fireboss he begins, if he is ambitious, to educate himself and make up for his lack of schooling. While acting as fireboss, if he makes the most of his spare time, studying a few hours a day, he can soon master any line of study that interests him. If he does not want to follow up mining, there is no necessity to do so.

The usual hours in which a fireboss must do his work makes it possible for him to devote much time to study. He starts out between one and two o'clock a.m. in order to be at the mine and ready to begin his examination at three. He returns home about noon, tired and hungry. But, after washing up and eating his dinner, he can often utilize an hour or so to good advantage as no one should go to bed immediately after a hearty meal.

If he is wise he will begin to study the common-school books first, such as arithmetic and spelling, and apply these to his daily work or the work he wants to follow. A little study along these lines each day will soon give him a broader view of life and a broader mind. But a man who makes no effort to improve his position or broaden his mind, will sooner or later have to step aside to make room for a more earnest, eager and deserving man who will take his place.

A. F. DICKSON.
Roscoe, Penn.

[We are glad to indorse these brief remarks of our correspondent, drawing attention to the many opportunities that mine workers *can* improve if they *will*. The man who toils with his hands, during 8 or 10 hours of the day, and devotes the balance of the 24 hours to recreation and rest, often thinks his time for study is less than that of the office worker. It proves the old maxim: "Distance lends enchantment to the view." Office men, who must often toil 16 and 18 hours of the day, have learned the value of spare moments that are so generally wasted by other toilers.—EDITOR.]

EXAMINATION QUESTIONS

Fan Ventilation

Ques.—What would happen to a mine-ventilating fan if the doors at the top of the upcast shaft were suddenly opened; would the fan stop, slow down, or increase in speed? Give reasons for your reply.

Ans.—If the doors at the top of the upcast shaft were suddenly opened (assuming, of course, that the fan is exhausting the air from the mine), the mine would be cut off from the action of the fan, the air current being short-circuited at that point and passing directly from the outside atmosphere into the fan drift and through the fan from which it is then discharged through the expanding chimney into the atmosphere again.

This cuts out the mine resistance, which always opposes the circulation of the air; and, as a result, a very large volume of air enters and passes through the fan, greatly increasing the work lost or the power absorbed by the fan. Assuming the power applied to the fan shaft remains constant, the effective power causing the circulation of air would be very much decreased. It is this effective power that turns the fan; and, under the conditions just named, the fan would run slower but would, as stated, pass a larger volume of air per minute.

Ques.—When do the workings of a mine give off the most gas, when the fan is running or when it is stopped?

Ans.—The answer to this question depends wholly on conditions not named in the question. For example, assuming, first, that the conditions in the mine remain unchanged with respect to the emission of gas from the coal and other strata, if the fan is a blower, the mine pressure will be reduced by stopping the fan, and the outflow of gas from the strata will be increased. On the other hand, for the same conditions in the mine with respect to the emission of gas from the strata, if the fan is exhausting air from the mine the mine pressure will be increased when the fan is stopped, and the outflow of gas from the strata will naturally be less than before.

There are other conditions, however, affecting the outflow of gas from the strata, which produce a far greater effect on the outflow of gas into the workings than that produced by the stoppage of the fan whether blowing or exhausting. The emission of gas from the strata is not regular, but increases or decreases, from time to time, according to conditions existing in the strata itself. There are periods when the outflow of gas from the strata is abundant and, again, it will almost cease for a time. Besides these conditions existing within the strata, the advance of the working face and the extraction of the coal open new feeders of gas continually. Owing to these conditions, no definite answer can be given.

Ques.—A fan 15 ft. in diameter, working alone, produces 40,000 cu.ft. of air per minute, under a water gage of 1.06 in., giving an efficiency of 50 per cent. At a distance of 4000 ft. from this fan and on the same entry, another fan is placed and driven by a 25-hp. motor. The efficiency of this second fan is such as to make available 60 per cent. of the power applied. What will be the quantity of air and water gage produced when both fans are running?

Ans.—This is one of those unintelligible questions to which no answer can be given that would be of any practical value. If it were possible to introduce another motor of a given power, into an air current circulated by a given motor, in the same manner as it is possible to increase the power moving a train of cars, at any point of the train, the increase of air or the quantity in circulation could then be calculated, assuming the quantity proportional to the cube root of the power applied to move the air or the effective power on the air. The effective power or power on the air, in the first instance, is

$$H = \frac{40{,}000 \times 5.2 \times 1.06}{33{,}000} = 6.68\ hp.$$

In the second instance, the effective horsepower is increased by the effective power of the second motor, which is 25x0.6 = 15 hp., which makes the total effective power or the total power on the air 6.68 + 15 = 21.68.

Then, if the quantity of air in circulation varies as the cube root of the power on the air, the quantity ratio will be equal to the cube root of the power ratio. Or, calling the required quantity of air in circulation, x,

$$\frac{x}{40{,}000} = \sqrt[3]{\frac{21.68}{6.68}} = 1.48$$

$x = 40{,}000 \times 1.48 = 59{,}200$, say 60,000 *cu.ft. per min.*

Then, since the water gage varies as the square of the quantity of air passing, the increased water gage will be

$$w.g. = 1.06\left(\frac{60{,}000}{40{,}000}\right)^2 = 1.06\left(\frac{3}{2}\right)^2 = \frac{1.06 \times 9}{4} = 2.385\ in.$$

The conditions, however, that exist in the mine, with respect to these two ventilators, make this solution very problematic.

Ques.—A fan, 12 ft. in diameter, having an equivalent orifice of 30 ft., is running at a speed of 90 r.p.m. If the equivalent orifice of the mine is 19 sq.ft., what is the manometrical efficiency of the fan and what is the quantity of air this fan should deliver.

Ans.—It is necessary, first, to calculate the value of the manometrical efficiency of this circulation, from the given values of the equivalent orifices of the fan and mine, respectively. This efficiency is the ratio of the square of the equivalent orifice of the fan to the sum of the squares of the orifices of the fan and mine. Thus,

$$K = \frac{O_f^2}{O_f^2 + O_m^2} = \frac{30^2}{30^2 + 19^2} = \frac{900}{1261} = 0.7137$$

The quantity of air circulated by this 12-ft. fan, running under a speed of 90 r.p.m., in a mine having an equivalent orifice of 19 sq.ft., is then calculated thus:

$$Q = 3\ O_m D n \sqrt{K} = 3 \times 19 \times 12 \times 90 \sqrt{0.7137}$$
$$= 52{,}000\ cu.ft.\ per\ min.$$

This style of question depends on the correct determination of the equivalent orifices of the mine and fan, respectively, which is a difficult matter.

Study Course in Coal Mining

By J. T. Beard

The demand for increased efficiency grows steadily in every industry, and in none is this demand greater, today, than in coal mining. The shortest road to efficiency is the *education of the workers.*

Large industries and corporations employing workers in every capacity, have long since felt the need of increased efficiency of the workers in the mine, the shop and the field. To meet this growing need, many of the larger companies have organized special training schools and classes for their employees and the progress of students is rewarded by the advancement of those who prove their fitness for the work.

The work done in this direction by several of the large coal companies has produced commendable and gratifying results. Mine workers today recognize more than ever what proper training and education can do for the man who has them. The evidence of this fact is shown by the number of ambitious mine workers who are anxious to study.

The cry that comes to Coal Age from these men is for "something simple—something that a man of little schooling can study and understand." The cry is pathetic when we reflect that these men must study while they work. Others of their number, with an overmastering ambition to learn, rob the much-needed hours of rest and burn the midnight oil while the family sleeps.

In response to repeated requests from readers—miners, mine officials and engineers—for the publication, in tangible form, of reliable formulas and rules used in calculating all kinds of mining problems, the editors of Coal Age have decided, after carefully considering the needs of these different classes of men, to publish each week one or more pages of useful formulas, constants, tables, etc., together with practical rules, examples and brief, clear explanations of important principles in coal mining.

This will appear each week under the title, Study Course in Coal Mining. The matter will be published in page form, as shown by the two pages printed below. The size of these pages, 3x5 in., will make them available for compiling later in book form, which will be done as soon as a suitable number of pages have been completed, to make a useful handbook.

The book will be published as The Coal Age Pocketbook and will be as complete a reference book for coal men as it is possible to make it. To this end the editors of Coal Age invite suggestions from all their readers.

The subjects treated will cover every branch of coal mining, but will give only what is most essential, avoiding duplications, and all unimportant matter. The pages will be complete in themselves, but will follow no regular order, as they first appear. In the later publication, they will be classified and indexed.

The Coal Age Pocketbook

AIR

Composition—

	By Volume	*By Weight*
Oxygen,	20.9 *per cent.*	23.0 *per cent.*
Nitrogen,	79.1 *per cent.*	77.0 *per cent.*
	100.0	100.0

Air also contains 0.04 per cent. of carbon dioxide (CO_2). Average mine air seldom contains less than 20 per cent. of oxygen, unless the air is diluted with other gases generated in the mine.

Quantity of Oxygen Consumed in Breathing—A man at rest consumes 263 c.cm. of oxygen per min., or 263 × 0.06102 = 16 cu.in. per min. and exhales an equal volume of carbon dioxide. Air exhaled from the lungs contains 2.6 per cent. carbon dioxide, 18.3 per cent. oxygen, 79.1 per cent. nitrogen.

In violent exercise, a man consumes from eight to nine times the amount of oxygen required when at rest; or, say 128 to 144 cu.in. per min. The exhaled breath may then contain 6.6 per cent. carbon dioxide and only 14.3 per cent. oxygen.

Depletion of Oxygen in Air, Effect on Life—Air containing 3 per cent. carbon dioxide can be breathed without discomfort, even when the oxygen content has been reduced to 16 per cent.; but 5 per cent. carbon dioxide causes headache, dizziness and nausea, after a short time.

When no carbon dioxide is present in the air the oxygen content may fall as low as 14 per cent. before much difficulty is experienced in breathing; but air containing but 10 per cent. is no longer breathable; but will cause death quickly by suffocation.

Weight of Air—The weight of air, for the same volume, varies directly with the pressure it supports, and inversely as the absolute temperature. There are two formulas for finding the weight of 1 cu.ft. of air, one in terms of the barometer (B), in inches, and the other in terms of the pressure (p) in pounds per square inch.

By the barometer,

$$w = \frac{1.3273\,B}{460 + t}$$

By the pressure,

$$w = \frac{p}{0.37\,(460 + t)}$$

The Coal Age Pocketbook

WATER

Water is a liquid; practically incompressible; freezes at 32° F. (0° C.); boils at 212° F. (100° C.), at sea level.

Decrease of pressure lowers the boiling point.

Increase of pressure raises the boiling point.

Elevation 10,000 ft. above sea level; pressure = 10.1 lb. per sq.in., water boils at 194° F.; but in steam boilers, under 150 lb. gage (150 + 14.7 = 164.7 lb. absolute pressure, sea level) the temperature of the water is 366° F.

Density of Water—Although water is practically incompressible, its density and, therefore, its volume, does change slightly with the temperature. Water reaches the point of maximum density at 39.2° F. (4° C), and expands in freezing at 32° F. It is this expansion in freezing that bursts water pipes and disintegrates porous rocks saturated with water. Taking the maximum density of water as unity, the relative density at any absolute temperature T is calculated by the formula

$$D = \frac{1000\,T}{500^2 + T^2}$$

Water as a Standard—Pure distilled water is an important standard in many ways. The melting point of ice being more uniform than the freezing point of water, is taken to mark the zero of the Centigrade and Reaumur thermometer scales or 32° F.; while the boiling point, at sea level, marks 100° C., 80° R. and 212° F.

As a standard of weight, the weight of water (max. density) is taken as unity or 1, and the weights of equal volumes of other liquids and solids are referred to this standard by what is called the specific gravity of the substance. Thus, the average specific gravity of anthracite coal is 2.5, which means that this coal weighs 2½ times as much as water, volume for volume.

As a standard of measure, 10 lb of water was, at first, adopted as the English gallon. In the metric (French) system, 1 kilogram of pure distilled water (max. density) = 1 liter (cu.decimeter).

As a standard of pressure or measure of pressure, the height of water column supported by the pressure is used to measure the pressure per unit of area. Thus

In pumping: 1 *ft. water column or head* = 0.434 *lb. per sq in.*

In ventilation: 1 *in. water gage* = 5.2 *lb. per sq.ft.*

SOCIOLOGICAL DEPARTMENT

The Financial Outlook of a Frick Employee

By Thomas W. Dawson*

SYNOPSIS—The H. C. Frick Coke Co. provides free insurance to all its employees, the maximum payment being $3000 in case of death. Pensions are paid to the old and incompetent. The company is endeavoring to enable the employee to increase his earnings by increased output and to conserve them by investment in U. S. Steel Corporation stock.

The H. C. Frick Coke Co. has not restricted its work to protection against accidents, but provides a plan whereby those who are injured, or whose relatives are killed, may be provided with a livelihood.

The plan of relief in case of death or accident was put into operation May 1, 1910, and was tried for one year to determine its success. It is purely voluntary, and was established by the company for the benefit of all employees injured, and for the families of all workmen who might happen to be killed in the service of the company. There is no contribution whatever from the employees. The principal features of this plan are that relief is paid regardless of legal liability, and without any legal proceedings. Even application for relief is not required.

The company provides treatment by surgeons and hospitals. No relief is paid for the first 10 days of disability, such restriction having been found necessary in all legislation on the subject. In case of accident, single men who have been in the employ of the company five years or less are paid 35 per cent. of the daily wages received at the time of accident, and an additional 2 per cent. for each year of service over 5 years. Married men in the service of the company for five years or less receive 50 per cent. of their daily wages at the time of accident, with 2 per cent. additional for each year of service, and 5 per cent. additional for each child under 16 years of age. The maximum payment is fixed at $2.50 per day and for the loss of a hand 12 months wages; of an arm, 18 months; of a foot, 9 months; of a leg, 12 months; and of an eye, 6 months wages.

For death by accident the company pays reasonable funeral expenses, and the widows and children of men so killed receive relief equal to 18 months wages of the deceased if in the service of the company five years or less, with an addition of 3 per cent. for each additional year of service above five years. An additional 10 per cent. is added for each child under 16 years of age, the maximum being fixed at $3000.

When the plan was put into effect, it was printed in the various languages and a copy given to each employee. One is now given to every arrival as he goes to work.

Pensions for the Old and Those No Longer Competent

The United States Steel Corporation, of which the H. C. Frick Coke Co. is a subsidiary, has provided $8,000,000, which, with the Carnegie Relief Fund, created by Andrew Carnegie on Mar. 12, 1901, makes a joint fund of $12,000,000, in which the employees of the H. C. Frick Coke Co. participate. Its principal features are; compulsory retirement for men at 70 years of age after 20 years of service; retirement at the request of the employee, or his employing officer at the age of 60 after 20 years of service; retirement by reason of permanent total incapacity after 20 years for a man under 60 years of age.

The basis of the pension scheme is; first, for each year of service, 1 per cent. of the average monthly earnings for the last 10 years of service; second, credit for service rendered to any of the plants of the subsidiary companies of the United States Steel Corporation, or to the predecessors of such companies; third, a minimum pension of $12 per month and a maximum pension of $100 per month.

Thus it has been seen that the company in the first place leaves nothing undone to protect its employees from injury, that when injured, as some of them are bound to be in the operation of some 65 mines, everything possible is done for their care and treatment; financial provision made for them and their families, and in case of death, for their widows and children; and when old age comes after years of service, the employees are assured sufficient income to take care of them to the end of their days. Thus, while conducting the great business done by the H. C. Frick Coke Co., it ever keeps in sight that one great factor "the employee."

Interest in Raising the Earnings of the Employees

The company has done much to increase the efficiency of their employees and to assist them in making the highest earnings possible under the contract prices. The company pays the highest wage in the region, and has always been foremost in increasing it when justified. It has established a standard efficiency basis, indicating what each employee, no matter what is his job, should accomplish for a day's work. This standard is not based on what the most capable man can do, but on the strength and endurance of the average man.

Daily reports are made showing the efficiency of each group of employees, setting forth the work performed by those mining or hauling coal, laying track, setting timber, etc. To aid the miner to earn all he can, steel track is used in headings and rooms, instead of the former wood track, on which the mine car can be far less easily moved. Haulage partings are continually moved up to the working sections. Empty cars are supplied to the miner as fast as he needs them, being delivered to the face

*Assistant chief engineer, H. C. Frick Coke Co., Scottdale, Penn.

Note—Abstract from paper entitled "Welfare, H. C. Frick Coke Co.," read before the winter meeting of the Coal Mining Institute of America.

of his working place. All loaded wagons are promptly removed.

General Rule No. 18 requires that: "Superintendents and foremen shall see that the turns are fairly distributed among the workmen on contract or piecework, and that no more men are employed than are absolutely necessary to perform the required amount of work well, and at the proper time."

Rule No. 21 states that: "Superintendents must pay strict attention to the rights and privileges of all employees, hear and give prompt attention to any reasonable complaint or claim for redress made by any employee, and not allow any discrimination on account of nationality or creed."

Where the working sections of a mine are a considerable distance from the entrance or shaft bottom, workmen are transported on "man trips" to and from a point near their work, thus eliminating the expenditure of a vast amount of energy which would be required in walking to and from their working places.

Inducements Offered for the Saving of Wages

Each year the employees of this company are offered stock of the United States Steel Corporation upon easy and especially favored terms which involve benefits beyond those granted to the ordinary stockholder. Of recent years the stock allotted has been over-subscribed. The figure charged is the market price or a little less, usually the latter. The minimum payment is $2 to $3 per share for preferred, varying in accordance with the price of the stock, and $1.25 to $1.50 for common stock.

The maximum which can be paid is 25 per cent. of the monthly earnings. A payment of $5 for preferred and $3.50 for common per annum for five years is paid on each share of stock purchased by employees under this plan. Non-paid-up subscriptions can be cancelled and the money paid in is refunded to the employee with 5 per cent. interest.

Premiums are not paid to employees who cancel subscriptions, sell their stock or leave the employ of the company, and the forfeited or unpaid premiums are kept in a fund and divided pro rata among the remaining stockholders under this plan at the end of the five years. If death occurs to an employee who has subscribed for stock and made payments under this plan, his estate receives the unpaid premiums for the full five-year period and a pro rata of the undivided premium at the time of death.

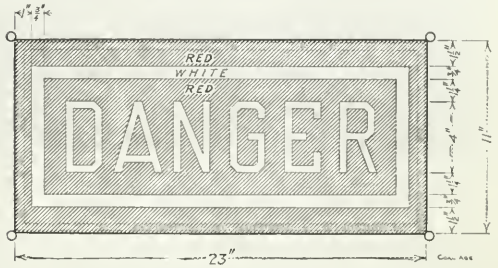
A Uniform Danger Signal

By L. R. Douglas*

During a discussion on the fencing off of bodies of gas, or other dangerous places, at a recent meeting of the Trinidad Chapter of the Rocky Mountain Coal Mining Institute, reference was made to a danger signal of some kind. Also a clause in the proposed mining laws for the state of Colorado alludes to a uniform danger signal. It is highly important that whatever warning device is used, should be uniform throughout the district. The majority of our miners today are foreigners, and unable in most cases to read the English language.

In the southern Colorado coal fields, where the mines are close together, it is common practice among the men to keep changing from one place to another. Wherever they would go the uniform danger signal would convey to them the same meaning, for the reason that it would look just the same as the sign they learned meant danger at the first or last place at which they were employed. Since "Safety the First Consideration" is the slogan now adopted by all operators, it seems that the uniform danger signal would be an additional step in this direction.

An efficient and serviceable signal is shown in detail by the accompanying sketch. It should be of No. 24 sheet tin, 12x14 in., with beaded edges, a wire being strung



Danger Sign

through the bead, and looped at each corner. The diameter of the loop should be about ¼ in., making it easy to hang up. The background should be enameled red, and the border around the word "Danger," and the letters should be white.

This would form a striking signal, and one not affected by water or humidity in the atmosphere. The enameled surface can be readily cleaned of dust and grease, with a piece of waste or cloth. This sign being durable and easily made, is presented to the mine operators for their consideration.

*Assistant engineer, Danford & Sanderson, Trinidad, Colo.

First Aid Demonstration of Pittsburgh Coal Co.

By H. G. Adamson*

On Thursday evening, Mar. 5, the Pittsburgh Coal Co.' first-aid teams in the Thoms Run district, gave their first competitive exhibition in the hall of the Knights of Pythias, at Federal, Penn. The three teams composing the organization were dressed in new white uniforms having a red cross on the left sleeve and these suits gave the contestants a neat and military appearance. The classes had been thoroughly instructed and drilled by Dr. Rittenhouse, of Federal, Penn.

An audience estimated at 500 persons witnessed the contest and many late arrivals were unable to secure admission to the hall. Among the visitors were several of the officials of the Pittsburgh Coal Co., including J. M. Armstrong, manager of mines, F. C. Fritchman, assistant manager of mines, J. M. Sloan, district superintendent, J. E. McDonald, superintendent of the relief department, Dr. Kennihan and Mr. Judd, also of that department.

The mothers, wives, fathers, brothers and sisters awakened to a realization of the fact that the men who are members of first-aid teams will help materially all the mine employees in the district. One feature that the company and its local officials much appreciate, is that a number of those who attended the exercises for the first time, expressed their desire to become members of the first-aid teams.

The company has furnished a hall at Federal, Penn., centrally located, and it is fitted with first-aid charts and a skeleton for the benefit of all the employees who wish to avail themselves of first-aid instruction. The classes meet once a week.

BOOK REVIEW DEPARTMENT

BRITISH COLUMBIA BUREAU OF MINES, BULLETIN NO. 1, 1913. PRELIMINARY REVIEW AND ESTIMATE OF MINERAL PRODUCTION, 1912. By Wm. Fleet Robertson, provincial mineralogist. Paper, 7x10 in.; 29 pages.

The bulletin has been prepared before the receipt of the official reports of the gold commissioners and mining recorders of the Province, for the year 1912; and before receiving the usual returns made annually by the managers of mines and reduction works. In estimating the net production for 1912, the bulletin has made allowance for a possible slight reduction in the total final figures, to be received later.

It is estimated that the coal mines of Vancouver Island have produced during the year 1,553,000 tons; those of the Crowsnest district 1,299,000 tons; while those of Nicola and Similkameen have produced 214,000 tons. Of this coal production 393,000 tons were made into coke, the coking operations being confined entirely to the Crowsnest district which fact reduces the production of coal in that district to 904,000 tons, net. The bulletin gives a brief summary of the important mining developments in the Province, during the year.

EINFUHRUNG IN DIE MARKSCHIEDEKUNDE MIT BESONDERER BERUCKSICHTIGUNG DES STEINKOHLENBERGBAUS. (An introduction to the study of subterranean surveying with particular reference to coal mines) by L. Mintrop, teacher at the Bochum Mining School. 209 pp. with index. 6¼x9⅜ in. 191 ill. and 5 double-page plates. Julius Springer, Berlin, 1912.

The title of this book sufficiently defines its character, and the author's standing proclaims its reliability. The discussion covers land surveying, the instruments used above and below ground and their use, and the estimation of areas and earthwork.

A few useless traverse tables are given, which are carried down only to even degrees, even meters from 1 to 10 and two places of decimals. We can hardly see what use these would be, even in a classroom. The plates are interesting and suggest that the German coal mines are not operated without considerable difficulty.

COAL MINES REGULATION ACT, 1911—HOW TO REMEMBER IT—Arranged by Henry Davies, director of mining instruction for the County of Glamorgan, Wales. 120 pp. 5⅜x8¼ in. Thos. Wall & Son, Ltd. Wigan, England. Cloth boards. Price, 1/6.

The writer of this book has taken the British mining law and rendered it into everyday English, giving each subject a bold and easily visible title. Moreover, the information is alphabetically arranged so that ready reference can be made to any part of the contents. It would be well if a book, following a somewhat similar method and containing the various state laws, were printed in this country.

It is probably well known to our readers that Great Britain is governed by both laws and Home-office orders. Several of the latter relating to coal mines are included in this book and also the Coal Mines (Minimum Wage) Act. This book is both cheap and handy, and should obtain a ready sale.

ANNALES DES MINES, RECUEIL DE MEMOIRES SUR L'EXPLOITATION DES MINES, Vol. III, Series XI, 1913. H. Dunod et E. Pinat, 47 & 49 Quai des Grands-Augustins, Paris; 5⅜x9. Paper.

This edition of the Annales contains a study on magazines containing black powder, by M. Saladin, chief engineer of the Schneider establishments, representing the committee on iron works and iron mines in Meurthe et Moselle, and M. H. Dautriche, chief engineer in control of powders and saltpeter.

It may be well here to quote the conclusions at length:

1. In case of an explosion in an underground magazine or one built on the cut-and-cover principle, the mine powder in grains, the compressed and unenveloped powder and that compressed and confined in cartridges produced almost equally destructive effects.

It appears to be justifiable to use the tables prepared for dynamite magazines, buried or sunk and covered over, for estimating the clearance needed around powder depots of like kind with the proviso that one pound of black powder be considered equivalent to half a pound of dynamite.

2. In the case of an explosion of a light magazine in free air, the mine powder compressed to a density of 1.5 produces effects comparable to those of powder in grains. It is the most important conclusion of the Droitaumont tests that the effects are considerably reduced when the compressed powder is carefully put up in paper cartridges.

This reduction results from the slow progress of the inflammation. Consequently the pressure produced was more marked when the magazine had light walls and presented less resistance to the discharge of the first gaseous products. The weakening of the effect was considerably greater for the light magazines than for those which were sunken.

3. We can therefore increase the safety of magazines of powder when compressed and made into cartridges by dividing the powder into such suitable sockets that the inflammation of one of them will not be communicated to neighboring sockets. The experiments at Droitaumont ought to promote the use of socket magazines having unit cells capable of containing 1, 5 or 50 kg. (about 2½, 11 or 110 lb.). In the building of such a magazine, it seems necessary to reduce to a minimum all combustible parts.

Nearly half of the concluding part of the book is taken up by a bibliography and a list of the personnel of the department of mines in France. We recommend this list to those people who believe that our own bureau is disposed to undertake too large a scope. There are commissions on steam engines, automobiles and cartography, all under the control of the Mines Council.

MINE-RESCUE WORK IN CANADA. By W. J. Dick, mining engineer, Commission of Conservation, Canada. 48 pp., with index. Paper, 6⅜x9⅝; 19 illustrations, mostly insets. The Rolla L. Crain Co., Ltd., Ottawa.

This book contains an account of the mine-rescue provisions of all nations and a full description of the excellent work being done in Canada. British Columbia requires rescue apparatus to be kept at all mines and it may surprise many to learn that when the book went to press in November, 1912, there were 182 mine-rescue apparatus in use or ordered, 22 belonging to the province of British Columbia.

An interesting chart shows the death rate in all the coal-producing countries. In 1902, Canada had a fatality of over 13 per thousand. Our own death rate in 1907, which approximated 5 per thousand, shrinks in comparison. Never before or since that time have our coal-mining operations been nearly so fatal as in that year.

Canada has difficulties which demand peculiar precautions. In some years past, its death rate has been lower than our own and this little volume shows that it has determined that the future risks of mining shall be reduced and is taking radical steps to that end.

COAL, ITS COMPOSITION, ANALYSIS, UTILIZATION AND VALUATION. By E. E. Somermeier, professor of metallurgy, Ohio State University. 169 pp., with index; 6⅛x9⅜; 8 ill. McGraw-Hill Book Co., 239 W. 39th Street, New York, Cloth boards. Price $2.

This book is written by undoubted authority and can therefore be recommended to anyone seeking information on coal as a heating agent. The word "composition" in the subtitle refers to its chemical characteristics, and has no reference to the physical and biological nature of the coal.

There are chapters on composition and heating value, chemical analysis, sampling, methods of analysis, determination of heating value, methods of reporting analysis, improvement of coal by washing, purchase of coal under specifications and on flue-gas analysis. Several analytical tables are contained in the concluding chapter.

It will be seen therefore that the book is valuable to the coal chemist and the coal user. The remarks on washing are purely applicable to the theoretical determinations of the chemist and do not take up washery practice and the efficiency of different methods.

Trifling exceptions may well be taken to the view that sulphur is an extraneous and not an intrinsic part of the coal, and to the use of analyses of ash which do not show the presence of titanic acid. This dioxide which runs from 0.10 to 1.30 per cent. in clays is usually found in coal, probably as an extraneous impurity. It is generally, as in these analyses, included as silica.

However, the exceptions we have taken detract in no manner from the value of a book which is intended for practical use and completely fits the place for which it was published. The coal analyst and coal burner will find in it those facts which are needed in their daily work and a book logically arranged and free from non-essentials.

COAL AND COKE NEWS

PENNSYLVANIA

Anthracite

Edwardsville—The Woodward Colliery of the Delaware, Lackawanna & Western R.R. Co., Coal Department, at Edwardsville, has been closed for repairs. The time of the suspension has not been announced, but it is expected to last about three weeks.

Scranton—The first strike to receive the indorsement of the district officers of the United Mine Workers since the signing of the agreement last spring is that at the Oxford Colliery of the People's Coal Co., at Scranton. The miners allege that the company is not abiding by the award of the strike commission of 1902 and the agreement of last spring, under which the mines of the anthracite field are being worked. The indorsement of the district union carries with it the support of all the anthracite miners, and implies that the union is to make an issue of the Oxford matter.

Mrs. Cora Evans, of West Scranton, widow of Joseph A. Evans, the rescue foreman of the U. S. Bureau of Mines, who lost his life in the Pancoast mine in Throop, Apr. 7, 1911, while leading a rescue party, has been granted a pension of $1320 by Congress. The pension is payable at once, and is equal to one year's salary.

Bituminous

Meyersdale—A coal mine is to be added to the varied industries of the Somerset County Home and House of Employment, according to the annual report of Poor Directors Jacob W. Peck, Chauncey F. Dickey and George F. Kimmel. The mine will be located on the county farm.

Pittsburgh—The meeting of the American Institute of Electrical Engineers will be held in Pittsburgh, Friday and Saturday, Apr. 18 and 19, under the auspices of the new committee, which has just been formed to discuss the use of electricity in mines. Of this committee Geo. R. Wood, consulting engineer of the Berwind-White Coal Mining Co., is chairman.

A number of interesting papers covering the various phases of this subject have been promised and it is expected that an interesting discussion will take place.

Owing to the location of the meeting in the heart of the bituminous coal mining district, it is expected that a large number of coal-mine papers will be presented.

OHIO

Columbus—Operators in Ohio are fearful that the Gilson bill now pending in the Ohio General Assembly, which gives the right of eminent domain to condemn an approach to a mine will pass. It is claimed the bill is so loosely drawn that owners of coal mines could seize another mine and use it as an entry to their own mines.

The Green anti-screen bill, providing that miners shall be paid on the basis of all coal mined instead for that which does not go through a screen, passed the senate of the Ohio legislature recently by a vote of 21 to 8. Senator Green, father of the measure, pushed the bill through suddenly although considerable opposition developed. Senator Green stated that between 25 and 38 per cent. of the coal mined in the state goes through the screen. The measure as it passed the senate does not become effective until Apr. 1, 1914, when the present miners' scale expires.

Bellaire—Fire of unknown origin, starting in the oil room of the general store of the Pittsburgh Belmont Coal Co., at Neffs, just east of here, destroyed that structure, the warehouse adjoining and the blacksmith shop of Alex Neff, and threatened the destruction of the entire town recently. The loss was $25,000 with $14,000 insurance.

KENTUCKY

Winchester—John C. M. Day, of this city, has discovered a seam of coal on his land, near Campton Junction, on the Lexington and Eastern R.R., east of here. He intends to begin working the mine at once.

Whitesburg—A 6-ft. seam of cannel coal is reported to have been discovered on the property of the Mineral Development Co., up Boone's Fork on the new Lexington & Eastern R.R. If the report is correct, the seam is one of the largest in eastern Kentucky.

Jenkins—John Potter, a farmer, will probably receive a fancy price for an acre of land now located in the heart of the town, which he reserved for his house when he sold his 200-acre farm to the Northern Coal & Coke Co., a few years ago. The Consolidation Coal Co., who bought the land and constructed the town, is said to have offered Potter $40,000 for his remaining acre, but he has thus far refused to sell.

Lexington—In connection with that part of the program of the Kentucky Mining Institute involving demonstration of first-aid work, to be given at its meeting on May 16 and 17, the treatment of various injuries will be required. For this purpose volunteers will be needed to submit themselves to the application of tourniquets and other first-aid devices, the use of the plumotor, and the like. Among the injuries which will be theoretically treated are listed right ear torn off, bright-red blood coming out in spurts (indicating a severed artery), compound fracture of right thigh, man unconscious, overcome by gas, broken back, electrocution, right hand cut off, and compound fracture of jaw. Naturally, it would be impracticable to produce these injuries for the occasion, and some skillful "faking" will be necessary in order to make the work as realistic as possible.

The Board of Examiners in the office of State Mine Inspector C. J. Norwood, at Lexington, Ky., has completed its examination of applicants for mine foremen's certificates, and has granted first-grade certificates to 7 men, second-grade to 17 men and third-grade to 2 men.

Under the gradings established by the Department, a first-class certificate entitles the holder to take charge of any mine in the state; a second-class qualifies him to assume the position of foreman in any nongaseous mine, and a third-class to take charge of any nongaseous mine not employing more than 26 men.

TENNESSEE

Coal Creek—A 30-ft. vein of coal has been discovered near Coal Creek, according to recent reports, on a farm which has been taken over by parties who intend developing it at once. The property is said to lie between the Southern Ry. and the L. & N., and to contain three veins of iron ore, in addition to the coal.

INDIANA

Princeton—William H. Raney, member of the district executive board of United Mine Workers, received a message from National President White, announcing that the National Board had given its consent for a 30-day test of a new explosive in the coal mine at Fort Branch, this county.

Indianapolis—The shotfirers' bill, which proposed to compel the operators to pay the shotfirers, failed to get through the Indiana legislature. The operators put up a stiff fight against it. The bill got through the House, but was killed in the Senate committee, of which Jacob C. Kolsem, operator, of Terre Haute, was chairman.

The new weights-and-measures law prohibits the selling of coal by the basket, unless the baskets are of standard bushel size. In the Ohio River towns, it has been the custom to sell coal by the "bushel" of 72 lb. and the "load," of 1800 lb. This will be superseded, probably by the 80-lb. basket and the full 2000-lb. load.

CALIFORNIA

Magalia, Butte Co.—The boiler building and hoist at the Crystal mine, formerly known as the Princess mine, was destroyed by fire. R. C. Andress is superintendent of the mine.

❖

Coming Meetings

ENGINEERS' SOCIETIES

The regular monthly meeting of the Engineers Society of Northeastern Pennsylvania will be held in the Board of Trade Auditorium, Scranton, Penn., Thursday evening, March 20, 1913, at 8:15 o'clock. Refreshments will be provided by the social committee. Subject: Centrifugal Fans, Design and Application, by E. B. Williams, manager mining department of the B. F. Sturtevant Company.

HILL PUBLISHING COMPANY

Notice to Stockholders

A special meeting of the stockholders of the Hill Publishing Company will be held on the 7th day of April, 1913, at 11:00 o'clock a.m., at the offices of the Company, 505 Pearl Street, New York, N. Y., for the purpose of voting upon the following propositions:

a. To increase the number of the directors to nine;

b. To increase its capital stock from $1,000,000 to $3,000,000, to consist of 30,000 shares of the par value of $100 each;

c. To classify the aforementioned increase of capital stock amounting to $2,000,000, so that $1,000,000 thereof shall be six per cent. cumulative preferred stock, also preferred on dissolution, and $1,000,000 thereof shall be common stock;

d. To alter the certificate of incorporation by eliminating the provision in Section 7 thereof relating to cumulative voting; and

e. To ratify the by-laws of the Company as amended by the directors.

Dated, New York, March 20, 1913.

JOHN A. HILL, President.
ROBERT McKEAN, Secretary.

Correction

In our issue of Mar. 8, Vol. 3, No. 10, in the third line of the last paragraph on p. 369, the word first-motion" should read "second-motion."

PERSONALS

M. D. Reyer, of Birmingham, Ala., has resigned his position as assistant general manager of the Galloway Coal Co., and the position has been abolished. The duties are now being looked after by Cyrus Garnsey, Jr., general manager, of Memphis, Tenn., we will make his headquarters at Carbon Hill, Ala., where the largest operations of the company are located.

William Hadley, who was appointed temporarily superintendent of the Foundry Furnaces of the Tennessee Coal Iron & R.R. Co. on Nov. 1 last, when E. P. Williams resigned, was on March 1 transferred to his former position as assistant superintendant of the company's furnaces at Ensley. W. E. Oldham, superintendent of Vanderbilt Furnace of the Woodward Iron Co. has been appointed to fill the vacancy as general superintendent of Foundry Furnaces, comprising four furnaces at Bessemer, Alice Furnace at Birmingham, and Oxmoor Furnace at Oxmoor. Mr. Oldham was for a few years superintendent of Alice Furnace for the Tennessee Coal Iron & Railroad Company.

John Markle, head of the firm of G. B. Markle & Co., the Jeddo coal operators, has given out an official statement contradicting the report that he was to resign from the firm. He sails on March 22 for Europe, where he will undergo treatment by noted oculists.

Announcement has been received that F. F. Taplin, formerly sales manager of the Youghiogheny & Ohio Coal Co., will be president of the recently incorporated Cleveland & Western Coal Co. This concern will do a rail and lake business in coal from Pittshurgh and Ohio districts.

CONSTRUCTION NEWS

Lansford, Penn.—Contractor Louis Riebe, of Lansford, is erecting a big washery at Hauute for the Lehigh Coal & Navigation Co.

Middlesboro, Ky.—The Mary Moose Mining Co., operating in the Middlesboro field, is planning to sink an additional shaft on its properties.

Osaka, China—The Osaka Shosen Kaisha has placed orders with the Osaka Iron Works for the construction of two 3000-ton steamers having a speed of 10 knots.

Syracuse, N. Y.—The Semet-Solvay Co. will build 20 additional coke ovens at Holt, Ala., increasing the plant 50 per cent., and daily capacity to 350 tons coal.

Hamilton, Ohio—Extensive improvements are being made at the plant of the Hamilton, Otto Coke Co., at Hamilton. These improvements will include a coal mixer.

Coshocton, Ohio—J. H. Daley, who has been operating a coal mine on the Lee Moore farm, at Mohawk, has opened up another mine on the L. N. McVey farm, near Walhonding.

Saginaw, Mich.—The Consolidated Coal Co., which controls the soft-coal mines in the Saginaw Valley, announced today that three new mines will be opened within the next month.

Monongahela, Penn.—A number of coal test holes are to be drilled in the vicinity of Eighty-Four this coming spring, with a view to the location of a number of coal shafts in that vicinity.

Lonaconing, Md.—Robert Izzett has a force of workmen engaged in reopening the mine on Big Vein Hill, near the Silk Hill. Mr. Izzett will devote himself to developing the fire coal business.

Topeka, Kan.—The Union Pacific coal chute that was destroyed a few days ago by fire, will be replaced by a new concrete and steel structure. The new chute will cost about $20,000, and its capacity will be about 200 tons.

Cumberland, Md.—The Stanton mine, at Short Gap, a mile east of Clarysville, will be ready to ship coal this week. This mine has been reopened by the Stanton Coal Co., of which Louis Stanton, of this place, is the president.

Tamaqua, Penn.—Besides ten dwelling houses the Lehigh Coal & Navigation Co. is erecting at Lansford and ten at Seek, near Tamaqua, it has contracted for twenty-five blocks of houses at Hauto for employees of the new electrical plant.

Pottsville, Penn.—The Kaska William Colliery, of the Alliance Coal Co., has been closed down for a full month. This was done to permit repairs, a fire having done great damage. A new shaft has been sunk 100 ft. and it is only about half finished.

Connellsville, Penn.—The interests which acquired the coal under the lands of the Peter Miller Estate, near Rogers Hill, in the Indian Creek Valley, will construct a coke plant of 50 ovens. The interests are represented by Charles Pore and H. N. Odbert, of Monessen.

Jenkins, Ky.—The Consolidation Coal Co. has started the construction of a large central hospital to be used by all of the company's constituent branches. The building is to be of brick and stone, and will cost in the neighborhood of $40,000. It will be completed within six months.

Greensburg, Penn.—Rockwell Marietta has purchased 134 acres of coal north of Wilpen and near to the plant of the Marietta Stillwagon Coal & Coke Co., of which he is president and manager. Engineers are now on the ground laying out the ovens, coal tipple and railroad sidings.

Pottsville, Penn.—The Locust Mountain Coal Co. has awarded the contract for breaker of 2500 tons capacity per day. Nine hundred thousand feet of lumber will be used in its construction. Baird Snyder, Jr. formerly superintendent of the Lehigh Coal & Navigation Co., is the head of the new company.

Wellesburg, W. Va.—The Finley Coal Co. will build thirty houses this spring to accommodate the employees of the company, fifteen of these will be built at their mines just north of the city and the remainder at the La Belle mine. The company also proposes to build a large electric plant at Buffalo Creek, near the old tipple.

Pomeroy, Ohio—Report is now extant among railroad men that the 12 miles' extension of the river division at Pomeroy, will commence when the good weather appears. Contractor John Lindsey secured the job. This extension will tap a virgin coal field in Meigs County, and should produce thousands of tons of tonnage annually for that division of the H. V. R.R.

Birmingham, Ala.—The contemplated construction of a railroad line in Walker County, joining the Jasper-Manchester R.R., to that now extending from Burgin, will mean development that will bring about expenditures of $2,000,000, at least. The Maryland Coal Co. is developing as fast as money and labor can do the work. Milton Fies is in charge of the coal developments in this section.

Homer City, Penn.—The Miller Construction Co. is beginning the building of a branch line for the Buffalo, Rochester & Pittsburgh R.R. in Indiana County, Penn., to tap the new mine opening of the Clyde Coal Co. A high trestle will be built in connection. A new mine opening at Craigsville, south of Punxsutawney, will also be given a railroad connection by the same construction company. The Clyde Company will put up about 45 houses for workmen.

Wilkes-Barre, Penn.—Sinking operations at the new shaft of the Butler Colliery, of the Hillside Coal & Iron Co., have been suspended temporarily, at a depth of seventy feet, in order to permit the concreting of the shaft for a depth of thirty-five feet. McConville and Fitzpatrick, of Pittston, are doing the concrete work. The inside dimensions of the shaft, after the concrete has been placed in position, will be twelve by twelve feet. After the completion of the concreting, the shaft will be sunk to a depth of about 150 feet.

Birmingham, Ala.—The Woodward Iron Co. is making improvements at its No. 2 Woodward mine, consisting of concrete and steel tipple and crusher building, electric hoist housed in a fireproof building built of brick with the tile roof. The ore will be handled in a 14-ton steel skip on the upper 1,100 ft. of the slope, to which point it will be gathered in the mine cars by an auxiliary electric hoist in the mine and dumped in to a 300-ton bin from which it will be loaded into the skip. The power for operating the skips comes from the electric plant at their byproduct coke plant at Woodward, about three miles distant.

NEW INCORPORATIONS

Blocker, Okla.—The Belt Coal Co.; capital stock, $25,000. Incorporators: James L. Brazel, Al Belt, and R. P. Harris.

Hazard, Ky.—The Kentucky Jewel Coal Co.; capital stock, $50,000. Incorporators: H. E. Bullock, D. C. Foley and T. F. McConnell.

New York City, N. Y.—Loyalsock Coal Mining Co.; capital stock, $100,000. Incorporators; F. C. Overton, J. R. Overton, E. P. Young.

Louisville, Ky.—The Drake Blue Gem Coal Co.; capital stock, $8000. Incorporators: T. B. Mahan, John Goias and Frank Owens.

Armerford, Penn.—The Armerford Coal Mining Co.; capital stock, $100,000. Incorporators: Charles C. Pfordt, C. F. Armstrong and A. L. Walker.

Birmingham, Ala.—The Donalison-Grant Coal Co.; to mine and sell coal; capital stock, $5000. Incorporators: G. J. Grant, G. M. and T. M. Donalison.

Salt Lake City, Utah—The Utah Coal Sales Co.; capital stock, $50,000. Incorporators: W. D. McLean, W. O. Bridgeman and George E. Forrester.

Blocker, Okla.—A charter has been granted to the Belt Coal Co.; capital stock, $20,000. Incorporators: James L. Brazell, of Hartshorne, president.

Nashville, Tenn.—The United Mining Co.; capital stock, $10,000. Incorporators: R. M. McMillen, S. M. Copper, Edward Maynard and Henry W. Curtis, Jr.

Nashville, Tenn.—The Southern Ice & Coal Co.; capital stock, $20,000. Incorporators: James H. McCall, O. T. McCall, A. McCall and James H. McCall, Jr.

Camden, Ark.—Dr. George Kimball, and associates, plan the organization of a $1,000,000 corporation to develop coal and clay property in Ouachita County.

Ashland, Ky.—The Southeast Coal Co. has been organized with a capital stock of $1000. The incorporators are John F. Hager, K. M. Fitzgerald and L. S. Wilson.

Charleston, W. Va.—The Camplatt Coal Co.; to develop coal; capital stock, $200,000. Incorporators: W. I. Robinson, H. C. L. Forler, R. M. Mackenzie, A. A. Meyers and A. Meyers.

Packard, Ky.—The Drake Blue Gem Coal Co. has been organized at Packard, Ky., with a capital stock of $8000. The incorporators are T. B. Mahan, John Goins and Frank Owens.

Phoenix, Ariz.—The Frontenac Mining Co.; to deal in coal and other mineral lands and mine coal and other minerals; capital stock, $100,000. Incorporators: Wm. C. Muntz, and others.

Prestonsburg, Ky.—The Beaver Pond Coal Co., has increased its capital stock from $20,000 to $50,000, with a view to extending its operations and enlarging its existing plants.

Houston, Tex.—The G. B. Zigler Co.; to drill, open and work mines for obtaining oil, coal ore, etc.; capital stock, $25,000. Incorporators. G. B. Zigler, W. A. Rowson and N. S. Wishenhunt.

Wheeling, W. Va.—The Richland Block Coal Co.; to develop coal fields; capital stock, $100,000. Incorporators: J. C. Long, H. B. Lockwood, L. W. Brown, Nelson C. Hubbard and L. L. Talbot.

Cleveland, Ohio—The Euclid Brick & Supply Co.; builders' supplies, coal, etc.; capital stock, $100,000. Incorporators: L. J. McFarland, Don B. Swisher, O. B. Long, C. M. Addison and D. Strader.

Phoenix, Ariz.—The Slug Gulch Mining Co.; to deal in coal and other mineral lands and to mine coal and other minerals; capital stock, $400,000. Incorporators: Fred H. Larsen, H. A. Babbitt and others.

Boston, Mass.—The Wakefield Coal Supply Co.; capital stock, $35,000. Incorporators: Edward P. White, F. Horace, Perley, Herbert M. Whitten, Albert R. Perkins, Daniel D. Peabody and George H. Smith.

Birmingham, Ala.—The Black Warrior Mill Co.; to develop coal and mineral lands and to do a general sawmill business; capital stock, $100,000. Incorporators: E. L. More, Cyrus A. O'Nealand, Henry Stanley.

Cleveland, Ohio—The Cleveland & Western Coal Co. has been organized by F. E. Taplin, F. C. Danielson and E. W. Astel. The new company will do a lake and rail business, principally from the Pittsburgh district.

Shawtown, Ohio—The Shawtown Grain Co.; general elevator business, coal, cement, fencing, etc.; capital stock, $10,000. Incorporators: F. S. Burhley, W. S. Moorhead, F. S. Robinson, B. J. Otte and George B. Mulford.

Wilmington, Del.—The Artificial Coal Co., of Philadelphia; capital stock, $100,000; to acquire lease, own and control coal mines of all kinds. Incorporators: J. Howard Much, John D. Wolf, John T. Waite, all of Philadelphia.

Cleveland, Ohio—The Cleveland & Western Coal Co.; to do a lake and rail business. Incorporators: F. E. Taplin, F. G. Danielson, E. W. Astel and J. M. Todd. All the members of the new firm were formerly connected with the Y. & O. Coal Co.

Pine Bluff, Ark.—The Ark-Ol Manufacturing Co. has been organized here to manufacture products from lignite coal. The officers are John Holmes, president and general manager, Clifton Howell, vice-president, and Frank Tomilson, secretary.

Hopkinsville, Ky.—The West Kentucky Fuel Company has been incorporated with a capital stock of $5000, to engage exclusively in the wholesale coal business at that point. The incorporators are Paul Wynn, Sam W. Wynn and James Breathitt, Sr.

Shamokin, Penn.—A charter has been granted to the Northumberland Coal & Coke Co., of Shamokin Dam, Penn., with capital stock of $10,000. The company intends to mine and market coal and will establish a coaling station at Shamokin Dam.

Jefferson City, Mo.—A charter has been granted to the George E. Smith Coal Mining Co., Hudson Township, Macon County; capital stock, $5200. Incorporators, George E. and Annie Smith, Andrew H. Clark, Roy D. Conley and John Parker McCanne.

Birmingham, Ala.—The Donaldson-Grant Coal Co., Inc., has been incorporated with C. J. Grant as president and general manager and J. M. Donaldson as secretary-treasurer; capital stock, $5000. The company will do a general coal mining and selling business.

Concho, W. Va.—The Rock Lick Coal Co.; to mine coal in Fayetteville district of Fayette County, W. Va., drill for oil and gas; capital stock, $200,000. Incorporators: Angus W. McDonald, Y. L. Black, O. P. Fitzgerald, John Wherle and L. G. Summerfield, all of Charleston.

Punxsutawney, Penn.—The Brush Creek Coal Mining Co.; to mine, quarry, excavate and bore for and otherwise produce coal, iron ore, limestone, fireclay and other minerals and substances. Incorporators: Lucius W. Robinson, Lewis Iselin, B. M. Clark, F. H. Beck and J. W. Brown.

Columbus, Ohio—Papers of incorporation have been filed with the secretary of state of Ohio for the Kittaning Coal Co. of Columbus with a capital stock of $10,000, to mine and deal in coal. The incorporators are, C. E. Leslie, A. H. Jones, J. C. Yontz, Herbert M. Myers and M. H. Recob.

Cincinnati, Ohio—The Beaver Fond Coal Co. has started new financing in the shape of an increase of the capital stock from $20,000 to $50,000. The new issue is to be in the shape of preferred stock at 8 per cent., par value $100. Headquarters of the company are at Prestonburg, Ky., at the mines.

Charleston, W. Va.—For the purpose of mining coal, drilling for oil and gas, operating coal washeries, mills and manufacturing plants, in Brooke County, W. Va., a charter has been issued Richland Block Coal Co., Wheeling; capital stock, $100,000. Incorporators: J. C. Mclnley, H. B. Lockwood, L. W. Brown, Nelson C. Hubbard, and L. L. Talbot, all of Wheeling.

INDUSTRIAL NEWS

Indianapolis, Ind.—The South Side Lumber & Coal Co., Kokomo, has increased its capital to $20,000

Columbus, Ohio—The D. A. Thomas Coal Co. will develop about 1000 acres of coal land near Seng, W. Va.

Sullivan, Ind.—Twenty-five land owners in Curry Township have filed deeds for part of thir land to the Indiana Coal Co., and it is expected mining operations will begin promptly.

Shamokin, Penn.—While engaged in driving a tunnel at the Bear Valley shaft, owned by the Philadelphia & Reading Coal & Iron Co., workmen uncovered a 7-ft. seam of fine anthracite coal.

Ryder, N. D.—While drilling for artesian water on the Ben Rosenberg claim near here, the drillers struck a seam of coal at a depth of 170 ft. Samples of the coal will be sent to experts at the university for testing.

Connellsville, Penn.—The Berwind-White Coal Mining Co. is developing a mine between Harborton and Pan, Va. The shaft will be 600 ft. deep. The company will build a town which will have 750 dwellings, and will open a 12,000-acre tract.

Philadelphia, Penn.—Philadelphia capitalists are making overtures for the purchase of the 10,000-acre tract of coal land recently taken over by Howard Davis, of Conemaugh, George Gore, of Johnstown and others, at Garway, near Hastings.

Artemus, Ky.—The Anchor Coal Co. has been purchased by J. B. Rogers and associates, and the company will be reorganized, with Mr. Rogers as general manager. The facilities of the plant, and its capacity, are to be increased by the installation of additional machinery.

Belle Vernon, Penn.—Men from Monessen will open a 540-acre tract of coal in the Indian Creek Valley next week. John I. Rogers' plant has been taken over by Pittsburgh men and the output will be increased to 200 tons a day. The Pittsburghers will take charge at once.

Altoona, Penn.—The Pennsylvania Coal & Coke Co., operating mines throughout Cambria County, will this summer electrify all its working. The Penn Central Electric Co. of this city will furnish the power. The company will also build new offices at several of its mines.

St. Louis, Mo.—The Mississippi River Commission, Major Clarke S. Smith, secretary, Liggett Building, is asking for sealed proposals for furnishing 380,000 bushels of coal in barges, to be opened at noon, on Apr. 5. Major Smith will furnish all necessary information on the subject.

Welch, W. Va.—The Pocahontas-West Virginia Coal Co., a new operation at Leckie, nineteen miles above Welch on the Tug Fork branch is pushing its work rapidly. Mine No. 1 is equipped with electric power and No. 2 with a gasoline engine to haul the coal. William Leckie is president.

Connellsville, Penn.—The Jamison Coal & Coke Co. is electrifying all of its mining and coking plants in the Greensburg-Connellsville field, substituting electricity for compressed air. Fifteen locomotives, electrical machines, dynamos and generators have been purchased, and nearly all of the new equipment has been installed.

Columbus, Ohio—Pennsylvania Railroad officials here have announced that the Sandusky docks of this company will be extensively improved before the opening of the navigation season. It is expected that the capacity practically will be doubled and new loading machinery added, which will greatly facilitate the coaling of vessels.

Pittsburgh, Penn.—The Buffalo & Susquehanna Coal Co. will hereafter pay the miners regularly on the 15th and 30th of the month, instead of at somewhat irregular times twice a month. In some of the mines the men are to be allowed to load something more than the former exact two tons to the car. This will result in an increase of earnings.

Irwin, Penn.—The Penn-Westmoreland Coal Co. a new organization, has taken over the J. A. Guy block of four-foot coal, just east of West Newton and expects to put the product on the market this summer. The tract comprises about 100 acres, $60,000. The company has purchased from Charles Suter ground for tipple. A. R. Byers, of New Stanton, is president.

Binghamton, N. Y.—With nearly 500 acres of land situated just northeast of Port Crane, leased or sold to Scranton capitalists, the plan to mine coal in that village is fairly well under way. The H. A. Allerton farm of 150 acres and the William Bunzey farm of 100 acres are among those said to have been leased to the Scranton people. Boring will be started as early as possible.

Brockwayville, Penn.—C. A. McDonald and other DuBois men have leased the mine property at Westville formerly operated by the Jefferson Coal Co. and are re-opening the same for the purpose of shipping coal. They will also lease an additional ten to twenty acres. The new company will be known as the Sandy Lick & Rochester Mining Co., and will be managed by Mr. McDonald.

Morgantown, W. Va.—A deal for the sale of 500 acres of coal in the Union district has been consummated. Surface, Pittsburgh, Sewickley and all other seams of coal were sold to W. H. Seymour, of Pittsburgh, and the price was $300 an acre. The property is situated between the Stewartstown and Warm Hollow roads in the Union district. The purchasers expect to develop it without delay.

Nicktown, Penn.—Options on what is probably the biggest undeveloped tract of coal in Cambria County are being taken by Anselm Kirsch and his brother, A. F. Kirsch. Between 6000 and 7000 acres are involved. It will eventually fall into the hands of the Manor Real Estate & Trust Co. The deal, if put through will mean the exchange of something like $600,000. Between 50 and 60 owners will get a portion of this sum.

Louisville, Ky.—Certain well-defined rumors current in the Harlan field indicate that foreign capital other than Welsh is on the verge of becoming heavily interested in that region. Exact details of the deal are not yet available, but it is stated on good authority that French interests are involved in a purchase which has practically been arranged. A few days more will probably see its consummation, and full details will be published.

Whitesburg, Ky.—A big Letcher County deal, recently reported, is that closed by Maxwell & Litts, of Wise County, Va., for a tract of about 2000 acres, lying on the proposed line of the Cincinnati, Licking River & Virginia R.R. The development of the property will probably await the construction of the road, which promoters intend to begin this spring or summer.

Waynesburg, Penn.—P. J. Bradley and J. J. Koelfert closed a big sale of coal with Fayette County parties last Saturday. They disposed of 490 acres of coal in Wayne and Gilmore Townships, Green County, at a consideration of over $100,000. Local parties who owned the coal are P. J. Bradle, J. J. Koebert, J. L. Rush, Delbert Orndoff, R. E. Kent, of Waynesburg; Frank Gump, of Mt. Morris, and Dennis and Peter Meighen, of Jollytown.

Pittsburgh, Penn.—At the request of a number of customers, the Goodman Mfg. Co. has decided to open a repair and supply department in Pittsburgh. This will be known as the Pittsburgh Repair & Supply Department, 700 Phipps Power Building. E. Kent Davis will be manager.

The electrical repairing done in this shop will be of the same high-grade character as they do in their Chicago shops.

The Goodman company is now carrying in Pittsburgh a small stock of shortwall machine parts, and expect, within a short time, to have a complete stock of parts for this type of machine.

St. Louis, Mo.—Representatives of the Eastern Coke and Coal Syndicate who have been here two months are said to have options on tracts of land on both sides of the river. They are reported to have obtained nearly 200 acres on both sides of the River Des Peres, between Broadway and the Iron Mountain Railroad.

Part of the tract was owned by the Laclede Gas Light Company. Julius Pitzman, civil engineer and investor, who owns a large tract there, says that he has been dealing with a prospective buyer, but that he does not know whom the agent represents.

Cincinnati, O.—Details have been arranged for the transfer of coal property which involves over half a million dollars and which will be the second large holding of the Canadian coal interests in the West Virginia fields.

Captain Michael Roach, the president of the New River and Ohio Coal Co., has arranged the sale of the properties to the Lake Superior Coal Co., which is a subsidiary of the Superior Co., the largest coal, iron and paper pulp producer of Canada.

This company bought the Cannelton Coal & Coke Co., in the Kanawha district. Coal from these mines is shipped to the headquarters at Sault Ste. Marie.

Pineville, Ky.—It is reported that the Harlan Coal Mining Co. has recently leased to the Lick Branch Coal Co., composed of John W. Williams and associates, its recently completed coal-mining plant at Croxton, Ky., in the Harlan field. The new plant is one of the largest in capacity and most up-todate in equipment in the eastern Kentucky field, and under the management of the experienced operators who have leased it, is expected to cut a considerable figure in the production figures. It is probable that with this plant off its hands the Harlan Coal Mining Co. will shortly begin the construction of another plant in that vicinity. The lease referred to is said to provide for minimum royalties aggregating $100,000 during the first five years, with the privilege of renewal for an additional five years, during which period the royalties are fixed at a minimum of $125,000.

COAL TRADE REVIEWS

GENERAL REVIEW

Anthracite orders for April delivery, when the spring discounts will be in effect, are coming in rapidly, and indications are that the trade will be active over that month. In fact, some believe that production will be so heavy through April and May that June, and even July, may find prices still below the April circular.

At the moment, the hard-coal market is slow and dull. It has been definitely announced that the customary spring discount will go into effect the first of the month, so consumers are cutting orders to the lowest possible minimum, in order to avoid carrying over any of the high-priced product. As a result, current orders are scarce. Production is still being restricted, and some stocks are being accumulated. Egg is particularly easy and is being freely offered at well below the April circular; pea size continues the strongest of the hard-coal grades.

Conditions in the Eastern coast-wise bituminous trade are unsettled and inclined to be a little tense. Pocahontas and New River operators are actively seeking contract business, but the consumers do not believe they are justified in the large increase they are demanding over last year's quotations, and, as a result, little business is being closed, and the contract market is decidedly dull. Spot prices are ranging 10 to 15c. below contract asking prices. Pennsylvania operators are holding off on prices, pending a more settled condition in the labor situation in West Virginia, which now appears to be assuming serious proportions. In the event of extensive trouble there, the Pennsylvania operators will be materially benefited. What contracts are being closed are for uniformly heavier tonnages than during the previous year.

The Pennsylvania and the Western Maryland railroads have both announced that, effective Mar. 20, they would accept consignments for Lake destinations, and it is believed the initial shipments will be heavy. Deliveries on the Northern border are still a trifle uncertain, but railroads are rapidly gaining control of the situation; consumers in this district point to numerous low prices being quoted, but dealers claim the trade is steady and showing a strong tone. In the Pittsburgh district shipments to the Lake trade are rapidly increasing.

The demand in Ohio continues fair, and there is considerable activity in renewing contracts; operators believe that industrial conditions are steadily improving and that consumers will soon be in the market for a large tonnage. The domestic dealers have fair stocks and will be out of the market until the fall stocking begins; prices remain at a rather low level. Coal continues to accumulate at Hampton Roads, in spite of some curtailment on the part of the operators, who are, however, firm in the belief that there will be a distinct improvement in the trade shortly. The dumping is rather light, and few contracts are being let, but there is a good demand on the existing ones, and the export business continues to show a steady increase.

The Middlewestern retailers have definitely concluded buying for the current year. Prices are down to the summer schedule and are showing no disposition to change. There is a total absence of activity in the trade.

BOSTON, MASS.

There is much uncertainty over bituminous prices. Most of the agencies for Pocahontas and New River are actively seeking contract business on the $2.85 f.o.b. Hampton Roads basis, but only a small share of the total tonnage of those coals for New England is understood to have been placed. The larger buyers particularly, are declining to accept so high a figure, feeling that conditions do not warrant so large an advance over 1912, both on coal and on water transportation. The result is that the contract market is decidedly dull. The fact that spot coal is still being offered more or less freely at from 10c.@15c. less than on contract, and that certain shippers are going slow on commitments after Apr. 1, in view of possible labor troubles in the New River field, makes the outlook rather complicated. The Georges Creek and Pennsylvania shippers are awaiting developments on the Southern coals before announcing their own season prices, so that in general the spring prospects on bituminous are more or less mixed.

Georges Creek is now coming to tide in better volume and the demand seems right up to the supply. Coals from the Pennsylvania districts are being railed only on orders and there is only a moderate call for the medium grades. Demurrage has been paid for coal standing at Philadelphia and at New York, but the accumulation was not significant and is now well cleared up. Prices at the mine are practically unchanged and the movement all-rail is steady for the more popular coals.

Water freights are strong at 95c.@$1, Hampton Roads to Boston, with 75@85c. on yearly contract on large vessels. The Reading barge rate on bituminous has been reduced, however, from 90 to 80c., Philadelphia to Boston. On Long Island Sound freights from New York are 40@50c., with a demand now for anthracite shipment the last of March at April prices.

Anthracite is expected to start in with a rush Apr. 1. Orders have been filed for all the Eastern points and shipments are expected to be heavy until the retailers get their storage filled and call a halt. There is quite a tonnage being carried over at almost all the New England points and the weather is so mild that this situation is not likely to improve.

With a fair amount of domestic sizes taken on in April and May the dealers are likely to rest on their cars until the demand from the public begins to deplete their stocks. Egg is in the least demand and continues to be offered by the independents at prices well below the anticipated April circular. There is a fear on the part of some anthracite buyers that there will be such a surplus of individual coal mined in July that prices then will be as low or lower than the companies' list for April. This feeling is not shared, however, by the dealers who have had experience before with dull years in anthracite. At least, those whom the companies served well in 1912 are apparently quite willing to let the same companies fill them up during April and May.

Present wholesale quotations are about on the following basis:

Clearfields, f.o.b. mine	$1.25@ 1.45
Clearfields, f.o.b. Philadelphia	2.50@ 2.70
Clearfields, f.o.b. New York	2.80@ 3.00
Cambrias, Somersets, f.o.b. mines	1.30@ 1.65
Cambrias, Somersets, f.o.b. Philadelphia	2.55@ 2.90
Cambrias, Somersets, f.o.b. New York	2.85@ 3.20
Pocahontas, New River, f.o.b. Hampton Roads	2.65@ 2.80
Pocahontas, New River, on cars Boston	3.80@ 3.90
Pocahontas, New River, on cars Providence	3.75@ 3.90

NEW YORK

Bituminous—There are rumors current in the local market that a number of the smaller operators have succeeded in closing contracts covering their production over the next contract year. This would seem to indicate an increased activity in contracting, but since only the smaller companies were mentioned in this connection, the tonnage involved is probably not large. As a matter of fact, operators are finding it difficult to close, particularly with the larger consumers, who are holding off, apparently in hopes of a sharp decline in the spot market, which would naturally have a sympathetic effect on contract business.

There has been little change in the prompt market, which still continues rather dull and weak, particularly on the lower grades. The better qualities are in good demand and slightly short in supply. Stocks of all kinds and size at tide have fallen off considerably during the week. Production is still being curtailed, especially those operations producing off quality. Prices have experienced no change, except on the West Virginia steam grade, which we quote 5c. off of the price prevailing over the last three weeks, the market being about as follows: West Virginia steam, $2.55@2.60 fair grades, Pennsylvanias, $2.65@2.70; good grades of Pennsylvanias, $2.75@2.80; best Miller, Pennsylvania, $3.05@3.15; Georges Creek, $3.25@3.30.

Anthracite—Several of the large companies have sent out instructions to their agents to the effect that the customary spring discount on the domestic grades will go into effect Apr. 1 as usual. With this feature finally eliminated from consideration, buying is becoming even more restricted, and there is an almost total absence of any demand for the domestic sizes; dealers and consumers generally have sufficient coal on hand to carry them over until the first of the month, and consequently there is no incentive to buy.

Production in the mining regions is still being curtailed, most companies laying off on an average of three days per week. However, this feature is being welcomed by the operating departments, who are taking advantage of the idle time to effect repairs which have been accumulating for several months, while the mines were working under a heavy pressure. With the lowest prices of the year in effect next month, it is expected there will be a great deal of activity in the trade. All sizes are in ample supply, with the exception of pea, which, as has been the case for several months, is a little difficult to obtain.

Quotations have not undergone any material change during the week. Both stove and barley have suffered a slight decline, while chestnut is quotable on a little higher basis. The following are the nominal New York prices on hard coal:

	Circular	Individual—Lehigh	Individual—Scranton
Broken	$5.00	$4.50 @ $5.00	$4.50 @ $5.00
Egg	5.25	4.55 @ 5.20	4.75 @ 5.25
Stove	5.25	4.70 @ 5.20	4.75 @ 5.25
Chestnut	5.50	4.95 @ 5.45	5.00 @ 5.50
Pea	3.50	3.45 @ 3.55	3.50 @ 3.60
Buckwheat	2.75	2.00 @ 2.45	2.50 @ 2.75
Rice	2.25	1.80 @ 1.95	2.25
Barley	1.75	1.10 @ 1.50	1.60 @ 1.75

PHILADELPHIA, PENN.

About all the dealers are doing now is waiting for Apr. 1, when the reduction in the price of anthracite goes into effect. It is practically understood now, that there will be the same reduction as customary in normal years. Some of the companies have already issued circulars making this announcement. The individual operators have been using this April price as a basis for some time past, and even so are not having particularly easy sledding in getting rid of their product. Dealers are loth to turn down an offer for a car of egg, stove or chestnut at fifty cents off the present circular prices, but when it comes to putting on coal now that they really do not require, that is another matter. The thought of the premiums of $1.50 to $2 per ton they were compelled to pay to these same individuals no less than three months ago, still lingers in their minds, and there will undoubtedly be lots of feeling manifested in the placing of orders during the coming season. Companies that took care of their own trade and gained new friends, are likely to hold on to them.

It is useless to speculate on the coming business for the month of April as it could not help being good. Every dealer has a little space that he would like to see filled up at the reduced price, and this will make an active demand, which perhaps may be duplicated in May. The weather for the balance of March is not likely to be conducive to the clearing up of stocks purchased at the old prices, and in almost every case, some coal will be carried over. It is understood that the large companies are still receiving orders for the prepared sizes, but they are few and far between, and it is further understood that they are obtaining the full prices.

Instead of reduction in quotations Apr. 1, there is talk among bituminous operators of advancing the price on contracts after March 31, and as a consequence, there is a little flurry to get as much of the old-priced coal as possible. This is particularly true at Tidewater points, where considerable coal is moving. Whether the threat will hold good remains to be seen, but judging from present conditions, it will be a difficult position to maintain. The soft-coal trade at this time seems to be willing to take almost anything that is offered, in the way of prices.

PITTSBURGH, PENN.

Bituminous—Mining and shipping of coal for the Lake trade has increased and is now of considerable proportions, although practically confined to Lake shippers who have mining interests of their own. The production of so much ¾-in. coal has naturally increased the supply of slack which has resulted in the premium for this coming off, the slack market being now quotable at the regular figure of 90c. The coal market as a whole is not overly firm, chiefly because a number of small operators are indifferently well supplied with contracts and are occasionally cutting prices. The large interests are adhering closely to schedule prices, which we continue to quote as the general market: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in., $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—Demand for both spot and contract furnace coke has continued extremely light, but for foundry coke it is slightly improved. Production has decreased a total of 30,000 tons a week, according to the last report, and the position is sound, as actual consumption is fully up to the record. The decrease in production has been due chiefly to restriction by operators making off coke, which can hardly find a market now at any figure. In December and January cokes running above 1.25 per cent. in sulphur and very high in ash were accepted in lieu of anything better, but today furnaces will hardly consider a badly cut price if it involves coke running even a tenth per cent. above the recognized sulphur limit of 1 per cent., or running much above 12 per cent. ash. Such off cokes are available, at least as low as $2.20 for prompt furnace, and perhaps might be had at $2. Standard furnace coke we quote fairly firm at $2.40, with contract nominally at $2.50. Foundry coke is quotable at $3@3.50 for both prompt and contract, depending on grade, per ton at ovens.

BALTIMORE, MD.

The orders so far booked by the Consolidation Coal Co., for delivery during the next six months, show an increase of over 500,000 tons as compared with the same period of the previous year; this is mostly for coal from the Fairmont field. This increase in tonnage has done much to revive hope in the Baltimore market.

By the last of the week, coal from the West Virginia and Pennsylvania fields will begin moving to the Lakes. The Western Maryland Ry., following in the footsteps of the Pennsylvania, has notified shippers that the road would accept Lake shipments on Mar. 20. All business received will be forwarded to Buffalo and other lake ports and held there until the Lake traffic opens. There is considerable business ready to be turned over to the roads, and it is believed that the initial shipments will be large.

Prices softened a bit on spot business during the week, where low-grade coals were concerned; sales were reported under $1. But only a slight change took place in the price of the better grades. The car situation seems to have been eliminated as a factor in the trade. About the usual activity was witnessed at the railroad piers. The coke market continues fairly firm and there has been a slight reduction in the output of the product, especially in the Connellsville region.

BUFFALO, N. Y.

There is still much complaint that the railroads are making uncertain deliveries and thus complicating the bituminous trade badly. One operator says that he has been billing out coal for ten days, but none of it has yet reached destination. It looks as though the roads were getting farther behind in certain branches of their business in spite of the fact that the weather is more favorable to quick despatch.

Another disturbing element in the bituminous trade is the resumption of shipments to the Lake ports. There is such a shortage of coal in the Northwest that much lake tonnage will be loaded before the opening of navigation. A favorite size for this trade is three-quarter, which necessitates the turning out of a great amount of slack and sometimes breaks that market badly. Often the Lake firemen refuse to handle anything but three-quarter for steamer fuel and that also increases the amount of slack.

There is more unsold bituminous on track generally than for sometime, so that everything indicates a period of quiet trade. There will be small fluctuations that the active salesman will take advantage of, while the slow one will get left. The contract season is on and there is some indication that prices are to be held stiffer than they were last year. The lowest bid for furnishing nut and slack, to the Buffalo State Hospital, is $1.99, as compared with $1.92 last year; the bidder who obtained the contract last year now bids $2.05, which shows what he thinks of the business. It is understood that there is likely to be a good amount of docking for ash and other tests.

Buffalo anthracite shippers are loading considerable hard coal into lake steamers, but the D., L. & W. is handicapped by a dispute with the government over possession of the dock. It now appears that the fast-accumulating anthracite will have to be dumped in great part, as a loaded steamer is grounded at the Lehigh Valley dock, blocking it completely.

Bituminous prices are held pretty firmly in spite of the lack of demand, on the basis of $2.80 for Pittsburgh lump, $2.65 for three-quarter, $2.55 for mine-run and $2.15 for slack, with Allegheny Valley and Reynoldsville 15 to 25c lower. It is said that coke is becoming firmer, but jobbers generally admit that it does not sell here for more than $5 for best Connellsville foundry.

COLUMBUS, OHIO

While the weather has not been favorable for an active coal trade, there has not been any great falling off during the past week. There is a fair demand for tonnage from

steam users and considerable activity is shown in the renewing of fuel contracts by the railroads. The domestic trade is a thing of the past and operators and shippers are looking forward to a rather active Lake trade.

Dealers have pretty fair stocks generally. This means that they will not be in the market for much coal until the stocking up period begins later in the season. On the whole the retailers had a pretty fair trade despite the unfavorable weather conditions. They secured good prices generally and not a great deal of trouble was experienced in obtaining prompt deliveries from the mines.

Operators, especially those who engage in the Lake trade, are anticipating a good demand from the Northwest. Reports from that section show that the docks have been well cleaned up and this means an active season. Improved dock machinery is being installed at many places in order to take care of the expected increase in tonnage.

Prices are still at a rather low level and no improvement in that direction is expected for the time being at least. Dock prices have not yet been determined and there is a strong movement to place them back to the level of two years ago, before the recent decline. Chartering of boats is going on and everything is being arranged for the opening of navigation.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawh
Domestic lump	$1 40	....	$1.50	$1.40
¾-inch	1.30	$1.20	1.35	1.30

HAMPTON ROADS, VA.

There has been little actual change in the coal situation at Hampton Roads; prices remain at about the same level, few contracts have been let and the dumping has been comparatively light. The accumulation of coal still continues notwithstanding light loading and some curtailment of output, the effect of which will appear later. An encouraging feature is the steady demand on existing contracts, which, with the growing export tonnage, represents about all of the coal loaded at the piers during the past week.

There is more talk of labor troubles in the smokeless coal fields and there is undoubtedly a deep feeling of unrest among the miners. To combat this one of the larger New River operators has voluntarily given some concessions to the men, in the shape of a two-weeks' payday and a nine-hour day. It is also said that the Berwind interests in the same field have announced substantial concessions.

What changes the coming two weeks will show in prices, it is difficult to predict, but those best informed anticipate a change for the better and a stronger demand. There is no doubt of the steady contract growth of the export business, emphasized by the shipments to markets not entered by our coals until lately and by the increasing prestige of these abroad, as shown by the items in the foreign trade papers regarding the American product.

LOUISVILLE, KY.

It is rather odd that there is almost as much domestic coal moving from the mines as during any time in the fall and in December, when the demand was brisk, in anticipation of some real winter weather, and the car shortage kept the mines down to about half-time. The poor demand now has cut operations down to about the same extent. Sales are only to supply current requirements, as dealers are doing little stocking, being generally pretty well supplied.

Prices remain at about the same levels as heretofore reported. The best grades of Jellico block are quoted at $2 a ton f.o.b. mines, with 3-in. lump and block at $1.85, and larger sizes at $1.90, but it is doubtful what sales are being made. Round is priced at $1.60, with domestic nut at about $1.50. The best grades of nut and slack from both the eastern and western Kentucky districts can be had for 75c., the lower grades being available in fair quantities at 50 to 60 cents.

BIRMINGHAM, ALA.

The increased requirements of the blast furnaces in this district are serving as an excellent stimulant to both the steam coal and furnace coke markets. Keen competition from other districts seems to have weakened the foundry-coke market, but the quality of Alabama cokes, due largely to superior methods of preparation, is enabling local producers to obtain higher competitive prices than ever before.

Contracts are being closed rapidly for the year on domestic coal, all protests against the recent increase in price having apparently disappeared. One of the largest producers of Cahaba coal reports their April output fully sold up. Industrial conditions in the South are, as a whole, on a prosperous basis and the outlook for the year is bright.

The state mine inspector's office has given out Alabama coal-production figures for the year 1912, the exact output being 16,513,040 short tons. These figures are somewhat below early estimates, the production for the latter half of the year having been cut down considerably on account of shortage of cars. Equipment is plentiful at this time and the rate of production is much higher than the average of 1912.

INDIANAPOLIS, IND.

There is little change in the Indiana coal situation; prices, having got down to about the summer schedule, are showing little or no change. It is reported that there are mines ready to make alluring concessions but operators in general say it would be useless, especially on domestic grades.

Retailers have practically finished buying for the present coal year and will be glad to be able to dispose of all they contracted for. Considerable more coal has been available since the new year opened than usual in this city. The declining prices at the mines, when January showed that the winter was going to be mild, enticed new ventures in the trade, for it was seen that the old established operators would have to hold up prices on account of having made high contracts in the fall, when the supply situation looked ominous. The smaller ones have been making considerable fuss about their cut prices.

The standard retail prices in this city are:

Anthracite, nut	$9.25	Winifred	4 75
Anthracite, grate, egg and stove	9.00	Falling Rock, cannel	6.50
Lump	6.50	Linton lump	3.75
Pocahontas, forked		Linton, egg	3 75
Pocahontsa, shoveled lump	6.00	Hocking Valley	4 75
Pocahontas, mine run	5.00	Hocking Valley, egg	5.00
Pocahontas, nut and slack	4.00	Brazil block	4 50
Blossburg	5.50	Gas house lump coke	7.00@8.00
Ohio Jackson	5.75	Crushed gas coke	7.00@8.00
Raymond	4.75	Citizens oven coke	7.00@8.00
Kanawha lump	75	Connellsville coke	7.50@8.00
Pittsburgh lump	4.75		

DETROIT, MICH.

Both steam and domestic consumers are showing much indifference in the matter of placing orders and the operators and shippers find business dull. There is little or no difficulty in getting shipments through from the mining districts, and buyers of steam fuel are taking advantage of this, and seem to think they will be able to pick up whatever fuel they require whenever they need it and at almost their own quotation; domestic coal users appear to be suffering no urgent need of replenishing their stock. Weather conditions during the week have been unusually mild. Operators and jobbers are looking forward to the opening of Lake navigation, which seems to be only about two weeks distant

The prevailing prices for today are as follows:

	W. Va. Splint	Gas	Hocking	Cambridge	Ohio No. 8	Pocahontas	Jackson Hill
Domestic lump	$1 40	....	$1.40	....	....	$1.75	$1 90
Egg	1 40	....	1.40	....	....	1.75	1 90
Nut	1 30	....	1.30	....	....	....	1 50
1½-in. lump	1.25	....	....	....	....	....	....
¾-in. lump	1 10	$1 10	1 10	$1.10	$1 10	....	....
Mine-run	0 90	0 90	0 90	0 90	0 90	1.25	....
Slack	0.80	0.80	0 80	0 80	0.80	1.10	....

Anthracite—Hard coal is coming in, in large quantities at present, and with the unusually mild weather, it is causing the market to be flooded with all sizes. The jobbers who have large supplies of independent coal on hand are disposing of it at from 25 to 50c. below circular. In a few instances demurrage has accrued on some of this fuel.

MINNEAPOLIS—ST. PAUL

The general brizzard which has prevailed during the past week has been a very great relief to both wholesalers and retailers, and should cut a large hole in the stocks of coal on hand. Wholesalers are again hustling for new business, and beginning to agitate the storage question. Salesmen, who have been idle since the first of the year are again on the road, and while their orderbooks are not being filled very readily they are turning in some business.

Circulars for Apr. 1 are in the hands of the printers and the phrase "Subject to change without notice" will be prominently displayed. Anthracite at Lake Michigan and Superior points on Apr. 1 circulars, is quoted at $6.25 for egg and stove, $6.50 for chestnut, $5.25 for pea and $4 for buckwheat. It is expected with continued mild weather the opening of navigation will be early this year in which event large shipments will reach the docks during April and May.

Prices on all grades of Illinois coal are still unsteady and Franklin County, Harrisburg and Carterville coals can be bought for anywhere between $1 and $1.50 for prepared sizes at the mines. New River, lump and egg, from the East is

selling for $1.35 at the mines and Pocahontas can be had at the same price; mine-run is selling for as low as $1 at the mines.

CHICAGO

There is a continued lack of activity in the Chicago coal market. No demand exists for domestic coal, retailers declining to increase their stocks lest they be compelled to carry a large part of them over into the summer. Domestic grades are not being produced by the mines except where it is necessary to do so in order to obtain fine sizes to apply upon contracts. Scarcely any orders are being received from the retailers for high-grade, southern Illinois coal. Operators in the Springfield district and producers of various Indiana coals are making no effort to sell their domestic product in Chicago. A number of them have changed their screens to make steam lump coal and others are disposing of what domestic they have at points nearer the mines.

The smokeless trade is unusually dull. Until the latter part of February, smokeless operators reported large sales at satisfactory prices. Business among dealers in anthracite continues to be slack. Prevailing prices in Chicago are:

	Sullivan Co.	Springfield	Clinton	W. Va.
Domestic lump	$2.47	$2.07 @ 2.22	$2.27	.....
Egg	2.47	.....	.....	$3.95
Steam lump	$2.12 @ 2.37	1.92 @ 1.97	2.17	.....
Mine-run	.....	1.87 @ 1.92	1.97	3.30
Screenings	1.67 @ 1.72	1.57 @ 1.62	1.67	.....

Prevailing prices for coke are: Connellsville and Wise County, $5.75 @ 6; byproduct, egg, stove and nut, $5.50; gas house, $5.50.

ST. LOUIS, MO.

A slight touch of winter, following an unusually pleasant spell of spring weather, brought about a slight demand for domestic coal in St. Louis the early part of the week, but it was of short duration and did not cause any change in prices.

Everything indicates that it will be a dragging market for the balance of the spring, and the operators are curtailing their tonnage, some of them having closed down.

There is considerable demurrage coal at diverting points, and it is usually sacrificed at prices far below the cost of production. The circular is:

	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard
2-in. lump	.....	.....	.....	$0.85 @ 0.90
3-in. lump	.....	.....	$1.25	.....
6-in. lump	$1.20 @ 1.25	.....	1.35	1.10
Lump and egg	1.25	$2.25	.....	.....
No. 1 nut	1.10 @ 1.15	.....	.....	.....
Screenings	0.90 @ 0.95	.....	.....	0.65
Mine-run	1.05 @ 1.15	.....	.....	0.85
No. 1 washed nut	1.40 @ 1.50	.....	.....	.....
No. 2 washed nut	1.35 @ 1.45	.....	.....	.....
No. 3 washed nut	1.25 @ 1.30	.....	.....	.....
No. 4 washed nut	1.15 @ 1.20	.....	.....	.....
No. 5 washed nut	1.00 @ 1.05	.....	.....	.....

OGDEN, UTAH

Coal shipments from Wyoming and Utah have dropped off in the past week and the mines in both states are experiencing idle days, due to lack of orders. This has decreased the production of slack and at present there is no appreciable surplus on the market.

Warm weather is prevailing generally over the territory west of the Mississippi River, and the demand for coal is decreasing. The over-production of nut coal continues, and there is quite a surplus of this grade at the mines drawing demurrage. Now that winter is practically over, and there is a diminishing call for lump, the mines will be compelled to decrease operation, and this will tend to keep down the surplus nut coal.

Conditions in Nebraska have not improved and it now develops that the Wyoming operators were unable to take care of the market during the fall and winter and the dealers were compelled to look elsewhere for coal. This gave the Colorado producers a chance to gain a foothold and as a consequence a portion of the spring and summer trade will go to them. This condition was caused by the car shortage during September, October and November.

May and June quotations for shipments to Nebraska have been announced as follows: Lump, $2.25; nut, $2; mine-run, $1.75; slack, $1. Quotations for the balance of the territory remain unchanged as follows: Wyoming Lump, $2.75; nut, $2.25; mine-run, $1.85 and slack, $1; Utah lump, $2.75; nut, $2.25; mine-run, $1.85 and slack, $1.25.

PORTLAND, ORE.

The coal market here is quiet at this time, being between seasons. The demand is light and prices are unchanged, with no probability of any occurring until the summer rates go into effect. This will probably be in July as usual, when people begin to put in supplies on the strength of the reduction of $1 per ton for storage. So far there has been no indication of any Australian coal coming this way during the summer, although it is yet early, since chartering of carriers for the summer and fall business has not yet opened, excepting in some cases for lumber.

PRODUCTION AND TRANSPORTATION STATISTICS

COAL MOVEMENT

The following is a comparative summary of the coal movement in January of this year and last year as reported by seven of the largest railroads or districts in short tons except where otherwise noted:

	1913	1912
Anthracite shipments (long tons)	6,336,419	5,763,696
Penn. R.R. (bituminous only)[1]	5,498,710	4,522,296
Baltimore & Ohio[2]	3,442,580	2,443,528
Norfolk & Western	2,218,125	1,819,588
Philadelphia & Reading[3]	1,624,298	1,088,697
Chesapeake & Ohio[4]	1,293,043	1,337,216
Virginian Ry.	453,886	317,405
Total	20,869,061	17,292,426

Net Increase 20.7%

[1]On lines east of Pittsburgh and Erie only. [2]Includes coke and that from affiliated lines. [3]Bituminous only. [4]Includes coke and anthracite.

Note—Tonnage included in this table covers nearly 10% of the country's production and the results may be taken as a fair criterion of the progress of business.

CHESAPEAKE & OHIO RY.

The following is a comparative statement of the coal and coke traffic over the lines of the C. & O. Ry., for January, and the seven months ending Jan. 31, 1912-13, in short tons:

	January		Seven Months	
Destination	1913	1912	1913	1912
Tidewater	377,520	335,290	2,068,111	2,305,754
East	393,493	212,524	1,518,698	1,282,149
West	489,985	749,893	5,437,455	6,485,458
Total	1,170,998	1,297,707	9,024,264	10,073,361
Coke	30,764	17,440	165,700	128,037
From Connections				
Bituminous	92,894	18,914	334,565	136,240
Anthracite	378	3,155	7,349	21,904
Grand total	1,295,034	1,337,216	9,531,878	10,359,542

NORFOLK & WESTERN RY.

The following is a statement of tonnages shipped over this road from mines in West Virginia and the commercial and company coal, for the month of February, in short tons:

Field	Shipped	Tipple	Total	Commercial	Company
Pocahontas	793,880	17,158	811,038	1,009,520	127,882
Tug River	192,545	3,809	196,354	158,212	38,142
Thacker	252,527	8,955	261,482	179,584	81,898
Kenova	64,018	9,173	73,191	61,491	11,700
Clinch Valley	.....	.....	.....	136,904	8,121
	1,302,970	39,095	1,342,065	1,605,801	267,743

Shipments of coke entirely from the Pocahontas field, were 121,058.

FOREIGN MARKETS

GREAT BRITAIN

Feb. 28—Large and small coals of all descriptions are scarce and values firm with an improving tendency. Today's quotations are approximately as follows:

Best Welsh steam	$4 62@4 71	Best Monmouthshires	$4.26@4.32
Best seconds	4 44@4 56	Seconds	3 44@4 20
Seconds	4 32@4 44	Best Cardiff smalls	3.72@3.84
Best dry coals	4 38@4 44	Seconds	3.60@3.72

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both exclusive of wrarfage, and for cash in 30 days—less 2½%.

SPANISH IMPORTS

Imports of coal into Spain during 1912 amounted to 2,322,657 tons as compared with 2,055,166 for the year previous and 2,021,116 tons in 1911. Coke imports during the same periods were: 355,149 tons in 1912; 316,448 in 1911 and 294,158 tons in 1910.

EGYPTIAN COAL IMPORTS IN 1912

Coal imports into Egypt for the year of 1912 were 1,638,417 tons, as compared with 1,581,619 in 1911.

FINANCIAL DEPARTMENT

Victor-American Fuel Co.

The following is a summary of the report of this company for the fiscal year ending June 30, 1912:

After providing for fixed charges and depreciation reserves, there remained a balance of $358,463 [against $510,688 in 1910-11]. Two dividends on the capital stock, aggregating $258,500, were paid. After making all adjustments, the credit balance in the profit and loss account, as of June 30, 1912, is $268,868 [as compared with $201,689 on June 30, 1911.]

The loss in earnings for the year was largely at the New Mexico mines, and due to a falling off in the tonnage of coal sold in Southern California and to increased cost from various temporary causes which have already been or will be removed. There is also a considerable loss as compared with the previous year in the falling off in the tonnage of coke sold. The Colorado mines, notwithstanding the halt in general business activity throughout the year, produced practically the same tonnage as the preceding year, with a slight increase in profits.

RESULTS FOR YEARS ENDING JUNE 30

Short tons	1911-12	1910-11	1909-10
Coal produced	2,228,448	2,256,041	2,358,909

Ashland Coal & Iron Co.—Dividend of 1% payable Mar. 20 to holders of record Mar. 19.

American Coal Products Co.—Dividend of 1¾% on the common, payable Mar. 31.

Island Creek Coal Co.—Dividend of 50c. on the common, payable May 1 to holders of record Apr. 26. Dividend on preferred of $1.50 payable Apr. 1 to holders of record Mar. 25.

Burns Bros.—This concern was recently consolidated with the Curtis-Blaisdell Co., forming the largest retail coal company in the world. The new company is a New Jersey corporation, and will have $2,000,000 7% cumulative preferred and $5,500,000 common stock.

Reading Coal & Iron Co.—It is popularly believed that the anthracite companies are working on a basis that produces an enormous profit for them. As a matter of fact, the companies are working on a remarkably narrow margin of profit, and one which has been gradually contracting during recent years. Thus, in 1903, the Reading company showed earnings at the rate of 53c. per ton of coal mined; in 1908, this had fallen to 32c. per ton, and for 1911 it amounted to only 15c. per ton.

Monongahela River Consolidated Coal & Coke Co.—This company was incorporated in Pennsylvania, in June, 1899, to consolidate coal interests along the Monongahela River, and coal traffic to New Orleans, etc., including 200 steamers and 4000 canal boats, barges, coal elevators, etc. In September, 1903, the Pittsburg Coal Co. purchased $15,000,000 of the $20,000,000 common and $2,500,000 of the $10,000,000 preferred stock at $15 and $45 per $50 share, respectively.

COAL AGE

Vol. 3 NEW YORK, MARCH 29, 1913 No. 13

The Dust Eaters

By Berton Braley

Written expressly for Coal Age

It is quiet in the breaker—you could hear a cannon clear
If they'd fire it off beside you with the muzzle at your ear
An' exceptin' for the crushers an' the screens an' other gear,
Why, you never hears a solitary sound!
There is coal dust on the winders an' there's coal dust in the air,
It's stickin' to the timbers an' it's settlin' everywhere,
It's clingin' to our eyelids an' our whiskers an' our hair
An' we eats it in the breaker by the pound!

Eatin' the dust,
Eatin' the dust,
Feelin' the breaker throb;
You wouldn't care
To be workin' there,
But it happens to be *our* job!

It ain't ever any picnic when you got to stand an' stand
A turnin' over clumsy lumps that's heavy to the hand,
They say the "joy o' labor" is a thing that's mighty grand
But they otta eat the breaker-dust awhile.
They'd find the same old story in a hundred diff'rent plants,
A lot of dirt an' sweatin'—not a flicker of "romance,"
With the dusty breaker shakin' like a hootchee-cootchee dance,
As the coal comes flowin' downward by the mile!

Eatin' the dust,
Eatin' the dust,
Wishin' the shift was through;
Early an' late
Pickin' the slate
We are the breaker crew!

O the dust is in the breaker an' the dust is in our hide
And it kind of lines our stomachs an' the whole of us inside,
It doesn't help our beauty an' it doesn't help our pride
Though we go on eatin' coal dust day by day,
An' maybe, in the breaker, though it ain't a bit of fun,
We're doin' of our duty in the way it should be done,
For the world's a sort of boiler an' it must have coal to run
So we reckon we are earnin' all our pay.

Eatin' the dust,
Eatin' the dust,
(Rumble an' crash an' bang!)
Husky an' rough,
Dusky an' tough,
We are the breaker gang!

Education in Coal Mining

By J. T. Beard

An Outline of the Next Question for General Discussion

We propose during the month of April to discuss broadly the question of the need of education in coal mining. We want to ask: What is education as applied to the mining of coal? Has the miner any need of more than a common-school education? Many miners today went into the mine as trappers or oilers at the age of nine or ten years, and if they know how to read and write, they are fortunate.

The average miner's knowledge of arithmetic goes no further than the four rudimentary operations—addition, subtraction, multiplication and division. Fractions are to him an unexplored wilderness. He knows nothing of percentage, ratios, decimals and other simple processes that are necessary in the solution of mining problems. He knows nothing of geometry—of lines and angles. He cannot read a mine map intelligently.

However, notwithstanding these untoward conditions, many miners have, with keen insight, discovered what education has done to advance the earning power of men around them, and are today reaching out for the same knowledge that will enable them to, at least, hold their own in the unequal race of life.

Regarding now the ambitious English-speaking miner who aspires to learn such principles, methods and processes as will increase his efficiency, and incidentally, his earning power, what are the essential qualities of such an education? Shall we call it education or training?

Recognizing the responsibilities that rest upon all mine workers alike to perform their work in a manner that will not endanger themselves or their fellows, and the greater responsibility of men who must act in an official capacity in the operation of mines, the mining laws of most states require the examination of all miners, mine foremen and firebosses, before they can enter upon their duties in the mine.

This requirement by law, is quite generally, we might say universally conceded to be right and just as a necessary protection against the dangers that would arise from the presence, in the mine, of men unfamiliar with mining conditions. The ignorance of a single worker may cost the life of every man in the mine. The first principle of safety, then, is the education or training of all mine workers.

The question has been asked many times in the last few years: What should be the character of mining examinations? It is important to discuss this question in all its bearings. It is a broad question. The views of practical men and prospective candidates are necessary to reveal the difficulties that confront men who must pass such examinations.

Of equal importance are the views of practical mining men who have made a study of mining conditions and are able to apply the theory and principles of mining in the solution of every-day problems, in the mine. It is these men, alone, who understand fully the relation of education to mining.

On the other hand, it is desired that the members of examining boards should take part in this discussion, and give their reasons why the examination is not made to conform more closely to the practical requirements of the men whom they are to certify as qualified for mining positions. Let these men say, if they can, why the examination of practical men should not be made to conform to the conditions in practice. Why, if the man in practice makes frequent and common use of mining textbooks should he not be allowed to use the same books in the examination that is to determine his ability to solve the given problems.

An unprejudiced mind will allow that to eliminate the use of textbooks, in certain sessions of mining examinations, is to give undue advantage to the man who is able to memorize formulas and constants; while the generally more able man, from a mining standpoint, is placed at a decided disadvantage because he is denied the privilege of working under the same conditions to which he is accustomed in the mine and in the office.

As secretary of the state mining board, for a number of years, I have seen good practical men abandon the examination and give their reason for not finishing the work, that they could not remember the formula that they wanted to use. There is an earnest call for the general use of textbooks in all sessions of mining examinations when practical problems must be solved. College students are now allowed to use textbooks, in such examinations; because it is realized that the requirements have become too severe to expect students to memorize what they should find in a reference book. We are glad to say some states have adopted this method. Why not all? Is the delay due to a desire on the part of some members of every examining board to hold in their possession the key that will make them the masters of the situation?

Simple Flywheel Calculations

By Chas. W. Beers*

SYNOPSIS—In a simple manner that anyone possessing a knowledge of only the rudiments of algebra can easily understand, the author develops the various formulas used in flywheel computations. He also shows how to obtain, in the case of a planer, the experimental data necessary before calculations can be undertaken.

The object of any flywheel is to equalize the energy and the work done, on or by, any piece of machinery in which the load varies through large and comparatively quick changes, thereby preventing sudden speed variations in the driving apparatus, due to the amount of the resistance to be overcome.

Sometimes flywheels are installed for economic reasons. This condition is frequently thrust upon those who purchase electric power on a minimum demand basis. This state of affairs is often encountered by large coal operators in Germany (and in this country, also) who find it economical to make use of large flywheels on their shaft hoisting equipments, thus reducing the demand peak loads to practically $\frac{1}{3}$ or $\frac{1}{4}$ of what they ordinarily would amount to without the flywheel.

This is well illustrated in Fig. 1, which shows the peak load on the hoist motor compared to the demand peak as required by a flywheel motor-generator set from which the hoist motor is operated.

To illustrate the manner in which a flywheel gives up its energy in order to overcome extreme load fluctuations, let us take the case of the ordinary punch-press. When the press was initially started, considerable energy was expended in bringing it up to speed, much of this being due to the flywheel.

This starting load decreases rapidly as the press comes up to speed, but the instant the punch enters the metal plate the speed begins to decrease, owing to the large resistance encountered. It is at this instant that the flywheel comes into service, for as soon as the decrease in speed occurs, the energy that was originally put into the wheel when bringing it up to speed is given out in an effort to prevent this speed decrease. This energy, is, of course, expended on the punch, and assists in driving it through the metal. As soon as the punch is complete, the press begins to speed up again, thus storing more energy into the wheel where it becomes available for the next punch.

In the preceding paragraph, we have intimated that the amount of energy given up by a flywheel is proportional to the energy *input*, when changing from a lower to a higher speed. It has also been intimated that the amount of speed change permissible is one of the important factors in the correct design of flywheels. The determination of these two points has been a stumbling block to many, and it might be well at this time to make these points clear.

The Mathematics of the Flywheel

It is well known that work equals the product of force and space or the distance through which this force moves. Expressed mathematically this becomes

$$\text{Work} = F \times S$$

The fundamental definition of force (F) says

Force is equal to mass times acceleration, or

$$F = M \times A$$

and since the mass of any body is equal to its weight (W) divided by gravity ($g = 32.2$), or $\frac{W}{g}$, we see that the work or energy in any moving body is:

$$E = \frac{WAS}{g}$$ (by making proper substitutions for F and M).

Let t = time in seconds required to bring the speed of the given weight (W) up to a uniform linear velocity of

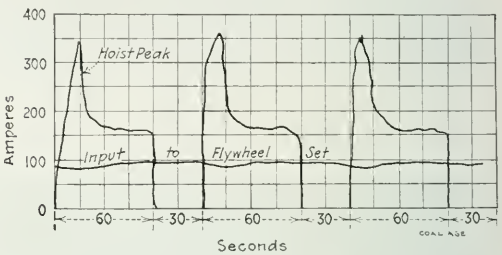

Fig. 1. Showing Input to Flywheel Set When Buying Power on Demand Basis

V ft. per second; then during each succeeding second of t, the speed was increased by $\frac{V}{t}$ ft. per second, hence we say the acceleration (A) $= \frac{V}{t}$ ft. per second. Substituting this value of A in the above formula, $E = \frac{WAS}{g}$, we obtain

$$E = \frac{WVS}{gt}$$

but S, or the space traveled in t seconds $= t\left(\frac{0 + V}{2}\right) = \frac{Vt}{2}$ (at instant of starting the velocity was zero, and at end of acceleration period of t sec. the velocity was V ft. per sec., therefore the average velocity $= \frac{0 + V}{2}$, and the space traversed in t sec. at an average velocity of $\frac{0 + V}{2}$ ft. per sec. $= \frac{Vt}{2}$). Therefore, substituting this value of S in the expression $E = \frac{WVS}{gt}$, we have

$$E = \frac{W \times V \times Vt}{g \times t \times 2} = \frac{WV^2}{2g}$$

This is the formula for the energy stored in a moving body during its acceleration period, or the time required to bring it from zero speed up to full speed. In the same way it can be proved that if the weight W had its speed accelerated up to V_1 ft. per sec., the energy stored in it would be $\frac{WV_1^2}{2g}$.

Hence if the weight W, while in motion, had its ve-

*Electrical engineer, Lehigh Valley Coal Co., Wilkes-Barre, Penn.

velocity reduced from V ft. per sec. to V_1 ft. per sec. the energy change would equal

$$\frac{WV^2}{2g} - \frac{WV_1^2}{2g} = \frac{W}{2g}(V^2 - V_1^2)$$

It will be observed that this expression is in terms of foot-pounds per sec. (Since V = velocity in feet per sec.) and since one horsepower is 33,000 ft. lb. per minute or 550 ft. lb. per sec., then dividing the above final expression by 550 will give the amount of power in terms of horsepower seconds.

The expression $\frac{W}{2g}(V^2 - V_1^2)$ is the fundamental equation of the flywheel, and shows that the amount of energy that is stored up or given out, is proportional to the squares of its particular velocities. Conversely, since $E = \frac{W}{2g}(V^2 - V_1^2)$, and its value is known, then by simple transposition we get

$$\frac{2gE}{V^2 - V_1^2} = W$$

which is the expression used for determining the effective flywheel weight.

This equation is also important is it shows that the greater the effective velocities are, the less is the required weight in the wheel, and consequent cost.

The Limit Set by Experience

Practical experience in electrical work has limited the change in speed from V to V_1 such that $V - V_1$ shall not greatly exceed 15 per cent, as beyond this point the energy gain is not so valuable in dollars and cents, all things considered. Individual cases may arise, however, in which it would pay to greatly exceed this figure. Therefore, in order to get the greatest value possible out of the expression $V^2 - V_1^2$ it is necessary to use the highest speed possible for V, consistent with safe rim construction.

In ordinary cast-iron wheels, the safe peripheral speed is quite low (3000 ft. to 5000 ft. per min.); in cast-steel wheels it is considerably higher, amounting to an average of 18,000 to 20,000 ft. per minute; steel plate wheels (those built up from steel plate) have safe velocities as high as 24,000 ft. per mn. From this it is readily seen that the effective weights for wheels of the above materials differ considerably, varying in the proportions of $\frac{1}{3000^2} : \frac{1}{20000^2} : \frac{1}{24000^2}$.

Up to this point in the discussion, the term velocity has been used in a general sense.

The formula $\frac{W(V^2 - V_1^2)}{2g}$ shows the importance of V in these calculations, hence for any particular flywheel, it is necessary to have some definite value therefor. This value is taken as the linear velocity per second of some point in the plane of the wheel, such that if the entire weight of the wheel were conceived to be concentrated at that point, it would still have the same energy effect as where distributed in hub, spokes and rim.

This point is known as the "center of gyration," and its distance from the center of rotation of the wheel is called the "radius of gyration." To the ordinary mind, the conception of this point may cause some mental gymnastics; such a point is, however, a mathematical fact, and its location and uses are essential to flywheel calculations, but the definition, as given above, is sufficient for this article.

In the type of wheel ordinarily employed, in which the depth of rim bears an appreciable ratio to the outside rim radius, the value of the radius of gyration is $\sqrt{\frac{r^2 + r_1^2}{2}}$, where r is the outside, and r_1 the inside rim radius. (In this type of wheel the hub and arms may be neglected with perfect safety. They introduce complications, and contribute but little to the finesse of the result.) For the plate, or flat type of wheel in which $\frac{r - r_1}{r}$ is very small, or does not exist at all, the radius of gyration is $\sqrt{\frac{r^2}{2}} = 0.707r$.

A Supposed Case

Suppose that a complete cycle of power has been calculated (or otherwise obtained) for a punch press, and it has been found that a flywheel could be used to advantage, and that it is required to give out energy to the amount of 24.5 hp.-sec. to assist the punch.

Now,

$$24.5\ hp.\text{-}sec. \times 550 = 13{,}475\ ft.\text{-}lb.\ sec. = E$$

but

$$E = \frac{(V^2 - V_1^2)}{2g}$$

Equating these,

$$13{,}475 \times 64.4 = W(V^2 - V_1^2)$$

Since the energy required is not large, the wheel will be rather small, and we may assume it to be made of cast iron, and its safe peripheral speed may be taken at one mile per minute or 5280 ft., or 88 ft. per sec.

If D = dia. of wheel in feet, and S = its rev. per sec. $= \frac{\text{r.p.m.}}{60}$ then $\pi DS = 88$ *or* $DS = 28$. In order to make the wheel low in cost, we may assume it to have a speed of 7 rev. per sec. and the outside diameter D of wheel will therefore be 4 ft. A good, stiff rim section for a wheel of this type would be 6 in. in depth and 2 to 3 in. in width, and if the outside rim radius $r = 24$ in., then $r_1 = 18$ in. and the radius of gyration $= \sqrt{\frac{24^2 + 18^2}{2}} = 21.21$ in., and the velocity per sec. of the radius of gyration equals

$$\frac{7 \times 3.1416 \times 21.21'' \times 2}{12} = 77.77\ ft.$$

Let the speed drop = 14.4 per cent. Then the final velocity of the center of gyration is 77.77 − (14.4 per cent. of 77.77 ft.) = 66.57 ft. per sec.

Substituting these values of V and V_1, in the expression $13{,}475 \times 64.4 = W(V^2 - V_1^2)$ we obtain $W = 536$ lb., which equals weight of wheel required. From this amount deduct 86 lb. for hub and arms. We now have 450 lb. equals the weight of rim.

To determine a correct section, let us assume the rim to be d in. wide, and since it is 6 in. deep, then its cross-sectional area $= 6d$ sq.in. The mean dia. of rim is 3 ft. 6 in., consequently the rim volumne $= 792d$ cu.in., and if 1 cu.ft. of cast iron weighs 450 lb. then since the rim weighs 450 lb., its cubic content must be 1728 cu.in. $= 792d$., or $d = 2.2$ in. = thickness of rim.

The Value of E Should Be Known

In the above discussion it will be observed that the value of E was assumed; this was done simply to show the method of using the formulas as far as the actual calculations of the flywheel itself were concerned.

In almost all flywheel calculations, it is necessary that the value of E be known, and usually the conditions of the problem are such that this value can be readily determined, either by actual calculation of the total cycle, as would be the case in new machinery design, or by means of graphic curve drawing meters, properly applied to existing machines. The latter method is more accurate, and has the advantage of simplicity and reliability.

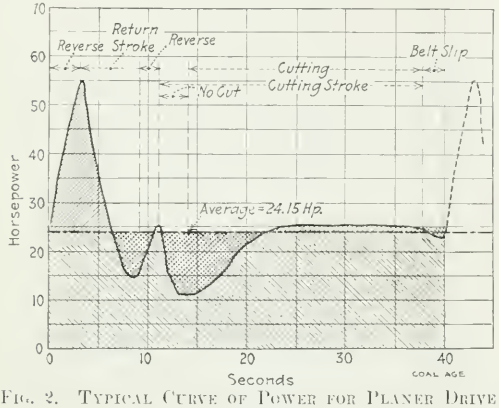

Fig. 2. Typical Curve of Power for Planer Drive

To make this clear, let us take the case of a large motor-driven planer, with a small flywheel attached, and, further, let it be assumed that it is desired to operate on heavier work, and that the present flywheel and motor have been found, by experiment, to be inadequate to properly meet these conditions. These would be excellent reasons for increasing the flywheel capacity of the machine and the method of procedure would be as follows:

Remove the present motor and flywheel, and attach a trial motor of same speed as original one, and of a capacity sufficiently large to perform the new operation without serious effort. A graphic curve ammeter is then properly inserted in the motor circuit (it may be found necessary to increase the speed of chart in order to get a diagram of respectable size).

The motor is then started up and the planer is operated at its desired capacity. At the conclusion of the test run, the graphic record should be carefully examined. This chart will be somewhat similar to Fig. 2, which may be taken as a type curve for one cycle of operation only. The consecutive steps in the process are clearly shown in the figure.

Now, if the total area of this cycle, expressed in hp.-sec., is divided by the length of the cycle in seconds, the result will be the average hp. required and indicates the size of motor that may be used on this planer, when provided with the proper size of flywheel. If such be the case, then the energy above the average line will be supplied, or given out, by the wheel, and that below the line will be supplied by the motor.

The cross-hatched portion below the line shows the energy, E, supplied by the motor to the wheel. The following calculations give the total hp.-sec. in the chart for one cycle, and also indicate the method used in determining the same:

Hp.-sec. at reverse for return stroke =	$\frac{24+55}{2} \times 3$	= 118 5
Hp.-sec. at return stroke =	$\frac{55+15}{2} \times 5$	= 175 0
	15×1	= 15.0
Hp.-sec. at reverse for cutting stroke =	$\frac{15+25}{2} \times 2$	= 40.0
Hp.-sec. at cutting stroke (cutting) =	$\frac{11+25}{2} \times 9$	= 162.0
	$\frac{25+11}{2} \times 2$	= 36.0
Hp.-sec. at cutting stroke (no cut) =	11×2	= 22 0
Hp.-sec. at belt slip at end of cutting stroke =	$\frac{25+23}{2} \times 3$	= 72
Totals	40 sec.	965.5

Then $965.5 \div 40 = 24.15$ hp. average.

Now the areas of the cross-hatched portions below the line are equal to the energy (hp.-sec.) supplied to the wheel by the motor, and, as indicated by the curve, this is given up by the wheel during each cycle, hence, if we determine the total of all areas above the line, we know the exact hp.-sec. or E that the flywheel must be designed for.

The Calculation of the Energy

This total area is as follows:

Hp.-sec. at reverse for return stroke =	$\frac{55 - 24.15}{2} \times 6.5$	= 100 26
Hp.-sec. at reverse for cutting stroke =	$\frac{25.5 - 24.15}{2} \times 1$	= 0 67
Hp.-sec. at cutting stroke =	$\frac{25 - 24.15}{2} \times 2$	= 0 85
	$(25 - 24.15) \times 13$	= 11 05
	$\frac{25 - 24.15}{2} \times 1.5$	= 0 64
Total hp.-sec		113 47

Call it 113.5 hp.-sec.

Now one hp.-sec $= 550$ ft.-lb., therefore $113.5 \times 550 = 62{,}425$ ft.-lb.-sec. equals the value of E, or the energy necessary to alternately absorb and give up. By equating this value against $\frac{W(V^2 - V_1^2)}{2g}$ and following the method indicated in the fore part of this article, the required size of flywheel may be easily determined to meet the above conditions.

In this discussion it has been the aim of the writer to illustrate the application of formulas in such a manner as to make the subject matter of interest to those who are not familiar with flywheels, and no effort has been made to introduce those finer details which, while they beautify the problem, quite often prove to be more of a hindrance than an assistance, and which have no direct value unless they are well tempered by experience. The hub and arms of any wheel have a definite effect upon the energy which may be stored up or given out, but this is ordinarily so small that it may be safely disregarded.

In conclusion the writer wishes to make acknowledgment to the *General Electric Review* dated June, 1912, for Fig. 1, which occurs on p. 401 of that issue, while Fig. 2 is reconstructed from Fig. 1, p. 79 of the same periodical for February, 1913.

Coaling Plants at Panama Canal

SYNOPSIS—Coaling stations are to be established at both ends of the canal. That at the Atlantic terminus is approximately twice the capacity of the one on the Pacific side of the isthmus. This article treats in more or less detail of the facilities and equipment necessary for loading, unloading and storing the coal.

::

(*Announcement of Isthmian Canal Commission*)

Speed in handling coal with the least possible amount of breakage is the main requirement of the coaling plants to be established at the Atlantic and Pacific entrances to the Panama Canal, at Cristobal and Balboa, respectively. Specifications for the machinery of the two plants have been completed and advertisement will shortly be made for bids.

Coal for Use in War Will Be Stored under Water

It is planned to have a coal-storage basin at Cristobal with a capacity of 290,000 tons, and one at Balboa with a capacity of 160,000 tons. In each place the storage will be within a large basin made of reinforced concrete, in which approximately half of the coal will be stored under water for use in time of war, and the other half above water to be added to and taken from continually for the ordinary uses of commercial and government vessels. It is also planned, if the policy should be approved, to be able to lease parts of the storage basin to such private coaling companies as may wish to maintain their own coal stores on the isthmus; but in such cases all of the handling will be done by the government plant, a suitable charge being made for the service.

The specifications are not hard and fast, but merely establish certain general methods and standards, leaving it to manufacturers to devise suitable machines. One of the limiting conditions is that the government shall build the substructure or storage bin and place upon the walls such tracks as cranes and other movable machines may require. This substructure will cost more than the coal-handling plant. The details will not be decided upon until the bids for the handling plant have been canvassed, because each plan will require its own special substructure, and one of the points considered in awarding the contract will be the cost of the substructure required under each plan.

Ships To Be Coaled from Barges, Not from Pockets

In general, however, the specifications call for cranes that will unload coal from ships; a conveying system that will transfer it to bridges that will span the storage basin and dump it at any place desired; and such a system of buckets operating upon these bridges as will make it possible to lift coal from the storage basin, and by means of conveyors raise it to loading machines that will dump it into colliers or lighters. The Cristobal plant must be capable of unloading 1000 tons and loading 2000 tons of coal each hour, and the Balboa plant 500 and 1000 tons.

In the ordinary operations of each of the plants, vessels requiring bunker coal will not go alongside the wharves of the plants to receive such coal, but will be coaled while lying in the stream from barges laid alongside, these barges having been loaded by means of the reloaders forming part of the specified handling machinery for each plant.

The storage basin at the Atlantic entrance will be 1000 ft. long and 250 ft. wide. The bottom of the basin will be 19 ft. below mean tide, and the elevation of the decks of the wharves 10 ft. above mean tide. There will be 41 ft. depth of water alongside the wharves. The wharves will be founded upon steel cylinders filled with reinforced concrete resting upon hard rock. The maximum tidal oscillation in Limon Bay is 2.65 ft.

For this type of storage basin, at least two layouts of coaling plant are feasible; the first being that in which the loading and unloading wharves occupy opposite sides of the basin parallel with one another with the coal piles between them, and the second that in which the unloading wharf will be at right angles to the loading wharf. The normal capacity will be 240,000 tons, capable of increase to 290,000 tons by piling coal to 10 ft. additional height.

The coaling plant at the Pacific entrance will be on the quay wall south of the entrance to the large drydock. The size of the basin will be 500 ft. long and 250 ft. wide for one design of plant, and the same length and 340 ft. wide for a second design. The extreme tidal difference here is 21.8 ft. As at the Atlantic entrance, the loading wharf will be founded upon concrete cylinders resting upon hard rock; the unloading wharf will be gravity section concrete wall resting on rock. The normal capacity of the Balboa plant will be 135,000 tons, capable of increase to 160,000 tons, by piling coal 10 ft. above normal height.

In the first plan a basin 500 ft. long and 250 ft. wide is provided for, with bottom at 18 ft. below mean tide and top of wharf at 16½ ft. above mean tide. The capacity of this plant must not be less than 500 tons of coal an hour to be unloaded and 1000 tons per hour to be loaded aboard colliers or barges. Two unloaders will be required with conveyors, and two single stocking reclaiming bridges. Two reloaders will also be required. The operation of this plant is essentially the same as that for the Atlantic entrance.

Alternate Plan Provides Larger Basin

An alternate plan for the Balboa plant provides for the same location of the wharves, but for a basin 500 ft. long and 340 ft. wide. The unloaders are the same as in other plans, but instead of dumping into conveyors they will discharge by means of the cantilever end directly into the basin, and large cantilever cranes will then pick up the coal and deposit it at any desired point in the storage basin. For reclaiming, these same cranes will pick up the coal and trolley it into their towers, where it will be dumped into cars or other conveyors, whence it will be carried away from the basin, along the front of the reloading wharf to the reloaders.

The purpose of this second plan is to make use of four berm cranes now used in the placing of concrete at Miraflores Locks and thus save the expense of the stocking and reclaiming bridges. Whether they will be used depends upon the cost and general desirability of this plant compared with one having entirely new handling machinery.

Units of the Plants

The following paragraphs refer particularly to the Cristobal plant, but with certain modifications, as indicated above, apply also to the Balboa plant.

The unloading operation will consist of taking coal from a collier and depositing it any desired place in the bin or basin. For this purpose unloading towers, a conveying system that will carry the coal lengthwise of the storage bin along the wharf, bridges spanning the basin, and a conveying system upon these bridges, which will take the coal from the first conveyors and dump it wherever required, are specified.

Four unloading towers of not less than 250 tons capacity per hour each, making a total capacity of 1000 tons an hour, form the first unit of the unloading system. These towers must be capable of mining coal from a vessel and depositing it into a hopper built within the tower, whence it may be delivered by chutes to the conveying system, or to Panama R.R. cars running on a track beneath the tower; or of depositing it by the bucket or shovel into the storage pile behind the tower; and of mining coal from storage pile behind the tower and depositing it in the hopper in the tower.

Each tower will travel on two parallel pairs of rails between which, at the level of the wharf deck, there shall run a railroad track so located that cars may be run beneath the unloading tower and receive coal from its hopper. The speed of travel in either direction must be not less than 50 ft. per min. against a wind pressure of 10 lb. per sq.ft. The track travel must be by motors or engines within each tower, and not by cable drive.

The bucket or shovel by means of which the tower will mine coal from the colliers will have a capacity of 100 cu.ft. liquid full. Larger buckets may be offered, however, provided small buckets are also supplied and a rapid means of making the change from one to the other is provided.

General Construction of Towers

Each tower will be fitted with a lifting or folding boom on the water side and with a cantilever on the storage-basin side. The cantilever may be movable if necessary to permit the passage of the reclaiming bridges. In any case the track for the trolley of the bucket shall be horizontal and continuous, between the extreme ends of boom and cantilever, when both are in a horizontal position, and the passage of the trolley over the hinge joints shall be made easily and without shock. Suitable buffers will be fitted at each end of the trolley runway. The distances through which the trolley or bucket will be capable of operation are as follows: Maximum height above wharf level, Balboa and Cristobal, 60 ft.; maximum depth for reclaiming coal from ships below wharf level, Cristobal, 30 ft.; Balboa, 45 ft.; maximum horizontal travel of bucket on water side beyond center line of tower legs next to water, Cristobal and Balboa, 60 ft.; maximum horizontal travel of bucket on land side, beyond nearest wall of coal basin, Cristobal and Balboa, 35 ft.; maximum depth below wharf level for reclaiming coal from storage on land side at Cristobal, 29 ft.; maximum depth below wharf level for reclaiming coal from storage on land side at Balboa, 34½ ft.

In addition to these operations the towers will be able to dredge the bottom of the slip in front of the unloading wharf 51 ft. below wharf level at Cristobal and 61½ ft. at Balboa.

Conveying System

The conveying system must provide for the transfer of coal from the unloading towers along the wharf to any point at which the bridges may be spanning the bin, and the transfer along the bridges to any point desired, where it may be tripped into the storage basin. It must have a sufficient capacity to handle the maximum amount of coal delivered by the unloading towers. It may consist of either cars or trains propelled by electricity or cable, belts or continuous conveyors of similar construction, or any other approved, tried out and guaranteed means of doing the work, due regard being had to the basic requirement that breakage of coal in handling must be reduced to a minimum.

At the Cristobal plant the conveying system must be capable of performing any one of eight specified operations, so as to facilitate in general the processes of unloading coal from one or two vessels simultaneously and conveying it either to the storage pile, the reloaders or the wharf bunkers, or of conveying coal from the storage pile itself to the reloaders, and in such manner that these various operations shall interfere with each other as little as possible. At the Balboa plant the requirements are similar but are necessarily modified by reason of the smaller size of that plant and the use of the berm cranes referred to.

Four Bridges across Basin—Reloaders

Two duplex or four single bridges are required in the proposed plan for the Cristobal plant. The former are fitted with two shovels or buckets, and the latter only one each. These bridges will span the coal-storage basin over the coal piles and move along the walls longitudinally of the basin, so that they can cover any point in the basin. Upon them will be mounted the conveyors, that will carry coal from the conveyors upon the walls to any point desired within the basin; and the shovels or buckets that will mine coal from the basin and carry it to the conveyors, which will transfer it to the wharf bunker and to the machines for loading it upon colliers or barges.

The reloaders will be machines moving longitudinally along the wharf at which colliers and barges will tie up to receive coal. They will move by their own power, but not by cable. They will receive coal from the conveying system and deliver it to the vessels, and, to this end, will be fitted with the following essential parts: (*a*) A hopper or hoppers for the reception of coal from the conveying system of sufficient size to regulate the flow of coal; (*b*) a conveying system to transfer coal to the discharging end of the reloader; and (*c*) an adjustable arm or boom equipped with a telescopic chute to deliver coal with a minimum of breakage. This boom will house in sufficiently to lie entirely behind the plane of the front wall of the wharf when the reloader is not in use, in order that the reloader may be moved past shrouds, yards, upperworks, rigging, etc., of vessels lying at the reloading wharf. The extreme conditions of discharge that must be met by each reloader cover such matters as size of cargo holds and hatches in vessels, distance of vessels from wharf, distance of deck of vessel above or below deck of wharf, etc. The reloader must also be able to adjust itself to various minor conditions peculiar to each vessel.

Electric Equipment at a Sumatra Mine

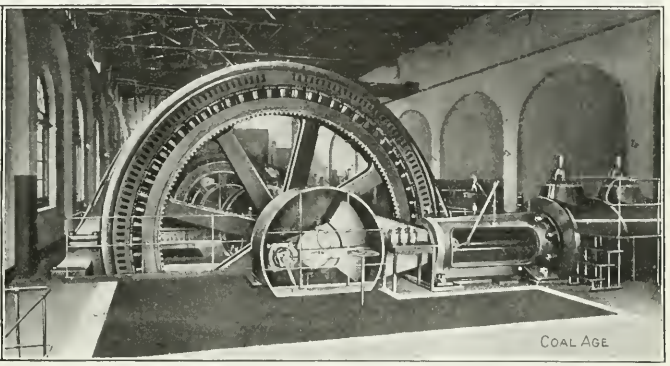
By Alfred Gradenwitz*

SYNOPSIS—A brief description of the electrical equipment at the Ombilin mines on the west coast of Sumatra. The installation is quite elaborate and modern in every respect. Electricity is used for hauling, lighting and pumping.

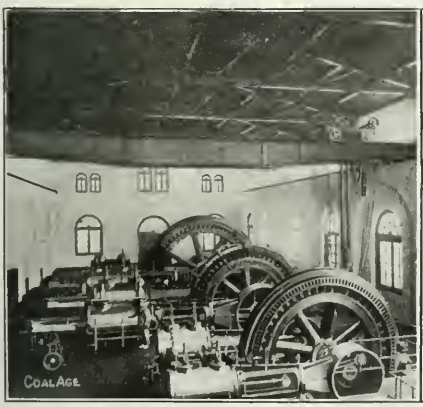
Electric operation was started as far back as in 1905 at the Ombilin coal mines, situated on the west coast of Sumatra, near Sawah-Loento, with a 900-kv.-a., 3-phase

Drift mining is used and there are three different seams worked. The coal is hauled on tracks having 600-mm. gage, and electric mine locomotives with adhesion drive. Since the mines are situated at a higher level than the town of Sawah-Loento where the railway—155 km. in length—to Padang and Emmahaven begins, the coal trucks are taken down on a chain railway to the screening house for sorting and loading into railway trucks.

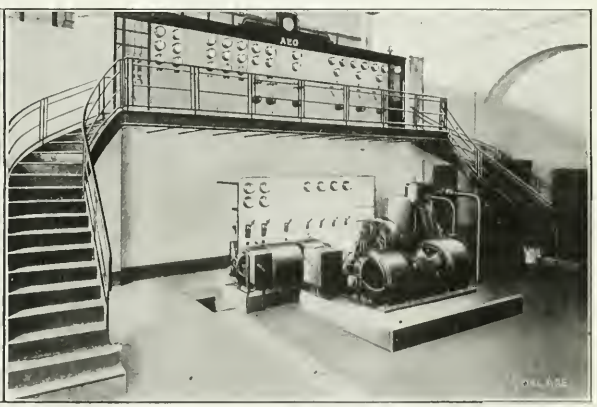
Back View of Switch Gear



1450-kv.-a. Three-phase Generator for the Ombilin Coal Mines



Interior View of Power Station



Front View of Switch Gear

steam dynamo, to which a 500-kv.-a. generator was added in 1907 and a 1450-kv.-a. unit in 1911. The generators are driven by horizontal, compound engines, manufactured by Stork & Co., of Hengelo.

Three-phase current is generated at a pressure of 6000 volts and is distributed, through overhead transmission lines, to the points of consumption where it is transformed down to a pressure of 225 volts. A curious feature of the mines is that there are no deep workings and therefore no electric winding plants are required.

An electric rack railway (see next page) runs parallel to the chain railway; this latter was constructed in the year 1908. It is used for carrying coal, but principally for taking up materials, mine timber, etc. The service is carried on with 7 electric rack locomotives; a photo of one of these on a trial track installed for experimental purposes is shown herewith. Besides for the transport and lighting, the current generated is chiefly employed for driving pumps, compressors, fans, small winches, and in the briquette factory, the screen house and the workshops.

*Gossenstrasse 20, Berlin, Friedenau, Germany.

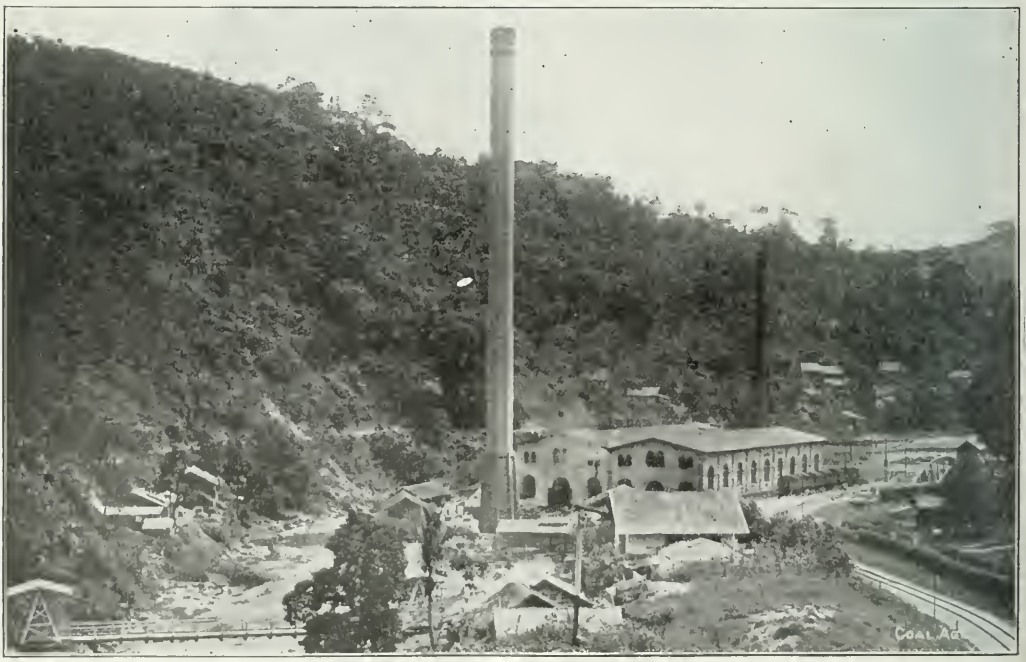
Inclined Electric Rack-Rail Haulage System

On the Ombilin River, 8.5 km. from Sawah-Loento, there is a pumping station for supplying water to the highest level of the mines. At the present time this station contains 2 centrifugal pumps for 1200 litres with a manometric lift of 424 meters; the pumps are driven by 200-hp. three-phase motors, running at a speed of 3000 revolutions per minute. With the increase in the output, which now amounts to approximately 1300 tons per day, on the average, the demand for electricity has also increased and the extensions to the power station have had to keep pace accordingly.

In the year 1907 the boiler house, which was originally equipped with three Steinmüller boilers, each having a heating surface of 240 square meters, was extended by adding two further units of the same kind.

View of Rack-Rail Locomotive

In 1911 a superheater was added and the iron chimney replaced by a reinforced concrete one. A view of the power station, which is situated on the small Loento River, is given herewith. The latter supplies the cooling water to the condenser, but during the dry season there is sometimes very little available.



General View of Power Plant, Which Is of a Modern and Permanent Character

The switch gear, which was not originally designed with a view to the extension of the power station, was entirely reconstructed in the year 1911, in accordance with the most recent practice. The building was extended at the back, a double busbar system was installed and the whole of the high-tension apparatus was arranged on the cell system, all these alterations being made without the slightest disturbance in the service of the station. The oil switches for the generators were fitted with remote control and automatic release by means of maximum and reverse current relays, and the switches for the transmission lines and transformers were arranged for hand operation with magnetic maximum release. A small battery of accumulators was installed for the remote control of switches, relays and emergency lighting. The lightning-arrester plant was also improved; each phase of all the transmission lines was fitted with rough and fine protection horn arresters, and water resistances mounted in cells, while water jet, earthing devices were connected to the busbars. The switchboard and high-tension room are shown in the accompanying illustrations. Since the recent improvements and extensions have been completed, the power station may be regarded in every respect as a model installation. It is now intended to modernize the transmission line and transformer stations in accordance with the more exacting requirements they have at present to comply with.

Electricity in a Group of Mines

Special Correspondence

SYNOPSIS—Aside from some of the equipment at one shaft, every one of the twelve operations of the United States Coal & Coke Co., in McDowell County, W. Va., is electrically driven from a central power station. This article enumerates most of the apparatus and gives some interesting figures on percentage of motor to generator capacity.

In extensive mining operations, the problem of supplying power to the various workings, which may be quite a distance apart, is best solved by electrification. The flexibility of an electric equipment, permitting the installation of motors at any point to which wires may be run, the ease of control of electrically driven machinery, the reliability and economy of the electric installation, all make for the most successful and economical operation.

The extensive mining operations of the United States Coal & Coke Co. in McDowell County, West Virginia, are electrically operated from a central power station located at Gary. This company operates twelve plants, all but Nos. 1 and 2 being drift mines. Plants 1 to 8 have coke ovens, while plants 9 to 12 have none, these latter being designed for mining and loading coal only.

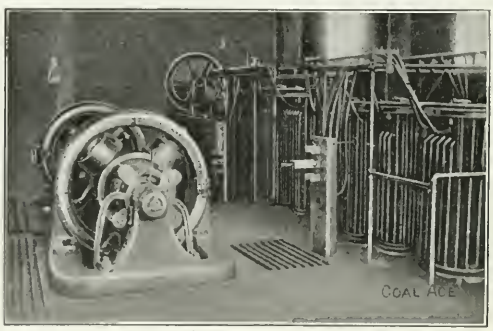
Electrical operation was gradually introduced, the first installation being made in 1902 and consisting of two 400-kw. generators, driven by direct-connected cross-compound engines. These furnished power for mine haulage, crushing, coke ovens, pumping, and fans. In the spring of 1904, one 750-kw., 6600-volt, engine-driven generator was added, this unit being duplicated in the spring of 1905. Power house facilities were further increased in the spring of 1907 by the purchase of two 1000-kw. turbines, one being high and the other low pressure, with complete condensing and cooling apparatus. This brought the power house capacity up to 3800 kw.

After three years of satisfactory experience with electrically operated machinery, it was decided to electrify mining operations, as regards mining machines. This was accompanied by the further installation of motor-driven air compressors, for lifting water from the deep wells.

Subsequently, electrically driven coke-drawing machines were installed to partially handle the coking processes at mines 1 to 8.

Capacity of Plant in Boiler Horsepower

The original boiler installation consisted of four 300-hp. Aultman-Taylor horizontal water-tube boilers. With the addition of power units, more boilers were installed until now, besides the four 300-hp. ones already mentioned, there are five 520-hp. boilers of the same type, making a total boiler capacity of 3800 hp., all of these being fired by Jones' underfeed stokers, which are supplied with coal from an overhead bin filled by a larry.



Interior of a Substation, Showing Transformers, Rotary, and Fan Motor

Duplicate feedwater pumps and heaters have been installed.

Every piece of the apparatus at the entire twelve plants, with the exception of the hoisting engine and the fan at No. 1 shaft, is driven by electrical power from the central station.

The generators are all 6600-volt, 25-cycle, three-phase machines and electrical power is transmitted at this potential to all the substations except No. 12. For transmission to the latter, which is about 12 miles from the central station, the potential is stepped up to 23,000 volts by oil-cooled transformers installed in the power station. All the transmission lines are calculated for 5 per cent. line drop.

The main station switchboard consists of twenty panels, six of these controlling the generators, while there are eight feeder panels controlling the lines to the different

plants, 5 panels controlling motor-generator sets used as exciters, and a Tirrill regulator panel.

Rotaries of 150-kw. capacity have been installed in each of the substations, nine plants having one rotary and three 2 rotaries each. These rotaries supply direct current at 275 volts for the operation of locomotives, inside mining pumps, mining machines, etc., the power being taken from the locomotive trolley, thus making it unnecessary to run another line into the mines, and greatly simplifying the installation.

The substation switchboards consist of from three to seven panels to control rotary converters, step-down transformers for both power and lighting, and synchronous motors driving generators or fans.

The transmission lines are supported on wooden poles with the exception of the line from the power house to No. 6 works, where for a distance of 7000 ft., a heavy galvanized steel tower line has been constructed. This line now carries two separate circuits, one for Nos. 6 and 7 and the other for Nos. 8 and 9 mines, and provision has also been made for a third circuit to proposed plants on the waters of Dry Fork.

Location of Substations

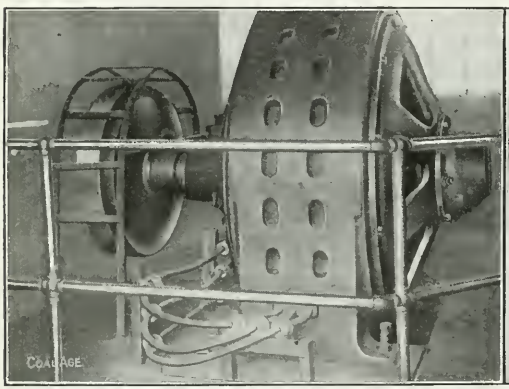
The substations are, for the most part, located at the pit mouths and, generally, the motors driving the mine fans are in this building. The power transformers for reducing the transmission potential to 440 volts for operation of the induction motors are located in these substations, although, at some works, it was found more economical to have the transformers nearer the tipples than the substations and they were installed accordingly in separate transformer houses. There are, in all, 87 single-phase transformers, having an aggregate rated capacity of 5745 kv.-a., which are used for power, and 27 of 400 kv.-a. total capacity used for lighting.

The transformer house switchboards consist of the necessary step-down transformers and out-going low voltage circuits for both power and lighting.

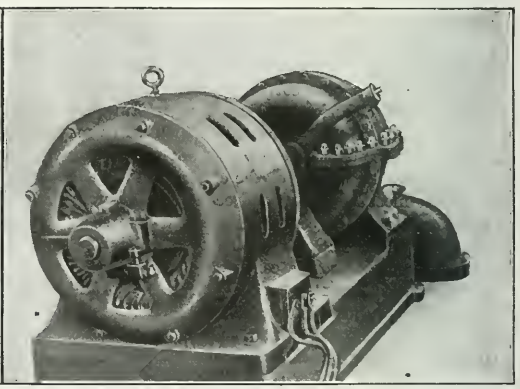
There are nine single and three double tipples, each of the latter receiving the product of two mines. At eight of the operations, steel tipples have been erected. All of the tipples are provided with Phillips automatic cross-over dumps and, in every case, the coal is discharged into a small hopper and from thence passed to the picking tables, all of which are 4 ft. wide, induction motor driven, and run at a speed of 50 ft. per min. The picking tables at all the coal plants, feed directly into a chute, from which the coal passes into the bins, while, at the coke plants, the coal is fed from the picking tables to chutes leading to the crushers and from thence it passes to bins.

At No. 2 mine, the dump is located at the foot of the slope, from which point an overlapping bucket conveyor, induction motor driven and working on a 40% incline, carries it about 260 ft. to the tipple. At No. 9 plant the difference in elevation between the two mines on opposite sides of the valley is so great that the coal from one is brought directly to the top of the tipple, while that from the other is lifted to the same elevation by a rubber belt conveyor 210 ft. long, working at an inclination of 28%. At No. 12 mine the coal is 600 ft. above the loading point, and about 1200 ft. horizontally from it, consequently, it was deemed best to locate the dump and picking tables at the top of the hill and to bring the coal down by three retarding conveyors, the first passing it to the second, the second to the third, while the third discharges it into the bin.

So satisfactory has been the electrical operation that individual drive by induction motors has been standard-



An Induction Motor Direct-Connected to a Fan through a Flexible Coupling



A Motor-Driven Centrifugal Pump for Domestic Water Supply

ized for the operation of the tipples of this company, the picking tables requiring, on an average, a 9-hp. motor, while a 40- to 75-hp. motor is required to drive the conveyors from the mine, the power demands varying with the grade.

At first the crushers were belt driven, but so much trouble was experienced with bearings and belts that they are now driven by direct-connected induction motors through a flexible coupling.

There are 14 crushers driven by motors ranging in capacity from 75 hp. to 300 hp., the total load being 2525 hp.

The Water Supply

At all the coke plants, the water supply for the ovens is obtained from the river or from its branches on which the plants are located, the water being pumped

from the streams into large steel storage tanks, by direct-connected, induction motor-driven, centrifugal pumps, the latter operating against comparatively low heads, the maximum being 250 ft. All plants have an auxiliary deep-well supply, which is used during the dry months of the late summer and fall. These wells also furnish an abundant supply of pure drinking water. Three of the plants, Nos. 2, 4 and 5, have deep-well pumps of the plunger type, each being driven by a 40-hp. motor, but at all the others air lifts are used, the water being blown into small tanks, from which the centrifugal pumps draw their supply. At four of the plants, Nos. 1, 3, 10 and 11, sumps have been cut out of the solid rock for the ground and stream waters to collect in. At Nos. 9, 10, 11 and 12 works, the water supply is for domestic use only and so nothing but deep-well water is pumped.

For inside pumping, 220-volt direct-current motors are used receiving their power from the locomotive feeders.

There are seven air compressors driven by induction motors, four of the latter having a capacity of 85 hp., two a capacity of 40 hp., while the seventh is a 75-hp. motor. These compressors supply air at a pressure of 100 lb. for the water lifts, and to operate gates under coal bins.

Ventilation is accomplished by means of fans, all motor driven, except the one at No. 1 mine, which is direct connected to an engine. The fans at works Nos. 2, 3, 5, 6, 7 and 8, are belt driven by motors. The fan at No. 4 works is driven by a 400-kw., 6600-volt synchronous motor, direct connected by a flexible coupling. The fans at works 9 to 12 inclusive are direct driven by induction motors through flexible couplings. In most cases the motors are two-speed machines, and are run usually for four or five years at the lower speed before increased size of the mine demands the full capacity of the fan. The motors direct connected to fans have a capacity of 150 hp. at 120 r.p.m. and 300 hp. at 240 r.p.m.

Improving the Power Factor

To improve the power factor, which otherwise would be low, owing to the large induction-motor load, two 400-kw. synchronous motors were installed at plants Nos. 4 and 6 to drive fans, one by a flexible coupling and the other by a belt, about 200 hp. being required for this purpose, and the excess capacity supplying leading current to improve the power factor. A 500-kv.-a., 6600-volt, synchronous-motor, direct-current generator set has also been installed for its condenser effect upon the transmission line.

Although for many years coke was made in beehive ovens at eight of these plants, its production has now been discontinued, and the entire output of the mines is shipped to Gary (Indiana), Joliet, South Chicago and other points, where, mixed with other coals, it is coked in the more economic byproduct oven. Such equipment as electric-charging larries, coke-drawing machines, etc., used in this process has, therefore, been disposed of.

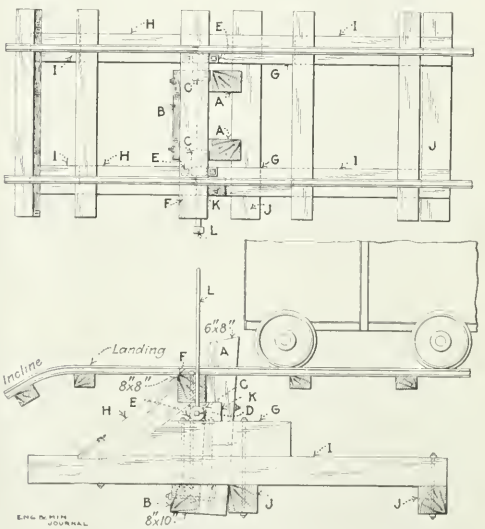
Motor-driven coal cutters are employed almost exclusively, there being 78 Sullivan machines, and eight Jeffrey short-wall machines each driven by a 30-hp., 250-volt, direct-current vertical-shaft motor, while, for a few low-vein machines, horizontal-shaft motors are used.

Gathering in these mines is performed mostly with mules. There are thirty 13-ton and eight 7½-ton, 250-volt locomotives for mine haulage.

The ratio of direct-current motors to direct-current generator capacity is 232%, while the ratio of all motors to generator capacity is 277%, and the load factor of the central plant is 30% with a total motor load of 16,000 hp. The consumption of electric power per month is approximately 1,200,000 kw.-hr., while the coal production is 15,000 tons per day.

Safety Block for Inclines

To prevent the accidental return of a car or skip that has been hoisted to the top of an incline and detached, the device shown in the accompanying drawing is recommended by William W. Jones, state mine inspector, Albany, N. Y. It consists, says the *Engineering and Mining Journal*, of two almost upright timbers *A*, fastened to the square shaft *D* by the straps *C*. The shaft is turned in two places to fit the boxes *E*. The bottoms of the timbers *A* are bolted to a transverse piece *B*. The hoisted car hits the timbers *A*, which revolve with the shaft, permitting the car to pass. The weight of *B* then brings them to the upright position and the cross piece *F* prevents their swinging in the other direction.



Automatic Safety Stop for Top of Incline

BILL OF MATERIALS FOR SAFETY BLOCK; TRACK 3-FT. GAGE

Timber	Iron
A 2 pieces 6x8 in.x4 ft. 4 in.	4 bolts ⅞x20 in.
B 1 piece 8x10 in.x2 ft. 2 in.	2 bolts ⅞x14 in.
F 1 piece 8x8 in.x5 ft.	2 bolts ⅞x17 in.
G 2 piece 8x10 in.x4 ft.	2 bolts ⅞x28 in.
H 2 pieces 8x8 in.x3 ft. 2 in.	2 bolts ⅞x34 in.
I 2 pieces 8x8 in x10 ft	4 bolts ⅞x10 in.
J 2 pieces 8x8 in.x5 ft	2 bolts ⅞x18 in.
K 1 piece 5x6 in.x1 ft. 1 in.	1 shaft 1⅞x1⅞ in.x4 ft. 4 in.
	1 piece ⅞x1½ in.x5 ft.
	2 clamps for shaft
	2 boxes 2½x8x2 in. bore.

To permit a car to go over the head of the incline, the lever, which is attached to a square portion of the shaft, is used to tip the timbers over so far that they clear the car axles and permit the car to pass over them.

The New Brunswick man who built and lined his own coffin with asbestos must be reasonably certain where he is going.

CURRENT COAL LITERATURE

Does Coal Contain Living Organisms?

John Harger in his recent book on "Coal and the Prevention of Explosions and Mine Fires," says:

The occurrence in coal of such large quantities of methane practically free from other hydrocarbons is mysterious from a purely chemical point of view. Among the thousands of organic compounds which have been made in the laboratory, not one is known which spontaneously decomposes with the evolution of methane. Furthermore, no process is known, with the exception of the reactions between zinc methyl or aluminum carbide and water, by which methane, unmixed with other hydrocarbons or with hydrogen, can be prepared in the laboratory. For these and other reasons, I think it necessary to conclude, on purely chemical grounds, that the formation of methane in coal seams is due to bacterial fermentation.

Possibly the chief factor in the transition from decaying vegetation to anthracite is a constant fermentation. At the present time most geologists accept the bacterial theory for the first stage in the transition from vegetable matter to coal. Bernard Renault proved the existence of micrococci in the petrified state in some coals; he showed also that the tissues in some petrifactions show all the phenomena of cells attacked by bacteria.

E. Galle* found, in the course of a bacterial study of different kinds of coal under both anaerobic and aerobic conditions, that, out of seven kinds of bacteria isolated, four, when grown on suitable media in presence of coal, produced combustible gas mixtures containing from 11.5 to 84.8 per cent. of methane and from 5.4 to 27.3 per cent. of carbon dioxide. He showed that these combustible gas mixtures were generated by the bacteria even under conditions approaching those which prevail in nature.

*"Central Bakter a Parasiteuk," 1910, 28, 461-473; "Chem. Zeit.," 1911, 1, 48.

Karns Reciprocating Heading Tunneler

By O. J. Grimes*

SYNOPSIS—The Karns tunneling machine consists of a drill head of diameter equal to that of the heading to be driven. This cutter is driven backward and forward, each stroke being seven inches long and each return being accompanied by a trifling rotation. Thus the machine breaks the rock into chips. It is said to advance from two to four feet per hour, and to operate at from one to five dollars per foot run.

The latest idea in tunnel boring, the Karns tunneling machine, is operated similarly to the small air drill now used in drilling and blasting. It simply takes the place of the drill steel that goes into the chuck of the air drill except that it is heavier and must have a supporting carriage. The motion of the machine in operation is exactly the same as that of the small drill, the blows being delivered against the obstruction by direct forward motion. On the back stroke, the reciprocating parts turn slightly by means of a rotating device, similar to the rifle nut in the small drill, so that with each succeeding blow the cutting points strike the rock at a different place. The rock, instead of being ground into dust, falls down in small chips, resulting in more rapid progress.

Constructs a 6-ft. Circular Tunnel at One Operation

The latest and largest machine constructed has a cutting head 6 ft. in diameter. It is not a combination of individual drills, but is a single drill with innumerable points, striking simultaneously and rapidly.

There are 41 cutter blades made of tool steel, each 1 in. thick, 5 in. wide and of various lengths. Points like saw teeth are machined on one edge and the other edge is fastened in the face of the head. These cutter blades are set in grooves 1 in. deep and backed on one side by an extra inch, to resist the pressure of the cut rock at the bottom when the head is turning. They are held in these grooves by two hook bolts to each cutter, which pass through the head and hold them firmly in place.

To remove the cutters, the nuts on the hook bolts are unscrewed about 1 in., permitting the cutters to be pulled forward and slipped off the ends of the bolts. The entire set of cutters may be removed and replaced in about 2 hr. One set will drive from 25 to 75 ft. of tunnel, depending on the hardness of the rock, although 97 ft. have been driven without a change.

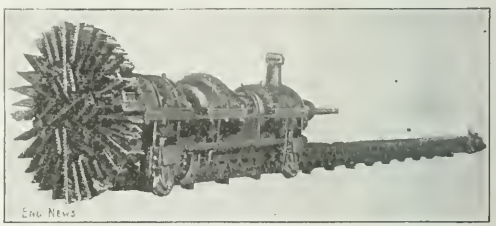


Fig. 1. Karns Tunneling Machine with Drill Head Measuring 6 Ft. in Diameter

Two to Four Feet of Progress per Hour

The reciprocating parts of this machine weigh 7¼

*Snow Apartments, Salt Lake City, Utah.
Note—Extract from the "Engineering News" of Mar. 6, 1913.

tons. This weight is thrown against the rock about 140 times a minute, each blow making a working stroke of 7 in., cutting from 2 to 4 ft. of tunnel per hour.

The cylinders are inclosed in a shell and connected to the supporting parts of the operating machine by heavy rods. The shell supporting the cylinders is held firmly in place by four columns, two in front and two in the rear, jacked to the top and bottom of the tunnel. The columns, shell and machine are advanced simultaneously with each 6 ft. of tunnel driven. The weight of the machine rests on four wheels under the supporting carriage

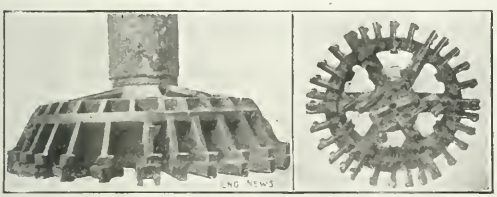

Fig. 2. Views of Rough Casting for Head of Karns Tunneling Machine

which run on heavy steel tracks on each side. These tracks are fastened to and move along with the carriage, eliminating the setting of tracks a second time.

Rotates on Ball Bearings

In the front cap of the machine are the front bearings, consisting of 48 steel balls, 3 in. in diameter, resting in 12 straight grooves, planed on the outside of the hub of the head casting. The other half of the grooves or bearings are on the inside of the heavy steel nut encircling the hub. The bearings at the back are under the rear cap and are similar to those in the front, except that there are but 8 races of 3-in. balls, three in each row.

On the forward stroke the motion is reversed and the nut turns, the dogs simply sliding over the ratchet teeth on the nut.

How the Machine Is Moved Forward

Having been fed ahead 6 ft., the moving up of the shell and holding columns under the cylinders by the feed screw is a very simple matter and requires but a few minutes. There is a truck under the shell supported by four wide-tired wheels on the rock. To move up, the columns are unjacked and made free. Then by a worm gear the surface of the supporting truck is raised so that the entire weight of the shell and columns rests on the truck. This done, it is simply a matter of turning the feed screw which pulls all under the cylinders again. The surface of the truck is then lowered and the columns rest on the rock, the jacks at the top are tightened and all is ready for driving another 6 ft. of tunnel.

The engine driving this machine is a double, 9½-in., tandem cylinder, with an extreme stroke of 8¼ in.

To operate a machine of this size, 2000 cu.ft. of air per minute are required, but a plant capable of furnishing 3000 cu.ft. per minute is always installed. The purpose of this excess of capacity is to avoid working the compressor and boilers to their full rating, thus lengthening their lives and providing extra power should a long stretch of hard rock be encountered. In such cases the additional air is used and the machine operated more rapidly, delivering much harder blows, with the result that the average speed is maintained throughout the work. A boiler of about 400 hp. is necessary to operate an air compressor of the required capacity.

Operating Expense

To operate the machine on each shift, one runner and helper, two muckers, one engineer and a fireman are necessary. A blacksmith and helper are required in one

Fig. 3. A 6-ft. Diameter Heading, on a 10-deg. Curve Driven with the Karns Machine

Fig. 4. Rear View of Karns Machine in Johnstown, Penn., Tunnel

The middle cap covers the rotating device. It is the same as the front and back bearing except that the races for the 3-in. balls are spiral. There are four races with three balls in each race. On the outside of the steel nut there are ratchet teeth with dogs to drop into them on the back stroke and hold the nut from turning. This compels the shaft within to turn, as the ball races are spiral.

shift in three. The cost per foot to drive a tunnel with this machine ranges from $81 to $85, according to the rock and cost of fuel and labor at the place of installation.

Tunnels of large size can be driven quickly, safely and cheaply. If a round tunnel 18 ft. in diameter is desired, a heading 6 ft. in diameter may be driven through the

center, and from it holes drilled 6 ft. deep in a circle with a small air drill. When blasting, the tunnel will be broken the full 18 ft. In enlarging, the rock will be shot into the tunnel, where there is sufficient room for handling the débris.

It was the idea of the late David H. Moffat to use a Karns machine to drive the gigantic tunnel through the divide on the line of his railroad, the Denver, Northwestern & Pacific. He went so far as to have a model 18 ft. in diameter constructed, but his untimely death halted all preparations.

Used in both Coal and Granite

The tests to which the Karns machines have been subjected have been severe and practical. The first was made with a machine 52 in. in diameter through more than 100 ft. of solid granite near Boulder, Colo. The most recent demonstration was a tunnel 6 ft. in diameter and 200 ft. long, driven for the Valley Coal & Stone Co., near Johnstown, Penn. To show the adaptability of the machine to requirements, a 10° curve was driven as shown in the photograph.

The machine is controlled by the J. P. Karns Tunneling Machine Co., Mercantile Bank Building, Boulder, Colo. The inventor, J. P. Karns, president of the company, has offices in Citizens' Building, Cleveland, Ohio.

The Committee on Science and the Arts, of the Franklin Institute, Philadelphia, last year awarded the Edward Longstreth medal to Mr. Karns for his invention of the tunneling machine.

European Practice in Hydraulic Filling

By L. O. Kellogg*

Speaking before the New York Section of the American Institute of Mining Engineers, George S. Rice, chief mining engineer of the Bureau of Mines, described various methods of hydraulic filling in European collieries and potash mines. The filling of excavated parts of workings is becoming the standard method of support in Germany, Belgium and France and has been brought to a high state of development.

The character of material used depends on the relative accessibility of the possible sources of supply. Sand, crushed rock, loam and clay are used in varying proportions, and granulated slag is not uncommon. The manner of handling the material and the amount of water necessary varies with its character. Slag requires much water to move it, whereas clay moves easily but is slow to dry when placed and is unsuitable except in mixtures.

Natural sand or glacial drift is often handled through a rather elaborate series of screens and crushers. One plant stowing about 5000 cu.yd. of material per day dumps it from cars on a trestle, and flushes the dumped piles by hydraulic monitors (flushing nozzles).

In the potash fields, rock salt is used for a filling material. Large chambers are excavated in the rock-salt foot wall, and the broken salt stowed away in the workings, where the potash has been excavated.

The problem of suitable pipe for handling the water and material has received much attention. In Westphalia, porcelain-lined pipe is used, while in Upper Silesia, a steel pipe with a removable cast-iron trough-shaped bottom is finding favor.

As the method is practiced, there is no great saving in timber except in the quality; poorer classes of wood are permissible, since it does not have to stand up for any great length of time. The cost varies exceedingly, probably averaging somewhere between 20 and 30c. per cubic yard. Because of the higher cost of labor, this would be much increased in the United States, and a figure of from 30 to 40c. per cubic yard is given, tentatively when material can be obtained within two or three miles.

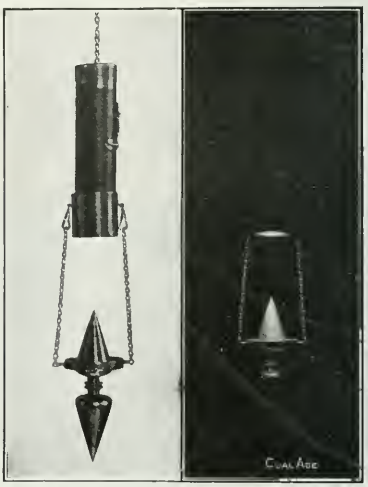
The use of the term "hydraulic stowing" is recommended for the purpose of designating the general process of flushing granular or fine material into mines to fill the excavations.

*Editorial staff, "Engineering and Mining Journal."

The Martin Plummet Lamp

Mining engineers will be interested in the following description of a plummet lamp recently invented by C. V. Martin, a mining engineer, of Zanesville, Ohio.

Every mining engineer and surveyor knows the difficulty in using safety lamps for fore- and back-sights where there is gas. Even when shielded carbide lamps, torches and reflectors are used, there are often many conditions in the work of the assistant that are trying to the transitman.



The Martin Plummet Lamp, Showing Its Appearance in the Dark

Two views of an improvement on the old methods are here given. One was taken in the outside light and the other by its own light as it hung from a spad in the mine. The illustrations are so plain that a description is hardly necessary. The device consists of a double plummet coupled and swung in gymbals by detachable chains from an electric cell lamp. The lamp has a sliding sleeve, to cover or expose the lens as occasion may require, and is fitted with a chain and hook for suspension from a spad. When not in use the entire device is conveniently carried in a leather case.

EDITORIALS

Metal Mining Accidents

We congratulate the Bureau of Mines on its work in collecting the statistics of metal-mining accidents and of the accidents occurring in mines producing nonmetals other than coal. A brief of these figures is contained in our sociological department.

There has been no public demand that this work should be done, because the mass of the people are interested only in great disasters affecting a large number of men at one time. An accident to an individual makes at best an unattractive headline and is relegated to those parts of the daily newspaper which contain advertising announcements. We fear that we would not have had a Bureau of Mines if it had not been for the Monongah, Naomi and Cheswick disasters. Even today the coal-mining division of that institution is the more popular and significant.

As we suspected, the returns diligently collected by Albert L. Fay for the bureau, show that the loss of life per man employed is higher than in the coal mines. The difference is actually about 12 per cent. And this is true, though there are no gas or coal-dust problems to be met and though 40 per cent. of the employees work in the open air, exposed to more easily avoidable dangers. The proportion of underground to outside workers in the bituminous mines of Pennsylvania is 17 per cent. and in the anthracite workings 28 per cent. It is obvious that all other things being equal, the coal-mining industry which exposes the larger number of men to the full risk would necessarily have the greater number of fatalities, should only equal care be taken.

It is unfortunately true that the metal-mining industry has not been conducted with the interest in safety which has marked the operations of collieries. This has not been because the metal industry has men of less liberal mold but because the general public, not being induced to consider the risks of metal mining by recurrent disasters of large proportion has never exercised so continuous a guardianship over the workers thus engaged.

The never wearying publicity which the coal operator has had to face has been irksome and expensive, but it has certainly been of great value and it has sustained admirably the hands of those who among the operating forces were disposed to regard the safety of the employee as one of the leading interests of the officers in charge of a mine.

The coal operator has to look back carefully if he would realize the progress he has made. Some 30 years ago, at the Long Valley coal mine, a mule driver was killed. As they brought his mangled body to the drift mouth, the foreman who till then had not heard of the accident strode up and blurted out "Was the mule hurt?" It was his first thought, and he narrowly escaped a lynching.

A few years ago, indeed, property was generally esteemed as more important than life as the anecdote of John Fulton at the Johnstown meet of the Coal Mining Institute of America last summer well illustrated. He stated that on one occasion when a man was killed by a vicious horse, the party in whose care it had been placed, remarked with considerable heat: "I don't care about your man Patsy; what I want to know is how I am going to explain the breaking of the buggy."

The loss of a life or the occurrence of an accident at a mine throws a dark shadow over the faces of all the officials. If a stranger happens to visit at the time, he is likely to receive but veiled hints of the misfortune, but if he once learns about it, there is no detail which is overlooked in describing it and it is likely that he will see the report to the inspector before he leaves.

We were interested in a recent article by Don D. Lescohier, of the Minnesota Bureau of Labor, in a recent issue of the *Survey*. He says:

"The key to the situation," said Michael Godfrey, general superintendent of the Canisteo iron district, "is the foreman. I hold my bosses responsible for every accident which occurs among their men. Their ability to prevent injuries and deaths is an important factor in determining promotion and an inability to prevent accidents is certain to result in their discharge. I have my foremen now where they come in and apologize for an accident. When the foreman is careful, the men have to be."

The point of view here stated is current wherever coal is being extracted. It comes as a shock that in the metal industry such a condition could be regarded as new.

Fuel Well Conference

The glamour of time, the obtaining of a great name, and the possession of a stately plant are needed to enable the Bureau of Mines to fill the requisite place in the public eye. Until a new generation has sprung up, replacing the present, the bureau will be an innovation to be resisted by every body of older establishment. Every element of conservatism in the republic, and many of these there be, will oppose itself to this new force, beneficent but too new for full national acceptance. The recent gas- and oil-well conference showed conclusively that local pride and petty jealousies are preventing the bureau from doing the large work, of which it alone is capable.

When a federal bureau calls a conference on a matter of national importance, and asks for the opinion of the public on this matter, it is unseemly for the persons who are employed by the various states for the promotion of a healthy public sentiment and for the enforcement of the law relative to such matters, to hold coldly aloof and try vainly to kill the conference by abstention.

Credit must be given to Richard R. Hice, the state geologist of Pennsylvania, F. W. DeWolf, director of the State Geological Survey of Illinois, I. C. White, state geologist of West Virginia, and to no others of the state institutions for their coöperation in the work of inquiry.

If the authorities in the various states think the federal conference without them will not be able to effect

anything, they are much mistaken. It is probable that the well represented gas and oil men have succeeded in providing a law to their liking by recognizing the conference, and that the abstainers may find themselves mated in every later play.

The man on the street evaluates the force on the Bureau of Mines as of more authority than the local inspectorates and with reason. The decisions of the courts will also be molded greatly by what at least appears to be concurrent testimony of the highest value.

It was proposed, as we explained in our issue of Feb. 22, to give an equal representation to the Bureau of Mines, the gas interests, the oil men, the coal operators, state geologists and coal-mine inspectors. The scheme apparently went awry for want of the coöperation to which the bureau was fully entitled and instead a subcommittee was appointed consisting of three men: W. S. McCloy, of Pittsburgh, Penn., district superintendent of the Philadelphia Co., which has extended gas interests; E. B. Moore, chief engineer of the Consolidation Coal Co., of Fairmont, W. Va., who has had much practical experience in the effects of gas leakages from wells passing through coal beds, and O. P. Hood, chief mechanical engineer of the experimental station of the Bureau of Mines.

They produced an act which appeared in our issue of Mar. 22, and which we criticized in an editorial of equal date. This act reduced many of the suggested enactments of the bureau in many important ways, yet it is easy to realize that Mr. Hood could not feel disposed to present a minority report to the conference.

When the meeting was called to consider the report, the following persons attended, whose 21 names we quote at length:

Gas Interests—John B. Corrin, assistant general manager, Hope Natural Gas Co., Pittsburgh, Penn.; H. H. Davis, superintendent, Land Department, Greensboro Gas Co., Pittsburgh, Penn.; John Gates, attorney, Land Department, Philadelphia Co., Pittsburgh, Penn.; M. P. Layton, Manufacturers Light and Heat Co., Pittsburgh, Penn.; E. D. Leland, Philadelphia Co., Pittsburgh, Penn.; C. M. Thorp, attorney, Pittsburgh, Penn.; and Henry Wittmeyer, American Natural Gas Co., Pittsburgh, Penn.—7 representatives.

Oil Interests—A. F. Corwin, South Penn Oil Co., Pittsburgh, Penn.; E. E. Crocher, vice-president and general manager, South Penn Oil Co., Pittsburgh, Penn.; William C. Edwards, Parker & Edwards Oil Co., Pittsburgh, Penn.—3 representatives.

Coal Mining Interests—James Burns, mining engineer, Penn. Salt Mfg. Co., Natrona, Penn.; W. E. Fohl, mining engineer, Pittsburgh, Penn.; C. H. Jenkins, Hutchinson Coal Co., Fairmont, W. Va.; C. B. Britton, mine inspector, Moreland Coal Co., Pittsburgh, Penn.; E. J. Taylor, chief engineer, Pittsburgh Coal Co., Pittsburgh, Penn.—5 representatives.

Bureau of Mines Representatives—George S. Rice, chief mining engineer; O. P. Hood, chief mechanical engineer; A. G. Heggem, petroleum engineer, all of Pittsburgh, Penn.—3 representatives.

State Geologists—F. W. DeWolf, director State Geological Survey, Urbana, Ill.; Richard R. Hice, state geologist of Pennsylvania, Beaver, Penn.; I. C. White, state geologist of West Virginia, Morgantown, W. Va.—3 representatives.

State Coal Mine Inspectors—None.

Thus the fuel-well interests outnumbered the coal men 10 to 5 or 2 to 1, though the safeguarding of gas and oil wells is largely a matter for the man who drills them. It is his apparent interest to make drilling as cheap as possible. Thus the act, as now formulated, is practically written by the parties it is to control.

The views of the fuel-well interests as to the importance of the conference are made abundantly evident by the presence of several attorneys who attended the last session in the interest of the gas- and oil-well owners.

Though some of the bureau's suggestions were not accepted by the assembled fuel-well men, it cannot but be evident that the federal organization has done its duty. It has asked for a discussion and has not attempted to dictate legislation. It is hoped that its more liberal point of view will find imitators, for in all matters discussed for the first time, differences of opinion are sure to occur.

The Buried Valley near Scranton

The buried valley occupied by the Susquehanna and Lackawanna Rivers and Newport Creek between Glen Lyon and Jermyn constitutes one of the geologic wonders of America. The sand is deposited in places over 300 ft. deep and for three miles near Plymouth, its depth is over 200 ft. When we compare these figures with those of the falls of Niagara where the water is precipitated only from 154 to 161 ft. we begin to realize what changes would take place in the topography of the buried valley were all the sand removed and snugly packed into the coal excavations below.

We remarked last week that such a removal in whole or in part would create engineering difficulties at least equal to those it would remove and it is easy to see that though the railroads might be moved back to the rock slopes and might thus be protected, yet crossings from slope to slope would be made with extreme difficulty.

The silt, being pervious and the outlet afforded by the Susquehanna River too high to lower the water considerably all the excavations would be converted into lakes; in fact, most of the sand would have to be removed by deep-water dredges.

The acid character of the water in the deep lakes thus formed would make it a difficult matter to maintain any buckets and chains in operating condition and the amount of water which would seep into the workings below would make their drainage almost infeasible.

Moreover, as the silt below the upper level of the Susquehanna waters near Nanticoke would be filled with water, it is probable that almost as fast as the sand was excavated, other bodies of sand would travel in to take its place with unfortunate results to cities and villages resting on the silt thus drawn away.

In fact, as far as filling is concerned we advise the Scranton people to look in large part "to the hills from whence cometh their help," rather than to the easy digging sand lying in the adjacent valley. It would be easier to crush rock than to dig it under such undesirable conditions.

Accident at Baskett Mines

As we anticipated when we published the report from the Baskett mine of the Pittsburgh Coal Co., Henderson County, Ky., the affair was much exaggerated. We were careful to throw some doubt on the character of the news by the nature of the wording. Alexander Blair, the general superintendent, in answer to our inquiries states that a part of the casing in the shaft broke loose and until it was repaired the cage could not pass it. Most of the men left the mine by the air shaft and those who did not want to climb the ladders remained below till the shaft was in condition. All the men got out and the hoisting of the coal was resumed at 3 o'clock the same day.

SOCIOLOGICAL DEPARTMENT

The Home of the Frick Employee

By Thomas W. Dawson*

SYNOPSIS—A half a million dollars spent in two years have revolutionized the Frick villages, and the improvements cover, among others: 105 small stables, 295 chicken pens, 150 pig pens, 38 miles of picket fence, 2700 stone cellars, 465 front porches, 650 back porches, water supply within 1200 dwellings, 132 new houses, 1379 concrete cesspools, 2500 garbage receptacles, 6600 shade trees and 61.7 miles of surface drains.

The H. C. Frick Coke Co. has spent during the last two years over one-half a million dollars in bettering the condition of the workman by improvements in sanitation and similar matters, and in making the home and its environments as comfortable as possible for the employee and his family.

The houses of the company are better than the ordinary dwellings erected by corporations for their employees. They are built on substantial stone foundations, and neat and sanitary cellars are being provided, there being 2700 such cellars built to date, and practically every house is equipped with spacious front and back porches. The company built 465 of the former and 650 of the latter this year. All dwellings are well painted a durable red with white trimmings. Running water has been placed in the kitchens of some 1200 dwellings, or in about 18 per cent. of the houses owned by the company. A number of bath rooms have also been provided, and many of them are electrically lighted, as are also the streets where electricity is available for this purpose.

Paling Fences Provided

Every tenant is provided with a lot, of suitable size, neatly fenced. Recently the company has been abolishing

Fig. 1. Model Alley at Standard, Mt. Pleasant, Penn.

Fig. 2. Street at Filbert, Penn.

It must be remembered that the majority of these employees are foreigners, many of them fresh from Europe. They are immediately encouraged in thrift and industry, and eventually become useful American citizens, much sooner than they would with environments not so elevating morally.

Unsightly Outbuildings Removed

One who visited the Connellsville coke region two years ago and returned to it today would be impressed at once with the wonderful transformation in the coke towns owned by the H. C. Frick Coke Co. Shacks or shanties which were standing on posts with unsanitary surroundings have been removed. At many of the towns whole rows of houses have either been replaced or moved to better locations. Nondescript outbuildings, built by the employee from all kinds of material, have been replaced by those of standard design and all these are neatly painted. The company built 105 stables, 295 chicken coops and 150 pig pens during the past year.

the old style of board fence and has replaced it with neat and durable palings. The gates have self-closing hinges. The company has built 202,000 lineal feet, or about 38 miles of this picket fence in the past year, representing 19.7 per cent. of the total fencing at all the plants. Fences are whitewashed each year. This is done by the householder, lime being furnished free by the company, which insists on the work being done. The rent which is received for the larger houses is about $7 per month; smaller dwellings rent for less. Free coal is given the tenant if he conveys it from the mine to his home. In the remodeling of these towns, in order to improve their appearance and make them more satisfactory, 67 shanties and old dwellings have been removed, and 132 in addition to these were torn down but replaced by new, uptodate dwellings.

Sanitation of Villages

The company has been replacing the old unsanitary wooden privy vaults by neat concrete cesspools. There have been 1379 of these constructed, and the recent type constitutes 38 per cent. of the total number of vaults at all of the towns. Similar vaults are provided for the employees around the mine buildings at the plant. Combin-

*Assistant chief engineer, H. C. Frick Coke Co., Scottdale, Penn.

Note—Abstract from paper entitled "Welfare, H. C. Frick Coke Co." read before the winter meeting of the Coal Mining Institute of America.

ation closets and coal houses to the number of 800 have been built in the last two years, replacing the old unsanitary closet.

The company has furnished 2500 neat garbage receptacles, which are emptied each week, or as often as necessary. These are found at all the towns, and at all times workmen and carts can be seen cleaning up streets and alleys to keep them free from rubbish and in a sanitary condition. To beautify the towns, 6600 shade trees have been recently planted.

Surface-water Drainage

Streets and alleys are graded and suitable concrete and brick drains constructed. Concrete water channels have been built where a short time ago unsightly and unsanitary water courses existed. The construction of 61,000 lineal feet, or about 11½ miles of brick drains; 71,000 lineal feet, or about 13.5 miles of concrete curb drain, similar to that laid in towns and cities; and 182,000 lineal feet, or about 34.5 miles of concrete drains of various sizes, in the past two years, as well as about 12,000 lineal feet, or about 2.2 miles of the larger type of concrete drain, has provided a complete system of drainage for each town. Thus all the towns of the H. C. Frick Coke Co. are in a first-class sanitary condition.

Specifications of Drains in Fig. 3

Illustrations accompany this article, showing standard methods of constructing drains. The cross walls in concrete curbs and gutters are 4 in. thick and the full width of the section. They extend to the minimum depth shown and further, when necessary to secure a firm bearing. Brick cross walls are 8 in. thick. All are set at 30-ft. centers. Expansion joints occur every 40 ft. These are made by inserting ⅛-in. sheet metal and withdrawing it when the concrete has obtained its initial set.

The wire rope used in concrete drains are old ropes of ½- to ⅝-in. diameter. Rope larger than the latter size are unstranded till the desired size is obtained. The brick are laid in 1:2 cement mortar.

Specifications of Drains in Fig. 4

Where wedge drains are used, subject to excessive wear, the bricks are laid on edge, and in 1:2 cement mortar at places of greatest abrasion; the excavation for brick laid on edge in wedge drains is 2 in. deeper than shown in the details. The brick used are ordinary hard-burned

red brick. The sub-base is of well tamped coke mixed with clay.

Fully Organized Health Department

A sanitary inspector is on duty in each town, makes frequent inspection and gives instructions to the tenants to keep their houses and surroundings in such order as will insure the health of the community. Moreover the doctors in the various towns have been requested to make reports on the general health conditions, and steps are taken immediately to remove any menace to the public health.

An ample sewer system is also provided, consisting of underground and surface sewers. Thus the company has made it possible for its employees and their families to

live under conditions which are positively ideal and sanitary.

Bacteriological Analyses of Water Supply

It has been the company's aim to provide good, pure water, and make the surroundings at the source of supply such that the water cannot be contaminated. During the year, 788 bacteriological analyses were made of the water supply at the many towns of the company. Samples were taken from all the wells, springs, hydrants and reservoirs and from the water rings in the shafts. It was found that 72 sources of supply were unfit for use and these were made unapproachable. In addition, 88 sources which were in an unsanitary location were entirely closed, thus, in

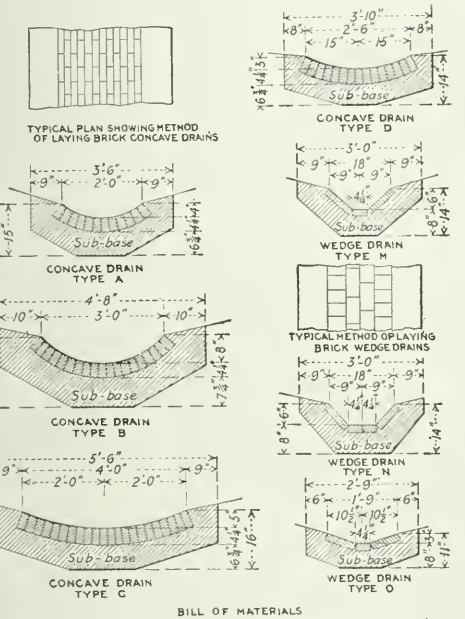

Fig. 1. Frick Standards for Brick Drains

all, the communities were protected against 160 possible sources of disease. These analyses are made periodically to make sure that the water is not contaminated.

⁂

First Aid Competition at the Kentucky Mining Institute

The program committee of the Kentucky Mining Institute, for the meeting to be held May 16 and 17, has selected 24 events, given below, for the state-wide first-aid contest to be held on May 16 at Lexington, in connection with the spring meeting of the Kentucky Mining Institute, and the judges, on the day of the contest, will select five of the problems, and these five events will be performed by each team participating in the contest, and the prizes will be awarded upon the work performed in the problems so selected:

Event No. 1. Lacerated scalp; top of head with bleeding. One-man event.

Event No. 2. Right ear torn off; deep cut on chin; bleeding. Two-men event.

Event No. 3. Broken left arm below elbow. One-man event.

Event No. 4. Lacerated wound on left side of head (the temple). Lacerated wound on top of right shoulder. Two-men event.

Event No. 5. Wound of right eye; simple fracture of left knee cap; full-team event.

Event No. 6. Lacerated wound in palm of left hand. Right thigh, compound fracture; improvise stretcher. Full-team event.

Event No. 7. Treat burns of face, ears and hands. Two men carry patient without stretcher. Two-men event.

Event No. 8. Compound fracture of lower jaw on right side; deep wound on inner side of left ankle. Bright red blood. Full-team event.

Event No. 9. Left ear torn off; ends of fingers cut off right hand; bright red blood. Two-men event.

Event No. 10. Dislocated shoulder left side; right foot smashed, bleeding. Full-team event.

Event No. 11. Fracture right collar bone; lacerated wound of palm of right hand. Full-team event.

Event No. 12. Dislocation of right hip; leg thrown outward and broken left collar bone. Full-team event.

Event No. 13. Broken back; simple fracture of right forearm. Full-team event.

Event No. 14. Man fallen on electric wire, face down, clothing burning; treat burns of breast and arms. Full-team event.

Event No. 15. Fracture of right leg above the knee; carry the patient on a coat and pole stretcher and place in ambulance; mine at top of hill, hospital in the valley, road down hill all the way. Full-team event.

Event No. 16. Man overcome by gas in a four-foot seam with a dislocated left shoulder. Remove 30 ft. to fresh air. One-man event.

Event No. 17. Compound fracture of left leg below the knee; bone sticking out on the inside of the leg. Full-team event.

Event No. 18. Man overcome by gas; shoulder, lift and carry to place of safety. Perform standard form of artificial respiration. One-man event.

Event No. 19. Broken ribs on right side; dislocation of left shoulder. Full-team event.

Event No. 20. Man squeezed between mine cars; broken pelvis and left elbow badly crushed. Full-team event.

Event No. 21. Man overcome by afterdamp; burns on hands, arms, neck and face. Full-team event.

Event No. 22. Man found under fall of coal with punctured wound of abdomen; broken ribs on left side; cut on right side of face; bleeding with bright red blood in spurts. Full-team event.

Event No. 23. Man run over by motor found with right hand cut off. Left arm torn out of shoulder socket. Full-team event.

Event No. 24. Man fallen on electric wire; back down, unconscious. Rescue, give artificial respiration one minute; treat burns on back and right upper arm. Improvise stretchers. Carry 50 feet.

There will be a large number of teams from coal companies in the western, northeastern and southeastern coal-mining districts of Kentucky.

H. D. EASTON, Chairman.
HYWEL DAVIS,
W. L. MOSS.

⁂

Kentucky Mining Institute

The annual meeting of the Kentucky Mining Institute will be held, May 16 and 17, at the College of Mines and Metallurgy of Kentucky State University, Lexington, Ky. The following papers will be read, with others not yet announced:

Workmen's Compensation: K. U. Meguire, president, Snead & Meguire Coal Co., Louisville, Ky.

Welfare or Sociological Work: W. C. Tucker, general superintendent, Wisconsin Steel Co., Benham, Ky.

Coal & Mineral Taxation: Hywel Davies and W. H. Cunningham, president and secretary, Kentucky Coal Operators Association.

Mineral Development of Western Kentucky: Fluorspar District, C. S. Nunn, manager, Kentucky Fluorspar Co., Marion, Ky.

Mining Laws of Kentucky: C. F. Fraser, mining engineer, Taylor Coal Co. of Kentucky, Beaver Dam, Ky.

Calorimeter Tests Made on Kentucky Coals: A. M. Peter, chief chemist, Kentucky Experiment Station, Lexington, Ky.

How Best to Handle the Dusty Mine: David Victor, chief mine inspector, Consolidation Coal Co., Fairmont, W. Va.

A first-aid contest will be an attractive feature of the program.

⁂

England's new coal-mines bill states that all newly opened coal mines shall have two main-intake airways, affording means of ingress and egress to the mine, one of which shall not be used for haulage purposes. Mines employing less than 100 men, or mines wet throughout, are exempt from this provision. Such mines are required to possess only two main airways, an intake and a return.

How Explosives Endanger the Miner's Home

By F. H. Gunsolus*

SYNOPSIS—There should be a storeroom for blasting powder, permissibles, caps and electric fuses at every mine. These dangerous explosives should not be taken home. The brightness of the caps attracts the eyes of the children and lures them to play with them. The use of permissibles and caps reduces fatalities in the mines and may increase the accidents in the home.

The subject of providing a house or storeroom in which miners can keep such powder as they have purchased but which they are not using, is of vital importance. This applies, particularly, to blasting powder. It is urged with reason that unless a storeroom is provided at the mines, the miners will have to take their powder to their homes, as the law does not permit them to take more than what is actually required into the mine.

A keg of blasting powder is not a particularly appropriate plaything for children, but how much more does this apply to blasting caps and electric fuses which are used by miners in places where permissible explosives and dynamite take the place of blasting powder.

Blasting Caps Are More Dangerous than Powder

The miner can, of course, gage the number of shots that he expects to make in one day closer than he can the exact number of pounds of powder or cartridges of Monobel, but he is less than human if he takes down into the mine the minimum number of detonators. As a matter of fact, he will usually allow himself several blasting caps more than he thinks he will need, and it is these blasting caps, when handled carelessly, which form a very decided menace to the health, happiness and prosperity of the community.

When the miner carries these articles loose in his pockets, they are apt to fall out or they may be removed by his wife when she puts his overalls in the wash. Being bright and attractive in color and outline, they excite the insatiable curiosity of youth to a much greater extent than the unattractive-looking powder.

The child may play with a small quantity of blasting powder without getting hurt, and it is unlikely that he would be able to drop a lighted match in a keg of powder, but it is the easiest thing in the world for a youngster to jab a pin or a nail in the open end of a blasting cap or to drop it into the kitchen stove, or hit it with a hammer, or do a number of other easily performed operations equally sure of disastrous results.

These blasting caps may be handled in the manner for which they were designed with practically no danger, but, on the other hand, they are exceedingly likely to explode if probed and a child is almost sure to lose several fingers, a hand or one or both eyes if he jabs a hat pin into the open end or holds a lighted match against it.

How the Permissible Explosives May Even Increase Fatalities

It is heartless and cruel, as well as shortsighted policy to contemplate these possibilities calmly. A child who has been blinded by a blasting cap, or has had a hand blown off, becomes a charge on the community and an expense to the tax-payer. Mine owners can ill afford to neglect their share in preventing these accidents after spending so much money in rendering the miner safe when at his place of work.

When the most progressive and enlightened mine owners go to enormous expense to reduce the number of accidents in their mines and the slogan of the entire industry is "Safety First," surely the prevention of the crippling and maiming of the children of their employees deserves instant consideration. There are over 600 accidents every year—practically all to children—due to the explosion of blasting caps and electric fuses. Unless some steps are taken to stop these articles from being carried home or thrown loosely into the pockets of the miners, this number is liable to increase, because more and more coal mines are abandoning the use of blasting powder and adopting the permissible explosives in order to promote safety.

Just imagine, for an instant, what a mine official would think if he saw his own youngster picking at the fulminate of a blasting cap with a hat pin to extract the explosive, so that the shell could be used as an ornament to a lead pencil. The picture of such an occurrence is not pleasant to contemplate. It is such an easy thing to prevent an occurrence like this, and it is so hard even to partially repair the damage, that no mine operator in his senses, appreciating the necessity for doing his share in preventing the maiming and crippling of children, should weigh for an instant, the trifling cost to him that is involved.

The miners, themselves, should, of course, be educated to do their part. It is not enough to provide a place where they can keep their powder and detonators when not in use, but they should also be warned of the danger of carrying these articles to their homes, and should be prevented, as far as it is possible to do so, from carrying blasting caps and electric fuses loose in their pockets and especially when they go home from the mine.

The Public Schools Will Assure the Safety of the Public

In some of the public schools in the large cities, children are taught how to avoid danger and it is explained to them in detail why they should not play on streets where traffic is heavy, why they should not coast in toy wagons on streets crossing others carrying heavy automobile traffic, why they should not hitch behind ice and other wagons, why they should look to the right on crossing the street until they get to the middle and then look to the left, and they are taught a number of other ways of taking care of themselves.

Would it not be fitting for the public-school teachers in the mining districts, to explain to the children, once in each session, at least, what a blasting cap is, how it is made, and what fearful things it sometimes will do to a child? It would seem that this instruction would be well worth the trouble involved.

Fatality Rates Compared in Coal and Other Mines

An inquiry just completed by Albert H. Fay, mining engineer, of the United States Bureau of Mines, shows that fatal accidents in metal mines in the United States are more numerous in proportion to the number of men employed than are the fatalities in coal mines. Of the 165,979 employed in the metal mines in the United States during the calendar year 1911, 695 were killed, which represents a rate of 4.19 per 1000 men employed, as compared with 3.73 per 1000 for the coal mines of this country for the same period.

Fatality Rate in Metal Mines 12 per Cent. Higher Than in Coal Mines

The total number of fatalities, serious and slight injuries due to accident is as follows: Deaths 695, or 4.19 per 1000 men employed; serious injuries 4169, or 25.12 per 1000; and slight injuries 22,408, or 135.01 per 1000. Of the total number of fatalities, 532 occurred underground, or at the rate of 5.18 per 1000, and 153 were killed on the surface, or 2.49 per 1000.

The figures show that approximately two-thirds of the total deaths and injuries that occur in and about metal mines were caused as follows:

Of the fatal accidents, 32.52 per cent. are due to falls of ore or rock from roof, wall or bank; 11.23 per cent. to explosives; 15.39 per cent. to falling down stope, shaft or winze, and 5.32 per cent. to mine fires.

Of the serious accidents, 31.37 per cent. are due to falls of roof, wall or bank; 19.05 per cent. to car and haulage systems; 12.19 per cent. to machinery, and 6.41 per cent. to timber and hand tools.

Of the slight accidents, 28.86 per cent. are due to falls of roof; 15.52 per cent. to car and haulage systems; 10.10 per cent. to machinery, and 8.02 per cent. to timber and hand tools.

Copper Mine Underground Fatality Rate 6.31 per Thousand

The figures for the copper mines show 396 operators employing 44,693 men, of whom 31,557 were employed underground and 13,136 on the surface. The total number of deaths and injuries due to accidents reported is as follows: Deaths, 238, or 5.33 per 1000 men employed; serious injuries, 1326, or 29.67 per 1000, and slight injuries 9016, or 201.73 per 1000. Of the total number of fatalities, 199 occurred underground, making this rate per 1000 men employed 6.31. The surface fatalities were 39, or 2.97 per 1000.

Iron Mines Kill 5.34 per Thousand Underground Employees

The figures for the iron mines show 207 iron-mine operators, who employed 45,953 men, of whom 25,161 were employed underground and 20,792 as surface men, including those engaged in steam-shovel work. The number of deaths and injuries resulting from accidents in these mines is as follows: Deaths 197, or 4.29 per 1000 men employed; serious injuries 2032, or 44.22 per 1000, and slight injuries 8690, or 188.3 per 1000. Of the total number of fatalities, 136 occurred underground, or 5.31 per 1000 men, and 61 employees were killed while engaged in surface work, making this rate 2.95 per 1000.

In Mississippi Valley Lead and Zinc Underground Workers Have Accident Death Rate of 3.46 per Thousand

The figures for the lead and zinc mines refer only to those in the Mississippi Valley. The lead and zinc mines of other states are grouped with miscellaneous metal mines on account of the difficulty of making a distinct classification, as lead and zinc occur in so many places as associated metals in silver ores, as, for instance, in the lead-silver mines of the Cœur d'Alene district, Idaho. The Mississippi Valley lead and zinc mines form a class by themselves and hence are easily segregated.

The statistics given embody the reports of 483 operators, employing 12,521 men, of whom 9247 are underground employees and 3274 surface men. The total number of deaths and injuries due to accidents is as follows: Killed 43, or 3.43 per 1000 men employed; serious injuries 177, or 14.14 per 1000; and slight injuries 1311, or 125 per 1000. Of the number of men killed, 32 fatalities occurred underground, making this rate 3.46 per 1000 men employed, while 11 men were killed on the surface, or 3.36 per 1000 men.

Fatality Rate at Other Metal Mines Is 3.95 per Thousand Underground

The figures for the miscellaneous metal mines show 3817 operators, employing 48,919 men, of whom 35,176 were underground and 13,743 surface men. The deaths and injuries due to accidents are as follows: Deaths 193, or 3.95 per 1000 men employed; serious injuries 540, or 11.04 per 1000; slight injuries 3078, or 62.92 per 1000. Of the total number of fatalities, 163 occurred underground, or 4.63 per 1000, and 30 on the surface, or 2.18 per 1000.

The rates of serious and slight injuries are low when compared with the iron and copper mines. This may be accounted for in part by reason of the fact that this group includes many prospectors and small mines, which keep no records. Fatal accidents impress themselves on the memory and are easily reported. The serious and slight injuries are soon forgotten if not recorded. Many of these mines are in states where there is no inspection, and they are not required to keep accident records. Many of the larger companies operating gold and silver and lead-silver mines of the West have, for their own protection, hospital service and medical aid for their employees.

Non-metal Mines Are Comparatively Safe

The non-metal mines employed 13,893 men, of whom 3182 were employed underground and 10,711 on the surface. The total number of deaths and injuries due to accidents reported is as follows: Deaths 24, or 1.73 per 1000 men employed; serious injuries 94, or 6.77 per 1000, and slight injuries 313, or 22.53 per 1000. When compared with the copper and iron mines, these ratios seem exceedingly low. Judging from the reports received, this is largely accounted for by the fact that the mines, being small and employing an average of only 12 men each, do not keep complete records. The majority of these mines are in states where there are no state inspectors, and are therefore not obliged to keep accident records and make reports thereon.

The statistics have been published in Technical Paper No. 10. Copies may be obtained by addressing the Director, Bureau of Mines, Washington, D. C.

DISCUSSION BY READERS

Post Timbering at the Working Face

Letter No. 8—I believe in systematic timbering, to a certain extent: but I do not think it would be advisable for the state to pass a law specifying the exact distance that timber should be kept up to the face. Neither do I think it would be possible for the state mine inspectors, to specify the distance the props should be set apart and away from the face, in each seam and at each mine.

While mine inspectors, almost without exception, are practical and experienced men and know the nature of the roof in the different mines they visit, yet in some cases to employ one or two timbermen would be both practical and economical, particularly in view of the many ignorant miners that are now employed. In pillar workings, for instance, it is not economical or well to fill the places with props, especially where these are not taken out, as the pillars are drawn back. At the same time, it would not be safe to go into a place and tell the men they are standing too many props. I have actually seen men go into the gob and stand new props, because some of the old ones were broken under the weight. They actually thought they were doing a wonderful thing and it is often difficult to make them understand that the roof should fall in the waste, in order to relieve the great weight on the pillars.

A timberman, say in each district, would generally save far more than his wages by seeing that the props were properly set and that enough and not too many timbers were stood. How seldom do we go into a place and find the props stood just where we would stand them. They are often too far away from the face, or too far apart. Sometimes, a man anxious to please the boss will stand his timbers so near the face that he cannot work. At times, the props will be set within a foot of the rib where under a good roof they can do no good.

It may not be generally known, but in Durham (England) the deputies (firebosses) set all the timbers, in the face. Each deputy has from 15 to 20 men to look after, and an accident from a fall of roof or coal is a rare occurrence. Of course, the men know enough to stand a prop to keep themselves safe, but it is only stood temporarily till the deputy gets around.

Accidents do not generally occur as frequently under a bad roof, as where the roof is fairly good, because the men are apt to trust a good roof too far. To illustrate this, we were drawing pillars where the roof was short and friable, about halfway up the rooms. Though the miners working there were good careful men we were anxious till they got under good roof again and we thought then all danger was passed, but a few days later a man was killed there by a fall of roof.

Examining the place after the accident, we found the props within 5 ft. of the pillar end, and a piece of rock about 5 ft. across had fallen out and crushed the man's head. No doubt, the rock would sound solid enough when tested, but it was loose. Any old miner can recall similar instances.

I often wonder why there is not more preserved (creosoted) timber used in this country. It lasts three or four times as long as ordinary timber. I have seen such timber still standing that I was told had been there 20 years. It was just as good as when first stood. No doubt it will cost a little more in the first place, but it is far cheaper in the end.

THOS. HOGARTH.

Heilwood, Penn.

Letter No. 9—One peculiar characteristic of the coal-mining industry is that, except in reference to purely mechanical features, no "hard and fast" rule can be given to overcome the various dangers that may arise from time to time. The greatest source of danger is the fall of roof and coal at the working face, which danger is usually met by some form of "posting."

While posting, however, is of prime importance, it is not the only consideration in maintaining a safe condition of the working face. It is equally essential that the development of the mine and the extraction of the coal should proceed in a systematic manner. In coal mining, as in every other industry, systematic work cannot be effective unless applied to all departments alike. The timber supply must be of uniform size and quality, and the timbers must be delivered promptly at the working face where they are required.

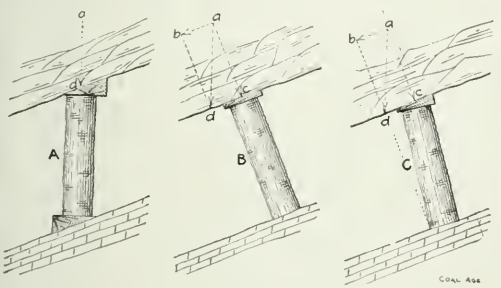
Posts are generally employed for three purposes, or to fulfill three conditions: 1. To make secure a bad and irregular condition of the roof. 2. To give warning of any movement in the roof strata or unsafe condition of the same. 3. To lend support to the roof strata over the opening and assist in the equal distribution of the load on the pillars. Each of these cases may be considered separately.

Before attempting to timber a particularly bad condition in the roof, or a bad piece of top, the place should be thoroughly examined to determine exactly its dangerous character. The person making the examination knows better where and how the several post timbers should be placed. I would not advocate the posting of a working place by men especially employed for that purpose. I believe greater safety can be secured by each miner timbering his own place under the instructions of a competent mine official, as this will make the miner himself responsible for his own safety and amenable to the mine regulations and discipline.

Under the present bituminous-mine law of Pennsylvania (Art. 4, Sec. 10), the foreman or his assistant must visit each working place "once each day while the employees are at work." In addition to this, in gaseous mines, the law requires (Art. 5) that each working place in the mine shall be examined twice each day, once before the men begin work and again during working hours. These several examinations of each working place should afford sufficient opportunity to give every miner the instruction he needs. My theory is that any ignorance on the part of the miner is best combated and overcome by careful inspection and patient instruction.

I consider the following points essential in post timbering: 1. In a level seam, a single post should be stood in a vertical position. 2. If the post is required for the support of the roof strata, it should not be wedged tight; and, in many cases where the roof or floor is hard, it will be necessary to set the post on a soft foot-piece, or a mound of dirt. In this case, the post should be twisted backward and forward to give it a solid bearing. 3. A cap-piece should always be placed above the post. 4. My personal preference is to stand the post with the large end down, as it grew in nature. The number of posts to be stood in a place and their arrangement, the distance apart, and the distance of the posts from the face of the coal, must be determined by the conditions in each place. My experience is that the use of long, heavy caps, or of crossbars, at the working face, will generally reduce the number of posts required.

I consider it generally a dangerous practice to set the first timbers so far from the face of the coal that the miner is unprotected. Under many conditions of the roof, it would be dangerous for the miner to be obliged to work between the posts and the face of the coal. Many accidents have resulted from this practice. Under particularly bad roof, places should be driven narrow and crossbarred. It may be often necessary to hitch the crossbars into the face of the coal, in order to give the miner the necessary protection.



Showing the Right and Wrong Way of Setting Posts In Steeply Inclined Seams

The use of posts for the second purpose mentioned; namely, to give the miner warning of any movement of the roof strata and enable him to escape the danger that threatens, arises in pillar work. When used for this purpose, the posts should be wedged tight, so that they will nip and crack upon the first movement of the roof. In neither of these first two cases can any regular system of setting posts be adopted. The arrangement must always be what the conditions require.

A systematic method of timbering can be adopted with advantage when, as stated in the third case, the purpose of setting posts is to lend support to the roof strata above the opening and distribute the pressure of the overburden evenly on the pillars. In this case, the system to be adopted must be determined by such conditions as the following: 1. The width of the opening. 2. The height of the coal. 3. The nature of the roof and floor. 4. The thickness of the pillars. 5. The location of the road in the room or working place. A system once adopted should be followed closely as long as the conditions remain unchanged.

Posting in an inclined seam differs materially from that in a level seam. In a level seam, the action of the weight of the overburden is vertical or perpendicular to the seam. In an inclined seam of coal, the action of gravity is still vertical; but, owing to the inclination of the seam, the vertical force *ad* is resolved into two resultant forces, the one *ab* parallel and the other *ac* perpendicular to the seam. In this case, the post must resist the action perpendicular to the seam; and, for this reason, must be set more or less at right angles to the floor and roof.

Referring to the figure, it would be obviously wrong to set a post vertical, as at *A*, when the seam is inclined, as in that position it could not be properly fastened but would slip out of place. Neither would it be right to set the post as at *B*, perpendicular to the roof and floor, although that would be in line with the force *ac*. But, the post in an inclined seam must be set, as at *C*, leaning slightly up the pitch, from a normal position.

J. C. Parfitt.

Jerome, Penn.

Letter No. 10—In the mining of coal, in Pennsylvania, the conditions often require a better class of labor than is found in the mines. The majority of miners who apply for work are unfamiliar with the conditions and often untrained. Owing to these facts and since about one-half of the fatal accidents in coal mines are known to be the result of falls of roof or coal, the question of timbering at the working face, is exceedingly important. Owing to the general lack of experience on the part of miners, it might seem best to have the timbering at the working face done by regular timbermen, whose knowledge of the conditions and whose experience would enable them to do the work more efficiently than the miners themselves.

As a matter of fact, however, it is generally better to have the miner do his own timbering, if for no other reason than to avoid his working under dangerous conditions while waiting for the timbermen to appear. Not only should the miner be made to timber his own place, but he ought to be taught to follow a *regular system* that experience has taught is best adapted to the conditions in that particular mine.

Since a general method of timbering that is applicable to one mine may be quite unsuited for another mine, each mine ought to have its own carefully worked-out system, modified to suit its own conditions. There are at least two reasons for not following a regular system of timbering: (1) The roof may be strong enough to require no timber; and, in that case, it would be a waste to set posts where experience has shown they are not needed. (2) Under certain conditions, the miners may be so well trained in timbering, as to render a regular system unnecessary. This latter case, however, is not common.

A regular system of post timbering, however, may be said to have the following advantages: (1) The roof strata are often cut by irregular slips, fault-lines or clay seams. These may draw back from the coal face in such a way that the trouble is invisible to the miner and little danger is anticipated. Under these conditions, the miner is prone to give little attention to the timbering of his place and is often caught by a sudden fall of roof, the break occurring at the face of the coal. Under such conditions, a regular system of timbering is absolutely necessary in order to make the place secure. (2) In a regular system of timbering, posts are set more promptly and

greater safety is secured. A regular system of timbering eliminates the judgment of the miner, and any delay on his part in setting posts is readily observed and condemned. (3) A regular system of timbering affords better opportunity for a rapid examination by the mine officials and inspectors, who can observe at a glance whether the system is being properly maintained. (4) The roof pressure is more evenly distributed and the coal breaks better after mining. (5) The timber is recovered in better shape and not so many posts are left behind in the gob.

M. D. Cooper, Mining Engineer.
Ellsworth Collieries Co.

Ellsworth, Penn.

Sudden Collapse of Working Places

I have been an interested reader of Coal Age from its first issue. The recent discussion on the timbering of the working face gives me the opportunity to mention what I am inclined to believe is one of the most dangerous conditions with which we have to contend in the work of mining coal. I refer to the sudden collapse of a working place without any premonition that would give the miner a chance for his life.

My attention has been attracted to this danger very forcibly by the second occurrence of such a disaster in the Connellsville region, in the last two months. In the first instance, two men were in the place; one was the miner who worked the place and the other a visiting miner, from another portion of the mine. The visitor was caught and killed by the falling roof, after a race for life of about 30 ft. The accident occurred in the rib workings of the mine, where they were drawing back the pillars.

The method adopted for working out the pillars was what is known as a "split." The pillar was supposed to be 31 ft. wide; and a 7-ft. roadway was driven up the center of the pillar, leaving 12 ft. of coal on each side of the road. This road or "split" was about 31 ft. in length and double-timbered from the place of beginning to where it cut through to the goaf or waste. It was the finishing up of an 80-ft. rib that had been crosscut halfway. The original pillar had goaf on its left side (inby) and goaf in front.

Starting at the rear end, the miners had cut through to the goaf in front and had started to make a cut over to the goaf on the left side. They had only gone a distance of 6 ft., carrying a working face or breast 10 ft. wide. In this distance they had set two double-timber frames, at the time the accident occured. The fireboss had examined the place at 3 a.m. and again at 7 a.m. and reported the timbers in good shape. The mine foreman had examined the place again at 10 a.m. and the driver had just loaded a wagon of coal about 30 min. before the accident occurred, which was 11:30 a.m. All these men reported that the place was apparently safe and in good condition, no timbers being broken and there being no indication of a fall.

The miner who was working the place and who escaped said that the only warning they had was the breaking of a post. When the post broke, the miner called to the visitor, "Run!" and they both ran for their lives, the one who escaped being only about 4 ft. in advance of the other man.

The question that presents itself is: What caused this place to suddenly collapse, and is there any way in which the danger can be foreseen and the accident avoided. If good, sound timbers, well set, cannot be depended on to give sufficient warning to allow a miner to make his escape, then what method or what means can be adopted to insure the safety of the workers.

I should have mentioned that the coal was 9 ft. thick, with a tender roof, and about 500 ft. of cover overlaid the coal. I mentioned the place was double-timbered, by which I mean that it was timbered with 5-in. round timbers, forming a three-piece set (two legs and a collar). These frames were set 3 ft. apart and lagged overhead to support the roof between the timbers. Each set of timbers was tightly wedged over the posts and the lagging fitted in snugly. The bottom, or floor, under the posts was hard. When the fall occurred, the timbers were not broken, but thrown out faster than a man could run, for a distance of 30 feet.

I have tried to explain, in detail, the conditions that existed at the time and place of this accident, hoping that some readers may be able to explain the possible cause of the accident and suggest a remedy or means for its prevention.

The second accident of this nature occurred recently in another mine. I am not so familiar with the conditions surrounding this accident, but I am told that the collapse of the roof was so sudden the rib boss and the miner were both killed. There was certainly no indication of immediate danger, in this place, or the rib boss would surely have gone out and taken the miner out with him, which would be his duty if he thought the place was unsafe.

J. H. Lane, Mining Supt.,
Oliver & Snyder Steel Co., No. 3 plant, Uniontown, Penn.

Our Future in the Export Trade

I have read with interest what has been said in Coal Age lately concerning our future in the export business and admit the question has been treated in a masterly way. But, so far, we have not yet heard what the people who might buy American coal have to say about it. American coals are not so unknown abroad that foreigners have not had a chance to form an opinion in the matter.

As a matter of fact, the foreign buyer is acquainted with the analysis, the heating value and the physical qualities of our coals. I was astonished some months ago, at the amount of information on American coal that could be found in some buyers' offices in Paris. As you well know, Paris is a large coal-buying center not only for France, but Spain, Italy, and the whole Mediterranean littoral. All the French railroads also have their headquarters in Paris.

They all agree, in Paris, that we have coals in America that will enable us to compete successfully with any coal coming out of either England, Belgium or Germany. But they complain of our unwillingness or inability to deliver the coal prepared just as they want it and as they have been used to receive it from the English, Germans and Belgians. They also complain of our insisting on being paid against bill of lading when the time-honored Continental custom is ninety days. Even the French Government pays at 90 days.

As far as I was able to ascertain, while on the other side lately, the complaint was general about preparation. There was also a great deal of comment about irregularity in quality, some cargoes having been received which contained coals of widely different analysis. In the same cargo a coal containing less than 20 per cent. volatile matter might sometimes be found in one of the compartments, while coal from another compartment showed 32 per cent. volatile matter.

A cargo of 6200 tons was given as an example of such irregularity. It had been ordered by a French railroad as a sample cargo. The specifications called for a coal with not less than 30 per cent. volatile matters. When the ship reached Marseilles, the coal was inspected on the surface. It was plain that the shipment was made up of two different coals varying widely in looks. One was more lumpy than the other. The more lumpy one was less glossy than the other. Samples were taken and analyzed in the railway's local laboratory. From 18 per cent. in the smaller kind of coal to 37 per cent. in the more lumpy coal, was the difference in volatile matters.

At about the same time, a cargo of American coal intended for some gas works reached a Spanish port. Less than one-half of it was up to the guarantee in volatile matter. The rest of the shipment contained 20 per cent. volatile matter. The sellers had guaranteed a minimum of 32 per cent. These unfortunate affairs were made much of and advertised broadcast. It was even said, probably by competitors' agents, that this was only a fair sample of American business methods and explained why Americans demand payment against bill of lading.

Wide difference in volatile matters is accounted for probably by the fact that the shippers have mines in different seams. It also happens that when a shipper is unable to complete a cargo within the specified time, he gets another shipper to help him make the cargo. In either case, it is carelessness. As to preparation, of which foreign buyers also complain, it may be due either to poor preparation at the mines, or to rough dumping at tidewater.

But, no matter how well a coal is prepared at the mines, it is bound to suffer to a considerable extent when dumped by means of such arrangements as they have at all our tidewater piers, where the aim is fast work. Whether the coal is pulverized or not while being dumped, does not seem to be taken into consideration. English shippers know well they have little to fear from us as long as we continue to load our coals into sea-going ships in the way we do now.

Study Course in Coal Mining

By J. T. Beard

The Coal Age Pocket Book

THE ATMOSPHERE

The atmosphere is the aërial envelope surrounding the earth. The term is also used to describe the air or gaseous mixture filling any given space; as, for example, the mine atmosphere is the air and gases filling the mine or any portion of the workings.

Atmospheric Pressure—The weight of the air surrounding the earth causes a pressure, which decreases as the height above the surface increases; and the density of the air decreases in like manner, with the elevation above sea level.

Variation of Atmospheric Pressure—Atmospheric pressure varies irregularly with the condition of the atmosphere in respect to storms; the storm center being always an area of lower pressure than that surrounding the storm. In this country, a variation of 2 in. of mercury (say 1 lb. per sq.in.) in atmospheric pressure, in 48 hr., is not uncommon.

There is also a regular daily variation, the pressure attaining a maximum about 10 o'clock and a minimum at 4 o'clock, morning and evening. There is, likewise, a yearly variation, the general pressure reaching a maximum, in the northern hemisphere, in January and a minimum in July.

THE BAROMETER

The Mercurial Barometer—The pressure of the atmosphere is measured by the height of mercury column it will support against a vacuum. The mercurial barometer is a glass tube, about 36 in. long, closed at one end. This is first filled with mercury and then inverted, the open end being immersed in a basin of the same liquid, the mercury in the tube will fall to a height above the surface of that in the basin, such that the pressure of the atmosphere acting on the surface of the liquid in the basin will support.

Barometric Pressure—The pressure of the atmosphere expressed in inches of mercury is called the barometric pressure. For example, at sea level, the atmospheric pressure will commonly support 30 in. of mercury column, or is equivalent to a barometric pressure of 30 in.

Calculation of Barometric Pressure—One cubic inch of mercury (32° F.) weighs 0.49 lb. A barometric pressure of 30 in., therefore, indicates an atmospheric pressure of

$$0.49 \times 30 = 14.7 \text{ lb. per sq. in.}$$

which is the normal pressure at sea level.

Calculation of Water Column—The height of water column, in feet, the atmospheric pressure will support is found by multiplying the pressure (lb. per sq.in.) by 2.3, or dividing the same by 0.434. Or the barometric pressure, in inches, multiplied by one and one-eighth will give the equivalent water column, in feet. For example, at sea level,

$$14.7 \times 2.3 = 33.8, \text{ say } 34 \text{ ft.}$$

$$30 \times 1\tfrac{1}{8} = 33.75, \text{ say } 34 \text{ ft.}$$

The Coal Age Pocket Book

SPECIFIC GRAVITY

The specific gravity of a substance—solid, liquid, or gas—is the ratio of the weight of that substance to the weight of another substance taken as a standard, volume for volume;

$$Sp.gr. = \frac{wt.\ of\ unit\ vol.\ of\ substance}{wt.\ of\ unit\ vol.\ of\ standard}$$

Standard for Gases—The standard adopted for gases is air, of the same temperature and pressure as the gas.

Standard for Liquids and Solids—The standard adopted for liquids and solids is water at maximum density. Except where great accuracy is desired, the weight of 1 cu.ft. of water is taken as 62.5 lb. Exactly, 1 cu.ft. of pure water, at maximum density weighs 62.4283 lb.; or 1 cu.in. weighs 252.89 grains = 0.03613 lb.

Use of Specific Gravity—To find the weight of any volume of a substance, multiply the unit weight of the standard, by the specific gravity of the substance, and that product by the given volume, or, expressed as a formula,

$$Wt. = unit\ weight\ of\ standard \times sp.gr. \times vol.$$

For example, taking the average specific gravity of anthracite coal as 1.5 the weight of this coal underlying 1 acre (43,560 sq.ft.) of land for a thickness in the seam of 1 ft.; or, as we say, per foot-acre, in long tons (2240 lb.) is

$$\frac{62.5 \times 1.5 \times 43{,}560}{2240} = 1823\ long\ tons$$

Or, taking the weight of 1 cu.ft. of air (60° F., bar 30 in.) as 0.0766 lb., since the specific gravity of carbon dioxide (CO_2) is 1.529, the weight of 100 cu.ft. of this gas is

$$0.0766 \times 1.529 \times 100 = 11.712 + lb.$$

Calculation of the Specific Gravity of Gases—The specific gravity of a gas can be calculated by dividing one-half of its molecular weight by 14.4. For example, the molecular weight of carbon dioxide is 44; therefore, $44 \div 2 = 22$, and $22 \div 14.4 = 1.528$. The actual specific gravity is 1.529.

Finding Specific Gravity of Gases—A glass globe, any convenient size, is first weighed empty (air exhausted), w; then full of air, w_1; and, lastly, filled with the gas, w_2, the temperature and pressure remaining constant.

$$Sp.gr. = \frac{w_2 - w}{w_1 - w}$$

Finding Specific Gravity of Liquids—A glass-stoppered bottle is first weighed empty, w; then filled with water w_1; and, lastly, filled with the liquid, w_2. The specific gravity is then calculated by the above formula for gases. Or, the specific gravity is determined by a graduated float (hydrometer).

Finding Specific Gravity of Solids—Weight of the solid in air, w; weight immersed in water w_2. The weight of the water displaced is then $w - w_2$, which is the same volume as that of the solid

$$Sp.gr. = \frac{w}{w - w_1}$$

EXAMINATION QUESTIONS

Ventilation

Ques.—What is meant by the "equivalent orifice," in fan ventilation?

Ans.—The term "equivalent orifice" is used to describe an opening in a thin plate, that will allow the given quantity of air to pass under the same pressure as is producing that quantity in the mine. The area of this opening is called the equivalent orifice of the mine. In the same way, the equivalent orifice of the fan is the area of opening through which the given volume of air would pass under the pressure absorbed by the fan.

Ques.—Explain the meaning of the term manometrical efficiency, as used in fan ventilation in estimating the efficiency of the fan.

Ans.—The term, manometrical efficiency, has been used to describe the ratio of the actual water gage produced by a fan at a given speed, to the theoretical water gage calculated by the formula

$$w.g. = \frac{1.2 \times 1^2}{1000} \times \frac{u^2}{g} = 0.0144 \times \frac{u^2}{g}$$

The above formula merely expresses the theoretical water gage, which it is assumed a fan whose tip speed is u will produce. It must be remembered, however, that the water gage produced is determined by the mine resistance and not by the fan. Cut off the mine, and there is no resistance or water gage. On the other hand, increase the mine resistance and the water gage is increased, for the same size and speed of fan. For this reason, the term manometric efficiency has no particular value, with respect to the fan alone.

Ques.—If 60,000 cu.ft. of air per min. is passing through an airway, under a pressure of 6.954 lb. per sq.ft., what will be the size of the opening in a regulator placed in this airway, to reduce the volume of air to 15,000 cu.ft. per min.?

Ans.—It is first necessary to find the natural pressure, or the pressure due to friction when 15,000 cu.ft. of air are passing in this airway. Since, for the same airway, the pressure varies as the square of the quantity of air in circulation, the pressure ratio is equal to the square of the quantity ratio. Calling the required pressure x, we have

$$\frac{x}{6.954} = \left(\frac{15{,}000}{60{,}000}\right)^2 = \left(\frac{1}{4}\right)^2 = \frac{1}{16}$$

$$x = \frac{6.954}{16} = 0.434 \text{ lb. per sq.ft.}$$

The pressure due to the regulator is now found by subtracting this natural pressure from the original pressure, which is assumed to remain constant; thus, 6.954 — 0.434 = 6.52 lb. per sq.ft. The opening required in the regulator to pass 15,000 cu.ft. of air per min. under a ventilating pressure of 6.52 lb. per sq.ft. is then

$$A = \frac{0.0004\ Q}{\sqrt{w.g.}} = \frac{0.0004 \times 15{,}000}{\sqrt{6.52 \div 5.2}} = 5.35 \text{ sq.ft.}$$

Ques.—A fan is 16 ft. in diameter and, running at a speed of 150 r.p.m., is passing 16,500 cu.ft. of air per min., under a water gage of 4 in. What is the equivalent orifice of the fan?

Ans.—First find the tip-speed u of the fan; thus,

$$u = \frac{3.1416 \times 16 \times 150}{60} = 125.66 \text{ ft. per sec.}$$

The theoretical water gage of this fan at the given speed, is then

$$w.g. = 0.0144 \frac{u^2}{g} = \frac{0.0144 \times 125.66^2}{32.15} = 7.07 \text{ in.}$$

The manometric efficiency, under these conditions, is therefore

$$K = \frac{4 \times 100}{7.07} = 56.57 \text{ per cent.}$$

Now find the equivalent orifice of the mine, thus

$$O_m = \frac{0.0004\ Q}{\sqrt{w.g.}} = \frac{0.0004 \times 16{,}500}{\sqrt{4}} = 3.3 \text{ sq.ft.}$$

The equivalent orifice of the fan is then calculated by the formula

$$O_f = \sqrt{\frac{K}{1 - K}}\ O_m = \sqrt{\frac{0.5657}{0.4343}} \times 3.3 = 3.76 \text{ sq.ft.}$$

Ques.—At a certain mine, there is installed a ventilating fan operated by an electric motor. The fan is producing 300,000 cu.ft. of air per minute, against a water gage of 4.2 in. The wattmeter registers 145 kw. for each of the two motors, or a total of 290 kw., in the fan house. At the power plant, one mile from the fan house, the meter registers 330 kw. What is the mechanical efficiency of the fan?

Ans.—The power lost in transmission is 330 — 290 = 40 kw.; or, 40 × 100 ÷ 330 = say, 12 per cent. of the power generated. At the fan house, it may be assumed that the efficiency of the motors is, say 95 per cent., which makes the power applied to the fan shaft, 0.95 × 290 = 275.5 kw.; or, 275.5 × 0.746 = 205.5 hp.

The horsepower on the air is

$$H = \frac{300{,}000 \times 4.2 \times 5.2}{33{,}000} = 198.5 \text{ hp.}$$

According to these data, the mechanical efficiency of the fan is

$$\frac{198.5 \times 100}{205.5} = 96.5 \text{ per cent.}$$

This is a very high efficiency for a ventilating fan. It may be that there were some factors assisting the ventilation in the mine that were unaccounted for, and that these operated to produce the high efficiency registered. It often happens, in conducting a fan test under mining conditions, that certain air columns, caused by the artificial heat of steam pipes in the shaft or slope, or the natural heat of the mine in dip workings, are powerful factors that must be considered in ascertaining the efficiency of the ventilator.

COAL AND COKE NEWS

Washington, D. C.

Under the present coal contracts made with the Isthmian Canal Commission, which have eighteen months to run from April, the present price of coal is about $4.09, plus the cost of discharging and other incidental items, the tidewater price being $2.70 and the transportation $1.39. The competitive price with the Government price will depend on the short haul from the United States, the proximity of supply to the canal and the means of getting it to the isthmus.

The efficiency of the uptodate vessels of the Government must be taken into consideration. It is understood that in the event of the free toll clause of the Panama act being repealed the Government may itself run a line of steamships through the Canal, which may act as a rate regulator against railway-owned steamship lines.

In this connection a memorandum recently issued by the Isthmian Canal Commission is of much significance as outlining the policy of the Government in regard to applications received from coal companies and fuel oil companies in reference to establishing private coal and oil depots on the Isthmus to supply shipping passing through the Panama Canal. The memorandum says, in part:

The act of Congress approved Aug. 24, 1912, authorized the establishment of Government plants for coal, fuel oil, etc., for supplying shipping, and steps are being actively taken to start the construction of the same. It is not, however, intended to prevent private interests doing business in the Canal Zone as regards selling coal and fuel oil to shipping.

Under the so called Taft agreement with Panama, coal and fuel oil may be brought into the Canal Zone by individuals and companies without the payment of duty to Panama.

It is estimated that oil can be, if required, transferred from one terminus of the canal to the other by pumping through a pipe line cheaper than by being carried across in oil vessels and paying canal tolls. Transportation of coal across the isthmus will probably be cheaper by vessel, including payment of tolls, than by railroad.

It will be the policy of the United States to retain complete control of the terminals, water frontage and transportation by land and water across the isthmus.

It will not be the policy of the United States to attempt to monopolize the fuel business, and every possible means will be taken to encourage the establishment of private coal and fuel-oil depots on the isthmus under proper conditions.

Under the conditions of a revocable license, it is doubtful whether an individual or company would be warranted from a business standpoint in making a large expenditure for dredging, wharf construction and similar improvements. From the standpoint of the canal, the duplication of such independent and separate improvements, the cost of which will have to be absorbed eventually by the selling price of coal and fuel oil, is not desirable whether suitable locations can be found and assigned for this purpose or not.

The Government plants are being laid out so as to afford ample wharf room and to provide ample modern coal-handling machinery for unloading colliers into the coal pile and reloading coal to lighters or barges. Likewise the Government fuel-oil plants will ultimately be combined with the Government coaling plants so far as wharfage is concerned. At Cristobal it is proposed to temporarily fit up docks 13 and 14, near the Cristobal dry-dock shops, with oil pipes and pumping plants in duplicate until the permanent combined coaling and oiling wharves are completed.

So far as coal is concerned, it has been decided to set aside a certain ground area that will be served by the coal-handling machinery with the same convenience as the area occupied by the Government coal pile for the storage of the different coal piles of individuals and companies.

This arrangement will obviate the necessity of any dredging, wharf construction, or purchase of coal-handling machinery by private owners and companies, and at the same time will enable them to obtain the benefits of the rapid coal-handling machinery to be purchased by the United States. It is expected that the Government coaling plant will be in operation before Jan. 1, 1915. Suitable temporary arrangements will be made to take care of any business originating before the permanent plant is completed.

With the large number of coal and fuel-oil lighters and barges at each terminus of the canal that will be maintained by the United States, the purchase and use of additional barges and lighters by individuals and companies will probably be unnecessary, for the United States will be in a position to make a price on lightering coal for individuals and companies in its own lighters that will result to the advantage of all parties concerned.

Any taxes levied in connection with private coal and oil depots will have two purposes in view for the interests of the canal: First, to reduce the unnecessary duplication of plant; and, second, to encourage the carrying of large stocks of coal and oil. To accomplish this, there will be a tax based upon the cost of improvements which would enable revenue to be derived in proportion to the investment made, which will probably be 1 per cent. per annum on the cost of improvements.

Inasmuch as the storage of large amounts of coal and oil on the isthmus should be encouraged, a tax similar to the present merchandise tax would not be satisfactory, as it would tend to discourage same. In lieu of a merchandise tax, therefore, a tax of about one per cent. on the sales of coal and fuel oil by individuals and companies within the limits of the canal will be levied. This tax will probably be 1¼c. per barrel of oil, and 5c. per ton of coal of 2000 lb.

Report on Coal Prices

The full text of the report on anthracite coal prices prepared by the Department of Commerce and Labor as the result of a House resolution passed some months ago, has just became available. In brief the most important of the results are as follows:

The increase in wholesale prices, as measured by the net receipts from sales of anthracite coal by the operators since the agreement of May 20, 1912, amounted to an average of 25.82c. per ton, if the prices existing in June, July, August and September, 1911, are compared with the prices realized during the same months of 1912. On this basis of comparison the average increase in the price of sizes of coal prepared for domestic consumption amounted to 31.23c. per ton and the average increase on pea coal and the smaller steam sizes amounted to 16.14c. per ton.

This increase was in part due to the unusually active demand for coal in the summer of 1912 and cannot properly be assumed to be a permanent increase. It seems to consider as the probable permanent increase the advances in the circular prices asked for coal. A weighted calculation of the average increase in the circular prices of the Philadelphia & Reading Coal & Iron Co. for the prepared sizes of white-ash coal shows that the average increase at tidewater was 34.3c. per ton and on sales for railroad shipments 23.2c. per ton. The average for all sales (allowing 25 per cent. of the total shipments for tide water sales in accordance with the results of 1911) was 26c. per ton on the prepared sizes. No similar calculation can be made for the steam sizes, since no circular prices are ordinarily issued to cover steam sizes at tidewater and even when issued have little significance.

Furthermore, the discounts on prepared sizes of 50 and 40c. a ton customarily allowed in April and May, respectively, were suspended in April and May, 1912. As a result the operators gained not only by selling their prepared sizes of coal during these two months at 40 or 50c. more per ton than during the corresponding months of 1911, but, in addition, the purchasers, who were unable to secure their customary supply of coal during April and May, were forced to buy it either during June, July or August, when the regular discounts were smaller, or in September and the later months when the full circular prices are charged.

The coal companies in 1912 received through the general increase in prices and through the suspension of discounts about $13,450,000 more than they would have received for the same tonnage at the prices previously existing. Of this amount about $10,900,000 was derived from the general increases in prices, and about $2,550,000 from the suspension of April and May discounts. In addition, a limited number of operators received immense sums through the sale of coal at premiums made possible by the shortage of shipments.

These amounts, it should be understood, do not represent the amount of increases in net profits to the operators, because out of these increased receipts had to be paid the cost of the six weeks' cessation of work in April and May, and also the increase in the wages of employees resulting from the settlement of May 20.

The reasons presented by the anthracite operators for these increases in prices are that they were necessary to cover (a) the advance in the wages of their employees resulting from the agreement of May 20, 1912, and (b) the various increases in the costs of production which have taken place between 1902, the date of the last general increase in prices, and 1912, largely as a result of increasingly difficult physical conditions of mining, increases in taxes and more stringent mine laws.

The anthracite mine workers were benefited by the agreement of May 20, 1912, not only through a net increase in their wage rates, which averaged 5.6 per cent., but through the concession of certain working conditions which were considered of importance, though they cannot be measured in terms of money. An additional item of importance to the miners was the partial recognition of their organization, both in the negotiations and in the form in which the agreement was signed. The advance of 5.6 per cent. in mine-workers' wages represents an average increase of 9c. per ton in the cost of producing coal, and on the basis of the shipments from June to December, 1912, amounted in round numbers to $4,000,000.

PENNSYLVANIA

Anthracite

Scranton—Suit has been commenced by the Lackawanna Coal Co. against the People's Coal Co. to restrain the latter from continuing to mine coal at the Oxford colliery. The grounds given are that the defendant company has been mining outside the boundaries of its lease and, further, that it is mining recklessly. It is charged that the People's company is taking out all the supporting pillars and that property in West Scranton is endangered.

Pottsville—Upward of 700 or 800 employees are on strike at the Philadelphia & Reading Coal & Iron Co.'s Otto colliery at Branchdale. Not a wheel is turning at the colliery and only those necessary to keep the fires and pumps going are on the job. The output is about 100 tons per day.

As a result of a mine accident, Mar. 20, at the Blackwood colliery three men were injured while working in the gangway. A loaded ear was pushed up the incline and somehow or other it got away and jumped the track.

Wilkes-Barre—The Avondale Colliery of the D. L. & W. Coal Co., which has been closed since Feb. 25, was opened on Wednesday, Mar. 26. The colliery was closed down on account of a strike among the workmen, and remained closed until repairs had been made by the company.

Thirty members of the Industrial Workers of the World, employed at Jermyn & Co. collieries at Old Forge, were notified by the company that they must join the United Mine Workers or quit their jobs. They have been given three weeks to comply with this order. The company officials say they will not stand for two rival unions.

Carrolltown—The coal tipple of the Blaine Coal Co. has been destroyed by fire. The blaze caused a $13,000 loss. It is expected that the mine will be tied up for six weeks. Four hundred men are idle.

Du Bois—On Mar. 24, the mines of the North-Western Mining Exchange Co., a corporation, subsidiary to the Erie R.R., were still idle, and were commencing their sixth week of inactivity. It will be recalled that they quit work on Feb. 10 because the company refused to make the dump pan self-cleaning. After two weeks' idleness, the men returned to work on an agreement. After four days the company, ascertaining that it was getting short weight, closed down to change the pan. This suspension was to last three weeks. The company repaired the mine but did not work on the pan till last week.

Brockwayville—The F. A. Lane mine is worked out. In 40 years it has never had an accident, but its production at no time was much over 100 tons per day. For many years it had no railroad connections. There is another seam and the company expects to open it and dump the coal over the present tipple.

Punxsutawney—L. M. Furniss, state mine inspector, caused the arrest of seven foreign miners in Indiana County, charging them with neglecting to use sprags under their coal and failing to make a proper examination after a blast. They were brought before James A. Crossman, justice of the peace, and fined $1 and costs in each instance.

WEST VIRGINIA

Moundsville—One hundred and fifty miners spent the night of Mar. 20 in the mine of the Mound Coal Co. because of a breakdown in the shaft. The shutdown was caused by the dropping of the cage, which put the hoisting machinery out of commission. Since this shaft is the only entrance to the mine the men were forced to remain below until the necessary repairs could be made.

The Parrs Run Coal Co.'s mine was partially destroyed by fire, Mar 19. The loss will probably reach the $5000 mark, and is fully covered by insurance. Officials of the company state that it will probably be two months before the mine will again be put in operation. The cage fell a distance of over 400 ft. When the new cables arrive this will be raised and repaired. The mine employs about 100 men. Many of these have secured employment in the various mines of this section, but the remainder, in all probability, will be out of employment until the mine resumes.

Fairmont—Considerable damage was caused at the Middletown operations of the Consolidation Coal Co. when four company houses were destroyed by fire. The loss is estimated at about $7000. The houses were all insured and it is announced that they will be rebuilt at once. The fire was caused by sparks from a passing engine.

Charleston—Governor Hatfield has ordered the unconditional release of 10 of the 49 prisoners before the military commission. "Mother" Jones and other leaders were not released.

The Black Cat coal tipple, near Crown Hill, and a tipple at the Maban mine on Paint Creek were burned Mar. 16. It is supposed that the fires were of incendiary origin.

KENTUCKY

Henderson—One hundred and thirty miners were imprisoned Mar. 18 in a coal mine of the Pittsburgh Coal Co. at Basketts because of a cave-in which clogged the mouth of the shaft. Reports state that there were no fatalities.

Louisville—A terrific wind storm passed over this city Friday, Mar. 2. The Consolidated Coal Co. suffered the loss of fourteen barges, tied up at Port Fulton, on the Ohio river near Louisville, which were blown loose and sunk by the storm. Each was loaded with 17,000 bushels of coal, worth about $10,000. The company also lost a pump boat valued at $2500. It may be possible to recover some of the coal by dredging, and perhaps to raise the barges. A number of other barges on the river were torn from their moorings, but were recovered without damage.

VIRGINIA

Norton—The Norton Coal Co.'s store in the coalfields which adjoin the Harlan and other eastern and southeastern Kentucky coalfields, was recently destroyed by a fire. The total loss was about $25,000, and of this only $8000 was covered by insurance. The coal company's store is to be rebuilt at once.

OHIO

Columbus—A bill has been introduced in the Ohio senate by Senator Moore of Jefferson County proposing to relieve a situation said to prevail extensively in mining sections of the state. The situation has to do with the instances wherein a farmer may have coal under his land, but finds himself completely surrounded by big interests that have bought up all the holdings. The farmer often finds himself unable to market his coal because of inability to get an outlet and thus is forced to sell his lands at a sacrifice. The Moore Bill would permit the owner of the land in such a circumstance, to condemn an outlet and pay for the appraised damages.

INDIANA

Brazil—Two hundred and fifty miners of Coal Bluff, together with sympathizers from surrounding towns attempted to mob John Beck, mine boss at the Monkey mine of the Clay County Block Coal Co. recently. Beck's alleged preference for Brazil miners is given as the cause of the outbreak.

Princeton—A temporary agreement has been made on the powder question at the Ft. Branch mine, where an explosion occurred recently. The state mine inspectors demanded that a new patent explosive be used instead of black powder. The company opposed the order and the mine was shut down. The new explosive is to be given a thirty-days' trial.

Dugger—Nine men were injured, four seriously, in an explosion of gas, Mar. 22, in Superior Mine No. 10. The mine belongs to the Vandalia Coal Co. Only 14 men were at work, cleaning up in preparation for opening again Monday. Usually there are 300 to 400 at work. The men injured suffered from burns and inhalation of flames and poisonous fumes. Two of them were taken to the hospital at Terre Haute.

ILLINOIS

Auburn—Two explosions in separate parts of the Solomon mine on Mar. 11 caused a serious injury to four miners. Officials of the mine are at a loss to find an explanation for the twin accidents, which occured a mile apart. The explosion extinguished the men's lamps and left them in the dark. It was some time before the rescuing party was able to locate the injured men and bring them to the surface.

OREGON

Portland—According to a newspaper article from Fossil, Ore., Anthony Mohr was at that place about a week ago and secured leases on coal lands wanted by the Pennsylvania Coal Co. The clipping from a Fossil newspaper says that Mr. Mohr is of the opinion that the fields he has leased are the most extensive in the West. The report also states that he has spent months in exploring them.

FOREIGN NEWS

A new company, of which Sir Owen Phillips, chairman of the Royal Mail Steam Packet Co. is a director, intends to establish a fueling station at Colon where the steamship company owns a pier, this property having been granted to it 60 years ago. The Packet Co. also owns an island not more than one hour's sail from Panama in the Pacific Ocean.

Bochum Germany—A sudden fire broke out, Mar. 19, in the President colliery cutting off the superintendent of the mine and an unknown number of miners. The fire started close to the main shaft and spread rapidly. Gangs of rescuers found the dead body of the superintendent at the bottom of the shaft. Later in the day they brought out all the miners alive and unhurt.

London, Eng.—It is understood that on behalf of a powerful syndicate D. A. Thomas, chairman of the Cambrian Trust, will soon proceed to the United States in order to complete the negotiations for the purchase of coal mines there, which he entered into during his visit to several American coaling centers in January last. It is feared here that the opening of the Panama Canal will to some extent decrease the export movement from the United Kingdom, particularly from South Wales to ports on the west coast of North and South America, but by the acquisition of coal fields on the other side of the Atlantic Mr. Thomas and those associated with him will be in a position to secure a big share of the supply.

PERSONALS

D. A. Thomas has completed in South Wales, since his recent visit here, a combination of several collieries, capitalized at $10,000,000. These mines produce nearly four million tons, and the output will be increased to six million.

Arthur E. Nelson has been appointed district sales agent of the Consolidated Indiana Coal Co., with headquarters at 403 Traction Terminal Building, Indianapolis. Mr. Nelson is in general charge of the sale of the company's coal in the State of Indiana, vice Frank Ragan, resigned.

J. G. Smyth, manager of the Consolidation Coal Co.'s operations at Jenkins, Ky., has been appointed chief engineer and expects to leave for Fairmont, W. Va., to take up his new work. E. Drennen, who has been superintendent of the power and mechanical department, at Jenkins, will become manager.

J. W. White, engineering salesman for the Jeffrey Mfg. Co., located until recently at their Athens, Ohio, offices, has been transferred to Duluth, Minn. Mr. White will look after the sales work of the above company in eastern Minnesota, northern Wisconsin, and the entire Upper Peninsula of Michigan. His headquarters will be 1905 East Superior St., Duluth, Minn.

CONSTRUCTION NEWS

Pottsville, Penn.—The Locust Mountain Coal Co. has awarded the contract for the erection of a new breaker.

Birmingham, Ala.—The Tennessee Coal, Iron & R.R. Co. has made an appropriation of $100,000 for the opening of a new coal mine near Blocton.

Punxsutawney, Penn.—The coming summer will see the work of building two hundred new coke ovens at Sykesville by the Cascade Coal & Coke Co. completed.

Erie, Penn.—The Pennsylvania R.R. Co. will build a dry dock, coal and ore docks and track extensions at the harbor of Erie. It is said that these improvements will cost in the neighborhood of $1,000,000.

Duluth, Minn.—The fourth immense coal dock to be constructed in Duluth will be erected this summer by the Berwind Coal Co., at a cost of $500,000. The dock will have a storage capacity for about 500,000 tons of coal.

Pittsburgh, Penn.—The Erie & Northern R.R., of Ontario, Canada, is perfecting plans for a new and more direct route for bituminous coal into the Canadian markets. New lines of car ferries from Erie, Penn., to the north shore of Lake Erie are planned.

Uniontown, Penn.—The W. Harry Brown Coke Co. is arranging for the erection of several hundred ovens on the Weltner farm, just opposite Masontown in Greene County. Some six weeks ago the Brown company purchased about 1000 acres of coal from J. V. Thompson.

Ager, Calif.—The Yreka Development Co. is proceeding systematically with the work of opening up its vast field of lignite coal near here. The company has 3000 acres of coal beds. J. E. Gamble, general manager, is prospecting the whole area thoroughly. W. W Barham is president of the company.

Johnstown, Penn. The Atlantic Coal Co., which has extensive operations in the Boswell field, is sinking test holes in an entirely new field in Black township and it is expected will start a new operation this year. Wilson Creek branch of the Baltimore & Ohio R.R. is to be extended into the territory that will be developed.

Lima, Ohio—Ground has been broken for the erection of a modern $25,000 coaling station for the Lake Erie & Western R.R. The work of completion will be pushed with all possible rapidity and will be completed not later than Sept. 1. Only steel and concrete will be used in the construction work. Steam hoisting engines will be installed.

Cincinnati, Ohio—A syndicate headed by John B. Farwell, of Chicago, is to build a railroad between Tucumcari, N. M., and Rotan, Tex., with a branch line to the Dawson coal fields in New Mexico. Ohio and Pennsylvania coal men and capitalists are interested in the project and have bought up more than one million acres of land in western Texas.

Tamaqua, Penn.—The Kaska William colliery of the Alliance Coal Co., has closed down for extensive repairs both inside and out. It is expected that these will require about a month to complete. The improvements which have been under way at this colliery are progressing satisfactorily and within a short time the output will be greatly increased.

Huntington, W. Va.—Work on the Beaver Creek extension of the Big Sandy division of the Chesapeake & Ohio railroad must begin not later than Apr. 1 under the terms of a contract entered into by the Chesapeake & Ohio with the Beaver Creek Consolidated Coal Co., before the holdings of that corporation were taken over by the Elkhorn Fuel Co.

Pittsburgh, Penn.—The Miller Construction Co. has commenced the construction of a two-mile branch of the Buffalo, Rochester & Pittsburgh R.R., from Craigsville, Penn., into Butler County. The purpose of the line is to tap the limestone and coal fields along Buffalo Creek and the lower part of Butler County. The line will be completed this summer.

Columbus, Ohio—The Hocking Valley Ry. Co. has awarded the contract for the extension of a branch line through Kerr's Run into what is known as Nease settlement in the Pomeroy Bend mining district. The work will be started at once unless obstructed in obtaining the right-of-way. The proposed line will open a large coal area east of Hamden, Ohio.

Kittanning, Penn.—The Allegheny River Mining Co. one of the Shawmut interests is about to build 100 new dwellings for miners on Furnace Run, three miles above this town on the right bank of the Allegheny. The new tipple is rapidly nearing completion and within 30 days it is hoped that coal will be dumped over it. Two new motors will be taken into the mine on Saturday.

Grafton, W. Va.—Work was started recently to construct a second coaling plant near Independence, that will develop the large tract of valuable coal land owned by Madame DeBiliers. Messrs. Late, of Clarksburg, and Irving, of Pittsburgh, have now leased the DeBiliers property and have been working for several weeks making tests of the coal and preparing for beginning active construction of a coal plant.

Superior, Wis.—Work has been started on the improvements at the Hanna dock. When completed this work will represent an outlay of $500,000. A contract for the superstructure has been awarded to the Mead-Morrison Construction Co. of Chicago. Other contracts calling for dredging and crib work are pending. The improvements will be made on a 12-acre tract recently acquired by the Hanna company at a cost of several thousand dollars. When all improvements have been completed the dock will have a handling capacity of over one million tons annually, an increase of 350,000 tons.

NEW INCORPORATIONS

Donaldsonville, La.—The Consumers Coal Yard & Supply Co.; capital stock, $10,000. President, R. N. Sims.

Clarksburg, W. Va.—Fifty-foot Fuel Co., was incorporated with a capital stock of $25,000 to develop coal lands.

St. Louis, Mo.—The Imperial Coal Co.; capital stock, $8000. Incorporators: D. G. Jackson, F. S. Suerer, and B. E. Hefter.

Hopkinsville, Ky.—The West Kentucky Fuel Co., capital stock, $5000. Incorporators Paul Winn, Sam Winn and James Breathitt.

St. Louis, Mo.—The Universal Smokeless Fuel Co.; capital stock, $50,000. Incorporators Jas. M. Moran, Asa A. Loudon, and Alfred Mueller.

Andalusia, Ala.—The Black Warrior Mill Co. has been incorporated with a capital stock of $100,000 to install sawmills and develop coal and timber lands.

Cincinnati, Ohio—The Cleveland & West Virginia Coal Co.; D. F. Bevington, C. F. Becker, L. E. Bevington, A. C. Becker and J. E. Matthews, all of Cleveland, Ohio.

Montgomery, Ala—Cahaba Central Coal Co. of West Blocton was incorporated by the Secretary of State, Mar. 12.

Capital stock, $20,000. Incorporators: W. R. Young and G. W. Randall.

Pueblo, Colo.—The Cañon City Coal & Development Co.; capital stock, $100,000; to mine coal and develop coal properties. Incorporators: Joseph Walton, Mrs. Joseph Walton and L. A. Wieland.

Chattanooga, Tenn.—The Tennessee Coal & Coke Co.; capital stock, $100,000; to mine coal in Hamilton County. Incorporators: J. F. Walters, L. N. Spears, W. D. Spears, G. D. Lancaster and M. O. Cates.

Nashville, Tenn.—The Hazel Creek Coal Co.; capital stock, $120,000; to mine, sell and deal in coal, ore and minerals; to bore for oil, etc. Incorporators: C. C. Christopher Lee Brock, John H. Carpenter, A. R. Hill and L. A. Powers.

Philippi, W. Va.—The Meriden Coal & Coke Co.; capital stock, $3,500,000. Incorporators: William P. Hurst, Harvey R. Hurst, Richard H. Parker, James R. Hurst, of Scottsdale, Penn., and Fuller Hoggsett, of Uniontown, Penn.

Logan, W. Va.—The Island Creek Colliery Co.; mining coal; capital stock, $50,000. Incorporators: H. M. Vest, Welch, W. Va., P. A. Grady, Roderfield, W. Va., Fred C. Prichard, Rufus Switzer and Thomas A. Wiatt, of Huntington, W. Va.

INDUSTRIAL NEWS

Rich Hill, Mo.—F. A. Griffin will develop 1000 acres of coal property, and is preparing to sink a shaft.

Toledo, Ohio—It is rumored that a gas well, estimated to flow more than 30,000,000 cu.ft. per day, has been drilled near Butler, Penn. The well started with 700,000 cu.ft. daily but after it had been cleaned out the great flow began.

Coshocton, Ohio—A bed of coal seven feet in thickness has been discovered on the Leander McVey farm in the Mohawk-Walhonding vicinity. Work of developing will be begun at once.

Pittsburgh, Penn.—It is reported that J. P. Morgan & Co. have concluded negotiations with Col. J. M. Guffey for the purchase of 100,000 acres of West Virginia coal land. The price paid is said to be $10,000,000.

Connellsville, Penn.—A mine, which has been operated until 1909 by the Ashville Coal & Coke Co., has been reopened under the direction of C. P. Burtner, of Altoona, and is now producing coal.

Reading, Penn.—The Philadelphia & Reading Coal & Iron Co. has started storing coal at Landingville. About 200 carloads are dumped daily. This is the first attempt to store coal for nearly a year.

Chicago, Ill.—The Susquehanna Coal Co. of Pennsylvania has acquired a tract of 24 acres of land at the corner of Muskegon Ave. and 116 St. which is to be used eventually as a coalyard. The price paid is said to have been in the neighborhood of $75,000.

Birmingham, Ala.—Judge Grubb has taken under advisement the petition filed by the trustees of the Alabama Consolidated Coal & Iron Co. asking for an order of sale for the properties of the company. It is probable that his decision will be announced Mar. 22.

Brownsville, Penn.—The Pike mine, owned by the People's Coal Co., will be sold to the Jones & Laughlin interests. This mine, which is located close to the Brownsville borough line, has been idle for nearly three years. The mine will employ about 200 men.

Birmingham, Ala.—The Tennessee Coal, Iron & R.R. Co. has struck coal in the slope sunk for the development of their No. 16 Pratt mine, on the Birmingham Southern R.R., about 10 miles northwest of Birmingham. The town at this point will be called Bayview.

Batavia, N. Y.—Within the last few days there has been considerable talk about prospecting for coal in this vicinity and making another effort to finance a project to continue work on the shaft which was sunk 40 years ago on the Gayton farm, a mile east of Stafford.

Shamokin, Penn.—Three large Cochrane feed-water heaters have been received by the Philadelphia & Rading Coal & Iron Co. for service at the Henry Clay, Burnside and Bear Valley collieries. The first Cochrane heater was tried out at the Locust Gap colliery and proved to be entirely satisfactory.

Jenkins, Ky.—The Consolidation Coal Co. has completed its big electric power plant, and will hereafter operate its mines with its own power. The plant will also supply current to the surrounding mining towns of Dunham, Burdine and McRoberts, as it possesses five power units, with an aggregate capacity of 13,000 horsepower.

Fayette, Ia.—A deal has just been closed by which the Big Joe Co. gets the Big Four mine on the Milwaukee, eight miles west of Centerville. The company has also leased 500 acres of coal land near Jerome and expects to sink a new shaft. Two hundred men will be employed by fall. Robert Hunter is the superintendent.

Clinton, Ind.—A visit of Clay F. Lynch, general manager of the Bunsen Coal Co., a United States Steel Corporation subsidiary, to the Miami Coal Co.'s two mines south of here, has led to a report that the Bunsen company is going to buy the Miami mines. It is said to own the coal lands surrounding the tract of the Miami company.

Charleston, W. Va.—The appointment of receivers to take charge of the properties of the New River Co. and its 17 subsidiary companies has been denied by the Supreme Court of Appeals of West Virginia. This reverses the decision of the Circuit Court of Fayette County. The New River Company, is a $30,000,000 coal corporation.

Morgantown, W. Va.—Holdings of the Kingwood Coal & Coke Co., situated on the West Virginia Northern and the Morgantown & Kingwood railroads, in the vicinity of Kingwood, have been sold to Cleveland capitalists. The consideration named in the sale of the property is $60,000. It is understood that the Cleveland purchasers will develop the properties.

Brazil, Ind.—At the Schrepfman Coal Co.'s mine No. 1 two seams of block coal are worked. Several hundred yards from the main shaft another shaft rises from the bottom seam to the top or rider vein. The coal mined in this seam is lowered to the bottom and thence hoisted by cages in the main shaft. This gives rise to the peculiar situation of two mines in one.

Pineville, Ky.—A deal has been consummated by which the Lick Branch Coal Co. has leased the mining plant of the Harlan Coal Mining Co. at Croxton. The minimum royalty for the first five years amounts to approximately $100,000. The Harlan Coal Mining Co. is composed of Barbourville and Louisville capitalists and will begin at once the development of other property which it owns in southeastern Kentucky.

Taylor, Ky.—An effort is being made by the Taylor Mining Co., which operates mines in Ohio County, in the western Kentucky coal field, to induce its employees to improve the appearance of their houses by the cultivation of gardens and lawns. To this end the company is offering a prize of $10 in gold for the best garden, with a second prize of $5, and a first prize of $7.50 in gold for the best lawn, with a second prize of $2.50.

Pottsville, Penn.—The Philadelphia & Reading Coal & Iron Co. at Shamokin has let a contract for a tunnel to be driven from the No. 5 seam which will cut Nos. 6, 7 and 8. All of these have been tested and found to be of excellent quality and of minable thickness. The recent improvements at Sterling and Burnside collieries will make the twin colliery one of the most valuable in this section of the anthracite region.

Cincinnati, Ohio—It is expected that plans for the dissolution of the Sunday Creek and other coal mining companies of eastern Ohio and West Virginia and coal carrying roads will be presented to the U. S. District Court Mar. 29. The railroads named in the dissolution order which was filed at Columbus include the Lake Shore, the Toledo & Ohio Central, the Hocking Valley, the Chesapeake & Ohio and the Kanawha & Michigan.

Charleston, W. Va.—Negotiations for the sale of the Dickson Pocahontas Coal Co.'s properties in the Pocahontas field have been completed. The purchasing company is the Lake Superior Corporation which owns the Cannelton coal properties in the Kanawha district, and has its principal headquarters at Sault Ste. Marie. The consideration is said to have been $500,000 and it is reported that the purchasing company has set aside $200,000 for development work

Pottsville, Penn.—The Lehigh Valley Coal Co. has equipped several additional fire cars for fighting fires in its mines. They consist of the truck of a mine car upon which is mounted an electric pump which is capable of delivering 300 gal. of water per min. In addition to this they each carry two large 30-gal. chemical extinguishers to be used where water is not available and a number of smaller extinguishers. Axes, buckets and complete first-aid outfits also figure in the equipment. These cars are kept above ground near the mouth of the shafts and can be lowered in a few seconds to be taken to any point of the mine where the track is laid.

COAL TRADE REVIEWS

GENERAL REVIEW

While there has been an occasional order for hard coal during the week, buying has been pretty definitely concluded, pending the arrival of spring prices on Tuesday next. April orders are not coming in as promptly as usual, and there is not much enthusiasm in the trade over the prospects for that month. Of course, dealers will lay in some stocks, but the disposition is to go slow. However, most of the hard-coal business automatically renews itself, and wholesalers are not seriously worried over the outlook, although the market is at a standstill and suspensions are the rule.

There is quite a volume of coal moving on spot orders in the Eastern bituminous trade, and also on contracts expiring Apr. 1. Consumers are obviously endeavoring to stock sufficiently to carry them over for some time. Shippers are inclined to hold off on April business, but are endeavoring to place prompt tonnages, while orders for same are not plentiful. The situation hinges to a greater or less extent on the West Virginia labor troubles; even in event of a general lockout, it is not probable there will be any great shortage of coal.

Shipments to the Northern markets are still heavy, but few companies are able to place their full output, and many mines are working short time. Still there is a large consumption due to considerable industrial activity, and prices as a rule are being well maintained, although quotations are uncertain and at times conflicting. Production continues to increase in the Pittsburgh district, due to the opening of the Lake trade; prices are fairly steady, but they may experience a break at any time, due to considerable shading of quotations in other fields. Large producers are holding especially firm, and although there is some price cutting on the part of the smaller operators, it is not regarded as of a serious nature.

Preparations are being made in Ohio for a heavy Lake tonnage, and business is fairly active; there has been some falling off in domestic, but prices continue firm. Steam business has also been restricted somewhat, but there is considerable activity in railroad contracts and production for the week has been fairly strong.

In the Middlewestern market, production is at a low point, the mines working half time or less; however, it is stated that orders as a rule are in excess of those for the same period last year, and the new contracts are being closed at the same figures. Contracting is the only active branch of the business at the moment. There was some increased demand for Illinois coal, but operators over-shipped the market and caused another break; it is stated that there is a movement under way to curtail production in this district. Demand in the Rocky Mountains has slowed down quite materially, due to warmer weather.

BOSTON, MASS.

Bituminous—The bituminous situation turns on the probability of strike troubles in the New River district. There is a dearth of anything like definite news on the subject but the same shippers who are striving to place spot coal at current prices are holding back on business after Apr. 1. The spot market, if anything, is a shade weaker and all the agencies have an abundance of coal at the Virginia terminals. Quite a volume has been fed to this market, either at prices considerably off the contract figure for the coming season or else shipments are being liberally applied to contracts expiring Mar. 31. Even if there should be a cessation of work in New River this market would probably get on for some months without any pronounced price movement. And if there is no trouble we are almost certain to have a dull spring followed by a summer not unlike that of 1911. What yearly business has been closed has been with the usual strike clause and the now customary protection against a decline in the market.

The shippers of Georges Creek have named a tentative price of $2.85 f.o.b. Baltimore, or $1.60 at the mine, but the trade is not taking it very seriously as a year-round price. Orders for this grade are plentiful now but this is early in the season. The Pennsylvania coals are mulling along on about the same basis as previously reported. There are signs of slightly lower prices here and there as operators find orders getting scarce. It may be said that for better grades from the Clearfield district, prices at the mine are about 5c. off from a week ago and the demand is more spasmodic. In the all-rail territory consumers are guarded in making purchases. There is no snap to the business in any quarter and the prospect is not particularly good for the prices set a few weeks ago.

Water Freights are also off, 70@80c. having been accepted for the largest vessels, Hampton Roads to Boston; 40c. is about the rate from New York to points on Long Island sound.

Anthracite—There is not much enthusiasm on the part of the anthracite dealers for early April shipment. Most of them will lay in a fair stock at April prices but the disposition is to go slow. The companies who are the largest distributors to this market are understood to have a fair amount of spring business in hand. Those, however, who did little for New England in 1912 are meeting with rather a cool reception, and buyers rather than sellers are drawing the lines this year. It is expected that retail prices in Boston will be reduced on or around Apr. 1 from $8 to $7.50 for stove and chestnut, with 25c. less for egg.

Current wholesale quotations on bituminous are about as follows:

Clearfields, f.o.b. mine	$1 00@ 1 35
Clearfields, f.o.b. Philadelphia	2 25@ 2 60
Clearfields, f.o.b. New York	2 55@ 2 90
Cambrias, Somersets, f.o.b. mines	1 25@ 1 50
Cambrias, Somersets, f.o.b. Philadelphia	2 50@ 2 75
Cambrias, Somersets, f.o.b. New York	2 80@ 3 10
Pocahontas, New River, f.o.b. Hampton Roads	2 60@ 2 80
Pocahontas, New River, on cars Boston	3 65@ 3 85
Pocahontas, New River, on cars Providence	3 45@ 3 75

NEW YORK

Bituminous—The local soft-coal market continues at the same relatively low ebb prevailing over the last few weeks. Interest is concentrated entirely on contracting, which is becoming more active as the season advances. In fact, the business became quite active on small contracts during the week, but it might be stated that this was the result of the most persistent endeavors on the part of the sales agencies. The large contracts are still hanging fire, the buyers being firm in the belief that plenty of tonnages will be available at last year's figures. What the ultimate result will be is more or less problematical, but present indications are that both sides will ultimately grant concessions.

Stocks at tidewater are about normal or a little low approximately the same as last week. Production in the mining regions continues at a good pace and is much more steady than in hard coal. The spot demand is rather slow with prices weak, particularly on the off qualities, there being a fairly steady demand for the high-grade fuels, and prices firm. The local market is not changed from last week, which we quote as follows: West Virginia steam $2.55@2.60 fair grades, Pennsylvanias, $2.65@2.70, good grades of Pennsylvanias, $2.75@2.80; best Miller, Pennsylvania, $3.05@3.15; Georges Creek, $3.25@3.30.

Anthracite—Production at the hard-coal mines is only about 50 per cent. capacity, and the trade is absolutely devoid of interest; the demand is scarce with the exception of pea size, for which there seems to be a fairly steady consumption. However, the large companies are most optimistic about the future. The Western stocks are well cleaned up, and a strong healthy demand is expected to develop when the April discounts go into effect on next Tuesday. So firm are some companies in this belief that they have issued instructions to the operating departments that, effective Apr. 1, the mines would work continuously. It seems reasonable to believe that such will be the case for two or three months at any rate, after which it is difficult to say what the conditions will be. Some dealers are of the belief that consumers were left with enough coal on hand to carry them over to next spring, because of the unusually mild winter. Also the comparatively long suspension last spring forced many hard-coal consumers to use bituminous, which they have continued with since.

Prices are quite easy on the following basis.

	Individual		
	Circular	Lehigh	Scranton
Broken	$5 00	$4 50 @ $5 00	$4 50
Egg	5 25	4 50 @ 4 70	4 55 @ 4 75
Stove	5 25	4 50 @ 4 70	4 55 @ 4 75
Chestnut	5 50	4 70 @ 4 95	4 75 @ 5 00
Pea	3 50	3.35 @ 3 45	3 45 @ 3.55
Buckwheat	2 75	1 95 @ 2 45	2 50 @ 2 75
Rice	2 25	1.80 @ 1 95	2 10 @ 2 25
Barley	1.75	1.25 @ 1.55	1.55 @ 1 75

PHILADELPHIA, PENN.

Coal yards are not a particularly lively asset at the present time as dealers are simply waiting for the opening prices. Occasional orders are being received, but most of them are employing their time in making needed repairs to yards, and getting things in shape to handle the April business. While orders for April delivery are not coming in rapidly, the dealers are looking forward to a good business at least during the coming month. Most if not all of them have a class of business which renews itself automatically during April, year after year. Large residences, churches, etc., with generous storage capacities, try to get as much of their winter supplies as possible, when quotations are the lowest, and it is this class of business that will keep the trade moving.

The wholesale market is almost at a standstill, at least, as far as the large companies are concerned. Suspension was universal over the Easter holidays, but operations were resumed at most collieries Monday, and will doubtless continue until April, surplus coal, being placed in storage. It is understood that many of the companies are already starting coal toward their shipping ports on the lakes, and will load vessels, as promptly as they can be secured. Ice conditions on the Lakes are such that the movement is not likely to become effective for a week or more at the least, and, of course, shipments in that direction are limited to the number of vessels available.

The bituminous market is still sluggish. Higher prices are still talked about for new contracts, and it is understood that more than one large buyer is holding off for this reason. The resumption of work in the West Virginia fields is not likely to improve conditions to any extent, and the advance in price may have been founded on the assumption that these fields were no longer a factor.

PITTSBURGH, PENN.

Bituminous—Mine operations in the Pittsburgh district at the increased rate in last report have continued, but the slight gain is due only to the starting of shipments in the Lake trade, since general demand has been far from good, owing to warm weather. Prices are fairly steady for Pittsburgh district coal, but are under fire on account of shading in other fields. Large producers are adhering to their regular prices more tenaciously than for a long while, and the shading by small interests is not regarded as of much moment. The market is generally quotable at regular prices, subject to occasional shading by small interests. Slack rarely brings a premium now, on account of heavier production through the shipping of Lake coal. We quote regular prices: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in., $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—A little light has been thrown upon the condition as to contract-furnace coke, which had for some time been nominally quoted at about $2.50, in the absence of sales or serious inquiry. A furnace company in Cleveland has closed a contract for 5000 tons a month for four months to July 1 at $2.25, ovens, it being understood that coke, standard in every respect, was secured. The majority of operators, however, would not touch this figure either for early shipment or for the second half. There is tentative inquiry for the later delivery, but no serious negotiations. Sales of standard coke for prompt shipment have been made at $2.43, while off coke continues to be offered at relatively low prices, a fairly well known grade running about 1.2 per cent. sulphur being freely offered at $2.15. We quote the market as follows: Prompt furnace, $2.45@2.50; contract furnace, $2.25@2.50, prompt foundry, $3@3.50; contract foundry, $3@3.50 per ton at ovens.

Production and shipments of Connellsville coke continues at record rate, although there may be a slight decrease this week from after effects of the Easter celebration. The labor supply, however, has been good in the past few weeks and no shortage may be experienced. Some operators are surprised at the maintenance of prices, for precedent shows anything above $2 to be above average, when the tonnage moved is so large, but consumption is likewise at record rate, since the country is making pig iron at the rate of about 34,000,000 tons annually and no serious decrease is likely in the near future

BALTIMORE, MD.

Although consumers have hesitated about renewing contracts because of the advanced prices asked by the trade, it is believed that practically all of them will have closed for their fuel requirements over the next year by Apr. 1. More complaint has been heard regarding the higher price which the trade is demanding for the better grades. A number have endeavored to procure coal at last years figures, but they have not succeeded, except in a few cases, where the operator thought that the price gave a pretty good profit in the first place. In order to get the best possible results from coal several consumers have conducted a series of tests for the purpose of ascertaining if the low-grade coals could be substituted for the more expensive product which they had been using.

The market was well stocked with fuel during the week, especially with good coking coals, due to the decrease in the output of coke.

BUFFALO, N. Y.

In anthracite the consumers and retailers are waiting for April prices, and the output of bituminous is now so large that only the expert salesman is able to sell up to full capacity. On this account a good many bituminous mines are again running on part time.

It is hard to say what the summer market is going to be. The Pittsburgh district operators are holding to their specified prices and Buffalo dealers who handle that coal or Youghiogheny agree that there has been no discounts offered yet. Still there is plenty of coal offering at less than $1, mine-run, at the mines, some of doubtful quality and some fair. Just how these conflicting prices are to be reconciled is not settled yet; it is not easy to see how both can be maintained. Some mines can put out coal at less than $1 but a great many cannot. The consumer is able to pay the full price, but he will, of course, buy as low as he can and this conflict in prices will be pretty sure to take up the entire season.

This section is consuming a large amount of coal and will continue to do so, as all industries are active and the number and capacity is steadily increasing. The territory east and north covered by Buffalo dealers in bituminous is well maintained, more coal being sold every year. The market for Pittsburg coal is steady, though not active at $2.80 for lump, $2.65 for three-quarter, $2.55 for mine-run and $2.15 for slack, with Allegheny Valley selling at about 30c. less. The coke market is still pretty slack, best Connellsville foundry selling at $5.

Anthracite will be dull till the April reduction of price is in effect. There is quite a large surplus now and the companies are loading lake vessels at a good rate, having about 100,000 tons afloat here now. Retailers are doing little business.

COLUMBUS, OHIO

Conditions in Ohio have been fairly good during the past week. The steam trade is moving along smoothly and preparations are being made for a record-breaking Lake movement. Taking it all in all the coal trade is as active as could be expected at this time of the year and the tone is satisfactory.

Prices have ruled firm dispite the falling off in the domestic demand. Only small orders are being received from retailers and not a great deal is expected from that source until the stocking up season starts. Steam business has been fairly large although some of the plants have curtailed their requirements. This is especially true of iron and steel concerns. Other lines of manufacturing are running full and the fuel requirements are normal.

Coal men generally believe that the slight falling off in the demand for steam grades on the part of manufacturing establishments is only temporary. They believe that industrial conditions will remain active and that many large users will be in the market for a greater tonnage in the near future. Outside of the railroad fuel contracts there is considerable activity shown in renewing steam contracts, many of which expire around Apr. 1.

Chartering of lake boats is now on in full sway. All of the operators which usually enter the lake trade have secured bottoms and some of the larger producers have started to load vessels. There will be a large tonnage ready for shipment just as soon as the ice is out of the Soo which it is believed will be around Apr. 15, but may possibly be earlier.

Production has been only fair during the weak. In the Pomeroy Bend field the output is estimated at 70 per cent. and the Hocking Valley produced about 65 per cent. of normal. In Eastern Ohio the production has been about 65 per cent. also. In the purely domestic fields the output has been small.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawh
Domestic lump	$1 45		$1 50	$1.40
¾-inch	1.35	$1 20	1 35	1.30
Nut	1.30	...	1.30	...
Mine-run	1 15	1.10	1.15	1.10
Nut, pea and slack	0 80	..	0 75	0.80
Coarse slack	0.70	0 80	0.65	0.70

HAMPTON ROADS, VA.

There is a distinct feeling of a coming improvement in conditions and contract prices for the new year are being closely adhered to, notwithstanding the fact that many large buyers are still holding off. Few, if any, of the large contracts have been closed; none of the Chesapeake Bay transportation lines, who use the greater part of the local product, have definitely arranged for their coal yet.

BIRMINGHAM, ALA.

Inquiries are now coming in from many of the railroads and specifications, as a rule, call for heavier tonnages than were bought during the year ending June 30, 1913. Most of the railroads are using more than the maximum of their contracts at the present time. One of the largest railroad inquiries is for approximately 300,000 tons for delivery over one year beginning July 1, 1913. A number of the roads have expressed a willingness to pay higher prices than heretofore if better prepared coal can be obtained.

There is no material change in the steam or domestic market, although prices are not as high as during March of last year on account of the unusual conditions prevailing at that time. Several new mines will be put into operation during the summer and a larger bid than ever will be made by the Alabama operators for export business. The foundry coke market is holding its own quite well indeed when it is considered that the pig-iron melt is somewhat below normal at the present time.

LOUISVILLE, KY.

Prices on Eastern Kentucky domestic grades are quoted almost without reference to market conditions. With best block at $1.50, lump and block at $1.40, and round at $1.15, it may be gathered that the demand is nothing brisk. Mine-run can be had at 85c., although there are quotations as high as $1.05. Whether these would yield to a bona fide offer of a substantially lower figure is another question. Firstclass nut and slack is in demand at 90c. to $1, and second grades at 75 and 80c. Pea and slack, from both sections of the state, is quoted at 45c.; western Kentucky lump at $1.25 and nut at $1.10 are not moving to any extent.

INDIANAPOLIS, IND.

With the movement of coal at the low ebb, operators are concerning themselves in renewing the expiring contracts. Notwithstanding the low prices prevailing in the open market, the companies say they are having little trouble in closing at the old figures. In domestic, buying is practically over for the winter, large retailers still having enough on hand or coming in to fill all probable needs. They believe they will sell some coal yet, though the periods of cold weather may be short. Mine-run, No. 4 is selling anywhere from $1.05 to $1.20. Screenings are strong at 90c. to $1 and scarce on account of the small demand for domestic.

Some of the larger mines are running better than half-time but the smaller companies do well to get in three days a week. The weather generally is spring-like but there is still an occasional day or two of winter; these cold spells bring a good sprinkling of coal wagons on the streets. Local retail prices still hold to the high winter schedule.

DETROIT, MICH.

Several large coal operators declare that their orders are greater than for the same period last year, by as much as 10 per cent., and also that the price basis per ton is approximately from 5 to 10c. better than were the figures obtained last season.

The prevailing prices on the local market are as follows.

	W. Va.	Gas	Hocking	Cambridge	Ohio No. 8	Pocahontas	Jackson Hill
Domestic lump	$1 70					$1 65	$1 75
Egg	1 10					1 65	1 75
1½-in. lump	1 20					...	
2-in. lump	1 00	$1 10	$1 00	$1 00	$1 00	...	...
Mine-run	0 90	0 90	0 90	0 90	0 90	1 15	...
Slack	0.80	0 85	0 80	0.80	0 80	0.95	...

Anthracite conditions have not changed much in the past few weeks. The usual light end-season demand is being handled with ease from stocks on hand, and shipments from the East to this point, have been comparatively insignificant.

CHICAGO

A large number of contracts are being negotiated in the Chicago market and this is, practically, the only activity. If operators were compelled to rely upon spot sales they would soon be out of business. There have been an unusually large number of sales of screenings and mine-run on contract. In all instances the operators have obtained what they call fair prices.

Chicago dealers have been participating, in a large measure, in the closing of contracts for Lake shipments. It is expected that a big tonnage will be moved at prices higher than those prevailing a year ago. The coke market is dull. Hocking Valley operators are not shipping any coal into this market and are reserving what free coal they have for the Lake movement.

Prevailing prices in Chicago are:

	Springfield	Franklin Co.	Clinton	W. Va.
Domestic lump	$2.07@2 22	$2 45@2.55	$2 27	
Egg		2.45@2.55		$3.95
Steam lump	1 92@1 97		2 17	
Mine-run	1.87@1 92	2 20@2 30	1.97	3 30
Screenings	1.57@1 62	1.90@1.95	1.67	

Coke—Connellsville and Wise County, $5.75@6; byproduct, egg, stove and nut, $4.75@5.35; gas house, $4.75@5.35.

ST. LOUIS, MO.

There has been some little encouragement to the retail coal man, inasmuch as there was a good demand for very small lots of coal, but on the whole this did not affect the shipping market in the least. As a matter of fact, if anything, it created a disturbance that brought prices lower than they have been thus far this season, and especially was this so on the better grade coals.

Over-production still continues, but there is hope now that conditions will improve, inasmuch as some of the operators are in a movement to suspend operations for the next three or four months. Washed coals are in fairly good demand, and from this time on these grades will continue to get better.

The prevailing circular is:

	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard
2-in. lump	...	...	...	$0 85 @ 0.90
3-in. lump	...	...	$1 25	...
6-in. lump	$1 20 @ 1 25		1.35	1.10
Lump and egg	1 25	$2 25	...	...
No. 1 nut	1 10 @ 1 15		...	...
Screenings	0 90 @ 0 95		...	0 65
Mine-run	1 05 @ 1 15		...	0 85
No. 1 washed nut	1 10 @ 1 50			...
No. 2 washed nut	1 35 @ 1 45			...
No. 3 washed nut	1 25 @ 1 30			...
No. 4 washed nut	1 15 @ 1 20			...
No. 5 washed nut	1 00 @ 1 05			...

MINNEAPOLIS—ST. PAUL

Steam business is reported rather lax as industrial concerns seem to be content with only enough stocks to run them a short period. It is generally thought that the early summer months will be slow for the wholesaler and jobber as conditions point to low prices at least up until the latter part of July or the first part of August. After that, with the oncoming of winter, business ought to be good with healthy prices prevailing. Then after the first of next year, wholesalers should find business exceptionally good in view of the fact that the present aggreements with the soft-coal miners will be drawing to a close.

PORTLAND, ORE.

Just as the people of the Pacific Northwest were beginning to believe that spring had come with sunshine and balmy breezes, a cold wave swept over the country with from two to eight inches of snow. The effect has been a revival in the coal business, giving the dealers their second inning this season; however, prices are unchanged and the present cool spell will have no effect on values.

OGDEN, UTAH

The Wyoming and Utah mines have had a great many idle days, due to lack of lump or nut orders. There have been flurries of storms and cold weather in various parts of the territory, but these have not been of long enough duration to effect shipments materially. The Wyoming operators have been watching the storm in Nebraska for the past week but to date the effect has not reached the mines.

Wyoming operators have announced April and May quotations for Nebraska shipment as follows: Lump, $2.25; nut, $2; mine-run, $1.75; slack, $1. This will have a tendency to decrease shipments during the latter part of March, but should increase the movement of coal in April.

While quotation of the various grades have not changed, the selling price on nut and slack has been fluctuating. Nut coal has varied $1.75 to $2.25 per ton, while slack is selling from 50c. to $1, according to the demand. Lump coal in the Northwest remained firm at winter quotations and will probably not be changed until summer storage prices are encountered.

PRODUCTION AND TRANSPORTATION STATISTICS

NORFOLK & WESTERN RY.

The following is a comparative statement of the coal and coke shipments over the lines of the N. & W. Ry. for the months of February and the first 2 months of 1912 and 1913 in short tons:

Destination	February 1912	February 1913	2 Months 1912	2 Months 1913
Coal				
Tidewater, foreign	107,689	122,944	219,893	267,006
Tidewater, coastwise	287,724	337,202	535,943	646,120
Domestic	1,388,888	1,413,398	2,716,413	3,030,292
Coke				
Tidewater, foreign	3,988	4,909	8,544	9,964
Domestic	133,936	147,938	261,020	291,134
Total	1,922,225	2,026,391	3,741,813	4,244,516

SOUTHWESTERN TONNAGE

The following is a comparative statement of the Southwestern production for September and October, 1911 and 1912:

State	September 1911	September 1912	Change	October 1911	October 1912	Change
Missouri	202,404	242,871	+40,467	228,248	315,419	+87,171
Kaosas	401,536	424,329	+22,793	447,699	524,315	+76,616
Arkansas	133,238	169,325	+36,087	147,409	205,031	+57,622
Oklahoma	229,300	249,604	+20,304	274,858	369,717	+44,859
Totals	966,478	1,086,129	119,651	1,098,214	1,364,482	+266,268

This statement only covers the tonnage of members of the Association which we estimate to be at least 95% of the entire tonnage produced in the four States.

IMPORTS AND EXPORTS

The following is a comparative statement of imports and exports in the United States for January 1912-13 and for the 7 months ending January 1911-12-13, in long tons:

	7 Months 1911	7 Months 1912	7 Months 1913	January 1912	January 1913
Imports from:					
United Kingdom	10,199	5,644	7,218	1,445	1,168
Canada	1,001,018	513,369	843,962	100,744	109,520
Japan	6,313	7,057	30,004		5,494
Australia & Tasmania	190,157	143,140	98,308	21,903	10,113
Other countries	4,709	915	448	696	
Total	1,212,396	670,325	979,940	124,788	126,295
Exports:					
Anthracite	1,691,981	2,069,493	2,863,111	221,638	305,569
Bituminous,					
Canada	5,164,428	7,079,617	7,002,875	402,966	565,196
Panama	291,134	250,273	269,759	19,588	64,567
Mexico	373,148	185,302	155,216	31,639	43,778
Cuba	523,237	638,032	706,776	78,789	117,109
West Indies	302,214	375,620	329,436	77,151	72,233
Other countries	348,240	439,717	563,114	57,346	113,080
Total	7,002,401	8,968,561	9,027,176	667,479	975,963
Bunker coal	3,692,418	3,913,684	4,480,343	553,140	612,689

COAL MOVEMENT IN 1912

The following is a summary of the combined coal and coke movement over various railroads for December and the years noted, in short tons:

	December 1911	December 1912	Year 1911	Year 1912
Bal & Ohio[1]	3,113,295	3,392,925	35,321,771	40,525,280
Buf Roch & P[1 2]	725,880	773,194	8,223,617	8,839,732
Buf & Susq[2]	183,147	164,235	1,951,256	1,810,930
Chesp & Ohio[2]	1,548,881	1,290,588	16,488,024	17,296,185
Hunt & Br'd T. M.[1 2]	692,427	688,248	8,031,163	7,803,773
N Y C & H R R R[2]	136,564	150,771	1,148,675	1,277,180
N. & W. R.R[1 2]	757,636	833,454	8,108,738	8,396,018
Penn R R[1 2]	1,931,313	1,832,251	20,954,839	24,112,787
Pitts & Lake Erie[2]	6,107,262	6,551,301	65,015,701	70,117,880
Pitts. Sha. & Nort.[2]	1,243,926	1,517,651	16,090,905	17,745,835
Southern	136,448	212,477	1,459,637	2,033,169
Virginian[2]	328,257	292,824	4,826,794	4,062,363
Western Md	258,869	317,508	2,817,201	3,584,202
	260,277	201,029	2,673,183	2,838,331

(1) Includes coal received from connecting lines.
(2) Includes company's coal.
(3) Does not include company's coal hauled free.

PENNSYLVANIA RAILROAD

The following is a statement of shipments over the P. R.R. Co.'s lines east of Pittsburgh and Erie for Feb. and first two months of this year and last year in short tons:

	February 1913	February 1912	Two Months 1913	Two Months 1912
Anthracite	988,036	1,107,226	2,002,295	2,147,761
Bituminous	3,857,304	4,086,917	8,067,500	6,668,282
Coke	1,220,360	1,023,253	2,508,874	1,964,184
	6,065,700	6,217,396	12,578,669	11,780,227

FOREIGN MARKETS

GREAT BRITAIN

March 14—New business is of a quiet character, owing to the fullness of colliery order-books and the difficulty of getting loading berths.

Prices are approximately as follows:

Best Welsh steam	$4.62@4.68	Best Monmouthshires	$4 20@4 26
Best seconds	4.50@4.56	Seconds	4.08@4.14
Seconds	4.38@4 44	Best Cardiff smalls	3 78@3.84
Best dry coals	4 44@4.50	Seconds	3.54@3.60

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both exclusive of warfage, and for cash in 30 days—less 2½%.

GERMANY

The following is a comparative statement of German production, imports and exports for January of 1912-13:

	Exports 1912	Exports 1913	Imports 1912	Imports 1913	Production 1912	Production 1913
Coal	2,452,695	2,386,249	759,501	663,319	13,365,606	16,536,115
Lignite	5,246	7,238	591,830	503,704	6,805,208	7,375,566
Coke	425,812	628,164	50,171	49,853	2,340,366	2,724,871
Coal briquettes	156,485	207,053	3,324	2,590	424,961	498,288
Lignite briquettes	59,613	129,129	13,223	9,294	1,497,060	1,771,187

COAL SECURITIES

The following table gives the range of various active coal securities and dividends paid during the week ending March 22:

Stocks	Week's Range High	Week's Range Low	Week's Range Last	Year's Range High	Year's Range Low
American Coal Products	90	90	90	87	87

Reading Co.—Regular quarterly dividend on the common stock of 2%, payable May 8, to holders of record Apr. 21.

St. Louis, Rocky Mountain & Pacific Co.—Regular quarterly dividend of 1¼% on the preferred, payable Apr. 5, to holders of record, Mar. 27.

Central Coal & Coke Co.—Regular quarterly dividends of 1½% on the common, and 1¾% on the preferred, payable Apr. 15 to holders of record Apr. 1.

Pittsburgh Coal Co—Regular quarterly dividend on the preferred of 1¾, payable Apr. 25, to holders of record, Apr. 15.

COAL AGE

Vol. 3 NEW YORK, APRIL 5, 1913 No. 14

NO matter what our present station in life may be, we are all prone to believe that we are striving for one thing—self-satisfaction.

However, that is the one state of existence we must not enter. When we are pleased with ourselves, there we will abide. It is only when we are dissatisfied with what we are that we desire to attain to what we are not.

In all the world nothing stands still—we either advance or retreat. To stop is to go backward, and to be satisfied is to stop.

"Be content but not satisfied" is a wise injunction. A man may aspire and yet be quite content until it is time to rise.

We, ourselves, must be and do, and not rest satisfied merely with reading and meditating over what other men have been and done.

Satisfaction is conclusion. A man who is gratified with himself will achieve no more. It is a case of arrested development—stagnation has set in.

The men who have performed the bulk of the world's work were always dissatisfied with anything short of an unattainable perfection. Contentment, therefore, with them was out of the question. They would not have been able to recognize it had it come their way.

Any man who is satisfied with his efforts to win success does not merit it. The wiser he is, the more clearly he knows how far his best falls below the best possible.

It is a lack of personal contentment that has made America great, while an excess of mental ease and self-satisfaction has made Spain humble. Her citizens are filled with self-approval, which leads to idleness, and an idle man is like a watch without hands—useless whether running or not.

True, there is some ambition which knows no gorge but the grave. It jumps at the stars, only to fall in the mud.

The man who would rise in the world must veil his ambition in the forms of humanity. He must not cut above his height, or he will get chips in his eye.

Nothing should be more humble than ambition when it is about to climb. And, when the topmost rung of the ladder is reached, we should not gaze off into the clouds and scorn to look again at the means whereby we did ascend.

It is also worth remembering that wealth is no more a crime than poverty is a virtue, and although we should prefer great principles to a great bank account, we need feel no shame in the possession of riches which come as an honest reward for toil.

Let us live in deeds, not years; in feelings, not figures on a calendar. 'Tis our actions, not our posterity, that will perpetuate our memory.

If contentment means absolute indifference, stupid slumber, or meek submission to circumstances, then no man has a right to be contented this side of death.

The Ethics of Organized Labor

Editorial Correspondence

SYNOPSIS—A local press, subserrient to the opinions of the mass of its readers, has greatly minimized what is developing into a serious situation in the anthracite fields. The labor organization, taking advantage of its irresponsibilities for its own acts, has consistently and repeatedly violated one of the basic principles of its agreement with the operators. Officials of the unions declare themselves powerless to control the situation; however, a suggested remedy is offered here.

Less than a year ago, a formal agreement was entered into between the anthracite operators and mine workers, binding employers and employees alike, for a period of four years. This was signed by ten coal-company officials and ten officers of the mine-workers organization, all duly authorized. It constitutes a binding agreement that should be scrupulously observed by every self-respecting employer and employee having the least conception of business ethics. In spite of this, the agreement has been violated, by the mine workers, openly, wilfully, knowingly and shamelessly, no less than 200 times, as reference to the files of the press will show.

In 1903, the Anthracite Coal Strike Commission, appointed by President Roosevelt, made an award in settlement of the great 1902 strike, containing the following excerpt:

IV. The Commission Adjudges and Awards—That any difficulty or disagreement arising under this award, either as to its interpretation or application, or in any way growing out of the relations of the employers and employed, which cannot be settled or adjusted by consultation between the superintendent or manager of the mine or mines, and the miner or miners directly interested, or is of a scope too large to be so settled or adjusted, shall be referred to a permanent joint committee, to be called a Board of Conciliation, to consist of six persons, appointed as hereinafter provided.

* * * * * * * *

The Board of Conciliation thus constituted, shall take up and consider any question referred to it as aforesaid, hearing both parties to the controversy, and such evidence as may be laid before it by either party; and any award made by a majority of such Board of Conciliation shall be final and binding on all parties.

* * * * * * * *

The membership of said Board shall at all times be kept complete, either the operators' or miners' organizations having the right, at any time when a controversy is not pending, to change their representation thereon.

At all hearings before said Board the parties may be represented by such person or persons as they may respectively select.

No suspension of work shall take place, by lockout or strike, pending the adjudication of nay matter so taken up for adjustment.

The subsequent agreement, Apr. 29, 1909, provided as follows:

4th—Any dispute arising at a colliery under the terms of this agreement must first be taken up with the mine foreman and superintendent by the employee, or committee of employees directly interested, before it can be taken up with the Conciliation Board for final adjustment.

And the agreement of May 20, 1912, further provides:

(d) At each mine there shall be a grievance committee consisting of not more than three employees, and such committee shall under the terms of this agreement take up for adjustment with the proper officials of the company all grievances referred to them by employees who have first taken up said grievance with the foreman and failed to effect proper settlement of the same. It is also understood that the member of the Board of Conciliation elected by the Mine Workers' organization or his representative may meet with the mine committee and company officials in adjusting disputes. In the event of the mine committee failing to adjust with the company officials any grievance properly referred to them they may refer the grievance to the members of the Board of Conciliation in their district for adjustment, and in case of their failure to adjust the same they shall refer the grievance to the Board of Conciliation for final settlement, as provided in the Award of the Anthracite Coal Strike Commission and the agreements subsequent thereto, and whatever settlement is made shall date from the time the grievance is raised.

The Irresponsibility of the Miners

These provide in a definite, fixed, unequivocal manner that: "No suspension of work shall take place, by lockout or strike, *pending* the adjudication of any matter so taken up for adjustment. Yet this latter clause has been violated wilfully, knowingly, even wantonly on no less than 200 occasions in the short space of ten months. Strikes have occurred weekly, and have been winked at, excused and even ordered by the union officials. They have also been condoned by the press of the country when such a flagrant violation of business ethics would have ordinarily resulted in the most bitter denunciation and an entire loss of prestige for the offender. The press may be able to justify its subserviency on the specious business reason—dictated by the circulation manager—that it must cater to the majority of its readers. With one eye upon the subscription list and an ear to the ground for the first sound of partisan disapproval from its interested and biased readers, it feebly reports the existence of another strike. If, perchance, it should express any opinion at all, it does not even straddle the fence but looks through a knot hole from the employees' side and explains away and condones the strike (a violation of a sacred agreement) by means of some absurd reasons advanced by the circulation manager. Perhaps a fair, unbiased, fearless press would have few readers. Possibly it might acquire many.

Why should these violations and strikes occur? Nearly every mine worker in the anthracite region is now a member of the union, and as such he is subject to its rules and regulations and represented by its officers. If, then, the miners violate an agreement entered into by their officers, they evidently do so with or without the consent of these officers. If with their consent, then the organization is guilty and irresponsible; if without it, then the union is irresponsible as to its obligations and agreements and its officers inefficient and incompetent. The miners' organization is not incorporated and cannot be sued. It is unwilling to incorporate so as to be, as the employers are, responsible legally as well as morally for its acts. An agreement between a body of incorporated, responsible employers with an army of unincorporated, irresponsible employees, must depend for its very existence upon the honor of the contracting parties.

The agreement of 1912 carries with it no penalties for violation. *Herein lies its fatal weakness!* Under the anthracite agreement there is no monetary penalty imposed upon either party for a violation. Here is the real cause of all the trouble, for obviously a law without a penalty is ineffective—a deadletter. Violations of many laws are punishable by fines; business agreements by forfeiture. Why not a penalty of fines in this case? Why not forfeiture in whole or in part of the benefits of this

agreement? If the labor leaders and officials were fair and sincere in the matter, they would discipline and punish members and groups of members who violate the agreement. Only by the strictest, almost military discipline can they hope to control the majority of the mine workers who make up their cosmopolitan army.

The anthracite agreement provides a means of adjustment for every possible dispute. There can be no dispute or action on the part of either party to justify a suspension of work upon any pretext. A walkout, concerted action in remaining away from work, or any other wilful suspension is a strike and a strike cannot occur without violation of the anthracite agreement. Yet there have been over two hundred!

A Remedy

In past agreements the operators have given an increase in wages or its equivalent. In return their employees agreed to do certain things. The employers have faithfully met every condition imposed upon them, while the employees have violated the agreement repeatedly and with no provocation whatever. If the operators ever again enter an agreement with the miners, they should demand a heavy bond to assure the latter acting in good faith. Or, if the agreement is violated by the employees, let there be a clause providing for an automatic suspension of certain conditions imposed upon the employers.

It is safe to say that if the last 10 per cent. increase in wages had been made contingent upon the employees living up to their agreement, there would not have been a single strike! To allay the fears that a strike might possibly be forced upon the men by unjust acts on the part of the operators, the Board of Conciliation, or the Umpire, could pass impartially upon the merits of such a case and the last vestige of an excuse for not accepting a penalizing clause disappears.

The bad faith, the lack of discipline, the failure to control its members, has placed the mine workers' officials in such a position that they are now technically obligated to call for a reassembling of the committee of twenty and offer to accept such a penalty for future violations. If they are acting in good faith, if they are sincere in their efforts to keep their agreement and maintain discipline in their organization they will suffer no unjust penalty and may still regain a reputation for business integrity which they do not now possess and without which they are a menace to society. In the name of industrial peace and business ethics, let the miners call for a reassembling of the committee.

National President John P. White, publicly and privately deprecates and denounces, but has not succeeded in preventing petty strikes. If he will advise, recommend and offer on behalf of his organization the enactment of an amendment or supplemental agreement along the lines suggested, he will insure the results he has, apparently, been so earnestly but futilly seeking. His sincerity is not in question, but his authority is. The business honor of his organization is at stake. It is badly shattered and likely to be lost. A practical solution is offered here and the miners' officials may some time be called upon to explain why they did not act upon it.

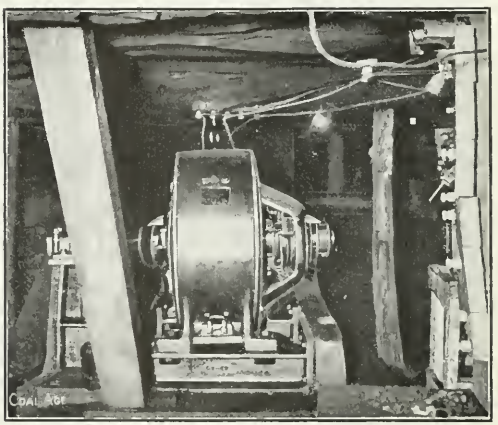
❖

The English Rescue Apparatus Commission reached the conclusion that liquid air was unsuitable for use in mine-rescue apparatus, as it did not meet the demands made upon it when excessive exertion was necessary.

Self-Starting Direct-Current Motors for Driving Mine Pumps and Fans

The electric motor has proved so thoroughly satisfactory for driving mine pumps and fans that it seems almost impossible to improve it. It can be placed wherever a pump or a fan can be located; a couple of wires supply it with the requisite power; and when running it requires no attention whatever beyond occasional inspection and oiling. In fact, motors have proved themselves so useful and economical that they are rapidly displacing all other forms of power for fan and pump service wherever electricity is available.

An improvement has, however, been recently developed by the Westinghouse Electric & Manufacturing Co. which increases the value of these machines for mine work. This improvement consists in making the direct-current motor self-starting.



Self-Starting Motor in Place Underground

Heretofore, while it has been possible under some conditions to control them from the power house, most motors driving mine pumps and fans had to be started by hand. Hence, if the power went off temporarily for any reason, the motors stopped, necessitating an attendant going to each station to start them again.

With the new self-starting machines, this inconvenience is done away with. When the power fails, the motors stop, it is true, but as soon as the power comes on again, they start automatically and settle down to work as though nothing had happened. Moreover, starting boxes are rendered unnecessary, and the wiring is of the simplest possible character. An occasional visit of inspection is all that is required by these motors. Otherwise they can be left entirely to themselves.

These motors have been thoroughly tried out in practical service and their advantages are commending them highly. Their electrical characteristics differ but little from those of the usual type, the only alteration being in the use of a heavier compounding winding, which reduces the flow of current when starting. Mechanically, there is no change. They are built in ratings up to 20 hp. for the voltages usually employed in mine work.

Electric Motors for Driving Mine Pumps

By W. H. Easton

SYNOPSIS—In this article the advantages, relative economy and reliability of the electric pump are compared with those of the steam and compressed-air driven machines. The types of motors available for such work are also enumerated and their relative merits discussed.

It is safe to say that unless electric power had proven thoroughly satisfactory for driving pumps, it would not be enjoying its present extensive and increasing use in coal mines. In most mines pumping is essential for successful operation and no power could be used that did not adequately fill the requirements of mine-pump drive. But electricity is not only satisfactory for this purpose, but has also shown itself to be in general superior to either steam or compressed air.

Advantages of Electrically Driven Pumps

The advantages of the electric motor-driven pump can be summed up under (a) ease of installation and control, (b) reliability, and (c) economy. In all three of these points it is at least the equal, and for the most part the superior, of its competitors.

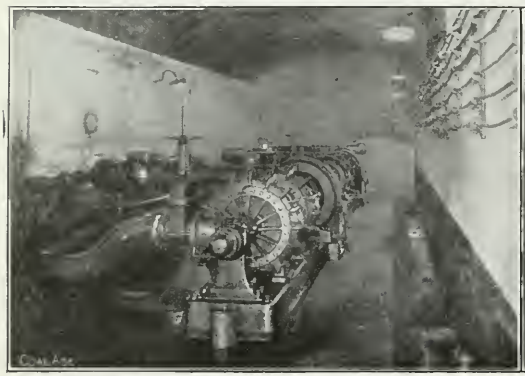
As to ease of installation, the unit formed by motor and pump is as compact and easily handled as the steam or air pump and can be placed wherever the others can be. It gets its power from wires, which are much more easily installed, altered and removed than are steam or air lines. There is no exhaust to consider, and the wires give off no heat as do steam pipes. It is therefore a comparatively simple matter to install an electric pump in the most out-of-the-way location, so that it is especially suitable for draining swamps. For the same reasons, motor drive is much the best for track and sinking pumps, the flexibility of the cables readily permitting the machine to follow the receding water level.

The adaptability of electricity is so great that the electric pump can be controlled in almost any desired manner. Many such machines are arranged to be started and stopped from the power house, even though they may be located miles away. Others are automatically started when the water level reaches a certain height and are stopped when the level is lowered to a predetermined point. The self-starting pump motor has been extensively employed of late. When one of these machines has been stopped because of a temporary failure of power, it will start automatically on the return of the current. This motor eliminates one of the principal objections to the electric pump, viz., that when no provision for remote control was made, a man had to visit each machine to start it after a shutdown of power.

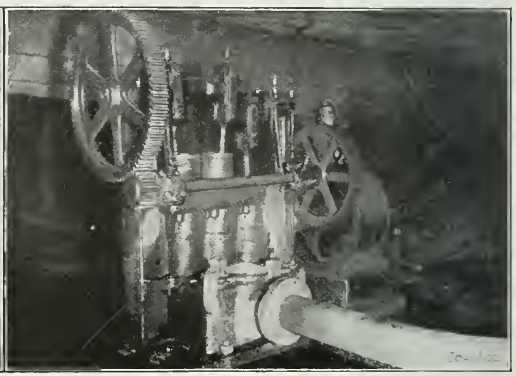
In reliability the motor is at least the equal of either the steam or air engine. The modern motor is so designed that it requires practically no attendance beyond an occasional inspection and oiling. A properly installed pump motor will run continuously for many years with no renewals or repairs beyond a few extra brushes.

The Economy of Electric Pumps

In regard to economy the small steam pump is notoriously inefficient, whereas the small motor has a high efficiency. That is to say, it will take less coal to run a half dozen small electric pumps than to run the same number of steam-driven machines of similar capacity. In large sizes, the economy of the steam pumping engine is greatly improved, but the motor keeps pace with it and is at least as good.



Centrifugal Pumps Underground



A Westinghouse Motor Driving a Plunger Pump

Air pumps are extremely uneconomical. In one installation in the central Pennsylvania bituminous field, it required 11 boiler-horsepower to obtain 1 water-horsepower from large air-driven pumps emptying a sump. Electric motors were substituted for the engines and it then required about 2 boiler-horsepower for the 1 water-horsepower. Since the load was large and continuous this increase in efficiency meant a great saving in the course of a year.

The efficiency with which electric power can be transmitted over great distances is of special importance in coal mining. The loss in electric wires is comparatively small, while the losses due to leakage of air or steam or the condensing of steam are always large and often prohibitive, especially in long lines.

For the most part, direct-current motors are used in

coal mines, it being the best for haulage. Alternating machines are, however, used in many instances, and motors of either kind can be obtained for driving any size or type of pump.

In applying direct-current motors to centrifugal pumps, and to reciprocating pumps starting with a by-pass, shunt field windings will usually be found most suitable. Such motors have better speed regulation than compound-wound machines, and will start under considerably more than full load.

For reciprocating pumps starting under full head, or where heavy initial effort is required, the compound-wound motor will prove more suitable, owing to its ability to exert greater power during the starting period.

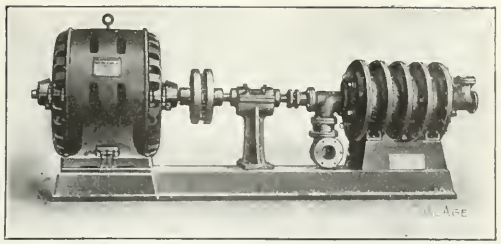
The Two Types of Motors

There are two types of alternating-current induction motors in general use, viz., squirrel-cage and wound-rotor machines. The squirrel-cage type of motor is the simpler

A Vertical Centrifugal Pump

and less expensive of the two designs. It is also easier to start and control. It is undoubtedly the most suitable and popular alternating-current motor for centrifugal pumps and is at the same time the one most advantageously employed for piston or plunger pumps which may be started with a by-pass; but if any such reciprocating machine must be set in motion against the full static head, more starting effort is needed and a wound-rotor motor will better fill the requirements.

After either a squirrel-cage or wound-rotor motor has been brought up to speed, there is no difference in operation; they will have approximately the same efficiencies, power factors and overload capacities and will also have the same speed regulation between no load and full load.



A Motor-Driven Multi-Stage Centrifugal Pump

Both types are essentially constant-speed machines, but if furnished with a special controller the wound-rotor motor may be used for variable-speed operation with a sacrifice in efficiency and regulation at reduced speeds.

The ordinary horizontal shaft motor is used for driving reciprocating and horizontal centrifugal pumps; for vertical centrifugals, a vertical shaft motor, which can be coupled directly to the pump shaft, is used.

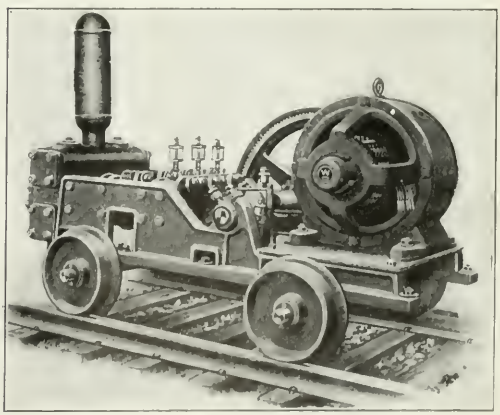
Special Machines Are Necessary

The conditions in coal mines are unusually severe on electrical machinery, so that a motor that would give perfect satisfaction in a factory would be out of commission in a short time in a mine. Hence motors especially constructed to meet the conditions should be used in underground installations.

Moisture-proof windings are of special importance. The insulation of the ordinary motor would soon become saturated with moisture in a mine and cause trouble, hence some manufacturers supply machines with specially treated windings which resist dampness indefinitely. Where the motor is subjected to drip, it should be protected by shields or inclosed in water-tight covers.

Motors are sometimes made for total immersion. One of the simplest methods is to place the machine in a kind of diving bell, closed above and open below; the air in the upper part of the bell keeps the water from contact with the motor even though the level should rise high enough to submerge the whole outfit.

Good commutation is especially desirable in mine-pump motors. Sparking at the commutator wears away both it



Westinghouse Motor Driving a Track Pump

and the brushes and makes renewals necessary. But by using commutating poles and designing the motor carefully, all sparking can be eliminated, so that the commutator's life is indefinite, brush renewals are rarely required, and the reliability of the motor is greatly increased.

Direct-current self-starting motors, previously mentioned, form a special class. Ordinary motors are sometimes used for this purpose but it is not considered good practice, as the stresses arising in starting a motor, not specially designed, without the interposition of a starting box, are quite severe and are sure to cause deterioration. In the self-starting type of machine, special coils are provided which keep within safe limits the rush of current at starting; such a motor will, therefore, not only give better service, but will cost less to operate than the non-special machine. These direct-current motors are built in capacities up to 20 hp. Almost any good alternating-current, squirrel-cage induction motor up to 20 hp. in capacity or even larger can be started directly from the line without injury.

Auxiliaries Should Be Specially Constructed

When a starting box is used in connection with a motor, it should also be of special design in order to withstand dampness. One manufacturer supplies a box in which the low-voltage release coil is made moisture proof and the resistance is embedded in a moisture-proof cement. This construction prevents the corrosion and deterioration that is apt to take place in unprotected apparatus.

In ordering an electric pump it is always advisable to specify a motor made by a reputable firm with extensive experience in mine work. Such a motor may cost a trifle more than one of inferior make, but will more than make up the difference by the better service it will give. Similarly, in buying motors to drive pumps already installed, it is advisable to consult such a manufacturer; the characteristics of different pumps and the requirements of different services vary so greatly that only an expert is qualified to select the proper motor for any given case, and if a wrong selection is made, trouble may result.

In order to secure the advantages of electric pumping it is not now always necessary for the mine to install its own electric plant. In many parts of the country central-station power is being used for driving part or all of the mine machinery. Where such power is available, it will nearly always pay to install electric pumps and in many cases the entire mine can be economically operated in this manner. At all events, the subject should be investigated carefully as an increasing number of mines are finding it profitable to buy their power.

❖ ❖

A Pump for Breaker Refuse Disposal

Special Correspondence

SYNOPSIS—A vertical, triplex, single-acting, cement-lined, motor-driven, plunger pump has been installed recently at an anthracite breaker to replace a bucket elevator and sluice system of refuse disposal. So far as can be judged at present, this machine will cut the cost of getting rid of the slush from the breaker to about one-half its former magnitude.

❖

The disposal of refuse and unmarketable sizes of coal from anthracite breakers is frequently a somewhat perplexing problem. If flushed into streams or rivers, as was once the custom, it soon fills up and clogs the channel, causing complications in time of high water, for which no mining company would care to be held responsible.

There are in general three methods of disposal for such refuse. (a) It may be flushed or otherwise stowed in the old workings of the mine. (b) It may be heaped or piled by cars or conveyors at some point close to the breaker, or (c) it may be flushed or conveyed to some point more or less remote from the breaker and where its likelihood of being washed into the neighboring larger water courses is reduced to a minimum.

The method to be employed in any particular case will be determined either wholly or in part by the location of the breaker and the topography of its immediate surroundings, as well as the conditions underground.

For several years past the practice at a certain anthracite colliery has been to dispose of the breaker refuse by elevating and flushing to a location considerably above the point of preparation, where it was allowed to settle and drain off in a depression beyond the first ridge in rear of the breaker.

This was accomplished by means of a system of bucket elevators discharging into sluices. And, altogether this method was efficacious, so far as the refuse disposal was concerned, it was decidedly unsatisfactory, both from a power-consuming and an operating standpoint.

Recently, therefore, a special slush pump and pipeline has been installed which does the work of the former system, occupies much less space and has thus far been vastly more satisfactory in operation.

The water carrying the refuse from the breaker passes through a steel plate filled with $\frac{7}{16}$-in. circular perforations into a vat or tank. What particles of slate, etc., remain on the screen are removed and disposed of by hauling away. From this tank the water passes to the suction of the pump and since the latter is considerably below the level of the water in the tank, it is provided with an air chamber.

The pump which has a capacity of 1000 gal. per min., is of the vertical-triplex variety driven by a 50-hp. open type slip-ring induction motor operating upon a 440-volt 25-cycle 3-phase circuit. The full load speed of the motor is 360 r.p.m., while the speed reduction, which is accomplished by means of a cut-steel herringbone gear meshing with a forged-steel pinion is in the ratio of 12½ to 1, making the full-load speed of the pump 29 r.p.m.

Bronze plungers 14 in. in diameter with a 16-in. stroke are employed. These are, of course, outside packed. The cylinders, valve chests and all parts of the piping are cement lined to resist the action of the acid and also the abrasion of the gritty slush.

The valves of this pump are unique. They consist of 5½-in. bronze balls operating within a cage, which is also of bronze, upon 3½-in. ports. The spherical form

of the valve renders it far less liable to uneven wear than were it flat while its composition possesses strong capacity for resisting corrosion.

A bypass is provided from the discharge to the suction pipe and drain cocks are so located as to thoroughly rid the pump and pipeline of all water. The apparatus must be thus drained not only to prevent freezing in cold weather but to rid the pump and discharge pipe of all slush when no water is flowing, as otherwise this material would settle in a compact mass effectually clogging the pipe. Relief valves are also provided in case of any contingency.

The liquid handled contains from 30 to 50 per cent. of solid matter by weight, as well as about $\frac{1}{10}$ of 1 per cent. of sulphuric acid. This is delivered against an actual vertical head of 109 ft. through an extra heavy cast-iron pipeline 12 in. in diameter and about 500 ft. long. The actual pressure against which the pump works, due to the increased weight and resistance of the liquid in the pipeline, is 65 lb. This, of course, includes the friction.

The power required to handle this slush is approximately 63 amp. at 440-volts tension. When pumping clean water, the current required at the same voltage was only 45 amp. The motor is mounted on top of the pump frame, where it takes up no floor space and requires no guarding of gears.

As stated above the slush was formerly disposed of by means of elevator towers and sluices. For some time before the installation of the pump, the operation, maintenance and repairs on this system cost approximately $600 per month. As nearly as can be foretold at the present time, the pump attendance, maintenance, power and repairs, in short, all items of expense connected with this latter system, will be approximately $300. The installation of this equipment has, therefore, cut the expense entailed in the disposal of slush at this colliery exactly in half.

Small Pumps for Hard Service

SPECIAL CORRESPONDENCE

The lover of horses is prone to discourse enthusiastically upon the speed, endurance or beauty of the genus equus, forgetting meanwhile the draft animal, which is the real servant of man, bearing his burdens, transporting his goods, drawing his agricultural implements; in short, performing much of the work and drudgery which renders our modern civilization possible.

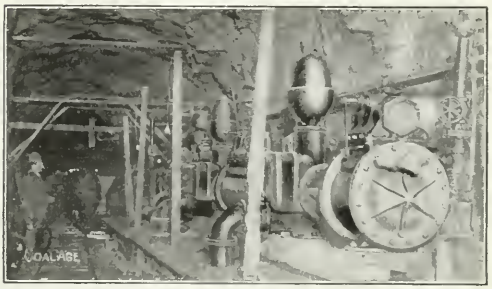
In like manner the operator or engineer familiar with mine drainage and the problems incident thereto, will persistently speak only of those pumps which have been purchased and installed to perform some special service, or those which occupy some conspicuous position, forgetting utterly the machines which are scattered about through the workings, each doing its share, even though that share be but small, toward enabling the underground worker to perform day by day his allotted task and thus securing to the mine its rated output.

The capacity of such pumps is not ordinarily great. The conditions under which they are called upon to work are usually far from advantageous. The fluid which they must handle is frequently aciduous and often carries more or less solid matter and grit in suspension.

Any pump which can successfully meet and cope with these conditions must be simple in design, constructed of the best materials, sufficiently heavy to withstand not only a considerable amount of abuse, neglect and rough handling, but also to retain a large percentage of its original efficiency over long periods of hard and continuous service. But above all other things, such a machine must be first, last and always absolutely dependable.

The A. S. Cameron Steam Pump Works have long produced machines to meet the exacting conditions of mining work. From the mechanical standpoint the most interesting feature of these pumps is the steam-valve mechanism. This is entirely inclosed and is in no way dependent upon the movement of any exterior cams, levers or contacts. The piston near the end of its stroke operates a small auxiliary or pilot valve which, through the action of the steam, causes the main valve to shift, thus reversing the direction of travel of the plunger. The advantages of this inclosed valve mechanism for use underground are too self-evident to require comment.

Another distinctive feature of this pump is the easy ac-



A REMOTE UNDERGROUND PUMPING STATION. THREE DUPLICATE MACHINES

cess to the water chamber. By merely removing the side cover or bonnet, the valves, guards, seats, stems and springs are in plain sight. This is an advantage that is much appreciated by the experienced engineer or pumpman.

It should also be noted that these parts are made heavier than those found in the average pump. There are no threads on the seats or stems, which project through the top of the water-valve chest, these being made fast by a cap nut and setscrew on the outside.

All the rubber valves in these pumps above the size 7x3½x12 in. are covered with heavy cast-brass cap plates, or guards, which are finished inside and permit the valve to fit snug. This preserves the upper side of the valve for use when the underside becomes worn.

Another special advantage in this valve-chest construction is that it is close to the ground and alongside the water piston instead of above the water cylinder as in some other makes. The valves are therefore just so much nearer the water and the suction lift is reduced accordingly. Furthermore, every water cylinder is made to withstand a pressure equivalent to a 400-ft. head.

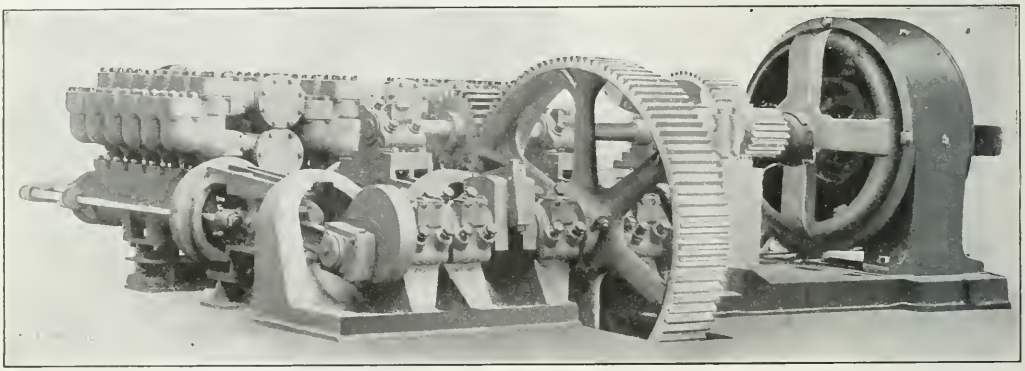
These distinctive features make the Cameron pump unusually strong and reliable throughout, which accounts in large measure at least for its remarkable record of long and severe service in coal mines all over the world.

The Advantages of Electric Pumps

By J. W. Matthews

SYNOPSIS—The electric system of power distribution is much more flexible than either steam or compressed air and electrically driven pumps are more efficient than those employing either of the above mentioned working fluids. There are other advantages also, such as portability and the space required, to say nothing of air vitiation or dry rot in mine timbers.

Electric pumps are now sold under guarantee to operate under water if flooded. They have been flooded by water at 165 deg. F. for twenty-four hours and have come out unhurt, have pumped themselves dry when flooded even after weeks of submersion, and have stood up under the attack of sulphuretted hydrogen for years in locations where attendants could not endure the gas. Add to this brief review a statement that the operating cost of electric pumps is generally less than that of any other power-driven pump, the efficiency frequently 20 to 40 per cent. greater than steam- or air-operated machines, and the reliability of operation supreme and some idea can be gained of the reasons which have caused widespread interest and adoption of electricity as a motive power for mine pumping.



A Horizontal Plunger Pump, Driven by a G. E. Motor through Double-Reduction Spur Gearing

Any statement of the principal advantages of electric power for mine pumps should include the general advantages of electricity as a motive power for mines, which also applies to the pumping-power system as a whole. A brief review of these, with a few remarks on the selection and application of motors followed by the experiences of some operators with electric pumps will be interesting.

Advantages of Electric Power

One power plant can be used instead of several. This means greater efficiency because of larger average load, larger size and less attendance and supervising. To assure continuity of operation, a smaller margin of reserve apparatus is necessary than the total provided at the several small plants.

The central station can be located solely with reference to the generation of power, the supply of boiler and condensing water, the handling of fuel and disposal of waste, etc., practically regardless of the relative location of the various points at which the power is to be applied.

The use of electricity eliminates the necessity for long lines of steam and air piping which are expensive to install and maintain and with which the danger of breakdown and the difficulty of obtaining the necessary working pressures increase with every extension of the service. For these conditions electricity substitutes a simple and thoroughly flexible system of transmitting power by means of conductors, which can be easily run and rapidly extended to meet changes involved in the progress of development, which are not affected by temperature variation and are not liable to mechanical injury or breakage due to floods or shifting ground.

They can be safely used in places where steam lines would introduce an element of danger, and finally they can, in many instances, be run in shafts or bore holes already in use for other purposes without occupying room that could otherwise be utilized. Many coal companies are at present economically transmitting or distributing current from central stations over lines more than 10 miles long and in some cases twice that distance.

A large percentage of the friction losses and repair charges can be eliminated by directly connecting the motor to the pump, as the modern types of both alternating- and direct-current motors lend themselves to this method of connection in the majority of cases with the assistance of a single gear reduction.

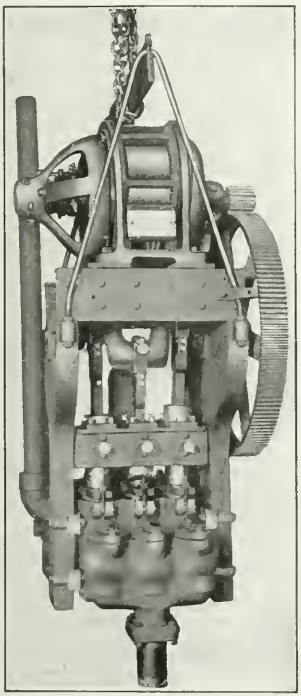
With electric power only a small part of the generating plant need be operated during a shutdown for the pumps, ventilating fans, etc., which must be kept in operation. This intelligent subdivision of the total power-generating equipment into units which can be operated at or near their full capacity during anticipated mining conditions, is a valuable intrinsic feature of electric power.

Electric Machines Have Higher Efficiencies

The efficiencies of electric pumps are 25 to 40 per cent. greater than steam or air, the centrifugal pumps in one case operating at 61 per cent. or 5.6 lb. of coal per i.hp.-hr., and in some cases efficiencies as high as 80 per cent.

are claimed for these machines. A few extreme examples of the extravagance of air pumps which have an efficiency of only about 15% under quite favorable conditions are known.

Steam pumps, of the compound condensing type, 20 and 38x13x36 in., require 10 lb. of coal per i.hp.-hr., including boiler loss, condensation, etc. Where air pressure



A Motor-Driven Sinking Pump

must be maintained outside of working hours, the efficiency of air pumps may be as low as 1 per cent.

The meters used in electric circuits show at a glance any abnormal operating conditions, and efficiency can therefore be maintained at all times and there is no possibility of undetected leaks as in the case of steam or air.

Economies in operating cost and maintenance greater by 15 to 40 per cent. are claimed for electric pumps over steam or air. In the case of the latter, pipes are not as quickly repaired as wires and the many joints are hard to keep tight.

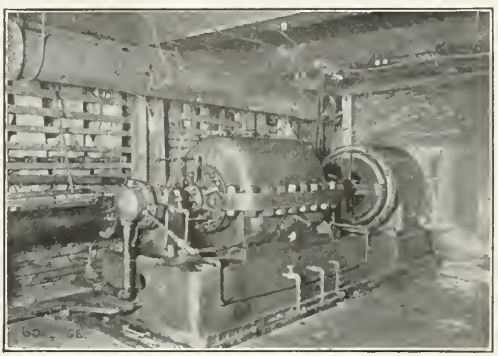
Electric pumps occupy from a fourth to a half less space than steam or air pumps, are easily moved and quickly put into operation without loss of time, can be controlled from a distance and can be arranged to maintain high pumping efficiency under widely varying loads.

Electric pumps are desirable in many cases because they do not vitiate the air nor cause dry rot in mine timbering, as is the case with steam, which also warms the water in sumps, so that its value for condensing purposes is lessened.

Both high- and low-lift centrifugal pumps, three-throw pumps, and special positive-valve pumps have been driven successfully with electric motors.

Electric track pumps can be moved with the greatest ease and can be operated from the nearest trolley or lighting circuit available. They are usually driven with a double-gear reduction, which can be made practically noiseless with cloth pinions.

Either compound- or shunt-wound direct-current or slip-ring or squirrel-cage alternating-current induction motors are suitable for the operation of pumps. Where varying voltage is encountered a compound-wound motor is better adapted to pump operation than the shunt machine. The shunt motors are satisfactory where a little increase in speed, due to their field heating up, is not objectionable, but the induction motor is most highly recommended because there is no electrical connection between its operating and stationary parts which, together with its insulation, renders it waterproof. Beside this its speed is constant and its efficiency high. These motors can be controlled from any convenient point, as by a float in the sump for automatic starting and stopping. They can also be controlled from a distant point, which may be



A Horizontally Split Motor-Driven Centrifugal Pump

miles away, and stopped or started by simply pressing a button.

The weight of the water pumped, multiplied by the height plus the loss in head due to pipe friction, divided by 33,000, should be divided by the efficiency of the pump to get the horsepower of the motor required. Excess power is needed for starting a column of water and for overcoming silt or sand in the intake pipes, but all liberally designed motors will take care of this.

When operating a number of alternating-current motor-driven pumps from one generating station, they should be kept well loaded or it may be necessary to install synchronous motors or rotary converters to improve the power factor.

The power factor is the ratio of the useful power in watts to the product of volts and amperes. The difference is lost in magnetising current and in charging conductors, but must be generated as well as the useful power. Fortunately this is very low, say 5 or 10 per cent. of the generated power, on a well loaded system, and is more than made up by the great economies in transmitting electric current and its possibilities for direct applica-

tion without countershafts or belts for mine machinery. The power factor can be better understood by considering a few examples of electric equipment.

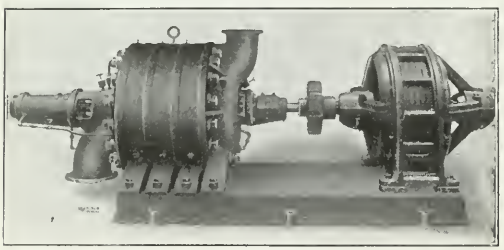
Some Examples of Electric Installations

At the Windber plant of the Berwind-White Coal Mining Co. there were installed seven 400- and two 150-kw. rotary converters, three 300- and two 225-hp. synchronous motors, totaling over 4000 kw. in synchronous apparatus. The inductive apparatus includes, in addition to 300 kw. in transformers, about 3000 hp. in induction motors. The power factor on the system is usually just at unity, that is, there is no so called useless power.

At the York Run plant of the H. C. Frick Coke Co., the synchronous load connected is 1200 kw., all rotary converters, while the inductive apparatus amounted to 2200 kw., consisting of 1350 kw. in transformers for the rotaries and the balance in induction motors from 50 to 400 hp. The induction motors are fairly well loaded and the power factor is over 90 per cent.

To illustrate the waterproof qualities of squirrel-cage induction motors, two examples will be instructive.

During a heavy thaw a 20-hp. induction motor, driving a mine pump at the bottom of a shaft at the mines of the Richmond Iron Works, was flooded, the top of the motor being two feet under water. The machine continued in operation and at the end of two hours had pumped itself clear. It was then stopped, cleaned and oiled and put into service again. This pump has been operating about twenty hours a day ever since and has apparently suffered no injury.



A Vertically-Split Centrifugal Pump Direct-Connected to Motor

The most remarkable motor-driven pumps in existence are probably those at the Comstock mines, where, during a changeover, water at 165 deg. F. submerged the pumps for twenty-four hours. The motors were dried out with voltages of 38, 110 and 440 and in a few hours were put to work. Although the motors were not damaged, a telephone receiver was melted out of shape and warts were raised upon it.

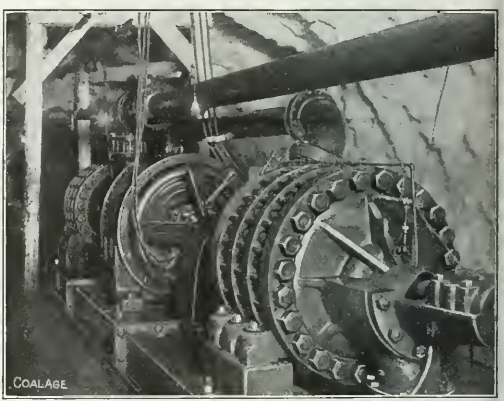
Whenever the air supply is insufficient the contractors on the Catskill Aqueduct stop the air pumps and rely entirely on the electric pumps. This is done where the compressor capacity makes it advisable to use the air pumps when demands are light, but wherever possible the air pumps are removed and electric ones substituted. In one case three air-driven pumps were displaced at the Hudson River Siphon by one 500-gal. per min. (1200-ft. head) centrifugal pump, driven by a 275-hp. ball-bearing water- and air-cooled squirrel-cage induction motor. This motor can be turned over with the little finger when disconnected from the pump and the air cooling has never been necessary.

Part of the government's test for the new dry-dock pumps recently purchased was to submerge the motors for three weeks and then turn on the current until they had pumped themselves dry. The water was 30 ft. deep in a well at the drydock, and was, I believe, sea water.

❋

A High Head Centrifugal Pump

Although many centrifugal pumps may be found in coal mines throughout the country, the vast majority of them operate against heads considerably below 1000 ft. Several installations exist, however, wherein this head is greatly exceeded. The Prescott turbine pump shown in the accompanying illustration and located in the Penn Iron Mining Co.'s mine at Vulcan, Mich., is an 8-in. 8-stage, composed of two 4-stage machines operated in series, one located on either side of a 500-hp., 2200-volt, 60-cycle, 3-phase induction motor, operating at 1200 r.p.m.



An Eight-Stage Centrifugal Pump Working under a 1300-Ft. Head

The shafts of the pumps are direct-connected to the motor shaft by compression couplings. The discharge from the first half is carried around the motor to the suction of the second half. The direction of flow of the water in the two parts of the pump being thus opposed tends to balance the end thrust on the impeller shaft. In addition to this, however, there is furnished a disk thrust bearing with oil cushions which completely takes up the thrust and maintains the impellers in their proper positions with respect to the diffusion vanes and prevents excessive wear on one side. As may be seen in the photograph, the discharge heads and pressure rings are of cast steel, split vertically and held in position by heavy external through bolts. The impellers and diffusion vanes are of cast bronze. The bearings are of the ring-oiling type and separate from the pump casings. The pumps and motor are mounted on and securely bolted to the cast-iron bedplate extending under the entire unit.

This machine delivers 1000 gallons per minute against a vertical head of 1300 ft. and has been in continuous and successful operation for over two years.

The Evolution of the Mine Pump

By Frank H. Kneeland

SYNOPSIS—Like most other pieces of mechanism employed in present-day arts and industries, the modern mine pump is the outcome of a gradual development. The early stages of its growth are linked inseparably with the names of such inventors as Worcester, Savery, Newcomen and Watt. However, during the past century, many other men have introduced various alterations and refinements.

Neglecting the experiments of Hiero, of Alexandria, who lived and flourished about the year 200 B.C., the real history of the steam engine and pump began with Edward Somerset, second Marquis of Worcester, about the year 1663. This inventor designed and built a device somewhat simila. in principle to the present-day pulsometer, lacking, however, the latter's automatic-valve feature.

That the pump should be the first successful heat engine developed and that it should find its primary application in ridding mines of water is not strange. Great difficulty had been experienced in satisfactorily draining British mines, particularly those of Cornwall, and the operators were, therefore, extremely anxious to make use of any device for lifting the water which might prove more economical than the horses then employed.

It is a strange but notable fact that many, if not most of the real improvements in coal mining, have come from men who were not themselves practical miners. The mine pump was no exception to this rule.

The First Steam-Driven Pump

The first steam-driven water-lifting machine to be successfully employed in mining was what was known as Savery's "fire engine." This was not altogether dissimilar to the Marquis of Worcester's device in principle. The main difference was that surface condensation was employed to hasten the insuck of water to the operating vessel. A safety valve was also employed as was a second or auxiliary boiler to force water into the main or working boiler without interfering with its operation.

The next great forward step in pump development was the invention of the famous Newcomen engine. In this machine a heavy vertical pump rod was attached by a chain to one end of a walking beam provided with a quadrant. To the other end of this beam, also provided with a quadrant, was similarly fastened the piston, which worked vertically in a cylinder. Steam was led from the boiler to the cylinder equalizing the pressure of the air and allowing the heavy pump rod to fall, thus raising the piston. The steam supply was then cut off and a jet of cold water introduced into the cylinder. This condensed the steam beneath the piston, which descended under the pressure of the air, thus raising the pump rod. Several improvements in this device were introduced from time to time, chief among which was an automatic valve gear, a fairly efficient method of packing the piston with leather or rope and its lubrication with tallow.

This machine was received with considerable favor throughout the mining districts. From about 1758 until the introduction of the engines of Watt, the Newcomen pump was the standard, and all but universal means of raising water from the mines. Some of these machines have been in use up to the present day.

The next improvement of the pumping engine came from James Watt, who added, first the separate condenser and later other improvements. This inventor also built the first successful rotary-motion engine or machine suitable for driving industrial plants.

The coal-producing industry as an industry is perhaps rather conservative. The operator finds it difficult to discard any piece of machinery that is in even fair working order and pay out good cash for new apparatus even though he is convinced that money would be saved thereby in the long run. Just as the older mining companies in the United States are clinging tenaciously to distribution of power by means of extravagant steam lines, so the English have stuck to walking-beam and bell-crank pumps with their long and heavy wooden pump rods.

Of course, these machines have their advantages and may be so constructed as to be economical in their use of steam. They are, however, extremely heavy for their power, clumsy, and require a special shaft or compartment within which the pump rods oscillate.

The direct-acting piston or outside packed plunger pump, either simplex or duplex, simple, compound or triple-expansion, has always been a great favorite in this country. And although some economical flywheel machines are in use at American collieries and have been for some years past, yet the great majority of our pumps, those which handle by far the largest percentage of the mine water encountered, are of the direct-acting type.

With the electrification of mines and the adoption of this form of energy, for various mining problems, has come the duplex, triplex and quintuplex electrically driven, geared pumps. These are frequently small machines, capable of being mounted upon a truck which can be run along any mine track, to be used wherever a dip or swamp is encountered.

The Centrifugal Pump Is a Favorite with Many

In comparatively recent years also another type of pump, known as the centrifugal, has been developed. This is as radically different from the older varieties as is a steam turbine from a reciprocating engine. Although the centrifugal pump is not popular for use underground with some operators, it is a great favorite with others. Its utility for this service seems to depend largely upon the size and shape of the impeller passages and the quantity and size of the pieces of foreign matter (chips, coal, rocks, etc.) suspended in or otherwise carried by the water. It cannot be wood lined and thus proofed against the action of acid, as may be the plunger pump. All parts subject to the action of the water may, however, be made of bronze, the corrosion resisting qualities of which are well known.

The great simplicity, light weight, large capacity and ease with which this type of pump may be connected to a motor or other driving apparatus, as well as a total lack of vibration or water hammer on the connected pipeline, due to the closure of valves, are all considerations which have greatly influenced the favorable reception of this type of water-handling apparatus.

A New Type of Centrifugal Pump

SYNOPSIS—The striking features of this pump are the absence of diffusion vanes and the use of double-inlet impellers. Since the shaft is theoretically in hydraulic balance, there is little or no tendency for it to move endwise, and the multi-collar bearings provided serve rather to keep the rotating parts in alignment than to resist excessive end thrust.

Practically ever since the beginning of coal mining as we know it today, the reciprocating pump has held a supremacy over all other forms which has been all but absolute. In many localities, however, the centrifugal mining pump is now rapidly encroaching upon the domain of the older and perhaps better known type. This is due not to any one particular point of excellence, but to a combination of reasons.

Throughout the entire field of mechanical engineering, almost without exception it has been found easier and more convenient to govern, control and lubricate a continuous rotary motion, than one which is reciprocatory or oscillating in its nature. The moving, or working parts of the centrifugal pump may be considered as a unit, revolving about a common shaft. The problems of operation have, therefore, reduced themselves to their lowest possible terms.

One of the principal difficulties which has heretofore confronted the designers or users of this type of pump has been the tendency of the shaft to move endwise in the casing and bearings, due to the reaction of the water handled upon the impeller. This has been counteracted or taken care of by the employment of ball thrust-bearings, or a bearing of the marine multi-collar thrust type upon one or both ends of the pump shaft. In many instances these have not been altogether satisfactory in service.

Another but less fruitful source of trouble has been the tendency of the pump to suck in air through the gland, or stuffing-box, on the suction or intake of the pump, thus destroying the vacuum and rendering it difficult to raise the water.

As an industry, mining presents problems peculiar to itself, no matter what may be the type, or kind or purpose of the apparatus under consideration. Particularly, if a pump be small, it is likely to be shifted about from place to place in the mine and therefore subjected to lifts and heads which are decidedly variable. Furthermore, it will frequently be placed in a poorly lighted and often cramped position. Add to this the fact that the labor available both for installation and operation is usually unskilled, or at best only semi-skilled, and it will be readily appreciated that the work which the mine pump has to perform is in most cases at least severe, if not exacting.

To meet these varying and strenuous requirements the Epping-Carpenter Co., of Pittsburgh, Penn., have recently designed a type of pump which contains many novel features. It is built either single or multi-stage depending upon the service required. A three-stage pump of this design is illustrated in Fig. 1.

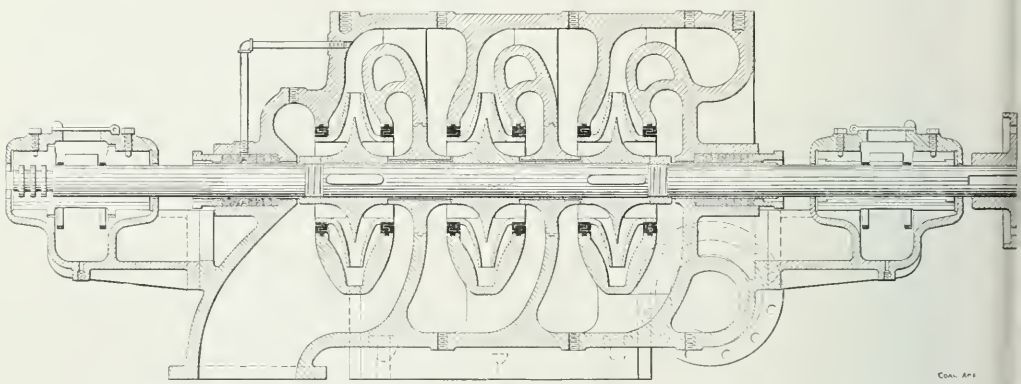


FIG. 1. CROSS-SECTION OF 3-STAGE PUMP. NOTE ABSENCE OF DIFFUSION VANES

To those familiar with this type of apparatus, two distinctive features in the construction of this pump are at once apparent. These are, first, the entire absence of diffusion vanes and, second, the double-suction impeller. The water entering the suction pipe, which is here shown to the left of the drawing, has easy access to both sides of the impeller of the first stage. After passing the first stage it is conducted to the second impeller which it enters in precisely the same way as the first and so on throughout the remainder of the stages.

The pump is so designed as to give as nearly as possible a uniform velocity of flow to the water throughout the various pump passages with the exception of the impellers, this condition being conducive to the maximum of efficiency.

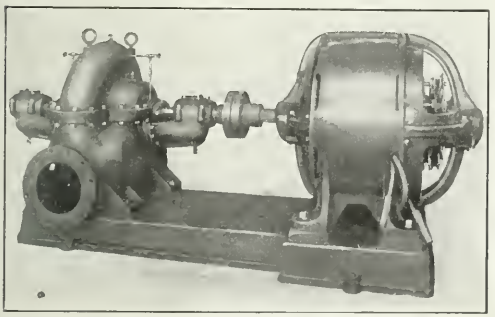
As will be noted from the drawings, the steel shaft upon which the impellers are pressed and keyed is incased from gland to gland of the stuffing boxes either by bronze sleeves or by the pump impellers themselves. It is thus entirely removed from the corroding action of the liquid handled.

As has been stated above, in pumps of this character there is a tendency for the air to creep or leak along the shaft through the stuffing box on the suction end of the pump. In this particular design, to avoid this leakage

of air an open "lantern" or frame work somewhat resembling the retainers of the ordinary ball bearing, is placed in the stuffing box in such a way that water may be conducted from the terminus of the first stage of the pump into this opening. A water seal is thus provided at a pressure which at all times exceeds that of the atmosphere and renders impossible any air leakage along the shaft.

The main bearings of the pump are of the vertically split ring-oiling type. On the suction end, as will be observed, a three-collar marine thrust is provided. Since the impellers are, however, hydraulically balanced the function of this marine thrust is rather more one of alignment—that is, keeping the impellers of the pump constantly in their proper position—than the taking care of any excessive end thrust which may come upon the shaft.

On the opposite, or discharge end of the shaft, a flanged or other coupling may be provided for attachment to motor, steam turbine or other driving apparatus. In order to take care of the rough usage and neglect to which these pumps are frequently subjected, all parts are made heavy. The casing is split horizontally and



Single-Stage Pump and Motor on Common Base

the entire pump may be dismantled for inspection or repairs without disturbing the base or foundation.

The single-stage pump is exactly similar to the multistage except, of course, that it has but the one impeller. A water seal is provided in both stuffing boxes, and a collar upon either end of the shaft takes care of any slight end thrust which may exist.

❖

Some of the features of a new electrical pumping installation at the Dover collieries, England, are more or less novel in mining work. Among these are the variation of output of the centrifugal pumps, the increase of the load on the alternators by means of air blades, and the fool-proof combination of switchgear for the starting of two motors coupled to the same pump. The high-tension motors are dried by means of a low-tension current.

❖

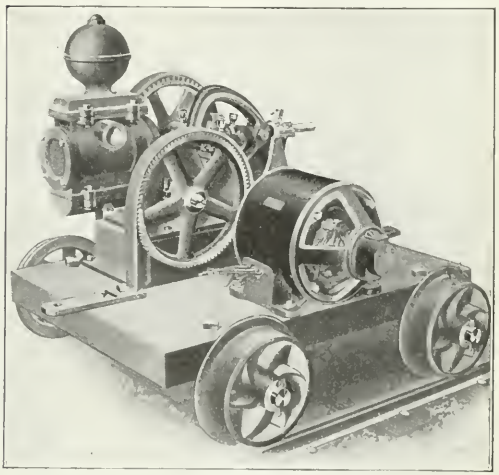
The Manor Powis coal field, Stirling, Scotland, presents a very interesting geological formation. The Carboniferous limestone series are underlaid by a great sheet of basalt, and the degree of anthracitization is determined, to a greater or less extent, by the distance of the seams from this basalt. At the time this sheet was thrust up it was intensely hot, so that its effect on the coal above was to reduce some of these seams to graphite and materially change the character of the others. The six seams of the horizon show, in regular gradation, the effects of this intense heat. The lowest are burned beyond anthracite, the next are anthracite, the middle seams, coking coal, and the upper, bituminous.

A Small Portable Electric Pump

The accompanying illustration shows a new type of portable electric mine pump which has recently been placed upon the market and is now carried in stock by the Harris Pump and Supply Co. of Pittsburgh, Penn. This machine is designed particularly for dips and entries or for follow-up work where but small amounts of water are encountered, and the head against which it is to be raised is not great.

The construction is such that air entering the suction even in considerable amount does not stop the operation, neither do small quantities of solid matter such as sand or mud clog or seriously interfere with the proper action of the valves.

The pump is ordinarily built for handling pure water



Pump and Motor Mounted upon a Truck

but the substitution of a solid bronze water end renders the machine capable of coping with water which is strongly sulphurous.

A valuable feature of this pump as illustrated is that the motor can be and regularly is made self-starting. One wire is grounded through the truck while the other may be hooked over the trolley wire which starts the pump instantly.

The cylinders of this machine are five inches in diameter while the stroke is four inches, the rated capacity being 30 gal. per minute while the maximum head against which the pump is intended to work is 100 ft. Connections are provided for a 2½-in. suction and a 2-in. discharge. The truck wheels are 12 in. in diameter and the height over all is consequently only 12 in.

This pump is usually made in from 39-in. to 44-in. track gage but if sufficient head room is available it may be raised up so as to accommodate any gage smaller than those above mentioned.

The motors ordinarily furnished with these pumps are either 230 or 500 volts direct current. Any other kind or type of motor of suitable power and speed could, however, be employed, the above being merely the voltages most commonly encountered.

A Large Triple-Expansion Pump

The general appearance and characteristics of operation of the ordinary duplex plunger steam pump are familiar to almost all mining men. Whatever may be the merits of such machines as concerns durability and reliability, they are notoriously extravagant in their consumption of steam. If such machines are, however, made triple expanding and such refinements as steam-jacketed cylinders, rotary valves, etc., are introduced the high rate of steam consumption may be decidedly reduced and the efficiency of the unit correspondingly increased.

The Goyne Steam Pump Co., of Ashland, Penn., which manufactures mine pumps exclusively, has just completed a large triple-expansion condensing pump for the Exeter colliery of the Lehigh Valley Coal Co. As the installation of this machine has not yet been completed, it has not, of course, been put in operation and no data are available from the operating standpoint.

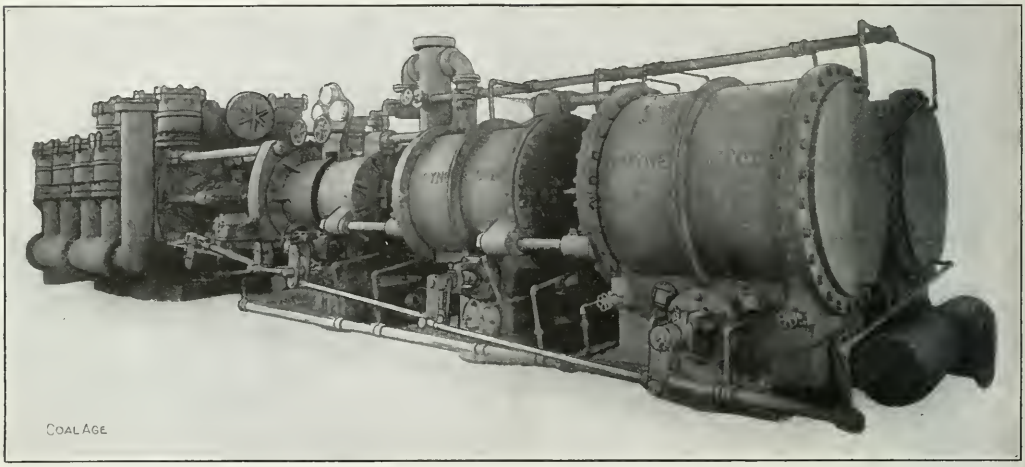
This machine was, however, designed to work against a vertical head of 650 ft. and to deliver 2,000 gallons of water per minute. The high-, intermediate- and low-pressure cylinders are 20 in., 30 in. and 45 in. in diameter respectively. The plungers are 14 in. in diameter and the stroke is 36 in. Both the high and intermediate steam-pressure cylinders and their heads as well as the heads of the low-pressure cylinders are steam jacketed.

The steam valves are of the semi-rotative type and the high-pressure cylinders are fitted with the Goyne adjustable cutoff, which is capable of alteration while the pump is at work. Each of the six steam cylinders is lubricated by a power-driven oil pump and a record of operation is made by a six-figure revolution counter.

The steam separator and cylinder jackets are drained by separate traps and steam is supplied to operate the condenser from the discharge end of the cylinder-jacket main drain pipe, which assures dry steam in the jacket. The arrangement of cylinders, cylinder heads and piston rods is such as to give the easiest possible access to the internal parts. The total weight of the pump, exclusive of condenser, is 160,000 pounds.

As this pump will be called upon to handle water which is strongly aciduous the water end is entirely wood and bronze lined as a protection against the corrosive action of such liquid.

Owing to the varying circumstances in colliery operation it is not always possible to maintain a steam pressure which is even approximately constant. Should a condition arise whereby the steam would drop to a pressure that would not give the required piston speed to meet the water conditions, this pump is fitted with an appliance such that by the manipulation of a valve (which can be accomplished in a fraction of a minute) the high-pressure cylinders may be thrown out of service and the pump for the time being operated as a compound machine.



A 2000-Gal. Triple-Expansion Pump for Use in an Anthracite Colliery. Note Rotary Steam Valves

It might be mentioned also that the manufacturers of this pump are now engaged in building four other large station pumps of practically the same type except that these latter will be compound instead of triple expansion.

A Filtration and Pumping Plant

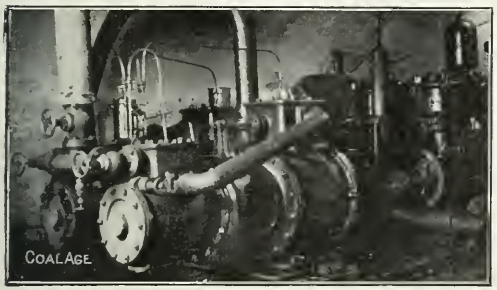
The problem of providing an adequate and suitable house-water supply at many of the larger mining operations, especially those which are isolated from any town of considerable size, is one which requires careful consideration upon the part of the designer in laying out the plant.

As the pumps supplying such a domestic water system will probably be called upon in the contingency of fire, they should be selected with a view to a large overload or emergency capacity.

The Pittsburgh-Buffalo Co., at their mine at Marianna, Penn., have such a plant installed. The machines selected for this purpose are two Jeansville compound duplex direct-acting plunger pumps which are duplicates of each other. The high- and low-pressure steam cylinders are 12 and 24 in. in diameter respectively. The

plungers are 8 in. in diameter and the stroke is 18 in. The suction and discharge of these pumps are each 10 in. These have, however, been bushed down to 8 in. in both cases. The steam supply pipes are 3 in. in diameter and the exhaust 6 in. The pumps are provided with rubber pot valves, 10 in. in diameter.

Steam is supplied to these machines at about 140 lb.



ONE OF THE TWO COMPOUND PUMPS HANDLING HOUSE WATER

pressure per sq.in., while the exhaust is made to the atmosphere. Both pumps are lubricated by means of a forced-feed oil pump. They are set upon solid concrete foundations in a brick pump house, with concrete floor about 6 ft. below the ground level. They ordinarily operate at approximately 50 strokes per minute. Each machine is provided with all necessary priming and drain pipes on both steam and water cylinders.

Under ordinary operating conditions, one of these pumps draws raw water from Ten-Mile Creek, and discharges it into a tank. From here the water flows to the treating plant where it is subjected to the action of a solution of alum to effect purification. After being thus treated chemically, the water passes through a filter from whence it is conducted to the suction of the second pump.

This machine draws its supply of filtered water from the purification plant, and discharges it into a house-supply tank located on a hill at an elevation of approximately 600 ft. above the pump. This tank is about 200 ft. above the highest point where water might be needed for fire purposes.

In case of emergency, provision is made so that both pumps may draw their water supply direct from the creek and deliver it to the reservoir through two separate 8-in. pipe lines. This places an abundant supply of water at a pressure equivalent to at least a 200-ft. head at the disposal of the company in case of fire or any other emergency.

A New Stripping Company

The exchange of big coal holdings and the organization of new mining companies are frequent occurrences in Pittsburg, Kan., and the surrounding coal fields. This is especially true of the strip pit mining industry. The most recent corporation to be formed is the Moka Coal Co., with Thomas W. Caffey, George Williams, William Williams, A. L. Blair and Oliver T. Jones as the members. Mr. Jones is the practical coal man of the group, he having had considerable experience in various phases of the business. The new company, capitalized at $30,000, has leased 165 acres of land with a shallow lying vein from Miller Bros., of Mulberry, toward the north end of the coal field and on the Missouri-Kansas line, from which fact the name "Moka" is derived. A big steam shovel will be put to work in the near future, and it is said $35,000 will be necessary to start operations.

Options on coal lands are being taken up or renewed all over the district, both in shallow and deep-vein tracts. The shallow coal is mined by stripping off 10 to 20 ft. of earth with steam shovels. The Southwestern Development Co., which is known as a subsidiary of the M. K. & T. Ry. Co., and George K. Mackie, of Scammon, a well known operator, recently have been buying options and renewing old ones to the south and west of the present prospected district, in Crawford and Cherokee counties. Miller Bros., coal-land dealers of Mulberry, have just completed buying options and renewing others on 3700 acres on the north edge of the district. Much of the territory has not been prospected, but great confidence is felt because of showings made on part of the holdings.

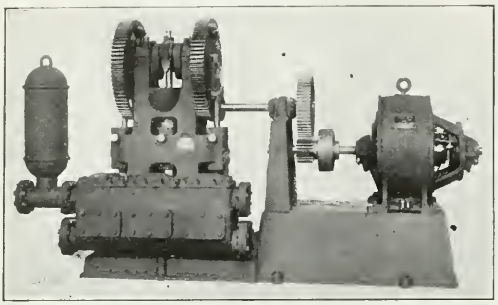
EXTERIOR VIEW OF FILTRATION PLANT, HOISTING PLANT AND BOILER HOUSE IN BACKGROUND

The United States Government still owns over 70 million acres of coal land in the West. Some parts of this immense acreage contain beds of high-grade coal ranging from 30 to 80 ft. in thickness.

An Electric Water Supply Pump

At many mining plants by no means all of the pumping which is done, is for the purpose of mine drainage. Power plants must be supplied, dwelling houses must be provided with drinking water, and provision must be made for fire protection.

At the Crescent mine, of the Monongahela River Coal & Coke Co., near California, Penn., there is installed an 8x10-in. Deming vertical triplex pump in a sump under the tipple. This machine is geared to and driven as to drive the crankshaft of the pump at approximately 47 r.p.m. when the motor is running at full speed.



THE PUMP, SHOWING HOW IT IS GEARED TO THE MOTOR

The pump and motor bases are separate, but are bolted securely together, thus forming practically one base plate. The motor is raised a sufficient height from the floor to largely obviate any danger from water which frequently accumulates upon pumphouse floors.

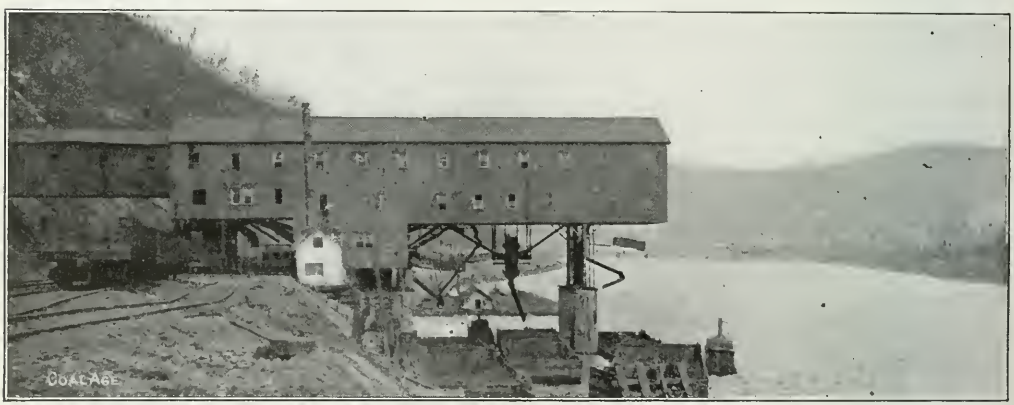
The pump is provided with a 6-in. suction and a 5-in. discharge. Both of these openings have, however, been bushed down to 4 inches.

The unit as a whole is compact and all parts are readily accessible. The plungers are of bronze, single acting, and the pump chambers are all wood lined.

This machine draws water from the Monongahela River, and forces it through about 2½ miles of pipeline to the town and power plant, at Crescent.

Panel Board Lightning Arresters

A great many railway, lighting, mine and industrial properties have certain "spots" where lightning conditions are particularly severe, and where it is difficult to secure thoroughly efficient and reliable protection. In other cases, particularly in central stations, there is certain electrical apparatus that needs, what may be termed, one hundred per cent. protection, as, for instance, power



THE CRESCENT TIPPLE OF THE MONONGAHELA RIVER COAL & COKE CO., BENEATH WHICH PUMP IS LOCATED

by a Westinghouse 25-hp. interpole motor, which operates at 685 r.p.m. upon a current of 500 volts.

The rawhide motor pinion is keyed to an extension of the motor shaft, which is attached thereto by means of a flexible coupling of the flange and rubber buffer type. This extension shaft is provided with an outboard bearing outside of the pinion.

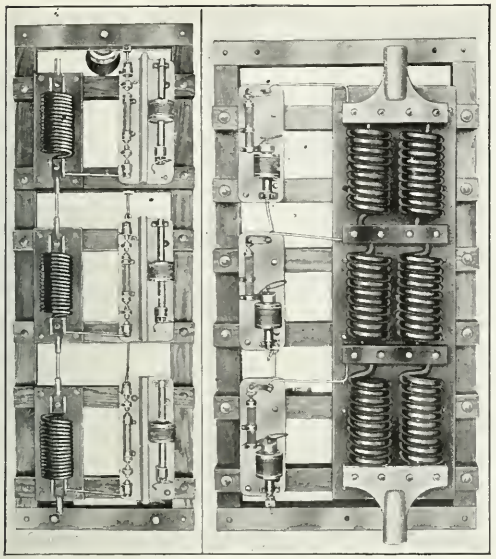
Meshing with the motor pinion there is a gear upon a countershaft, which extends across the frame of the pump. This shaft carries two pinions, which engage the main or driving gears upon the pump shaft.

The two gears above mentioned serve not only to drive the crankshaft, but are themselves crank disks, pins being provided to drive the two outer plungers of the pump. A center crank is also located between the two main pump bearings, which drives the middle plunger.

All gears are cut and the ratio of reduction is such for the fans and pumps. For the protection of these important installations, the Electric Service Supplies Co., Philadelphia, has placed on the market a line of panelboard lightning arresters, for both direct- and alternating-current service; illustrations of typical boards for both are shown herewith.

These boards are built on the well known law that no matter how efficient a lightning arrester may be, it will never carry off the entire discharge from a given line; some small portion will always find its way past an arrester and into the apparatus to be protected. With an efficient lightning arrester, however, and a suitably designed choke coil, this leakage will be small and usually not enough to damage the apparatus, but with heavy induced strokes, and under certain other conditions, this is not the case.

The arresters here described effectually take care of



Direct- and Alternating-Current Arresters

this leakage by interpoling additional choke coils between the line and the apparatus to be protected, and by connecting lightning-arrester units ahead of these coils. Any leakage passing the first arrester unit, for instance, in a triple board, must pass through three choke coils and by two additional units before it can get into the apparatus.

With but a single choke coil and a single arrester unit, and assuming that nine-tenths of the discharge goes to ground through the arrester, it is seen that one-tenth will be left to enter the apparatus. If an additional choke coil and a second arrester unit be placed back of the first, and assuming that the second unit takes nine-tenths of the one-tenth leakage to ground, obviously only one-one hundredth of the original charge remains to flow into the apparatus. Similarly with a third choke coil and a third arrester unit, but one-one thousandth of the original charge will leak through. In other words, by the addition of extra arrester units and extra choke coils, the protection has been increased ten times by a double panel board, a hundred times by a triple board and a thousand times by a quadruple board.

These arresters are not new by any means, having been furnished numerous companies all over the country for the protection of apparatus under unusally severe conditions. The boards are regularly furnished in station type, mounted on heavy impregnated oak framework and are furnished complete with insulators for attaching to any suitable support. The arresters are furnished with highly polished and lacquered metal work. Choke coils are of copper, black enameled and baked.

They are designed especially for the protection of apparatus up to 6600 volts alternating current, 2500 volts direct-current railway and 6000 volts direct-current arc circuits, and are furnished in any ampere capacity for voltages within this range.

❖ ❖

Recovery of Mine Timber

By J. W. Powell.*

SYNOPSIS—The need of drawing timber in all worked-out places is emphasized by the fact that timbers left standing in the waste cause a loss of coal by throwing undue weight on the pillars and crushing them, and by making it necessary to build packwalls, etc., that would not otherwise be required. The Sylvester machine for drawing timber is described.

❖

The timber needed daily in the operation of a colliery often exceeds the cost of any other kind of material or supplies. Any means, therefore, of reducing the heavy expenditure should be at once welcomed. Although mine props and sets of timber are often broken a short time after being set, the broken ends are valuable as they can still be utilized for the purpose of cap-pieces, wedges, track ties, or for the building of "cogs" or "chocks." Also, post timber broken in a thick seam can often be used again, in a thinner seam at the same colliery.

In some mines there is a considerable loss of timber, through the carelessness of miners who will let them lie in the waste where they are finally buried. By keeping a careful watch in their daily rounds through the mine, the mine officials can do much toward reducing this loss or waste of timber.

I want to emphasize the importance of drawing all kinds of timber, as the work proceeds, using, if necessary, some suitable appliance for this purpose. Timbers left standing in the waste often cause a loss greater than

Fig. 1. Drawing a Post in the Third Row from the Face of an Advancing Room

*Mine Manager, Columbia Coal & Coke Co., Coalmont, B. C., Canada.

their own value, by preventing the roof from caving and frequently making it necessary to build extra packwalls or timber cogs to keep the roads open. The material for these packwalls often has to be transported a considerable distance; whereas, if the timber was drawn and the roof allowed to fall, there would be plenty of material for the building of all necessary packwalls in most cases.

Again, under many conditions, when the roof does not fall but a large standing area is kept open a great weight is thrown on the timbers standing next to the face of the coal, with the result that these timbers are broken more quickly, or they kick out and the roof is ruptured at the face. When this occurs, the condition is bad, as the influence of the roof in breaking the coal after the latter is undermined, is destroyed. When the roof is of such a nature that it breaks readily, I believe it is a good policy to set a line of large breaking posts, with good sized cap-pieces, on one side of the track, which should be carried along the straight rib of the room.

Under these conditions, when the timbers are drawn

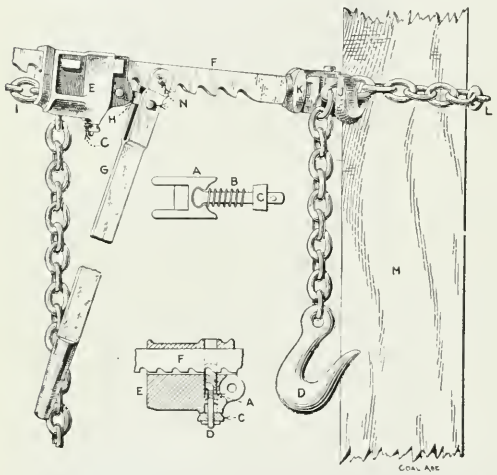


FIG. 2. SHOWING DETAIL OF THE SYLVESTER MACHINE FOR DRAWING POST TIMBERS

in the waste, as the face of the room advances, up to the last crosscut, there is not only a saving of timber, but the caving of the roof prevents the crushing of the pillar coal when the roof "weights" and cannot fall. In heavy-pitching seams, the recovery of timbers is much more difficult and dangerous than in flat seams; because the worked-out portion, from which the timbers are drawn, is located up the pitch, and any loose pieces of rock that fall when the post is drawn are liable to roll or slide down upon the men engaged in drawing the timber who are unprotected.

The danger may be avoided, in part or wholly, by using a long ½-in. steel cable or chain that will reach from the timbers to the first crosscut, in which the drawing machine should be placed. This will not only afford the necessary protection for the men, but will enable them to recover a larger percentage of timbers. The cost of timber in pitching seams is much greater than in flat seams, owing to the labor required in handling the timber on steep pitches. In a seam pitching 35 deg. I have found the cost of timber to amount to an average of about 5½c. per ton of coal mined. This was in a mine where the roof conditions were fairly good.

Although most mine managers are, no doubt, familiar with the appliances in use for drawing timber, a brief description of the Sylvester machine, which I have found is the best for that purpose, will be of interest. The general method of using this machine in a flat seam is seen in Fig. 1, which shows a miner in the act of drawing a post, in a thick seam of coal. In general, the head of the post resting on a cap-piece will be dislodged more quickly than the foot of the other post to which the machine is anchored, especially if the bottom is rough or soft. Caution, however, is always necessary to see that the machine is properly anchored before attempting to drawn another post. If this is not done the post to which the machine is anchored may be dislodged and the miner operating the machine be caught by the falling slate and killed or severely injured.

The Sylvester machine is very simple in construction, and is shown in detail in Fig. 2. It consists of a notched bar *F*, 3 ft. long, 1½ in. deep and 5 in. wide. The notches are cut 1 in. apart and ½ in. deep and shaped as shown in the figure. To one end of the bar is attached a 3-ft. chain *L* which is passed around the post *M* and fastened or held by the chain block *J*. Sliding on the rack is a heavy block *E*, to which a 3-ft. hand lever *G* is attached by the link *H*, and by which the block *E* is worked along the bar, from notch to notch.

One end of the long chain *I*, having been attached to the post that is to be drawn, the chain is attached to the block *E*, by slipping a link into a recess in the side of the block. The bolts *N* in the end of the hand lever are 1 in. apart, which gives a leverage on the block *E* of practically thirty times the force applied to the lever. As the block *E* is moved along the notched bar, it is held by the pawl shown in detail below, in the same figure. The pawl *A* is actuated by the spring *B*. A detailed section of the block showing the operation of the pawl is shown also below. When it is desired to release the block *E* the lever *G* is moved forward slightly to relieve the pressure on the pawl, which is then drawn out by pulling on the crossbar head *C* and giving it a half turn, to place it crosswise of its recess. This holds the pawl back, and the block *E* can be moved in any direction. The large hook *D* on the end of the chain *L* is for use, if needed for attachment in another manner than what is shown in the figure.

Limiting Coal Profits in France

On Mar. 4 the French Chamber adopted an amendment to the Finance Bill, which has the support of the government. It takes the form of a tax on each ton of coal shipped or sold, on all mines whose net earnings amount to 20c. or more per ton. The tax, it is understood, will become operative on Oct. 1. In the case of mines whose net profit is quoted as from 20c. to 30c. per ton, the tax imposed will be equal to the excess in the value over 20c. As reckoned, the tax will therefore amount to 10c. or more per ton when the profit is 30c. or over. The estimate of the finance minister is that the tax will bring in $2,800,000.

A Pump Designed for Acid Water

SYNOPSIS—A mine pump should be sectionalized to facilitate transportation and erection underground. It should be as nearly acid-proof and as efficient as possible, but above all it should be dependable. This article describes a pump which has been designed with all of these points kept constantly in mind.

In different sections of the country and even in various mines in the same district, the conditions under which the pumps operate vary to a considerable degree. In some instances, the pump rooms are large, well lighted, comparatively dry, and the water free from acid. The engineer, or pump runner, is a competent man supplied with the necessary tools and equipment for properly taking care of and getting the best results from the apparatus placed under his charge. In such cases, standard pumps similar to those used in stations on the surface will often meet all requirements.

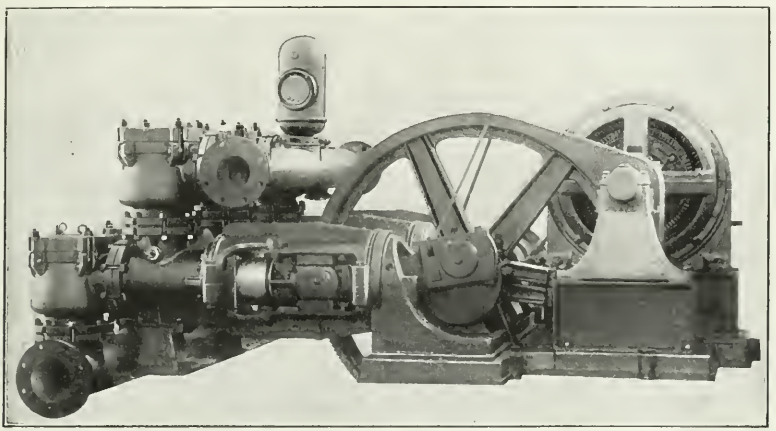
Frequently, however, the conditions are quite different, and special construction is necessary to satisfactorily cope with the exacting service, and a careful study of the actual operating conditions is essential in order to provide reliable and efficient machinery.

In general, a mine pump must have the following characteristics embodied in its design, together with any special features that may be necessary to meet local conditions. The various parts must be sectionalized to such an extent as to permit their being lowered through shafts of limited dimensions, and the separate castings must be of such size and weight as to be readily handled in limited quarters without the use of a crane. Furthermore, in order to lessen the liability of flooding the mine, the pump must be as reliable as possible, extra heavy in all its parts, provided with large wearing surfaces, protected from corrosion, and of such construction that replacement and repairs can be made in a minimum of time.

While reliability is a primary consideration, yet the cost of power must by no means be forgotten. Many pumps, particularly in coal mines, have to handle water containing such a percentage of acid that it will attack and quickly eat out cast iron. The water ends of such machines must be so protected, that none of the iron castings come in contact with the water.

The accompanying illustration shows a pump designed and built by the Dean Steam Pump Co., Holyoke, Mass., which is intended to meet the severe conditions of coal-mining service.

The pump is of the triplex type maintaining a practically constant and uniform flow in the discharge column. It is fitted with one air chamber on the suction pipe located directly in the line of the suction flow and with three air chambers on the discharge so located that one is directly over the outlet from each cylinder, thus tending to take the peak of the discharge and overcome any tendency to acceleration or retardation in the flow of the discharge column.



Triplex Pump Geared to Motor

A uniform rate of flow makes the load on the motor constant and tends toward a high efficiency. The plungers which operate horizontally are 12 in. in diameter with a 12-in. stroke giving at 18 r.p.m. of the crankshaft a capacity of 800 gal. The total head is equivalent to 400 ft., making 81 hp. in the discharge column. The mechanical efficiency of the pump is approximately 85 per cent. so that the 125-hp. motor used for driving has an ample surplus capacity.

The speed of the driving motor is 365 r.p.m. and the crankshaft is driven through single reduction herringbone gears, protected by a sheet-steel guard.

The motor is placed on a heavy base plate securely attached to the pump base and is raised a sufficient amount to prevent damage in case of water on the pump-room floor. A heavy outboard bearing on the armature shaft maintains the alignment of the pinion with the gear.

The main gear is mounted on the crankshaft of the pump between two of the main bearings and is thus rigidly supported upon either side. Perfect alignment of herringbone gears, which is essential to their proper op-

eration, is thus secured by the ample supports provided for both members of the train.

The crankshaft is a steel forging carried in four babbitted bearings each provided with chain oilers. An open-hearth annealed steel casting disk with a large crank-pin made as an integral part thereof is pressed upon the crankshaft at either end. A center crank is also provided which drives the middle plunger. The connecting-rods are steel forgings fitted with wedge and screw adjustments on each end. The crossheads operate in bored guides and are fitted with adjustable shoes both top and bottom. They carry large engine-type taper-fit steel wristpins.

All parts are readily accessible for adjustment, a particular feature being the split cradle or yoke which permits the removal of the upper half without disturbing the other parts of the machine. The enlargement of the yoke at the water end offers ample facilities for access to the glands and stuffing boxes.

Provision against Grit and Acid

All waterways are made large, thus avoiding the high velocities which are so detrimental to pumps carrying acid or sand in the water. As these machines are designed for use where the fluid handled is aciduous, it is necessary that the whole water end be protected against the corrosive action encountered. The cylinders, valve pots, suction and discharge pipes are therefore carefully lined with soft wood, and the valve details and plunger coverings are of acid-resisting bronze.

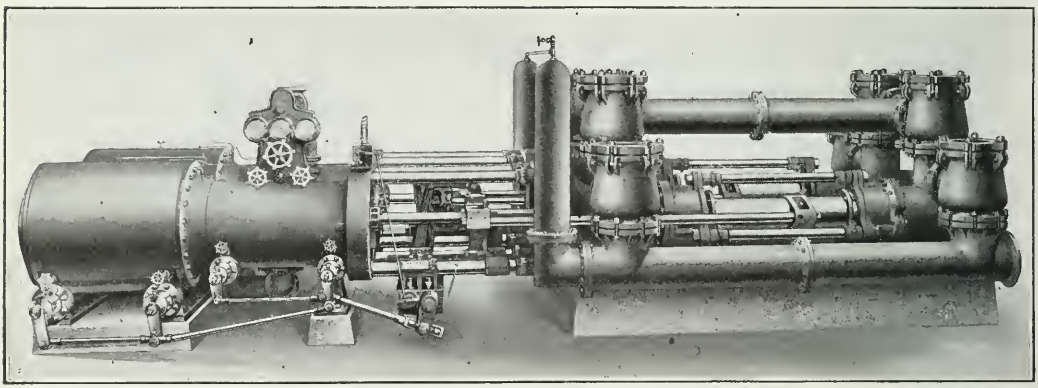
The valve seats are securely held in place by a flange bolted between the valve pots and the adjacent castings. The wood lining is fitted around the valve seats in such a manner that no water can gain access to the valve pot casting. Each pot contains a single large bronze valve with rubber face of the double-port type giving an ample area and unrestricted flow. All valves are readily accessible through large covers secured by swing bolts making inspection quick and easy.

The valve pots, which are all duplicates of each other, are held by through bolts in slotted holes on both flanges so that the replacement of a complete pot is easily accomplished. A large by-pass connection made of bronze pipe and fitted with a gate valve of similar material is provided to relieve the load when starting. Connections which may be used either for priming or washing out are made on all the cylinders and valve chambers. In the design of the entire water end of this pump, one of the principal objects in view has been to secure permanency and reliability, while at the same time providing means for making any necessary repairs or replacements in the shortest possible time.

A Steam Pump at an Anthracite Colliery

In many coal operations throughout the country, particularly those where adequate power facilities were installed a number of years ago, or where the mines are so gaseous as to render electric power distribution dangerous, the steam pump is still largely employed. In the majority of such cases, not only is the steam consumption of the machine important, but the accessibility of all parts is a feature which must be carefully taken into account.

The accompanying illustration shows a compound, condensing, direct-acting, duplex, Jeanesville mine pump built for the Lehigh Valley Coal Co., and installed at the Dorrance Colliery, at Wilkes-Barre, Penn.



Compound Pumping Engine. Note Arrangement of Crossheads

This pumping engine has a capacity of 1500 gal. per min. and operates against a head of 650 ft. with 80 lb. steam pressure at the throttle. It is supplied with an independent steam-operated jet condenser. The steam end of the pump is of the standard compound type with high- and low-pressure cylinders, 22 in. and 34 in. in diameter, respectively, while the stroke is 36 in. Each cylinder is provided with two semi-rotative steam valves placed below the cylinders.

The pump end of the machine is of an improved design. It is of the four-plunger outside center-packed type in which the front and rear pump plungers are coupled to the cross head located between the pump cylinders. This plunger cross head is connected to the main cross head by two side rods placed upon either side of the pump-water cylinder.

This arrangement eliminates internal rod or plunger connections and thereby assures perfect accessibility to the plunger stuffing boxes. As the water to be handled is strongly aciduous, the pump end, its valve pots and pipes are wood lined and bronze fitted.

Safety First

By J. E. Jones*

Written expressly for "Coal Age"

In the morn on your way to work,
Safety first.
In the darkness, dangers lurk,
Safety first.
Be cautious as you pass along,
Life's not all a cheerful song;
Watch; you may find something wrong.
Safety first.

As you reach your place of toil,
Safety first.
Lest some mishap your welfare spoil;
Safety first.
Sound your roof for fear it might
Have been weakened through the night,
Then test it often; don't trust sight:
Safety first.

If it's hard to keep the turn;
Safety first.
Don't chance your life, you'd better learn
Safety first.
A minute's risk will sometimes mar
An entire life, so better far
Be careful; rather miss a car.
Safety first.

If you have to ride a trip,
Safety first:
Take precaution lest you slip,
Safety first.
"Riding in between's" a crime
Against yourself; against your mine:
Ride where safe and take your time.
Safety first.

When making "dope," take off your lamp;
Safety first.
Be very careful while you tamp;
Safety first.
Fuse it so there'll be no fear
Of firing until all is clear:
Don't fail to use good judgment here.
Safety first.

If the mine is making gas,
Safety first.
Use great care or you may pass
(Safety first.)
Into realms beyond the sky
In the twinkling of an eye
If you do not heed the cry
Safety first.

❖

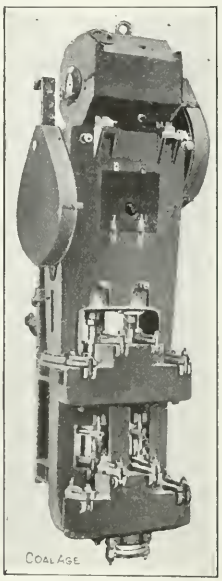
Firebosses, who must necessarily go their rounds alone by the dim light of a safety lamp, should insist that the miners make good manways, especially on steep pitches, in order that their work be as safe and easy as possible. Unless this has been done, compel the miners to stop work until the defect is remedied.

*505 West Madison St., Danville, Ill.

An Electric Shaft Sinking Pump

The sinking of a shaft has been one of the mining processes which up until recently has usually called for some kind of a steam pump to rid the opening of water as rapidly as it was encountered. Recently, however, electric machines have been introduced which will compare favorably with those driven by steam.

The accompanying illustration shows an electric mine-sinking pump which had been placed upon the market by the Goulds Manufacturing Co., of Seneca Falls, N. Y. It is of the quadruplex outside-packed plunger type. The four plungers, operated by connecting rods from the 2-throw crankshaft, produce an almost continuous flow of water, the cranks being set at 90°. All exposed working parts are protected by iron casings so the pump cannot be injured by coming in contact with the sides or framing of the shaft or from falling rocks.



Electric Sinking Pump and Motor

The main frame and guides are cast in one piece and provided with hand-hole openings for examination of working parts. Wrought-iron hanging bars and clamps are also provided. The gear wheel is of charcoal iron, meshing with a bronze motor pinion, both being cut from the solid and fully protected by gear covers. The cylinders and valve boxes are of charcoal iron made in one casting. The four cylinders are each fitted with a bronze lining.

The plungers are of cast iron and are operated by steel plunger rods. The valves are rubber disks on bronze grid seats with cylindrically wound springs. Any type of motor may be used on this type of pump, the power ranging from 10 to 30 hp. while the capacity varies from 75 to 205 gal. per min., according to size, all of the pumps being designed for a working pressure of 130 lb.

WHO'S WHO—IN COAL MINING

Hitherto we have not recorded the lives and characters of those who are changing the face of the South by opening up its coal deposits. When we begin to describe a Southern operator, we are impressed immediately with a new atmosphere. The Southern planter has always had a paternal interest in his farm hands and the activity of the Southern coal operators and managers in studying hygienic conditions, in engaging others to aid them in that study and their willingness to put into expensive operation such improvements as their inquiry shows to be necessary, reflects the generous spirit of the South.

In this respect, W. C. Tucker, "father of Benham," and bred in the South and hoping ever to make it his home, is typical. To him, the coal plant he manages at Benham, Harlan County, Ky., is no mere industrial venture, it is a community development and it is destined to set a number of valuable precedents like those of the other steel-plant collieries throughout the States.

W. C. TUCKER

W. C. Tucker was born at Columbus, Miss., in 1864. Had it not been for the Civil War and the consequent impoverishment of the South, Mr. Tucker would have been a lawyer and planter, for his leaning was toward the law and the call of the land is strong in the South.

His father's failure in '79 permitted him to stay but two more years at school and at 17 years of age he started work with an engineer corps on railroad construction. The work finished, he entered the coal industry by assisting in the survey of several coal lands in Walker County, Ala., then newly opened. Some knowledge of the underground operations was obtained by the monthly "measuring up" in which he took part.

This work being finished, he returned to the farm but the free yet strenuous life of the engineering corps appealed insistently and another railroad survey being started in the vicinity, he entered the corps as a rodman. Returning to the farm at the completion of this work, he filled in an interval by farming, teaching school and getting married.

But he soon returned to railroad construction, being promoted this time to assistant resident engineer, in charge of the completion of 13 miles of track. This work done he left for another road with promotion to assistant chief engineer. Leaving this position because a promised leave of absence was withheld, he entered business life for a brief period as a partner of a cotton broker.

A serious illness of his wife caused him to withdraw from all activities for several months and he then entered the real practice of coal mining as a weighman. He left this company to act as a surveyor for another coal corporation. A little later he entered the office of which he was soon put in charge.

A change of management, and Tucker was back again on the farm, but the mine life seemed more exciting and he was soon employed in prospecting a number of coal properties. These condemned, he went to a furnace at Middlesboro, Ky., staying there a year and being transferred by the same concern to be manager of their mines in Tennessee and North Carolina. This first independent command was held for several years, each year being signalized by an increase in salary.

He resigned this position to go as chief surveyor and prospector for a large acreage in Kentucky, a portion of this land covering the site of the present town of Benham. The land was purchased by a Northern syndicate, and although left undeveloped for a number of years, Mr. Tucker was retained as engineer in charge.

Tiring of the trivial duties of managing an undeveloped land holding, he crossed into Virginia to accept a position as superintendent of the Imboden Coal & Coke Co., and in two years was made manager. He held the position for a year and resigned to be division superintendent of the Southern Iron & Steel Co., with his headquarters at Chattanooga. He was in full charge of that division, including its coal and ore mines, quarries, coking plants and furnaces. His work was appreciated, but after a few months the panic of 1907 caused the company's failure.

Then followed a small coal plant in Kentucky which he managed for friends. Money being scarce and the market poor, the plant was a failure and for a year he went as superintendent of the Federal Coke Co.'s plant, at Grant Town. While there the properties which he approved for purchase many years before were repurchased by the Wisconsin Steel Co., a subsidiary of the International Harvester Co. They had decided to build a coking plant and offered him the superintendence.

This plant, which embodies all the ideas acquired in long years of thought, is now nearly complete, and is Mr. Tucker's "labor of love."

EDITORIALS

The Mine Pump

The danger of our careful distribution of charges as indorsements on the payroll is that we overlook their inevitable inaccuracy as guides to the true expenses of operation.

Thus what we head as "Drainage" covers only a few of the costs to which we are subjected by the presence of excessive water in the mine. The cost of inadequate pumping facilities crops up in nearly every item in the column of distributed charges.

For instance it appears under "Haulage" because cars dragged through water lose the oil in their bearings and are hard to haul, because the mules and motors are unable to do their best if the road is wet and because when many working places are filled with water, the work is scattered and the territory to be served by one unit is too widespread.

Water losses are hidden under "Headings and Dead Work," because additional yardage prices have to be paid to men who have to work in wet places. If the foreman holds down the price, he either loses his men or has to credit the heading men with more yardage than they have driven. Often concessions for water result in increased yardage prices in wet and dry places alike.

Inefficient drainage at the face necessitates the construction of frequent crosscuts from heading to heading and of driving of the airway backward up the rise, which, where sights are not used, often greatly increases the yardage driven without increasing the territory developed.

If sights are used, the engineer's work is increased and in any event the trackmen's time is wasted laying additional partings and in moving track. As for the surveyor he finds his work less accurate and made far slower by the presence of water and parts of the mine remain unsurveyed because inaccessible.

The health of the live stock is undesirably affected and the charge, "Mule Barn," remains excessively high in a wet mine. The item, "Supplies," is increased because rails, pipe and cars left in water impregnated with sulphuric acid are often only fit for the scrap heap when the water is removed.

And, furthermore, all the other items are affected though not in equal measure or in the same direct manner. For example, fixed charges are distributed over a smaller tonnage, when water disorganizes the mine.

In many cases mine development is so delayed by lack of pumping facilities that the operation fails to produce at any time over 50 per cent. of its rated capacity. The headings are delayed or closed down and even the opened portions of the mine stand idle for lack of adequate means to keep them dry.

Most operators buy pumps only when they feel they *must* have them. They do not keep a sufficient reserve supply on hand though any day a flood breaking through the caved areas may fill the workings with water. An operator may always feel sure that, as his worked-out areas increase, the water to be handled will continuously augment and a pump in excess of present requirements will find plenty of work to do.

Too many are looking for some great scheme to lift their mines from profitless to successful operation. Yet in nine cases out of ten, the need is not for a reconstruction but merely for the following up of the simplest principles of foresight.

The Widespread Flood

We can all see now the folly of it, of those light frame houses on the riverside destined some day to be engulfed in the river flood and some to be burned while crowded with the very people who lived in and erected them.

Clearly now we view the thoughtlessness which made them raise feeble levees against ever-rising rivers instead of straightening them and giving them greater cleansing qualities than provided by nature. They built their firetrap shells in the floodbed of the waterways and the rivers rose in their might and claimed their own. We all, as a people, have been unwise in granting unrestricted rights up to the river bank without discrimination, to all those claiming the ground bordering on water courses. In many cases, even further encroachments have been permitted.

No coroner's jury will be called, nothing but sympathy will be extended to those unfortunates who are yet living to see the consequences of their mistakes. We hope the disaster, however, will convince them that all distress above the ground and below it, does not argue a real perversion of human nature.

Mine misfortunes, floods, fires, explosions and the like, are the outcome often of a desire for profit and of a hope born of lack of personal experience that some threatened event will never happen.

And this disaster, was it not caused by a desire to save money in buildings that it might be spent on personal adornment and what is known as the American style of living? A little money would have replaced temporary and combustible dwellings and stores with reasonably floodproof, fireproof structures. A few hundreds of dollars would have made each smaller dwelling as resistant as were the French in a recent flood. A reasonable addition to the costs of living would have strengthened dams, dikes and levees and widened streams to meet all requirements.

But the hope existed here also, as in the mines, that the delayed disaster would never come or if it came, that it could be mitigated by energy and decision. It is now we know no time to condemn. It is our duty to see that profit, comfort, ease, luxury and avarice, do not stand between us and the duty of preventing loss of life.

It is true the flood has been unprecedented in severity. Similarly in the mines, not only do problems of unequaled intensity often occur but new phenomena frequently appear which the imagination of the human mind has been totally unable to foresee.

The Individual Operator

How the individual anthracite operator will fare under the changed conditions in the hard-coal trade is a subject of much speculation among the trade. Some are of the opinion that it means a reversal, in part at least, to the conditions in effect previous to 1900, when the coal was sold in the open market in about the same way that bituminous is handled today. Again, there are others who feel that a way will be found to discourage the individual operator from flooding the market with low-priced coal. In any event, a broad change in the basic principles upon which a large industry of this character is built up, offers grave possibilities.

The outlook in the anthracite trade is dull enough at the moment, without being further aggravated by having the independents flood the market with a low-priced product. To those familiar with the conditions of marketing anthracite coal, it is generally conceded that the present method has proved advantageous to both the consumer and the operator. It has induced the buying of coal during the slack season, thus assuring the mines continuous work the year round, and at the same time offering the consumer the opportunity for storing his winter's supply of coal at the lowest quotations in effect at any time during the year.

In addition, it is a well-known fact that the maximum economy of operation cannot be effected by intermittent work at the mines, and the railroad man is free to confess that the transportation facilities of the country are not adequate to meeting the excessive demands which develop at times during the winter. Nor can the railroads afford to provide sufficient equipment for handling this abnormal tonnage, since it would be idle during much of the year.

A plan that has been evolved from years of experience, such as the one referred to, is not to be lightly cast aside without mature consideration. Last fall the individual operators gave ample evidence of their disregard for the companies' circular when they withdrew from selling arrangements of long standing in order to obtain the extra profit that was being freely offered for premium coal. Now that conditions are reversed, these independents are finding it necessary to sell at less than the companies' circular in order to place their product. And even at discounts ranging from 15 to 40c. per ton under the circular, the consumers are not inclined to give them business.

The country will be fairly well stocked by July and August, and it is interesting to consider what steps the independents will take to place their product. It is doubtful if they will, as a rule, put any curtailment policy into effect, and it seems more probable that this period will find them offering large discounts in order to move their long sizes.

It is to be hoped, however, that such will not be the case, as it is obviously as much to the advantage of the independent operator not to force his coal on an unresponsive market, as it is to the larger companies.

He should also recognize that his corporation neighbors have facilities for fulfilling their agreements and a prestige among the consumers that the individual operator can scarcely ever expect to obtain. It is to be hoped that the current year will see the trade moving along in the same channels of other years, and that the individual operator will support to the best of his ability the orderly method of distribution which has meant prosperity to the anthracite industry for the past decade.

❖

A Mix-Up at St. Louis

The coal industry in and around St. Louis seems to be on the verge of a complete demoralization, with the producers fairly fighting for an existence. The cause is, primarily, a condition of ruinous competition, prices being cut down to, and even below the cost of production, by operators who are determined to keep their mines working at any cost. While instances of overproduction in the bituminous industry, are all too common throughout the country, in this case it has attained most exaggerated proportions.

The trust-busting enthusiast, who has so aggressively demanded the dissolution of the big anthracite combine in the East, would do well to study conditions in the St. Louis market and observe the results where there is a lack of cohesion in the industry. If economic conditions of the country demand that competition be so severe, that company after company is becoming defunct, then the dream of the trust-smasher has been realized in the southern Illinois field.

When overproduction is accompanied by an aggressive campaign among the individual operators to force their competitors into bankruptcy, we must confess that the situation appeals to us as unusual, to say the least.

Everyone knows that it is an expensive proposition to close down a coal mine, and in the case of many of the older operations it is sometimes fatal. Maintenance expenses such as drainage and timbering, continue, regardless of whether the mine be working or idle and, in some operations having a large territory developed, these charges are invariably heavy. And, again, there are other conditions. For example, a mine having a capacity of say, 1600 tons per day, has a contract at $1.02½ to $1.05 per ton for 1000 tons of its production, the cost of producing which is $1 per ton. The best price obtainable in the spot market is 85c. per ton, so that on the face, it appears that the production must be curtailed down to the contract requirements. As a matter of fact, however, operators find that this last 600 tons, which is produced without any additional day men or increase in fixed and running charges, is obtained at a figure which makes it entirely feasible to market it at 85c. per ton in spite of the fact that the average cost of production is 15c. higher. Thus, it is easy to see why odd tonnages of a low-priced coal may occasionally find their way into the market.

This latter condition applies more particularly to the Williamson and Franklin County field. Operators in the Standard field, which comprises the fifth and ninth districts, freely admit that they are losing money and it is difficult to understand why they should persist in the face of such discouraging conditions. The cost of production in this district varies from 85 to 90c. per ton, with a few who can possibly produce at a trifle under this minimum, while the average selling price is only about 75c. a ton.

To further aggravate conditions, the St. Louis Coal Traffic Bureau, made up of all the local coal-carrying roads, has announced a general advance of 5c. a ton into St. Louis. This arbitrary action of the transportation companies is, however, meeting with bitter opposition.

SOCIOLOGICAL DEPARTMENT

The Leisure and Pastimes of the Frick Employee

By Thomas W. Dawson*

SYNOPSIS—The Frick company endeavors to promote healthful sports, providing and maintaining baseball diamonds and making donations for suits and equipment. A swimming pool is provided at Leisenring No. 1. Forty-five playgrounds were constructed in 1912.

The H. C. Frick Coke Co. has built churches of all denominations and encourages the establishing of schools. It coöperates with the school authorities in every possible way, many of its superintendents being members of local school boards.

Sports and recreation of an elevating character are furnished for the young and old, and athletics are encouraged among the young men.

The Frick Baseball League

At every plant there is a baseball team, and all these are in a league with regularly scheduled games. They use the official playing rules of organized baseball, and the winning team at the end of each season receives the Thomas Lynch loving cup as a trophy. Keen rivalry exists among the teams, and public interest in the outcome is well sustained. In the larger towns you will find crowds of people scrutinizing the board which records the scores of the games played by the Frick teams.

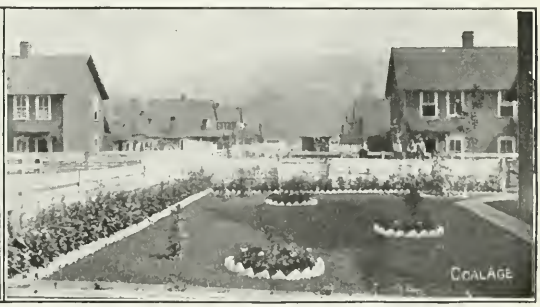
It is doubtful whether any amateur league in the country sustains as many good ball players. All of them are required to work in or about the mines, and only employees who have been in service 30 days immediately before playing are permitted to take part in the league games; furthermore they must be employed at the plant or plants which the club represents.

In 1911, the Leisenring No. 1 ball team won the cup, and in 1912 Edenborn was the victor. The company provides the ball diamond, keeps it in condition, and makes donations for suits and equipment. However, many of the teams are self-supporting, raising money by festivals, picnics and other means. The baseball diamonds are so well constructed and kept that they would do justice to independent municipalities.

The Swimming Pools

The Leisenring No. 1 plant is the first to have a swimming pool, which the company has constructed. It is a rectangular concrete tank, 80 ft. long and 40 ft. wide, and its depth ranges from 30 in. at one end to 7 ft. at the other. Each person using the pool is required to take a shower bath for cleansing purposes; he then dons a bathing suit, before entering the pool. The water is frequently changed so that it is always pure. On certain afternoons the pool is reserved for the exclusive use of women. A competent guard or instructor is in charge of the pool at all times to lend assistance to the bather and see that all rules are complied with.

Park and Playground Provided for the Trotter Youngsters



Lawn and Flowers Which Drew First Prize at Baggaley, Penn.

The Village Greens

In addition to this, tennis courts, croquet greens, parks and playgrounds are provided for all forms of outdoor sport and amusement. They are conducted by organizations overseen by a competent party. Forty-five large and well equipped playgrounds were laid out in 1912. They are equipped with seesaws, flying rings, horizontal bars, roly-polys, dancing pavilions, and the like. In some of the towns, bands made up of employees of the company furnish concert music during the summer evenings. The amusement hall for basket ball, dancing, entertainments, etc., provides exercise and equipment during the winter months.

An employees' bath house has been built at the Collier

*Assistant chief engineer, H. C. Frick Coke Co., Scottdale, Penn.

Note—Abstract from paper entitled "Welfare, H. C. Frick Coke Co.," read before the winter meeting of the Coal Mining Institute of America.

mine as an experiment to see if such an innovation will be appreciated and to educate employees along lines of cleanliness. Workmen leave their clean clothes here during the day, and when they return from the mines at night, they take the shower or bath, as the case may be, leaving the clothes they wore during the day, don clean garments, and are ready for supper as soon as they reach home.

Every Lot Is a Garden or a Lawn

During the summer season, remarkable vegetable and flower gardens and lawns are seen in all the towns owned by the company. The superintendent of each plant is authorized to do the necessary grading, to soil the gardens where good soil does not exist, to fertilize and plow them, and do all he can to assist the employee and teach him how to sow and tend his garden and make a lawn. He is told that every part of his town must be green at the summer season of the year.

It is really remarkable the manner in which the people have interested themselves in the care of their little gardens and lawns, and now little or no persuasion on the part of the superintendent is needed to secure rows of well-kept lots. Cash prizes are offered for the best vegetable and flower gardens and lawns. Committees composed of disinterested parties, doctors, business men, farmers or the civic committees of the nearby towns are called in to award the prizes.

It frequently happens that this committee finds as many as a half dozen gardens, any of which would be entitled to the first prize. In a case of this kind, cash equal to first-prize money is awarded to each. Neatly framed certificates, printed from steel dies, are presented to the owners of the prize vegetable and flower gardens and lawns. These certificates are signed by the various members of the committee awarding the prizes. They bear the name of the owner, the house number, and the name of the mine. Should a prize winner move away from the colliery before these certificates are filled, they are forwarded to him as his property.

In 1912, there were 5150 gardens occupying 72 per cent. of the total area covered by the company-house lots. In 1913, we look for 100 per cent. of them to be cultivated. If we estimate the value of the average garden at $50 (and many of them are worth $75 and $80), we find that last year the employees of the H. C. Frick Coke Co. enriched themselves $257,500 through their gardens alone. Fresh vegetables are usually a scarce commodity, but all the Frick employee has to do is to go out into his little garden and find wholesome food. Should a certain employee be able to cultivate more than the plot of ground allotted to him around his dwelling, the corporation will provide him with land adjacent for cultivation if owned by the company.

Leisenring No. 1 Team, Which Won the Thomas Lynch Cup in 1911

The Early Use of Coal

Probably the earliest mention of the use of coal in the United States is contained in the journal of Father Hennepin, a French missionary who, as early as 1679, reported a "cole" mine on the Illinois River, above Fort Crèvecoeur, near the site of the present city of Ottawa. Coal was not mined in the state of Illinois, however, until 1810, when it was produced in Jackson County, at a point on the Big Muddy River.

Later, coal was found at Fort Duquesne, now Pittsburgh, in 1758, when that frontier post fell into the hands of the English under General Forbes. On Oct. 4, 1770, General Washington, while in Fayette County, Penn., made the following entry in his journal:

> At Capt. Crawford's all day. We went to see a coal mine not far from the house, on the banks of the river. The coal seemed to be of the best kind and burned freely.

The coal mine here referred to was at the site of the present town of New Haven, opposite Connellsville, then known as Stuart's Crossing.

Coal was known to be present in Virginia as early as 1700, though mining did not begin until the latter part of that century. In 1789, shipments were made to some of the Northern states.

It is not known when the anthracite deposits were discovered in Pennsylvania, but in 1776 coal was shipped down the Susquehanna River, from the Wyoming Valley to Harrisburg, and hauled in wagons to Carlisle for use in making firearms.

Wyoming Mining Examinations—Notice has been received from George Blacker, state coal mine inspector, District No. 1, Cumberland, Wyo., stating that the Board of Examiners will meet in Kemmerer, Wyo., Apr. 24, 25 and 26, 1913, to examine those who may desire to take the examintaion for mine foreman and fireboss certificates.

DISCUSSION BY READERS

Post Timbering at the Working Face

Letter No. 11—In my opinion, a miner is the proper person to timber his working face. As all practical miners must admit, a great many difficulties arise in a working place, in a very short time; and as the miner is employed in the same place every day, he is in a better position to know when and where posts are most needed.

I do not think that any systematic method of timbering should be introduced in mines, unless the company is prepared to give their men a particular size and grade of timber that would be suitable in every way for the purpose intended. We can hardly say timbering is being done systematically where we are using timber of various sizes and grades. Say, for ordinary work, the miner is supplied with a number of black-spruce posts, eight inches in diameter, and a number of fir posts of smaller dimension. After a short time the fir posts will be badly broken, while the spruce posts will show scarcely any signs of strain. Under these conditions suppose the posts are to be set six feet apart in every direction, in an endeavor to equalize the weight on every post. If they are not of the same size and grade of timber, it is evident there would soon result a very bad looking place, particularly if the roof was "weighting." The smaller-sized timber of inferior wood would be broken, while the better grades and larger sizes would stand firm.

I claim that every miner should be held reasonably responsible for the proper timbering of his place, and when the foreman is making his usual visits, if the place is not properly timbered he should promptly send the miner out for neglecting a very serious duty.

JOHN A. MCDONALD.

Reserve Mines, Cape Breton, N. S., Canada.

Letter No. 12—In considering the question of timbering at the working face, the safety of life and limb should be of more importance than the cost of the timber. The post plan of timbering, in seams of coal 6 ft. thick or less, is generally found to be efficient; but where the seam is from 8 to 12 ft. thick, with a drawslate over the coal, this plan may have to be modified. It may be, and often is, necessary to modify the general plan of extracting the coal to suit the conditions and to insure safety.

The Miners' Circular, No. 9, published by the Bureau of Mines, pp. 6 and 7, gives four principal causes of accidents from falls, and a table showing the percentage of fatalities at the working face, as compared with those on entries and in pillar workings.

This table suggests to me that the entries of a mine are often more closely inspected and are timbered by more experienced men than the working places, particularly in the anthracite mines, where the number killed at the working face is from six to seven times the number killed on the entries and in pillar workings, although the latter is the most dangerous work. The fact is that miners are too often left to do their own timbering in such manner as they see fit. The posts are set haphazard, according to no particular system. It is true that the percentage of men killed at the working face would naturally be larger on account of more men being employed there, representing a larger number of working hours than is true for the entries or gangways in the mine.

In this connection, I want to state that the second largest producing mine in the state of Montana has adopted a systematic division of the entire work. Machine operators are employed to undercut the coal, by contract; drillers are employed to drill the holes, by contract, power drills being used; the coal is loaded by loaders working on contract. The company employs shotfirers to tap and fire all holes; trackmen are employed to lay all tracks and switches, and timbermen are employed to set all timbers. The seam of coal is from 6 to 10 ft. thick, there being from 1 to 3 ft. of drawslate between the coal and solid roof.

As a result of such a systematic division of the work, this company reports a less number of accidents per thousand men employed, and a greater tonnage or output per fatal accident and, I believe, a larger percentage of coal won, than in most mines in this state. If the plan works well in this mine, why not adopt a similar six-department plan in all mines? The work is better done, track is better laid, which makes hauling easier; timbers are better set, which reduces the number of accidents; and the machinemen, drillers and shotfirers all perform their work with less trouble and better results.

In such a system, if there is any fault to be found, the coal broken too fine, timbers not set right, or cars frequently derailed, a word from the foreman to the man in charge of that work is sufficient to remedy the trouble. Furthermore, machinemen, drillers, shotfirers, trackmen and timbermen all get more experience in their particular line of work and better results are obtained.

Answering, briefly, some of the questions asked in the outline, Feb. 22, p. 286, I would say: The province of a mine post is to indicate the condition of the roof and uphold the roof slate; rather than to sustain any great amount of weight due to the overburden, which must rest on the pillars. Posts should be set as quickly as the working face is advanced 4 or 5 ft., not more; a less distance would be better under many conditions. The posts should be set perpendicular in a flat seam; but when the seam is inclined, they should lean a little up hill from the normal position in the seam. The advantage to be derived from a systematic system of timbering is that the roof has less chance to move or draw and there is greater protection against a chance slip or fault line in the roof.

I believe, however, special timbermen should be employed for the work, as they become more experienced and better results are obtained. An experienced forester, in this locality, when asked in regard to the cutting, storing and preserving of mine timber, notwithstanding his knowledge of the present practice in mines, advised that mine timber should be cut when the sap is up, say from June to September, claiming that the bark is more easily removed, which should be done, and that the timber sea-

sons better, and the wood is stronger than when the timber is cut in midwinter, when the sap is down. The wood then, he states, is harder to work, drier and more brittle.

He also advises storing mine timber in horizontal layers rather than standing the same on end. Strips or slats should be laid between each layer to allow the air to circulate. He advises treating mine timber with creosote or a zinc preparation to preserve it and prevent fungus growth.

J. B. McDERMOTT,
Chief Mine Inspector.

Helena, Mont.

Utilization of Abandoned Mines

I have seen references, from time to time, in COAL AGE, to the question of developing power directly from the coal, in mines, according to the suggestion of Sir William Ramsay. It seems to me that practical use will be made of this suggestion some time, and why not now? It has occurred to me, in this connection, that the large abandoned coal areas that have been worked out could be utilized for the purpose of testing this method for the development of power.

There are right here in western Pennsylvania, large areas, containing several thousand acres of coal land, the coal of which has been worked out and the mines abandoned. These coal fields originally belonged to Jones & Laughlin and the H. C. Frick Coke Co. and were long ago entirely exhausted. The field forms a triangle extending from Broad Ford to Dawson; and, bounded on the north by Jacobs Creek, reaches almost to Scottdale. There are similar abandoned fields near here, Smithdale.

It seems to me that these abandoned fields would form an excellent opportunity for making the proposed experiment. The Jacobs Creek field is on fire, already, in two places. As I understand the suggestion, all that would be required to try out the method would be to close the mine openings and sink drill holes at suitable points for the introduction of air sufficient for the partial combustion of the coal remaining in the mine. Other holes would then have to be drilled and cased and connected with pipe lines that would carry the gas from the mine in which it is generated, to the several points where it is to be used, say Connellsville, Scottdale and other places. I believe this question should be brought to the attention of men who have the capital necessary to carry forward the project.

E. KRAUSE, Mine Foreman,
Forest Hill Mine, Pittsburgh Coal Co.

Smithdale, Penn.

[While the suggestion of Sir William Ramsay, regarding the development of power directly from coal in place, has a practical bearing and appeals to men in the sense that it would eliminate the dangers incident to the mining of the coal, the proposition has not as yet been reduced to a practical basis. The suggestion of piping sufficient air into old abandoned workings to insure the partial combustion of the coal and the generation thereby of combustible gas that could be piped to the surface and distributed to the points where it is to be used, presents a danger that might eclipse the present dangers of coal mining.

Briefly, the probable dangers are: (1) The generation of large quantities of poisonous gases from underground fires, which, under the conditions that would naturally exist, could not be retained in the mine and in the pipe system, owing to the rupture and crevicing of the overlying strata and frequent breaking of the pipeline. (2) The surface damage that would result both from the subsidence of the strata as the coal is burned out, and from the heat of the underground fire, which in some cases would destroy vegetation. These dangers are of such a nature as to hold the proposition in abeyance until some method of converting the energy of the coal into available power is devised that would not entail risks greater than what now invest the industry.—ED.].

An Echo of the Discussion—Reducing Ventilation When Firing

With the consent of the director of the Bureau of Mines, we publish the following excerpt from the report of the chief engineer of the bureau, to whom the matter of conducting a series of experimental tests in the Bruceton mine belonging to and operated by the federal government for the sole purpose of experiment and investigation, was referred.

Several of the contributors who took part in the February discussion, in COAL AGE—Reducing Ventilation When Firing in Mines—made the suggestion that the federal government should be asked to conduct such experiments, at their testing station, as would throw some light on the question discussed. In response to these requests, the director of the Bureau of Mines referred the matter to his chief engineer who reported in part as follows:

> The problem of the effect of the movement of air in a mine at the time of shotfiring has been one of the features of investigation at the experimental mine. Owing to the lack of sufficient funds these tests have been suspended, and, therefore, the bureau is not in position to make any authoritative statements, and will not be until the tests have been resumed this coming fiscal year.
>
> It may be pointed out, however, that in the few tests that have been made in which there has been a variation in the air current, that this variation appears to have no effect on the initiation of a dust explosion; a number of tests were made with the air intaking toward the initiating shot, and in several other tests the air was returning from the point of the initiating shot; there was no appreciable difference in the results of the initiating shots. Explosions of dust resulted under both conditions, although other variations prevented drawing conclusions as to whether the explosion was more violent in the one case than in the other. In the last explosion test, which was a very violent one, the maximum pressures being 115 lb. per square inch, the initiating shots were fired in a perfectly quiet atmosphere; all the crosscuts being closed by stoppings.
>
> From these tests the chief mining engineer gives his personal opinion that the movement or nonmovement of the air is of relatively small importance in the initiation of a dust explosion; although it is quite plausible that in the propagation of a dust explosion, where the dust has been thrown up into suspension by previous shots, that the chances of a continued explosion are greatly increased by a strong air current.
>
> The influence of the composition of the atmosphere in a mine prior to an explosion is another matter, and no large-scale tests have yet been made at the experimental mine, or so far as known in the foreign experimental galleries. From the laboratory tests it does not appear that the presence of small quantities of carbon dioxide have any appreciable effect on either a gas or dust explosion, but the amount of oxygen present is all important. This, however, is yet to be demonstrated on a large scale.

While there was much diversity of opinion manifest in the discussion of this important subject, the point was brought out and the fact quite definitely established that there are conditions existing in some coal mines that

make it safer to fire shots in still air, in the mine, than when the air is sweeping the face with more or less velocity.

Just how far, if at all, the suggestion of reducing the ventilation when firing, or closing the upcast shaft can be applied with safety or advantage, under the varied conditions of coal mining, is yet to be determined.

We note with pleasure the willingness of the Bureau of Mines to look further into the matter and ascertain if possible, the true bearing of the facts brought out in the discussion of the question in COAL AGE. We desire to draw the attention of the bureau to the offer of Mr. Waterman, Genl. Supt. of the Fleming Coal Co., Pittsburg, Kan. (COAL AGE, Feb. 22, p. 311), to assist representatives of the Bureau of Mines "to obtain samples of the air in mines where the fan is entirely stopped for from 30 min. to 1 hr. before firing shots."—Ed.

Textbooks in Mining Examinations

I would like to say a word in reference to your editorial, A Good Suggestion, Mar. 22, p. 456, urging the free use of textbooks, by candidates, in mining examinations. I think every man who takes the examination should possess the ability to answer the questions asked by the examining board, independently. I am in favor, however, of the board giving the proper formula with each question. There is no reason why any man who has the ambition to learn and will take the time to study cannot equip himself properly. The reason why so many applicants fail to pass the examination is because they do not get down to study until the time comes to take the examination.

Many mine foremen who have passed a successful examination set their books aside as soon as the examination is over, and, as a result, they are as far behind today as ever. I would not say that all men who pass do this, but I think it would be safe to say that 60 per cent. of the successful candidates in mine foremen examinations never look at their books after the examination is over.

Study is important in order to keep up with progress, and every mine foreman must continue to study new systems of mining if he would be successful. To give up study is to go back; therefore, I believe in hard study, and I believe the present system of examining applicants for mine foremen should be continued. Also, I think that every mine foreman should be examined again, once in four years. If this plan was followed out, and men would study, I do not think there would be any need for using textbooks in the examination.

WM. K. RAY, Mine Foreman,
Quemahoning Coal Co.
Ralphton, Penn.

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

FLOW OF WATER

Water, like all fluids, assumes a level surface when at rest; and, conversely, a difference of level causes water to flow from a higher toward a lower point, in obedience to the law of gravity. The theoretical velocity of the flow is the same as that of a body falling through the same vertical height, as determined by the formula,

$$v = \sqrt{2gh}$$

in which v = velocity (ft. per sec.); h = height of fall (ft.); and g = force of gravity (32.16 ft. per sec.).

FLOW OF WATER IN DITCHES

The flow of water in a ditch or pipe, like the flow of air in an airway, is impeded by the friction of the sides or the rubbing surface of the conduit. The formulas for calculating the velocity and quantity of water flowing in a ditch are identical with the same formulas, in mine ventilation, for finding the velocity and quantity of air flowing in an airway, except that the flow of air is expressed in terms of the pressure p, while the flow of water is expressed in terms of the "head" or vertical height h through which the water falls.

Mean Velocity of Stream—Let v = mean velocity of water flowing in a ditch; h = head or vertical fall (ft.) in a distance l (ft.); o = wet perimeter of ditch, in feet; a = area of cross-section of the water; and c is a coefficient expressing the resistance offered by a unit of rubbing surface (1 sq.ft.) to a current having a unit velocity (1 ft. per sec.). Then

$$v = \sqrt{\frac{h}{cl}\frac{a}{o}}$$

In calculating the flow of streams and water in flumes and ditches; $s = \frac{h}{l}$ = slope or grade of ditch, and $r = \frac{a}{o}$ is called the hydraulic radius; and the formula for the mean velocity may then be written

$$v = c_1\sqrt{sr}$$

Following are values of c, for different kinds of material lining the channel and different values of the hydraulic radius:

	Value of c_1 for Different Values of the Hydraulic Radius, $r = \frac{a}{o}$								
Kind of Channel Bed	0.25	0.50	1	2	3	5	10	25	50
Smooth cement lined	125	135	141	144	145	146	147	148	148
Smooth brick lined	95	110	119	124	126	128	130	131	131
Rough rubble masonry	57	72	87	98	104	108	112	115	116
Rough earth bed	26	36	48	62	70	80	91	100	104
Very rough rocky bed	18	25	35	46	53	62	72	81	86

The Coal Age Pocket Book

Example—Find the mean velocity of the water flowing in a ditch that measures 10 ft. wide on the surface, 6.4 ft. on the bottom, the water being 3 ft. deep. The ditch is fairly smooth, brick lined, and has a fall of 4 in. per 100 lb.

Solution—The area of cross-section of water is $a = 3\ (10 + 6.4) \div 2 = 24.6$ sq.ft. The length of each sloping side is $\sqrt{3^2 + \left(\frac{10 - 6.4}{2}\right)^2} = 3.5$ ft. The wet perimeter is then $2 \times 3.5 + 6.4 = 13.4$ ft. The hydraulic radius is therefore, $r = \frac{a}{o} = \frac{24.6}{13.4} = 1.8$. The slope is $\frac{4}{100 \times 12} = \frac{1}{300}$. The value of the constant taken from the table above, for a brick-lined channel, having a hydraulic radius $r = 1.8$, is $c_1 = 123$. Then the mean velocity is

$$v = c_1\sqrt{sr} = 123\sqrt{\frac{1}{300} \times 1.8} = 9.6\ ft.\ per\ sec.$$

FLOW OF WATER IN PIPES

Gravity Or Pressure Head—The flow of water in a pipe line is caused by a certain "head," which is the vertical distance of the point of discharge below the surface of the water in the supply basin or reservoir. This head causing the flow is called the "gravity head" or the "pressure head."

Friction Head and Velocity Head—The gravity head is wholly absorbed or taken up in overcoming the friction of the water in the pipe and in producing the velocity. That portion absorbed by the friction is called the "friction head," and that producing the velocity, the "velocity head." If h of these heads depends on the quantity of water discharged per minute and the diameter of the pipe and the friction head, further, depends on the length of the pipe line. The formulas follow:

Friction head, $h_f = \frac{lG^2}{800\,d^5}$

Velocity head, $h_v = 0.0026\frac{G^2}{d^4}$

In which, h_f = friction head (ft.); h_v = velocity head (ft.); l = length of pipe line (ft.); d = diameter of pipe (in.); and G = quantity of water discharged (gal. per min.).

Example—Find the friction head and the velocity head in a 6-in. pipe line 5000 ft. long, discharging 700 gal. per min.

Solution—Substituting values in the formulas above:

Friction head, $h_f = \frac{5000 \times 700^2}{800 \times 6^5} = 304\ ft$

Velocity head, $h_v = 0.0026\frac{700^2}{6^4} = 0.93,\ say\ 1\ ft$

INQUIRIES OF GENERAL INTEREST

Calculating the Flow of Water in a Siphon

I have taken the following formula from a textbook of W. Wardle and have been told that it is approximately correct as expressing the flow of water through a siphon, in cubic feet per min. As the formula is a simple one, I would like to ask if it is correct. The formula is as follows:

$$Q = \sqrt{\frac{d^5 h}{l}} \times 4.71 \ (cu.ft.\ per\ min.)$$

A. L.

Gastonville, Penn.

The above formula, in many cases, is only approximately correct. It errs, first, in giving too high a value for the constant, 4.71, which is only adapted to pipes of a comparatively smoth bore. Under ordinary mining conditions, the pipes become more or less obstructed by corrosion due to the acid nature of the mine water. On this account, the constant 4.71 should be 3.78, in order to adapt the formula to mining conditions.

Again, the formula is deficient, for general application, because it takes no account of the velocity head, which is the head absorbed in creating the velocity of the water in the pipe. For a low velocity, the pressure or head absorbed in producing the velocity is small and may be disregarded. At other times, however, for higher velocities or when greater accuracy is desired, it is important to allow for the velocity head, in addition to the friction head. Making this allowance for the velocity head, the formula becomes, expressing the flow in cubic feet per minute, or in gallons per minute, as desired,

$$Q = 3.78 \sqrt{\frac{d^5 h}{l}} = 3.78\, d^2 \sqrt{\frac{dh}{l}} \ (cu.ft.\ per\ min.)$$

or

$$G = \sqrt{\frac{800\, d^5 h}{l}} = 28.28\, d^2 \sqrt{\frac{dh}{l}} \ (gal.\ per\ min.)$$

These formulas express correctly the flow of water in a siphon, under mining conditions, taking the coefficient of friction for the flow of water in the pipe as 0.01, which conforms closely to mining practice. If the siphon has a rise h_1 and a fall h_2, the effective head producing the flow is $h = h_2 - h_1$.

The formula given by our correspondent, even correcting the constant and using 3.78 instead of 4.71, will still give too high results, in many cases where the velocity in the pipes is great. The percentage of error, in the use of that formula, will vary with the ratio of the diameter of the pipe, in inches, to the entire length of the pipe, in feet. The percentage of error is practically equal to the ratio of the diameter of the pipe, in inches, to the length of the pipe, expressed in hundreds of feet. Thus, for a 1-in. pipe 200 ft. long, or a 4-in. pipe 800 ft. long, or a 6-in. pipe 1200 ft. long, this ratio is $\frac{1}{2}$, and the percentage of error, in the use of the first formula, is one-half of one per cent. Again, for a 1-in. pipe 100 ft. long, a 2-in. pipe 200 ft. long, or a 6-in. pipe 600 ft. long, etc., the ratio is 1 and the percentage of error, in this case, is 1 per cent.

Suppose, for example, it is desired to ascertain the flow of water in a 4-in. siphon, having a rise of 12 ft. in 60 ft., followed by a fall of 24 ft. in 900 ft. The entire length of the pipe is 960 ft. The effective head, in this case, is $24 - 12 = 12$ ft. This question was submitted by G. H., Johnstown, Penn. In this case, the ratio of the diameter of the pipe, in inches, to the length of pipe expressed in hundreds of feet, is $\frac{4}{9.6} = 0.416$; and therefore, in this case, there is less than one-half of 1 per cent. of error in disregarding the velocity head and using the first formula with the corrected constant. Making the calculation by this formula the quantity of water this siphon will deliver, since $h_2 - h_1 = 24 - 12 = 12$ ft., disregarding the velocity head, which in this case is only 2.58 ft. per sec., is

$$Q = 3.78 \times 4^2 \sqrt{\frac{4 \times 12}{960}} = 13.5\ cu.ft.\ per\ min.$$

Or,

$$G = 28.28 \times 4^2 \sqrt{\frac{4 \times 12}{960}} = 101.2\ gal.\ per\ min.$$

In this case, using the second formula, allowing for velocity head, the flow of water in the siphon is 100.7 gal. per min., instead of 101.2 gal. per min., which is a reduction of $101.2 - 100.7 = 0.5$ gal., or less than one-half of 1 per cent.

We will now take a case in which the loss, by using the first formula and disregarding the velocity head, will equal at least 2.5 per cent. For example, find the discharge of a 4-in. siphon, which has a rise of 12 ft. in 60 and a fall of 20 ft. in 100. This siphon will work properly, because

$$\frac{34 - 12}{2.08 \times 4 + 60} \ is\ greater\ than \ \frac{20 - 12}{2.08 \times 4 + 100}$$

(Coal Age, Vol. 1, p. 386).

The discharge of this siphon, in gallons per minute, calculated by the approximate formula, first, and then by the corrected formula, is as follows:

$$G = 28.28\, d^2 \sqrt{\frac{d\,(h_2 - h_1)}{l}}$$

$$= 28.28 \times 4^2 \sqrt{\frac{4\,(20 - 12)}{160}} = 202.3$$

Again,

$$G = 28.28\, d^2 \sqrt{\frac{d\,(h_2 - h_1)}{2.08\, d + l}}$$

$$= 28.28 \times 4^2 \sqrt{\frac{4\,(20 - 12)}{2.08 \times 4 + 160}} = 197.3$$

The difference in the results obtained in the use of these two formulas amounts to 5 gal. per min., showing an error of 2.5 per cent. in the use of the first formula.

EXAMINATION QUESTIONS

Drainage and Pumping

Ques.—Knowing the head of water, in any case, how is the pressure, in pounds per square foot and pounds per square inch, calculated?

Ans.—Since the weight of 1 cu.ft. of water is 62.5 lb., the pressure, in pounds per square foot, is found by multiplying the head in feet, by this weight. Thus, the pressure due to a head of 100 ft. of water is $100 \times 62.5 = 6250$ lb. per sq.ft.

The weight of a prism of water having a base of 1 sq.in. and a height of 1 ft. is 0.434 lb. Therefore, the pressure due to a head of 100 ft. of water is $100 \times 0.434 = 43.4$ lb. per sq.in. The pressure must always be expressed in the same units of measurement as the head.

Ques.—What is meant by "friction head," in the flow of a fluid in a conduit?

Ans.—The friction caused by the flow of water through a pipe or of air in an airway must be overcome by pressure, in order to allow the water to flow. This pressure expressed in water column, in pumping, is called the friction head.

Ques.—What is the "velocity head" in pumping?

Ans.—The velocity head is that portion of the actual head that is absorbed in producing the velocity of the flow. Except in small pipes and high velocities, the velocity head may be disregarded. When, however, a large quantity of water is discharged through a small pipe, a high velocity is produced, which represents a considerable portion of the head or pressure producing the flow. In such case, it is necessary to consider the velocity head.

Ques.—In pumping, in a shaft 500 ft. deep, what is the pressure on the piston of the pump, due to the depth of the shaft?

Ans.—The pressure due to the depth of the shaft, in this case, is $500 \times 0.434 = 217$ lb. per sq.in.

Ques.—If it is required to discharge 250 gal. per min. through a 4-in. column pipe, in this shaft, what will be the total pressure against which the pump must operate, disregarding the friction of the valves, and, likewise, disregarding the velocity head, which, in this case, is small.

Ans.—Before calculating the pressure due to pumping in a shaft, it is necessary to calculate the friction head, or the additional head due to the friction of the water in the column pipe; and this must be added to the depth of the shaft, in order to obtain the actual head against which the pump is operating. When 250 gal. of water are discharged through a pipe 4 in. in diameter and 500 ft. long, under usual mining conditions, the friction head due to the flow of water through the pipe is

$$hf = \frac{lG^2}{800\,d^5} = \frac{500 \times 250^2}{800 \times 4^5} = 38 + ft.$$

Then adding this friction head to the depth of the shaft the actual head against which the pump is operating is $500 + 38 = 538$ ft.; and the pressure on the piston of the pump is then $538 \times 0.434 = 233.5$ lb. per sq.in.

Ques.—Find the size of pump that will be required to discharge 300 gal. per min., from a shaft 200 ft. deep. Give the size of suction and column pipes. Assume a steam pressure of 80 lb. per sq.in. at the throttle of the pump and a piston speed $S = 100$ ft. per min.

Ans.—The diameters of the suction and discharge pipes, respectively, are as follows:

Suction, $d = 0.35\sqrt{G} = 0.35\sqrt{300} = 6.06$, *say* 6 *in.*

Discharge, $d = 0.25\sqrt{G} = 0.25\sqrt{300} = 4.33$, *say* 5 *in.*

Calling the entire depth of the shaft, including suction and discharge, 225 ft., it is first necessary to find the additional friction head due to the flow of water through the suction and discharge pipes, calling each of these 5 in., for the purpose of calculation. For a flow of 300 gal. per min., through a 5-in. pipe 225 ft. long, the friction head is

$$hf = \frac{lG^2}{800\,d^5} = \frac{225 \times 300^2}{800 \times 5^5} = 8 + ft.$$

The total head against which this pump operates is therefore $225 + 8 = 233$ ft. The diameter d of the water end of the pump is calculated thus:

$$d = 5.37\sqrt[4]{\frac{G}{S}} = 5.37\sqrt[4]{\frac{300}{100}} = 9.3, \text{ say } 10 \text{ in.}$$

Having found the diameter of the water end, $d = 10$ in., the diameter D of the steam end, for a head of 233 ft. and an available steam pressure of 80 lb. per sq.in., is calculated thus:

$$D = 0.7\,d\sqrt{\frac{h}{p}} = 0.7 \times 10\sqrt{\frac{233}{80}} = 11.9, \text{ say } 12 \text{ in.}$$

In this formula, we have assumed an efficiency of 85 per cent. in the water end and 75 per cent. in the steam end, which is usual pumping practice. Taking the length of the stroke as 16 in., for a piston speed of 100 ft. per min., the pump is running at a speed of $100 \times 12 \div 16 = 75$ strokes per min. The pump required, in this case, is, therefore, a duplex, direct-acting pump 12x10x16 in., the steam cylinder being 12x16 in. and the pump cylinder 10x16 in.

Ques.—At what speed should a pump be driven to insure safety, continuous service, and economy of operation?

Ans.—The safe piston speed of a pump will depend on the style of pump and the service for which it is designed; namely, the quantity of water required to be discharged and the vertical lift of the pump. Under ordinary mining conditions, pumps are designed to make from 50 to 150 strokes per min., according to the style and size of the pump. A pump having a 6- or 8-in. stroke may make 150 or 160 strokes per min., while a pump having a longer stroke, say 2 or 3 ft. or more, is commonly designed for 30, 40 or 50 strokes per min. In usual mining practice, the piston speed varies from 75 to 100 ft. per minute.

COAL AND COKE NEWS

Washington, D. C.

The Interstate Commerce Commission has handed down an important decision regarding the rates on coal from Western Kentucky and Alabama mines to Memphis, Tenn., and points taking Memphis rates. This is the case of the Memphis freight bureau versus the Louisville & Nashville R.R. Co. In substance the Commission holds that a rate of $1.10 from the Kentucky and Alabama mines to Memphis is not unreasonable and it therefore dismisses the complaint. In summarizing the Southern coal situation as exhibited by this case, the Commision says:

Many comparisons were made by defendants with rates from Western Kentucky and Alabama mines to stations intermediate to Memphis, in all of which instances the intermediate rates were higher. On the Louisville & Nashville the maximum is $1.50; on the Frisco, $1.25. As the Frisco is the short line and as water competition cannot be held responsible for the Memphis rate, there is little probative force in the Frisco comparison and but little more in the $1.50 rate on the Louisville & Nashville, which, with 67.3 per cent. of the total rail coal tonnage to Memphis for the year 1910-11, experiences little discomfiture by reason of the 4.85 per cent. handled by the Frisco, and is not seriously disturbed on account of the 24.93 per cent. transported by the Illinois Central. However, compared with other coal rates in the Southeast, the $1.10 rate does not appear to be too high. For example, the rate from Alabama mines to Atlanta, Ga., 168 miles, is $1.20; to Meridian, Miss., 177 miles, $1.10; to Chattanooga, Tenn., 167 miles, $1.10; from Illinois Central mines in Kentucky to Jackson, Tenn., 207 miles, $1.20.

Coke Rates Are Upheld

In another coal decision—that of the St. Louis Blast Furnace Co. versus the Louisville & Nashville, the C. & O. Ry. Co., etc.—and in sundry allied cases, the Commission has ruled that the charges imposed upon shipments of coke from the Virginia, West Virginia and Pennsylvania fields to Missouri are not unduly high and should be sustained in consequence.

In reaching the conclusion thus indicated, the Commission notes that the essential claim is that the rate of $2.80 per ton is unjust and that it discriminates against the city of St. Louis. As to this the point is made that very little testimony was presented in behalf of the complainant in support of the contention that the rate of $2.80 per net ton charged for the transportation of the coke from the various ovens to the furnace was unreasonable, discriminatory, and prejudicial.

The existence of dual rates on coke, whereby blast furnaces at other points, particularly Chicago and other lake ports, enjoyed lower rates on coke intended for their use was alleged in the complaints and admitted by some of the defendants as relating to the time covered by the shipments in question, though it appears that following the condemnation of such rates in the Anaconda case, 19 I. C. C., 592, they were canceled, at least so far as concerns the defendants in the present cases.

Further Anthracite Regulation Anticipated

It is understood that in view of the facts regarding the cost of production of anthracite coal that have been brought to the attention of Congress in the report on the production and prices of anthracite coal lately issued by the Department of Commerce & Labor it is probable that an attempt will be made at the forthcoming session to secure further regulation of the rates charged for the transportation of coal from the mines to points of sale. This may be done through further legislation designed to improve the commodities clause of the Interstate Commerce law. The attention of legislators is being directed to that portion of the coal report in which this subject is discussed and which says in part:

Where there is a common control of the coal mines and railroads (as in all the companies included in this report), the capital invested derives its income from both the mining and transportation of the coal, and the failure to realize profits in mining may be, and often is, compensated by the profits in the operation of the railroad on account of the coal tonnage. In such a case it is not a matter of importance to the controlling financial interests whether the profits are derived from the mining or from the transportation. The purpose is simply to operate the coal mines and the railroad so as to produce the maximum profit from both together and not simply to secure profitable results from each source of income separately.

Under these conditions the motives to increase the efficiency and decrease the cost of mining coal are much weaker than in the case of a corporation dependent for its profits entirely on the results of its mining.

Furthermore, where there is a joint control of the mines and the railroad, and where the failure to realize profits on mining can be compensated by the profit in the transportation of coal over the railroad it might well be advantageous in order to secure all the coal that could be profitably hauled to market to operate at a loss certain collieries that could not be worked independently of the railroad support.

PENNSYLVANIA

Anthracite

Scranton—More than 1200 employees at No. 1 and No. 2 collieries of Jermyn & Co. at Old Forge have gone on strike because of the refusal of about 20 of their number to join the miners' organization. The plants are completely tied up. The strike of the employees at No. 14 colliery of the Pennsylvania Coal Co. at Hilldale has been settled and the men have returned to work.

Wilkes-Barre—Officials of the Lehigh & Wilkes-Barre Coal Co. at Wanamie have not come to any agreement with their employees and the result is that over 900 men and boys are still on strike.

Pottsville—The six miners who were entombed at Buck Run Colliery at Mt. Pleasant, worked their way to the surface through a forgotten airway, greatly surprising the rescuing party, two members of which had been killed while at work. Every man was not only active, but well.

The flooded condition of the Susquehanna and Lackawanna Rivers has caused the closing down of several mines in the valleys of those two streams. All collieries in Plymouth were closed, with the exception of those belonging to the D. & H. Co., and the washeries of the Gaylord and Dodson collieries. Of the collieries operated by the Susquehanna Coal Co., the Glen Dyon, Richards and William Penn collieries were obliged to suspend operations, the latter two owing to the fact that the surface water was entering the workings. The water from the Susquehanna entered the old workings of the Enterprise colliery of the Lehigh Valley Coal Co., and operations were suspended in the Henry Colliery, adjoining the Enterprise.

Bituminous

Stoneboro—The engine and boiler house of mine No. 7 of the Mercer Iron & Coal Co. has recently burned to the ground and the tipple badly damaged. Two hundred men are idle as a result of the fire, but a large force is at work making the necessary repairs. Mine No. 7 is one of the largest in the county and has a daily output of 1600 tons. The origin of the fire is not known.

Punxsutawney—Trouble still exists between the miners and operators at the Eriton shaft at Du Bois. The men quit work Feb. 10 because the company refused to repair the tipple and make the pan self cleaning. For the past three weeks the company has been repairing the workings, especially at the bottom of the mine. Last week a crew started work on the tipple.

Du Bois—The miners of the Buffalo & Susquehanna Coal Co. Shaft No. 2 struck Mar. 25 because J. E. Brown was discharged. This man had been a regular employee for some time. He obtained permission to lay off for a period, desiring to go to Harrisburg to argue in favor of certain labor bills. On his return he did not immediately return to work and when he did attempt to resume work he was not permitted to do so. The strike has been declared off and the men returned to work Mar. 29 pending a settlement by agreement or arbitration.

WEST VIRGINIA

Fairmount Lake coal shipments from Fairmont regions have been stopped and the local mines cut out of much work by an embargo placed by the Baltimore & Ohio R.R. The destruction of the track and of railroad equipment by the flood were the reasons for the order which will cause the local regions to go on about half time for a week or more.

Charleston—John P. White, president of the United Mine Workers of America, held a lengthy conference with H. G. Hatfield, governor of West Virginia, recently during which he handed the governor a letter containing various demands

of the mine workers. The changes demanded in this letter were as follows: That no discrimination should be made against mine workers for joining an organization, and that all employees should return to work. The establishment of a nine-hour day applying to all classes of labor. A semi-monthly pay-day should be established. The miners at any one mine shall be accorded the right to select a check weighman, and the ton shall consist of 2000 lb. That a joint commission shall be established, and also a board of arbitration.

The fan house of the Paint Creek Collieries Co.'s Scranton mine near Mucklow was destroyed by fire recently. The fan was put out of commission and the coal took fire and burned to a distance of 300 ft. back from the fan mouth. Forty men were at work in the mine at the time, but all escaped without serious injury. The mine has been operated by nonunion labor since the middle of last April. The loss is approximately $2000.

Bluefield—As a result of the conference held by the mine owners and their superintendents in the New River and Virginia district, a nine-hour day will be inaugurated Apr. 1. About half of the mines will also adopt a two-weeks' pay-day. Many of the miners do not approve of the two-weeks' pay-day as they claim they can save more money if paid only once a month.

ALABAMA

Indio—One miner is dead and three seriously burned as a result of a gas explosion in the Indio mines. The mine was closed down following the accident. The explosion is said to have occurred when a naked light ignited the gas. The mine is operated by the De Soto Mining Co.

TENNESSEE

Chattanooga—According to a statement issued by C. E. Buck, the merger which has been pending for several months relative to the amalgamation of the City Gas Co., the Durham Coal & Iron Co., and other mineral and coal interests in this immediate section has completely failed and all negotiations are now broken off.

OHIO

St. Clairsville—Six hundred miners in the Provident mine of the Provident Coal Co. have struck, claiming that the scales used by the company are not correct, and that they are being cheated out of many tons of coal every day. The miners have asked the state authorities to examine the scales.

Massillon—Workmen are making great efforts to recover the bodies which are believed to have been buried under the wreckage of the Malcom Mining Co.'s main building when it was destroyed by a fire and gas explosion. Five bodies have been recovered and many more are believed to be under the ruins. The property loss is $100,000.

Columbus—The Thomas resolution providing for the naming of a commission by Governor Cox to investigate conditions surrounding the mining business in Ohio with especial reference to the scale of wages paid was passed by the house by a vote of 61 to 49. The resolution seeks to delay action on the Green anti-screen bill which was passed by the Ohio senate and which is now pending in the House of Representatives. The commision will be named at once and is to report at the extraordinary session of the General Assembly called to meet during the fall or early winter.

Stillwater—Fire recently destroyed the engine house at the new shaft of the Stillwater Coal Mining Co. The origin of the blaze is unknown and the loss has not been estimated. As a result of the fire, which damaged the hoisting engine, the mine has been closed down until repairs can be made.

INDIANA

Blicknell—The Indian Creek Coal Mining Co. hoisted from their shaft mine on Mar. 10, 3103 tons. This mine is gradually increasing its output.

ILLINOIS

Herrin—The Southern Illinois Coal & Coke Co. has brought suit in the United States Court for $500,000 damages against the Illinois Central R.R. on account of failure of the railroad to provide cars to ship coal, between August 1909 and the present date. It is alleged that the railroad favored certain mining companies in the distribution of cars, and damages are claimed under an Illinois statute, requiring the railroads to furnish cars to persons demanding them for the transportation of coal.

De Soto—The State Mine Inspector has closed down the mine of the J. B. Kreikemeier Coal Co., on account of the failure of the mining company to provide its miners with a sufficient amount of air. It is probable that the mine will be closed down for several months.

IOWA

Eldon—A bad fire is raging in the mine belonging to the Anchor Coal Co. at Laddsdale. All operations are suspended. The mine has been in operation for 45 years. It is likely that the 50 men who are thrown out of employment will have to move to other places. The loss to the men is placed at $500, while the company's loss is hard to estimate.

Knoxville—A bed of coal 5 ft. 7 in. thick, has been found within less than 14 blocks of the court house. This is the result of the extensive prospecting work which is being done by Geo. H. Ramsey.

SOUTH DAKOTA

The Interstate Commerce Commission has ordered an inquiry into carload coal rates from producing fields in Wyoming and Montana to South Dakota points. These rates have been the subject of much complaint to the commission, and it has begun an investigation on its own motion. All leading roads in the three states are defendants.

NEVADA

Goldfield—H. A. Darm, who has been developing coal near Coaldale, in this county, has received notice from Washington that the coal land that he has sought to secure by location and purchase has been re-opened to entry. This land was withdrawn sometime ago by presidential order.

ARKANSAS

Russellville—The Russellville anthracite coal mines are in operation after having been idle for more than two years This property is one of the largest in this section, and is owned by Detroit capitalists.

OKLAHOMA

McCurtain—Three hundred and twenty-six miners were thrown out of work when mines Nos. 1 and 3 of the Sans-Bois Coal Co. were shut down. The mines have been thoroughly cleaned and all tools removed, indicating that the shutdown will be for a considerable period.

McAllister—It is rumored that because the Oklahoma legislature repealed the mine-run law, the headquarters of district No. 21, United Mine Workers of America, composed of Texas, Oklahoma, Arkansas, Kansas and Missouri, are to be removed from McAllister, Oklahoma, to Fort Smith, Arkansas

FOREIGN NEWS

Odessa, Russia—The coal famine at present existing in Russia has had the effect of arousing the attention of the state administration to the possibility of vastly increasing the present insufficient output of Russian coal. To this end an expert commission of mining engineers and specialists has been appointed to study and report upon the whole question. It is believed that the Dombrovo coal field can increase its output 25% through improved systems of mining. It is thought that the Donetz basin collieries are also capable of a like improvement.

PERSONALS

James V. Coryell, a lawyer and coal expert, has been appointed receiver for J. K. Dimmick & Co., which firm failed recently in Philadelphia.

William Andrews, of Lansford, chief coal inspector for the Lehigh Coal and Navigation Co., has been appointed foreman of the company's yards, succeeding B. H. Stockett.

It is rumored that United States Senator Clarence W. Watson may be elected president of the Elkhorn Fuel Corporation, which was recently organized with a capitalization of $30,000,000.

Alexander Bennett, former division mine superintendent for the Delaware & Hudson Co., has been appointed to succeed John G. Hayes, as general superintendent of the People's Coal Co. He has assumed the duties of his new position.

John Hines was recently appointed superintendent of the Nay Aug Colliery at Dunmore and of the Mohawk Colliery at Carbondale. Mr. Hines has for several months past acted as foreman at the Nay Aug mine

A. F. Wolf, of Wilkes-Barre, has bought out the interests of the Central Coal Co., of Scranton in a property of ninety-seven acres of coal land in Plains township, near Hudson

His intention is to erect a modern breaker and to start operations as soon as possible, probably within six months. Mr. Wolf is the head of the Wolf Coal Co., with offices at Freeland, and extensive operations at Lattimer.

Max G. Voelker, northern sales manager of the Skeele Coal Co. at Buffalo, has been appointed northern sales agent of the Youghiogheny & Ohio Coal Co. at the same place, to fill the vacancy caused by the promotion of H. L. Findlay to the position of general sales manager of the Y. & O., with headquarters at Cleveland. Mr. Voelker will be succeeded by Frank J. Honan, from the New York office of the Skeele Company.

TRADE CATALOGS

Sullivan Machinery Co., Chicago, Ill. Bulletin No. 58-O. Portable drilling rigs. Illustrated, 16 pages, 6x9 in.

Ingersoll-Rand Co., 11 Broadway, New York. Form 4017. "Butterfly" hand hammer drills. Illustrated, 8 pages, 6x9 in.

Electric Service Supplies Co., 17th and Cambria Sts., Philadelphia, Penn. Booklet. Garton-Daniels lightning arresters. Illustrated.

The Baldwin Locomotive Works, Philadelphia, Penn. Record No. 72. Mallett articulated locomotives. Illustrated, 44 pages, 6x9 in.

The Sullivan Machinery Co., Bulletin No. 66-G on hammer drills for various classes of mining construction work and 65-A on diamond prospecting core drills.

Wm. Johnson & Sons (Leeds), Ltd., Armley, Leeds, England. U. S. Enginering Co., 80 Wall St., New York, representatives. Catalog. Briquetting machinery. Illustrated, 16 pages, 7½x10 in.

The Link Belt Co. have recently issued a new 48-page book illustrating and listing their line of steel chains. This book should be of interest to the trade and will be mailed free upon request.

The Economical Burning of Coal—The Valley Iron Works, Williamsport, Penn. 32 pp., 8½x11 in. Describes the construction and possibilities of Ajax grates, with notes on the economical burning of coal, the treatment required to efficiently burn various kinds of coal, the air supply, firing methods, etc.

The National Tube Co.—Bulletin No. 12. Under the headings of uniformity, chemical composition, physical properties, bursting strength, threading, improvements, full weight pipes, and spellarizing, this bulletin contains a vast amount of concise information about pipes which the average consumer wants to know.

The Ingersoll-Rand Co., 11 Broadway, New York City, has just issued a 40-page, 6x9-in. catalog, form 3008, covering their class "PE" duplex direct-connected electrically driven compressors. Among the principal features of design and construction are: The clearance controller, the hurrican inlet valve, auxiliary water separator, inclosed flood lubrication for main bearings, crank pins and cross heads, liberal wearing surfaces, maximum valve and port ares. The catalog is illustrated and shows a table of sizes and capacities.

RECENT COAL AND COKE PATENTS

Miners Drill—W. Channon, Des Moines, Iowa. 1,055,608, March 11, 1913. Filed Sept. 13, 1911. Serial No. 649,189.

Mining Transit—W. A. Berger, Boston, Mass. 1,055,309, March 11, 1913. Filed April 30, 1908. Serial No. 430,054.

Cupola Furnace—P. Anderson, Arvika, Sweden. 1,054,381, Feb. 25, 1913. Filed August 11, 1911. Serial No. 644,338.

Mining Apparatus—I. N. Henness, Moclips, Wash. 1,054,410, Feb. 25, 1913. Filed July 18, 1910. Serial No. 572,542.

Rotary Steam Engine—J. Prosseda, Fredonia, N. Y. 1,054,612, Feb. 25, 1913. Filed Sept. 13, 1912. Serial No. 720,246.

Train Coaling Station—C. C. Brackett, Chicago, Ill. 1,054,272, Feb. 25, 1913. Filed Sept. 13, 1911. Serial No. 649,035.

Coal Screening Tower—G. E. Titcomb, Philadelphia, Penn. 1,056,472, March 18, 1913. Filed May 29, 1911. Serial No. 630,107

Blast Furnace Charging Apparatus—J. W. Shook, Holt, Ala. 1,055,671, March 11, 1913. Filed May 14, 1912. Serial No. 697,196.

Check Holder for Mine Cars—O. E. Dickinson, Herminie, Penn. 1,054,513, Feb. 25, 1913. Filed July 23, 1912. Serial No. 711,122.

Conveyor—G. H. Mueller assignor to Jeffrey Mfg. Co., Columbus, O. 1,054,305, Feb. 25, 1913. Filed April 8, 1903. Serial No. 425,903.

Turbine—J. L. Moore assignor to Kerr Turbine Co. Wellsville, N. Y. 1,054,134, Feb. 25, 1913. Filed Dec. 17, 1912. Serial No. 737,292.

Safety Device for Cable Railways—R. H. Williams, Shamokin, Penn. 1,055,249, March 4, 1913. Filed Dec. 26, 1911. Serial No. 667,789.

Preparing Coke for Charging Blast Furnaces—M. C. Steese, Youngstown, O. 1,054,051, Feb. 25, 1913. Filed Feb. 24, 1911. Serial No. 610,653.

Apparatus for Drying Washed Coal and Other Material—C. Catlett, Staunton, Va. and D. Hancock, Birmingham, Ala. 1,056,738, March 18, 1913. Filed June 1, 1912. Serial No. 701,102.

Manual Coal and Rock Drilling Machine—Theo. Lippiett, D. Lippiett, T. Lippiett, S. Lippiett, B. Lippiett and W. Lippiett. Tredegar, Eng. 1,054,925, March 4, 1913. Filed Nov. 4, 1911. Serial No. 658,574.

CONSTRUCTION NEWS

Meyersdale, Penn.—The Boynton Coal Co. is sinking an air shaft in their mines just out of Meyersdale.

Shenandoah, Penn.—The contract for building the new Mammoth breaker of the Locust Mountain Coal Co. has been awarded.

Hauto, Penn.—Contractor Lewis Riebe, of Summit Hill, is erecting a new washery for the Lehigh Coal & Navigation Co., at Hauto.

Moundsville, W. Va.—Riggs Brothers have been awarded the contract for erecting a new tipple at the Hitchman Mine at Glendale.

William, W. Va.—The Roberts & Schaeffer Co., of Chicago, have closed a contract with the Western Maryland Ry. for a large Holmen coaling station for installation at William.

Mt. Pleasant, Penn.—The W. Harry Brown Coke Co. is arranging to erect several hundred coke ovens on the Weltner farm in Green County. The contract will be let and work started at once.

Gary, W. Va.—It is reported that the U. S. Coal & Coke Co. is making preparations for the erection of 200 houses around its various operations. It is said that the work will be begun at an early date.

Charlestown, W. Va.—It is reported that Barboursville is to be the terminal of the Guyan Valley branch of the Chesapeake & Ohio R.R. Work will soon be started on the construction of more than two miles of trackage. It is expected that the improvements will cost over $150,000.

Centralia, Ill.—The Roberts & Schaeffer Co., of Chicago, have just closed a contract with the Marion County Coal Co. for a new Marcus conveyor installation at Centralia. This new Marcus equipment, which this company has brought out during the past year, has met with much success.

Terre Haute, Ind.—The Clovelly Coal Co., H. B. Talley, President, is building a large modern shaft mine northwest of Terre Haute. The plant will have large capacity and will be entirely modern. An order has been placed with Crawford & McCrimmon Co., Brazil, Ind., for a large hoisting engine.

Youngstown, Ohio—Thos. MacDonald, district superintendent of the Carnegie Steel Mill, has returned from New York, where he attended a meeting of the U. S. Steel Corporation coke committee. It is the intention of the Carnegie company to commence next fall, the construction of coke ovens at MacDonald.

Pottsville, Penn.—The Philadelphia & Reading Coal & Iron Co. has awarded a contract for the sinking of a 700-ft. shaft to the Seven Foot Vein in the vicinity of Beechwood drift at Mt. Laffee. The contract calls for a three-compartment shaft, 7x12 ft. 8 in. These dimensions will be continued to a depth of 600 ft. It is possible that a new breaker will also be built at Mt. Laffee.

Scranton, Penn.—The Delaware & Hudson Co. will soon place a new breaker in operation in the southeastern part of Archbald. The breaker has been in the course of con-

struction for eight months and is now practically completed. All the adjoining buildings, such as fan houses, pumping houses, engine and boiler rooms, have been finished. The new slope which was driven about a year ago has been in operation some time. The new structure was built at a cost of about $300,000. The old White Oak breaker will not be abandoned, but the machinery will be removed and it will be used as a culm washery.

NEW INCORPORATIONS

Wytheville, Va.—The Wythe Mining Corporation; capital stock, $50,000.

Cleveland, Ohio—The Provident Coal Co. has increased its capital stock from $300,000 to $600,000.

Louisville, Ky.—The Tennessee Jellico Coal Co. is increasing its capital from $300,000 to $400,000.

Bristol, Va.—An amendment has been issued to the Mount Morgan Coal Co., decreasing the capital stock to $25,000.

Belleville, Ill.—The Southern Coal, Coke & Mining Co. Incorporators: W. K. Kavenaugh, J. Y. Lockwood and J. B. Kennard.

Pittsburgh, Penn.—The American Fuel Co.; capital stock, $10,000. Incorporators: E. F. McMillan, E. R. McMillan and T. R. Roberts, Jr.

Osceola Mills, Penn.—The Grace Coal Mining Co.; capital stock, $5000. Incorporators: S. B. Isenberg, G. W. Minns, E. C. Trees, Robert Wyatt and L. R. Somerville.

Punxsutawney, Penn.—The Brush Creek Coal Mining Co.; capital stock, $750,000. Incorporators: L. W. Robinson, B. M Clark, F. H. Beck, J. W. Brown and Lewis Iselin.

Harlan, Ky.—The Martins Fork Coal Mining Co. has been organized with a capital of $20,000. The incorporators are W. F. A. Gregory, W. A. Brock, Geo. W. Creech, and H. M. Brock.

Frankfort, Ky.—The Butler County Coal Co., of Aberdeen, has been organized with a capital of $2000. The incorporators are J. A. Watkins, C. E. Sullivan, J. C. Haney and C. L. Drury.

Columbus, Ohio—The Maple-Gallia Coal Co. has been organized with a capital of $100,000. The incorporators are F. A. McManigal, W. J. Hamilton, A. Morse, M. L. Phelps, L. E. Ridgway.

Frankfort, Ky.—The Hobson Coal Co. has been incorporated with a capital of $30,000. The incorporators are A. Maben Hobson, S. Delaney, and W. R. Carter. The incurrence of debt is to be limited to $100,000.

Phoenix, Ariz.—A charter has been granted to the Tanaha Goldfield Mines Co.; capital, $10,000,000. Incorporators, M. O. Bicknell, Harry E. Jarman and Edgar McLaren, all of San Francisco, Calif., to mine gold, coal, etc.

Boston, Mass.—The Wakefield Coal Supply Co. has been organized with a capital of $35,000. The incorporators are Edward P. White, E. Horace Perley, Herbert M. Whitten, Albert R. Perkins, Daniel D. Peabody and Geo. H. Smith.

INDUSTRIAL NEWS

Pottsville, Penn.—It is reported that the Reading company is preparing to develop abandoned mines in the anthracite region.

Indiana, Penn.—R. W. Webrle, of Indiana, is the sole owner of about 1200 acres of coal land in Blacklick Township, and is making openings to mine the same.

Coal Creek, Tenn.—A 30-ft. coal seam is said to have been discovered on the property which lies between the Louisville & Nashville and the Southern railroads.

Birmingham, Ala.—The Tennessee Coal, Iron & R.R. Co. has made an appropriation of $100,000 with which to open a new coal mine near Blocton, in Bibb County.

Morgantown, W. Va.—Pittsburgh coal operators, who recently purchased large tracts of coal along Cheat River, are preparing to develop the same and openings are being made.

Lansford, Penn.—All the collieries in the Panther Creek Valley are closed on account of an oversupply of coal. The collieries have been working only a few days during the latter part of March.

Connellsville, Penn.—The Penn-Westmoreland Coal Co. has recently purchased 100 acres of 4-ft. coal near West Norton and will develop it at once. A. R. Byers, of New Stanton, is at the head of the company.

Cleveland, Ohio—Bankruptcy schedules filed in Federal Court by the Buckeye Clay & Coal Co., operating in Jefferson and Columbia Counties, show liabilities of $75,417, and assets of $83,395. I. E. Mathers is treasurer.

Morgantown, W. Va.—Holdings of the Kingwood Coal & Coke Co., situated on the West Virginia Northern and the Morgantown & Kingwood R.R., in the vicinity of Kingwood, have been sold to Cleveland capitalists, who will develop the same.

New Florence, Penn.—A big coal-land deal has just been closed in which the consideration is said to be over $20,000, and the land purchased lying between New Florence and Seward. It is believed that the Berwind-White Coal Co. is behind this deal.

Charlerol, Penn.—It is understood that negotiations have practically been closed for the purchase of the Pike mine of the People's Coal Co., at Brownsville, by the Vesta Coal Co. This mine, which opens into a tract of coal of between 1000 and 1200 acres, has not been in operation for about three years.

Pittsburgh, Penn.—The Buckeye Engine Co., of Salem, Ohio, have appointed the Federal Engineering Co., of Pittsburgh, Penn., as sales agents for the Pittsburgh district, to handle their full line of steam and gas engines and other products of their manufacture. This appointment takes effect Apr. 1, 1913.

Buffalo, N. Y.—Rumors persist that the Buffalo & Susquehanna railroad and mining interests are soon to be taken over by the Shawmut company, which is expected soon to be out of the hands of the receiver. Still it seems hardly probable that the Shawmut could swing the property without very material help from some source.

Uniontown, Penn.—Floods in the Middle West are responsible for the temporary shutdown in the coking industry. The H. C. Frick Coke Co. has announced that three-fourths of its ovens have been shut down for four days and independent companies have closed down for an indefinite period. Railroad companies are refusing to take shipments.

Birmingham, Ala.—The development work at the mines of the Maryland Coal Co.'s new operation is progressing rapidly, twenty drifts having been already opened. They will begin shipping coal about July 15 and will have the largest output of Black Creek coal of any mine in the State. About six miles of railroad is being constructed and a rich mineral district is opened up by it.

Bayview, Ala.—The opening of mine No. 16 of the Tennessee Coal, Iron & R.R. Co. is progressing rapidly. The company has been working for some time and has struck a fine bed of coal about a month sooner than was expected. Although no preparations had been made for mining the coal the company has started their men to work on a new opening in order that there may be no delay.

Steubenville, Ohio—It is understood that Chicago capitalists are about to purchase several thousand acres of No. 8 coal in the vicinity of Morristown, in Belmont County. If present plans do not miscarry, at least two mines will be opened on the property as soon as the sale is completed. It is believed that a further extension of the Belmont Central R.R. will be made in the direction of Morristown as soon as the sale is completed.

Bluefield, W. Va.—A new branch line of the Norfolk & Western is being constructed from Norwood up Laurel Hollow, a distance of four miles. It is the opinion of residents in that section that it will be but a short time before the road will be extended to Pineville. It is said that this extension will be made eventually with a view to tapping the coal deposits which are found in that section in large quantities.

Birmingham, Ala.—The Standard Steel Co. has recently purchased from the trustee in bankruptcy all the lands, works, merchandise, accounts and business of the Southern Iron & Steel Co., and have taken over the title to and possession of said property and business. The business of the purchased company will be conducted without the slightest interruption, and the various departments will be handled by the same staff of officials as heretofore.

Wheeling, W. Va.—The Richland Coal Co. has purchased the property of the Beech Bottom Coal Co., located south of Warwood. The sale was a conditional one, and the purchase price amounts to approximately $600,000. The property contains about 2500 acres of coal land, a modern mine and machinery, and a number of miners' houses. The new owners expect to increase the working force from 100 to 200 or 300 men. Bids will be received within a short time for the erection of 50 additional houses.

COAL TRADE REVIEWS

TRANSPORTATION CONDITIONS IN THE FLOOD ZONE

The most serious consequences of the recent flood, insofar as the coal industry is concerned, will be in the loss of tonnage due to the restricted transportation facilities and curtailment in demand, because of the general suspension of manufacturing in the affected area. At the moment, the transportation problem in the flooded zone is the controlling feature in the situation. While the trouble is being cleared up rapidly, there is still a considerable territory along the Ohio Valley, upon which reliable reports are wanting. In general, however, the situation is now fairly well in hand, and the conditions are about as follows:

New York Central & Hudson River R.R. and Subsidiary Lines—The New York Central reports all main lines open and conditions normal. On the branches, however, particularly down through the Miami Valley, in which are located Dayton and Piqua, there is still considerable uncertainty as to when traffic will be restored. Aside from a number of small landslides and washouts, which delayed traffic for not to exceed a few hours, the situation in Pennsylvania, except immediately in the Pittsburgh district, was at no time serious. Conditions at the latter point are normal and the main line open and working to Ashtabula on Lake Erie, so that consignments to the Lakes will not be interfered with. They report no congestion of any kind and, owing to the light traffic recently, expect to be able to handle everything offered without any trouble.

Pennsylvania Railroad—This company reports conditions as normal on their lines East of Pittsburgh. They concede trouble to the west in Ohio, but are not prepared at the moment to make any estimate of the extent. Western shipments were embargoed, most of last week, and production fell off to less than half capacity, but these embargoes were raised the first of the current week, and the shipments are now about 60 per cent. capacity. The first movement is, of course, being confined to flood sufferers, then to perishable freight, after which the coal consumers will be considered, and finally the Lake shipments. Fortunately, the traffic has been light over the past few weeks, and the roads generally are in an excellent position to recover rapidly from the high waters. One large coal company on the Pennsylvania lines reports no trouble of any kind at their operations, and this in spite of the fact that they are ordinarily subject to minor floods of all descriptions.

Norfolk & Western Railroad—This road reports the Eastern movement as normal in every respect, but with embargoes against everything North and West of the Ohio River. Their service across the river seems to be very seriously crippled, and indications are that Lake consignments will not be accepted for between one and two weeks.

Baltimore & Ohio Railroad—As in the case of the other roads, the Baltimore & Ohio reports the movement East as steady and normal in every respect. This road has declared no embargoes, and are accepting freight of all kinds, but with the understanding that it is subject to delay. It expects to have western connections completed at the end of the current week.

Chesapeake & Ohio Railroad—At noon on Tuesday of this week, the Chesapeake & Ohio succeeded in restoring its tidewater service, which had been out for several days. Their Western end is still under water, and the movement beyond Ashland, Ky., is restricted. Indications are that connections will be restored between Cincinnati and Chicago by the last of the current week. The Chesapeake & Ohio connections into Ohio over the Kanawha & Michigan Ry. at Point Pleasant, are all intact, and service would be normal except for trouble on the latter line, the extent, of which it is impossible to estimate at the moment.

GENERAL REVIEW

With the spring discount of 50c. per ton on all the domestic grades now in effect, the winter season on hard coal is technically closed. The summer trade opens with an unusual lack of activity. Ordinarily, there is a strong demand for April tonnages, since these are the lowest official prices of the year. Offerings at the spring circular have been freely made for some time, while many dealers still have some of their winter supplies, and the combination of these two conditions has resulted in rumors that the companies' circular will be liberally cut throughout the summer. Naturally, in the face of such conditions, buyers are hesitating to enter the market.

Many of the Eastern bituminous consumers are still holding off on contracts and do not appear to be uneasy over the outlook; shipments on the old agreements continue heavy, prices are not changed, and little interest is shown over the future. The Middle Western floods have not affected the Eastern situation in any way, as all the lines shipping those markets have experienced little or no trouble, and it is doubtful if anything short of a protracted and general suspension would be felt at the present time. As a matter of fact, the closing of shipments to the Northern and Western markets has resulted in these extra tonnages being thrown into the Eastern trade, creating a large surplus at several points.

Contracting has naturally increased, most of the old ones having expired on Tuesday of the current week. Some offerings off of the regular circular are still being reported, but the trade as a whole is holding remarkably firm for advances all along the line, and it is evident that they will not in any event recede to the low level of last year. In the Pittsburgh district, on the outskirts of the flooded area, the market is rather unsettled, and rests entirely on transportation conditions.

There is practically no market in Ohio, and the trade is at a standstill, with the exception of a few odd tonnages of domestic coal for flood refugees. The coal movement in the state was probably never more completely paralyzed. The mines proper appear to have suffered comparatively little, from what information is available at the moment, and the greatest loss will be sustained by the falling off in tonnage. Many manufacturing concerns have been indefinitely crippled, and with the train service practically at a standstill, the consumption has dropped to little or nothing. Some of the Southern roads have issued embargoes on all shipments to the Lakes through Ohio, but it is expected that these will be raised before very long.

The railroad companies in the Middle West are in such poor condition that there is liable to be a serious shortage of steam coal. Contracting is not being very actively carried on, as buyers evidently prefer to pick up what they require in the spot market. There have been some heavy storms and snow, but these have not helped the situation much. There are rumors of an important coal consolidation among certain Illinois operators, which, if consummated, may establish a new condition in the Middle Western trade.

BOSTON, MASS.

Bituminous—The shippers argue variously on the outcome of the strike talk in the New River field. The general opinion is that the recognition granted in Kanawha County means that the New River operators must either concede this point now or face a strike that may be more or less serious. The prospect is rather in doubt. Meanwhile, the receipts at tide are ample and the agencies are still trying hard to place spot coal. Buyers decline to be scared into long purchases and shipments on old contracts continue to arrive in liberal amounts. Prices are unchanged and there is little interest shown in any of the Southern coals for future shipment.

It is understood that the largest producers of Georges Creek have marked prices up to a new high level; $2.95 is being talked now for a contract figure f.o.b. Baltimore. The impression seems to be that with the volume of business offshore and coastwise trade already in hand, the Georges Creek district is reasonably well supplied with orders.

The Clearfields show no change from a week ago. The heavy rains are being heard from and some of the operations are temporarily out of commission, but the market is dull and anything short of a general cessation will have little effect. Prices are weak and consumers are slow placing orders. In Somerset and Cambria counties there is a disposition to hold for prices at least 5c. higher than last year, and to curtail if the program is not realized.

Anthracite—April is is bound to be a disappointment to the producing companies. Spring prices have announced 50c discount from the March circular on all sizes, but they had been so generally anticipated that little interest was shown.

The least quibble on the part of a transportation company as to towing or docking is enough to divert the order elsewhere. The outlook is that May will be a dull month, for New England will be fairly well stocked by the end of April.

Current wholesale quotations are about as follows:

Clearfields, f.o.b. mine	$1 00@ 1 35
Clearfields, f.o.b. Philadelphia	2 25@ 2 60
Clearfields, f.o.b. New York	2 55@ 2 90
Cambrias, Somersets, f.o.b. mines	1 25@ 1 50
Pocahontas, New River, f.o.b. Hampton Roads	2 60@ 2 80
Pocahontas, New River, on cars Boston	3 55@ 3 80
Pocahontas, New River, on cars Providence	3 35@ 3 65

NEW YORK

Bituminous—With many of the old contracts having expired and the new ones not renewed as yet, production for the current week will probably experience some falling off. However, consumers are showing a more active interest in contracts, and there has been considerable done in this line during the week. Furthermore, the operators generally are obtaining the substantial advances over last year's quotations, for which they have been so firmly holding out. Conditions during the week appear to have taken a turn for the better, and there is a good healthy demand which has placed the sellers in a strong position. As compared with last year at this time, the price level is about $1 lower at the moment, but such comparison is hardly fair because of the unsettled labor conditions prevailing at this time in April, 1912.

The movement into New York is fairly strong, and the spot market comparatively good. Because of the number of contracts which have not been renewed, there will probably be an increase in this business for the time being. Prices continue at the low point for the year so far, as follows: West Virginia steam, $2.55@2.60; fair grades, Pennsylvanias, $2.65@2.70; good grades of Pennsylvanias, $2.75@2.80; best Miller, Pennsylvania, $3.05@3.15; Georges Creek, $3.25@3.30.

Anthracite—The hard-coal mines were, in a great many instances, closed down between one and two days as a result of the flood. As all the companies were, however, working under a curtailed production, the matter was of no consequence. The anthracite movement, as a whole, has not been seriously interfered with by the high waters except for the comparatively small shipments to the West, where the flood conditions are more severe. Car supply has been in excess of requirements for several weeks, and as freight traffic has been generally light, there is little cause for the roads to become congested because of the recent trouble.

April business did not open up as strong as in previous years, and the consumers are apparently undecided about entering the market at the present time. A number have carried fairly large stocks over from the past winter, and there are rumors to the effect that April prices are liable to continue well into mid-summer, so there is not much inducement to stock heavily this early in the season. The larger companies are again working full time, and apparently expect to continue so indefinitely. Both steam and domestic grades are moving rather slowly, the only active demand being for pea.

No important change is noticeable in the New York market, with the exception of the automatic decrease of 50c per ton on the prepared sizes, the market now being quotable as follows:

	Circular	Individual — L. Eagle	Scranton	
Broken	$4 50	4 75		4 50
Egg	4 75	$4 50@ 4 70	$4 50@	4 75
Stove	4 75	4 70		4 75
Chestnut	5 00	4 70@ 4 95	4 75@	4 90
Pea	3 50	3 25@ 3 45	3 25@	3 50
Buckwheat	2 75	2 10@ 2 45	2 10@	2 25
Rice	2 25	1 90@ 1 95		2 75
Barley	1 75	1 20@ 1 50	1 55@	1 75

PHILADELPHIA, PENN.

To all intents and purposes the winter season in the coal trade is over, and the past week marks the first of the new coal year. Mining has again been resumed on an all week basis, and the tonnage is moving off well, but there seems to be a marked apathetic attitude by the trade. Reports from all sides indicate an unusual indifference at the inception of the coal year. Perhaps this may be due to the fact that many dealers carried over considerable coal, owing to the unseasonable weather that has prevailed, another factor which is determining the policy of many dealers, and causing them to lay in supplies as economically as possible, is that prices in the summer will probably be even less than they are at present because of price cutting by the individual operators. It is current gossip in the trade that even April prices are shaded, and offers have been made of a straight price all through the summer up to Sept. 1, which would net even less than the company's prices in this vicinity. It is these rumors that are keeping the dealers from tieing up money in coal now, when they possibly may be able to secure all the tonnage they want in midsummer at even less than they are paying now. This is the proposition that is keeping many of them wondering what is best to do.

The individual operators are not having an easy time in disposing of their product, and it is only by making concessions such that consumers cannot well turn down, that they are doing any business at all. Everything being equal, the dealer who was not held up for heavy premiums, is going to place his business where he was fairly treated during the past winter, but a saving of $10 to $15 a car is likely to cause many of the trade to swallow their resentment. At any rate, the month of April is likely to show good business, both from a wholesale as well as retail standpoint, but as has been indicated, it is the result of the number of units, rather than the volume of tonnage requirements.

In the bituminous trade, they are still playing a waiting game. An increased price on contracts is being asked but consumers feel that they will not be justified in paying the advance. It is understood that some contracts are being signed up, but many orders are still being held, with the hope that lower prices will prevail.

PITTSBURGH, PENN.

Bituminous—The Pittsburgh coal district was affected by last week's floods only in the matter of transportation, although some Pittsburgh interests have mines in Ohio which were closed by the high water. Tuesday and Wednesday of last week coal shipments from Pittsburgh to the West were entirely suspended, railroads embargoing all coal and coke. On Saturday night the Pittsburgh & Lake Erie began accepting shipments again for all points on its lines, including Connellsville coke for Chicago. Sunday the Pennsylvania had everything open to Lake Erie points, also the Fort Wayne line as far as Orrville and the Pan Handle as far as Dennison, with prospects that it would be nearly the close of the week before transportation could be resumed to points farther west.

The Pittsburgh district fell to operating less than half capacity toward the close of last week, but is opening the new week with operations at nearly half capacity, and the week will probably close with above 50 per cent., and perhaps above 60 per cent. Full shipments are not possible, even where lines are opened up, as there is a marked shortage of empties. As a rule the railroads are refusing to accept coal destined for the Lake trade, holding that supplies for flood sufferers should be cleared up first, then perishable freight, and then coal for consumers, before lake coal is moved. However, there is reason to believe that a little lake coal is being moved.

Many consumers west of Pittsburgh are suffering badly from lack of coal, but there is not much demand marketwise since it is simply transportation that is involved. Coal operators are not undertaking to arrange for delivery, in offering coal, and purchases of prompt coal being made are simply f.o.b. mine, and at regular prices, the buyer looking after the movement. We note one sale of this sort, where the buyer (in the west) took 25 cars and hoped to have a train made up which could be moved expeditiously.

Apr 1 marks the beginning of a new year, on many coal contracts. Not all expiring contracts have been renewed, the slowness of buyers being attributed to the higher prices this season, but the leading operators have been adhering to these prices quite well and report that they have lost little business on account of cut prices by small operators. We continue to quote: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ⅜-in., $1.40; 1¼-in., $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—The floods last week stopped practically all coke shipments to the West, or about one-half the total normal movement out of the region. As already noted, railroad movement is being resumed. A large tonnage of coke has accumulated in the region, little effort being made to curtail production, by the merchant operators. The H. C. Frick Coke Co. banked many ovens, practically in proportion to the steel corporation furnaces which had to be banked. There is little wire communication with Western points affected, and the condition of blast furnaces is not fully known, but reports gathered by one of the railroads are to the effect that eight furnaces have chilled, and will therefore have to be shoveled out, requiring two to three weeks, and perhaps relined, involving more than double the time. Other furnaces affected are resuming as the water goes down.

The coke market has been entirely upset, and fresh prices will have to be developed as demand appears. At the moment there is no demand at all, while some operators are offering prompt coke and would naturally take low prices. It is out

of the question to mention prices at this time which would be at all informative, and even a week hence a market may not be clearly established.

BALTIMORE, MD.

Interest here, at the moment, is centered in the floods in Ohio and adjoining states during the past week, which practically brought Lake shipments to a standstill on the Baltimore & Ohio and other roads. Large tonnages had started to move to Loraine and Cleveland on Mar. 20, and other operators were preparing to forward cargoes, when the roads notified shippers that they would be unable to handle fuel traffic to the West and Northwest. During the latter part of the week the Baltimore & Ohio was closed, West of Parkersburg and Wheeling, and its Cleveland, Loraine & Wheeling line, over which most of the Lake coal traffic is carried, was also put out of commission. Such shipments accumulated rapidly during the week.

BUFFALO, N. Y.

It is claimed by bituminous jobbers that prices are firmer than they were a week ago, as the leading operators, especially in the Pittsburgh district, are holding firm on their season's quotations. While it is conceded that there is more or less coal offered at reduced prices, the trade as a whole is refusing to consider such business and is determined not to recede to the low level of last summer.

The beginning of shipments to the Lakes always disturbs the bituminous market, especially as it develops a surplus of slack. In addition to this the floods have practically shut down the mines and absolutely held up the movement in many cases.

Bituminous quotations remain at $2.80 for Pittsburgh lump; $2.65 for three-quarter, $2.55 for mine-run and $2.15 for slack, with Allegheny Valley 25 to 30c. lower. Coke is steady on the basis of $5 for best Connellsville foundry. There is next to no demand for anthracite, though the April price will revive it.

The drop in prices has been more pronounced in the East than it has here; all quotations appear firmer towards the West. The great scarcity of anthracite Westward no doubt has something to do with that. Flood conditions will tend to make that still scarcer in the West and as it now appears there will not be much relief possible till the lakes are open. There is a large amount of both sorts of coal going afloat and it may begin to move very soon. Buffalo ships only anthracite by lake, having about 125,000 tons afloat now, with all shipping docks active; tonnage is plentiful.

CHICAGO

It is estimated that half of the domestic supply and 25% of the steam production has been shut out of the Chicago market because of the floods in Ohio and Indiana. As a result, prices here are increasing. Cold weather has also stimulated the demand. Almost half the mines which supply domestic coal to this market are now unable to ship. Chicago is dependent, at present, upon the mines of the northern central part of Indiana and the more northerly operations in Illinois. There are but a few of the Indiana producers able to get their coal into this market. Companies in a position to make shipments here are able to get fancy prices, about on a level with those obtained for the better grades of Illinois coal. The coke market remains steady as a result of a curtailment in supply. New circular prices on byproduct coke place the price of that commodity at $4.45 for April delivery.

Prevailing prices in Chicago are:

	Sullivan Co.	Springfield	Clinton	W Va.
Domestic lump	$2.47	$2.07	$2 27	.....
Egg	2.47	.....	.....	$3.95
Steam lump	$2.12 @ 2.37	1.92 @ 1.97	2.17	.....
Mine-run	.....	1.87 @ 1 92	1.97	3.30
Screenings	1.67 @ 1.72	1.57 @ 1 62	1.67	.....

Prevailing prices for coke are: Connellsville and Wise County, $6@6.25; byproduct, egg, stove and nut, $4.45; gas house, $4.75@4.85.

COLUMBUS, OHIO

The heavy floods of last week completely demoralized the coal trade in this state. Railroads are paralyzed, and in fact work of all kinds was suspended after Tuesday, when the worst of the flood occurred. As a result of the high waters communication with almost every section of the state was cut off and it has been impossible to estimate the damage.

Generally speaking the greatest loss will result from the stoppage of work and the fact that many large consumers were put out of commission, temporarily at least. Only a few of the mines of the state were flooded and the damage from that source will not be large. Some of the tipples at the mines of the Sunday Creek, New York Coal Co. and the New Pittsburgh Coal Co. were badly damaged, entailing some loss.

There was a rush of small domestic orders during the latter part of the week because of the flood necessities, the colder weather after the waters subsided making is uncomfortable for the refugees. This demand is only temporary and will fall off just as soon as the homeless people have been housed.

Steam tonnage is not so much in demand because many of the factories were put out of commission. Some of the electric light plants bought more heavily but this does not counteract the falling off in tonnage from other sources. There was not quite so good a demand for railroad fuel, due to the small train movement. Thousands of bridges in Ohio are out and it will be some time before repairs are made and the movement again normal.

Preparations had been made for an active Lake trade but the high waters have made shipments impossible for the time being. Considerable coal has been loaded on boats, however, and this will be moved as soon as navigation opens.

In eastern Ohio a number of the mines were flooded and some damage is reported although it is a little early to estimate its extent. In the Pomeroy Bend field some of the mines were out of commission but most of them were on higher ground and will be worked just as soon as the railroads are able to move the coal. Prices along the list were held at the same level as the previous week.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1.45	.....	$1.50	$1.40
2-inch	1.35	$1 20	1.35	1 30
Nut	1.30	.....	1 30	.....
Mine-run	1.15	1.10	1.15	1.10
Nut, pea and slack	0.80	.....	0 75	0.80
Coarse slack	0.70	0.80	0.65	0.70

BIRMINGHAM, ALA.

The continued cold weather is a relief to many of the dealers who were fearful that they were not going to be able to clean up their yards. Considerable trouble is being experienced by some of the local mines on account of too much water and the production at many is below normal at the present time. The recent storms damaged the surface plants of a few of the mines and production was thus further reduced by this cause.

Smithing coal is very scarce, none of the producers of this grade of coal being able to promise anything like prompt shipment. There has been no material change in the coke market, the demand for high-grade foundry product continuing to be good.

LOUISVILLE, KY.

The railroads have been so hampered by washouts and weakened bridges that the movement of all kinds of traffic has been seriously interfered with. The Louisville & Nashville and the Chesapeake & Ohio, in the eastern field, and the Illinois Central and the Louisville, Henderson & St. Louis, in the western, have all had their troubles in getting out coal, although the latter is in the best condition of any. While the water is still high, and will probably recede slowly, the railroads in Kentucky are rapidly recovering, and conditions will probably be approximately normal by the end of the week.

Prices are from $1.75 to $1.85 on Jellico and Straight Creek, with block and lump selling at $1.60 and $1.75, and round at $1.25 to $1.40. Second-class coals are being offered to the trade at $1.50 to $1.60 for block, $1.35 to $1.50 for block and lump, and $1.10 to $1.15 for round. Straight run-of-mines is available at $1 to $1.10 for the better grade, and 90c. to $1 for No. 2. There is a keen demand for nut and slack as high as $1, with Western Kentucky nearly as high, in some cases, although some straight mine-run has sold at 80 cents.

ST. LOUIS, MO.

The heaviest snow of the winter came the middle of the past week, but it did not help the market. Coal is still dragging and there is nothing out of the ordinary from reports of the past two or three weeks.

There has been some little encouragement to the retail coal man, inasmuch as there was a good demand for very small lots of coal, but on the whole this did not affect the shipping market in the least. As a matter of fact, if anything, it created a disturbance that brought prices lower than they have been thus far this season, and especially was this so on the better grade coals.

Overproduction still continues, but there is hope now that conditions will improve, inasmuch as some of the operators are in a movement to suspend operations for the next three or four months. Washed coals are in fairly good demand.

and from this time on these grades will continue to get better.

The prevailing circular is:

	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard
2-in lump				$0.90
3-in. lump			$1 25	
6-in lump	$1 20 @ 1 25		1.35	1.10
Lump and egg	1 25	$2 25		
No. 1 nut	1 10 @ 1 15			
Screenings	0 90 @ 0 95			0 65
Mine-run	1 05 @ 1 15			0 85
No. 1 washed nut	1 40 @ 1 50			
No 2 washed nut	1 35 @ 1 45			
No 3 washed nut	1 25 @ 1 30			
No. 4 washed nut	1 15 @ 1 20			
No 5 washed nut	1 00 @ 1 05			

MINNEAPOLIS—ST. PAUL

Wholesalers representing Illinois coals, report business dull with prices inclined to be rather weak. Carterville district coal is selling for $1.15 to $1.25, and Franklin County lump is quoted from $1.25 to $1.40. Dock circular prices, quoted Apr. 1, are as follows: Youghiogheny, Hocking and Splint lump, $3.55; Hocking screenings, $2.30; Youghiogheny and Splint screenings, $2.25; Splint and Youghiogheny dock run, $3.25; Hocking dock-run, $3.15, Smokeless lump or egg, $4.75; Smokeless lump and egg, $4.50; Smokeless mine-run, $3.50; Smokeless screenings, $2.90. The above prices are 15c. above the opening prices at this time last year.

OGDEN, UTAH

The storms which have visited the inter-mountain territory during the past 10 days have stimulated the demand for coal. This was noticed first about Mar. 24, when urgent demands were made for immediate shipment of both lump and nut. The movement of coal into the Nebraska and Kansas territory picked up slightly and no doubt will continue to do so until it is again normal. Naturally the summer prices, effective Apr. 1, have had a tendency to curtal shipments during the last of March owing to the reduction of 50c. per ton on lump coal, f.o.b. mines.

Quotations on Wyoming coal for shipments to Nebraska and Kansas are: Lump, $2.25, egg, $2; nut, $1.75; mine-run, $1.75; slack, $1. For shipment to the Northwest from Wyoming and Utah: Lump, $2.75; nut, $2.25; mine-run, $1.85; Wyoming slack, $1; with Utah slack, $1.25.

PORTLAND, ORE.

The weather in the Pacific Northwest the past week has been conducive to a good cleanup of coal stocks. Indications and records are to the effect that the cool spell cannot well be expected to continue longer, milder weather having already been noticed in the vicinity of the coast. Prices have shown no fluctuation since last fall when winter quotations were put into effect.

What effect the opening of the Panama Canal is going to have on the fuel situation in the Pacific Northwest, is one on which there is much speculation. That there is ample room for lower prices and that such would tend to increase the consumption is the general belief of the buyers, if not of the dealers.

PRODUCTION AND TRANSPORTATION STATISTICS

VIRGINIAN RAILWAY

Total shipments of coal over this road for February of the current year were 399,267 tons as compared with 294,041 tons for the same month last year. Shipments for the first two months of the year were 853,153 tons for the current period and 611,446 tons in last year

IMPORTS AND EXPORTS

The following is a comparative preliminary statement of imports and exports for February and last 8 months in long tons.

	8 Months		February	
Imports—	1911	1912	1913	1912	1913
Anthracite		2,184	1,645	15	
Bituminous	1,345,447	789,246	1,114,209	118,921	134,269
Coke	122,535	38,663	79,924	5,241	4,084
Exports—					
Anthracite	1,911,812	2,301,177	3,224,604	231,684	361,493
Bituminous	7,714,369	9,664,216	9,923,966	695,655	896,790
Coke	615,230	514,421	566,403	59,536	71,541
Bunker Coal	4,189,020	4,453,131	4,794,912	530,272	564,222

OHIO COAL TRAFFIC STATEMENT

The following is a comparison of the coal shipped over the different Ohio roads during the past three years in short tons:

Railroads	1910	1911	1912
Hocking Valley	4,777,478	3,621,794	4,172,908
Toledo & Ohio Central	2,186,435	1,902,304	1,965,893
Baltimore & Ohio	2,455,473	1,828,320	4,283,998
Cleveland, Lorraine & Wheeling	3,053,998	3,018,267	3,368,863
Zanesville & Western	1,245,103	1,151,434	1,208,628
Toledo Division (Pennsylvanie Co.)	2,331,160	1,942,145	6,603,773
Lake Rrie, Alliance & Weheling	1,328,594	1,256,636	1,103,177
Marietta, Columbus & Cleveland Ry	94,101	30.131	36,707
Wabash, Pittsburgh Terminal Ry	63,291	53,920	183,440
Kanawha & Michigan Ry		121,682	183,440
Detroit, Toledo & Ironton			255,427
Total	21,307,370	18,601,509	25,828,745

THE CAR SITUATION

American Ry. Association reports surpluses and shortages of coal equipment for two weeks ended Mar. 15, as follows:

	Surplus	Shortage	Net*
New England Lines	79	0	**79**
N. Y., New Jersey, Del.; Maryland; Eastern Penn	3,279	1654	**1,625**
Ohio; Indiana; Michigan; Western Pennsylvania	3,434	260	**3,174**
West Virginia, Virginia, North & South Carolina	1,004	462	**542**
Kentucky, Tenn.; Miss.; Alabama, Georgia, Florida	683	835	**152**
Iowa, Illinois, Wis., Minn.; North & South Dakota	2,099	496	**1,603**
Montana, Wyoming, Nebraska	764	40	**724**
Kansas, Colorado, Missouri, Arkansas, Oklahoma	3,026	0	**3,026**
Texas, Louisiana, New Mexico	438	6	**432**
Oregon, Idaho, California, Arizona	3,061	23	**3,038**
Totals	17,867	3776	**14,091**
Greatest surplus in 1912 (Apr. 25)	94,692	2,144	**92,548**
Greatest shortage in 1912 (Oct. 10)	6,491	14,897	**8,406**

*Bold face type indicate a surplus.

BALTIMORE & OHIO R.R.

The following is a comparative statement of the coal and coke movement over this road for February and the first two months of this year and last year:

	February		2 Months	
	1913	1912	1913	1912
Coal	2,550,417	2,695,874	5,553,821	5,139,402
Coke	371,355	366,777	810,531	696,333
Total	2,921,772	3,062,651	6,364,352	5,835,735

FOREIGN MARKETS

GREAT BRITAIN

Mar. 19—With the near approach of the holidays, business is of a quiet character. Sellers are firm in their ideas of prices for April loading.

Quotations are approximately as follow:

Best Welsh steam	$4 62@4.74	Best Monmouthshires	$4.20@4 26
Best seconds	4.50@4.62	Seconds	4 08@4 14
Seconds	4.38@4.44	Best Cardiff smalls	3.78@3.84
Best dry coals	4.44@4.50	Seconds	3.54@3.60

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days—less 2½%.

British Exports—The following is a comparative statement of British exports for February, and the first two months of the last three years in long tons:

	February			2 Months	
	1911	1913	1911	1912	1913
Anthracite	205,275	187,057	430,564	447,199	485,365
Steam	3,996,361	4,046,314	7,126,219	7,941,579	8,46,307
Gas	903,273	875,335	1,548,601	1,730,474	1,776,699
Household	125,224	147,861	247,708	264,903	293,587
Other sorts	284,911	313,350	489,552	552,007	620,277
Total	5,514,984	5,569,917	9,812,644	10,936,159	11,640,235
Coke	108,160	98,755	169,873	222,010	205,850
Manufactured fuel	161,251	154,253	284,884	310,183	350,992
Grand total	5,784,404	5,822,925	10,297,401	11,468,382	12,197,077
Bunker coal	1,550,319	1,539,410		3,066,978	3,297,089

GERMAN EMPIRE

The following are the German imports and exports for the years 1911 and 1912:

	Imports		Exports	
	1911	1912	1911	1912
Coal	10,913,948	10,380,482	27,046,193	31,143,115
Lignite	7,069,061	7,266,116	58,071	56,965
Coke	598,958	589,713	4,559,975	5,849,020
Coal Briquettes	94,822	52,562	1,958,826	2,119,541
Lignite Briquettes	116,111	135,714	518,666	726,995

FINANCIAL DEPARTMENT

Lehigh Coal & Navigation Co.

The following is summary of President Warriner's report for the year ended Dec. 31, 1912:

The decrease in commercial production during the year is accounted for mainly by the suspension of mining during the month of April and part of May, pending the conclusion of negotiations between the operators and the United Mine Workers of America. Production was further curtailed by interruptions at several collieries which occurred in the month of September and lasted for a period of nineteen days, due to trouble among the men over the question of union membership. The decrease in production was general throughout the anthracite trade in 1912, as the official statistics show that the total shipments of anthracite during the year amounted to 63,610,578 tons, a decrease of 6,343,721 tons as compared with 1911. The cost of mining increased on account of increased maintenance charges during the suspensions of work above referred to, as well as on account of increased wages and cost of supplies.

Market conditions were satisfactory during the year, excepting for the company's inability at times to supply the demand for its coal, a condition resulting from the suspension above referred to. This inability to meet the demand is now almost overcome, and it is expected that within a short period the production will be able to fill every demand. The company sold its entire production during the year as well as its supply of stock coal. The tonnage sold was 3,646,431 gross tons, an increase of 467 tons compared with the previous year.

During the past year the company expended for additions and betterments the sum of $649,743, and charged off for depreciation, and abandonment on account of obsolescence, $522,667.

During the year an exhaustive investigation was made into the operating and accounting methods of the company and in accordance with the advice of certified accountants, your board are agreed on the wisdom of a policy of accounting under which there shall be established proper reserves for coal lands depletion, depreciation of improvements, insurance, mining hazards and similar items entering into mining costs; and have, beginning with the current year, in accordance with this plan, transferred the securities and cash in the coal lands sinking fund and the insurance fund into the general funds of the company, under appropriate accounts establishing the proper reserves, which will appear in the balance sheet for the year 1913.

The gross revenue from all sources for the year amounted to $13,862,437, an increase of $128,659. Expenses increased $453,572.

The tonnage of commercial coal mined by the Lehigh Coal & Navigation Co. and by the Alliance Coal Mining Co., and the tonnage of these companies, during the past four years (in gross tons) compares as follows:

Mined by:	1912	1911	1910	1909
Company	3,275,585	3,615,141	3,375,541	2,828,788
Lessees	181,505	215,887	285,822	224,927
Alliance	88,067	39,645		
Lessee of Alliance	71,776	130,334	188,492	134,264
Total	3,616,933	4,001,007	3,849,855	3,187,979

*

Northern Securities Co.

President Jas. J. Hill, of this company, states under date, Jan. 10, 1913:

Checks are herewith transmitted for a dividend of 2% on the stock declared payable on this date.

For the year ending Dec. 31, 1911, the company received one dividend of 1% upon its holding stock in the Crow's Nest Pass Coal Co., but during 1912 no dividend was received from this source. The Coal company resumed operations about Nov. 1, 1911, following a prolonged strike. We are informed that the business of the Coal company has been satisfactory during 1912, but that it has been the policy of its directors to apply the net earnings to the reduction of the floating debt. That the debt at the end of the year 1911, amounted to about $1,374,000 (as against their paid-up capital stock of about $6,213,000), and we are informed that at the end of 1912 it had been reduced to about $900,000.

The by-laws of the Northern Securities Co. have been amended and the number of directors of the company reduced from fifteen to six.

RESULTS FOR CALENDAR YEARS

	1912	1911	1910

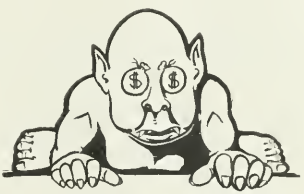
COAL AGE

Vol. 3 NEW YORK, APRIL 12, 1913 No. 15

"A Carpenter is known by his Chips;" likewise the butcher, the baker, the candlestick maker. If you can't find yourself in any of the above classes, just add: "So are we all."

Now for the chips. Well; did you ever know trackmen who always had useless pieces of rail to hide in the gob at the completion of each switch; and of brattice-men who supplied the camps with kindling because of mis-fits and mis-measurements; and of blacksmiths who swelled scrap accumulations with short ends and burnt pieces, etc., etc?



We are acquainted with a man who has worked his way from trapper boy to managing director of a large mining corporation. Step by step, unaided except by sheer personality, he has overcome every obstacle, every difficulty, until now his very word is all but law to a vast army of toiling, struggling mining folks. Viewed from most any angle his career is both romantic and inspiring.

But just now we are thinking of neither inspiration nor romance.

We are trying to apply a world-old proverb as a measure of a man; to do this we must eliminate the man and examine the chips he scattered while he builded.

We must forget that he completed for himself a fortune and a name, and think only of the material that he used; the hands, the feet, the brains of his workingmen.

Were their lives abused and wasted that he might accomplish his ends? How were they housed and fed; were they furnished with schools and churches and what about their recreations?

Go into their towns, the towns that he planned and must leave behind for future generations, and search out the women folk in their homes, the children at their play, the men as they come from work; look for their minister, their doctor, their school teacher.

Do you find here any evidence of want or waste or criminal negligence? Perhaps you are startled to find that the welfare of thousands of toiling human beings had been entirely overlooked simply because the man who was the moving spirit in the establishment of this vast enterprise was neither moralist nor philanthropist.

This brings us back face to face with the proverb.

We are reminded that time was when a man might sacrifice an entire forest in order to obtain enough choice timber to build one mansion, if such were his whim; the conservationist would plaster that mansion with ridicule today.

Wait until our humorists are able to compare men with trees; the fellow who has played fast and lost, may decide that the laugh is on him.

The Buttonwood Washery in Pennsylvania

By Frank B. Davenport*

SYNOPSIS—Description and detailed drawings of an efficient and modern anthracite washing plant in Pennsylvania. The portion here described acted as an auxiliary to the main washer and was equipped for handling the steam grades only. Concrete hoppers are used and the structure is quite stable.

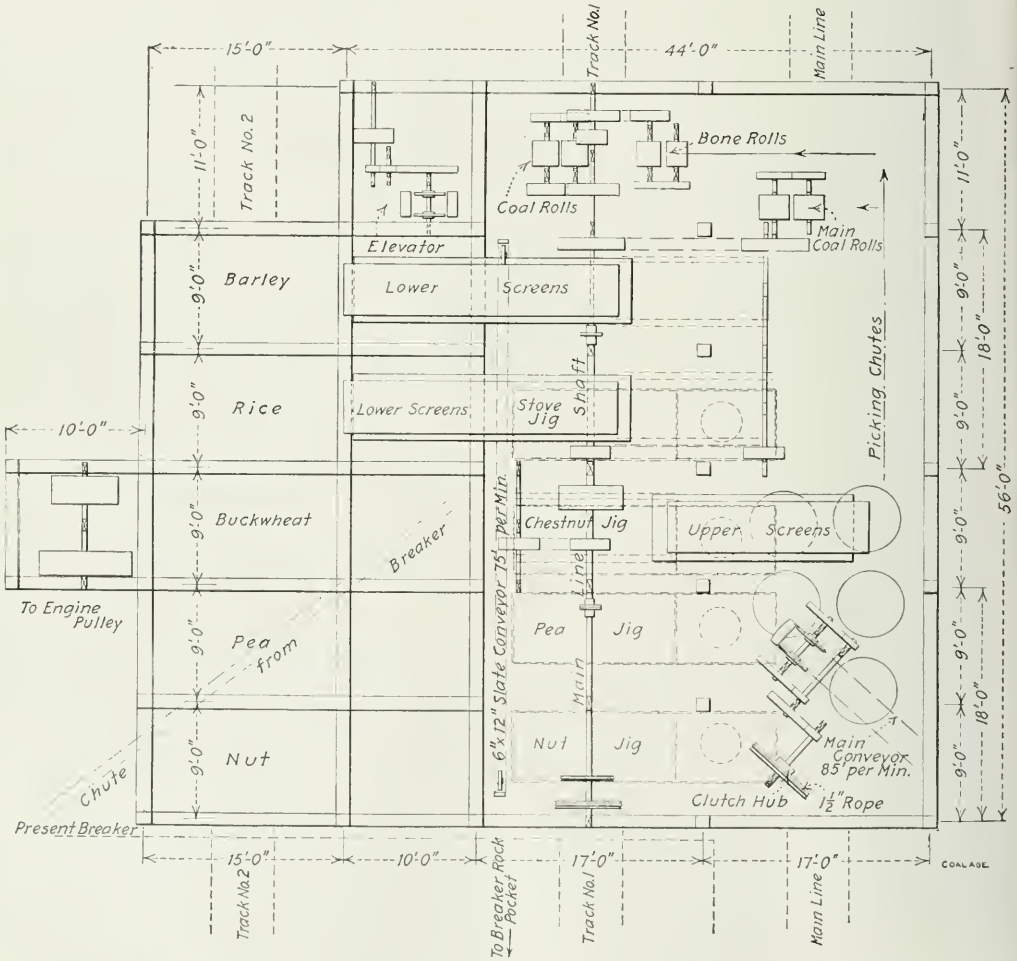
The washery at the Buttonwood colliery of the Parrish Coal Co. at Buttonwood, Penn., is one of the largest of its kind in this region. It cleans and prepares about 800 to 1000 tons of bank coal daily and was designed and built during the summer of 1911, by the Parrish Coal Co. On Feb. 1, 1913, the property and holdings of the Parish Coal Co. were taken over by the Lehigh & Wilkes-Barre Coal Co. and it is now worked under the supervision of that company.

*Engineer, Room 35, Welles Building, Wilkes-Barre, Penn.

Some Features of the Modern Washers

This washery was designed by the writer to relieve and better prepare the fine or small-size coal from the large breaker and at the same time handle the bank coal. It was, therefore, built adjoining the south side of the present breaker and takes most of the pea, buck, rice and barley coal, where the facilities are better for a cleaner preparation.

While washeries have been built for a considerable time back, their use was confined primarily to the preparation of steam size from the waste or refuse of the older collieries, dumped there when there was no demand for such grades. The banks often contain large per-



General Plan of the Buttonwood Breaker, Showing Scheme for Sizing the Coal

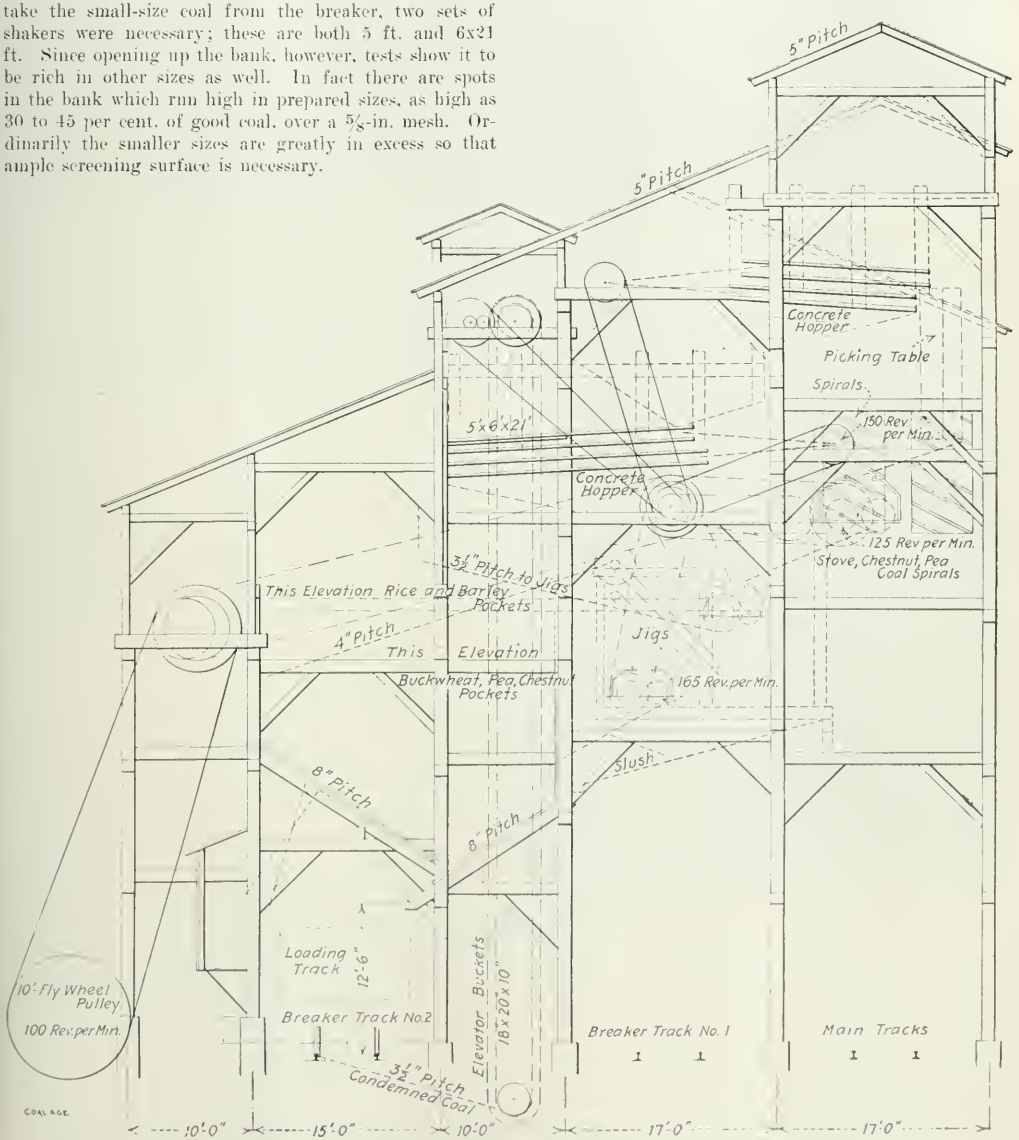
centages of domestic sizes condemned years ago, probably because it was easier to put it on the bank than to reprepare it. Up to a few years ago this coal was ground down to pea and the smaller sizes. With the improvements in mechanical pickers, this bank material is now reclaimed, and today domestic sizes are as important in this plan of operation as the smaller or steam sizes.

Conditions Found in the Bank

Tests of the banks show a large percentage of the smaller sizes. To meet this condition and at the same time take the small-size coal from the breaker, two sets of shakers were necessary; these are both 5 ft. and 6x21 ft. Since opening up the bank, however, tests show it to be rich in other sizes as well. In fact there are spots in the bank which run high in prepared sizes, as high as 30 to 45 per cent. of good coal, over a 5/8-in. mesh. Ordinarily the smaller sizes are greatly in excess so that ample screening surface is necessary.

The building itself covers an area of 50x59 ft. and contains almost 400,000 ft. of lumber. A wet preparation is used so that a substantial plant was desired. All the machinery was built by the Vulcan Iron Works, which includes the conveyor lines, shakers, jigs, rolls, line shafting, etc.

All the bank material is brought into the washery by a 12x24-in. double-strand Keystone Straight Line Riveteless Conveyor, built on a 27 deg. pitch. The drive was compounded and every means taken to make it as substantial as possible so as to eliminate breakdowns and at



End Elevation of the Buttonwood Colliery, Showing Method of Sizing the Coal, and the Location of the Concrete Hoppers

General View of the Buttonwood Steam Plant, Washery and Breaker, Looking North. The Culm Banks Are on the Opposite Side of the Breaker

the same time yield a large capacity. From this main conveyor the coal goes onto the upper screens, 5 ft. and 6x15 ft. These make egg size and larger, the finer grades going to one or both of the lower or fine-coal screens. The material from the upper deck, egg coal and above, is hand picked and the coal sent to the large rolls, where it is ground down to chestnut.

The Prepared Sizes

The prepared sizes are sent to the spirals direct from the upper screen. An arrangement was made to jig the tailings from these spirals if necessary. Four Lehigh Valley Jigs were installed and five Anthracite Spirals. No stove coal was to be prepared for shipment; however, this size is prepared, being sent to the middle set of rollers and ground down to chestnut. The other set of rolls grind any bone coal from the hand pickers to pea size; this also goes to the elevators. All the elevator material goes to the fine-coal screens, which have a special deck hung underneath the top deck. The chestnut, pea and buck sizes can be returned to the jigs if necessary.

The hoppers underneath the shakers are of special note in that they are of concrete, reinforced by stout wire

Buttonwood Washery and Breaker, Showing Main Conveyor and Incline to Washery

mesh. This construction has proved quite satisfactory. The plant is substantially built and steady. The rice and barley pockets were built higher than the others on account of the larger percentage of these sizes and hold about two cars of coal. Ample light is provided, especially for the pickers on the large-size coal. The slush and fine culm goes to a bore hole and is flushed inside the mine.

Use of Coal in Stoves

The use of stoves dates back to the Roman times. They were not, however, made of iron or cast metal of any kind, but were constructed of slate and like material. They were probably first cast in Alsace in 1490 and certainly were cast at Ilsenberg in 1509. The first American stove was cast at Lynn, Mass., in 1642. All of these were for use with wood or charcoal.

In the United States, coal stoves came into use about the close of the 18th century. But in 1774, Dr. Franklin, who was then in England as a representative of the American colonies, constructed a stove for burning bituminous coal, which consumed its own smoke.

The introduction of anthracite made it necessary to adopt some type of stove that would burn such a coal. Dr. Eliphalit Nott, president of Union College, constructed a stove for that purpose which, however, had the unpleasant property of blowing up when it was opened. Jordan L. Mott and James Wilson, both of New York, made self-feeding stoves, sometime between 1827 and 1831, which would burn English or Welsh coal. In 1833, the former constructed a self-feeding base burner, which would burn anthracite coal of chestnut size, fed in thin layers from a magazine.

Doubtless, in England, coal has been burned for several centuries in open grates. The first reference to coal, in England, is found in the records of the Bishop of Peterborough, in 850 A.D. Chimneys were introduced about the 15th century, and the open grate is probably at least as old.

In Great Britain, open fires consuming barely half the coal fed to them are still preferred to the economical and freely burning coal stove. The desire to see the fire burning is the reason for this practice, but it has many disadvantages. A stove acts as a regenerator storing up caloric energy and the heat which it emits serves to ignite new fuel and to keep the room at a uniform heat.

The Illinois Coal Fields

By A. Bement*

SYNOPSIS—A general and valuable review of mining conditions throughout the state. The seams lie level and are comparatively thick as a rule, so that conditions are favorable for economy in production. The room-and-pillar system is most commonly used, although longwall is found quite frequently. The state is estimated to have a productive capacity of from two to three times its requirements.

Knowledge concerning Illinois coal fields has been derived, not so much from geological investigation, as from engineering experience. Notwithstanding this fact, more is known regarding the fields than would usually be expected under such circumstances. This is due very largely to the fact that the seams as a rule are quite uniform in thickness and persistent throughout their known areas.

Coal Resources and Geology

The territory covered by the principal seams is shown in Fig. 1, which also outlines the area of the coal formation covering about three-fourths of the state, or a little over 37,000 square miles. My estimate of the original coal is 201 billion tons, which conclusion is illustrated somewhat in detail by Table No. 1, giving the known thickness of beds; it assumes that such beds are underlain by certain others of less thickness, and that a little over 10,000 square miles in the center of the basin contains coal averaging 18 in. in thickness. F. W. DeWolf, Illinois state geologist, places the original coal at 136 billion 960 million tons, and M. R. Campbell, of the United States Geological Survey, estimates 240 billion. It is difficult to form an estimate of this kind, because while the upper and more important seams have been extensively operated and are well understood, those in the lower measures have not been exploited to any great extent. Total production of coal up to the present time is approximately 811 million tons, which on a basis of a 57 per cent. recovery, represents an exhaustion of 1159 million tons, which is about 3 per cent. of the known thick coal.

TABLE NO. 1. ORIGINAL COAL RESOURCES

Area in Square Miles	Known Thickness, Ft.	Estimated Thickness, Ft	Tons
674	9	6	10,352,640,000
3,883	7	4	43,738,112,000
12,546	4	3	89,929,728,000
10,184	3	1	41,713,664,000
10,199		1 5	15,665,664,000
37,486	Total.		201,399,808,000

Briefly, the coal formations of the state may be divided into the upper and lower measures, the most important seams being in the lower. These are sometimes referred to as the lower productive and the upper barren measures. Illinois is a low-lying state, being usually only 500 to 700 ft. above sea level. For this reason the coal measures have not been much eroded by water courses, now existing.

An early geological survey described 16 coal seams in the state, but the number is greater. That survey gave a numerical designation to the seams reading upward, No. 1 being the lowest. Under this classification the known seams operated are Nos. 1 to 7 inclusive, but Nos. 3 and 4. are only mined in a small way.

Production of Different Fields

Illinois may be designated as a thick-coal state. The thickness of the beds have largely dominated the commercial aspect of production. The commercially workable coal seams in the northern part of the state are thin,

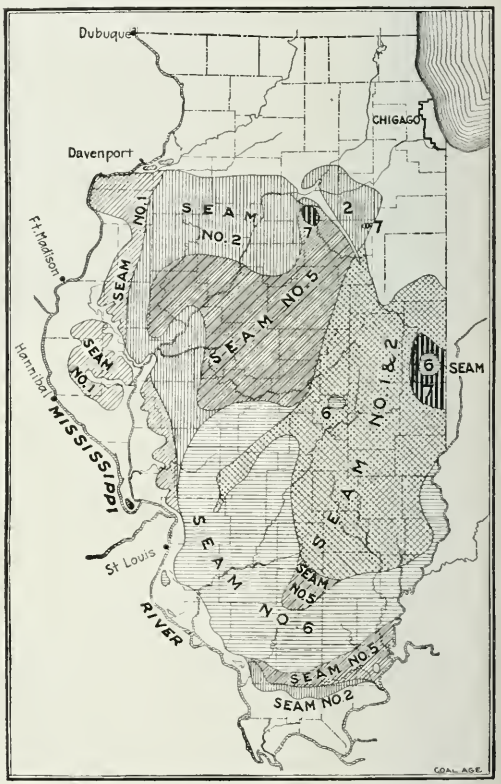

Fig. 1. Map Showing Areas of Different Seams

but they become thicker advancing southward. As the markets are largely to the northward, someone has said that from the coal standpoint, "Illinois was made wrong end to." Others have taken an opposite view, feeling that the distance from the markets is compensated by the advantage due to the thick coal. At all events, if the larger seams were in the north instead of the south, the bulk of production would have always been there. Although markets are principally north and northwest, the center of production has migrated from north to south, until now the southern end of the state leads in commercial importance.

The first mining of any importance was in Jackson County, and immediately following in St. Clair County;

*Consulting engineer and coal expert, 29 South La Salle St., Chicago.

both of these localities are in the southwest portion of the state where Illinois was first settled by the French. Later, however, the northern part became settled and the population rapidly extended southward, the reverse of its initial trend, and when coal production first assumed important proportions it was in the northern part of the state instead of the southern. When the thick seams were discovered and their advantage realized, the center of production began its southern migration, which is illustrated by Table No. 2. From 1906 to 1910, the southernmost county has been the leading one in production. St. Clair County led in 1911, and Franklin will probably lead in 1912.

Referring to Fig. 1, a thick coal area is shown in LaSalle County. This was a small bed of seam No. 7, which had a considerable thickness and was a most active producer for many years, although at the present time it is exhausted. It was this bed, in fact, which gave LaSalle County its lead in 1882 and 1887. As illustrating the influence of thick coal on output, Table No. 3 shows the percentage of production from different thicknesses of seam, from which it appears that about 79 per cent. is from the thick seams. Table No. 4 shows the percentage of output of the different beds, in the fields, as illustrated by the circles in Fig. 2, the production being proportionate to the size of the circle.

Roof Conditions and Faults

Table No. 5 presents such data referring to each of the fields as conveniently lends itself to a classification of this character. It will be observed that no ash values are given for mine-run coal for the Northern and Wilmington fields as these produce no mine-run. The designations under the column headed "Mining" show where the longwall or pillar-and-room methods are in use.

Roof conditions are generally good, although it is often necessary to have some of the top coal as a roof. The stratum above the No. 6 seam is shale or slate. Where slate, it is timbered and the full height of the coal mined. As a general rule, however, shale immediately overlays the coal, and it is necessary to leave up some top coal, which forms a satisfactory roof and requires only a minimum amount of timber.

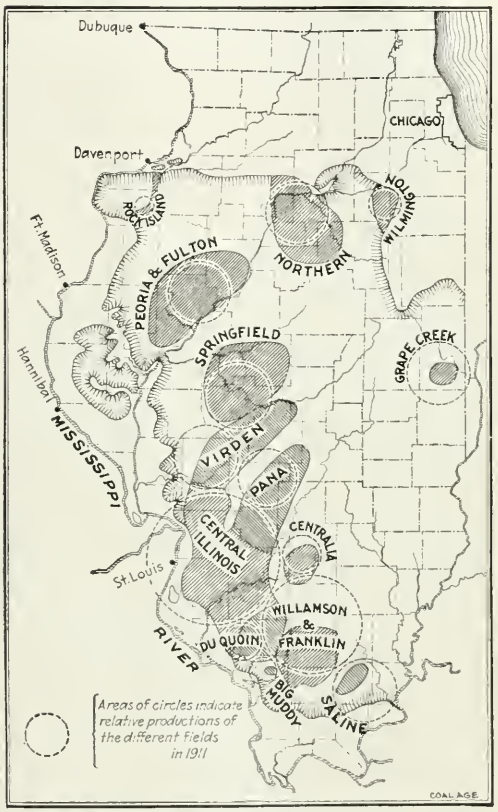

FIG. 2. COAL FIELDS AND RELATIVE PRODUCTION OF EACH

The No. 5 seam has various kinds of roof in the three districts where it is worked, all of which readily allow mining the full height. This seam varies to such an extent as to justify the belief occasionally that the beds are not identical. But the conclusion of both the first and second Geological Survey is that the three beds are one and the same seam. The No. 2 seam, in the north, has a shale roof especially suited to the longwall method of mining. The strata underlying all seams are generally a fairly soft fire clay, although the floor of No. 5 seam in the Saline field is quite hard.

There are comparatively few faults and disturbances in the coal measures, the most important being the LaSalle anticline, which separates the Wilmington from the Northern field, and which extends the greater part of the

length of the state on its eastern edge. The DuQuoin is another anticline of importance, passing through the city of DuQuoin in Perry County in a north and south direction.

There are a number of minor faults, more particularly in the southern part of the state, which, however, are not serious, except in a few instances. The No. 5 seam in the Springfield district contains what are known as horse-backs, an intrusion of the roof material through the seam until it meets with the floor. It has been estimated that these horse-backs will add about 1 per cent. to the ash content of the seam; they are removed separately, and not mined with the coal. The No. 5 seam in the Peoria and Fulton field has been somewhat disturbed and eroded, attributable, according to John A. Udden, to glacial action.

The coal seams lie practically horizontal in all parts of the state, the pitch being so slight as to have no effect on mining except in a few instances, the most important of which is on the west limb of the LaSalle anticline, which throws the No. 2 seam abruptly to the surface.

TABLE 5. MISCELLANEOUS DATA, ILLINOIS COAL FIELDS

Coal Field		Seam			Composition of Coal			
Number	Name	No.	Thickness	Depth in feet	Mining	Moisture at Mine	Ash in Dry Coal Mine Run	Ash in Dry Coal Lump	B.t.u. per lb of Pure Coal

Mining Methods

The coal as hoisted from the mine, in practically all of the pillar-and-room operations, is delivered by self-dumping cages to a weigh hopper, from which it is discharged, onto shaker screens and separated into various sizes, and dumped directly into railway cars, or the fine coal may be diverted to a separate screening or washing plant; there are often as many as five parallel railway tracks. Much of the fine coal is washed, other cleaning, except in a few instances, being confined entirely to selection in the mines and hand picking of the larger coal on the railway cars. In 1911 the output of 50,165,099 tons of coal produced was divided into the following percentages: Mine-run, 26; lump, 38.5; egg, 7; raw screenings, 8.5; washed screenings, 10. The coal was marketed principally as shown in Table No. 6, which gives the leading grades produced, some twenty-one, although there are actually about forty.

Forty per cent. of the coal is undercut by machines, and 50 per cent. is shot from the solid. The other 10 per cent. is worked on the longwall system, where the coal is supposed to be undercut in the fireclay by hand, and broken out by roof pressure.

During 1911 the average days worked by Illinois mines was 169. The total capacity of the mines of the state is at least from 100 million to 150 million tons per annum.

Table No. 7 shows the relative standing of the coal carriers. Many of the mines are counted more than once, as some are served by more than one railway.

There were 845 mines in the state in 1911, of which 458 were local country openings, producing but a few tons. The total output for these local openings, which are mostly drifts in the outcrop, amounts to only 2 or 3 per cent. of the state's production. The remaining 387 mines, shipping their coal by railway, are those with which this paper deals.

TABLE NO. 7. COAL RAILROADS OF THE STATE AND PERCENTAGES HANDLED

The openings of the shipping mines in Illinois are almost exclusively shafts, ranging in depth from 12 to 1000 ft. At the present time I recall no drift of importance, and only one hoisting slope, which is in the No. 2 seam on the west limb of the LaSalle anticline, although in earlier days a few slopes and drifts were operated.

The hoisting record for Illinois is held by Mine No. 3 of the Superior Coal Co., located in the southern part of Macupin County. This mine produced over 790,000

tons of coal in 1911, and has hoisted over 4500 tons in one day with two single-deck cages, from a depth of 350 ft. Other shafts in the state have equipment justifying larger capacities than this, but as the Superior Coal Co.'s mines deliver their coal to the Chicago & Northwestern Ry., for railroad use, the car supply is practically continuous, and no time is lost. The Assumption Coal & Mining Co., in Christian County, has a shaft, 1004 ft. deep, and mines what are considered to be seams Nos. 1 and 2, ranging from four to six feet thick, and operated by the longwall method. The Lovington Coal Mining Co., in Moultrie County, has a shaft 920 ft. deep, and is working what is considered to be seam No. 6, which is eight feet thick.

Hoisting shafts are all double-compartment. The standard hoisting equipment, for the pillar-and-room mines, is a self-dumping cage, holding one car, but some of the longwall operations hoist two cars tandem on a cage, and others have double-deck cages. With the longwall mines, however, about one car in five hoisted contains dirt; for this reason self-dumping cages have not been used, as it is customary to make a separation between the coal and dirt cars before they are unloaded.

A Review of the Fields

This subject would not be complete without some individual treatment of the various coal fields, which is presented as follows:

No. 1—The Rock Island Field, in the early history of mining in Illinois, was a most important one in supplying the northern markets. At present, however, there are only two companies shipping coal, the principal railway is the Chicago, Rock Island & Pacific and the main towns are Sherrard and Cable.

No. 2—The Northern Field, like the others in the northern part of the state, formerly occupied a leading position; in fact, until within recent years the output has steadily increased, although not at the same ratio as for the state as a whole. The Chicago & Northwestern Ry. was formerly a heavy producer in this field, largely for use on its own lines. A few years ago, however, they purchased a large field in the southern part of Macoupin County and extended their line to the City of Peoria in Peoria County, and by a trackage agreement with the Chicago & Alton Ry., now haul coal from Macoupin County, through the Northern Field. The diversion of this large tonnage has had a marked effect on the production in the latter district.

The principal operators in this field are the Spring Valley Coal Co., which formerly supplied the Chicago & Northwestern Ry.; the St. Paul Coal Co., which is controlled by the Chicago, Milwaukee & St. Paul Ry., the LaSalle County Carbon Coal Co., and the Oglesby Coal Co. A thick area of the No. 7 Seam at the City of Streator was an important factor in the production of this territory some years ago but the coal has been exhausted. The principal railroads are the Chicago & Northwestern; Chicago, Milwaukee & St. Paul; Chicago, Rock Island & Pacific and the Chicago, Burlington & Quincy. Principal towns are LaSalle, Spring Valley, Streator and Oglesby.

No. 3—The Wilmington Field was an important producer in the early history of Illinois, at one time furnishing 17 per cent. of the production of the state. The Elgin, Joliet & Eastern Ry., formerly hauled a considerable tonnage from this district, but they are now taking coal from the Grape Creek Field, and the loss of this business has had a marked effect on the production. In addition to this, the increasing popularity of the Franklin County coal has also contributed to the reduction of output.

Thus, coal from the Wilmington Field is being supplanted by that which has to stand a 300-mile greater transportation cost. The principal railways are the Chicago & Alton, Atchison, Topeka & Santa Fe and the Elgin, Joliet & Eastern and the main towns are Coal City, South Wilmington, Braidwood and Braceville.

No. 4—The Peoria and Fulton Field is not an important one, as far as local consumption is concerned, the product being largely shipped away from the state. The principal railways are the Chicago, Burlington & Quincy, Iowa Central and the Toledo, Peoria & Western, the principal towns being Peoria, Farmington, Canton and Cuba.

No. 5—Grape Creek is a field quite remarkable in some respects, the area being small and the output large. The reason for this latter is that the field lies close to Chicago, and the transportation facilities are favorable for the movement of the large output; the Illinois Steel Co. has taken its supply from here for many years.

The largest operator in the field is the Bunsen Coal Co., which is a subsidiary of the United States Steel Corporation. The principal railways are the Chicago & Eastern Illinois and Cleveland, Cincinnati & St. Louis, the main towns being Westville and Steeltown.

Mining conditions here are the least favorable of any in the No. 6 Seam, due especially to the roof. The great activity and large output, however, neutralizes this disadvantage so that the field enjoys considerable prosperity.

No. 6—The Springfield Field is made up of a large number of mines which center about the City of Springfield. They are an average size group which have maintained a fair production for a good many years, and the field is as active today as any time in its history. The principal railways are the Chicago & Alton; Illinois Central; Chicago, Peoria & St. Louis; Cincinnati, Hamilton & Dayton, and the Illinois Traction System (electric). The main towns are Springfield, Greenview, Lincoln and Athens.

No. 7—The Virden Field was at one time quite an active one, but its output has declined in the last few years, as scarcely any new mines are being opened. The principal operator is the Illinois Midland Coal Co., with a territory of some sixty thousand acres. This property is operated by the Peabody Coal Co. The Chicago, Burlington & Quincy Ry. is the next largest property holder. The principal railways are the Chicago & Alton; Illinois Central; Wabash; Baltimore & Ohio Southwestern and the Chicago, Burlington & Quincy. The main towns are Virden, Thayer, Diverman, Pawnee, Taylorville, and Girard.

No. 8—The Pana Field is essentially a new one. Mining has been conducted at the City of Pana for a good many years, but the remainder of the field was not opened until quite recently. The Chicago & Eastern Illinois Ry. is the largest property holder and its lands are operated by the Peabody Coal Co. The principal railroads are the Chicago & Eastern Illinois; Illinois Central and the Cleveland, Cincinnati, Chicago & St. Louis, the main towns being Pana, Hillsborough, Nokomis and Witt.

No. 9—The Central Illinois Field is much larger in area than any other in the state. This is due to the fact that there is practically no difference in the condition or the quality of coal over this area and hence it cannot be subdivided. This is a district of small mines, although at the same time it has some of the largest. The seam is only a few feet below the surface in St. Clair County and having a good roof, the opening of a mine is quite a simple proposition.

The largest operator is the Superior Coal Co., a subsidiary of the Chicago & Northwestern Ry.; it owns fifty thousand acres of coal, and operates three mines, which are the largest producers in the state. The Consolidated Coal Co. and the Western Coal & Mining Co., subsidiaries of the Wabash Ry., are also large operators. The principal railways are the Illinois Central; Louisville & Nashville; Southern; Baltimore & Ohio; Southwestern; Terre Haute & Indianapolis; Wabash, and the St. Louis, Troy & Eastern. The main towns in this field are Belleville, Collinsville, Edwardsville, Gillespie, Mt. Olive and Staunton.

No. 10—Centralia is a small, but quite active field. The towns are Centralia, Sandoval, Salem and Oden, the principal railways being the Illinois Central and the Chicago, Burlington & Quincy.

No. 11—The DuQuoin Field is an old one. Mining was begun at an early date, owing to the outcrop of the No. 6 Seam. The field, however, has never been especially active, the distance to the market being considerable, and the quality of coal rather inferior to the Williamson County product. Therefore, when shipments from this locality are to bear a high freight rate, preference is given to the latter county. The principal towns are Pinckneyville, Willisville, Tamaroe and DuQuoin, the main railways being the Illinois Central; Mobile & Ohio; and the Wabash, Chester & Western.

No. 12—The Williamson and Franklin Field is today the best known, the best advertised and the most spectacular field in Illinois, particularly the Franklin County portion of it. The Williamson County coal area of the No. 6 Seam is practically all in the hands of a large number of comparatively small operators, some of the most important of which are Big Muddy Coal & Iron Co., the Taylor Coal Co. and the Peabody Coal Co.

The Franklin County portion is new, mining beginning in 1904, when Mr. Joseph Leiter acquired eight thousand acres and erected an elaborate and expensive mining plant, which he attempted, with only partial success, to operate with nonunion labor. This fact, together with spectacular advertising methods, made Franklin County known in a way that no other coal field has ever been advertised before. This, followed by the intelligent and progressive methods of the United Coal Mining Co., and other operators, has given the Franklin County product a valuable prestige.

The seam was formerly designated as No. 7, an error due to mistaken interpretation of the seams at the City of DuQuoin in Perry County. The anticline there has thrown the seam to the surface and the apex was eroded leaving what appeared to be two outcrops, the eastern one of which was exposed, while the western one was covered. This led to a belief that the exposed outcrop on the east was a seam lying above the one to the west, which latter was known to be the No. 6 and the other was, therefore, called No. 7. The second geological survey, however, has made the matter clear, and the seam is now generally recognized as the No. 6.

The largest property holders in Franklin County are the Bunsen Coal Co., a subsidiary of the United States Steel Corporation, the Chicago, Burlington & Quincy Ry., United Coal Mining Co., D. W. Buchanon, the Chicago, Wilmington & Vermillion Coal Co., Brazil Block Coal Co., Consolidated Indiana Coal Co., and the Ziegler Coal Co., whose property is now operated by the Bell & Zoller Mining Co.

The mines of this county are deep, and for Illinois they are quite gassy, requiring more than usual care in mining. The coal has practically the lowest sulphur content of any in the state, and some experiments toward coke making have been carried out, which appear to indicate the possibility of it being a good mixer with lower volatile fuels for the production of a metallurgical coke. The principal railways are the Chicago, Burlington & Quincy; Chicago & Eastern Illinois, St. Louis, Iron Mountain & Southern and the main towns are Carterville, Herrin, Marion, Christopher, Benton, West Frankfort and Zeigler.

No. 13—The Big Muddy Field, although a small one, is in other respects the most important in Illinois. It is the oldest field, having produced the first coal in the state and having continued with a uniform output up to the present time. The quality of the coal is the best in the state. While it has been known to many by the old name of Big Muddy, for a number of years it has been marketed as New Kentucky coal.

The principal operator is the Big Muddy Coal & Iron Co., whose product is marketed by the New Kentucky Coal Co. Coke from this seam made the first iron produced in Illinois in a coke furnace. When the iron-ore deposits at Pilot Knob and Iron Mountain in Missouri were discovered, furnaces were erected at St. Louis, and in Illinois. Coke made in the Big Muddy Field was used in these furnaces and this was continued until the iron deposits were exhausted. Principal towns are Murphysboro and Carbon and the main railways are the Illinois Central; Mobile & Ohio, and the St. Louis, Iron Mountain & Southern.

No. 14—The Saline Field, next to Franklin County, is the newest in the state. The coal is of a high quality, and the mining conditions are especially favorable although the seam is variable in thickness; in this latter respect it differs from all other fields. It is known to the trade as Harrisburg, after the town of that name, which is the county seat. The O'Gara Coal Co. is the leading operator. The principal towns are Harrisburgh and Eldorado and the railways are the Cleveland, Cincinnati, Chicago & St. Louis; Illinois Central, and Louisville & Nashville.

The use of iron and steel in place of mine timbering has increased rapidly during the last few years. Iron and steel give good results as props at the coal face or as girders or bars where the pressure is great or in return airways where timber decays rapidly. Where iron girders are used in a permanent lining, great care should be taken to prevent rupturing the masonry and bending the girders. Lay pine planks 3 in. thick and 12 in. wide along the top of the side walls and place the girders on them. Each girder must be absolutely plumb with webs at right angles to the plane of the roof and with ends clear of the ground or stone on either side. The side walls should be from 2 to 5 ft. thick. It is advisable to use quick-setting mortar, which must be allowed to obtain a perfect set before the girders are put in position, as otherwise it is liable to failure.

SYNOPSIS—A current of 18 miles an hour will remove loose coal dust from a mine. Equal quantities of pulverized coal and dust form a noncombustible mixture. Bitumen electric cables are preferable for high-tension work below ground. A fireboss who has been trained to judge gas percentages at one air pressure is not capable of estimating them when the pressure is changed. In England, it is still being taught that firedamp is a highly complex mixture containing ethane, propane, butane, hydrogen, carbon monoxide, sulphureted hydrogen, carbon dioxide, oxygen and nitrogen, as well as methane. An interesting attempt is made in England to reduce carpet-bagging.

W. E. Garforth, in a lecture at Nottingham, stated that, according to experiments, an air current at a velocity of 700 ft. per min. is not sufficient to remove coal dust from the rock ledges and the tops of cross-bars on which it has been deposited. At a velocity of 1500 to 1600 ft. per min. coal dust is raised and carried away by the air current, but stone dust is left undisturbed. At 2200 to 2600 ft. per min., stone dust is also carried away, leaving the surface of a roadway entirely free from dust.

The Cost of Effective Stone Dusting

Twelve miles of mechanical haulage roads at the Altofts collieries have now been treated with stone dust. The approximate cost has been $1.80 per thousand tons of coal produced, including the loading of the rock in the mine, the haulage of rock to the mortar mill, the transport of the stone dust to the point of distribution, the work of grinding, the cost of raising steam, the depreciation of the mill and the total cost of application underground.

Stone dust should be sprinkled wherever coal dust is found, and not merely in occasional zones. The proportion between coal and stone dust should be continually maintained. Although coal dust when mixed with an equal quantity of pulverized rock is rendered incombustible no matter how much of the mixture may be present, yet the proportion used at Altofts is about 14 parts of the ground stone dust to 1 of coal dust, on the principle that it is better to be sure than sorry.

Precautions to Reduce the Coal Dust in the Mine

Much can be done to prevent accumulations of coal dust. The dust made on the surface need not be carried down the shafts, the cars can be made dust tight, the bumping of wagons along roadways and at junctions can be reduced and other causes of disintegration of coal and distribution of dust prevented. But as long as coal continues to be mined, so long will dust be made in the process of working, and this will remain in the mine. Its presence is inevitable, but now we know that it is not necessary that this dust be a potential danger.

The underground roadways can be kept free from accumulations of pure coal dust in the same degree that the workings are kept clear of accumulations of firedamp or water. Coal dust should be diluted as faithfully as noxious gases. Its treatment is as much a part of mining as the maintenance of pumps or the use of timbering.

In process of time, precautions against the danger of coal dust will form part of the ordinary routine of the mine. At Altofts, the application of stone dust has not caused the slightest discomfort to the workmen, nor has it interfered with the haulage system, or injured the ropes or other appliances.

Electric Cables in Mines

For installing electric light or carrying power below ground, the cables may be provided with any of four kinds of insulation: (1) Rubber, (2) paper, lead covered, (3) paper, leadless, (4) bitumen. Discussing these in a paper before the Manchester Geological and Mining Society, G. W. T. Anderson says that bitumen cables are by far the most suitable for average colliery work. For use in shafts they are certainly the most serviceable.

Until quite recently great difficulty was experienced in getting the bitumen insulation to such a consistency that in moderately high temperatures the conductors would not decentralize. On the other hand, if the bitumen were made too hard, at low temperatures it would become brittle. It is possible today to avoid these troubles over a range of temperature which covers all ordinary working conditions—say from 28 to 120 deg. Fahrenheit.

Bitumen Cables No Longer Contain Hygroscopic Material

Whereas it was formerly necessary to introduce in the construction of the cable, mechanical reinforcements, such as tapes, braids, etc., the improvements in the physical properties of the bitumen and in the methods of manufacture now available enable cables to be made without these hygroscopic and electrically undesirable components. For instance, the "solid" three-wire bitumen cable which is familiar to most colliery engineers, is so constructed as to contain no hygroscopic material whatever within its sheath, so that in effect the conductors are imbedded in a solid cylinder of vulcanized bitumen.

A recent form of construction called "Cracore," consists in the laying up of the separately insulated cores on a central cradle of vulcanized bitumen shaped to receive them. The whole is then sheathed over all with a tube of vulcanized bitumen, which is cylindrical on the exterior but shaped internally, so as to fit the interstices of the laid-up cores. This construction, by distributing the mechanical pressure between the cores over a large area, enables even twin bitumen cables to be made without the inclusion of hygroscopic substances anywhere within the boundary of the vulcanized bitumen sheath.

The Cables Above Ground

Bitumen cables should not be installed immediately after direct exposure to frost or cold winds. The space between generating station and headgear is perhaps the most prolific field of any for cable breakdown. The best means are either to build a well ventilated surface culvert (open or covered with checker plate) in which the cables can be carried on brackets, or to sling them overhead from a catenary wire. Old haulage rope can

generally, be used for this purpose, made taut with socketed ends and tightening screws.

When shaft and power house are some distance apart, paper lead-covered cable laid solid is worth considering. In such a case, a disconnecting box should be inserted at the top of the shaft. For even greater distances, especially on the "extra-high-pressure" lines where the tension normally exceeds 3000 volts, bare overhead conductors are frequently used. In bitumen cables, the conductivity of the metallic coverings should be equal to 50 per cent. of that of the largest conductor which they inclose.

Atmospheric Pressure and Gas Caps

C. J. Wilson, of Heriot-Watt College, Edinburgh, in an article entitled "An Investigation into the Influence of Variations of Atmospheric Pressure on Gas Caps," read before the Mining Institute of Scotland, showed how a fireboss trained to estimate gas in a mining school might fail to determine the correct proportion of gas in an actual mine owing to the air feed being insufficient in the laboratory or because in the mine a greater pressure of air might be encountered.

He declared that the gas cap in a lamp represents the combustion of the gas in the mixture and not the burning of the oil of the lamp which we can ignore. It must be borne in mind that the size of the cap depends on the proportion of gas present and on the presence of air capable of supporting its combustion. The height of the cap represents the proportion of gas to air or the volume of gas in the mixture.

If we compress the mixture, we compress the gas in the same proportion. The reduced volume of the gas results in a reduced size of the cap but the flame increases in intensity. Dr. Thornton, of Armstrong College, Newcastle, has suggested that the higher the heating value of the gas, the smaller would be the gas cap. In the compressed mixture we get a greater heat for the same volume of gas. As the height of the cap varies inversely as the heat of the combustion of the mixture, the cap decreases in size as the pressure increases.

Height of Flame and Cap, in Inches, for Varying Pressures

Percentage of Coal Gas	Atmospheric Pressure	546 ft. Deep	1092 ft. Deep	1638 ft. Deep
5¼	8.29	6 99	5 69	4.38
5	6 01	4 87	3 75	2 60
4½	4 03	3 25	2 46	1 67
4	2 09	2 22	1 73	1 24
3½	2 17	1 83	1.49	1 16
3	1 97	1 68	1.41	1.13
2½	1 85	1 58	1.34	1 09

Increase of pressure has no effect on the oil flame when no gas is present, but when testing mixtures of air and gas under varying pressure the flame has to be reduced as the pressure increases, if it is to render a proper test flame. As the pressure increases, this flame changes, whether it augments merely in luminosity or whether it also increases in height has, unfortunately, not been observed. There is merely the record of the fact that the wick has to be pulled down as the pressure goes up, and vice versa, if the standard flame is to be maintained.

The Effect of Depth on Caps

The importance of this effect of pressure is that it is hard to estimate the percentage of gas present in a mine when the pressure of the air is higher than it was at the point where we have learned to estimate the amount of gas present from the appearance of the flame in a test chamber. The percentage is bound to be understated if measured only by the standard, which has been acquired in the laboratory, near the sea level. If the atmosphere rarified, the cap will grow longer.

There is a limit to the height of cap due to increased percentage; a point is soon reached at which the tip of the cap becomes indistinct. It begins to feather at certain percentages; at higher proportions, this feathering extends throughout the full length of the space beneath the gauze and the mixture explodes. When the cap feathers strongly, it gathers first with a good, clear tip, and more or less slowly rises to a certain maximum height; from that it suddenly drops, then as suddenly rises and feathers, filling the whole lamp.

Composition of Firedamp

In the course of a paper before the Yorkshire branches of the National Association of Colliery Managers and the Association of Mining Electrical Engineers, David Bowen, the mining lecturer at Leeds University, said, that the term "firedamp" is ordinarily used to describe all explosive mixtures of air and gas met with in mines, but frequently also in reference to the gas itself, as it issues from coal or rock, before it diffuses into the air of the mine to form an explosive mixture.

Investigations have shown that these natural gases are not simple bodies but are mechanical mixtures which vary within wide limits. The most essential constituent of firedamp is the hydrocarbon, methane (CH_4). Many blowers consist entirely of this gas.

Associated therewith, usually in much smaller proportion, are frequently found several of the heavier hydrocarbons. These are, according to more recent investigations chiefly ethane (C_2H_6), but occasionally also propane (C_3H_8) and butane (C_4H_{10}). Hydrogen is also frequently found, but the presence of carbon monoxide and of sulphureted hydrogen in firedamp appears to be exceptional. Carbon dioxide is seldom absent, and in addition, nitrogen and oxygen are frequently met with.

Bonus Scheme for Miners

For some time Lord Hythe has been trying to get the Powell Duffryn directorate to adopt a bonus scheme for the mines. The present annual output of the company exceeds four million tons, and fourteen thousand men are employed. To make his scheme better known, Lord Hythe has described it in the "Western Mail." It is practically the bonus system which he introduced in the mines in Sardinia and the principal provisions of which he thinks applicable to the South Wales coal field.

Every workman is furnished with a booklet, in which is set down every year, the rate and amount of the bonus, the sum standing to his credit and the interest upon it, for the preceding year.

The workman cannot withdraw any part of the sum standing to his credit till after he leaves the company's service.

In the event of a workman's death while still working for the company, the sum standing to his credit is paid to his dependent relatives.

Only men who have been in the service of the company a certain period (Lord Hythe would make the qualifying period three years), are entitled to participate. This clause is proposed to prevent those men who are restless from shifting constantly from mine to mine.

"Horsebacks" in Oliver No. 3 Mine

By E. S. Moore*

SYNOPSIS—Under lateral pressure from earth movements, the bottom clay of the Pittsburgh bed in Oliver No. 3 is lifted in places so that in part it cuts out the coal. The rolls or lifts in the floor are by some termed "horsebacks." They bear no relation to the original deposition of the coal and are not sand or clay bars, such as we find occasionally deposited by a primeval stream. Pyrite is often found to increase at rolls and the writer suggests reasons for this phenomenon.

The word "horseback" is used in different senses in the coal areas of the various states. What in Pennsylvania are termed "clay veins" are named in Kansas "horsebacks." On the other hand, the word "roll" in Kansas is synonymous with "horseback" in Pennsylvania. The words are used in Iowa with almost the same meaning as in the latter state.[1]

Derivation of "Horseback"

The Germans have long used the term "horst" for a geologic structure where a mass of rock has been pushed up into the overlying stratum. Among American metal miners, a portion of the country rock which occurs in an ore deposit is termed a "horse" whether it was forced into that position by the sidewise pressure of the measures or existed before the ore was deposited, and whether it has been partly or wholly surrounded by the ore.

Although the structures are somewhat alike in origin and the words "horst" and "horse" have a similar sound, it is doubtful whether the adoption of the English word was at all influenced by the use of the German. The word "horse" as used by the miner has doubtless been employed because it is used in ordinary parlance to indicate either a truss or something which must be overridden, both meanings being suggested by the fact that the miner must pass around or over these masses, for they are often left and they act as supports when the ore is removed.

The confusion between the terms "horseback" and "clay vein" may have arisen from the fact that in many cases, at least, the metal miner's "horse" and the coal miner's "horseback" are both developed from lateral pressures which cause the floor of the coal seam to buckle in places of weakness. The clay vein marks the pushing of clay into a fissure in the coal while the "horseback" is a mound formed by the clay being squeezed out of place and thus compressing the coal overlying it.

Either of the terms "roll" or "horseback" is quite appropriate for the wave-like structures which appear in the floor of the coal seam just as "hogback" is sometimes used in geological literature to describe a pitching anticline on the earth's surface from which the softer layers have been partially removed by erosion so that the harder beds stand out as a ridge resembling at a distance the back of a thin hog.

Uniformity in Direction

In the mine under discussion the arrangement of the "horsebacks" is remarkably uniform, as will be observed from the accompanying map. (Fig. 1.) They are small, nearly parallel anticlines produced by gentle folding, and, owing to the coal being less resistant than the underlying floor, the folding is almost entirely expressed in anticlines without prominent synclines. (See Fig. 2.) These undulations have somewhat the arrangement of the

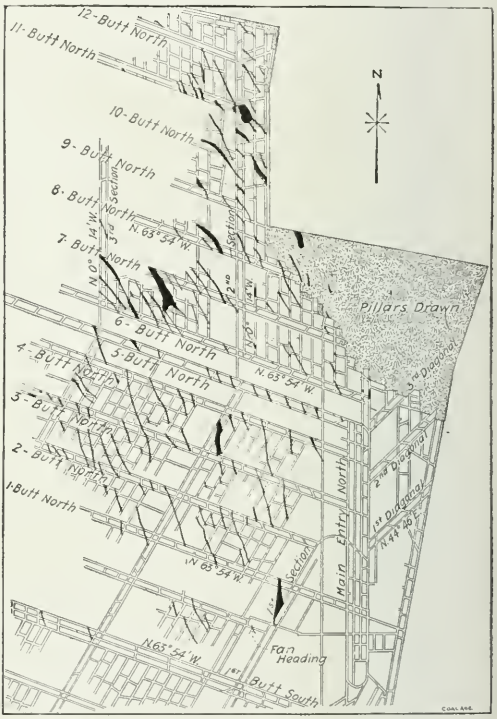

Fig. 1. Map Showing "Horsebacks" in Oliver No. 3 Mine near Connellsville, Penn.

large and small waves on water, when there is a gentle ground swell, and they die out longitudinally like a wave. The largest one traced was about 50 ft. wide and they vary from this to a few feet in length. They rise from 6 in. to 4 ft. above the general level of the floor of the seam and the coal is invariably compressed and thinned above them. (See Fig. 2.) The mine superintendent at Oliver No. 3 stated that only in one case did they find the full thickness of coal in the seam and in that case the draw slate was arched above the "horseback."

In its structure the "horseback" shows the strata which compose it dipping away from its crest and often much fractured and slickensided where slipping has occurred. The laminae in the coal overlying, are bent and fractured and the coal is harder than is natural to the seam. The rock forming the "horseback" may be shaly sand-

*Pennsylvania State College, State College, Penn.

[1]The words "horseback," "roll" and "clay vein" vary in meaning extensively in the state of Pennsylvania. They are popular words without generally accepted interpretation. A mine report in Pennsylvania once declared that a man was "Filled by a fall off horseback." Evidently the word "off" was a typographical error and the word "horseback" referred to a slickensided agglomeration of clayey material in the roof. Such bodies are frequently termed "bells," "camel-backs" and "tortoises"—Editor.

stone, shale or clay. Frequently the upper part of the mound consists of fairly rigid rock while underneath is a jumbled mass of clay which has been squeezed in from beneath.

In the center of the fold bunches of pyrite often occur and it is stated that scarcely any of this sulphide is found elsewhere in the floor of the seam. The reason for this is explained later.

Origin of the "Horsebacks"

The folio of the United States Geological Survey shows that the region in which Oliver is situated is folded so that the axes of Laurel Ridge and the basin lying along its western side run almost N. 25° E. this being approximately parallel to the greater Appalachian folds in this

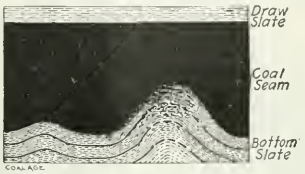

Fig. 2. A Typical "Horseback," Showing Secondary Undulation

region. These small ridges and basins have in turn developed upon them still smaller ridges and basins and the structure of the Appalachian Mountains is seen on a diminutive scale in the "horsebacks" of the coal mines.

Fig. 3, which is a reduced copy of a portion of the geological map of the Masontown-Uniontown quadrangle, shows the contours on the Pittsburgh coal seam and the position of the Oliver No. 3 mine with relation to the large coal-bearing basin. The mine is located along the southwest side of the basin where the contours indicate that the coal bed is less disturbed than farther north, and the folds have been produced by pressure from two directions only, resulting in nearly parallel and narrow "horsebacks" with their long axes nearly parallel to the strike of the rocks at this point.

Farther north, nearer the center of the basin, the contours are more irregular and I am informed that the "horsebacks" tend to run in various directions because cross folding is produced by thrust from all four points of the compass. Under these conditions there would be a tendency to develop, in some cases, dome-shaped structures which would be higher and broader for their length. The Pittsburgh seam averages over 9 ft. in thickness over large areas in this region and the coal is readily compressed sufficiently to allow a buckling of the strata in the floor without materially disturbing the roof. There are often considerable areas even in the same mine where no "horsebacks" occur because the strata are either almost uniformly strong throughout or not rigid enough to fold up and compress the coal. One fold tends to produce another in some cases and where the strata are weak in some locations and strong in others they tend to buckle in the places where the resistance is least.

"Horsebacks" Are Not Depositional

There has been an opinion prevalent among some mining men that the "horsebacks" are sand and clay bars left by streams which flowed into the basin in which the coal now lies. It is to be observed, however, that the present basin was not there, as it now exists, when the coal was laid down and that if a stream of sufficient size to make the bars flowed through the swamp where the coal was deposited, it would be impossible to have such a great mass of vegetation, so free from sediment, laid down in the basin.

Moreover, these structures show the strata dipping away from the crest of the fold as in any ordinary bend in the earth's crust, the coal is shattered and squeezed and in some cases slickensided where compressed by the folding action. The laminae in the coal also conform to the bedding in the "horseback" and the draw slate is uniform. A number of narrow fissures, without displacement were seen in the seam and roof running roughly parallel with the long axes of the "horsebacks" and probably due to tensional stresses which accompanied the bowing upward of the floor.

From the above statements it seems clear that these structures are due to folding and that the folding occurred subsequently to the development of the coal seam and not in the bottom of the swamp previous to the deposition of the vegetation as has been supposed to have happened in rare cases.

A preliminary study of the structure of an area where "horsebacks" occur may in some cases aid the miner greatly by establishing the general trend of these structures so that if they be regular he may drive the main headings parallel or normal to them when desired.

The Development of Pyrite in a "Horseback"

The more frequent occurrence of pyrite in the "horsebacks" than in the other portion of the floor of the coal seam is apparently due to two conditions; in the first

Fig. 3. Contours of Pittsburgh Bed at Oliver, Penn.

place there is more pyrite in the strata a little below the coal than in the floor of the seam as the latter often contains little or no iron, and secondly where the strata are bowed up and fractured in the folding there will be greater freedom of movement of water tending to carry iron sulphate and deposit it where the sulphate is reduced by oxidation of carbon, as the water will come more readily in contact with the metamorphosing coal in these fractured folds than where the fuel is protected by an impervious floor of clay.

I am indebted to F. C. Keighley, general superintendent for the mine map illustrating the "horsebacks" at Oliver No. 3, and for some of the information in this article.

The maintenance of a constant humidity rate throughout the year is said to be of material benefit to mine roofs as the yearly expansion and contraction, due to moistening and drying is thus avoided.

Folding Troubles in the Bering Field

By W. R. Crane*

SYNOPSIS—The coal beds being weaker and less resistant than the rock masses with which they are interstratified have suffered considerable distortion, in some places being pushed together in a mass toward the tops and bottoms of the folds. In others the broken rock has been pushed into the coal mass. But some beds are free from all irregularities other than bad roof, broken coal or complex cleavage. The fourth of a special series of articles by W. R. Crane.

The irregularities in coal beds caused by folding are of a large variety of forms, among the most common and consequently important being the thickening and thinning of the stressed beds. An excellent illustration of the squeezing out of a thin bed of coal on the sides of a fold and its massing at the crest in the form of a saddle is shown in Fig. 1.

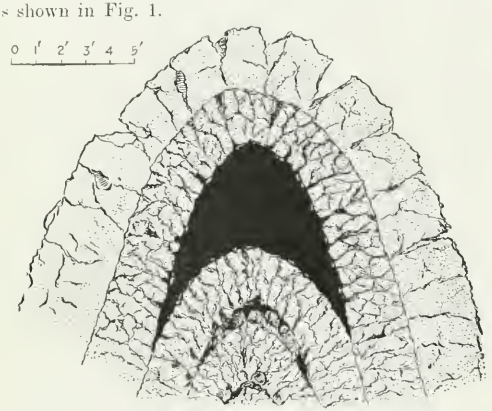

Fig. 1. Massing of Coal at Crest of Fold

Illustrations of the massing of coal beds in both the troughs and crests of folded strata can be found without end in practically every district of the Bering River field. In certain localities masses containing thousands of tons of coal have been forced together by the folding back upon themselves of coal beds ranging from 18 to 40 ft. in thickness. Usually the crowding together or massing of the coal has seriously disturbed or broken up such rock strata as are folded with it as they must of necessity be displaced to make room for the increased volume of coal. Such massing of the fuel is shown to good advantage in Fig. 2.

In fact the thickening of coal beds is of such frequent occurrence that when a large deposit of coal is encountered and there are signs of folding the inference is that an abnormal thickness is shown rather than the normal width of the bed.

Faults

Excessive folding usually results in the rupture of the rock strata inclosing the coal beds and if continued will produce displacements, forming faults. There are many such dislocations in this field displacing the bed from a few inches to probably hundreds of feet. Among the most important of the large faults are those inclosing the Lake Charlotte portion of the Kushtaka and Carbon ridges district, the two on Kushtaka Ridge, one extending southwestward from Lake Tokun, one on Clear Creek, and one cutting across the ridge in a northeast

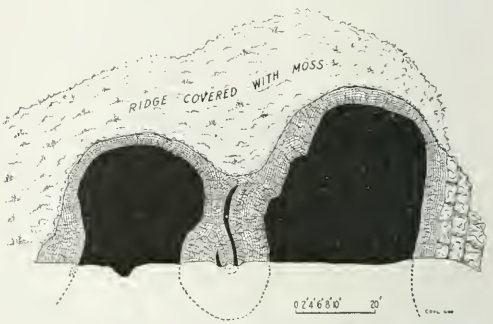

Fig. 2. Outcrop of Coal, Showing Massing of Coal Due to Folding

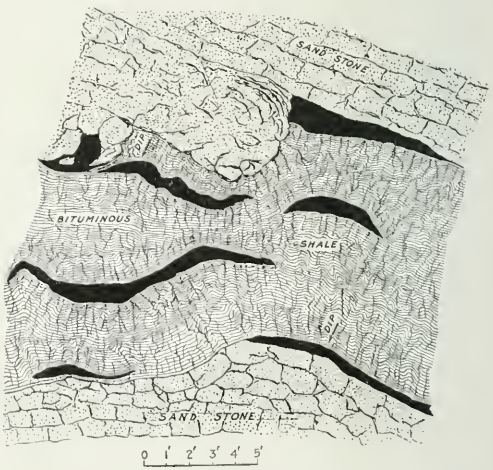

Fig. 3. Shove Fault on Falls Creek, Bering Lake District

and southwest direction just north of the Bering Lake district.

In the first instance an area of coal-bearing rocks has been completely isolated from the rest of the district by two extensive fault planes. The faults on Tokun and Clear Creek have so shattered the rock strata that the fissured zones have presented lines of least resistance to mountain streams which have cut deep gorges for considerable distances along the lines of the faults.

Owing to the much greater frequency of faults of less magnitude they are of more importance economically. The effect of faults upon bedded deposits is so well known

*Professor of mining, Pennsylvania State College, State College, Penn.

that such disturbances of the coal beds of this field will not be considered in this connection. When, however, faulting is accompanied by compression of strata, due to folding or otherwise, shove faults may result. Two illustrations of such disturbances occurring in this field are of more than passing interest and will therefore be cited here.

In the Bering Lake district on Falls Creek, a thick bed of shale containing a high percentage of bituminous matter and closely resembling coal, containing, in fact, many stringers of real fuel, has been both faulted and folded. The result of this combined action is that the top rock has been badly broken and a large portion forced forward into the bituminous-shale bed. Detached masses of the top rock are embedded in the coal and shale and the gnarled and twisted mass of the beds shows indisputably the nature of the movement which has taken place. See Fig. 3.

Fig. 1. Shove Fault and Horse on Carbon Mountain

The other illustration of a similar occurrence, although in this case not accompanied by actual displacement of the whole bed, was observed on Carbon Mountain. Here the coal bed was fractured and a lateral movement of the top-rock has forced a mass into the upper portion of the bed actually shaving off, as it were, a mass of the coal. Many nodules of bituminous shale and pyrite as well as fragments of rock occur around this disturbed portion of the coal bed. See Fig. 4.

As was previously pointed out, it is not an easy task to determine in all cases whether the occurrence of an irregularity is wholly normal or whether it is partially due to subsequent action. A case in point is shown in Fig. 5, taken from the face of a tunnel in the Bering Lake district. Were it not for the broken condition of the sandstone inclosing the coal, as shown in this section, it might readily be assumed to be a normal occurrence.

Could a greater extent of the face be examined it is possible that the true condition of affairs might be readily determined. Under the circumstances the most natural conjecture is that the coal bed has been broken up and masses of the top and bottom rock have been forced into it, otherwise the jagged rock masses could not be explained.

Another peculiar occurrence belonging to the same class of irregularities as the last above mentioned is shown in Fig. 6.* There are several explanations of this irregularity worthy of consideration, namely, first, the end of a roll occurring next to the top rock has been forced into it; or second, that a fissure was formed by

Fig. 5. Face of Tunnel, Showing Coal and Broken Sandstone

rock movements and some foreign material has been forced into the coal bed between it and the top-rock. The occurrence of nodules of pyrite would tend to indicate a disturbance of the coal bed, thus permitting the percolation of water, which assumption is also strengthened by the broken condition of the coal itself.

Dikes and Sills

Action subsequent to the formation of the coal beds has been responsible for another interesting class of irregularities occurring in the coals of this field, namely, the occurrence of dikes and sills, produced by igneous

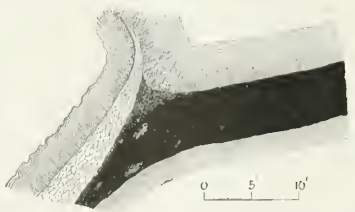

Fig. 6. Either a Contorted Clay Vein or a Filled Fissure from a Fold, Carbon Mountain

intrusions, following the line of fissures and planes of deposition.

Dikes may extend in any direction irrespective of the

*This illustration is taken from the article in this series published Mar. 22, Fig. 1A. All three sections A, B and C, differing widely in appearance as they do, were taken from the same side of the tunnel on Carbon Mountain at distances not exceeding 30 ft. apart along the line of the tunnel. However, this section occurs at right angles to the heading line being on a rib of coal where a room was turned off.

bedding planes, while with sills the rupturing force is not sufficiently intense to form fissures crossing the beds. They are able merely to follow the contact between the coal beds and the top and bottom formations.

Dikes and sills are of fairly frequent occurrence in this field, but the former are usually small. A number of sills of moderate size were observed, attention being given particularly to those associated with the coal beds. Both dikes and sills are composed of basalt and diabase and seldom exceed 3 or 4 ft. in width, although in one place, I observed a 20-ft. dike.

Two particularly interesting occurrences of diabase sills intruded into coal beds are to be found at the south end of Carbon Mountain and on Clear Creek, just below the falls, at an elevation of about 700 ft. In the first mentioned locality the coal has been changed wholly to coke, while in the other there are evidently two sills following the contact of the coal bed with both top and bottom rock. Only a few feet of the coal beds immediately

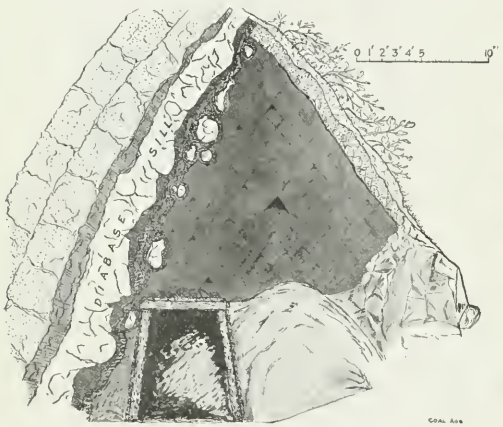

FIG. 7. OUTCROP OF COAL BED, SHOWING TOP ROCK, IGNEOUS SILL, NATURAL COKE, "BOMBS" AND COAL

adjacent to the sills, particularly the top one, have been altered and the transition from columnar coke to coal is clearly shown. A section of the coal bed, sills and associated formations is shown in Figs. 7 and 8.

In this section the massive sandstone strata are shown, immediately beneath which is some 6 in. of shale oxidized to a reddish color by the intense heat and considerably altered by being burned. Directly below the burned shale occurs the diabase sill, which ranges in thickness from 20 to 30 in., and directly below the sill is from 8 to 24 in. of natural coke. The occurrence of the coke is as follows: Columnar coke 4 to 18 in.; dense, hard coke, merging into a flaky form, 4 to 6 in., and at irregular intervals half-coked coal 1 to 6 inches.

Considerable labor was required to uncover the bottom-rock of this coal bed, which accomplished, gave 17 ft. 8 in. of coal and coke. A mass of diabase boulders was also uncovered, indicating that there had been an igneous intrusion along the bottom rock also. No coke was observed next to the lower sill, which is probably due to the extreme weathering action to which the bed had been subjected at this point, the coal even being reduced to a fine powder bordering on muck.

Numerous rounded masses of diabase varying in size from 4 to 18 in. occur along both the top and bottom of the coal bed, some of which are detached and entirely independent of the main body of the sill, while others are connected by stringers of varying size. These isolated masses of rock are in turn inclosed in layers of natural coke, which have approximately the same order as to form as was previously given in connection with the sills proper, but the coking action has extended less far.

SUMMARY OF IRREGULARITIES IN COAL

The detached masses or bombs constitute a great source of danger when considered from the standpoint of mining, having in this respect the nature of nodules of shale and pyrite.

Many minor irregularities occur in the coals of this field but they are insignificant when compared with those mentioned and they differ but little from coal troubles occuring in other fields.

While particular emphasis has been placed on the irregularities occurring in the Bering River field and on those which are peculiar to it in many respects, yet not

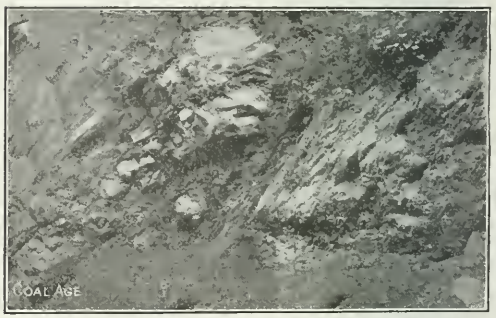

FIG. 8. OCCURRENCE OF DIABASE SILL BETWEEN TOP ROCK AND COAL. COLUMNAR COKE AND DETACHED MASSES OF SILL ARE SHOWN

all of the beds are troubled by every disturbance mentioned and many are apparently free from all irregular occurrences of a serious nature, except possibly shale partings and other impurities common to all coals.

There are, however, two conditions, which are in themselves irregularities strictly speaking, which are particularly troublesome in this field, namely, bad top formations and irregular and extensive fracturing of the coals or complex cleavage. Many of the coal beds have, however, excellent sandstone top-rock which will be a great assistance in mining the coal.

Coal in South Africa

An estimate of the coal resources of the Union of South Africa, based upon geological surveys, yet only approximate, places the aggregate quantity at 55 billion tons. Most of the coal, about 36 billion tons, it would appear, is in the Transvaal, while in Natal the given quantity is 9400 million tons. The remainder, equal to say 9600 million tons, is distributed among the other provinces. The Union produced over 7½ million tons in 1911.

Co-operation in the Coal Industry

By J. F. Callbreath

SYNOPSIS—The present law restricts efficiency as much as monopoly and therefore is being extensively evaded. The public should be protected against monopoly, only when those combining, seek to make an unreasonable profit. While the laws against producing and selling trusts are drastic, there is no law against buyers who conspire to obtain an unreasonable price. Conservation and safety are neglected where a corporation is losing money.

The Sherman anti-trust law was enacted for the purpose of preserving equal opportunities by means of unrestricted competition. Its purpose was laudable and there are many today, who still believe that in the end, it will accomplish the purpose for which it was designed. However, we must admit that since its enactment, the most far-reaching monopolies the world has ever known have been developed, enormous aggregations of capital have been amassed and, to an extent, through disregard of its provisions, the most marvelous industrial prosperity that the world has ever known, has been created.

Why have its provisions been violated? Because the law attempted to prevent efficiency as well as to destroy monopoly. Its prevention of monopoly, all will approve, but no system can be devised, no law can be enacted which can ever force intelligent men to choose cumbersome and unproductive methods.

The Anti-trust Laws Should Be Operative Only When Public Is Injured

It must be apparent that when a man with a small business investment is asked to compete with one having an operation involving an outlay of $1,000,000, he is told to perform a feat which is utterly impossible. Production upon a large scale is necessary if we would attain the highest efficiency. There is a magnitude in operation, however, beyond which the cost of production naturally and necessarily increases.

When this point is reached by a business, it naturally seeks, by control of transportation rates, by manipulation of the market, or some other unfair means, to make up the deficiency brought about by its more cumbersome machinery. At this point, the Sherman Law should begin to become effective. If it fails it creates a condition which absolutely drives out the small operator by competition, who, notwithstanding the efficiency of production, is unable to compete, in the market, because of the increased cost of sale and delivery.

Over-production has made exceedingly burdensome the increased cost of such safety appliances as are necessary for the protection of the miners. It has forced entire disregard for every principle of conservation. The Sherman Law has not prevented the aggregation of buyers, but it has debarred the small operator from joining hands in an effort to even up the advantages necessarily coming to large aggregations of capital.

In almost every other line of business, there are combinations, understandings or general agreements, by which cut-throat competition is avoided. In the bituminous coal-mining industry, the one industry upon which all others depend, the one which cannot close down, except with enormous loss, a most startling and dangerous condition exists.

Depreciation and Interest Charges Are Provided, Other Overhead Cost Is Not

In the latter part of 1911, our office sent out 2300 letters of inquiry to the various coal operators, with blank forms, asking for information, outlining the then condition of the business. A large number of replies were received. The information contained in these answers was tabulated, and upon the basis of information furnished, a paper was prepared by B. F. Bush, of St. Louis, Mo., and presented to the Chicago Convention of the American Mining Congress, by A. J. Moorehead, also of St. Louis, Mo.

This paper shows the average cost of producing bituminous coal at the mines, to be 95c. per ton, and that the average selling price, for a number of years was $1.11, leaving but 16c. per ton, to meet the cost of selling, accounting, insurance and taxes, legal expenses, interest upon investments, depreciation of property and exhaustion of resources, to say nothing of profit.

At the same convention, a paper was presented by James Douglas, of the Phelps-Dodge company, owners of the Copper Queen mine, in Arizona, which operates its own smelters, railroads and coal and coke plants. Doctor Douglas described one of the coal mines of his company, with 10,000 acres of coal land, with an uptodate plant designed for 40-years' operation, with a continuous demand for its product and no selling cost, and demonstrated that a sinking fund of 15.62c. per ton of production is necessary to meet the interest on the investment at 5 per cent., depreciation of plant and exhaustion of coal reserves. The Phelps-Dodge plant probably reaches the maximum of possible efficiency. The charge of 15.62c. must be greatly increased, to meet the cost of the same items for smaller plants with a limited acreage and designed for but a few years' operation.

The Possibility of Nation-wide Insolvency of Coal Interests

How many coal operators are there in the country who, after meeting their payroll, could have put aside a sinking fund of 15c. on each ton of coal produced during the last five years? There may be a few, but the number is small. The fact is, that the bituminous-coal industry is facing a critical situation and its danger menaces all lines of production in which the use of coal is a necessary factor. The bankruptcy of the coal business, with its investment estimated by Mr. Moorehead, at over a half billion dollars, will create a panic, the like of which has not been experienced since the days of '73.

This is the condition. What is the remedy? Co-operation, a joining of hands in a general effort to effect a greater economy in production and to protect the operator against the brutality of big buyers of coal, to the end that coal shall not be sold at a loss; to the end that

---

*Secretary American Mining Congress, 602 Munsey Building, Washington, D. C.

Note—Address delivered at the fourth annual banquet of the Southern Appalachian Coal Operators' Association, Knoxville, Tenn., Feb. 11, 1913.

coal buyers may, at all times, be able to do business with going concerns and not with referees in bankruptcy, to the end that the small consumer of coal in the future will not be obliged to pay back the losses now being made to enable the big consumer to scalp the small producer.

The Bill for a Regulation of the Coal Industry

To meet this situation, a bill has been prepared, providing for the creation by Congress, of an Interstate Trade Commission, with powers similar to those exercised by the Interstate Commerce Commission, over transportation companies.

By the provisions of this bill, the commission is authorized to consider and pass upon all existing or proposed trade combinations and to issue a permit to all those whose purposes are fair and reasonable and which will not result in monopoly.

The Effectiveness of Restraint

It makes possible the highest and most beneficial cooperation for the betterment of any industry and, at the same time, provides a most wholesome check upon monopoly. Senator Clapp, chairman of the Senate Committee on Interstate Commerce, said to me: "When you will show me how it is possible to open the stable door and still have it closed, or, having it closed, may at the same time have it open, I will understand how what you want can be accomplished."

My reply was this: "Between the stable and the garden is a plot of grass going to waste, and needing to be cropped; in the stable is a horse suffering for want of this grass, I am going to put a halter on that horse, give you the end of the halter strap and allow you to supervise the grazing and whenever the horse attempts to go over into the garden, you can pull him back and, if he persists you can put him back in the stable."

The coal operators should demand:

1st. That the lives of the mine workers shall be given the best possible protection.

2d. That the operators shall have a fair profit.

3d. That the public shall have its coal at the lowest price consistent with economical production expenses and a reasonable profit.

4th. That unnecessary waste of coal resources shall be prevented.

A Storage and Reclaiming Machine

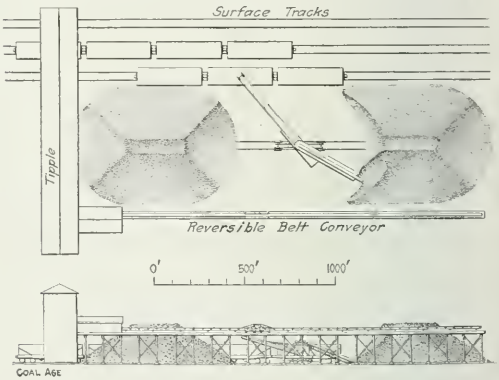
In common practice, coal as soon as mined goes directly to the tipples, over the screens and into railroad cars. If none of the latter are to be had the mine must shut down. It is apparently impossible for the railroads to furnish at all times cars in sufficient numbers to meet the rated capacity of all the mines tributary to them.

Frequently, also, operations are halted because there is no means of disposing of such grades as nut and slack, even though bins or bunkers of a limited capacity have been provided. But from whatever cause the shut-down may arise, it is certain to prove not only expensive in dollars and cents, but highly demoralizing in its effect upon the operating organization.

To overcome these difficulties, to a certain extent at least, the Jeffrey-Hamilton storage and reclaiming machine has been placed on the market by the Jeffrey Manufacturing Co., of Columbus, Ohio. This machine is self-contained, combines the elasticity of the locomotive crane with the reach of a traveling bridge, is without the limitations of either, and with a conveyor, gives a capacity and speed superior to both, dispensing with the crushing clamshell, or grab bucket, and the rough handling of coal incident to their use.

Storage capacity is limited only by the ground space available. The coal yard may be from 50 to 150 ft. in width, and of any length desired. The standard-gage machine takes care of a yard 70 ft. wide, which with coal piled 20 ft. high, contains 30 tons per each foot of its length. The same equipment stores a thousand tons, or a hundred thousand tons, and at a lower cost than any other mechanical method now in use.

If the storage yard can be located with one end near the mine tipple, run-of-mine coal may be conveyed to the machine from a chute beneath the weigh-box. When cars are available, the machine reloads the coal from the stock pile into the same conveyor, which, when reversed,



Storage and Reclaiming Machine in Conjunction with a Belt Conveyor

discharges directly onto the tipple screen. In reclaiming nut coal and other sizes which do not require rescreening, the machine handles coal from the storage pile and delivers it directly into the railroad cars.

As the machine can be operated so that the coal does not roll down from the apex of the pile, does not avalanche or slide in massed quantities, its employment causes less breakage than any other method. The coal is gently handled by the rubber-belt delivery conveyor and placed without fall immediately in its permanent position. It is not disturbed by continued operation of the machine and does not move until reclaimed for shipment.

The demand for coal constantly fluctuates. The mine which has, say, ten thousand tons in stock that can be shipped immediately (being loaded out at the rate of a ton per minute), will frequently be able to secure orders which otherwise would be lost. During the summer season, when trade is dull and prices are low, men are more plentiful and production is easier. By then accumulating a stored surplus at a minimum cost, the operator prepares for the season of rush orders and best prices; since this machine can be equipped with a screen to make one separation, as the coal is loaded directly into the car the reclaimed material will go to market in the best condition.

In addition to the benefits heretofore mentioned, both the operators and the railroad companies will appreciate relief from the constant controversies over the distribution of empties, and better car service may be thus secured.

EDITORIALS

Mining Legislation in British Columbia

Two important mining bills have recently been introduced into the British Columbia legislature, providing, respectively, for the inspection of mines by persons appointed for that purpose by the employees of the mine, and prvoiding for a minimum wage in coal mines.

The bill providing for the inspection of mines by mine workers, Bill No. 47, introduced by Mr. Place, is entitled "An Act to Amend the Coal Mines Regulation Act," and is as follows:

His Majesty, by and with the advice and consent of the legislative assembly of the province of British Columbia, enacts as follows:

1. This act may be cited as the "Coal-Mines Regulation Act Amendment Act, 1913."

2. The "Coal-Mines Regulation Act," being Chapter 160 of the "Revised Statutes of British Columbia, 1911," is hereby amended by striking out Rule 37 of Section 91, and reënacting the following in lieu thereof:

Rule 37. The persons employed in a mine may from time to time appoint two competent persons to inspect the mine at their own cost, and the persons so appointed shall be allowed, once or oftener in every shift, day, week, or month, accompanied, if the owner, agent, or manager of the mine thinks fit, by himself or one or more officials of the mine, to go to every part of the mine, and to inspect the shafts, levels, planes, working places, return airways, ventilating apparatus, old workings, and machinery, and shall be afforded by the owner, agent, and manager, and all persons in the mine, every facility for the purpose of such inspection, and shall make a true report of the result of such inspection; and such report shall be recorded in a book to be kept at the mine for the purpose, and shall be signed by the persons who made the same. And if the report state the existence or apprehended existence of any danger, the person or persons making the inspection shall forthwith cause a true copy of the report to be sent to the inspector of mines for the district: Provided always that where the miners in any mine fail to appoint two competent persons to inspect the mine, the chief inspector of mines shall select from the men, in alphabetical order where possible, two competent miners, who shall comply with the provisions of this section, and the said owner, agent, or manager may withhold from the wages of the underground employees a sufficient sum pro rata to remunerate the persons making such examination.

The Minimum Wage Act, Bill No. 18, introduced by Mr. Williams, is entitled "An Act to Establish a Minimum Wage in Coal Mines," and reads as follows:

His Majesty, by and with the advice and consent of the legislative assembly of the province of British Columbia, enacts as follows:

1. This act may be cited as the "Minimum Wages Act."

2. Every adult person working underground in any coal mine shall be paid a wage of not less than $3 per day.

3. No contract shall be entered into that provides for the payment of a wage less than herein specified. Provided always that contracts entered into previous to the passing of this act shall be of full force and effect.

4. Any employer who employs any person in contravention of this act may be enjoined therefor, and shall also be liable to prosecution under the "Summary Convictions Act" and amending acts before two justices of the peace or a police magistrate; and upon conviction for such offense shall be liable to a penalty or fine not exceeding $100 nor less than $10 in each instance.

5. This act shall come into force upon the first day of May, 1914

These acts now before the Canadian assembly are in strong contrast with the acts presented to legislative bodies in many of the mining states, in our own country. We have in mind, at present, a number of conflicting acts that have been presented to the Pennsylvania legislature and are now awaiting their action. These acts are so numerous and embody such a variety of views and opinions in relation to mining conditions and requirements in the state, that the situation can only be described as wild and chaotic.

The mass of mining bills now before the legislature or in the hands of the committee on Mines and Mining, has been referred to, by one of the oldest and best informed mining men in the state, as a "crazy quilt." It yet remains to be seen which of these bills and how many will ever get beyond the committee, and be presented to the legislature for their action. Little is to be expected that will improve mining conditions in that state, in the present session of the Pennsylvania legislature; unless, by a miracle, the House and Senate approve of the report of the commission charged with the revision of the anthracite code. That commission has presented two reports some time since—one a majority report, File of the Senate, No. 656; and the other a minority report, File of the senate, No. 657. The former of these bills was amended in a few slight particulars by the committee, Apr. 1.

*

"Red Tape in the Geological Survey"

In the department "Discussion by Readers" in this issue, appears a reply from Director Smith, of the U. S. Geol. Survey, to a previous editorial on this subject. We publish Mr. Smith's remarks with the belief that some of the information contained therein will be an agreeable surprise to many American engineers. We quite agree with him that doing business under an inflexible appropriation is a serious handicap, although as a matter of fact much of the construction work of the country is done under such restrictions, as most any engineer can testify. But this question has been discussed at such length that further comments along this line would be superfluous. To our mind, it is not so much a question of how the appropriations are made, or of the amount, but of the most effective way of applying them.

No complaint is evident in our editorial, because of the fact that certain sheets are occasionally out of print, as Mr. Smith seems to infer. Furthermore, we wish to congratulate the Director on the fact that, of the 2200 sheets now in existence, only eight of these are, at the moment, out of print. It is incidentally interesting to know the reason thereof.

On the matter of substitution of maps, when the same are out of stock, we grant that the Director has offered some extenuating circumstances in this connection, but we still maintain that our comparison is a fair one. There can be nothing more exasperating to an engineer than to order a map covering a particular district, and receive one which only shows the territory immediately adjoining that in which he is interested. We repeat: "Engineers generally know what they want and resent this apparently indifferent attention to their requests." It would be more satisfactory to them to know when they can get the map they want, than to be surfeited with others in which they probably have no interest whatever.

In reply to the Director's anxiety to see that those ordering maps obtain the advantage of the wholesale rate, we would suggest that this could be accomplished easily by adopting some method of coupon books; the books could be bought at the wholesale rate and the coupons torn out and sent in as the maps were ordered. This would also eliminate the uncertainty of sending cash ("the exact amount") by mail, as is always specified in the instructions for ordering maps.

We do not think Mr. Smith is justified in reminding us of the fact that no "firm" sells maps worth from one to three dollars at ten cents each. When we said: "The high excellence of the government publications, and particularly its maps, is too well known to require comment," we believed we were paying the Survey a high compliment, and if these maps are selling at far below the cost of manufacture, the people of the United States are standing the loss, and it is assuredly no cause for self-complacency on the part of Mr. Smith or the Geological Survey.

That it is possible for engineers to wire the Survey for maps is a revelation to us, and if such is the case, we certainly feel that we owe an apology in this instance. Obviously, however, this was far from being generally known to engineers throughout the country, and we are sure that now it has been brought to light, there will be many who will avail themselves of this new convenience.

Mr. Smith's figures of the number of maps handled per day are most interesting. Furthermore, the extra rush occasioned by the change in the prices of the maps seems a good explanation for the excessive delay of eight days in getting maps from New York. Engineers generally, however, are of the opinion that the Survey has always been rather lax in this respect, and we do not see why even 24 hours, and surely not 48 hours should elapse before an order is filled.

We think the Director has either misunderstood or evaded our point in regard to estimates of the probable time that reports will be issued. We know that the Survey occasionally publishes announcements of the "probable" date of issue for certain reports. However, what we referred to more particularly was a specific personal inquiry regarding a certain report or map. Unless such could be answered on one of the blank forms of the Geological Survey, we still contend that it would be ignored. If a certain report that an engineer has been patiently waiting for, month after month, is hopelessly buried in a mass of other matter and possibly will not appear for a year or two, it would surely be a relief to him to know that such is the case.

The Unearned Increment

The public has seen coal lands rise in price continuously, has watched coal territory advance in value from 66c to over $1000 per acre, and wonders if the people as a nation cannot enjoy the profits which have fallen to some of the people as individuals. The thought is natural, the purpose is patriotic, and if it is practical and fair to the states in which public lands are still found, it is to be commended.

But we must not be blind to the nature of those increments in values or to the examples we see daily where the increase failed to accrue, where large land holders comparable in a degree to the United States Government failed utterly to get profits per acre in any way comparable to those of the small holder.

In a small boom town, a millionaire held his lots at $600 per acre; another land holder charged $100 or $200 for properties of slightly less value. Today the lots which sold for the smaller price are held for far more than those of the millionaire, for a thriving town has been built on the cheaper lots and competition has raised their value immensely. On the other hand, the millionaire's lands still serve merely for the grazing of cattle.

Increment is not always unearned. When a coal company has made a market for its coal, despite opposition, and at great expense, the value of its property rises. The company has demonstrated the ability of the fuel to fill the needs of the market. Having shown the character of the bed and the popularity of its output, all the neighboring lands become of greater value.

Still more important increments arise when new industries are started owing to the availability of fuel, and when railroads are built which provide for its transference to market. Thus the demand constantly grows and the value of the fuel in the bed augments.

But there are other causes for increase. The new industries attract people to the field and the customers in the market learn of the new coal region. The coal is its own constant advertisement and it is not long before the holdings pass into the hands of the new arrivals in the field, the users of the coal, or of the jobbers who have learned its value.

The American public shuts its eyes to these facts and believes like some purblind millionaires that coal land of a certain quality should be worth as much as coal territory of the same character elsewhere. They forget that increment demands time for attainment. It is indeed a growth.

The publications of the U. S. Geological Survey, unaccompanied by drillings, cannot give the purchaser of coal land an assurance of profit such as he would have if he saw a department of the coal industry doing a successful business. The excellent but unappealing bulletins of the Geological Survey do not travel into every part of the country like cars of coal. Moreover they can never appeal to the untechnical as can the coal itself, in use or for sale and, needless to say, the Bureau of Publications does not provide the railroads for the marketing of the product which its bulletins describe.

To rely on these bulletins, therefore, to raise the price of coal lands to the fancy figures placed on coal territory by the Department of the Interior is to put a padlock on the states in which coal is found, to restrict their future, and to deprive them of their rights. The intentions of the British Parliament, in those days of lesser enlightenment before the revolution, in suppressing the American iron trade may have been animated by less exalted purposes but did not result in any greater hardship than is entailed by the desire of the Interior Department to acquire an increment which it has not earned and for which it has not waited.

Even if coal land should be sold at the price for which the department haggles, in a few years, it will be still more valuable and the increment will go to the owner because increases in value are products of somebody's use if not of the use of all those who benefit by the increment.

EXAMINATION QUESTIONS

Mine Inspector's Examination, Held at Pittsburgh, Penn., April 1-4, 1913

(*Selected Questions*)

Ques.—(a) Define the term manometric efficiency, as relating to fans. (b) What is the manometric efficiency of a fan producing 2.7 in. water gage, the blowing-in pressure being 2.4 lb. per sq.ft. and the blowing-out pressure 5.5 lb. per sq.ft.?

Ans.—The manometric efficiency of a fan is the ratio of the actual pressure on the air, as indicated by the water gage in the fan drift, to the theoretical pressure or water gage, which, in this case, is represented by the sum of the mine pressure and the blowing-in and blowing-out pressures of the fan, assuming these can be obtained or are known. The mine pressure corresponding to a water gage of 2.7 in. is $2.7 \times 5.2 = 14.04$ lb. per sq.ft. The manometric efficiency is then

$$K_m = \frac{100 \times 14.04}{14.04 + 2.4 + 5.5} = \frac{14.04}{21.94} = 64\%, \textit{ nearly}$$

[N. B.—This is not a practical question, for the reason that it is impossible, practically, to obtain the blowing-in and blowing-out pressures of the fan and these must be assumed.—Ed.]

Ques.—At a certain mine, the temperature of the inlet is 38 deg., and that of the outlet 62 deg. F.; the mine resistance is equal to 15 lb. per sq.ft., and the atmospheric pressure, 14.7 lb. per sq.in. The quantity of air entering the mine is 100,000 cu.ft. per min., and the return-air current is found to contain 4 per cent. of marsh gas. Please state: (a) What quantity of marsh gas is given off in this mine? (b) What is the least amount of decrease in the quantity of air that will render the return air explosive? (c) What increase of gas will render the return air explosive?

Ans.—The intake air, in this case, is expanded in two ways: First, by the increase of temperature from 38 deg. to 62 deg. F.; and, second, by the decrease of pressure, 15 lb. per sq.ft., on the return airway. The expansion due to the increase of temperature is

$$100{,}000 \times \frac{460 + 62}{460 + 38} = \frac{100{,}000 \times 522}{498}$$

$$= 104{,}820 \textit{ cu.ft. nearly}$$

This air is again expanded by the decrease of pressure. Assuming the fan is blowing air into the mine against a mine resistance equal to 15 lb. per sq.ft., the absolute pressure on the intake is $14.7 \times 144 + 15 = 2131.8$ lb. per sq.ft. The pressure on the return air, in this case, is the atmospheric pressure, $14.7 \times 144 = 2116.8$ lb. per sq.ft. The ratio of expansion is equal to the inverse ratio of the absolute pressure; and the expanded volume is therefore

$$104{,}820 \times \frac{2131.8}{2116.8} = 105{,}562 \textit{ cu.ft. (air)}$$

(a) If the return current contains 4 per cent. of marsh gas, there is $100 - 4 = 96$ per cent. of air. In that case, the total volume of air and gas on the return airway is $105{,}562 \div 0.96 = 109{,}960$ cu.ft. per min. Subtracting from this the expanded volume of the return air gives, for the gas generated in the mine, $109{,}960 - 105{,}562 = 4398$ cu.ft. per min.

(b) Assuming the lower explosive limit is reached when the mixture of gas and air contains 7.14 per cent. of marsh gas, $4398 = 7.14$ per cent.; and the total volume of gas and air is then $4398 \div 0.0714 = 61{,}596$ cu.ft. Subtracting this result from the volume of gas and air previously found gives, for the decrease of air necessary to make the return current explosive, $109{,}960 - 61{,}596 = 48{,}364$ cu.ft.

(c) Again, assuming the mixture first becomes explosive when there is 7.14 per cent. of gas present, the proportion of air is $100 - 7.14 = 92.86$ per cent. Then, dividing the expanded volume of air on the return current by this percentage, the total volume of air and gas, at the lower explosive limit, is $105{,}562 \div 0.9286 = 113{,}678$ cu.ft. Now, subtracting from this the volume of gas and air previously found, the quantity of gas necessary to be added, to make the mixture explosive is $113{,}678 - 109{,}960 = 3718$ cu.ft. per min.

Ques.—Twenty-five loaded cars weigh 4600 lb. each; the length of the engine plane is 6000 ft., the weight of the rope, 1.2 lb. per ft., and the grade of the incline, 5 per cent. Find the tension on the rope and the horsepower of the engine required to hoist this trip at a speed of 13 miles per hour.

Ans.—The weight of the loaded trip is $25 \times 4600 = 115{,}000$ lb.; the weight of the rope, $6000 \times 1.2 = 7200$ lb., which makes the total load hoisted, when the trip is at the bottom of the incline, $115{,}000 + 7200 = 122{,}200$ lb.

Calling the angle of inclination a; $\tan a = 0.05$; $a = 2° 34'$. The tension or pull on the rope is equal to the sum of the gravity pull and the friction pull; thus,

Gravity pull $= 122{,}200 \times \sin 2° 34'$
$= 122{,}200 \times 0.04424 = 5{,}405$ lb.

Friction pull $= \frac{1}{10}(122{,}200 \times \cos 2° 34')$
$= \frac{1}{10}(122{,}200 \times 0.99911) = 12{,}209$ lb.

Total pull on rope ..... 17,614 lb.

A speed of 13 miles per hour is $13 \times 5280 \div 60 = 1144$ ft. per min. The horsepower of the engine required to draw this load up the incline at the given speed is then

$$H = \frac{17{,}614 \times 1144}{33{,}000} = 180 + hp.$$

Ques.—What are the chief points to be considered in establishing and maintaining substantial and reliable ventilation in bituminous coal mines?

Ans.—Equip the mine with a well-designed centrifugal ventilator of sufficient power and capacity to supply the required air at the necessary water gage and built reversible. Plan the mine with regard to proper ventilation, drainage and haulage. Build substantial, air-tight stoppings, doors, air bridges and brattices and split the air to give a moderate velocity sweeping all working faces.

DISCUSSION BY READERS

Education in Coal Mining

Letter No. 1—The practical and theoretical education of the miner, in its broadest scope and in its relation to the manner of conducting state mining examinations, is one of the most important questions in present-day mining. I may say frankly that I do not favor giving candidates, in examinations, textbooks or helps of any kind, other than the necessary paper, pencil, rubber, rule, protractor and all the scrap paper they want.

Because there are intelligent men in the mine who did not have the advantages of an education in their early days and who now realize what they have missed and desire to make a short cut to secure their papers, is no reason for making the examination easier or more simple. It would not be fair to one who has made good use of his time, to discount his efforts for the sake of those who are handicapped for lack of early training.

In my opinion, there are few men now in the mines who are capable of studying and who started to work before they were 12 years of age. Recent mining legislation prohibits boys under 14 and 16 years old from working in the mines. The aim of legislation today is to give every boy a chance to educate himself, and after so much has been accomplished in this regard, it is no time to raise the cry to allow the use of textbooks in examinations. Would it not be lowering the standard of the examination to suit them to the needs of those who have not had an early education. If we have missed our opportunities we alone are the losers.

The rapid advance in coal mining, requiring larger and deeper shafts and improved machinery to handle the increased output has brought increased responsibilities for the men in charge, and these increased responsibilities should require greater knowledge on the part of mine officials. There are men in my own district in charge of first-class mines, who could not successfully pass a state examination, but I believe if these men had had the facilities offered them today, to secure a technical education in coal mining, they would have made good and have secured their certificates in the regular way.

But, denying the use of textbooks in examinations, the question arises, what can be done to help those miners who did not enjoy early advantages. I answer, teach them in a way they can understand and that will be interesting, so that they will have a desire to learn. Let the desire for knowledge supplant the desire to pass an examination. It is often discouraging to have men ask the way to work a problem or to answer a question, for the sole purpose of enabling them to pass a coming examination. They expect to obtain their certificates by a few weeks', instead of a few years' study. The question we must answer is: Which is the best for the advancement of coal mining—to lower the standard of the examination or bring these men up to that standard? I would say, lift the men to the higher level.

In dealing with this question of education, can we do better than follow the example of Great Britain and establish schools in every county, where workingmen can secure the needed education. Those who have no chance in early life, let them take ordinary school subjects on certain nights and other more practical subjects other nights. In such schools, in Great Britain, the men study coal mining, surveying, geology, machine construction and drawing, mechanics, mathematics, etc. These subjects are taught every year, in some districts, at a nominal cost, only sufficient to pay for the gas and coal and varying from 25 to 60c. a subject, for the whole term extending from September to April or May. Good teachers are employed. My experience has been that good education at low cost does not overcrowd the school. I remember not over 30 were in attendance regularly, in my home town of 4000 coal miners.

There is a crying need, in this country today, for the education of miners, in technical subjects. The knowledge must be conveyed in an interesting way that is simple to understand and that will develop a love for study. This can only be done by beginning in a simple way, coming down to the level of the student and helping him to rise, step by step. In this way, the ventilation formulas become simple, if the student is first acquainted with the rules and principles of arithmetic, by which he can work out his own formulas and not be obliged to carry them in his head. The same is true in calculations on pumps and steam engines.

The Study Course in Coal Mining just commenced in COAL AGE, is a good start in the right direction; but to get the best results one must attend a school where a teacher can help and explain what is not understood. I enjoyed reading in COAL AGE, Jan. 18, p. 107, how Thomas Thomas, of the Lehigh Valley Coal Co., overcame difficulties and got his education. Just a few weeks ago I met one of the mine examiners (firebosses) in my district, who was going to high school, studying during the day mathematics and physics and examining the mines for gas at night. It is my hope that textbooks will never be allowed in Illinois, in mining examinations, but that the high standard of the examination will be maintained so that one who passes successfully can look upon his certificate with pride, because it was honestly earned without any artificial aid at the examination.

State Mine Inspector, 8th District.
East St. Louis, Ill.

Post Timbering at the Working Face

Letter No. 13—The question of post timbering at the working face is important, and its discussion in COAL AGE cannot help but result in great benefit to both mine officials and miners. Firedamp and coal dust are often regarded as the greatest evils in coal mining. All statistics, however, prove this conclusion to be in error. The second annual report of the director of the Bureau of Mines, 1912, gives the loss of life, due to falls of coal and roof, as 1310 in 1910 and 1321 in 1911.

According to the report of the engineers of the Bureau of Mines, the immediate cause of this class of accidents is the delay or failure, on the part of miners, to place sufficient timbers. The reports of the Pennsylvania mine inspectors, for a period of 33 years, show that 59.38 per cent. of all the accidents underground was caused by falls of roof and coal. The report for 1910 shows 63 per cent. of all underground accidents due to this cause. The subject, however, is important not only as a question of safety but as a matter of economy, since the cost of mine timber in many localities makes this the heaviest item in the operating expenses of the mine.

In considering post timber, one of the first requisites is the elasticity of the wood. A good mine post is one that will bend and still retain its efficiency to support the loose fragments of roof, before finally breaking under the maximum pressure. All experienced miners know that the maximum roof pressure is irresistible and that it would be foolish to try to resist such a pressure with timber. The use of dry, brittle timber, in mines, is often the cause of serious accidents, because such timber is broken instantaneously without bending and the roof falls without a moment's warning. A good mine post, by bending, gives the miner warning that danger is imminent and he must either set other timber or seek a place of safety. In this locality, the pine wood of which the Douglas, or red fur, is a specie, will meet these requirements.

Another important point is the thickness of the seam. I consider it a good rule to adopt to make the diameter of the post proportional to its length, other conditions being equal. However, some mine posts are better seasoned and more sound, not being infested with vermin or containing knots. A knot, of course, may upset all calculations of the strength of a mine post, but the rule nevertheless is a good one for general application. The rule that the strength of a mine prop varies as the ratio of the square of the diameter to its length has reference only to the bending strength of the post. The rule first given provides equal resistance to crushing and bending.

Again, it is important to consider the essential principles of timbering. The first of these is to *timber in time.* Never judge of the roof ahead by that exposed to view. The roof ahead is an unknown quantity and may at any moment so change in character from that overhead as to present new dangers. It is a common thing for a stone to fall out of the roof, or for an unsuspected slip to draw back from over the face of the coal in such a manner as to leave the roof suddenly unsupported over the miner. The only safe rule to adopt is: Trust no roof further than is absolutely necessary.

Another essential point is to timber in the line of pressure. In a flat seam, the line of pressure is vertical and posts must be set perpendicular to the roof and floor. In a pitching seam, owing to the tendency of the roof to slide downhill, it is necessary that the posts should be "underset" from 1 to 9 deg., depending on the inclination of the seam. Any slip of the roof downhill will then tighten the post. In every case, post timbers should be set with a "lid" or cap-piece, which should be from 3 to 4 in. thick and at least 3 in. wider than the prop. The length of the cap-piece must be governed by the nature of the roof, but should never be less than 18 in. The cap is a very essential part of the mine prop, as, when the roof "weights," the head of the post sinks into the soft wood of the cap, which then acts as a hoop to bind together the fibers of the post and prevent its splitting.

I believe that the miner should be held personally responsible for the safety of his own place. In this way alone can the coöperation of the miners be secured, for their own safety. To obtain this coöperation is more important than reprimanding the men or imposing penalties for neglect in this regard. It is the duty of every miner, on entering his place, to examine the roof carefully before proceeding to work. If the roof is dangerous, he must secure it in such a manner as to make it safe or come out and fence off the place. A failure to do this is an offence against the Coal Mine Regulation Act. A miner violating this act should be prosecuted and there should be no mistaken sympathy that will prevent such action being promptly taken when required.

Coalmont, B. C.,Canada.

"Red Tape in the Geological Survey"

In connection with the editorial in your issue of Mar. 8—"Red Tape in the Geological Survey"—I may be pardoned for making some comment. There are certain restrictions and limitations in probably all government bureaus which are not appreciated by outside business men who come in contact with them. One of these is the hard and fast, and often restricted, appropriations under which the bureaus must work.

You complain that the topographic maps of the Geological Survey are sometimes reported out of stock. Owing to the inadequate appropriation available for map engraving and printing, not only is new map-engraving work considerably in arrears, but there is involved a tremendous pressure on the engraving division to keep on hand the 2200 topographic sheets which now represent the Survey stock. Furthermore, certain sheets must be at times reported out of stock for the reason that they are being revised and brought uptodate, and with a new issue in sight it is not considered advisable to print the obsolete map. There are at the present time, for these reasons, eight sheets out of stock. In cases where a map is soon to be issued or reprinted, an estimate is given to the correspondent as to the probable date.

You further complain that in filling an order for topographic maps, substitution is sometimes made and that such a procedure would not be contemplated by any editor of a magazine in sending the number immediately preceding or following, in place of the one asked for. I do not consider the comparison a fair one, for the cases are not exactly parallel. You will note that the explanation on the map index, which serves as the public's guide in ordering these maps, states that small substitutions will be made by the Survey; that is, rather than return the 10c. or 20c. remitted with an order for maps, where one or two sheets are out of stock, substitution of sheets covering adjacent territory will be made. The substitution of a map adjoining the one of the area required is apt to be of more service than the issue of a magazine preceding the one which you may order. *If, however, such map substitution is not desired and the correspondent so states in his order, substitutions are not made.*

Furthermore, these substitutions of one or two maps are frequently made strictly in the interest of the re-

mitter, in order to give him the benefit of the wholesale rate. For example, if he remits $3 for 50 maps (the minimum amount which will give him the benefit of the wholesale rate) and two of these are out of stock or have not been published, substitutions are made for the purpose of bringing the order up to the required number, for if the purchase was for 48 maps the price instead of $3 would be $4.80.

I would call attention further to the fact that no "firm" sells for 10c. each, maps worth from $1 to $5 and in fact costing that, if the actual expenditure in field surveys, office editing, and engraving and printing are all included. The Geological Survey does not *substitute* in the case of its book publications, such as the monographs, which are sold at the higher prices.

You further remark that unless one has connections in Washington, to whom he can wire for a map, in case of urgent need, he is sure to be disappointed. My answer to this is that the Survey is in frequent receipt of telegrams from engineers and others requesting maps sent and such requests receive the immediate attention they deserve.

The aim of the Geological Survey is to handle its distribution of publications—maps and reports—on as nearly a business basis as possible. I believe some progress is being made. Ordinary orders for topographic maps, which do not involve some especially difficult conditions, are filled within 48 and many of them within 24 hours. Some of the larger orders require longer to complete because of the time required to assemble from among the 2200 racks in which the stock is stored. During the past winter, due to the numerous misunderstandings, or account of the increase in the price of the maps and because of the receipt of a great number of very large orders, placed during the last two months of the year for the purpose of taking advantage of the old rate, there have been more instances of delay than usual. The normal sale distribution by the Survey of its topographic maps is over 2000 a day.

Concerning your complaint that questions as to when certain reports will be issued are ignored, it is the Survey's practice to give estimates to the public of the issuance of reports whenever it is possible to forecast with any degree of certainty the probable date of such issue. In this matter, however, the state of the appropriation for printing and binding is frequently the controlling factor. The Geological Survey has at the present time sufficient manuscripts of scientific reports, practically ready for printing, to consume a printing fund approximately twice the amount appropriated for the current year. To forecast when these reports will be printed would be worse than guessing.

GEO. OTIS SMITH, Director.

Washington, D. C.

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

FLOW OF AIR IN AIRWAYS

The flow of air in a conduit or airway is in obedience to an excess of pressure at one end of the conduit over that at the other end. Air always moves from a point of higher pressure toward a point of lower pressure. The moving air is called the air current.

Velocity of Air Currents—The rate of motion or the distance traveled per unit of time is called the velocity of the air current. The velocity is commonly expressed in feet per second or feet per minute, as most convenient.

Relation of Pressure and Velocity—To double the velocity of air in an airway or conduit requires four times the pressure; and since $2 = \sqrt{4}$, the velocity v varies as the square root of the pressure p; thus

$$v \text{ varies as } \sqrt{p}$$

or, vice versa,

$$p \text{ varies as } v^2$$

For example, if an airway in a mine is of such size and length that the presure per square foot at the intake is 3 lb. greater than that at the discharge opening and this difference of pressure produces a velocity of 5000 ft. per min.; it will require a difference of pressure of $4 \times 3 = 12$ lb. per sq.ft. to produce a velocity of 1000 ft. per min. in the same airway.

Solution by Ratios—Expressed as ratios, the solution is always simpler and shorter, because the method admits of ready cancellation, thereby keeping the numbers small and reducing the amount of necessary work. For example, when quantities are proportional their ratios are equal. Or, in this case, the velocity ratio is equal to the square root of the pressure ratio. Calling the first velocity v_1 second velocity v_2; the first pressure p_1 and the second pressure p_2 we have

$$\frac{v_2}{v_1} = \sqrt{\frac{p_2}{p_1}}$$

or, vice versa,

$$\frac{p_2}{p_1} = \left(\frac{v_2}{v_1}\right)^2$$

Example—What difference of pressure per square foot will be required to produce a velocity of 1200 ft. per min. in an airway where the air is moving at the rate of 500 ft. per min., under a moving pressure of 3.5 lb. per sq.ft.?

Solution—Let x = the required difference of pressure; then

$$\frac{x}{3.5} = \left(\frac{1200}{500}\right)^2 = \left(\frac{12}{5}\right)^2 = \frac{144}{25}$$

$$x = \frac{3.5 \times 144}{25} = \frac{0.7 \times 144}{5} = 20.16 \text{ lb. per sq. ft.}$$

The Coal Age Pocket Book

Resistance of Airways—The resistance that an airway offers to the passage of air is of two kinds: frictional resistance due to the rubbing of the air on the inner surface of the airway, and the resistance due to the air striking against obstructions such as timbers, roof falls, sharp bends, etc.

How Resistance Varies—In mine ventilation, the entire resistance of airways is rated on a frictional basis, according to the extent of rubbing surface and the velocity of the air. It is assumed that when the velocity of the air current is doubled, each resisting particle in the airway is struck twice as often and twice as hard, by the passing air, which makes the resistance offered by each particle $2 \times 2 = 4$ times as great as before. If the velocity is increased three times, the resistance of each particle is increased $3 \times 3 = 9$ times, etc. On this assumption, the resistance of an airway varies as the extent of rubbing surface (s) and the square of the velocity ($v \times v = v^2$), or as the expression $s\,v^2$ for that airway.

Unit Resistance or Coefficient of Friction—The amount of resistance, per unit of rubbing surface (1 sq.ft.), for a unit velocity (1 ft. per min.) is called the unit of resistance or the coefficient of friction. The values most commonly adopted for this unit are

$k = 0.00000002$ *lb.* (Atkinson, revised)

$k = 0.00000001$ *lb.* (Fairley)

Calculation of Resistance of Airways—To find the resistance of an airway, for any given velocity, multiply the unit resistance (k) by the rubbing surface in square feet (s), and that product by the square of the velocity in feet per minute (v^2); the final product will be the total resistance (R), in pounds, as expressed by the formula

$$R = k\,s\,v^2$$

Example—Find the resistance of an airway having 60,000 sq ft. of rubbing surface, when the velocity of the air current is 800 ft. per min.

Solution—The resistance, in this case, is

$$R = 0.00000002 \times 60{,}000 \times 800^2 = 768 \text{ lb.}$$

Ventilating Pressure—The ventilating pressure is the total pressure exerted on the entire sectional area of the airway, to move the air or produce an air current. If the sectional area of an airway is $a = 50$ sq.ft., and the pressure created by the ventilating fan is $p = 8$ lb. per sq.ft., the total pressure on the air is $p\,a = 8 \times 50 = 400$ lb.

Unit of Ventilating Pressure—The pressure exerted on 1 sq.ft. of the sectional area of an airway, or the pressure per square foot on the air is the unit of ventilating pressure, often called the unit pressure (p). In speaking of ventilating pressure or the "pressure on the air," either the total or unit pressure, it is the excess of pressure in the intake over that in the return or the gage pressure that is meant.

Absolute Pressure—The absolute pressure is the actual pressure supported by the air; or the atmospheric pressure plus the gage pressure when the ventilating fan is blowing, and minus the gage pressure when exhausting.

SOCIOLOGICAL DEPARTMENT

The Half-Time System

The two documents following are half-time contracts, such as have created so much attention in Great Britain and in certain towns, notably Cincinnati, in the United States. We present them because we feel that they can be easily rendered applicable to mining needs.

The boy of 14 has a taste for labor. He is anxious to be regarded as a man. He soon tires of his new work and indeed it is, at first, quite exhausting, and he needs an occasional release from the hard grind. A day at school reinvigorates him. Thus he is better fitted physically for his daily work and is week by week growing more efficient. The school is frankly vocational. It tells him of the dangers of his work, instructs him in it and makes him a competent workman. His occupation becomes not merely his daily toil, but his life hobby.

For years people have thought that the training in vocational schools was to be urged because it helped a man to rise and displace his fellows, or because it aided the United States to hold its own against Europe. Efficiency, however, is best described as the means by which man wrests from nature the largest spoil possible.

If the boy or man can do a larger work because of his efficiency he can obtain a better living. The wage earner of today earns a larger real wage than the laborer of the 15th century, because by efficiency and machinery he can turn out more in a day than the artisan of that time could in all probability produce in two weeks.

The discontent of the working classes is only to be met by giving them a better living. The only way to provide that desideratum is to teach them to earn it. When men are scientifically expert, are taught to study causes and results, the industries of the world will take a rapid bound forward.

Every mine worker will inspect his own working place and will take a pride in making his part of the task move without friction. Conditions will not arrive at their maximum efficiency till every coal cutter and motorman can make at least the less important adjustments on his machine or locomotive just as every chauffeur is supposed to be able to take care of the automobile he drives.

If our miners were educated, their pride in their order would be increased and the exodus to other trades would cease. The other industries have already a start in this respect. Nothing retains a body of men at their employment so fixedly as a reputation that the trade practiced demands intelligence, that it is something more than a daily grind.

The contracts were presented to us by C. M. McDaniel, superintendent of schools at Hammond, Indiana.

CONTRACT

Articles of agreement made and entered into by and between the School Trustees of the City of Hammond, Lake County, Indiana, party of the first part, and..... of the City of Hammond, Lake County, Indiana, party of the second part:

Witnesseth, that

Whereas, The Board of School Trustees of the City of Hammond, Lake County, Indiana, are desirous that the boys and girls of said City may become more efficient industrially, and that more of them may be able to remain in school a longer period, it is therefore understood and agreed, by and between the said School Board of the City of Hammond, Lake County, Indiana, party of the first part, and..... ..... of the City of Hammond, Lake County, Indiana, party of the second part.

1. That certain boys and girls of said City, over the age of fourteen years and under the age of twenty-one years, are to be given opportunity to devote one-half of each school day in attendance at school and the remaining portion to be devoted to the services and employment of the said..... and that a copy of all contracts with the parents or guardian of any such school apprentice shall be approved by said School Board and signed by the superintendent and become a part of this agreement as fully as though it were embodied therein.

The party of the first part agrees:

1. To submit a course of instruction which shall be offered in the school for the approval of the party of the second part, and to provide proper facilities and competent instructors for the teaching of said course.

2. Not to demand the attendance of the apprentice during the time when he should be in the service of the party of the second part.

3. To employ a competent vocational director who shall be familiar with the work of both the shop and school, whose duty it shall be to see that the terms of this contract are fulfilled.

The party of the second part agrees:

1. Not to employ a school apprentice during the time that he should be in school.

2. To submit a course of instruction in the art or trade to which the boy or girl is to be apprenticed for the approval of the Board of School Trustees, and further agrees to offer this instruction to the apprentice.

3. To allow a representative of the School Trustees entrance to their establishment or factory at appointed times when the apprentices are employed, providing such representative does not interfere directly or indirectly with the work or employees.

The term of this apprenticeship shall be four years. At the end of the apprenticeship each party to this agreement shall issue a diploma to the apprentice if the work has been satisfactory.

In Witness Whereof, the said parties have hereunto set their hand and seal this.....day of .....19...

By.....

Superintendent of Schools.

APPRENTICE CONTRACT

W. B. CONKEY COMPANY

Entered into between the W. B. Conkey Company, of Hammond Indiana, and . . .
(parent or guardian) of Hammond, Lake County, Indiana.

This Indenture Witnesseth that . . .. of the County of Lake and State of Indiana, has voluntarily, of his own free will and accord, put and bound..... .. of Hammond, Lake County, Indiana, to learn the art and trade of.....and as apprentice to serve from this date for and during and until the full end and term of four years next ensuing; during all which time the said apprentice shall serve his employers faithfully, honestly and industriously,

all lawful commands readily obey, and conduct himself in a modest, courteous and accommodating manner toward his employers and all other persons employed in and about the premises and business of his said employers; at all times protect and preserve the goods and property of his said employers, and not suffer any to be wasted or injured; and that the apprentice may acquire an education, he shall attend the Hammond Public Schools one-half of each day that school is in session, at such time as shall be arranged by the employer and the school authorities, and shall employ himself about the premises of his employers during the time five hours per day during the full term of his apprenticeship, unless otherwise ordered, and the said employers shall use their best endeavors to teach or cause him, the said apprentice, to be taught or instructed in the art or trade of.....and to pay the said apprentice for the first year the sum of ten cents per hour; for the second year of his serviees, the sum of twelve and one-half cents per hour; for the third year of his services, the sum of fifteen cents per hour; for the fourth year of his services, the sum of seventeen and one-half cents per hour.

Beginning the second year of his apprenticeship the W. B. Conkey Company will deposit to the credit of the apprentice one dollar ($1.00) each two weeks with the treasurer of the W. B. Conkey Company. This money will be deposited as a joint account of the apprentice and W. B. Conkey Company. At the completion of the apprenticeship the entire sum to the credit of the apprentice in the treasury of the W. B. Conkey Company plus twenty-five dollars, will be paid him. If for any reason the apprenticeship is not completed, this money reverts to the W. B. Conkey Company. The apprentice will be given a pass-book showing the amount paid in for his account, said pass-book to remain in his possession. It is understood that this money placed in the bank is not in any sense wages or payment for services rendered, but is a voluntary contribution by the employer, to be paid the apprentice in consideration of good behavior and the completion of his apprenticeship.

At the end of his apprenticeship, a diploma will be awarded to the apprentice by the W. B. Conkey Company, stating that he has served the full term of apprenticeship, and giving his status as a workman, and he shall at once be put on the pay-roll at $15 per week, and should said.....be in the employ of the W. B. Conkey Company when he arrives at the age of 21 years, he shall at once be put on the pay-roll at the regular journeyman's wages.

In case the W. B. Conkey Company by reason of destruction of, or injury to, their buildings or their machinery by fire, explosion, necessity for repairs, disturbance of business by strike, or by any calamity or other cause beyond their control, shall find it necessary to shut down their plant or suspend business in the whole or any part, during such time of suspension the W. B. Conkey Company shall not be liable for wages or damages.

And should the said apprentice fail in any of the above requirements to faithfully perform the duties, trusts and obligations required of him then the W. B. Conkey Company may, if they see fit, discharge the aforesaid apprentice and this contract at once become null and void.

Miners' Summer School

By H. D. Easton*

The Kentucky University offers the following opportunity to miners, mine foremen, managers and others who desire to improve their knowledge of the principles underlying correct methods of mining.

*Professor of mining, College of Mines and Metallurgy, State University, Lexington, Ky.

1. COAL MINING

(a) The different systems. Laying out the workings. Methods for thin and thick and for flat and pitching seams. Management of squeezes, etc. (b) Mining and blasting. Various explosives. Evils from improper blasting. Dangerous and safe methods. "Safety" powders. Machine mining. (c) Supporting excavations, including the principles underlying timbering; the different methods employed; computing the strength of pillars, etc. (d) Ventilation. Methods of obtaining it and of coursing, splitting, and regulating the current. Its measurement; use of anemometer, water gage, etc. Study of furnaces and fans. (e) Haulage and drainage. (f) Sinking Shafts and Slopes. Safety appliances for shaft and slope mines.

2. MINE GASES AND TESTING

(a) Nature and origin of each and the indications which they furnish of their presence. (b) Testing for explosive and inexplosive gases. Principle of the safety lamp, and various types of such lamps. Use of safety lamps, etc.

3. EXPLOSIONS AND FIRES

Their various causes. Relation of coal dust to explosions, and management of dust. Relation of blasting to coal-dust and other explosions. Demonstration of coal-dust explosions. Prevention of explosions. Causes and management of fires.

4. SURVEYING AND MAP DRAWING

Use of compass (or of transit, as the case may be); putting up sights, marking off rooms at various angles, grading track (use of level), laying out curves, etc. Drawing the mine map. Men may devote all of the course to surveying if they so desire.

5. USE OF MINE RESCUE APPARATUS

Different types of apparatus. Practice in use of the Draeger oxygen helmet, and of the "Pulmotor" reviving apparatus.

The equipment used in demonstrating includes: A mine fan (running either exhaust or forcing), a working model of a Sirocco fan, anemometers, water gage, safety lamps of various types, electric and acetylene lamps, gas-chamber for testing with safety lamps, gas-testing machine, Smith appliance for gas-testing in mines, apparatus for showing characteristics of gases and effect of red-hot coal-dust on carbon dioxide, coal-dust explosion box, spray nozzles, samples of various explosives, mine telephones, pneumatic mine signal, safety, shaft-hoist, Cameron pump (dissected), Harrison coal puncher, coal and rock drills (Nixon ratchet, pneumatic hammer etc.), various makes of pit-car wheels, wire-rope and electric transmission-wire bonds, mine trolley hangers, steel entry sets, 6-ton electric locomotive, surveying instruments, etc.

The session begins May 19, 1913, and ends on July 12. By coming May 15, students can attend the meeting of the Kentucky Mining Institute, which opens on that date. The Board of Examiners of the state mine inspector's office has always held an examination at the close of the practical miner's course, thus avoiding the extra trip to Lexington for this purpose. Fee, $10. Room and board, $2.50 to $3.50 per week.

Garden Awards

The Taylor Coal Co., of Kentucky, offers the following cash prizes to its tenant employees for the best garden and yard cultivated during the season of 1913. The information is furnished us by C. F. Fraser, the mine manager. The mines are situated at Beaver Dam, Ohio County, Ky.

Inspection will be made June 18 and 19 by Messrs. C. M. Barnett, Hartford, Rev. A. B. Gardner, Beaver Dam, and a representative of "Coal Age." The inspectors will take into consideration neatness, kind and quality of crops raised and the natural advantages and disadvantages of the location. All tenants will be entitled to compete for prizes regardless of the amount of ground under cultivation or the kind or style of the houses. No salaried employee will be eligible to compete for any prize.

	In gold
For the best garden cultivated by white tenant.....	$10.00
For the second best cultivated by white tenant.....	5.00
For the best garden cultivated by colored tenant....	10.00
For the second best cultivated by colored tenant.....	5.00
For the best yard cultivated by white tenant.	7.50
For the second best cultivated by white tenant.....	2.50
For the best yard cultivated by colored tenant.....	7.50
For the second best cultivated by colored tenant....	2.50

COAL AND COKE NEWS

Washington, D.C.

The Interstate Commerce Commission has rendered a decision in the case of the New Kentucky Coal Co. vs. the Louisville & Nashville R.R. Co., in which it holds that through rates on coke were applicable to shipments to Chicago and that when reconsignment occurred at Chicago there was no authority for demanding such reconsignment on the basis of the through rate. In dealing with this question the Commission says in part:

Complainant's contention is that under the rule quoted from the Louisville & Nashville Co.'s tariff, that company must be considered as having joined in the reconsignment rules and regulations published by the Chicago, Indianapolis & Louisville and Big Four roads, and that by such rules and regulations reconsignment of carload shipments of coke at Chicago is authorized on basis of the through rates from points of origin to points of final destination.

The Louisville & Nashville Co. contends that reconsignment of coke is authorized by it only under the three conditions named in the circular of instructions referred to. It denies that it was the purpose of the rule in question to join in any reconsignment privilege granted by terminal lines. One of its traffic officials testified at the hearing, as to the purpose of the rule, as follows:

It was put in there simply for the purpose of notifying the shippers under our joint tariff that there might be privileges granted by some parties to those rates, and which, if they were interested, they could look them up and enjoy them if they were entitled to them. That is the only reason that note was ever put in that tariff.

Question. That was put in there, as I understand, for the purpose of enabling the shippers to obtain the benefit of any reconsigning arrangements or any other arrangement, terminal or otherwise, that the lines other than the L. & N., parties to that tariff, were willing to grant?

Answer. Yes, sir. It was simply to give them the privilege, the benefit of any privilege that any individual line was willing to grant.

The circular of the Louisville & Nashville referred to relates primarily to reconsignment of shipments on the lines of the Louisville & Nashville, and does not, in terms or by necessary implication, prohibit reconsignment by connecting lines on the basis of through rates when such rates are in effect. The rules and regulations of the Chicago, Indianapolis & Louisville Co. authorize one reconsignment, without charge, on basis of the through rate, where the identity of the freight is preserved, the point of reconsignment is in direct line to ultimate destination, and the lines over which the shipment moves are parties to the rate. These conditions were met in this case.

The rules and regulations of the Big Four, while providing for reconsignment of carload shipments of coke, further provide that as to shipments received from connecting lines reconsignment which involves change of destination will not be made without authority of the road from which the shipment is received, and they contain no provision for the application of through rates in the event of reconsignment.

Recurring to the Louisville & Nashville Co.'s tariff, we do not find that it contains any authority to connecting lines for reconsignment on a through-rate basis. The rule referred to does not in itself authorize reconsignment at all.

PENNSYLVANIA

Anthracite

Scranton—An investigation conducted by the members of the bureau of mine inspection of Scranton has disclosed the fact that the settling on Pittston Avenue near River Street some weeks ago was not caused by a mine cave, but by the faulty back-filling of a sewer. The commissioners secured entrance to the abandoned workings of the Lackawanna Coal & Iron Co., which have not been in operation for at least fifty years, and found conditions even better than they thought they had any right to look for.

Scranton—The Scranton Coal Co. has dynamited the overflow dam near Keyser Valley in order to prevent a further flood of their workings. The water was rushing into the mine at such a high rate that it gained 9 ft. on the pump in one night.

Wilkes-Barre—The Stanton Colliery, of the Lehigh & Wilkes-Barre Coal Co., has been tied up for over a week on account of the great inflow of surface water during the recent heavy storms, there being several feet of water in the shaft.

Hazleton—In obedience to the request of the Upper Lehigh Coal Co., the residents of No. 3, Upper Lehigh, have moved to another section of the town. It is the intention of the coal company to strip the land in the deserted section of the settlement.

Mahanoy City—Demanding an increase of wages, seventy-five breaker boys employed at Maple Hill Colliery, the largest Reading operation in the Mahanoy City region, are on strike.

Bituminous

Du Bois—Powder exploded in the miners' changeroom, a part of the supply house at the Cascade Coal & Coke Co.'s shaft in Sykesville. The building was destroyed, and two miners out of a number in the changeroom were badly burned. The shed was worth only $300 or $400 and its loss by explosion and fire serves solely to emphasize the importance of taking care of the miners' explosives on leaving the mine.

The men employed at the Eriton shaft of the Northwestern Mining & Exchange Co., returned to work Monday, Apr. 7, when the repairs were declared complete. They had been idle nearly two months. The Union regarded the enforced idleness as a virtual lock-out and distributed nearly a thousand dollars among the needy.

Indiana—Options for 1700 acres of coal between Vintondale and Strongstown have been taken this week by Charles E. Altemus of Morreilville, Penn. The options are said to have been contracted at $115 an acre.

The mutual rectification of the boundaries of the Rochester and Pittsburgh Coal and Iron Co. and of the New York Central interests continues. The exchange will increase the mining facilities of all concerned.

Much activity continues near Heilwood, Indiana County, Penn., where the Greenwich Coal & Coke Co. and the Penn-Mary Coal Co. are competing for options.

Harrisburg—The McDermott bill, to prohibit the use of electricity in gaseous coal mines, is being strenuously opposed by the operators. Representatives of the latter contend that if electricity were prohibited, it would prevent them from entering into competition with mines in states which permit its use and would also force great expense for equipment of mines.

WEST VIRGINIA

Moundsville—The Fort Pitt mine tipple for river shipping has been swept away by the recent flood.

TENNESSEE

Chattanooga—The Continental Coal Corporation recently set aside Apr. 5, which fell upon Saturday, for clean-up day in their camps. On that date, in accordance with circulars which had previously been issued, people were urged to gather up their trash and refuse and otherwise put the villages in a sanitary condition. The company furnished wagons to haul away the litter and plenty of lime for use in bad places. This move is expected to have a pronounced effect in preventing sickness in the camps during the warm weather.

KENTUCKY

Louisville—The Harlan Coal Mining Co. was one of the operating companies of the southeastern Kentucky field which suffered some inconvenience on account of the high water, having lost three piers from under its conveyor structure. This company is considering a number of propositions with reference to leasing parts of its large acreage in the Harlan field, but nothing definite has been announced as yet.

The flood in the Ohio and Mississippi rivers has been turned to good advantage by the Monongahela River Consolidated Coal & Coke Co. The company has shipped out of Pittsburgh several large tows bound for Louisville and the South. The Louisville offices of the company have received advices to the effect that the Sam Brown cleared from Pittsburgh with fourteen coal boats and six barges of coal destined for the Louisville market. Likewise, the steamer "Helen White," of the United Coal Co. has left with seventeen barges, bearing 218,000 bushels, and the Jim Wood and J. A. Donaldson are expected to leave with tows totaling forty-five barges. The Diamond Coal Co.'s steamer "Monitor" has started with seventeen barges, containing 300,000 bushels of coal for Madison, Ind., and Louisville.

OHIO

Columbus—A coal famine in many of the cities and towns of Ohio is threatened because of the inability of railroads to move coal cargoes. This condition prevails especially in the northern part of the state where the railroad connections with the coal mining districts have been broken. It will be some time before normal transportation conditions prevail.

Nothing has yet been done toward a settlement of the strike which has been in progress since January at the Glouster mine of the Hisylvania Coal Co. which has offices in Columbus. The strike was in the nature of a lockout. The managers of the mine wanted the men to protect their own lives to a larger degree and they refused.

The Sunday Creek Co. which has headquarters in Columbus has sustained some damage to a bridge connection with one of its mines in the Hocking Valley owing to the flood. The New Pittsburgh Coal Co. sustained the loss of a trestle which will put one of its mines out of commission for several weeks. The New York Coal Co. also suffered some damage at its mines in the Hocking Valley.

Martins Ferry—The Gaylord mines Nos. 1 and 2 have resumed work in full, together with the Red Bird, Yorkville and Y. & O. mines. Every important mine in this immediate vicinity is now in operation.

ILLINOIS

Springfield—A raging fire which has broken out the bottom of the Capital coal mine has consumed property to the extent of $1000, despite the efforts of the company's men to check its progress; 330 men are thrown out of employment as a result of the blaze.

Harrisburg—On Apr. 5 practically all of the coal mines in the vicinity of Harrisburg had been closed down, and employees were working day and night in an effort to prevent water from getting into the shafts. The back water from the Ohio had covered the entire country surrounding Harrisburg, and levees several feet high had been built up around the air shafts and main shafts of practically every mine in this field. Even with this precaution there threatened to be a tremendous loss by the washing away of mining property, such as timbers, wash houses, etc.

Marion—The cyclone that recently swept over Southern Illinois caused a loss of $3000 at the Illinois Hocking Washed Coal Co.'s mine. The smoke stacks were blown away and the roofs of all the buildings were torn off. The property of the Chicago Big Muddy Coal & Coke Co. suffered a loss of about $8000. The engine room was completely destroyed, the boilers dislodged, stacks blown down and the tipple stripped of everything but the heaviest timbers.

MISSOURI

St. Louis—The largest piece of coal ever taken from a mine in Madison County was hoisted by the Home Trade Coal Co. recently. The piece is 3 ft. square, and weighs 1050 lb. Several months ago a piece weighing several tons was mined, but on account of its size could not be brought to the surface. The coal will be placed on exhibition at Edwardsville.

ARKANSAS

Hartford—Miners working at No. 7 Central mine, better known as the Hoffman mine, have received orders to clean up and put their tools away. It is reported that the company intends installing electric mining machines. Another report is also current that the company intends shutting down mines Nos. 2 and 5. If such is the case, over 500 men will be thrown out of employment temporarily.

COLORADO

Fort Lupton—Another strike in the coal fields of northern Colorado has been ordered, involving over 1000 miners in the employ of the American Fuel Co. The miners claim the company owes them back pay aggregating $20,000. This they have not received.

SOUTH DAKOTA

Pierre—A new find of lignite coal is reported near Isabel. The seam is said to be 12 ft. in thickness, and is especially desirable, as it is covered with only 16 ft. of earth, allowing for stripping operations. Mining by tunneling is not practicable on account of the lack of stone or other substantial covering for a roof.

NORTH DAKOTA

Hebron—There will be $17,500 donated for the maintenanco and permanent improvements at the Hebron Lignite Coal Experimental Station, at the University of North Dakota, according to E. J. Babcock, Dean of the School of Mines.

FOREIGN NEWS

Bridgeburg, Ont.—A dangerous blaze which caused the destruction of hundreds of tons of coal broke out Mar. 26 on the big Grand Trunk coal chute at this place. The western end of the chute was completely destroyed. The loss is placed at $2500.

Manleon, France—Four men were killed and seven others injured by an explosion in a mine at Osser, Mar. 29.

PERSONALS

Edward V. d'Invilliers announces the removal of his general engineering offices to No. 51 Walnut St., Philadelphia, Penn., opposite Independence Square.

Wm. B. Neal, who has been in charge of the New Orleans office of Bonnyman-Norman Coal & Iron Co., has resigned that position to become connected with the sales department of the Central Foundry Co., located at Holt, Ala. His successor has not been announced.

Edward Lynch, of Wilkes-Barre, formerly employed on the U. S. Bureau of Mines Rescue Car, giving instruction in first aid, has accepted a position on the G. B. Markle engineering corps at Jeddo, Penn. The appropriation for this car has run out, and Mr. Jessup, general manager for the Markle Co., secured Mr. Lynch to take charge of the first aid and rescue work of the company.

OBITUARY

Wm. Harding, 83 years old, for many years manager of the Consolidated Coal Co.'s properties, and one of the best known coal operators in the southern Illinois field, died recently at his home at 539 North 13th St., East St. Louis, Ill. Death was due to pneumonia.

CONSTRUCTION NEWS

Wilkes-Barre, Penn.—A. F. Wolf has bought out the interests of the Central Coal Co. of Scranton in a property of 97 acres of coal land in Plains Township near Hudson. His intention is to erect a modern breaker.

Moundsville, W. Va.—The tipple at the Glendale mine of the Richman Coal Co. is being torn down by the Riggs Bros., contractors. The work of building a new tipple has already been started and will be rushed to completion.

Martins Ferry, Ohio—It is understood that the coal territory in the southern part of Belmont County is soon to be tapped by an 80-ft. shaft and Pittsburgh coal will be mined. About $100,000 will be required to install the necessary equipment.

Connellsville, Penn.—Work on the coke plant along the Youngwood branch of the Southwest R.R., is progressing rapidly.

The shaft of the United Coal & Coke Co. has been sunk to a depth of 100 ft.

Wheeling, W. Va.—Extensive improvements are under way at the Johnston coal mine at West Wheeling. Sixteen new entries will be driven in the mine in the near future and a new 8-ton motor has been purchased from the Goodwin Manufacturing Co., of Chicago.

Sturgis, Ky.—The contractors who are working on the branch line being constructed by the West Kentucky Coal Co. to its new shaft, No. 9, have about completed the heaviest part of the work, which was the trestle over Cypress Creek, and the remainder of the work is not expected to take long.

Wichita, Kan.—The Kansas Gas & Electric Co. is rushing to completion a $50,000 traveling grab bucket crane, which will unload coal from the cars. A contract has been let to the Dieter & Wenzel Construction Co., to extend their dock on the river 100 ft. eastward. It is expected that the crane will be completed by Aug. 1.

Susquehanna, Penn.—Scranton capitalists are making good

headway in sinking a shaft on the George Young farm at Port Crane, near Binghamton, N. Y. All the drilling machinery has been set up and the shaft is down twenty feet, work is under the supervision of Engineer Yates, of Scranton.

Hillsboro, Ill.—It is rumored that work may resume at the local mine of the Clover Leaf Coal Mining Co., in the near future. The new airshaft has now been sunk to a depth of 450 ft. and the work of finishing is only a matter of a few weeks. When these improvements are completed it is expected that work will be resumed.

Carbondale, Penn.—The Salem Hill Coal Co.'s property here has been sold to the New England Coal Co., owned by Scranton capitalists. The coal land of the company is located above Wayne street, and the assessed valuation of the breaker and coal lands is in the neighborhood of $30,000. It is the intention of the new company to drive a slope.

Monndsville, W. Va.—The old machinery in the Big Run coal mine, in Ohio, has been replaced with modern electrical equipment. The work to date has cost in the neighborhood of $175,000 and it is expected that before the improvements have been completed the total cost will reach $400,000. Plans for a modern steel tipple are now being drawn up. The Rail & River Coal Co., owner of the mine, plans to double the output.

Uniontown, Penn.—Improvements which will cost in the neighborhood of $40,000 will soon be made in the three mines of the Evans Coal & Coke Co., formerly the Superba Coal Co., at Evans Station. It is understood that plans have already been made and the contracts have been awarded. These improvements will consist of the construction of a 60-oven coke plant and also of a new tipple. It is also the intention of the company to install a big coke crusher. When the three plants are in full operation, about 800 tons of coal will be produced daily.

NEW INCORPORATIONS

Como, Texas—E. G. King, of McKinney, has purchased the stock of the Como Coal Co., incorporated for $40,000.

Birmingham, Ala.—The Alabama Co.; capital stock, $6,919,000; to succeed the Alabama Consolidated Coal & Iron Co.

Chicago, Ill.—The Villija Co.; capital stock, $10,000; coal, wood, ice, etc. Incorporators: M. M. Dudas, L. J. Petrulis and P. M. Dudas.

Nashville, Tenn.—Rhea-Stone Coal Co., Shelby County; amendment changing the name of the corporation to "John White & Son Coal Co."

Fort Wayne, Ind.—The E. W. Williams Supply Co.; capital stock, $10,000; to deal in coal. The directors are E. W. Willams, E. M. Williams and C. S. Tumbleson.

St. John, N. B.—The New Brunswick Coal, Iron & Clay Co.; capital stock, $298,000; to develop the province in Queens County. H. W. Woods is president.

Chicago, Ill.—The Citizens Coal & Supply Co.; capital stock, $100,000; fuel, ice, building material. Incorporators: Ward Zyfarth, F. W. Koenecke, E. E. Zyfarth.

Oklahoma City, Okla.—A charter has been granted to the Omego Oil Gas, Mineral & Coal Co.; capital stock, $15,000. Incorporators: A. C. Ahorn, and others of Omega.

Harboursville, Ky.—Barboursville Blue Gem Coal Co., Barboursville; has been formed with a capital of $200. Incorporators, A. D. Smity, G. W. Tye and Myrtle Tye.

New York, N. Y.—The R. J. Buchholz Coal Co., Inc.; coal and other fuel; capital stock, $25,000. Incorporators: Richard J. Buchholz, Charles E. Buchholz, John V. Koch, Jr.

De Queen, Ark.—A charter has been granted to the Mexico Mining & Development Co. of De Queen; capital, $50,000; incorporators, C. Mendosa, P. Aleman and J. O. Johnson; to mine coal.

St. Louis, Mo.—The American Coal and Ice Co. has been incorporated here, with a capital stock of $5000. The incorporators are W. C. Vogel, A. J. Schmandt, Clara E. Vogel and Edna M Schmandt.

Parkersburg, W. Va.—The Cub Fork Coal Co.; capital stock, $25,000; to develop coal land and oil and timber lands. Incorporators: W. E. Deegans, J. B. Hoffmier, John Faulkner, Wm. Brown and E. C. James.

Wilberton, Okla.—The Gaines Creek Coal and Mining Co. has been organized with a capital stock of $10,000. Incorporators: William J. Hammers, Adamson; David R. Bridges, Wilburton; Martin L. Murdock, Wilburton.

St. Louis, Mo.—The Haddaway-Curd Coal Co. has been incorporated here, to do a wholesale coal business, with a capital stock of $6000. The incorporators, all of Webster Groves, Mo., are J. H. Curd, W. S. and W. J. Haddaway.

Seng, W. Va.—Opperman Coal Co.; to develop coal and timber lands in McDowell County; capital stock, $50,000. Incorporators: J. H. Opperman, of Cambridge, Ohio; Thomas E. Richards, C. Riggs, A. C. Orcutt and S. G. Campbell, of Seng, W. Va.

Phoenix, Ariz.—A charter has been granted to the Western Plaster Company of Phoenix; capital, $100,000; incorporators, Henry Mitchell, G. M. Satterfield and Grant Monical, all of Phoenix; among the objects are to deal in and operate coal lands and mines.

Phoenix, Ariz.—A charter has been granted to the Papago Placer Mining Co. of Phoenix; capital, $500,000; incorporators, Ned Creighton, Roy N. Davidson and H. V. Young, all of Phoenix; company to deal in and operate coal lands and coal mines, and other minerals.

INDUSTRIAL NEWS

Falliston, Ala.—The Eureka Coal Co. will have its new mine in operation by May 15, and will produce the high-grade domestic coal for which the Cahaba field is noted.

Waynesburg, Penn.—James L. Rush, has become the owner of 260 acres of coal located in Center Township. The property was purchased from George G. Gaus, of Uniontown, for $39,000.

Klondike, Tenn.—J. M. Robinette announces that he will develop 200 acres of coal property which he owns in that vicinity. The extent of the operation is not at present definitely determined upon.

Coshocton, Ohio—Joseph Norman of Keene, who discovered a deep seam of coal on his farm near that village about a week ago, has stated that he expects to start developments about June 1.

Lincoln, Ill.—The Chicago & Alton Ry. is now concentrating a large number of coal cars in the field in the southern part of the state, and operators there are planning to run their plants on full time.

Indiana, Penn.—Dr. Charles E. Altemus, of Morrellville, has taken options on 1700 acres of coal land between Vintondale and Strongstown, this county, this being about the only idle tract left in the country.

Owosso, Mich.—The New Haven Coal Co. has sold 196 acres of coal property in the New Haven Township to Wm. McAvoy, and it is expected that local capital will make another attempt to operate the mine successfully.

Louisville, Ky.—The Louisville agency of the Continental Coal Corporation has contracted with the Louisville Water Co. for a year's coal supply for the operation of its river pumping station. About 5000 tons are required.

Morganfield, Ky.—The Drury Coal Co. has sold its mine and 1800 acres of coal rights at Waverly, Ky., which for a time have been operated by A. Maben Hobson, of Birmingham, Ala., to the Hobson Coal Co., of Birmingham, Ala.

Mahanoy City, Penn.—Twenty collieries are idle in this region, owing to the rapidly rising water in the mines. In some instances pumps are runing under water. Preparations have been made to hoist the mules at a moment's notice.

Knightstown, Ind.—During the recent cyclone that cut through the southern part of Indiana, fourteen barges, containing seven thousand tons of coal were sunk at the coal landing here; also a pumping boat. The total loss is over $25,000.

Huntington, Penn.—A large vein of coal was discovered at Rocky Ridge, in the new drift of the Possum Hollow Coal & Coke Co. The vein is 6 ft. 6 in. of pure coal. Mr. Jacobs, general manager, is at the mines and no doubt will make many improvements.

Hazleton, Penn.—Preparations are now being made for the reopening of the Silver Brook mines which were abandoned several years ago. Bids have been prepared for the coal royalties and these will shortly be opened. A large amount of coal remains to be taken from the mine.

Mecker, Colo.—Charles Gates has purchased the big David Morgan place north of here, comprising 8000 acres, the consideration being $160,000. Land is located in the anthracite

section and was purchased for the coal it contains. It will be mined extensively during the coming summer.

Grand Forks, N. D.—An experimental station in charge of the department of the University of North Dakota has worked out a process which makes it possible for railway engines to use lignite coal. The Chicago & Northwestern and Burlington railways are now making practical tests upon 40 locomotives in actual service.

Sebree, Ky.—The Sebree Mining & Development Co. has sold the mine at Sebree, with 1050 acres of coal rights, to Messrs. J. W. Miller and J. D. Smith, of Birmingham, Ala., who will organize a new company to operate the property. The mine is now producing about 300 tons per day and is located on the Louisville & Nashville Ry.

Cumberland, Md.—The Empire Coal Co. of Allegheny County has leased to Geo. C. Pattison and Louis B. Brydon, of Bloomington, the right to mine coal on Military lots Nos. 5 and 6, included in lot No. 1 and No. 2, of Stone Ridge, for a term of ten years from May 1, 1913. The lessees are to pay a royalty of 7c. per ton.

Indinnapolis, Ind.—The coal rates from Indiana mines to Indianapolis are to be advanced 5c. a ton, effective April 14, on the Illinois Central, Chicago, Terre Haute & Southeastern and the Evansville & Terre Haute. The present rate is 50c. a ton. The Vandalia and the Big. Four have not notified the railroad commission that they will follow the advance.

Morgantown, W. Va.—Cleveland capitalists have purchased the holdings of the Kingwood Coal and Coke Co. on the West Virginia Northern and the Morgantown and Kingwood Railroads near Kingwood. The Kingwood company owned 1100 acres there but never installed a plant. The purchasing company will develop the tract at once. Price, $60,000.

Brownsville, Penn.—The Isabella Connellsville Coal & Coke Co. is about to erect another coke plant in this vicinity. The proposed site of the new plant is on the Rush Run branch of the Monongahela R.R. The Isabella Co. refuses to discuss the probability of a new plant, but certain activities in this region by that corporation imply the erection of this plant in the near future.

Connellsville, Penn.—The Titlow Waste Heat Power Co. proposes to utilize the waste heat of the process of coking in the ordinary beehive or rectangular ovens, in making steam and thus developing power for the manufacture of electricity. The plans are covered by patents just issued, after a four-years' struggle, and contemplate the installation of boiler units over the trunnel head of the oven.

Spottsville, Ky.—The mine of the Pittsburgh Coal Co., in the Henderson district, has been flooded rendering operations impossible. Eighty men are employed in the mine, but warning of the rise was received in time to enable all to make their escape before the water reached the shaft. It is stated by Manager Blair that it will be not less than four months before the mine can be pumped out and operations resumed.

Washington, D. C.—The Democratic tariff bill presented by Chairman Underwood of the Ways & Means Committee to the House on Monday, Apr. 7, places coal on the free list. This includes the following grades and materials. Coal, anthracite, bituminous, culm, slack, and shale; coke; compositions used for fuel in which coal or coal dust is the component material of chief value, whether in briquettes or other form.

Waynesburg, Penn.—Two coal deals aggregating more than $1,000,000, and involving lands in this vicinity were closed Mar. 31. The Baily Block, comprising 1500 acres near Carmichaels, has been sold to Pittsburgh operators for $900,000. It is reported that the buyers will open up the coal at an early date. Fifteen hundred acres of coal land in Jackson Township, known as the Nettle Hill Bluff, have been sold to eastern capitalists for $100 an acre.

Birmingham, Ala.—During the week Judge Grubb, sitting in the Federal Court at Birmingham, signed a decree, ratifying the sale of the Alabama Consolidated Coal & Iron Co. to the protective committee, composed mostly of Baltimoreans. This committee prepared the reorganization plan of the company. A new company, known as "The Alabama Co.," has been incorporated under the laws of Delaware, which concern will take over the property of the old concern.

Pittsburgh, Penn.—The Lilly Coal & Coke Co., and the Reliance Coke Co. have entered the West Brownsville field. The former company has about 600 acres of coal under development and its mine and plant are near completion. It is understood that no coke will be made at present. The Reliance Co. will manufacture coke and has already started work on the development of 600 acres. The company is now erecting 230 ovens. Approximately 175,000 tons of coke will be produced annually.

Boonville, Ind.—An important deal in the southern Indiana field has been consummated in the purchase by William T. Blair of 400 acres of coal land for $40,000. The purchaser of the property is reported to represent Indianapolis and Chicago interests. He had options on more than $200,000 worth of coal land in the Boonville district, and the land purchased represents the cream of the lot. It is announced that the coal will be removed by surface mining, which is a new method in that section.

Spokane, Wash.—The annual meeting of the stockholders of the International Coal & Coke Co. was held in Spokane last week and the following officers were elected: A. C. Flummerfelt, Victoria, B. C., president; Hugh Davidson, Vancouver, B. C., first vice-president; D. H. Kiser, of Spokane, second vice-president; John Keegan, of Coleman, Alberta, treasurer; W. G. Grave, of Spokane, secretary; R. W. Riddle, of Coleman, Alberta, managing director. The directors elected are A. C. Flummerfelt, Hugh Davidson, F. H. Graves, D. H. Kiser and W. G. Graves.

Tamaqua, Penn.—Silver Brook is to be reopened. This operation, near McAdoo has an immense body of coal in it which was barely touched by J. S. Wentz & Co. who worked it about 25 years ago. Reading, Lehigh Valley, Jersey Central and others have an interest in the operation. Bids have been prepared for the coal royalties that will be paid and will be opened in a few days. Baird Snyder, of Pottsville, formerly general manager, of the L. C. & N. Co. at Lansford, who is opening a mine on Locust Mountain, near Shenandoah is said to be after the place also.

Louisville, Ky.—The Snead & Meguire Coal Co. is one of the two conceris which will divide the state penintentiary contract, amounting to about 13,000 tons a year. The other contractor is the Gem Coal Co., operating in the Kanawha field along the Big Sandy. This is the first time for six years that rail coal has figured in the penintentiary contract, the installation of a switch into the institution having made this possible. Heretofore the favorable location of Frankfort on the Kentucky river rendered conditions particularly favorable to those having river coal, and practically excluded rail operators and selling agencies.

Greenville, Ky.—It is reported that a lease of 3000 acres is being reopened for operation by George Krouth and others, of Louisville, who own 2150 acres of the property on which the lease applies. Work was started on this tract 3 years ago by the Louisville interests. Coal was originally found on the property at a depth of 135 ft. This seam has recently been entered, and found to be of No. 9 grade, 5 ft. 10 in. thick, with a solid slate roof. Analysis shows the product to be of good quality, and the owners are making preparations to get the coal out in quantities. Machinery will be installed at once for this purpose.

Lexington, Ky.—The stockholders of the Northern Coal & Coke Co., recently met to consummate the sale of that company's properties to the Elkhorn Coal & Fuel Co. Among the other operating coal companies whose properties are likewise to be taken over by the Elkhorn company are the Blackstone Coal Co., the Cokeland Coal Co., the Howard Coal Co. and part of the holdings of the Beaver Creek Co.

The Elkhorn company, which is generally understood to be the operating agency of the recently organized Mineral Development Co., is making active preparations for the beginning of development work on its new holdings, both in coal and timber, especially in the Boone's Fork and Millstone Creek sections in Letcher County.

Mine Rescue Apparatus

S. F. Hayward & Co., 39 Park Place, New York City, announce that they are now the exclusive American agents for the complete line of Westfalia Mine Rescue Apparatus and Oxygen Reviving Apparatus, formerly sold by the Westfalia Engineering Co. of 42 Broadway, New York.

They have a department devoted exclusively to the perfection and manufacture of respirating devices for all the various conditions of service.

The Westfalia apparatus possesses the advantages of being easily adaptable for either mouth breathing or helmet connection, is entirely without valves to impede the circulation and possibly clog with saliva, and has a perfect cooling system, the metal regenerator dissipating the heat without coming in contact with the body of the wearer.

The circulation in the apparatus is not dependent on the wearer's lungs but is actuated and maintained by an injector, thus avoiding additional strain and fatigue on the wearer and insuring a good supply of oxygenated air throughout the whole period of working.

COAL TRADE REVIEWS

GENERAL REVIEW

An unexpected cold spell has created a temporary snap to the market, which is not, however, showing the activity that ordinarily follows the announcement of the spring discounts. However, mining is being carried on at the full-rated capacity, and there are sufficient orders now on hand or in sight to eliminate any necessity for curtailing production through the current month at least. In spite of the generally soft market, a shortage of broken and egg is developing in some sections, due probably to the fact that the companies are putting the large sizes back through the breakers to provide for the increased demand on stove and chestnut. Operations in the mining regions were affected to some extent the early part of last week by the flood, but conditions were restored to normal before the end of the week. Prospects are for a rather inactive market during the summer.

It is becoming obvious that the stiffest kind of curtailment will be necessary to maintain bituminous prices in the East, as some companies are entirely without contracts and there is no further apprehension being felt over the West Virginia labor situation. Occasional cargoes of consignment coal are being forced on the buyer, and quiet discounts are being made on many of the standard grades at a number of points, all of which are rather bad signs. It is generally conceded that the market has been maintained for over a month in the face of a production exceeding the consumption, and the pressure is beginning to tell.

There is a most optimistic feeling in the Pittsburgh district over the season's prospects in the Lake trade. Reports from the upper lake ports are uniformly to the effect that stocks are low, and since the prices realized on the Lake business have been materially higher, in keeping with the general advance in the market, the producers feel they are on the eve of a record-breaking year in this branch. Most of the steam contracts in the Pittsburgh district have been closed at prices which are said to represent a material advance over last year; production for the current week was scheduled to be at full capacity. As noted in the last week's review, the greatest loss to the Ohio trade will be in decrease of tonnage. The industry is slowly recovering from the flood, but it will be several weeks yet before normal transportation conditions are restored. Railroad consumption has been reduced to a minimum, and many factories are out of commission and will probably remain so for a number of weeks in some instances.

There has been a general shading of prices on steam business in the Southern market, due to a shortage of domestic orders for nut, but such a condition is customary at this period of the year. Transportation in the mining regions of the Middle West appears to be at a complete standstill, but as a like condition prevails in industrial circles, the situation about balances itself. Small shipments are being made by roundabout ways, and the railroads are rapidly restoring their tracks, and expect to be in a position to handle most of the traffic by the end of the current week. Arrivals at Chicago are below normal, and prices are showing a tendency to advance as the stocks are depleted.

BOSTON, MASS.

Bituminous—In the absence of any strike news from the New River district the market is decidedly dull, with only a listless interest on the part of buyers; $2.85 f.o.b. Hampton Roads is apparently being maintained, especially since Apr. 1, although there are sceptics to be found. Some of the agencies are practically without contracts and either there must be the stiffest kind of curtailment, or, lower prices. At Providence and Boston there are occasional "market cargoes" being forced on buyers which is a bad sign. It is even a worse expedient than in former years, for a greatly increased proportion of tidewater coal for inland delivery is now handled by concerns that operate their own forwarding plants and are in close business connection with agencies which depend upon them for outlet. There is not so much opening, therefore, for coal that is shipped outside these arrangements.

There is nothing new to report on the situation here with regard to coals from the Pennsylvania and Georges Creek districts. There are quiet discounts here and there to buyers who will take on coal now and this applies to practically all the standard grades. The price of $2.95, f.o.b. Baltimore, for Georges Creek is the talk of the trade. All-rail there is little doing and manifestly some of the operating interests are worrying over keeping their mines supplied with orders.

Anthracite—In the face of what is generally regarded as a "soft" market there appears in certain quarters a shortage of broken and egg. This is due to the companies putting the large sizes back through the breaker on account of the increased demand for stove and chestnut. As a consequence there is even a slight premium being paid for broken for special uses and on large contracts. The movement of anthracite, all-rail and at tide, is about normal for April in a dull year, with perhaps a rather less demand.

Wholesale quotations on bituminous are about as follows:

Clearfields, f.o.b. Philadelphia	$2.35@2.60
Clearfields, f.o.b. New York	2.65@2.90
Cambrias, Somersets, f.o.b. mines	1.25@1.50
Cambrias, Somersets, f.o.b. Philadelphia	2.50@2.75
Cambrias, Somersets, f.o.b. New York	2.80@3.05
Georges Creeks, f.o.b. mine	1.67@1.77
Georges Creeks, f.o.b. Philadelphia	2.92@3.02
Pocahontas, New River, f.o.b. Hampton Roads	2.85 *and less*
Pocahontas, New River, on cars Boston	3.70@3.80
Pocahontas, New River, on cars Providence	3.45@3.78

Boston retail prices were announced Apr. 1 to be as follows:

Broken	$6.50	Pea	$5.50
Egg	7.00	Shamokin	7.50
Stove	7.25	Franklin	8.50
Nut	7.50	Lehigh Egg	7.25

Bituminous, $4.65 to Oct. 1, and $4.90 thereafter. Screenings, $3.00 to Oct. and $3.25 thereafter, all net tons.

PHILADELPHIA, PENN.

An unexpected cold wave the early part of the week, had the effect of instilling a little ginger into the trade, but it still lacks the snap that generally characterizes the business at this season of the year, after the low prices are made effective. Many householders had drawn their fires, and as a consequence, a ton or two of coal from those who usually postpone their purchases until the following winter, had to be ordered, to run over the cold period. Outside of this, there is nothing of moment. It is understood that all of the collieries of the companies are now again working full after a rather trying week, owing to the flooded condition of the mines. Orders are plentiful enough to keep operations at the mines continuous for at least the month of April, but the month of May does not look particularly good.

The demand at present is, of course, centered mainly upon the prepared sizes. Pea coal, while in fairly active demand, is not being entirely absorbed, and as a result, some of this size is going into stock. This is by no means a new feature at this season of the year as the minute fires are drawn there is an appreciable falling off in the demand for this size. Buckwheat coal is still being taken care of, many of the large buildings and apartment houses using this size for their boilers, and as cold weather is still in evidence requisitions for this size are absorbing all that is produced. Rice coal is far from active, and it is understood that much of this grade has been, and is still going into stock; the season just passed has not been a particularly active market for this size, and it is understood that some of the companies have quite large stocks.

The bituminous market still continues in anything but an active condition. Many contractors are still holding off in their purchases, feeling that they will be able to renew at the old figures, at least, and the operators are just as steadfast in their position, that late summer and fall may find the situation such as will make their present contract offerings look acceptable. Much cheap coal is being offered on the market, for current business, but the volume of tonnage sold is not great.

NEW YORK

Bituminous—The soft-coal market is rather quiet and dull, but, on the whole, steady and with prices being well maintained. Contracting continues somewhat slower than the operators would like to see, it being evident that consumers generally believe that they can do better by buying in the spot market for the time being at least. On the other hand, operators are showing no disposition to recede from their determination to obtain higher prices on this year's business,

and this fact is being forced home so conclusively on the buyers generally, that they are gradually signing up for the new year.

The spot market is quiet, the movement being confined almost entirely to contracts. Prices are being well maintained as supplies of soft coal in the open market are restricted. It was feared for a while that the flood situation in the Middle West would divert a large surplus tonnage into the Eastern markets, but such has not proved to be the case so far. Mines are working fairly well, but operators are careful not to overship the market so that some curtailment is being practiced. The local market is not quotably changed from over the past two weeks, and we continue quotations on the following basis: West Virginia steam, $2.55@2.60; fair grades, Pennsylvanias, $2.65@2.70; good grades of Pennsylvanias, $2.75@2.80; best Miller, Pennsylvania, $3.05@3.15; Georges Creek, $3.25@3.30.

Anthracite—Business in hard coal is quite active at the moment, but it is generally conceded that the spring trade is lacking in much of the strength that it has customarily shown in previous years. For the time being, however, there is a good, steady demand, which is absorbing the full possible production of the mines; this is general on all grades and sizes, there being no abnormal surplus or shortage in any particular branch. The steam grades, which ordinarily begin to ease off at this period of the year, have been somewhat stimulated by a short spell of rather cold weather, which created a temporary demand and an advance in prices. Production at the mines was interfered with during the first part of last week, but since Wednesday, mining has been up to full rated capacity, and the outputs are being readily absorbed.

Some individual coal is being offered at 10@15c. below the regular company circular, and, in some instances, such sales are being made for delivery into May and June. The nominal New York market is quotable about on the following basis:

	Circular	Individual—Lehigh		Individual—Scranton	
Broken	$4 50		$4 45		$4 50
Egg	4 75	$4 60 @	4 70		4 75
Stove	4 75	4.65 @	4 70		4 75
Chestnut	5 00	4.85 @	4 95		5 00
Pea	3.50	3.35 @	3.45		3 50
Buckwheat	2.75	2.15 @	2 45	$2 50 @	2.75

PITTSBURGH, PENN.

Bituminous—The Lake coal shipping season formally opened today, with all the railroads open to receive consignments. The first movement of Lake coal from the Pittsburgh district occurred about the middle of March, when certain railroads accepted coal destined to be loaded on specific vessels, which would clear later for upper lake ports, but this movement was small, and was entirely interrupted by the floods ten days ago.

A heavy lake movement is expected this season, prospects being that all records will be broken, as, according to all accounts, there are no stocks in the Northwest, and demand is good. Prices realized on Lake coal have been much better than last season, in keeping with the general strength of the market.

The railroads are now fairly well opened for traffic to Western points, since the floods closed practically everything. The main breaks are, that the Pan Handle is not open beyond Dennison, Ohio, while the Ft. Wayne is not open beyond Orrville. It is, however, open to many points beyond through the Cleveland, Akron & Columbus. Lines to the Lakes are all open. Most of the Pittsburgh district mines were scheduled for practically full operation this week, owing to the regular starting of lake shipments.

Nearly all the steam coal contracts for the twelve months beginning Apr. 1 have been closed, and it is claimed that in practically all cases full circular prices have been obtained, representing a very decided advance over prices in the past two seasons, and promising, with the large tonnage in prospect, by far the best year the Pittsburgh district coal industry has had for many years.

Premiums on slack disappeared several weeks ago, and the market now stands at the regular price, while there may be some cutting later on account of heavy production of slack during the season of lake shipments. We quote regular prices well maintained, as follows: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in., $1.55 per ton at mine, Pittsburgh district.

Connellsville Coke—Regular channels are now open for coke shipments to almost all regular consuming points, but the furnaces have not been getting into operation very rapidly, and as they had coke on the way the shipments early this week have not been up to normal. The coke market has stood the sudden cessation of shipping facilities to points West, involving about half the total output of the Connellsville region, very well indeed, since there has been no open offering of standard furnace coke at less than $2.25, the market before the floods having been $2.40 to $2.50. It is possible a few special deals have been made whereby operators unloaded coke on furnaces at cut prices, the furnaces merely stocking the coke, but there is no evidence that much of this was done, and the open market is clearly quotable at $2.25 for standard furnace coke, both prompt and contract. Foundry coke, prompt and contract, is quotable at $3 and $3.50, depending on brand and tonnage.

BALTIMORE, MD.

Interference with shipments to Western points, on account of the floods, resulted in the local market being overstocked and prices were considerably lower than had conditions been normal. Western consumers prefer the two- and three-inch gas coal, and ordinarily, this kind of fuel will bring from 10 to 30c. more in that section than in the East. In marketing this they were compelled to meet the prices of three-quarter gas coal, which commands a readier market in the East. Toward the end of the week, the movement improved considerably, and the trade believes that by the time Lake traffic opens, transportation conditions will be normal.

Contract renewals continue, but some consumers are still holding off, preferring to take their chances for some weeks to come in the spot market. The car situation is satisfactory and the movement East good. The warm weather prevents any improvement in the anthracite business. The demand for coke has slackened, and the output has also been reduced; operators say that just enough coke is being produced to meet present requirements.

It is not believed that the damage done by the flood will materially affect the coal business in the West and Middle West, which means a great deal to the Baltimore companies. More contracts were renewed during the week, but a number of the larger consumers are still holding back, preferring to supply their current needs in the spot market. Cars were plentiful all the week. In many instances the supply was much greater than the demand, and this will continue until operations become normal again in the West.

There was no pronounced change in the coke market during the week; there is still a curtailment in output. Freezing weather the first half of the week, improved the anthracite market.

BUFFALO, N. Y.

Bituminous is quiet as usual at this time of the year and the weather for the past few months has created a surplus of anthracite. The railroads have for some time contributed to the bituminous surplus and, in this section and beyond, at least, they are still doing so, for the flood conditions did not last long enough in this section to seriously interrupt the movement. Reports from various Canadian points state that bituminous coal is still pouring in from the stranded shipments of some weeks ago. If the present stand of the leading shippers continues, there will be no further decline in prices.

In fact, the firmness in the bituminous market has been maintained for a month or more in the face of a demand less than the recepits, so that the trade is quite well satisfied as a whole. The opening of the Lake trade is at hand, though it is not now expected that much, if any, through sailing will be done till after Apr. 15. Buffalo Harbor has now about 150,000 tons of anthracite afloat, and rates have been made on the basis of 30c. a net ton to Lake Superior and 35c. to Lake Michigan, with an extra charge to minor ports. It is expected that more coal will be shipped to the upper-lake ports than ever before. There is still considerable bituminous on the market at cut prices, but the general trade holds up well to former quotations, $2.80 for Pittsburgh lump, $2.65 for three-quarter, $2.55 for mine-run and $2.15 for slack, with Allegheny Valley about 25c. lower. Coke is not very strong, but prices hold on the basis of $5 for best Connellsville foundry.

Facilities for moving coal northward over the Buffalo and adjacent routes are steadily improving, though possibly no faster than the traffic increases. The two coal-car ferries across Lake Erie are active and the one across Lake Ontario at Charlotte is to be enlarged. An arrangement is in operation by which coal for Canada over the Pennsylvania R.R. will no longer be stopped in Buffalo, but trains will be made up on the Pennsylvania line and run to the Canadian side of the Niagara intact. This will stop much of the complaint of coal being stranded in the city, while in process of rerouting for Canadian points.

Just now the local coal trade is commenting on the outcome of the tender for bids on the city waterworks coal sup-

ply. On the day for opening it was found that only one bid had been put in and that for $2.15, which was something like 30c. more than it usually is. Specifications were for "nut and slack," a sort of antiquated way of asking for slack and a little better. The lack of bidders and the high price is a direct protest against the practice of testing the coal and docking the contract severely on account of some supposed excess of ash. Coal men grew to regarding this practice as unfair and unjust to them.

COLUMBUS, OHIO

The coal trade here is slowly recovering from the effects of one of the most disastrous floods in the history of the state. While the damage done to coal mines directly was comparatively slight, still the loss to the industry as a whole will be large, this will be due mostly to the cessation of trade and the fact that railroads are not able to move coal cargoes promptly.

The flood caused quite a rush of small orders from dealers who either sold their stocks to take care of flood victims or had them floated away by the high waters. This business demanded immediate delivery, which the mine owners and the railroads were unable to make. It will be several weeks before all the railroads resume normal operations, and in the meantime the market will be more or less interfered with.

Prices became firmer under the influence of the flood, but operators and jobbers did not take advantage of the situation to boost quotations. Instead, they were content to let prices remain at the level which has prevailed for some time. There is a good demand for both domestic and steam grades with the latter becoming heavier as the temporary flood wants are satisfied.

Many factories were put out of commission by the high waters and it will require several weeks to get ready for operation. In some instances their stocks of coal were floated away and this will mean re-stocking at once. Railroads have not been taking a large tonnage because of their inability to run trains, but the demand from that source is expected to increase soon. Some railroad fuel contracts are pending, but little has been done recently toward closing them. It is generally supposed that prices on railroad contracts will be much higher than last year. There is a fair demand for the fine sizes and prices on those grades have advanced materially.

While the flood has interfered with the movement of coal, active preparations for the Lake trade are going on. Considerable coal has been loaded on boats at the lower Lake ports and it is believed that navigation will be formally opened by Apr. 15 and possibly earlier. The Northwest is anxious for the shipments to start.

Retail trade was active immediately after the waters subsided, but that condition is expected to be only temporary. Natural-gas connections in many places was cut off and this made an additional market for coal. Dealers' stocks are depleted and there is expected to be scattering orders from this time on.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawh
Domestic lump	$1.50	..	$1.50	$1.40
3-inch	1.35	$1.20	1.35	1.30
Nut	1.30	..	1.30	
Mine-run	1.15	1.10	1.15	1 10
Nut, pea and slack	0.90	..	0.90	0.90
Coarse slack	0.80	0 75	0.80	0.80

BIRMINGHAM, ALA.

The only feature in the market during the current week was a general shading of prices on desirable steam-coal business. This adverse condition is due principally to a shortage of domestic orders for nut and this surplus, thrown on the steam market, has made it top heavy. No serious alarm is felt, however, as this condition usually appears annually about this season of the year. Relief will come as soon as dealers begin taking in regular tonnages of nut coal for stocking purposes.

The best grades of 72-hr. foundry coke are quoted at from $3.90 to $4.25 per net ton f.o.b. local ovens, with furnace-coke prices running from $2.75 to $3.25. The supply and the demand seem to be well balanced.

LOUISVILLE, KY.

While the flood waters have been subsiding now for a week or more, the railroads are in such poor condition that receipts at the consuming centers are far below normal. The coal industry suffered both directly by damage to operations, and by the interference with transportation on the railroads; with the mail and passenger service so completely demoralized as it has been, coal shippers have, of course, received little consideration. The heavy Lake shipments which should be well underway by this time are at a complete standstill.

As a result of the crippled railroad service many operators themselves, or their agents, are being forced into the market to obtain tonnages with which to maintain their contract agreements. This forced buying has inflated the market, and prices as high as $1.35 and even $1.50 f.o.b. the mines are being freely reported. Many of the distributing companies in the river towns and cities are entirely out of commission, their plants being from 100 to 300 ft. from the present shore line. This has, of course, had its effect on the wholesale trade. Western Kentucky mine-run has been eagerly taken up at 80 to 85c., although this grade seldom gets into the market except when screened. It is believed shipments for storage will be actively underway as soon as the transportation companies regain their grip on the situation.

INDIANAPOLIS, IND.

When, on Mar. 25, the flood waters in Indiana began carrying away railroad bridges, they stopped further shipments of coal to most of the industrial cities of the state. As a large number of factories were under water, however, the immediate arrival of coal was not of consequence. After two weeks, the railroads are beginning to haul freight again and small shipments of coal are coming in by roundabout ways, but the bulk of that moving is for the railroads themselves and for public utilities. Practically no coal is going through Indianapolis, which was the main sufferer by the flood. Operators believe that within another week they will be able to resume normal operations and shipments.

Indianapolis happened to be well supplied with coal, and as the weather was mild, the domestic needs were moderate and some of the largest steam users were incapacited by the floods. There were some large stocks of coal in the city, the Pennsylvania R.R. having the largest. No reports have reached here yet of flooded mines, but there is considerable damage in trackage washed away, etc. Mail, telegraphic and telephonic communication was cut off several days, as well as facilities for traveling, so that sales departments have had a vacation. Coal dealers have not raised prices and are selling at a discount, or giving coal away to flood sufferers.

DETROIT, MICH.

The general trade in and about Detroit, is suffering from a slump due to a between season condition, and coal operators and shippers are turning their attention to preparations for a large season in the lake trade. At the present time, the market is decidedly weak; however, it is predicted there will be quite a movement in steam trade, because all coal-carrying roads south of this point have been washed out by the floods. This is liable to cause a serious shortage in steam coal if the conditions are not remedied shortly.

The lake trade is drawing considerable attention from the operator. It is predicted that there will be some trouble in getting coal moved by cargo; on the other hand, it depends largely upon the way coal comes from the mines. Shippers say that if the mines and railroads are able to furnish as much coal as they would like throughout the season Lake Michigan consumers will not buy freely unless the rate is satisfactory to the vessel men; that 30c. per ton will not be attractive, is certain.

The following quotations prevail today:

	W.Va.	Gas	Hocking	Cambridge	Ohio No. 8	Pocahontas	Jackson Hill
Domestic lump	$1.50	..	..	..	..	..	$1 90
Egg	1 50	..	..	..	..	$1 75	1 90
Nut	1 40	..	$1 50	..	..	..	..
1¼-in. lump	1 20	..	..	..	..	..	..
¾-in. lump	1 10	$1 10	1 10	$1 10	$1.10	..	..
Mine-run	1 00	1 00	1.00	1 00	1 00	1 25	..
Slack	0 85	0 85	0.85	0.85	0.85	1 05	..

CHICAGO

As a result of the floods, shipments of coal to the Chicago market have been curtailed and storage piles are diminishing rapidly, while quotations on a number of varieties of coal have been advanced.

There has been an increase of 10c. a ton in the price of screenings. Lower-grade screenings from central Illinois have been commanding from 95c.@$1 a ton, and the price of other fine coal has been on a proportionate basis. Almost all of the fuel arriving in Chicago is being used for steam-making purposes. As a general proposition, it may be said that the supply is not more than two-thirds of the normal amount. It is expected that several weeks will elapse before the shipments of Indiana coal will be up to the average. The mines south of the Wabash and the White Rivers have been shut out of this market as a result of the floods.

Much difficulty has been encountered by Illinois operators in meeting the demands made upon them, due to lack of transportation facilities. The market for coke is strong.

Prevailing prices in Chicago are:

	Springfield	Franklin Co.	Clinton	W. Va.
Domestic lump	$2.07	$2.40	$2.27	
Egg		2 40		$3.95
Steam lump	$1.92@1.97		2.17	
Mine-run	1.87@1 92	2.20@2.30	1.97	3.30
Screenings	1.77@1.82	2.00@2.05	1.77	

Coke—Connellsville and Wise County, $6@6.25; byproduct, egg, stove and nut, $4.45; gas house, $4.75@4.85.

ST. LOUIS, MO.

There has been nothing out of the ordinary in the coal market here for the past week, and weather conditions are not such to make the future look encouraging. Prices are still the same, with practically no demand, and coal still comes in under demurrage. Several of the mines in the southern Illinois field have been put out of commission on account of the high waters, and this, of course, has had a tendency to keep a small tonnage out of the market for the present.

There is a rumor to the effect that certain Chicago operators are making arrangements to take over several Franklin County properties and consolidate them. However, there is some question as to whether this deal will go through on account of a difference of $75,000, it is rumored, between what one owner wants and what the Chicago people are willing to give. The property in question has never been considered a paying one, and it is possible that the stockholders may differ with their agent and let the property go. If an arrangement of this kind went through, it would be a wonderful help to the Franklin County operators by putting the scavengers of the coal business at the present time out of the way.

The anthracite companies are not as popular in this section as heretofore, and especially in this so with the jobbers. After the business in Illinois had been worked up by the jobbing interests in St. Louis, the anthracite combine has advised them that jobbers will be no longer allowed a discount off the circular, as the anthracite shippers are going after the small one-car customer direct themselves. However, it is a question as to whether anthracite will be in favor in the future on account of the utter disregard shown this market during the past winter. The preparation and sizing of practically all the anthracite shipped west this winter was poor.

One of the most discouraging features developed during the week was the price war between two or three of the retail anthracite dealers. At the moment the coal is being delivered consumers at the same price demand f.o.b. tracks.

The prevailing circular is:

	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard
2-in. lump				$0.90
3-in. lump			$1.25	
6-in. lump	$1 20 @ 1 25		1.35	1.10
Lump and egg	1 25	$2 25		
No. 1 nut	1 10 @ 1 15			
Screenings	0.90 @ 0.95			0.65
Mine-run	1 05 @ 1.15			0.85
No. 1 washed nut	1 40 @ 1.50			
No. 2 washed nut	1 35 @ 1.45			
No. 3 washed nut	1 25 @ 1.30			
No. 4 washed nut	1 15 @ 1.20			
No. 5 washed nut	1 00 @ 1.05			

MINNEAPOLIS—ST. PAUL

Like the preceding months this year, March proved itself a disappointment to the coal trade and especially the wholesale end of it. While the retailers have been doing a fair business some of them will have to carry certain grades over to next year. In a number of towns in the Northwest, dealers have been unable to get hard coal during the past two or three months, while in other places, retailers stocked so heavy last fall that they will be forced to carry anthracite over for next year.

Steam users are reluctant about signing up contracts and at present are ordering sparingly, evidently expecting a repetition of last year's erratic market. While it is true contracts were taken at any price last year, the leading wholesalers in this territory are talking firm quotations, and it is thought the strife for tonnage will not be repeated again this year.

PORTLAND, OREGON

There is nothing new of particular interest to report in this district, excepting that spring weather has set in and the demand for fuel for domestic purposes is consequently lighter. Australian and Wyoming coals are quoted at $10, retail, delivered within a reasonable distance of the city center. While no Australian coal was imported here during the winter the supply is said to be abundant for whatever business may be expected until new shipments can be secured.

FOREIGN MARKETS

GREAT BRITAIN

Mar. 28—There is more inclination to enter into fresh business, although it is evident that the holiday influences have not been altogether overcome.

Quotations are approximately as follows:

Best Welsh steam	$4.68@4.80	Best Monmouthshires	$4.26
Best seconds	4.44@4.56	Seconds	4.08@4.14
Seconds	4.44@4.50	Best Cardiff smalls	3.78@3.84
Best dry coals	4.44@4.50	Seconds	3.54@3.60

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days—less 2½%.

FRANCE

Production of coal in France for the year of 1912 was 43,227,647 as compared with 41,229,090 tons for 1911. Production of coke in 1912 was 2,603,965 tons as compared with 2,487,183 tons for the year previous. Briquettes manufactured during 1912 amounted to 2,649,380 tons and in 1911, was 2,519,144 tons.

French Imports and Exports for January of this year and last were as follows:

	Imports 1912	Imports 1913	Exports 1912	Exports 1913
Coal	1,303,900	1,351,300	151,412	95,287
Coke	186,000	286,400	14,680	20,842
Briquettes	98,500	78,800	12,944	9,611

SPANISH IMPORTS

Imports of coal into Spain for January of the current year were 192,390 tons as compared with 194,789 tons in 1912. Coke imports were 25,327 tons in January of this year and 37,956 tons for the same month last year.

COAL SECURITIES

The following table gives the range of various active coal securities and dividends paid during the week ending Apr. 5:

No Important Dividends were announced during the week.

The Lehigh Valley Coal Sales Co.—This company, which was incorporated last January, as a subsidiary of the Lehigh Valley Coal Co., in order to comply with the provisions of the Hepburn law preventing a railroad from carrying commodities owned by itself, declared its initial dividend of 2¼ per cent. recently. The company has a capital stock of $6,080,800 outstanding.

Roby Coal Co. (Cleveland)—The authorized capital stock of this company is $800,000, all of one class. It is an Ohio corporation, which, in January, 1902, increased its capital stock from $100,000 to $400,000, and in August, 1905, to $800,000. It is said to be producing at the rate of 1,000,000 tons per year.

PRICES OF MINING SUPPLIES

THE MARKET IN GENERAL

Business was better at the end of March than at the beginning. Sentiment improved more in the first week of April than in any month this year. This was not without several adverse factors, which would ordinarily force business in a contrary direction, but apparently the tide of pessimism has run its course, for the time being at least, and merchants and manufacturers are willing to take more risk in business, and assume more responsibility.

The settlement of disturbances in Europe helped matters materially, and the averted squeeze in money in Germany resulted in Europeans taking more interest in American affairs.

In pig iron, there is no discernible improvement. Prices have declined slightly, due in some instances to an oversupply and lower prices for coke, and a reluctance on the part of consumers to speculate in the market. The floods in the Middle West have, of course, upset all calculations in the last ten days, but it is evident that the damage to the large industrials particularly the iron and steel, is going to be much less than was at first believed.

The situation in metals has improved much more rapidly than any other line of industry. In the copper market there have been large sales, prices have advanced, and exports to Europe, the key of the copper situation, have been at record-breaking figures. It is believed now that copper will be still higher within the next few months as surpluses are being rapidly reduced.

LABOR

Labor all over the country is well employed, particularly rough labor, and it is almost impossible to secure enough competent men to do the work planned for this summer. Miners are in especially good demand. All the labor agencies in New York are reporting more orders for this class of help than can be filled. There is also a large inquiry for handy men and workers around mines.

Unrest among skilled workmen is not general, and aside from the firemen's strike, or the controversy over wages raised by them, there seems to be little dispute among the better paid employees. An extension of time has been granted to the arbitrators in the firemen's strike, and award will not be made for three weeks at least. One of the bitterest strikes in some time is that of the street car operators in Buffalo, N. Y., and another strike exists in New York among the employees of the International Harvester Co. or one of its subsidiaries. It will be recalled that last fall there was much discussion that the wages paid in this plant were extremely low, but that may have been largely due to politics. The demand for miners continues large, and exceeds the supply. Surface workers are also in excellent demand.

IRON AND STEEL PRODUCTS

Numerous features of interest developed early in the month of April in the iron and steel market. The chief of these was the flood of a number of plants in Ohio. This had a greater effect on the finished materials than on the blast furnaces, but in such districts as Hanging Rock, most of the furnaces were out of blast and one company had 55 furnaces out of blast at once. The American Sheet & Tin Plate Co., the largest manufacturer of tinplate and sheets, at one time was operating to only 40% of its tinplate capacity, and the sheet situation was almost as bad. Not as many wire mills were affected as others, but enough to have an effect on the situation. The floods will exert another potent influence on the market to buy in the near future, increasing the demand considerably for finished products. These will be used for rebuilding, and while the entire loss is estimated at a quarter of a billion dollars, it will not be replaced at once, and only a portion of it is covered by iron and steel, still there is a great deal of steel which will be used in replacement. Another factor of prime importance is the introduction in Congress of a new tariff bill which reduces duties all along the line in the iron and steel industry, as well as in the metal trade. While tariffs are never finally disposed of until they are signed by the President, it is now as good a time as any to take account of conditions, and from the present state of the market in both the United States and abroad, the new tariff will have little effect on iron and steel prices. It may be that some of the commodities used by large consumers along the Atlantic seaboard and the Pacific Coast will be imported rather than purchased from mills in this country. These, however, will in no way effect the coal trade.

Rails—The buying of rails was neglected by the railways during March, and only a few thousand tons were disposed of. The demand for light rails, however, was large, and mills rolling this kind of shapes have practically all the work on their books that they care for, for a few months to come. At the same time, street railway companies have been buying rails in large quantities, and this will take a good deal of the capacity from the T-rail rolls. Deliveries are not at all satisfactory, being made in eight and twelve weeks after orders are received.

Quotations continue unchanged at 1.25 cents per lb. for standard sections weighing 50 to 100 lb. per yard; 1.21 cents for 40- to 50-lb. rails; 1.30 cents for 16• to 20-lb. rails; 1.35 cents for 12- to 14-lb.; 1.40 cents for 8- to 10-lb. rails. These quotations are in carload lots f.o.b. Pittsburgh. In Chicago, 16- to 20-lb. rails are 1.30 cents; 12-lb., 1.35 cents; 8-lb., 1.04 cents. Relaying rails in Chicago sell at $24 per gross ton, and at times these rails can be had for delivery other than Chicago.

Track Supplies—The demand for track material has been unusually heavy. Before the floods, all the railroads of the country were trying to get as much material as possible, and since that time there has been such an urgent demand for prompt deliveries that railroads have reshipped material from one point to another. Spikes are held at 2.10 cents base for large lots, track bolts with square nuts, 2.40 to 2.50 base, and tie plates at $34 to $36 per net ton. These quotations are for Chicago delivery. In Pittsburgh, angle bars at 1.50 to 1.60 cents; spikes, 1.95 to 2.15 cents, and as high as 2.25 has been paid for prompt delivery.

Structural Materials—Structural mills are now figuring on much replacement work for the railroads, and as this is heavy material, and the orders come from their best customers, it will be pressed through, regardless of any other work. For this reason, deliveries for the next few months are bound to be slow, and for fabricated work of a light character, prices will be correspondingly higher. This applies only to the fabricating of the work, and not the actual steel. Some of the mills are not disposed to make contracts for the delivery of roof trusses and other light work until they learn how much bridge material will be required. Similar conditions apply to the plate market, although not as urgently as in the market for other structural shapes.

Quotations are unchanged at 1.50 cents, Pittsburgh, for future shipment, and 1.75 cents for prompt shipment. In Chicago, the quotation for future shipments is 1.68 to 1.73 cents, and prompt delivery from $1 to $2 per ton higher. Plates are 1.55 cents. In Chicago, plates are 1.68 to 1.73 cents on contract, and 1.78 to 1.83 for near-by shipments. All of these prices are per 100 lb. in carload lots and over.

Pipe—The flood damage affected several of the pipe mills, but it was not as serious in heavy lines as in other cases. The demand for pipe is large, especially the smaller sizes. Mills are making fairly prompt shipments, and within a month should be doing considerably better.

Discounts continue unchanged as follows: Steel pipe, 1½-in., in large lots from mill, black, 77%; galvanized, 66⅔ ¾- to 2-in. black, 80%; galvanized, 70½%; 2½- to 6-in. black, 79%; galvanized, 70½%.

Based on these discounts, the net prices of pipe are as follows in carload lots, f.o.b. Pittsburgh:

Size, inches	Cents Black	Cents Galvanized
¼	2 30	3 40
⅜	3 40	4 85
1¼	4 60	6 55
1½	5 50	7 70
2	7 40	10 30
2½	11 50	16 70
3	15.40	21 75

Sheets—The sheet mills of the country are more seriously affected by the floods than any other line. At one time, fully 50% of all the sheet mills operating in the country were compelled to close on account of high water, lack of power, or lack of material. Some of the mills, which for the

last month have been making low prices, were compelled to close on account of the high water. This removes the feature of weakness in the market, and prices may be expected to advance. Those of the trade who recall the San Francisco disaster, will remember at that time, there was a tremendous demand for sheets for temporary structures. While this present disaster is somewhat different, there will undoubtedly be a large inquiry for sheets in the affected districts. Deliveries can be made on contracts in about eight weeks. The general quotations are $1 per ton higher than last month. The following prices are for lots of a few bundles f.o.b. Pittsburgh and Chicago. This should not be confused with the quotation for carload lots, which is based on a price of $2.30 f.o.b. Pittsburgh for No. 28 black.

	Cents per Pound			
	Pittsburgh		Chicago	
	Black	Galv.	Black	Galv.
Nos. 22 and 24	2 75	3 55	2 70	3 50
Nos. 25 and 26	2 80	3 70	2.75	3 65
No. 27	2 85	3 95	28.0	3 90
No. 28	2 90	4 00	2.85	2 95

WIRE PRODUCTS

Wire—Activity in this line continues, and the fact that a great many wire mills in the Central West were put out of commission by the high water has stimulated interest in this market to a marked degree. Quotations are $1 per ton higher and considerable delay is experienced in securing delivery. For large lots, quotations are as follows: Painted barbed wire, $1.80 Pittsburgh; galvanized, $2.20; annealed fence wire, $1.60; galvanized, $2.05. In Chicago, annealed fence wire is $1.78, and galvanized $2.18. Barbed fence wire in that market is held at $1.98, and galvanized at $2.38. All of these quotations are per 100 lb. in fairly large lots. In small quantities, prices are advanced about 25c. per 100 lb.

Wire Rope—Business is more active, but prices are unchanged. Two-inch rope is held in Pittsburgh at 57c. per lin.ft., 1¼, 23c., ¾, 10c. These quotations are for the highest grade, and for large lots. Cheaper grades can be secured at slightly lower figures.

Telegraph Wire—The demand has been much larger than usual. Deliveries are slow, and it is practically impossible for small consumers to buy from manufacturers, and they are compelled to secure supplies from outside interests. Prices are as follows in cents per pound for wire measured in the Birmingham wire gage: "Extra Best Best," Nos. 6 to 9, 4¾c.; Nos. 10 and 11, 4½c.; No. 12, 4⅝c.; No. 14, 5⅛c.; "Best" Nos. 6 to 9, 3½c.; Nos. 10 and 11, 3⅝c.; No. 12, 3½c.; No. 14, 4c. Actual freight is allowed from Trenton, N. J., where it does not exceed 25c. per 100 lb.

Copper Wire—The market is much better, the demand large, and deliveries slow. Quotations have advanced ½c., and the base price of copper wire in fairly large lots is now 16½c. per lb.

HARDWARE

Bar Iron and Steel—Prices are firm, and stocks are fairly well assorted, and consumers secure supplies desired with little difficulty. Quotations from jobbers' store in New York and Chicago are as follows:

	Per lb.
Refined iron:	
1 to 1¾ in., round and square	2 15c.
1¼ to 4 in. x ¼ to 1 in.	2 15c.
1¼ to 4 in. x ¼ in. to ⅞ in.	2 35c.
Norway bars	3 60c.
Soft steel:	
¼ to 3 in., round and square	2 10c.
1 to 6 in. x ¼ to 1 in.	2 10c.
1 to 6 in. x ¼ and ⅞ in.	2 25c.
Rods—¼ and ⅜ in.	2 20c.
Bands—1½ to 6 x ⅛ in. to No. 8	2 40c.
Beams and channels—3 to 15 in.	2 25c.

Nails—While the demand for nails is not especially heavy, there is a shortage in the supply, due to the flooding of many nail manufacturing plants in the Middle West, and, at the same time, railroads are unable to move supplies from mills that have not been flooded, so there has been a fair amount of anxious buying among consumers who wished to secure supplies promptly. Quotations are higher at $1.80 Pittsburgh for large lots, and $2.08 in Chicago. In New York, wire nails from store at $2.10, and cut nails from store are at the same price In other jobbing centers, prices prevail equal to those in New York.

Rivets—Deliveries of rivets are unsatisfactory, because of the inability to get raw material promptly. Quotations are without change at $2.20 for structural rivets and $2.30 for boiler rivets. These prices are per keg of 100 lb. in carload lots, f.o.b. Pittsburgh.

Chain—Prices of chain are firm, but the buying has not been especially large. Ruling quotations per 100 lb., f.o.b. Pittsburgh, are as follows:

⅝ in	$7 50
½ in	4 95
⅜ in	3.95
¼ in	3.40
5/16 in.	3.20
½ and ⅝ in.	3.00
⅜ and ½ in.	2.90
⅜ and ⅝ in.	2.80
¼ and ⅜ in.	2 70
1 to 1¼ in.	2.60
Extras for BB	
⅝ in.	1 50
½ in.	1.50
⅜ in. and larger	1 25
Extras for BBB	
⅝ and ½ in	2c.
⅜ and larger	1 75c.

METALS

Copper—Seldom has feeling so changed concerning any single commodity, as has been the case in the copper market during the last month. Prices are now advancing steadily, and copper is selling at around 15½c. compared with 14¾c. a month ago. The exports to Europe during March were the largest on record, totalling nearly 42,000 tons, and the report of the Copper Producers' Association was especially satisfactory, showing a decrease in American stocks of over 18,000,000 lb. American consumers have bought largely, not only for present, but for future, delivery, and it is evident that they will have to buy more in the near future. The market for copper sheets is steadier, and sheet copper is selling at around 18½c. base in New York, and slightly higher prices at interior points. Quotations on copper sheets are for comparatively small lots.

Tin—Prices of tin advanced steadily, and in wholesale weights, tin is selling at around 5c. per lb. New York and Chicago. Solder, half and half guaranteed, sells at 27½@28c.

MISCELLANEOUS

Horse and Mule Shoes—The price of iron shoes f.o.b. Pittsburgh is $4.10 per case of 100 pounds. Steel shoes can be had at $3.85 per keg of 100 pounds.

Brattice Cloth—Seemingly, there is little change in the market for brattice cloth compared with last month, and although consumers are looking for lower prices, there is little hope of this for several months to come. Deliveries are somewhat better: at least, importers are promising better deliveries and while the demand is large, the supply is greater than two months ago. The new tariff as now planned, will not have any great effect on the brattice cloth market, and while it changes the method of levying the duty from a flat rate to a percentage rate, this does not at present operate in the consumer's favor.

Portland Cement—Makers of cement have more business on their books than ever before. All of the cement companies are holding prices very firm at around $1.58 in Pittsburgh and New York. This corresponds to a price of 90 to 95 cents per barrel in bulk at the mills, with an additional charge of 40 cents for bags or barrels. It would not be at all surprising if there were a serious shortage in cement later in the year, especially in the Middle West, for the consumption there promised to be larger than ever before previous to the flood.

Rope—It has been a number of years since the prices of rope have been as high as those now recorded. This is due to the world wide demand for all kinds of hemp and Manila products, and prevailing prices are nearly double those of last year. Best grades of Manila rope sell at 15 cents per pound in New York, while second grade is at 14 cents per pound. Sisal sells at 9 to 10½ cents.

Bars, Concrete Reinforcing—The market is active, and shipments are being urged by consumers of all classes. Stocks in the warehouse are considerably better than two months ago, but they are not at all large . Quotations from warehouse stocks in comparatively small lots are as follows:

PITTSBURGH PRICES IN CENTS PER POUND

	Warehouse Stock
¼-in.	2 00@2 10
½-in	2.05@2 15
¾-in.	2.10@2.20
1-in.	2.25@2.35

Triangular Mesh—Business continues active, and makers of this material have little difficulty in making prompt shipments From mills in De Kalb, Ill., quotations are 18c. per 100 lb. higher than those quoted below, which are 100 sq.ft. f.o.b. Pittsburgh. These are for lots of less than 10,000 sq.ft.

No. 23	$1 23	No. 32	$2.62
No. 23	2 05	No. 36	1.05
No. 26	1 42	No. 40	3.25
No. 28	1 97	No. 41	2 48

COAL AGE

Vol. 3 NEW YORK, APRIL 19, 1913 No. 16

Breakers Ahead!

IT is about time that some of the lookouts in the coal-mining industry shouted a warning: "Rocks ahead!" In a half-dozen states today, legislative programs have been proposed, which, if enacted into laws, would paralyze the coal business.

This is no time to sit idly in our hammocks and smoke the pipe of peace. The industry as a whole is asleep. The most it has done in years is to wiggle a toe or bat an eye when some "Idol of the People" has jabbed a harpoon into its anatomy.

Supposing all the citizens in Ohio knew that the "Green" bill, which seems about to pass the legislature of that state, is a measure that eliminates all premium on skillful mining. Under this act the men can shoot the coal to atoms if they please, and they will do this if the bill becomes a law.

Talk of conservation—can anyone conceive an act more inimical to all that the term means? Miners as a whole are as decent, as careful, and as intelligent as any other class of labor. But they are working for dollars, not fun, and when they are paid as much for dust as for lump coal, they will let explosives do the work, regardless of the quality or size of their product.

We stake our reputation that the result will be as follows: The percentage of slack coal will increase from 10 to 30 per cent, and the large sizes will decrease that same amount. The price of lump coal to the consumer will advance materially. More timber will be needed; more lives will be lost and general operating costs will increase.

If the miners of Ohio want more money for their labor, and can prove the justice of their claim, let them get it in some other way.

The "Green" bill is a step backwards, and in the end will not add luster to the fair name of coal mining in Ohio. The citizens will hold Mr. Green and his colleagues responsible when it becomes evident to all that the consumer has to pay the added freight.

Glance for a moment at Arkansas and Oklahoma, where, in addition to being shot from the solid, the coal is paid for on a mine-run basis, such as is suggested in Ohio. Since the law went into effect, screenings have gone up from 30 to 55 per cent. of the total output, and the price of lump coal has increased nearly 70 per cent.

Fortunately the solid-shooting law in Oklahoma has just been replaced by a bill recently enacted and to become effective July 1, which forbids any more coal to be shot unless it is first undercut. Legislation, some years ago, resulted in placing Oklahoma a decade behind Ohio in common mining practice. Proposed new legislation in Ohio may reverse the order of the two states.

Coal Age has always maintained its absolute independence and has based its every action on what seemed fair to miner and operator alike. We have never violated our belief that the industry can make no permanent headway except on lines of unquestioned integrity. Our policy has ever advocated fair wages and decent treatment to the men in return for honest labor.

We have been heart and soul with the miners in many of their fights for better conditions. However, in such matters as the "Green" bill in Ohio, and the 200 petty strikes that have occurred in the anthracite field since the recent wage agreement was signed, we question not only the honesty of the men, but the sincerity of President White and the Union officers in the different states concerned.

IDEAS AND SUGGESTIONS

Efficiency Improvement through Education

Education in basic principles increases the efficiency of the workman in all other handicrafts and professions, and one would be greatly surprised to learn that coal-mining was outside the scope of its influence.

The arbitrary popular division of industries into those requiring some skill in the manipulation of tools, or the exercise of some degree of mental dexterity in directing their peculiar operations; and those in which it is alleged brute force and a somewhat instinctive action alone are needed in their pursuit, is, of course, a mistaken one, with a mischievous prejudice as the result.

We have yet to be convinced that the skill considered requisite to carve a piece of wood, cut a block of stone along geometrical lines, apply the necessary temperature to the welding of iron, or direct the operations of the machine that reduces pieces of steel to symmetrical proportions, differs in aught else than degree from that necessary to the mining and blasting of a section of a coal-seam, in an atmosphere which may carry a deadly agent, whose detection depends upon the skillful handling of such a delicately adjusted piece of mechanism as a safety lamp.

There are incompetent masons and carpenters, just as there are inefficient miners, men who are a source of concern and loss to their employers, and whose bungling attempts to earn a livelihood are a menace to whole communities.

In either case the predisposing cause, as a rule, is directly traceable to lack of knowledge of a special kind.

From being an industry distinguished by the great simplicity of its operations, coal mining is rapidly being transformed into one of remarkable complexity, and its successful pursuit calls for special knowledge of a wide and varied character on the part of workmen and officials, and a general mental alertness that educational processes in theory and principle alone can provide.

It is no argument against education to aver that many apparently superior practical men have attained marked efficiency without much, if any, assistance from schools or text-books.

The uneducated efficient man does not exist.

Time and again some weak link in the chain of his arduously acquired experience gives way, and exposes his incompetence with terrible consequences to himself and others.

I have wrought alongside many so called practical men who boasted of their independence of theory, and who professed a contempt for book-knowledge. I rarely parted from even the best of such individuals without an opportunity for demonstrating the value of some despised principle, or theory, presenting itself.

It is education and its theories that have enabled the mine worker to displace the pick with the machine, the wedge with the explosive, the furnace with the fan, steam with electricity, the mule with the motor, the tallow-dip with the safety-lamp. It has enabled the miner to raise himself from the degradation of a chattel, through successive grades of improving self-respect, to the position he occupies today, where labor challenges the supremacy of capital, and calls for recognition on terms of equality when issues that affect the destinies of the industry are at stake.

In some mining districts in Scotland there is an agitation afoot to have instruction in the principles of mining incorporated in the elemetary schedules of the common schools.

In this matter it is the miners themselves who are moving; and they reason that in a mining community where the majority of the boys must inevitably follow the calling of the mines, many of the principles whose possession will be essential to their efficiency as breadwinners in after years, may be as successfully inculcated at the schoolbench as at the face of the coal-seam.

⁂

Is the Mine Telephone a Failure?

By Sim and William H. Reynolds

The foreword in Coal Age of Feb. 8, on the mine telephone, or rather on the neglect of the mine telephone generally, should be of universal interest to mining men.

For some unaccountable reason many coal operations try valiantly, if foolishly, to get along without its invaluable aid. It is a safe assertion that not 5 per cent. of the coal mines in the Pennsylvania bituminous regions have telephones in running order. During the past year I have had occasion to visit, in a business way, more than 100 mines in the states of Pennsylvania, Ohio and West Virginia, and I, therefore, speak from observation.

While there are few modern mines that have not had a telephone system in use at one time or another, in dozens of them only the remains are to be seen today. Sometimes we find that the same official who had it installed has allowed it to disintegrate, but more often a shift in officials is the cause. If it were possible to interview all the foremen and superintendents who have had mine telephones and given them up we would probably find their reasons were: "Out of repair too often"; "Wires broken too frequently by falls"; "Too much moisture"; "Someone fooling with the line all the time." We have the first to find yet who did not acknowledge the great convenience and actual necessity of the system, and we have interviewed many on the subject. But because of one or more of the above reasons the upkeep was allowed to become neglected and final abandonment was the result.

In our opinions the failure of most mine telephone systems is because the management fails to recognize that it must be given the same consideration as a trolley line or a pipeline. If a wire carrying power to the mine is short-circuited or broken, somebody is "on the job" immediately. If a rail is broken or a pipe "busted" or a

pump "bucking," somebody is generally held responsible for getting it into shape again. But pity the poor telephone line; it is usually installed and then left to take care of itself, which is something mine equipment of any sort does not generally do.

Yet this is not because the utility of the system for mine use is not understood. There are too many hours of messenger service, too many bits of quick action can be taken, when quick action means money in the owner's pocket, for its practical qualities to be denied.

Several years ago the foreman of an old drift mine in Ohio found that the main haulage motor was losing a great deal of time because the motorman when in one of his two sections, which were a mile and half in, did not know what the conditions were in the other. Many times the motor waited for loads at one sidetrack while the drivers were waiting for empties at the other. At other times, near the finish of the day, when the motor had barely time to make another trip, the driver would err on the safe side (for himself) and not start in, for fear of meeting the drivers coming out, when if a telephone had been in service he could have notified the trapper at the sidetrack that he was coming. The loss of this last trip at that mine meant a great deal in the cost of the day's output. This was but one phase in the daily work where the need was urgent. The workings being so far removed from where the supplies for the mine were kept, caused a great deal of inconvenience and expense, and was a decided drawback to the proper management of that mine. So the foreman determined on having a telephone system rigged up, as the "made-for-the-mine" outfits were not on the market then as they are today, and the installation of a system which would serve for mine use was largely a matter of ingenuity, and subject to a great many discouragements. This one was no exception, and for sometime was very irregular in its service. Like Finnegan's report it was "Off agin, on agin" quite often. Sometimes a little fall would break the wires; at other times somebody would twist them together just for pure oneryness, and, on one occasion someone, evidently thinking the batteries were not strong enough, ingeniously connected a fine wire to the trolley line and "burned her up!"

But the foreman of that mine stuck to it, and finally placed the entire responsibility of keeping it in running order on a certain employee. He had that man make an examination of the entire line every morning, and *on foot*. And that system is in good use yet, though it has never consisted of anything more complex or expensive than the ordinary wooden case as used on the surface, protected from the mine air by a large box made by the mine carpenter, the latter being heavily coated on the inside with pitch, and covered on the outside with tarred roofing paper. The outfit consisted also of a good tight-fitting door, with ordinary steel wire for the line.

Aside from its advantage as a business proposition in the equipment of a mine the utility of a telephone system as a safety device can hardly be overestimated. This service alone should impel mine managers to install the 'phone. Instances innumerable are recorded where not only have accidents been avoided but relief brought more promptly when they did occur, and much valuable time saved when minutes meant both dollars and life. One instance we recall at a mine in West Virginia, where the man in charge had installed a telephone from the engine room at the shaft into the workings two miles underground.

A driver was injured by getting his head between a mine car and a post, and rendered unconscious. His fellow workmen notified the superintendent on the surface, who in turn called up the hospital two or three miles distant. As a result the hospital ambulance was on the spot before the injured man reached the shaft top, and within an hour of the accident the victim had received expert attention just in time to save his life.

Another instance we recall of a large mine fire in one of Pennsylvania's largest mines. A gas feeder was ignited as the machine cut into it; ordinary methods of fighting it proved futile, and flames were soon rolling back yards from the face. The mine telephone was put into action and the manager on top hurriedly decided to borrow a thousand feet or so of hose from the local fire department, and rushed it into the mine on a motor. Connection was made to a large pump line and the fire put out before it had a chance to get the entire section, if not the whole mine going.

Coal Prices at Suez and Panama

In a review of investigations by the United States as to the supply and relative cost of coal on the Suez and Panama routes to the far East, the *Manchester Guardian* notes that American and British coal will be brought into sharp competition, and prices at the coaling stations will, in many cases, determine whether the new or the old route will be taken by vessels sailing to the Orient, Australia and some ports of South America.

From Europe to Australia and the Orient generally the advantage of distance will be with the Suez route, but if, as is anticipated, in certain quarters, coal prices at stations on the new route can be maintained materially below those on the old, it will be cheaper for many vessels to make the longer voyage.

Prices of British coal at Suez are relatively high, ranging from $5.10 to $6.30 per ton, whereas it is expected that American coal will be supplied at Panama for $4.60 at the outside, and that in due time the price may be gotten as low as $4.15, or thereabout, at the Pacific end of the new canal.

Obviously if good American coal can be bunkered substantially below $4.90 a ton, many vessels will be inclined to take the new route to the Orient, Australia and New Zealand. At Norfolk, New River coal is only $2.70 a ton, and the freight rate from there to Panama is about $1.10. It is expected that eventually the government will be able to make contracts on the basis of $2.65 Norfolk, and with $1.10 for freight, and 50 cents to cover charges for storage, labor, etc., the coal can be supplied f.o.b. at the Atlantic end of the Canal at about $4.60 a ton, and that the price at the Pacific end will not exceed $5.

In 1913, the contract price for Welsh coal at Port Said was $6.33 per ton, the price to those companies renewing previous contracts being $6.21. It is probable that the United States government can profitably sell coal at Christobal for about $4.75, and at Balboa for $4.25 less than the price charged at the Suez Canal. This will be made possible, however, only by the government maintaining coaling stations at the Canal termini and by selling the coal at cost or with but very slight profit.

Mining in the Pocahontas Field

By Audley H. Stow*

SYNOPSIS—The Pocahontas district has long occupied a preëminent position among the famous bituminous coal fields of the world and the methods adopted there are watched with interest. The best portions of the district are controlled by two holding corporations who lease the land on a royalty basis to the operating companies. To insure the maximum recovery, under these leases, exhaustive studies into the best methods of mining have been conducted, and the results are quite interesting.

The famous Pocahontas coal is characterized more particularly by its relatively low percentage of volatile matter, as compared with other bituminous coals. It is, however, somewhat soft and friable, so that under the rather strenuous methods of modern mining and handling the

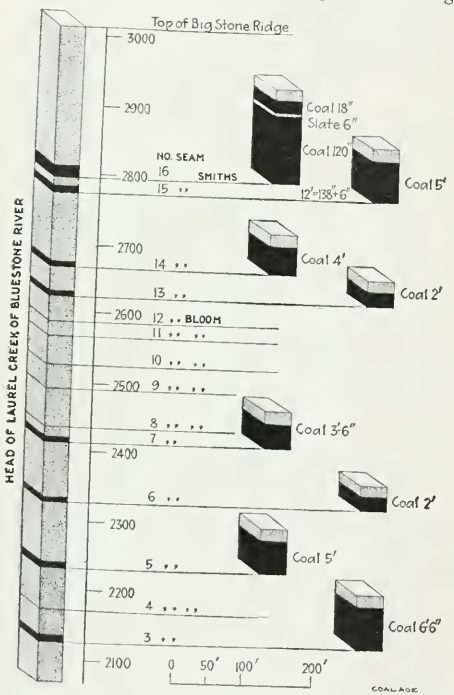

Fig. 1. Section of the Pottsville Measures, Showing the Pocahontas Seams

percentages of lump, egg and nut are not always as high as would be desired. In texture and appearance, Pocahontas coal resembles the Kentucky, Elkhorn or Jenkins seam of the Consolidation Coal Co.'s new operation, although, on the other hand, the latter has a high percentage of volatile matter, resembling the Pittsburgh coal in this respect. The analysis of the Pocahontas and certain Welch coals is much the same in regard to volatile matter, although as to physicial characteristics, hardness

*Consulting mining and civil engineer, Pocahontas, Virginia.

more particularly, they are the direct antithesis of each other.

The physical features of the Pocahontas field are unusually interesting. The mountains here, as in a considerable area in both West Virginia and Kentucky, are the result of erosion. The district was doubtless at one

Fig. 2. A 12-Ft. Outcrop of the Famous Pocahontas Coal

time an immense plains country, which was lifted to a great elevation, with a pitch of three feet in a hundred, toward the Ohio River. Erosion has since been rapid and with the exception of narrow bottoms along the creeks,

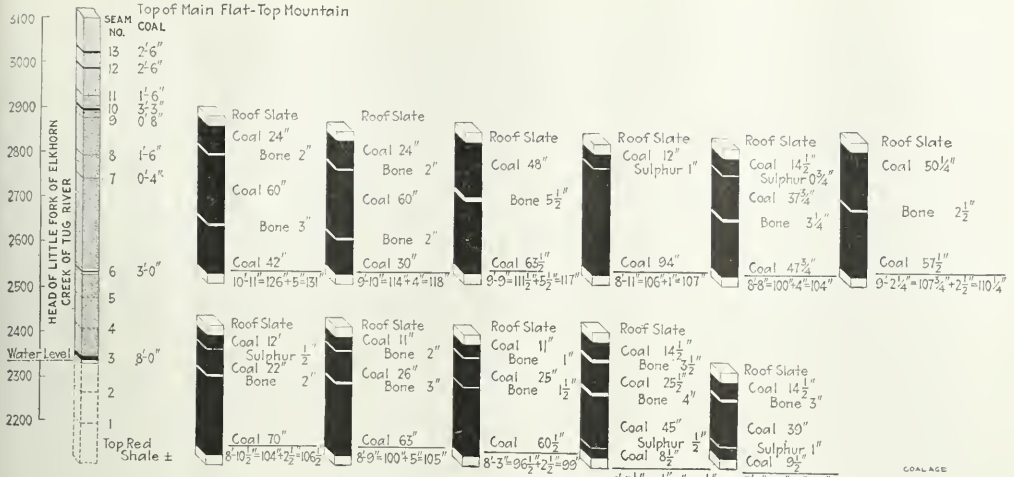

FIG. 3. THE POTTSVILLE MEASURES ON ELKHORN CREEK AND SECTIONS OF THE POCAHONTAS NO. 3 SEAM

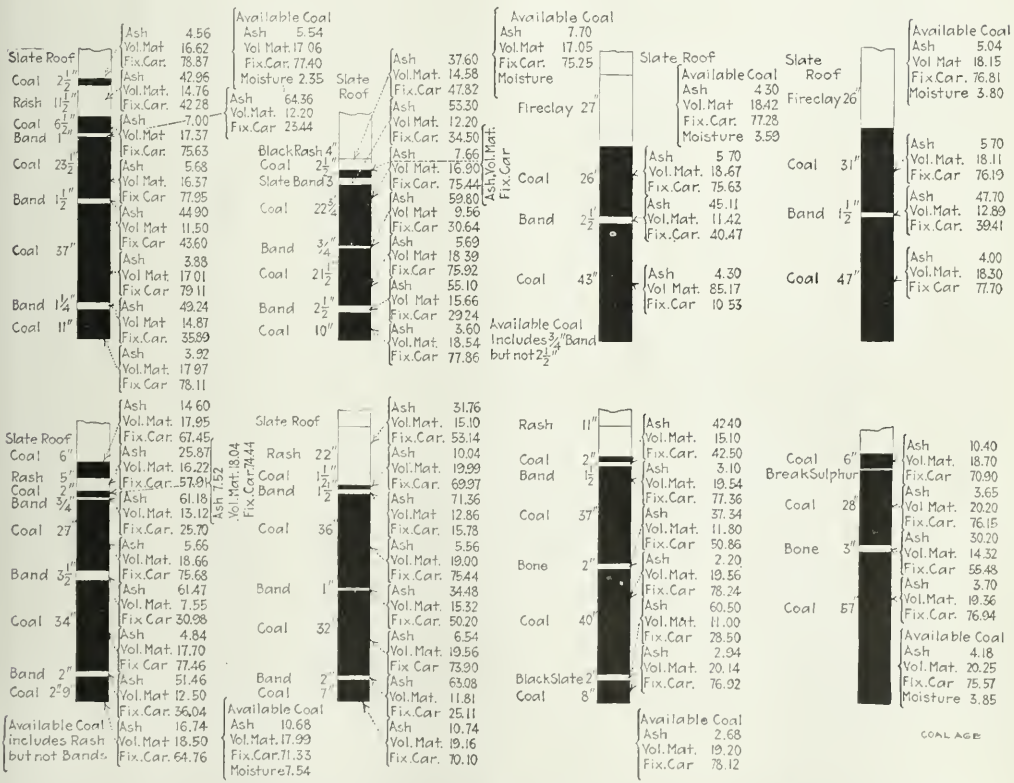

FIG. 4. ANALYTICAL SECTIONS OF THE POCAHONTAS NOS. 3 AND 4 SEAMS IN THE MINES OF THE UNITED STATES COAL & COKE CO., AT GARY, W. VA.

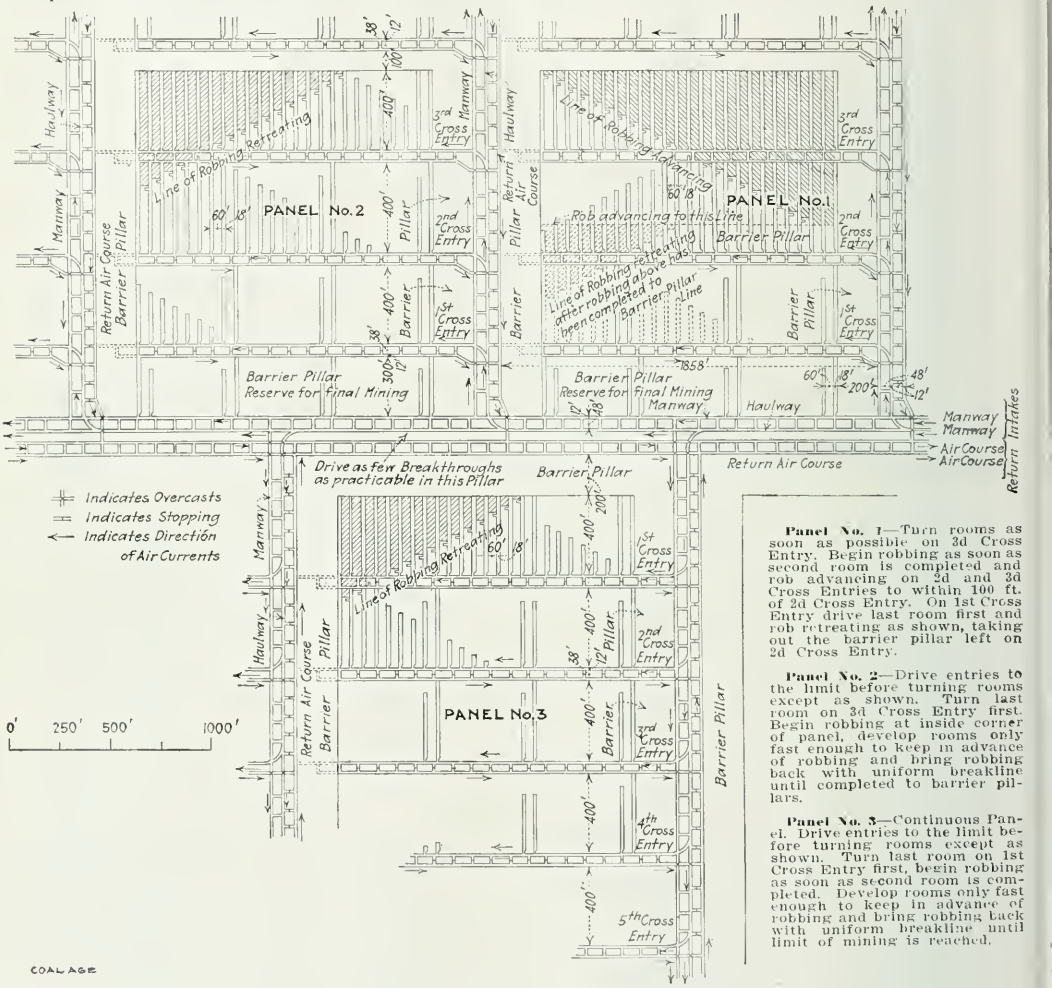
there now remains practically no level land, outside of a few comparatively small areas on the Flat-top Mountains. It is hardly plausible, either, that these areas or plateaus represent the surface of the original plains country.

The geology of the Pocahontas field, which is substantially the same as that of the New River, is well known and even the general statement that these measures are the equivalent of the Pottsville Conglomerate is almost that of the great No. 3 seam, as is shown by Fig. 1. Judging by sections shown later, large areas of the upper seams, equal in development perhaps to the New River field, have been eroded.

It is considered that the Pocahontas field is a shore deposit. However this may be, the No. 3 seam increases in thickness from Welch, the county seat of McDowell County, W. Va., toward Pocahontas, Va., where it reaches its maximum of 16 ft. in the No. 2 operation of the



Panel No. 1—Turn rooms as soon as possible on 3d Cross Entry. Begin robbing as soon as second room is completed and rob advancing on 2d and 3d Cross Entries to within 100 ft. of 2d Cross Entry. On 1st Cross Entry drive last room first and rob retreating as shown, taking out the barrier pillar left on 2d Cross Entry.

Panel No. 2—Drive entries to the limit before turning rooms except as shown. Turn last room on 3d Cross Entry first. Begin robbing at inside corner of panel, develop rooms only fast enough to keep in advance of robbing and bring robbing back with uniform breakline until completed to barrier pillars.

Panel No. 3—Continuous Panel. Drive entries to the limit before turning rooms except as shown. Turn last room on 1st Cross Entry first, begin robbing as soon as second room is completed. Develop rooms only fast enough to keep in advance of robbing and bring robbing back with uniform breakline until limit of mining is reached.

FIG. 5. GENERAL PLAN OF MINE DEVELOPMENT FOR THE POCAHONTAS COAL & COKE CO.

superfluous. The main producing horizon in the Pocahontas field is, however, nearer the underlying red shales than in the New River field. If, however, the Davy field on the Norfolk & Western Ry. be considered a part of the Pocahontas, then we also have what is nearly the equivalent of the New River field.

In certain portions of the holdings of the Pocahontas Consolidated Collieries Co., in the Pocahontas field, some of the upper seams have a development of coal rivaling Pocahontas Consolidated Collieries Co. This development of the seam is, however, abnormal, a more average thickness being 8 to 9 ft., although this is often considerably exceeded, as shown by Fig. 2, taken along the outcrop at Pocahontas, Va.

We have not, however, reached the Abbs Valley fault, where our No. 3 seam is turned up, rather abruptly, and stands on edge. Whether the location of this fault bears any relation to the original limit of the field, that is, of

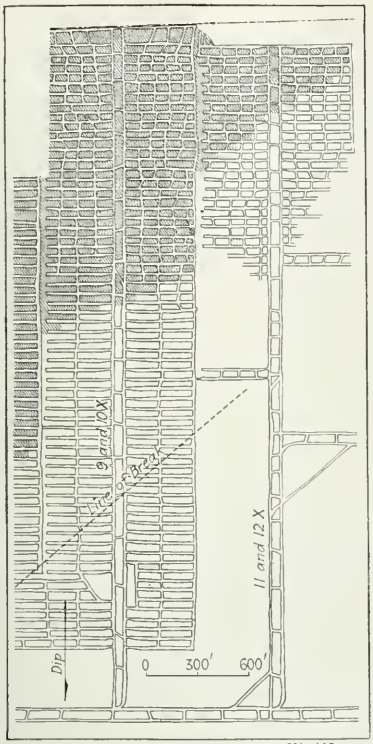


Fig. 6. Plan Showing Double-Entry System of the Upland Coal & Coke Co.

the ancient shore line, is a question of some interest; if this seam continued to increase in thickness on past the Abbs Valley fault, a rare and valuable body of fuel has certainly been lost. The fault line, however, is certainly the limit of the field on this side and may have also been substantially the original shore line; therefore, it is at least possible that it is also the limit of the somewhat thicker portion of the earth crust on which the Pocahontas coal was formed or deposited.

Beginning at a point on Bluestone River, say 25 miles down stream from Pocahontas, the No. 3 seam increases in thickness until the town is reached, but shows no further increase beyond, although it apparently holds its own.

Limits of the Field

The Pocahontas field proper is a relatively well defined area, bounded on one side by the Abbs Valley fault, and on the opposite by a line approximately parallel to this fault, and crossing the main line of the Norfolk & Western Ry. at the town of Welch, the county seat of McDowell County. The limits along this line are Susanna, on the Dry Fork, in one direction, and Pineville, the county seat of Wyoming County, on the Guyandotte River, in the other. This is the western limit adopted by the Pocahontas Coal & Coke Co., the Norfolk & Western Ry. in their car-allotment distribution, and by J. J. Lincoln in his tabulated statements of the annual shipments. This limit, however, is not an entirely satisfactory subdivision, as the measures of the No. 3 seam, for instance, really extend still further westward, getting, however, deeper and probably thinner, while the water and gas to be contended with, are necessarily considerable.

The two remaining and opposite sides are less sharply defined. In going from Pocahontas down Bluestone River, the seam becomes rapidly thinner, reducing to

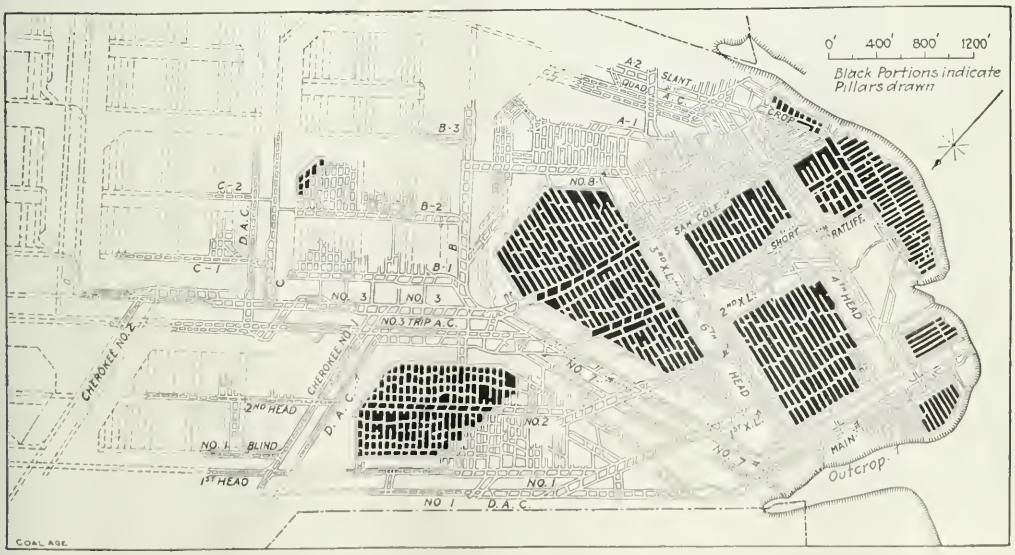

Fig. 7. General Plan of the Pocahontas Consolidated Collieries Co.'s Angle Mine

about 4 ft. in thickness, although it remains above drainage level, so that there is no gas to contend with. In the opposite direction from Pocahontas, along the Abbs Valley fault line, the No. 3 seam becomes deeper and deeper, finally going below water level, and, insofar as I have been able to ascertain, it is no longer found beyond a certain point.

Dip of Strata

From Welch to Pocahontas is nearly directly up the maximum pitch, which is about 3 per cent, or 150 ft. per mile. From Bluestone River to Pocahontas, and along the Abbs Valley fault, is roughly along the general strike of the measures.

There is one feature here that is of considerable interest from a mining standpoint and one which I have never seen referred to elsewhere. With the Caswell Colliery (Pocahontas Consolidated Collieries Co.) as a center, there is quite an area of the field in which there is practically no general dip. The local hills and hollows in the seam are very moderate and might be likened to the waves of the sea, or rather as the long ground swells on a calm day.

From the Caswell Colliery toward, and past, the town

Fig. 8. Surface Plant at the Original Pocahontas Tipple

of Pocahontas, roughly on the line of strike, a zone is reached between the Abbs Valley fault, and the usually regular dip toward the Ohio River, in which there is a marked change in the general dip of the strata; a broad anticline having a gentle slope is developed here, along the summit of which the No. 3 seam is locally eroded. From this anticline toward the Abbs Valley fault the pitch is again sharply reversed, immediately at the fault line, resulting in a syncline, one side of which is almost vertical near the surface.

The sections of the No. 3 seam shown in Fig. 3 were obtained in the vicinity of the Pocahontas Consolidated Collieries Co.'s property and are typical of the best of the field in which this company is located. The thinner sections of the No. 3 seam are due to a split that occurs near the top of the seam at different points, Welch, for instance. However, there is, roughly, 6 ft. of coal, divided into three benches, one of 4 ft. and two of 1 ft.; the partings are about 10 in. thick, so can hardly be termed partings, in the usual sense of the word. In spite of the fact that this field was almost entirely bought up 25 years ago, the number of inquiries for strictly number one, low-priced properties, is certainly amusing.

The sections shown on Fig. 4 are from the holdings of the U. S. Coal & Coke Co. and were furnished by Howard N. Eavenson, chief engineer.

Plans of Mining

The entire Pocahontas field proper is practically all leased out on royalty by two large holding companies, the Pocahontas Coal & Coke Co. and the Crozer Land Association. Under the lease contracts, the holding companies have reserved the right to define the method of working, and the result, on the whole, has been highly satisfactory to all concerned.

A standard plan of mining, by Thomas H. Clagett, chief engineer of the Pocahontas Coal & Coke Co., is shown in Fig. 5; this is largely followed by their lessees, although in instances materially modified, due to local conditions. This large holding company owning or controlling some 275,000 acres of Pocahontas coal, has in active operations some 45 leases, covering about 145,000 acres. The Pocahontas Coal & Coke Co. and the Crozer Land Association control about 75 per cent. of the Pocahontas field, proper, the holdings of the former extending over into the head waters of the Guyandotte River. The Virginian Ry. traverses the northeastern part of the Pocahontas field.

One of the special advantages of the system of mining

Fig. 9. Angle-Norfolk Collieries of the P. C. & C. Co.

adopted by Pocahontas Coal & Coke Co. is the relatively quick recovery of the pillars, and the panels are so driven that the rooms and all entries split the pitch; thus if the maximum pitch is 3 per cent., then the maximum for the workings will not exceed 2 per cent. and may be even slightly less.

The method of working adopted by the Upland Coal & Coke Co. on one of the Crozer leases, as furnished by John J. Lincoln, chief engineer, is shown in Fig. 6. Were the crop line shown on this plan it would be evident that the break line is carried in from the crop and does not involve, strictly speaking, breaks in the solid. There may be several "lifts" where the width of lease is too great to admit of one lift only, as shown. This plan of mining, Mr. Lincoln states, was evolved from a number of years of revisions and has been found entirely satisfactory under all conditions. The main entry is to be driven as near the line of the strike as possible, in order that the reverse grade against the loads may be negligible. If the cross entries are turned off at more than 90 deg. from the main, and the rooms are less than 90 deg. off the cross entries, grades in favor of the loads may be obtained. The Crozer Land Association has 12 operations under active mining.

The Pocahontas Consolidated Collieries Co.'s Angle colliery, as of July, 1912, is shown in Fig. 7. Soon after

taking up the work of the old Norfolk Coal & Coke Co. (which was essentially the nucleus of the Pocahontas Consolidated Collieries Co.) in 1904, the work of revising the systems of mining was taken up in detail. One of the first improvements adopted was the introduction of the multiple air-course system, as illustrated in *The Engineering and Mining Journal,* Jan. 26, 1907, under the title of "Ventilation in Flat Coal Seams." After further discussion, James Ellwood Jones, then general manager of the old Norfolk Coal & Coke Co., and now of the Consolidated, finally approved and authorized the panel system, which was afterward illustrated in a series of articles by myself, in *The Engineering and Mining Journal.*

The Pocahontas measures are not merely the geological equivalent of the Pottsville Conglomerate, but they are also in many instances actually like it, particularly toward the top, where the hard, flawless sheets of sandstone are studded with white quartz pebbles. Even where the pebbles are absent, the sandstone is about as low and dense, the thickness being commonly 50 to 80 or 90 ft. without the smallest trace of cleavage or bedding planes. The shearing force of these great sandstones must certainly be enormous and materially affect the pillar work, owing, in part, to the absence of sufficient soft material to pack and thus aid in carrying the weight. The immediate overburden is at times disintegrated, particularly when the surface has been eroded fairly close down to the coal, but squeezes are usually of a vicious nature, if such an expression may be used in this connection. It is due to this that the barriers are much larger than would be necessary in many mining districts.

In my opinion, 1000 or 1200 ft. square is the minimum area that can be safely robbed, in the solid, under these conditions; that is, without a free edge. The second panel, entirely in the solid and with, say, 500 ft. of cover, as shown in Fig. 7, has been almost completed. In the Angle mine, as in the Norfolk, this method of robbing has, so far, been entirely satisfactory. It need hardly be said that the smaller the panel the quicker the returns that may be had from a given territory.

Tipples

There is, essentially, a Pocahontas type of tipple, not that there are two in the field (except, possibly, the U. S. Steel Corporation tipples) that particularly resemble each other, in detail, yet the "family resemblance" between many of them is quite noticeable. The Pocahontas tipples are a compromise between the simple low structure common to Ohio and Indiana where several grades of coal are screened directly into the railroad cars, and an anthracite breaker.

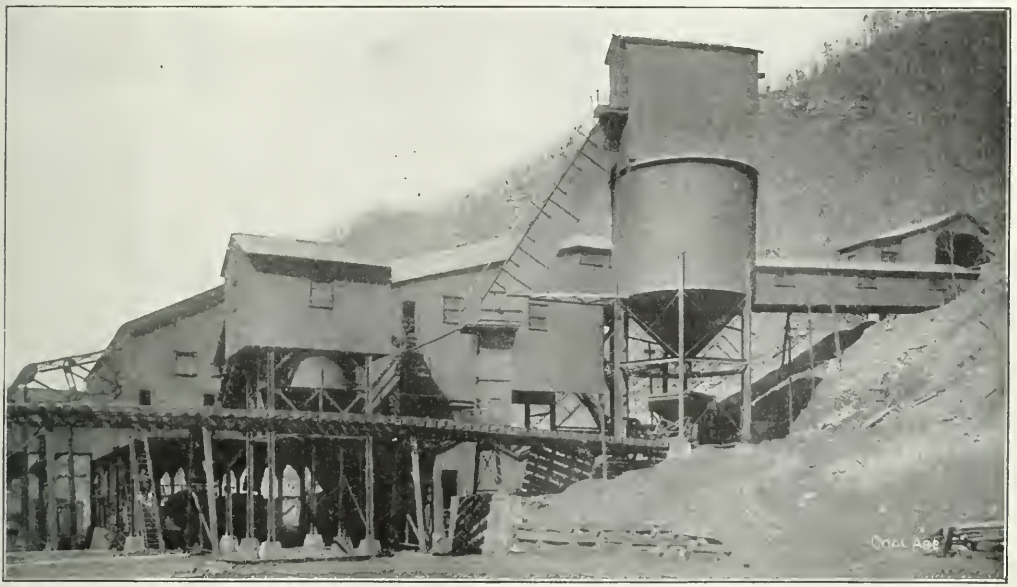

Fig. 10. General View of the Empire Coal & Coke Co.'s Surface Equipment

Quite a few of the more influential engineers in the Pocahontas field in the earlier days, were from the anthracite field. Our valleys are quite narrow and by the time a bank of railroad coke ovens with tracks and miner's houses and other buildings were arranged for, it is not difficult to understand that room for a two-track tipple in the earlier days, appeared to be about the limit; thus storage was necessary for the other grades. In the Pocahontas type of tipple either egg or nut, and slack are usually stored, and commonly all three.

The egg and nut coals thus stored were screened over top screens just before being loaded into cars, so that the slack accumulated in storage was removed, and returned to the slack bin, to be coked. The loss in size of the stored coal at that time appeared negligible, while the slack thus recovered was just that much less to be crushed.

Today the constant conversion of, say, ½-in. egg coal,

into slack at a time when the former may be selling at a fancy price, with perhaps little or no demand for coke, appears a serious loss, compared with which the additional outlay for two or three extra tracks where same are at all practical, is a relatively small item.

The original Pocahontas tipple and a new steel tipple, both within the limits of the town of Pocahontas are shown in Fig. 8. Fig. 9 shows the Angle-Norfolk tipple, and Fig. 10 the Empire Coal & Coke Co.'s new steel tipple in which breakage in handling is thought to be reduced to a minimum. The Consolidated has already authorized a new tipple, with two others underway, in

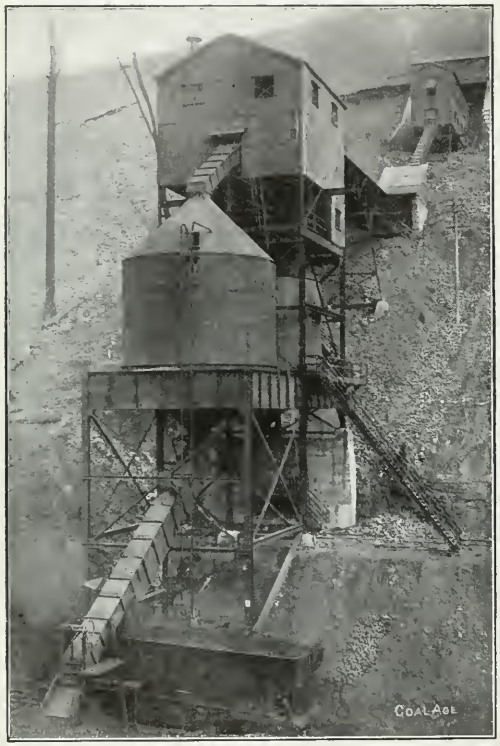

FIG. 11. THE NO. 4 TIPPLE OF THE U. S. C. & C. CO.

which there will be at least four, if not five, loading tracks.

The steel tipple at the No. 4 works of the U. S. Coal & Coke Co. is shown in Fig. 11. In this tipple, after the coal is dumped, it goes to a picking table, and from there through a chute and then over a rubber belt conveyor; it is then either crushed, going into a bin, to supply the ovens, or is sent without crushing into another bin, to be stored as mine-run. In a general way, the main output of the U. S. Coal & Coke Co.'s works is at present crushed slack.

⁂

Coal was for a long time mined extensively on the west coast of British North Borneo on the island of Labuan, but owing to misfortune work was abandoned and the machinery taken out about two years ago. The only mine now worked in North Borneo is at Silimpopon on the east coast near the border of Dutch Borneo.

Production of Coal and Coke

The advance sheets of the report of C. B. Ross, mine inspector for the second bituminous district, in Pennsylvania, shows 53 out of a total of 54 mines in operation; of these, eight are gaseous and 45 nongaseous. Three new mines were opened and one mine abandoned during the year. The total production of coal for the district, during the year, was 8,521,201 short tons, of which 7,102,581 tons were produced by pick mining, 1,072,954 tons by compressed-air machines and 345,666 tons by electric coal-cutting machines. The total number of persons employed inside the mines was 5472; the number of fatal accidents in the mines 29, and nonfatal 53. The coal produced, per fatal accident inside, was 293,834 tons, and the number of persons employed inside, per fatal accident, 188. The number of coke ovens in operation was 4679 out of a total of 5791, and the coke produced was 2,395,393 tons; number of persons employed at the manufacture of coke, 1450.

The advance report of W. H. Howarth, mine inspector for the 16th bituminous district, in Pennsylvania, shows 37 mines in operation out of a total of 43, of which 28 are gaseous and nine nongaseous. The coal produced during 1912, in this district, was 7,634,497 short tons, of which 3,469,935 tons were produced by pick mining, 2,007,773 tons by compressed-air machines and 2,156,789 tons by electric coal-cutting machines. There were 5224 persons employed in the mines and a total number of 24 fatal accidents occurred, making the number of tons of coal produced, per fatal accident inside, 318,104 tons. The number of persons employed, per fatal accident inside, was 217. There were 5487 coke ovens in operation, out of a total of 5987; while the coke produced was 3,679,233 tons and the number of persons employed at the manufacture of coke, 1165.

⁂

Binders for Fuel Briquettes

Experience in European countries and investigations made at the fuel-testing plant of the United States Geological Survey at St. Louis, and later by the Bureau of Mines at Pittsburgh, have shown that lignite may be successfully briquetted without the use of any additional binding material, and that the most satisfactory binders for anthracite, semi-anthracite, bituminous and subbituminous coals are coal-tar pitch, gas-tar pitch and asphaltic pitch, or inexpensive cementing mixtures that are practically waterproof.

Of the 19 briquetting plants in commercial operation in the United States during 1912, 10 used as a binder coal-tar pitch, or mixtures in which it is the chief ingredient; one plant used asphaltic pitch, two used water-gas pitch; four used mixed binders whose composition is not made public, and two (one operating on peat and the other on carbon residue) used no binder. The number of plants using coal-tar pitch as a binder exceeded all the others put together.

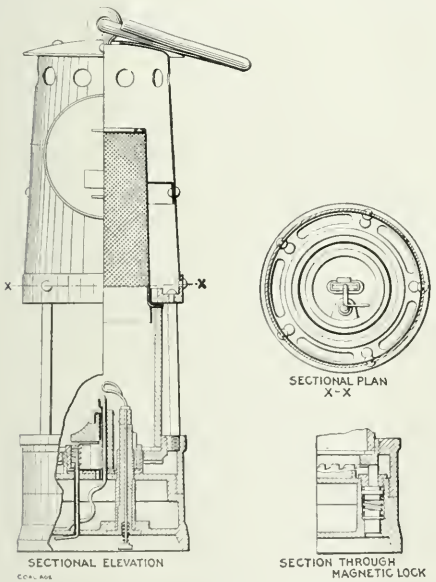
Inorganic binders, such as cement, have not given satisfactory results, for, although they may form efficient binders they have the serious objection of increasing the ash and adding nothing to the combustible elements of the fuel. Binders made of organic material, however, such as pitches from coal-tar, gas-tar or asphalt, contribute combustible material and do not increase the amount of ash.

Our British Coal-Mining Letter

Special Correspondence

SYNOPSIS—A review of recent improvements in by-product coke-oven processes and tar distilling. Power can be made at a low price by using gas from coke ovens. Electricity from coke-oven gas is sold in Belgium for less than 7 mills per kilowatt-hour despite the high cost of the fuel used. Much oven gas is purchased by the city of Ghent. The "minimum wage," as provided by arbitration, is so low as to have inappreciable influence on wage scales. Power cables in shafts should be light and unarmored. Some lamps are described which are approved for use by the British Home Office.

Reference has already been made* in a previous issue to a paper on the "Progress in Byproduct Recovery at Coke Ovens" read by F. E. Christopher before the Manchester section of the Society of Chemical Industry, and since



The Hailwood Lamp Approved by British Home Office

published in the Journal of that society. The following is a summary of his remarks.

The recent changes in coke ovens are in the direction of increase of size and decrease of coking time. In the United States, ovens of the Semet-Solvay type, utilizing the continuous regenerator system, are being built, 5 or 6 flues high, of such size and duty that they will coke 16 tons of coal within 24 hours.

Tar Is Removed Mechanically

Some of the newer byproduct plants remove the tar particles at a relatively high temperature and then pass the gas thus purified through sulphuric acid, thus saving much of the heat and complication and reducing the waste liquor. In the Simon-Carvé system, the heavier tars are removed by passing the gases through a cyclone extractor without moving parts. The rapidity of the rotation throws the drops of tar to the periphery and causes their deposition. Only the lighter tars go to the extractor. Here the rapid motion of vanes removes the light oily globules and concentrates them centrifugally. To Mr. Christopher, the separate extraction of light and heavy oils seems to be based on correct principles.

The really direct process of making ammonium sulphate, thus briefly sketched, appears to have tempting advantages as far as thermal losses are concerned. The gases contain all the water originally to be found in the slack and that due to the combination of the elements of water in the coal. If these are kept at a temperature above 176 deg. F., the dew point will not be reached and the water will be carried without deposition through the various processes to the place of combustion.

Difficulties with Benzol Recovery

When benzol is not to be recovered, the direct process is clearly the best to adopt. To obtain the benzol, the gases must be reduced to 77 deg. F. This causes the water vapor to condense but the effluent is clear because of the mechanical removal of tar which precedes such cooling. As no additional water is used in the absorption of the ammonia, that retention being effected chemically by the sulphuric acid, the effluent is only one-half that usually formed.

Fuel Savings in Tar Stills

Tar distillation is now receiving more attention from designers and several coke-oven firms are also erectors of tar plants. In a coke-oven plant of the Evence Copper Co., fuel is saved by using the heat in the vapors from the latter portion of the distillation to drive off the water and oils in the earlier part.

The Hennebutte process of tar distillation is now being installed by the Coke Oven Construction Co. Several plants on the continent of Europe are using the process. The tar is first heated by an inclosed steam coil. Then it is passed on to a still, into which air is injected. Some of the hydrogen in the tar combines with the oxygen to form water. The heat thus liberated is amply sufficient to provide for distillation.

Little change can be observed in the design of benzol plants. The tendency today, however, seems toward the production of refined products at the works.

Power at 3 Kw.-Hr. for 2 Cents

Contracts have been signed for the supply of coke-oven gas to the existing municipal gas-works at Ghent. The gas is to be supplied from ovens of the Semet-Solvay type and the contract is for 105 to 210 million cubic feet per annum at a price equivalent to 10.8c. per thousand cubic feet. Power is also to be supplied at 0.66c. per kilowatt-hour for a guaranteed consumption of 3 to 6 million kilowatt hours.

The importance of the byproducts is shown by the fact that the relative values of the output of an oven are:

*"Coal Age," Mar. 22, Vol. 3, , 452.

coke 60 per cent., byproducts 25 per cent. and gas 15 per cent.

The Minimum Wage Not Harmful Because Ineffective

It was explained by G. A. Mitchell in a lecture at Glasgow University on "The Minimum Wage in the Coal Trade," that the men at the face are usually paid on contract, because supervision is impracticable. In Scotland, the minimum wage is about $1.50 per day for every man and boy employed underground. Owing to the advance in miners' wages in Scotland, since the act was passed, the minimum-wage rates have had little effect on wages.

It may be anticipated that when times again become normal the act may (1) destroy, to some extent, the incentive to work, (2) cause many workmen to lose employment, and (3) result in men losing earnings by being sent home frequently from their work. The workmen, in the view of Mr. Mitchell, will not gain any great advantage by the act, except in some cases where the day-wage rates have been raised by its operation. There is no margin of profit to pay the increase of cost, and it must be passed on to the consumer if the collieries are not to stop.

Increased prices might cause a loss of export trade and hamper home industries, unless increases in wages in Great Britain are accompanied by increases in competing countries or lower cost is brought about by improvements. The workmen should coöperate for their own advantage with the operator in reducing costs instead of hampering him by working short time and by opposing labor-saving devices.

Cables for Mine Shafts

At the present time in Great Britain much attention is being directed to the use of electric cables in the mines; and among other papers, one has been read by E. Kilburn Scott before the Association of Mining Electrical Engineers. Briefly some of his points are: (1) The weight of shaft cables is a most important factor in their design, and in order that it may be reduced, high-tension aluminum cables should be used without steel armoring. (2) The place of the latter as a return-current path can be taken by continuous metal work already in the shaft, or by old haulage ropes suspended for this purpose. Cab tire sheathing may be employed to give more flexible and impermeable mechanical protection than ordinary steel armoring. (3) Telegraph poles sawn longitudinally are more suitable than plank casing, such as has hitherto been used. Such casing would be cheap and easy to erect, and it would form a complete protection to the inclosed cable.

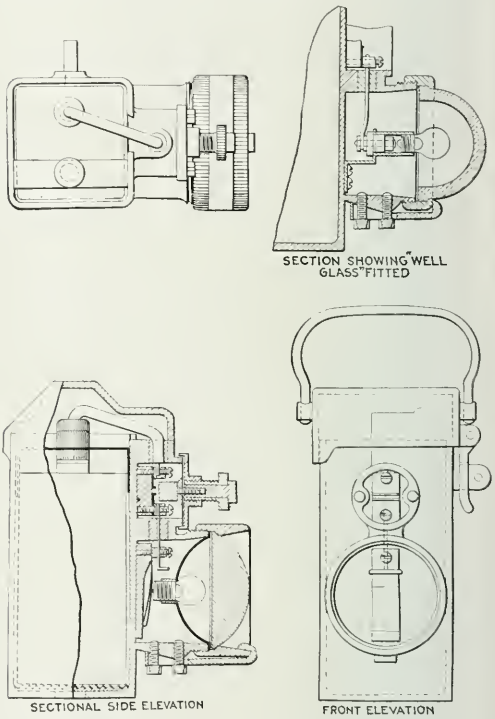
Saccharine for Preserving Casing for Cables

It is better to impregnate wood for casings or cleats with saccharine than with tarry or other chemical substances, because it has no action on insulation or metals. When wood is impregnated with both saccharine and arsenic it is proof against white ants. In a New South Wales mine the armor on a shaft cable was rendered useless by the atmosphere in less than six months, and in Great Britain a steel rope, used in a shaft as the earth return, became so corroded that a special copper cable had to be put in its place.

In discussion the British Electrical Inspector of Mines, Robert Nelson, declared that he was not in favor of aluminum cables for shafts.

Approved Safety Lamps

The first lamps approved by the Home Secretary under the Coal Mines Act for use in all mines to which the Act applies are the Hailwood Lamp No. 1 (made by Ackroyd & Best, Ltd., Morley, near Leeds), and the Oldham "Emergency" Electric Lamp (made by Oldham & Son, Denton, near Manchester). The Hailwood lamp is approved, provided that the strength of material and at-



The Oldham "Emergency" Electric Lamp Approved after British Official Test

tachments throughout the lamp are not less than in the sample submitted to the mechanical tests; that the oil and wick used in the lamp are such that it can maintain all around in a horizontal plane a light of not less than 0.30 cp., as determined by a pentane standard throughout a period of not less than ten hours; that the glass is of an approved type and its dimensions within stated limits.

The Oldham lamp is approved, provided that its total weight is not more than 4.5 lb.; that the strength of material and attachments throughout the lamp are not less than in the sample submitted to test; that the lamp is capable of maintaining a light of not less than 1.5 cp. throughout a period of not less than ten hours; that the lamp is used only for the work of rescue or exploration in the case of an accident or other emergency or by officials.

Use of Purchased Power in Coal Mines

By H. C. Eddy*

SYNOPSIS—The writer shows that the central station has most power to sell at the time of day when the operator has most need of it, so that a low price is possible for the coal-mining requirements. Many of his arguments apply equally well to the establishment of private central stations with high-tension current.

The ideal corporation may be defined as a coöperating aggregation of individuals of specialized ability.

The practical application of this idea has produced industrial companies whose activities frequently become so extensive and so diversified as to make it desirable to separate them into component parts, each exercising those functions which it is especially fitted to perform. Thus we find the huge industrial organizations of today made up of a number of departments, each complete in itself and each virtually a corporation, in the sense of the definition given above.

Competent Heads of Departments Impoverish Small Companies

This division and segregation of corporate activities is practicable only in comparatively few instances, as the cost of thoroughly competent heads of departments becomes too great a burden for the companies of less than extraordinary size to carry. In the majority of cases it becomes good business policy to carry out this division of effort by depending upon outside agencies, whose sole function is to supply, in the most economical way, some certain requirement.

Thus the function of public-utility companies is to supply transportation, transmit information and distribute electricity, water and gas, each a highly specialized branch of service calling for the expenditure of much capital, technical knowledge and broadgage thought, to reach the fullest possible development.

There is then a sound fundamental basis for the existence of an organization whose sole business is to make and sell power in both large and small quantities.

However sound the abstract theory of the central station as a power merchant may be, its continued existence depends upon its ability, in practice, to supply power on a basis which shall be reasonably profitable to both parties concerned in the transaction.

An analysis of the conditions of use of power in the bituminous coal mines in Pennsylvania and Ohio discloses certain general facts which are decidedly favorable to the purchase of power, when available, as compared with the operation of independent plants.

Mine and Domestic Demands for Power not Synchronous

There are but few mines in these fields that operate more than sixteen hours per day, and many that run but a single shift. The double-shift basis of operation is, however, sufficiently common to be considered typical. The load curve of such a mine shows that approximately two-thirds of the total kilowatt-hours per day of twenty-four hours, is used between 7 a.m. and 4 p.m., the remaining one-third being used between 6:30 p.m. and 1 a.m.

During the working day the demand is quite variable, fluctuating between wide limits for short periods. The widely different conditions existing in the individual mines make it practically impossible to give accurate values to the various elements of load. In one mine the grades may be in favor of the loads to be hauled by the locomotives, while in another case the reverse may be true; tipples may be above or below the level of the mine opening; fan operation may be required continuously at a high rate of air discharge or the reverse. Notwithstanding all these variables, the general characteristics of the total load are quite uniform in being removed from the central-station peak.

The application of alternating-current motors to mine equipment is not general, practically all mines operated by electric power using direct current at either 250 or 550 volts. This necessitates the use of either synchronous converters or motor-generator sets when power is purchased. When the latter are used it is the general practice to specify synchronous motors, on account of the somewhat better efficiency to be obtained, as compared with induction motors, and also for the improvement of the power factor.

Power Companies Covet Coal-Mine Business

The advantages to the central station which justify low prices for mine power, may therefore be summed up as follows:

The considerable amount of power used.

The "off-peak" load.

The extensive application of synchronous motors, tending to raise the plant power factor, with the attendant advantages.

From the standpoint of the mine operator the advantages of purchased power are more numerous.

Coal Mines Should Use Purchased Power

The most important consideration is that of cost. It is obvious that in this presentation of the subject, no comparisons of actual figures can be made, but it lies within my province to indicate the essential reasons for a relatively high cost of operation of independent mine power plants.

The controlling element lies in the load factor, which may be defined as the ratio of average use of the equipment required to meet the maximum load conditions.

The daily load factor is much higher than the monthly ratio due to the fact that during the month the average number of working days ranges from 15 to 20, due to car shortage, market conditions and temporary labor difficulties. The annual load factor is even lower, due to the same general conditions, but upon a more extended basis.

The result of this condition is that the investment in power plant and equipment is idle for much of the time, and as interest, depreciation and taxes are continuous charges, the result is that the actual output of

Note—Paper read at the Pittsburgh meeting of the American Institute of Electrical Engineers, Apr. 18 and 19, 1913.

*Contract agent, American Gas & Electric Co., 30 Church St., New York, N. Y.

the plant carries a very high fixed charge per kilowatt-hour.

This condition does not exist when power is purchased, except so far as it applies to the current-transforming apparatus. The cost of equipment per kilowatt of capacity being much lower than the cost of complete plant equipment, there is a substantial saving to be effected in this item of power costs.

The actual manufacturing cost, exclusive of overhead charges, under conditions of widely varying load and intermittent use of generating equipment, becomes much higher than would be found with exactly the same apparatus working more continuously.

The Necessity for High-Tension Distribution for Economy of Operation

The individual mine plant is usually located at the least favorable point, considered electrically, i.e., at the mouth of the mine. As the mine is developed the electrical center of the load recedes from the plant location and the losses in the distributing system constantly increase. The extent to which it is advisable to increase the investment in copper to minimize voltage losses can be determined only by a careful survey of the conditions applying to each particular installation.

Aside from the actual copper loss, the low voltage obtainable at the point of delivery of current brings in its wake a high maintenance cost for motors on locomotives and coal cutters, chiefly in the form of armature and commutator repairs. These troubles are directly traceable to the abnormal volume of current required by reason of the less than normal voltage. Aside from this actual expense there is the loss of possible output due to reduced capacity of motors brought about by the unfavorable conditions of current supply. This loss is far greater than the actual cost of repairs and its magnitude is often unappreciated by mine operators.

These conditions may be remedied to a great extent, if not practically eliminated, where power is purchased, by placing converters or motor-generators so that the mine distributing system may be fed at several points, thus materially reducing line losses, equalizing line voltage, and bringing it up to the normal working voltage of the motors in use. As the mine is developed and new conditions arise with respect to the distributing system, the location of the conversion equipment may readily be changed. This flexibility is impossible with a complete steam plant.

In Any Mine Low-Tension Station Equipment Soon Becomes Useless

In any successful concern the growth of its operations is ordinarily greater than originally expected. The coal-mining industry is no exception to this general rule, and operators are periodically faced with the proposition of extending and enlarging individual plants to meet the greater demands for output.

Usually this problem is solved by adding boilers, engines and generators, with a resulting greater investment of capital than would be required by the addition of a motor-generator set. The capital invested in plant equipment in excess of the cost of motor generators would earn much more per year, if put into strictly mining machinery.

The Intelligence Charge

The operators of mine plants are ordinarily handicapped by the character of labor available for power-plant operation. In some cases mines are so located with regard to living conditions that really skillful engineers may be obtained and kept. In more instances, however, the conditions of work and locality of the mines do not prove attractive to the best men except as a temporary expedient. It is more often than not, a case of a more or less regular procession of engineers through the cycle of being hired, endured and "fired."

As a natural result the average mine plant receives less than an ordinary amount of skilled attention, when, by reason of the severe conditions under which it operates, it should receive more. Under such circumstances it is to be expected that the cost of maintenance and repair will be high. Aside from labor conditions the item of boiler repairs and replacement is usually excessive on account of the bad water conditions that are so commonly found in coal districts.

Where power is purchased the care required by conversion apparatus does not call for an expert man in constant attendance. The ordinary daily care required may be furnished by the necessary switchboard operator.

It is obvious that the employer's liability hazard, so far as power supply is concerned is greatly reduced when power is purchased than when a steam plant is operated.

The tendency of labor and other costs entering into the production of power is upward. This can only be met and compensated for in the case of the central station through the use of generating equipment of the very highest economy, by the securing of business of a diversified character of use, enabling the operation of the plant under good load conditions each hour of the twenty-four, and through quantity production.

Summary of Advantages to the Purchaser

The advantages gained by the mine operator by the purchase of power are direct and may be summed up as follows:

Reduction of fixed charges on investment.

Reduction of actual operating costs due to the fact that only power is paid for, without stand-by charges due to intermittent operation, and by reason of the higher efficiency of electrical apparatus at any load, as compared with steam-generating equipment of the character available for mine work.

Material reduction of distribution losses.

A considerable increase in the output of mining machines and locomotives due to maintenance of speed through normal voltage.

Flexibility of location of motor-generators, enabling them to be placed at points giving the best operating results, and to be readily and cheaply moved as conditions change.

Reduction of labor costs for attendance.

Elimination of high maintenance, repair and replacement costs for boilers, piping and engines.

Reduction of cost of superintendence, enabling the mine superintendent to devote his entire attention to securing output.

Reduction of liability.

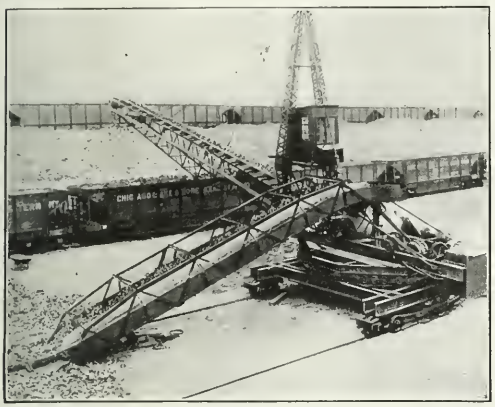
Insurance against constantly increasing power costs, through term contracts at fixed rates.

Additional coal available for sale.

Storage and Reclaiming Machine

On page 572 of our issue of Apr. 12, we published a description of the Jeffrey-Hamilton storage and reclaiming machine, together with a line drawing of a possible installation.

We illustrate herewith one of these machines which was designed by William E. Hamilton, built for the Illinois Steel Co. and installed at Stockton, Ill. This machine is identical with that illustrated in our previous issue with the exception that it is for a wider gage of track. It has successfullly loaded 2000 tons of coke per day which is equivalent in bulk to 3000 tons of coal and it can be used with equal facility for either piling the material upon the storage yard or reloadiug it into railroad cars.



Machine Reclaiming Coke from Yard

Nearly all storage systems in use today break the coal more or less, making careful rescreening and regrading necessary. This may be quite an important item in the cost of coal storage. As an illustration, let us take the case of anthracite coal which we will assume has an average value, including the freight charges, of $5 a ton. The breakage and degradation resulting from ordinary methods of storing and rehandling is often as much as 10 per cent., causing a depreciation of from 30 to 50c. per ton in total value.

By using a storage machine of this kind in conjunction with a rubber-belt conveyor if necessary, the breakage in storing and reclaiming is practically nil and this item alone, the manufacturers claim, will, in many cases, pay the first cost of the machine in a single season.

So Near and Yet So Far

There is a tiny hamlet in southern Alaska, called by the natives Katalla, boasting of a few hundred inhabitants, which really knows what the high price of coal means. Each and every ton burned in that town costs exactly $21.75. And within 25 miles is one of the richest coal deposits in the world. It is the famous coal region about which the Pinchot-Ballinger-Cunningham-Guggenheim controversy was waged. The Federal government now controls those deposits, and the inhabitants of Katalla are prevented, through this control, from mining their fuel needs, which total only 60 tons annually, and are forced to depend upon fuel mined many hundreds of miles away.—*The Wall St. Journal.*

The Two Wise Pumpmen

By J. K. Allardyce

(Written expressly for "Coal Age")

You fellows who would like to learn
Just how to run a mine,
Get near the pumpman and his pal,
When these two worthies dine.

They know it all from A to Z,
And "never had no school";
Where clean-drilled talent cautious creeps,
They rush without a rule.

And while they munch their bread and cheese,
Or wrestle with a chop
The whole mine scheme is up for trial,
From motor to a prop.

Hank lights his pipe, and slowly puffs,
While Slade tucks in a chew—
'If coal is what they want, says Slade,
I know what I should do."

The mine is on the bum—that's clear—
And faster, every day,
Things peter to a little point,
Where some fine morn they'll stay..

Hank dumps the ashes from his pipe,
And fills it up again
From Tim, the trackman's sack; and says—
"I can't make out our men."

"I told the boss the other day—
Says I—it's strange to me
How that wet west can ever pay."
"You mind your pumps," says he.

It happened once, this clever pair
With complex problems wrought—
When through the trap door popped a light—
The boss was on the spot—

"Six men, says he, have just gone home
From water in the south."
Slade's chew went down, and Hank's old pipe
Slid from his nerveless mouth.

Pennsylvania Bituminous Examinations

Examinations of candidates for the office of mine foreman, assistant mine foreman and fireboss, in the bituminous region of Pennsylvania, will be held, May 6, 7 and 8, by the examining boards in each of the several inspection districts.

Central-Station Power for Mines

By J. S. Jenks

SYNOPSIS—Abstract of an address before the Pittsburgh meeting of the American Institute of Electrical Engineers. The paper is devoted chiefly to a historical sketch tracing the development of the West Penn system from its original installation of 120 hp. to its present aggregate of 15,000 hp. in coal-mining service alone.

❖

This subject covers such a broad field that it would be folly to undertake to cover more than a limited portion of any particular branch; hence I will deal only with the historical side of the question as it has to do with the development of central-station service in connection with coal mining on the West Penn system.

Central-station power for mine service has been greatly handicapped by the prejudice of some engineers and mine inspectors who have actually fought the installation of such power, stating that it was not as reliable as an isolated plant, was more dangerous on account of the high voltage and more costly.

In order to overcome these objections it was necessary to prove the reliability and advantages of central-station service. The objection of the mine inspectors was the hardest to overcome. Even after the operators were convinced that purchased central-station service was more economical and were in favor of installing it, the inspectors frequently prohibited its adoption for some uses in and about the mines, particularly for fan service.

They contended that mine ventilation was of such importance that no mining company should be dependent on another corporation for its power for fan operation. It was only after years of successful employment in all other classes of mine service that we were able to overcome this prejudice and succeed in getting the mine inspectors to approve central-station service for fans, much less recommend it.

The engineer, and the electrical employees, opposed central-station service for obvious reasons, one of which, frequently frankly admitted, was, that with its adoption they would have no job. The truth of the matter has been that it has actually enlarged their field of labor, as more mines are being electrified every day on account of the many advantages which it offers, thus requiring the services of an engineer and electricians to most efficiently install and operate central-station power.

The first installation of central-station service in a mine on the West Penn system was made at the Larimer mine of the Westmoreland Coal Co. in 1896. It consisted of a 120-hp., 4000-volt, single-phase, 133-cycle, induction-type synchronous motor, belted to a 100-kw., 500-volt, direct-current, multipolar generator.

The switchboard consisted of a standard direct-current marble panel with ammeter, voltmeter, circuit-breaker and switches. The alternating-current board consisted of a wooden panel having mounted on it a small two-pole oil switch for controlling the large motor, a two-pole knife switch for the starting motor, pilot and synchronozing lamps. This apparatus was located in an underground substation as it was feared it might be damaged by employees during strike periods if it were above ground.

In order to supply this service there was installed at the power house of the Irwin Electric Light & Power Co., at Manor, one 150-kw., single-phase, 2000-volt, 133-cycle alternator and a 125-kw. transformer for raising the generator voltage to the transmission and motor voltage.

The line consisted of two No. 4 insulated wires carried by glass insulators on a two-pin crossarm over private right-of-way from Manor to the substation located near Circleville, except through the town of Irwin, where the pole line was on the street. The length of this line was about five miles. A telephone line consisting of duplex insulated wire was strung on a ridge pin on the top of the pole.

The entrance to the underground substation was made by sinking a bore hole through which lead cables were carried to a tunnel which led to the machine room. In order to protect the lead cable where it entered the ground, a high circular stone wall was built around the bore hole.

The apparatus supplied from this substation consisted of six mining machines, a 10-hp. pump and a 60-hp. haulage, but no fan service was supplied for reasons already explained.

The first trouble that developed was the falling in of the substation roof, which not only damaged the apparatus, but put the mine out of service for some time until the débris could be removed and a brick lining put in to prevent a recurrence of similar trouble. This brick lining sweated so that it made all the apparatus wet, which resulted in frequent burnouts of the starting motor. In order to insure reliability, duplicate starting motors were provided and at times it was a problem to keep one in condition for service. This difficulty was partially overcome by putting a wooden lining inside the brickwork.

The next difficulty arose from a breakdown in the lead cable, caused by lightning. This had the effect of charging everything in the substation. It was overcome by removing the lead from the cable and supporting it on glass insulators, except where it passed through the bore hole.

The next weakness developed in the oil switch which consisted of eight ½-in. brass rods working through small brass bushings, mounted on a wooden board submerged in oil. This two-pole switch had eight breaks of about ¾ in. each and was contained in a tank 8x10x9 in. and operated by handwheel and pinion. This made a slow-operating switch, with which it was difficult to synchronize. After numerous interruptions, caused by failures of this apparatus, a make-shift device consisting of an ordinary two-pole, two-break, knife switch on a marble base was mounted on insulators in the bottom of a half barrel. The switch handle was removed and a broom stick tied to the crossbar with a belt lace. Leads were brought over the edge of the barrel and connected to the switch. The barrel was then filled with oil, and the switch operated by pulling or pushing on the broom stick.

This switch was so much more easily operated and such improvement was made in the time of synchronizing that the consumer would not have it changed and it re-

mained in service until the substation was finally abandoned on account of the mine being worked out.

The Irwin Electric Light & Power Co. was acquired by the West Penn interests and in 1905 the 133-cycle power house at Manor was discontinued and service established from a 60-cycle turbine station at Connellsville through 28.52 miles of 22,000-volt transmission lines and a substation at Manor. This necessitated the reconstruction of the motors from 133 to 60 cycles. The work on the large machine was done in the field and the starting motors were sent to the factory one at a time. This reconstruction had the effect of reducing the capacity and resulted disastrously in the case of the starting motors, making it necessary to provide larger machines.

The next trouble to develop was rather peculiar in that the large motor started to drop out of step without any apparent cause and would do so when pulling practically no load. This was a puzzling circumstance and no amount of adjusting by the attendant seemed to remedy the trouble. It was found, however, when the supply from Connellsville was generated by a single unit that this departure from synchronism was most pronounced. Later it was discovered that there was a splice in the belt between the motor and generator that caused a jerking which would get in step with the governor mechanism on the turbine, causing the latter to hunt. This hunting was exaggerated in the motor, making it drop out of step. The remedy consisted in direct connecting the motor and generator, which happened to be the same speed.

On account of the high voltage of the motor it was necessary to have its frame insulated and a satisfactory insulating coupling became necessary. This was solved by turning the shafts end to end, setting the pulleys about six inches apart, drilling and tapering their rims and laying a piece of belt around inside of both pulley rims and securing it in place with capscrews. This proved a satisfactory flexible insulating coupling, which gave no trouble and operated for a number of years until the mine was worked out.

Notwithstanding the difficulties enumerated, this installation proved a satisfactory one to the mining company, and led to many other large installations.

The first mine where West Penn service was used for fan operation was at the Penn Gas Coal Co.'s mine near Penn Station, and consisted of a 100-hp., 500-volt, direct-current motor, belted to the fan. This was installed about 1901 when the mine was completely electrified with direct current. The equipment consisted of numerous pumps, mine machinery and a large haulage. The fan operated until 1907 when this motor was replaced by a 200-hp., alternating-current, two-phase, 60-cycle machine. This installation, which originally consisted of about 500 hp., has been increased from time to time until it now has about 1250 hp. in electric motors.

In 1907 our first high-tension installation was made at a coal mine. This was at the Naomi mine of the United Coal Co., near Fayette City. In this case the Coal Co. built its own substation and bought current at 22,000 volts, installing three 200-kw., 22,000- to 140-volt transformers, one 300- and one 150-kw. synchronous motor-generator sets, one 150-hp., alternating-current haulage, a 100-hp. chain lift, two 75-hp. fan motors, alternating-current pumps and numerous haulage locomotives and mining machines.

Another prominent example of a coal-mine installation where the most minute detail was worked out by the engineers in charge with the idea of producing the most efficient results is illustrated by the Keystone Coal Co.'s installation at its Crows Nest substation. Here 1500 hp. is delivered at 2300 volts from 22,000-volt transformers installed in the substation, together with the necessary switches and lightning protection. This installation consists of a 750-hp., alternating-current haulage, two 300-kw. synchronous motor-generator sets, two 150-hp., alternating-current pumps and many locomotives, mining machines and small motors.

While the growth of central-station service was slow at first, it is now growing rapidly, and from the original installation in 1896 of 120 hp. we have steadily added all kinds of mine installations until at the present time we have in operation 76 coal mines, consuming 14,831 hp. and have contracts with 10 companies which aggregate 5701 hp., which is being installed as rapidly as possible. This will make a total of 20,532 hp. In addition to this we are at the present time figuring with a number of coal companies and have every reason to believe that in a short time we will have under contract more than 10,000 hp. additional, which will increase our total to over 30,000 hp. in coal-mine service only.

The Alaska Land Frauds

SPECIAL TELEGRAPHIC CORRESPONDENCE

The cases of Raymond Brown and William Dunn, of Spokane, Wash., Charles Doughten, formerly of Spokane but now of Los Angeles, Calif., Charles Mackenzie, of Seattle, Wash., Donald Mackenzie, of Washington, D. C., Seattle, Wash., and Alaska, who were indicted in the federal court at Spokane, November, 1910, charged with conspiracy to defraud the government out of valuable Alaska coal lands, will not go to trial as Attorney-General Townsend will ask that the cases be dismissed.

Coincident with the filing of this petition, similar petitions were entered at Seattle and Tacoma, Wash., Portland, Ore., Boise, Idaho, and Juneau, Alaska, desiring that prosecutions be dismissed against other persons indicted for Alaska land frauds during the winter of 1910. The action of the Attorney-General results from the failure of the government to convict Albert C. Frost in Chicago on a similar charge. Townsend planned in case of a conviction of Frost, to press the Western cases through trial during the summer and clear the criminal docket.

The land involved in the present cases consists of 20,000 acres in the Kayak district, valued by the government at many millions of dollars. There are 131 claims, each of a quarter section, which the government declared had been fraudulently obtained. These claims will not be lost to the present owners, among whom are John H. McGraw, ex-governor of Washington, James N. Gillett, ex-governor of the state of California, and Henry T. Oxnard, of New York City, president of the American Beet Sugar Co. These men are assignees of the original claimants.

About 4100 square miles of the state of Tennessee are underlaid by coal measures and about half of this area contains workable seams. It is calculated that these beds originally contained 25,665,000,000 short tons of coal.

"Fools Butt In—"

The upright and most righteous mayor of Boston, Mass., recently wired in great excitement to the President of the United States that "anthracite tonnage was curtailed by restrictive measures for the purpose of preventing a surplus accumulation of coal, according to one of the coal-trade journals." The mayor further asserts that the public was compelled to submit to a heavy increase in the price of coal, owing to a lack of production last summer and hopes that the President will include in his message to Congress "pertinent suggestions in regard to the anthracite trade."

The mayor would do well to look over a few statistics before placing himself on record in such an absurd light. As a matter of fact, there was a tremendous shortage in the supply of anthracite coal last year, due to the suspension in mining during the labor conferences in April and May. But immediately following the fixing of an agreement, the hard-coalers began straining every nerve and concentrating all their powerful resources on the task of overcoming the deficiency with the result that there was a general and consistent smashing of all production records, month after month, during the late summer and early winter. Furthermore, they made every effort to allay the fears of the public that there would be a shortage (which fears speculators were trading upon to their own profit) by issuing periodical statements to the effect that they had the situation well in hand and that there were no prospects whatever of any suffering from a lack of fuel—a boast which as everyone now knows they made good.

Has Boston *another* Lawson?

Hydraulic Stowing

The remarks of George S. Rice, chief mining engineer of the Bureau of Mines at the recent meeting of the American Institute of Mining Engineers, have a large degree of timeliness. He stated that:

"In the Upper Silesian coal field, about one-half of the collieries are using hydraulic filling. About fifty independent plants provide for this feature of colliery activity. At one mining plant 5000 cu.yd. of sand are being stowed every day.

"In Westphalia, 27 collieries have adopted the system with 10 independent installations; in Belgium, ten collieries have such plants and in France, several such flushing operations are installed."

Mr. Rice says it will cost American coal-mine owners 30 to 40c. per cu.yd. to make such filling. We hope he is too conservative in this estimate, and that it will be found that when we decide to do the work, we can perform it more rapidly and efficiently than our European competitors.

We get three tons of coal in the anthracite region for every man employed, whereas in Belgium barely half a ton is obtained per man engaged. Applying the rule of three, the Belgian labor in stowing should be divided by six in the American fields.

This law of proportion, of course, may not hold good, but if stories of the pernicious extent to which division of labor has been carried in Europe are true, we can well believe that here, where there is no such demand for arbitrary divisions, there should be no difficulty in reducing any European costs. Especially should this be the case in the rural districts, where the opposition to the overlapping of trades has not destroyed the efficiency of labor.

But even if Mr. Rice is right, and flushing proves as costly as he anticipates, yet in many places that practice would pay today, by its preservation of the surface, its saving in coal, its extension of the effective life of the colliery and mining town, its complete use of headings and tunnels which must be constructed in any event, its assurance of continued profit to the railroad which has been built to handle the colliery output, its delaying of the time at which the longer hauls with long transmissions of compressed air or electricity will have to be made, its saving of the cost of coal and of drilling, its reduction of the area exposed to fires and favoring the accumulation of firedamp and its effect on beds not yet workable.

The value of a ton of coal in place is more than the royalty payment. Coal should be worth all the outlay which has been expended on its development, whether the expenditure be direct or indirect. In fact, from a broad community point of view, factories and non-company mining towns may be regarded as integral parts of the expenditure on the coal, for on the continuance of coal supply their usefulness largely depends.

Furthermore, we may recall that in Silesia, it has been customary in some places to fill the workings only in certain parts of the whole excavated area and that practice may be possible here. This will largely reduce the cost of flushing per ton mined.

Another Coal-Dust Explosion above Ground

There are still a number of persons who do not believe that coal dust is explosive and others who have an utter disregard of its dangers above ground as can be seen in many crusher rooms where dust is made in great quantity and no system of suction is used to remove it or to dampen the deposited dust. That some precautions were taken at the plant where the accident occurred which we are about to describe only emphasizes the danger to which men working in a dry, dusty atmosphere are exposed.

The accident occurred at the Hays yards of the United States Steel Corporation's Homestead works on Saturday, Apr. 5. Five men were shoveling coal into stoker cars from a pit 15 ft. deep. At these works, 10 cars of coal are ground every day for use in the rotary stokers of the steel plant. At 4 o'clock, the coal dust ignited and an

explosion occurred; the workmen near-by rushed up to the pit and saw the five men writhing in the smoke on the floor. The men were pulled out by their fellow-laborers at much risk to themselves. Four are dead and the other is dying.

The Breaker Boy and Other Youths

The Republican State Committee of Pennsylvania has prepared a second tentative draft of an act to regulate the employment of minors in Pennsylvania. One of the provisions puts the breaker "boy" into past history. He must now, if the law be passed, be at least sixteen before he goes to work.

The committee appends the following footnote to the clause which prohibits youths under sixteen from working in breakers:

"This section provides a list of occupations all of which are more or less dangerous or injurious, especially to children. Children have been found to be more liable to accident than adults on account of inexperience or carelessness; moreover, through lack of development and physical strength they are more seriously affected by injurious and unhealthful occupations."

A Solomon has indeed come to judgment. Can any statement be less reasonable than that youths should be prevented from working because of inexperience. Surely such lawyers as constitute the state committee, who have repeatedly grilled witnesses on the stand, know that experience is the result of years of practical use of certain materials or of actual performance of specified duties. How can anyone have experience as a beginner? Consequently because there is danger in beginning, why bar youths from labor? The risk of the green hand cannot be avoided. It is, however, to be supposed that the committee really referred, not to inexperience, but to immaturity of judgment.

We are about to present some figures. They are not conclusive because all American statistics are collected in a most incomplete manner and cover only a few parts of human activity. But seeing that they all run counter to the committee's conclusions, they largely weaken the reasoning of that political caucus.

The State Department of Mines of Pennsylvania shows the following numbers of juvenile deaths among outside mine workers at the following stated ages in 1911:

DEATHS OF JUVENILE OUTSIDE MINE WORKERS, PENNSYLVANIA 1911

	Boys of the following ages						
	14	15	16	17	18	19	20
Anthracite	0	1	5	4	5	7	7
Bituminous	0	1	0	0	2	1	1

The evidence of these figures is that the youth of 14 has the advantage of the adult of 20. He is probably not so careless, is not placed in so dangerous a situation and is more carefully watched. This is even more apparent underground. In 1911, only five youths working inside the anthracite mines were killed at 16 years of age whereas 20 were fatally injured at 19 years. The evidence shows therefore that forces other than legislative are already protecting the adolescent labor around the mines.

The statement that "through lack of development and physical strength, boys are more seriously affected by injurious and unhealthy occupations" is generally admitted, although, indeed, not by any means, is it necessarily true. In fact, it is probably absolutely false. In digesting the following figures our readers must remember that in 1900 a still larger amount of child or youthful labor than today, was everywhere in existence, yet the federal statistics show a continuous and well marked increase in the death rate from all causes from the ages of infancy onward.

POPULATION AND DEATHS IN THE UNITED STATES IN 1900

Years Inclusive	Population	Deaths
5–9	8,889,339	2,986
10–14	8,091,951	3,663
15–19	7,577,324	10,647
20–24	7,402,483	17,765
25–29	6,583,206	17,606
30–34	5,591,545	15,053
35–39	4,988,601	13,706

From these figures we see that if we would employ the most resistant persons only, to do the world's work, we would require a period of idleness or mental culture between 20 and 30 and put the children and youths to work.

These figures are backed up by known facts as to the effects of disease. Parents are rather desirous than not that their children shall contract measles and mumps for these diseases have a milder effect on children than on adults and do not recur when once their time has run.

Similarly the American and English statistics show that tuberculosis of the lungs is more fatal in adults than in children:

DEATHS FROM CONSUMPTION IN EARLY LIFE

Years Included	Consumption United States Totals	Consumption England—males per Million
5–9	525	205
10–14	719	134
15–19	3274	161
20–24	6839	676
25–29	7154	1858
30–34	6285	2114
34–39	5686	1964

Moreover, authorities have shown that while children are more responsive to typhus fever, they cast it off with far greater facility than adults. In England, many years ago, when fevers were less adeptly treated, children under 15 years of age who had developed the fever had a death rate of 5 per cent., while adults over 50 years old had a fatality rate of cases incurred of 46 per cent.

But specifically, is mining peculiarly harmful to the young? We apologize for using the figures of the federal census in 1900, so incomplete and so old are they but there is no recourse.

DEATH RATE OF MINERS

Years Inclusive	Percentage of All Deaths of Miners	Death Rate per Thousand Miners
15–24	13.9	5.4
25–44	46.4	7.8
45–64	21.7	13.1
65 and over	17.7	116.6

Clearly the young have more resistance than those in early manhood.

Our figures and our argument should not be pressed too far, but we would urge that reasonably healthy labor for children above the age at which they are willing or are compelled to go to school is not detrimental but advantageous. It braces them physically, mentally and morally and this wealth of labor should not be thrown away. The product of the human race is the pay of the race. He who legislates against labor robs the pay envelope of its purchasing power.

The neurotic's assumptions that children are being ruthlessly hurried to an early grave has never been subjected to careful proof. We need information which will enable us to take a safe and sane action in regard to labor, and the coal industry would welcome a scientific inquiry, which would ascertain the proper course of procedure.

SOCIOLOGICAL DEPARTMENT

Rescue Work in Fifeshire, Scotland

SPECIAL CORRESPONDENCE

It is now a legal requirement in Great Britain that collieries provide breathing apparatus and all the equipment for rescue work, including carefully trained brigades, or they must make arrangement with some central rescue stations within easy call, so that a fully equipped brigade may be available at short notice.

Some time ago the Fifeshire Coal Owners' Association appointed a committee to make inquiries regarding rescue apparatus for use in mines. Among other matters, the committee reported:

1. That a central station equipped with about 20 sets of apparatus ready for use in case of emergency is necessary for the needs of the county of Fife. This station should be in telephonic communication with every colliery in the district and located at Cowdenbeath.

A MOTOR CAR FOR A SCOTCH RESCUE STATION

2. That a certain number of sets of apparatus (say not less than five) should be kept ready at every colliery.

3. That at least 20 men at every mine, including all the officials who are acquainted with the workings, should be instructed in the construction and use of the apparatus.

4. That an intelligent man should have the care of the central station. He should be capable of instructing the men in the use of the apparatus and in the manner in which it should be kept in condition.

It almost seems unnecessary to remark that a central rescue station, however well it may be equipped in other respects, would be of little avail in time of need if it were not furnished with the means of speedily getting to the colliery from which the call for help may come. In view of this, the various central stations have been provided with specially fitted rescue motor cars. The Fife and Clackmannan Coal Owners' Association has purchased a car for the Dunfermline Station from the Albion Motor Car Co. A photograph of this truck accompanies this description. The car resembles an ambulance wagon.

The inside of the car is arranged to seat ten persons, and there is also accommodation for two passengers on the chauffeur's seat outside. Beneath each seat inside the car, there is space for a set of rescue apparatus.

At the front end within the car a space is provided for three oxygen cylinders, and in cabinets, also on the forward end, four smoke helmets are carried, with three cases of caustic potash and two ambulance boxes. Two stretchers are suspended from the roof. On the floor in the center of the car a hand pump is placed, so arranged that passage is not obstructed in passing to or from the wide doors at the rear of the car.

The body is built throughout of best ash and oak framing with mahogany panels. It is painted an artistic shade of gray with red lines, the inside dimensions being 9 ft. 9 in. by 5 ft. 9 in., complete with canopy over the chauffeur's seat and two windows in the center at either side with louvers above.

The chassis upon which the body of the wagon is mounted is a 32-hp. Albion of four-cylinder, chain-driven type, with single solid tires on front wheels and twin solid tires on the rear.

There are several groups of plants, in the United States, which should combine to provide a car of this kind. They are situated so far from a locomotive yard that an engine is not always available for use. The adoption of motor cars has been delayed, however, by the fact that most large coal corporations are affiliated with railroad companies and naturally rely on rail connections in planning their rescue work. Another obstacle has been found in the condition of the roads which a rescue motor car must travel.

A Census of Benefit Funds

The *Dodge Idea* contains the following statement, entitled "Benefit Funds for Factory Employees" and written by W. L. Chandler. This paper is published monthly by the Dodge Manufacturing Co., of Mishawaka, Iowa. The editorial staff of the journal has recently sent out twelve inquiries to which those controlling over 100 funds replied. The information has been extended by the use of the reports of the Bureau of Commerce and Labor in reference to over 400 funds:

1. Does a Company Profit by Having a Benefit Fund among its Employees?

Thirty per cent. of the funds which have reported, receive regular contributions from the operating company, but this seems only to lower the cost to members, as no reasons are apparent why all the funds cannot be entirely self-sustaining.

Four cases were found where funds controlled by employees alone had disbanded. The failures, as far as investigated, were not of such a character that they should influence others against the starting of benefit funds.

The membership of all funds comprised on an average 48 per cent. of the total number of employees of the factories at which the funds were established.

2. Should a Fund Insure against Temporary Disability due to Sickness?

Ninety-three per cent. of the funds provide this feature and such as do not are organized for the purpose of paying death benefits only, except one which only provides for permanent disability and superannuation and two which only pay superannuation pensions.

Of all funds (comprising about 350,000 members) the average cost per member per year for temporary disability due to sickness and accidents combined (these cases not being reported separately) was $3.42. The amounts paid weekly and the duration of the payments were so varied as to make it impossible to strike an average. Dues and benefits will be discussed later.

3. Should a Fund Insure against Temporary Accidental Disability?

Ninety per cent. of the funds now pay such benefits regardless of compensation paid by the operating company. They settle with the fund membership much as other accident insurance companies adjust the claims with their clients. Of these funds 22 per cent. are managed, at least in part, by the firms which have created them. Some establishments reimburse the funds for any mony paid out to compensate members who may have been hurt at work. This is done in lieu of direct payments to the injured. Some of the funds do not pay for any accidents for which the establishments are liable under the law.

Ninety-three per cent. of the funds, managed by employees alone, pay temporary disability benefits for accidents. A few funds restrict the accident benefits to cover only certain definite accidents such as those which are incurred when at work or when going to or from work or when not on duty, etc.

Ninety-one per cent. of the funds managed entirely by establishments or jointly by employees and the employing firm now pay temporary disability benefits for accidents.

It remains to be seen what may result later from the enactment in various states of employers' liability laws and workmen's compensation acts.

4. Should a Fund Insure against Permanent Disability Resulting from Sickness?

Twelve per cent. of all funds pay benefits for permanent disability and one-third of these, or 4 per cent., apply the benefits to cases due to sickness as well as accidents.

Of the funds paying benefits for permanent disability (sickness and accident cases not reported separately) a quarter of one per cent. of the members received such benefits in one year.

The average cost per member covering botn sickness and accident for the year was 48c. The various schedules of benefits are too varied to permit of averaging.

5. Should a Fund Insure against Permanent Accidental Disability?

Data given with the previous question should be considered here also. It will be noticed that twelve per cent. of the funds now have such provision. It remains to be seen what effect may follow the enactment of employers' liability laws and workmen's compensation acts.

6. Should a Fund Insure against the Death of a Member through Sickness?

Eighty-three per cent. of the funds have this provision. The amounts which in these funds are payable at death of a member (sickness and accident cases not reported separately) vary from ten to one thousand dollars, but the average death claim paid in one year was $209.76, or an average of $1.45 for each member of all funds paying death benefits. The death rate per 1000 members of all funds reporting their deaths was 6.7. This is lower than the general death rate of the country, because only able-bodied persons can gain or retain employment in a majority of establishments.

7. Should a Fund Insure against the Accidental Death of a Member?

Figures given above for amounts paid for death benefits apply here also, as the funds did not distinguish in their reports betwcen sickness and accident.

Ninety per cent. of all funds have benefits for members dying from the effects of an accident. Ten per cent. of these apply it only for accidents when on duty.

8. Should a Fund Insure against the Deaths of Members' Wives?

Twenty-two per cent. of all funds have this provision. The average annual cost to these funds for death benefits for members' wives averaged 25c. per member. This experience covers 65,889 members.

9. Should a Fund Insure against the Deaths of Other Dependents of the Members?

Ten per cent. of all funds have this provision. The average annual cost of these funds for benefits for death of dependents other than wives, average 28c. per member. This experience covers 44,381 members.

10. Should Any Distinction Be Made between Salaried Employees and Day Workers?

Of the funds under observation there seem to be few which make any distinction.

11. Should Membership Include both Males and Females?

Eleven funds divide the sexes and provide separate regulations for each, covering dues, benefits, etc. Of the total membership of all funds, 10 per cent. are females, and of the members of funds reporting female members, 11 per cent. are females. Fifty-six per cent. of the establishments where more than five females are employed have a provision for female members. The suffragettes may have something to say on this question.

12. Should Membership Be Compulsory?

Where funds were managed by employees only 30 per cent. of the employees of the establishment were enrolled.

Where the management rested with the establishment, 75 per cent. were enrolled and where the firm and employees managed jointly 66 per cent. enrolled. Of all the funds, 15 per cent. had more or less compulsory membership. Various exceptions are found; some excuse office clerks, boys and girls, those employed before the organization of the fund, and those earning less than a fixed sum per day.

Twenty-five per cent. of compulsory funds were managed by employees but were evidently strongly endorsed by the establishments, while 50 per cent. were managed jointly by employees and the firm for which they worked.

One fund writes that they had 95 per cent. of their employees enrolled before compulsory membership was required of all employees.

Some establishments having pension funds, require membership in the benefit funds to entitle employees to pensions, thus stimulating the employees to accept membership in these funds.

Swimming Pools

It is reported that the H. C. Frick Coke Co. is so well pleased with the experimental erection of a swimming pool and amusement hall at Leisenring, that it purposes establishing pools, measuring 75 ft. by 40 ft., and building gymnasiums at all its plants. Instructors will teach the employees how to swim. Cinder tracks will also be built for track events.

West Virginia Mining Institute

The executive committee of the West Virginia Coal Mining Institute has selected Morgantown as the place for holding the summer meeting, which will be in session June 24, 25 and 26.

Papers will be read and discussed on the following subjects:

"Gasoline Motor Haulage in Mines"; "A New Type of Undercutting Machine"; "Welfare Work in the Mining Communities of West Virginia"; "The Qualifications of a General Manager from a Superintendent's Point of View"; "Hydro-Electric Power in Mining; A Description of the Cheat River Installation."

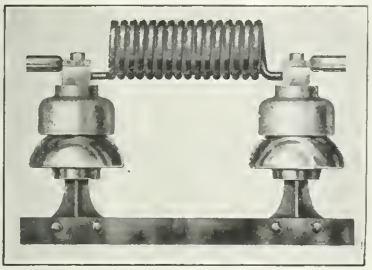
The program is so arranged that approximately one-half of the three-day session will be spent in sight-seeing and pleasure-seeking. Papers and discussions will occupy Tuesday and Wednesday mornings. On Wednesday afternoon, the members of the institute will be conveyed by automobiles to Mt. Chateau, a noted summer resort along the Cheat River, and from there to Sabraton, where an inspection will be made of the tin-plate plant of the American Sheet & Tin Plate Co. and the mammoth glass industries. The return to Morgantown will be in ample time to enjoy a banquet to be tendered by the city board of trade.

Thursday will be devoted to visiting the most representative mines in the Connellsville coke region. This will permit an examination into the methods of mining and coking the celebrated Connellsville coals, and furnish bases for comparison with the conditions and methods at home plants. Committees, selected jointly from the local membership and the city board of trade, are actually preparing to provide for a large attendance at the summer meeting.

Choke Coils and Disconnecting Switches

The choke coils and disconnecting switches illustrated herewith were recently bought out by the Electric Service Supplies Co., Philadelphia, Chicago and New York, and several unique points in the design of this apparatus deserve comment.

The bases of both the choke coils and disconnecting switches are of standard 3-in. channel iron. These bases permit the apparatus to be installed either inside or out, to be attached to switchboards direct, to cross-arms, to poles, to pipe or to any other suitable means of support.

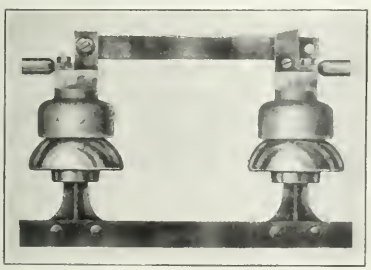


Choke Coil

Iron pins are riveted to this channel, and insulators cemented to these pins support galvanized iron tops, cemented to them, which tops in turn support brass terminal blocks for either the choke coil or the switch mechanism.

Choke coils are sweated into these blocks, which in every case are provided with separable terminals. The coils are air-insulated between turns; this is advantageous, because if arcing should occur between adjacent coils, the insulation (air) is immediately reëstablished after the passage of the discharge.

The manufacturers claim that these choke coils are rugged in construction, possess great electrical and mechanical strength, and that their design has been worked out so that they afford great protection to electrical ap-



Disconnecting Switch

paratus when used in conjunction with their standard types of lightning arresters. They are made for voltage ratings up to 23,000 and for all standard ampere capacities.

In the disconnecting switch, the clips are sweated into the brass terminal blocks, and are made of machine finished, pure, hard-drawn copper. The blades are hung in the clips as shown, and tension screws are provided at each end to secure proper contact. Separable terminals are provided on these switches for all capacities.

These disconnecting switches are designed and intended for use not only as lightning-arrestor disconnectors, but also as switches for disconnecting and controlling high-voltage lines, branch feeders, emergency feeders, etc., and for other purposes for which such switches are required.

They are made for voltage ratings up to 23,000, and of ampere capacities to meet any operating condition.

A Good Boiler Test

The Narragansett Electric Light Co., of Providence, R. I., recently ran an eight-hour boiler test on a 390-hp. Babcock & Wilcox boiler equipped with a Riley self-dumping underfeed stoker with five retorts, during which 216.3 per cent. of the builder's rating of the boiler was developed.

The boiler in question was 16 ft. long, 12 tubes high and 18 tubes wide. It was operated throughout the test at a pressure (practically without variation) of 175 lb. per sq.in.

Nineteen thousand seven hundred and five pounds of coal were fired, thus making the rate per hour 2463 lb. Analysis of this fuel showed 77.44 per cent. fixed carbon, 15.42 per cent. volatile matter, 5.46 per cent. ash and 1.68 per cent. moisture. As fired the coal contained 14,728 B.t.u. per lb. The weight of water fed to the boiler was 217,600 lb., the average temperature being 196.6 deg. F. The actual evaporation per pound of coal as fired was 11.04 lb. of water, the equivalent evaporation from and at 212 deg. F. being 11.81 lb.

The stoker was narrower than the boiler, so much so that two more retorts could have been installed which would probably have given correspondingly greater consumption of fuel and evaporation of water. The boiler was 12 years old and was one of a battery of two, the other being cold at the time of the test.

The fire appeared to be in about the same condition throughout the entire trial and the boiler was kept on the line after the test was over. One notable advantage was that there was no period of dumping as the stoker automatically cleaned itself of ashes continuously and thus avoided fluctuations incident to periodic ash removal. The coal was thoroughly burned, there being but a slight excess of air.

First Aid at Old Forge Colliery

The contests of the first-aid teams of the Old Forge Colliery, of Jermyn & Co. were held on Saturday evening, Apr. 5. The outside team won first prize, making 91 points out of a possible 100. Inside team No. 2 was second with 82 points, and inside team No. 1 was third with 68 points. Between 600 and 700 people witnessed the exhibition. Following the contests a banquet was held, and President Joseph Jermyn presented the winning team with a large silver loving cup. He congratulated the winners on their excellent work, and also Dr. Edwards, of Taylor, who drilled the teams. Mr. Jermyn promised to send the winners to Pittsburgh next fall to participate in the annual state contests.

Each member of the winning team was also presented with a watch fob, appropriately engraved. The following men made up the winning team: David Davis, captain; William Williams, Lawrence McDermott, Charles Llewellyn, and Lawrence Fallon. The members of the other teams are: Inside No. 1, John B. Price, captain; Walter Tibbs, Patrick Kelly, and Harry Edwards. Inside No. 2, James McGinley, captain, William Riddel, Michael McNulty, Joseph Hart, and James Marino.

DISCUSSION BY READERS

Education in Coal Mining

Letter No. 2—Referring to the discussion on Education in Coal Mining, allow me to make a few remarks on this subject, gained from my observation as inspector of mines during the last decade. I wish to draw attention briefly to the importance of higher education along this line.

It is my opinion that a higher educational standard should be set by our examining boards, in addition to the technical and practical requirements. It is true that many of the workmen in the mines have not had the advantage of a common-school education; but this feature will be less prominent as time goes on, owing to the school law requiring that children attend school until they arrive at a certain age. Those who follow mining will, in the future, have an easier road to travel than did their fathers, who, seeing the advantage of a mining education, have spent much time and burned the midnight oil at their studies. Many have had to start at their A B C's; but, step by step, they have finally mastered the object of their ambition through the assistance of mining books and papers and correspondence schools. By their efforts many such men have risen to high positions in the mining world; and have become successful general managers, superintendents, mine inspectors, mine foremen, etc.

I have noticed that the average man, after receiving a certificate for mine foreman, which was evidently the height of his ambition, has thrown his books aside. He begins to think he is competent to fill that position at any mine. He fails to understand why some foremen can obtain positions at mines where a high salary is paid, while he holds a less important place. But the secret of the matter lies in the fact that the higher positions with good salaries require a man having more thorough and uptodate education on mining problems, and who can make an intelligent report to higher officials on any conditions they may meet in the mine. Such men earn the support of their superiors. By their education they learn to exercise good judgment and are successful in handling the workmen. In other words, education is the means of making a broad-gaged official—one who, while he has all these qualifications, is still pursuing his studies as an ardent student of mining conditions, reading uptodate mining literature and having always the ambition to attain higher honors.

I do not mean by these statements that the successful foreman is compelled to keep in his head all the formulas pertaining to mine ventilation, chemistry and mechanics; but he should be so familiar with the subjects that he could readily refer to his library and know where and how to get the information he desires and how to apply it, just as a mining engineer refers to his field book for the sine, cosine or tangent of a required angle; or a lawyer refers to his library to ascertain the law on a certain case.

This point leads to the use of textbooks at mining examinations, and as I have been a member of examining boards for mine foremen and firebosses for the last ten years, I am firmly of the opinion that we would get some very good men as mine officials were they permitted to refer to their textbooks and work out the questions asked at these examinations; whereas, if they are required to work out such problems by trying to remember the formula in the particular case, they would make a failure. I know of several such cases where the party can sit down and work any ordinary ventilation problem if allowed to refer to his textbook for the formula, but he cannot remember the formula in an examination. I will say that if textbooks are allowed at examinations, the books should contain only formulas, and be so arranged that it would be up to the student or applicant to know just what formula he should use for the question under consideration.

It is the desire of the examining boards to make the examinations for mine foremen and firebosses as nearly practical as possible. Only such technical questions as are absolutely necessary are generally included. But I am of the opinion that there should be more technical questions, in addition to the practical questions asked, in order to ascertain the capabilities of candidates along certain lines. I am also of the opinion that all miners should be urged to read certain mining literature bearing on their duties and explaining the dangers pertaining to certain methods that they persist in following, and describing how they can increase their efficiency.

I believe that every person should serve a certain length of time as assistant mine foreman or fireboss before he is allowed to assume full charge of a mine—especially a gaseous mine; and if he serves under a good foreman, his chances are better for becoming himself a successful foreman. I have seen old practical miners, who had a good education, pass a good examination and yet make a failure as mine foremen and superintendents, because they were unable to manage men; their judgment was bad and they could not apply their mining experience and education to the proper supervision of the mine.

I am of the opinion that a person wishing to attain a mine foreman's certificate should educate himself along the following lines: Reading, spelling, writing, elementary English, arithmetic, to cube root of numbers. A mining course should include mine gases, safety lamps, mine ventilation, blasting, timbering of mine workings, mine haulage, mine mechanics, electricity, practical methods of developing and operating mines, and should teach men how to read and understand mine maps. If one attains a fair education on the above subjects, in connection with the practical experience required by the state mining laws, there should be no question about his being able to pass an examination.

I will say further that the advantages education offers to those wishing to better their condition are as accessible as the air we breath. Institutions, as well as private instructors, have offered their services free to those wishing to avail themselves of the opportunities, and I am glad to say that many have taken advantage of

these golden opportunities; but, on the other hand, there are many who have not availed themselves of these opportunities. Some have started who did not have the will power to give up pleasure and have dropped back in the old rut, spending their spare time in idleness. My advice to the young man connected with mining is: Avail yourself of any opportunity to secure a good mining education. These opportunities, for first-class ambitious men, are increasing daily.

F. W. Cunningham,
Mine Inspector, 21st Bit. Dist.

Charleroi, Penn.

Letter No. 3—I want to say I favor the use of textbooks at mining examinations. There are so many branches of science connected with coal mining and the scope of the questions asked in the examinations is so great, that the average man cannot undertake to memorize a sufficient number of the formulas required to answer the questions, which he must do if he is to pass a satisfactory examination. I believe where the answer to any question involves the use of sines, cosines, tangents, etc., these should be given in the questions. It might be well where a formula is required to work the question, to print the formula with the question, as this would save the candidate much time looking through the textbooks to find the formula he wants to use.

I may say that I have been successful in seven examinations, held in three different states; but I would add that the time spent in these examinations was, for the most part, a season of anxiety for me. My brain was not as clear and I could not collect my thoughts, in the examination, as when going about my daily occupation. Had I been allowed the use of a textbook, as at home, it would have been a wonderful help to me.

I have often thought that many of the questions asked at mining examinations were too far advanced in mathematics for the average miner to answer without a textbook to which he can refer. It is one thing to ask a question and another thing to give the proper answer to the question asked. Anyone can ask a question that will require an educated man to answer. For these reasons, I think textbooks should be allowed in some of the examinations of mine foremen and firebosses.

R. J. Pickett.

Shelburn, Ind.

Letter No. 4—There appears to be a large difference of opinion among mining men as to whether textbooks should or should not be used at mining examinations, by candidates seeking certificates of proficiency that would make them eligible to the position of mine foreman or fireboss. Some men who are opposed to the use of textbooks in examination, claim that the proper formula should be given with each question. Others argue that neither formulas nor textbooks should be provided, but that the candidate should take the examination without helps of any kind.

In my opinion, it would be much better to conduct these examinations without allowing the use of textbooks or giving any formulas. A candidate will often show that he knows nothing of the question by using a wrong formula, and to give the formula with the question would, in this case, be giving the candidate just the information he needs to answer the question correctly. If textbooks were to be allowed in a mining examination, I believe such a practice would tend to lower the standard of the examination. Men would depend too much on the books and grow careless about reading and studying the theory and principles of mining. They would not be so anxious to know the reason "why." Many of them would not be able to transpose the many formulas pertaining to mine ventilation.

I will give here an instance where I believe the use of textbooks in an examination would do the candidate more harm than good. I believe if the following question was asked and textbooks were allowed in the examination, 95 per cent. of the candidates would apply the wrong rule. The question is:

> In a certain mine, a current of 66,000 cu.ft. per min. is passing under a pressure of 5 lb. per sq.ft.; what quantity of air would be circulated in this mine if the pressure was increased to 8 lb. per sq.ft., the power remaining the same?
>
> Ans.—41,250 cu.ft.

Looking in the book the candidate would find a rule reading somewhat as follows: "The quantity of air in circulation in a mine or airway varies as the square root of the pressure." Applying this rule, he would get about double the right quantity of air for his answer. When the "*power remains the same,*" as stated in this question, the quantity of air in circulation varies inversely as the pressure.

Another reason why textbooks should not be allowed in examination is that the man who has a good school education, but who knows nothing at all about mining, would be more likely to pass the examination for mine foreman than the man with only a fair education, but who has worked all his life in the mines. I think that to encourage such a practice would be doing an injustice to those who, by hard study, have reached their present standard.

Joseph Northover.

Seanor, Penn.

Sudden Collapse of Working Places

In reading Mr. Lane's letter regarding the sudden collapse of mine roof, Coal Age, Mar. 29, p. 500, it occurred to me that the trouble, in the instance he describes, was due to leaving too small a rib when driving up the center of the pillar. It seems evident, from his description of the occurrence, that the side pressure probably shoved the legs of the timbers in at the bottom. Mr. Lane states that the bottom was hard, and probably the timbers stood erect, without any batter or other provision against side pressure.

I would not consider two 12-ft. ribs, in this high coal, a sufficient thickness to support a roof pressure due to 500 ft. of cover. Under these conditions, we might expect a creep or squeeze to start; and, in my experience, no timbering of this sort was ever effectual in stopping a squeeze. The most that could be expected of the 5-in. timber frames, mentioned in Mr. Lane's letter, in a 9-ft. seam of coal overlaid with 500 ft. of cover, would be to steady the immediate roof strata and possibly give warning when the pressure came on or the "weighting" of the roof occurred.

When an undue weight is thrown on the pillars, it is not always shown by "nipping" of the top coal, or the "heaving" of the bottom; but when the pillars or ribs are narrow and the weight comes on, the coal begins to spall off at the middle of the seam, just as a post under great

pressure bows out and breaks in the middle. However, assuming that the "bearing in" or mining, in this seam, is near the bottom, the bottom coal would be broken when the squeeze first came on; and the great pressure would then be apt to kick out the timbers at the bottom if they did not break.

Permit me to say that I think this accident would not have occured if, instead of splitting the pillars, which were already weak, they had cut across near the face, each time, in lifts of about 15 ft. I have always thought that splitting should be avoided unless the pillar is about twice as strong as necessary; because by so doing the rib is weakened at the very time it most needs its strength. Ample pillars and a regular breaking line will do much to guard against the loss of coal and timber and avoid the sacrifice of many lives. It seems to me there is no reason why large pillars should not always be left, except where a maximum of mach ne coal must be obtained. In most cases, after the room centers exceed about 35 ft., the wider the pillars between the rooms the fewer times does the track turn have to be laid, for a given tonnage. If the centers are wide enough to require a turn anyway, they might as well be sufficiently wide to give ample support to the roof pressure.

E. C. TAYLOR, Supt.,
Keystone Coal & Coke Co.

New Alexandria, Penn.

Another Letter

In reading of the sudden collapse of a working place, as described in COAL AGE, Mar. 29, 1913, p. 500, it seems to me that there are two good reasons that may be given as causing the sudden collapse of the roof in that ease.

Mr. Lane does not state the time the miner quit work the day before the accident; but we will say it was 4 o'clock, and from that time until 3 o'clock the next morning when the fireboss made his first round, the roof had been working continuously. In this condition, it was about ready to fall when the fireboss made his examination, but was held in place by the frail timbers, which were 9 ft. long and only 5 in. in diameter. When the mine started again in the morning, the roof began to work the second time, and the breaking of the light post at the face started a heavy fall of roof that kicked out the timbers in order, back from the face, as it fell.

The second reason that may be given is that the timber was altogether too light for use in a seam of coal 9 ft. thick, under the heavy roof cover. It is impossible to wedge a 9-ft. post 5 in. in diameter very tight, without first bracing the legs from one timber frame to the other, with a plank spiked between them. I would say that heavier timbers should have been used in the working face.

Scranton, Penn. THOMAS R. PIERCE.

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

MINE AIRWAYS

Definition of Terms—The term "airway," in mining, generally relates to a passageway for the circulation of the air current, in distinction from a haulage road or travelingway, although these entries may serve also as airways. The entry by which the air current enters the mine is called the "intake," and that by which it is carried out of the mine, the "return." In like manner, the two shaft or slope openings in a mine are called, respectively, the "downcast" and the "upcast."

The "perimeter" of an airway is the distance measured around the circumference of its cross-section. The "area" or "sectional area" of an airway is the area of its cross-section.

The "rubbing surface" of an airway is the entire inner surface of the same; and is found by multiplying the perimeter o by the length l, of the airway; thus,

$$s = lo$$

Essential Features of Mine Airways—Airways in mines should be as straight as possible and void of sharp bends and other obstructions that increase the resistance of the airway to the flow of air. The shape of the airway is important as affecting the pressure required to pass a given quantity of air.

Shape of Airways—The cross-section of an airway may be a circle, square, rectangle, ellipse, or any combination of these that best meets the needs or conditions. For the purposes of ventilation, that form of airway is best that has the shortest length of perimeter, for the same area of section.

In this respect, the circular airway is first; the ellipsoidal airway next, until the major axis exceeds 2.73 times the minor axis when, for the same area, the perimeter is equal to that of a square airway. The square airway is then third in the series and the rectangular and trapezoidal forms last.

There are, however, other requirements than those of ventilation. Haulage requires a level bottom for the roadway. Roof conditions or economy of driving entries may make an arched roof out of the question, making it necessary to adopt the square, rectangular, or trapezoidal shape. Again, a weak coal and heavy side pressure may demand an ellipsoidal shape of section or a special type of timbering approaching the same. It is not uncommon to arch the roof of airways for a distance, using either a semicircle or a semiellipse to form the arch, the latter being called a "flat arch."

The closer the ellipse approaches the circle or the nearer a rectangle comes to being a square, the less is the perimeter of the airway, for the same area of section. For the same length of airway, the perimeter is proportional to the rubbing surface of the airway.

Calculation of Airways—In order to facilitate the calculation of the perimeter and sectional area of the different shapes of airways, we give the diagram shown on the following page, which explains these calculations for each case.

The Coal Age Pocket Book

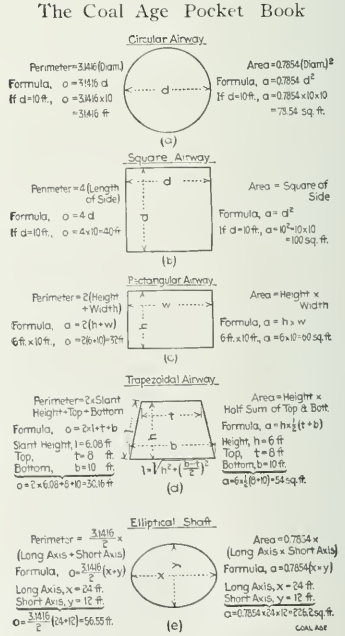


DIAGRAM SHOWING METHOD OF CALCULATION OF PERIMETER AND AREA OF AIRWAYS OF DIFFERENT SECTION

INQUIRIES OF GENERAL INTEREST

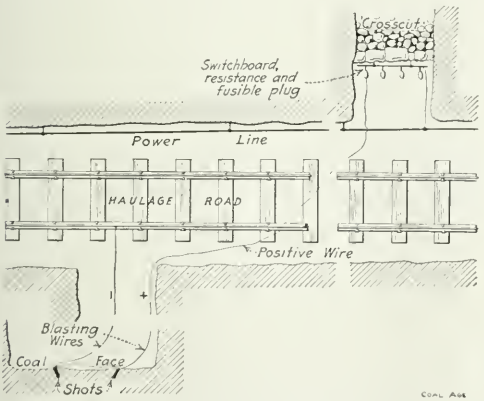
Firing Blasts by Trolley Connection

I want to ask if it is a dangerous practice to fire a heavy charge of, say eight or more holes together, by connecting the blasting wires with the trolley wire on the main haulage road, or with any other live wire conducting current into the mine. Will such a connection for that purpose affect, in any way, the dynamo at the power plant?

RICHARD EVANS.

Olyphant, Penn.

The usual practice in electric firing, in mines, is to employ a magneto machine for generating the electric current, although it is not an uncommon practice to use the power lines for the purpose of firing. In such cases, however, a special arrangement is generally preferred, similar to that shown in the accompanying figure, which consists in introducing a safety or fusible plug into the positive wire conveying the current from the power line to the coal face. There should also be introduced into



SHOWING ARRANGEMENT FOR FIRING BLASTS BY POWER-LINE CONNECTION

this wire a sufficient resistance consisting of several incandescent lamps, to reduce the current. While this is not absolutely necessary, it is generally considered safer practice. The negative, or return wire, may be connected with the rail.

A switch is also introduced into the positive line to enable the current to be turned on after all connections have been made. To insure greater safety, the fusible plug in the positive wire should always be removed and only introduced after everything is in readiness for firing. This forms an extra safeguard against the current being suddenly turned on at the switch before everything is ready.

It is possible to fire shots in mines, without taking the precautions named; but there is more liability of accidents occurring and the blasting wires may be fused by the strong current flowing in the power line. This, however, would not prevent the explosion of the blast. In presence of gas, there is always the danger of the sparking of the wires at the switch igniting a possible explosive mixture.

The firing of the charge, in any case, could not affect the dynamo at the power plant, any more than does the change of load due to turning on or shutting off the current of the motors used in haulage or coal cutting and drilling. A little experimenting may be required to ascertain the number of lamps that should be introduced as a resistance to reduce the current sufficiently for the purpose of firing.

Percentage of Fuel Consumed

There are two boilers in operation at a certain plant. No. 1 boiler burns 1168 tons of coal in the same time that No. 2 boiler burns 652 tons. I want to ask what per cent. of fuel does No. 1 boiler burn more than No. 2?

G. S. T.

Harrisburg, Ill.

No. 1 boiler burns $1168 - 652 = 516$ tons more coal than No. 2 boiler consumes. This quantity of coal is

$$\frac{516 \times 100}{652} = 79.1 \text{ } \textit{per cent.}$$

of the coal consumed in No. 2 boiler. Therefore, No. 1 boiler consumes 79.1 per cent. more coal than No. 2 requires.

Barometric Pressure

Since warm air is lighter than cold air, why does the barometer record the same pressure in summer as in winter, at the same elevation above sea level? I should think that the warm air in summer would cause a less pressure and the reading of the barometer be lower than in winter.

N. M. RIGSBY.

Sale Creek, Tenn.

The change of seasons does not affect the temperature of the air surrounding the earth, for a great distance above the earth's surface. Very little of the heat of the sun is absorbed in its passage through the atmosphere; but the heat absorbed by the ground is radiated back into the atmosphere and warms the lower atmosphere in contact with the earth, making this air lighter. The effect, however, is not sufficient to cause a great change in barometric pressure.

It is true, nevertheless, that the average barometric pressure is greater, in the northern hemisphere, in the winter months than in the summer season, reaching a maximum about January and a minimum about July. This is explained under "The Barometer," Study Course in Coal Mining, Mar. 29, p. 501. The daily variations of barometric pressure and the variations due to atmospheric changes are so much greater, however, as to wholly absorb the effect of the change of seasons.

EXAMINATION QUESTIONS

Surveying

(Answered by Request)

Ques.—Calculate by sines and cosines the bearing and length of the closing line of the following traverse of a survey:

Station	Bearing	Distance (feet)
1	N 43° 18′ E	145
2	S 62° 25′ E	122
3	S 72° 43′ W	93
4	S 69° 55′ E	232
5	S 8° 15′ W	173
6	N 81° 10′ W	141
7	S 3° 05′ W	128
8	S 43° 18′ W	136
9	N 9° 08′ E	285

British Columbia Exam.

Ans.—The plat of this survey is shown in Fig. 1. The first step is to calculate the latitude and departure of

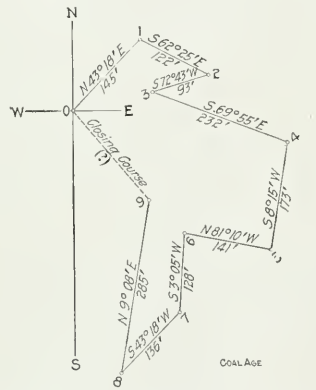


Fig. 1.

each course. The latitude is either a "northing" or a "southing," and the departure either an "easting" or a "westing," as indicated by the bearing of the course.

The latitude and departure of each course is found by multiplying the length of the course by the cosine and sine, respectively. Thus, the latitude of the first course being a northing (N) and the departure an easting (E), they are found as follows:

$$N = 145 \cos 43° 18' = 115 \times 0.72777 = 105.53 \text{ ft.}$$

$$E = 145 \sin 43° 18' = 115 \times 0.68582 = 99.44 \text{ ft.}$$

In this manner, the northing or southing and the easting or westing of each course is calculated and written in the proper column as follows:

Course	Bearing	Distance	N	S	E	W
1	N 43° 18′ E	145	105.53		99 44	
2	S 62° 25′ E...	122		56.49	108 13	
3	S 72° 43′ W	93		27 63		88 80
4	S 69° 55′ E....	232		79 67	217.89	
5	S 8° 15′ W....	173		171 21		24 82
6	N 81° 10′ W....	141	21 65			139 33
7	S 3° 05′ W....	128		127 82		6 89
8	S 43° 18′ W	136		98.98		93 27
9	N 9° 08′ E..	285	281.39		45 24	
			408 57	561.80	470.70	353 11
Closing course			153 23			117 59
			561 80			470.70

The next step is to calculate the angle of bearing of the closing course, which must have a northing of 153.23 ft. and a westing of 117.59 ft., in order to make the sum of the northings equal to that of the southings and likewise the sum of the eastings equal to that of the westings, in the completed survey. Referring now to Fig. 2, the angle of bearing a is found as follows:

$$\tan a = \frac{departure}{latitude} = \frac{117.59}{153.23} = 0.7674$$

and $a = 37° 30'$.

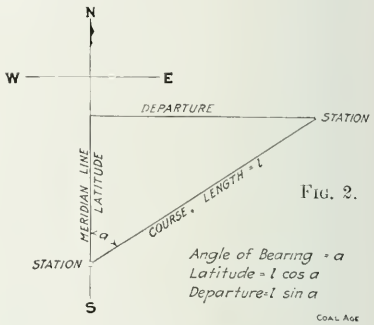

Fig. 2.

The length of this course is then calculated by dividing either its latitude by the cosine of the angle of bearing, or its departure by the sine of the same angle. For example, the length of the closing course 9-0, in this case, is

$$l = \frac{latitude}{\cos a} = \frac{153.23}{\cos 37° 30'} = \frac{153.23}{0.79335} = 193.1 \text{ ft.}$$

or

$$l = \frac{departure}{\sin a} = \frac{117.59}{\sin 37°30'} = \frac{117.59}{0.60876} = 193.1 \text{ ft.}$$

The closing course of the survey is, therefore, N 37° 30′ W, 193.1 ft.

Correction

(See p. 575, last issue)

Ans.—The weight of the loaded trip is 25 × 4600 = 115,000 lb.; the weight of the rope, 6000 × 1.2 = 7200 lb., which makes the total load hoisted, when the trip is at the bottom of the incline, 115,000 + 7200 = 122,200 lb.

The tension or pull on the rope is equal to the sum of the gravity pull and the friction pull. In this case, the inclination being small, the gravity and friction pulls are calculated as follows, taking the coefficient of friction as 0.025:

Gravity pull = 122,200 × 0.05 = 6110 lb.
Friction pull = 122,200 × 0.025 = 3055 lb.

Total pull on rope..... 9165 lb.

A speed of 13 miles per hour is 13 × 5280 ÷ 60 = 1144 ft. per min. The horsepower of the engine required to draw this load up the incline at a given speed is then

$$H = \frac{9165 \times 1144}{33{,}000} = 317.7 + hp.$$

BOOK REVIEW DEPARTMENT

FIFTEENTH BIENNIAL REPORT OF THE STATE INSPECTOR OF COAL MINES OF COLORADO FOR THE YEAR ENDING DEC. 31, 1912. James Dalrymple, Chief Inspector Denver, Colo. 138 pp.; 6x9; paper.

Besides the usual statistics giving the production of coal and the accidents in mining, the report contains many valuable recommendations. Attention is drawn to the failure of the attempt to obtain new mining legislation in 1910. At that time a commission was appointed to investigate the great loss of life in mines and prepare a new mining bill, which was presented to the 18th General Assembly, but so mutilated in the Senate as to be later vetoed by the governor. The report states that the present mining law is the same as it was nearly 30 years ago, and draws attention to the incompetent class of miners now employed, which, together with the improved machinery, is responsible for the high death rate in the state. It is stated the death rate in Colorado is double that of the United States taken as a whole.

The report gives an account of the Hastings mine explosion, June 18, 1912, when 12 men were killed; also an account of the Piedmont explosion, August 29, 1912, entailing the loss of two lives.

ANNUAL REPORT OF THE MINE INSPECTOR FOR ALLEGANY AND GARRETT COUNTIES, MD., FOR THE YEAR ENDING APRIL 30, 1912. John H. Donahue, Inspector. 36 pp.; 6x9; paper.

The production of coal in Maryland for 1911 was 4,166,736 long tons, being a decrease of 496,792 tons from the production in 1910.

The report gives an account of the drainage of the old Borden shaft, abandoned 21 years ago, and which had recently become dangerous from the accumulation of water, and was a menace to adjoining properties. A brief description is given of each of the mines in operation.

ANNUAL REPORT OF THE STATE INSPECTOR OF NEVADA MINES FOR THE YEAR ENDING NOVEMBER 30, 1912. Edward Ryan, Inspector of Mines. 79 pp.; 6x9; paper.

This report is practically confined to the metal mining industry in Nevada, but is of interest in coal mining as referring, page 24, to "Nevada's only known coal deposits." The report states that the mining of coal in the state is an "infant industry," which may never get out of its "swaddling clothes." The principal coal operation is that of the Nevada Coal & Fuel Co., which recently received its lease from the Nevada Coal Co. and is developing a 16-deg. slope, described in the report as "an inclined shaft." The slope is 725 ft. long and has a vertical fall of 200 feet. The seam of coal varies from 3 to 5 ft. in thickness. The quality of the coal improves as the development progresses. The mine is not as yet productive, although numerous shipments have been made at different times. The property of the Darms Coal Co. lying adjacent is being prospected with core drills.

FIFTEENTH ANNUAL REPORT OF THE BUREAU OF LABOR AND INDUSTRIAL STATISTICS FOR THE STATE OF VIRGINIA. 148 pp.; 6x9 in.; cloth bound.

The report is of great interest to the coal industry of Virginia, including as it does on pp. 98-110, a copy of the new mining law, approved March 13, 1912. This law is Chapter 178 of the Virginia code, entitled: An act concerning coal mines and safety of employees, creating a department and inspector of mines under the Bureau of Labor and Industrial Statistics.

The new law is a vast improvement in coal-mining legislation in Virginia. The law makes numerous specifications, providing for the safety of employees and determining the duties of both miners and operators, providing also suitable penalties for the violation of its provisions. The law specifies a standard cotton-seed oil for use in the mines.

ANNUAL REPORT OF THE STATE COAL MINE INSPECTOR OF WYOMING FOR THE YEAR ENDING SEPT. 30, 1912. 57 pp., 6x9 in.; paper.

The publication includes the report of the two district mine inspectors, George Blacker, state coal mine inspector, District No. 1 Cumberland, Wyo., and W. E. Jones, coal mine inspector, District No. 2, Sheridan, Wyoming.

The report of the first district describes the Susie Mine explosion of the Kemmerer Coal Co., Jan. 20, 1912. Some important recommendations are made in the report of the second district. These include: A standard grade of miner's oil; rock stoppings for cross-entry crosscuts; precautions in the handling of powder and methods of blasting; employment of shotfirers, or electric shotfiring; daily inspection of all working places, instead of every alternate day; prohibiting use of compressed air for brushing out gas in working places; adoption of a Qualification Act, providing apprenticeship for underground employees; adoption of a suitable compensation act to avoid the present difficulties concerning the liability of employers for injuries of workmen.

COAL-MINE STATISTICS OF STATE OF ALABAMA FOR 1911. C. H. Nesbitt, chief mine inspector. Paper, 13 pp., 9⅝x12⅛. Alabama Mineral Map Co., Birmingham, Ala.

This is a somewhat belated publication of mine statistics. It includes a statement showing the output of the largest producers in 1912, which proves that it is barely dry from the press.

The record shows the location of mines, the operating companies, superintendents, mine foremen post-office addresses, coal thickness, seams worked, types of openings, whether the mines are gaseous or non-gaseous, number of employees, mode of ventilation, explosives used, method of mining, production in various sizes, prices paid per ton for mining, number of days worked and railroad connections, output of the different companies and the annual output since 1870.

The report is almost wholly economic and contains only a few references to fatalities. That record, though short, is not very favorable; in 1911 one man was killed, for every 108 employees, the tonnage per fatality being 71,827. The record was even worse the year before when one in every 92 employees was killed.

COAL FIELDS OF GRAND MESA AND THE WEST ELK MOUNTAINS, COLORADO. By Willis T. Lee. 6⅜x9⅛ in.; 219 pp. with 21 full-page plates and a few text illustrations. Pocket with a large map—U. S. Printing Office, Washington, D. C.

Without desiring to exhibit any national complacency but seeking rather to defend in all fairness our national bureaus which are assailed so unmercifully that we sometimes forget that we have abundant reason to be proud of them, we propose to compare this bulletin with the Report of the Committee on the Carboniferous Limestone Formation of the North of England.

The American report is in every respect superior. There is a careful attempt to correlate beds, the illustrations give us a correct idea of the formations, and the descriptions of the strata are much clearer and more specific. The analyses are many (88) in the American work and almost entirely absent in the English. The British report has only one analysis and that unofficial and, whereas the book of the survey has several paleontological plates, the foreign monograph has none. The map is more complete and detailed and has many valuable cross-sections. The English map is, it is true, a beautiful example of the almost unexcelled British cartography with all the clarity of color of the Philip Bartholomew maps. However, some of the clearness and color value is due, of course, to the paucity of detail.

This report of the Geological Survey is no better than the average publication of that bureau. It is not more worthy than any other of our commendation. In fact, W. T. Lee labored under some considerable disadvantages. The territory, he describes, has been only locally operated whereas the English area has been mined since 1736. One would therefore expect the British report to be far superior to the American but it is not. It is creditable to the Survey that it is able to equal and even to surpass the work done in the country where geology had not only its birth but much of its early development.

The coal described is in the Upper Cretaceous series. It is therefore comparatively recent, geologically speaking, having been ripened by the mellowing heat of the bodies of volcanic material which found vent in its midst. The coal found therefore varies from anthracite to sub-bituminous, though the area of the former is restricted. Bodies of natural coke are also found

COAL AND COKE NEWS

Washington, D. C.

In spite of the hostility to many of the rates in the new tariff bill, it seems to be pretty generally conceded that there will be no interference with the determination to keep coal on the free list. It is certain that that policy will be followed throughout the time that the measure is in the House of Representatives, and careful investigation has indicated but little disposition to oppose the item in the Upper Chamber.

In addition to coal of all kinds the free list includes charcoal, coal tar, mineral salts, crude minerals not advanced in value by refining or grinding and "miners' rescue appliances designed for emergency use in mines where artificial breathing is necessary in the presence of poisonous gases, to aid in the saving of human life, and miners' safety lamps." Tar is also included in the free list.

There has been a strong demand for so long for the inclusion of coal as a non-dutiable article that the movement to remove the tariff from it would have strong support in any case. This backing is greatly strengthened, however, by the fact that within the past year there has been so much dissatisfaction regarding the price of coal and the relations between mine owners and railroads.

It is believed that the removal of the tariff, while under ordinary circumstances not very important, may affect the price of the article quite materially at times when there would otherwise be a disposition to advance the price charged the consumer, owing to domestic shortage as was the case during the coal strike of 1902. It is also believed that special benefit will be had by New England and by the Northwest, both of which regions are fairly close to the coal fields of Canada. In this way it is supposed, some portion of the effect of the reductions of duty on the products of those sections may be offset.

Albert C. Frost Has Been Acquitted

Information received here to the effect that Albert C. Frost, who was under prosecution in Chicago for alleged conspiracy to obtain illegal control of a large tract of coal land in the Matanuska Valley in Alaska, has been acquitted, has led to an unofficial statement that the Government has no intention of relaxing its Alaska conservation policy.

Frost and several others were indicted about two years ago for conspiracy to obtain control of 64 coal locations by the use of dummy entrymen. It was claimed that the accused had caused various employees to apply for coal lands with the intention of turning over the whole amount thus obtained to Frost.

It was pointed out here, as soon as news of the verdict was received, that this does not open the way for any further work on the claims, as the coal lands are still withdrawn from entry and will remain so until released by the Department of the Interior. The construction of the proposed road depends upon the opening of the coal lands, and is admittedly at a standstill so long as the country is closed to locators.

Alaskan interests have been eager to secure the relaxation of the Government policy with respect to the opening of the coal lands and it is expected that the verdict in this case will considerably strengthen their activity. They have desired that the subject should be taken up at the special session of Congress with a view to passing some legislation that would pave the way for what they want to do in opening up the country.

It is not believed that anything of the sort will be attempted now, but the adoption of legislation on this old question may be taken to regular session next winter. It is admitted that there should be some change in the present legal situation in regard to the opening of Alaskan lands if it is desired to have the growth of the territory proceed at all rapidly in the future.

While there is a strong conservation sentiment in Alaska there has apparently been some relaxation of feeling in recent years with respect to what are considered the somewhat overdrastic regulations on this subject.

Erdman Act Redrafted

A redraft of the Erdman act, framed with the purpose of extending the provisions of that legislation to mining and other industries, involving the movement of commodities in interstate commerce, but with particular reference to mining has been completed and is understood to have the approval of the Civic Federation of New York.

This is along the lines of the bill proposed about a year ago, but is understood to have been more carefully prepared. It will probably be introduced in Congress at an early date and will be referred to the Committee on Interstate and Foreign Commerce, but it is not expected that anything will be done at the current session. Something may be undertaken next winter.

WILKES-BARRE, PENN.

Work on the tunnel which is to connect the Parrish Colliery of Plymouth with the Buttonwood Colliery in Hanover Township, has begun and will be rushed to completion. Mechanics are at work improving the machinery in the breaker of the latter colliery. Patent pickers, etc., are being placed and the breaker will be enlarged. If the fire in the Red Ash Vein at the Buttonwood, which has been sealed tight for the last few months, is not out by the time the tunnel is finished and breaker repairs made, a landing will be made in the shaft to the end that cars may be caged from the upper as well as from the lower veins.

The coal from the new Inman shaft of the Lehigh & Wilkes-Barre Coal Co. will also be run through the Buttonwood breaker, obviating the necessity of erecting a second structure. Surface tracks will be laid from the Inman to the Buttonwood, and the coal taken to the latter. When this work is completed, the present little Buttonwood will be one of the largest and greatest producing collieries in the anthracite region.

The Pennsylvania Coal Co. is building a new breaker at the Underwood Colliery, and work is progressing so rapidly that the officials hope to have it in operation in the early fall. Reinforced concrete and steel are being used in the construction. The main building will be of steel, and the coal and rock pockets and part of the washery will be of concrete. The washery will be located in the main building. There are many new ideas contained in the plans for the structure, prominent among them being the use of concrete for the coal and rock pockets, and the manner of their arrangement. Coal cars will be loaded directly beneath the pockets, while the box cars will be loaded outside the building, from a chute leading from the center of the bottom slab of the pocket. The width of the pockets varies from 10 ft. 8 in. to 16 ft.. The walls of the pockets are designed as usual to carry that part of the load which comes from the arching of the coal in the pocket, and also to withstand the pressure against them when one pocket is full and another one empty. The pockets will have a capacity of 3500 tons. The breaker will be fed by coal from a new tract that is now being opened by the company in Throop and vicinity. It is being built by contractors Williams & Richardson.

PENNSYLVANIA

Anthracite

Scranton—Every colliery in the anthracite region was idle Apr. 1, while the mine workers celebrated the fifteenth anniversary of the 8-hour working day. This day is a holiday for the miners throughout the country.

Shenandoah—Fifty-two breaker boys at the Maple Hill colliery have struck for higher wages notwithstanding the recent agreement between the miners and operators. The company filled their places, however, and the colliery was not idle.

In a fall of top rock at the Knickerbocker colliery near Shenandoah, one miner was killed and another was fatally injured. The men had fired a shot while robbing pillars and before they could get out of the way the roof came down, completely shutting the mouth of the breast. Another accident, caused by the premature explosion of a blast, occurred at the Packer No. 4 colliery of the Lehigh Valley Coal Co. One miner was killed and another was seriously injured.

Shamokin—A fall of coal at the Cameron colliery, Apr. 5, caused the death of Robert Boyd, a miner. Arthur Neely, who was working with him, had a narrow escape.

Bituminous

Sharon—Two hundred and fifty miners were temporarily thrown out of work when the coal tipple and boiler house at mine No. 3 of the Filer Coal Co., was destroyed by fire.

Apollo—Because their demand for higher wages has been refused the employees at the Paulton plant of the Hicks Coal Co., have struck and the works have been closed.

Charleroi—About 1500 dock employees of the Monongahela River Consolidated Coal & Coke Co., who are employed at the marine mines of the company in Allenport, Monongahela and Elizabeth, have struck for an increase of 50c. a day. They have been receiving $3 a day.

Brookville, Penn.—Mine Inspector Thomas Furniss of Punxsutawney is bringing charges of violating the mining law against John Jacob and Martin Mescavick in the Jefferson County Court. Alkinn Sheri of Brockwayville is charged by Andy Lovas with removing car checks from loaded wagons in the West Clarion mine of the Northwestern Mining & Exchange Co.

Washington—The Pittsburgh Coal Co. has started proceedings in the local courts against the Carnegie Natural Gas Co. to restrain the latter from drilling a well on the Gault farm in Nottingham Township.

Connellsville—The H. C. Frick Coke Co. has decided to establish swimming pools and gymnasiums at all its plants in this territory. Instructors will teach the employees. The tanks will be 40x75 ft. Cinder tracks will also be built at plants where track events can be held.

Efforts of a professional diver, employed by the Latrobe-Connellsville Coal & Coke Co., to enter the shaft at Derry No. 2 mine to examine the pumps buried beneath 50 ft. of water have proved unavailing. The company is renewing its efforts to pump out the water which has been flooding the mine for months.

WEST VIRGINIA

Charleston—The department of mines of West Virginia will conduct examinations for mine foremen and firebosses at the following places: May 13 and 14, at Logan; June 3 and 4, at Mt. Hope; June 18 and 19, at Charleston.

About 125 men employed at the Long Branch Coal Co.'s mine, near Mt. Hope, have struck because certain of their number were discharged for trying to induce the men to strike in a body.

Reports are to the effect that the United Mine Workers' leaders have decided to issue a call for a state-wide strike, to become effective in the near future. If this report is true, it will be the most important development in the coal trade for at least a decade. Should the suspension in West Virginia become serious, it is believed coal would advance at least $2 a ton at the mine from Pittsburgh territory.

Hughesston—Part of the tipple and a barge of coal belonging to the Hughes Creek Coal Co. were destroyed by fire, Apr. 7. The blaze is thought to have started from a fire which was built by some careless persons.

St. Clairsville—Two hundred men employed in the Pursglove mine went on strike Apr. 8, compelling the mine to suspend operations. The trouble arose over some difficulty concerning the wage scale.

ALABAMA

Empire—The Maryland Coal Co., the new operation in the Sipsey basin, near Empire, will be shipping coal July 1. An announcement to this effect was made recently by local officials of the company. The improvement of the Maryland Coal Co are the beginning of a development to involve over $2,000,000 when the Panama Coal Co. makes its improvements.

Birmingham—It is reported that the Mine Inspectors Institute of America will hold its annual convention in Birmingham, commencing on June 10. It is expected that 100 mine inspectors of the United States, accompanied by their wives, will attend. The Institute will be welcomed to Alabama by Governor O'Neal and to Birmingham by the president of the city commission.

Montgomery—Former State Mine Inspector Hooper, who was recently appointed to examine into conditions at the Banner and Flat Top mines, has submitted a report commending the conduct of the Banner mine, criticising the water furnished at Flat Top and recommending that a portion of the earnings of the convicts be used for the support of their families. He declares that there is less whipping at the Banner than at any other place where convicts are worked.

In regard to the matter of ventilation used in the Flat Top, however, Mr. Hooper's opinion seriously clashes with the opinion of State Mine Inspector C. H. Nesbitt. Mr. Nesbitt declares that the Banner mine is as safe as it is possible to make a mine.

KENTUCKY

Louisville—A recent decision of the Kentucky Court of Appeals in the case of the Bennett-Jellico Coal Co., of Artemus, Ky., against the East Jellico Coal Co., will operate almost to put the latter company out of business, as far as its present workings are concerned. The land involved consists of 146 acres and is located in the heart of the East Jellico Co.'s holdings of 1000 acres, and contains the entries opened by that company and all of the equipment used by it in the operation of the property. The East Jellico Coal Co. has consequently suspended operations and shut down the mines for an indefinite period. In the meantime it is preparing to open other entries on parts of its property not claimed by anybody else.

Several hundred miners working in the western Kentucky field have brought suit against the Illinois Central R.R. Co. for damages because of its failure to supply cars, thus throwing the men out of employment. The men ask reimbursement from the railroad for the wages which they lost by reason of the car shortage. The individual amounts are small, but the aggregate is in the neighborhood of $100,000.

Spottsville—The Green River flooded the mine of the Pittsburgh Coal Co., located at this place, on Apr. 4, and on Saturday, Apr. 5, at 10 a.m. the water in the mine reached water level outside. The mine is worked by a shaft. The coal crops out above low-water mark and it is proposed that a drift be driven into the mine to drain the water, this waterway being closed in periods of flood.

OHIO

Logan—At the annual convention of Subdistrict 1 of District No. 6 of United Mine Workers, held at Logan, Ohio, recently, steps were taken to prepare for the struggle between the operators and miners on Apr. 1, 1914, when the present wage scale expires. John Moore, president, and Leo Hall, vice-president of the Ohio organization, attended the meeting.

Crooksville—The fan house of the Standard Hocking Coal Co. was destroyed by fire, Apr. 8, with a loss of $650. The origin of the fire is unknown. At the time of the fire 93 men were at work in the mine, but all were brought to the surface in safety. As a result of the fire the mine has been closed down until a new fan house can be erected. One hundred and twenty-five men are idle.

Columbus—The Thomas resolution, providing for the appointment by Governor Cox, of Ohio, of a commission to investigate the question of wages paid to coal miners in Ohio has been finally passed by both houses of the Ohio General Assembly, and is now a law. The resolution was vigorously assailed in the senate after it had been passed by the house of representatives by a vote of 69 to 40.

In the senate the fight against the resolution was made by Democratic Floor Leader William Green, author of the anti-screen bill, which has passed the senate and is pending in the house. The matter of passing the Green bill is now up, but it is believed the bill will be allowed to rest in statu quo, because of the passage of the Thomas resolution.

Elyria—The loading and coal docks of the Lake Shore R.R. were destroyed, Apr. 8, by a fire which was supposed to have been started by spontaneous combustion. The docks were valued at $50,000 and are a total loss together with 600 tons of coal.

INDIANA

Boonville—The transfer of title to 300 acres of land near here and the organization of several coal companies now in progress, means the investment of considerable capital in the coal industry in this part of Indiana. The fields hereabout have many shallow coal beds which, in the past, have been mined with great danger to the workers, from falling slate due to bad roofs and several mines were abandoned on this account. The beds run from five to twenty-five feet in thickness. The new companies will use the stripping process and the huge steam coal shovels used, after the removal of the soil from the top of the coal, are said to mine one thousand tons a day.

Indianapolis—The Chamber of Commerce of this city has filed a protest with the Indiana Railroad Commission against the proposed increase in freight rates for coal shipped from Indiana mines into this city, from 50 to 55c. a ton.

Sullivan—W. E. Woods and M. A. Haddon, of this city, have located a drill for coal on the land of Wilton Howard, Jeffersonville Township and propose to test the entire territory in the south part of Sullivan County. They have options on 16,000 acres. They will also drill test holes on a 6000-acre tract north of here and on a 12,000-acre option in Fairbanks Township.

Evansville—About four hundred miners employed in the Sunnyside, Crescent and Ingle mines have gone on strike because the management at the Sunnyside refused to reinstate a discharged miner. The three mines are controlled by one company.

NEW YORK

Geneva—One hundred employees at the Empire coke plant in Border City struck, Apr. 2, for an increase in wages and a shorter day.

KANSAS

Pittsburg—Mine No. 11 of the Cherokee & Pittsburg Coal & Mining Co., has been closed by the order of Francis Keegan, assistant labor commissioner. This is the largest mine in the district and employs 300 men. Mr. Keegan declared the mine to be in a dangerous condition. Refuge holes for the miners had not been provided along the haulage way, and the ventilation was poor. The officials state that they will put an extra force of men at work to make the necessary alterations and repairs.

PERSONALS

John T. Parry, foreman at the Butler Colliery of the Pennsylvania Coal Co., at Pittston, has been transferred to the Barnum Colliery, taking the place of Thomas Huntley. The latter is transferred to No. 9 breaker, taking the place of William Wertz, who goes to the Butler.

Earl Martin, of Chattanooga, Tenn., has resigned as president of the Continental Coal Corporation, of Tennessee and Wyoming. The cause of the step taken by Mr. Martin is not definitely known. H. L. Cory, of Chattanooga, who has been vice-president and sales manager of the Tennessee branch of the company, will assume the office of president of that company, and White L. Moss, of Pineville, vice-president of the Wyoming side of the corporation, will be acting president of that company until the annual meeting of the stockholders in June.

FORTHCOMING MEETINGS

The annual convention of the Canadian Retail Coal-dealers Association will be held in Toronto, Ont., on June 18 and 19. An especially interesting program is in preparation.

The Southeastern Passenger Association has granted special return rates for the Kentucky Mining Institute meeting to be held in Lexington, Ky., on May 16 and 17, 1913. The special return fare will be one first-class one-way fare plus 25c. Tickets will be on sale May 15, 16 and 17, and void after May 19, 1913. Fares will apply from and tickets will be on sale at all agency stations in Kentucky on the Cincinnati, New Orleans & Texas Pacific Ry., Louisville & Nashville R.R. and the Lexington & Eastern Ry., and also at various other stations in Kentucky and Tennessee.

TRADE CATALOGS

Stephens-Adamson Mfg. Co., Aurora, Ill. "The Labor Saver." Mar., 1913. 24 pp., 6x9 in.

Williams Patent Crusher & Pulverizer Co., St. Louis, Mo. Catalog. Coal crushers. Ill., 46 pp., 10x12½ in.

CONSTRUCTION NEWS

Birmingham, Ala.—The Mountain Valley Coal & Iron Co. is reopening its mines at Mountain Valley. The company will spend about $20,000 in new developments, with equipment for a 400-ton capacity.

Topeka, Kan.—Work has been started on the new Union Pacific coal chute, west of the city. The new chute will have a 250-ton capacity, 150 more tons than could be held by the old chute, and will cost $15,000.

Fairpoint, Ohio—The large coal tipple and trestle of the Provident Coal Co. has been completed and put in operation. The structural-steel work was furnished and erected by Wm. B. Scaife & Sons Co., Pittsburgh, Penn.

Greensburg, Penn.—Byrne Brothers, who recently purchased the Mathias, Miller and Keller tracts of coal in Sewickley Township, have begun operations on the Miller tract. A force of men is at work driving the main entry for the mine.

Evans Station, Penn.—The Evans Coal & Coke Co. has awarded contracts for extensive improvements to cost about $40,000. A new tipple and a 60-oven coke plant will be built and a coke crusher installed. The company has 1050 acres of coal still unmined.

DuQuoin, Ill.—Preliminary work on a new shaft of the Bell & Zoller Coal Co., at Zeigler, was begun Apr. 10. The new mine will be sunk near the famous Leiter colliery and will be equipped with modern machinery throughout. The colliery will have a daily capacity of 3000 tons.

Punxsutawney, Penn.—The Maderia Hill Coal Mining Co. has purchased 5000 acres of coal land in the Clover Run district. A tipple will be erected at once. Surveys have been completed for a two-mile spur from the Bellwood division of the Pennsylvania R.R. to the new operation.

Birmingham, Ala.—The Montgomery Coal Washing & Mfg. Co. has been awarded the contract to construct a Montgomery coal washery, for the Black Mountain Coal Land Corporation, whose main offices are in Bristol, Va. The plant to be erected by the Birmingham concern will be at Pockett, Va., on the Virginia & Southwestern R.R., and will cost approximately $25,000.

Pittsburgh, Penn.—A deal has just been consummated whereby the American Metal Co. has purchased 2500 acres of Pittsburgh coal and 350 acres of surface land on the line of the Pan Handle R.R., in Washington County. The American Zinc & Chemical Co., a subsidiary of the American Metal Co., is being organized under a Pennsylvania state charter to operate a new $2,000,000 zinc smelter which will be erected at Burgettstown.

Connellsville, Penn.—The Connellsville Coal Co. is contemplating the erection of a modern coal-storage and sales plant at its property on South Arch St. The project calls for the erection of six 50-ton bins, a 200-ton drop open storage, a large bin for anthracite coal and a bin for coke. A switch is to be run from the tracks of the Baltimore & Ohio to the company's property. The proposed plant will have a capacity of over 500 tons.

Stewartsville, Ohio—The mine of the Franklin Coal Co. will be shut down for a period of five weeks. This suspension is necessitated as a result of the fire which occurred there recently, when the entire power plant was practically destroyed by flames. Plans for the new structure are now being drawn up and it is understood that the new building will be much more substantial than the old one. Officials of the company estimate that it will cost $15,000 to replace the damage.

NEW INCORPORATIONS

St. Louis, Mo.—The Imperial Coal Co.; capital stock, $8000. Incorporators: D. G. Jackson, F. S. Suerer and B. E. Hefter.

Punxsutawney, Penn.—The Lorenze Mining Co.; capital stock, $25,000. Incorporators: F. A. Lorenze, J. W. Wingert and J. G. Adams.

Pueblo, Colo.—The Smith-Tanner Coal & Mining Co.; capital stock, $50,000. Incorporators: G. T. Ortner, L. F. Schumm and V. G. Garnett.

St. Louis, Mo.—The Universal Smokeless Fuel Co.; capital stock, $50,000. Incorporators, Jas. M. Moran, A. A. Loudon and Alfred Mueller.

New York, N. Y.—The Mineral Lands Co.; to acquire, own, use, develop, sell and deal in lands containing ores, minerals and stone; capital stock, $100,000.

Boton, Mass.—A firm has been incorporated under Massachusetts laws as the Staples Coal Co., of Boston, with an authorized capital of $1,000,000.

New York, N. Y.—The R. J. Buchholz Coal Co., Inc.; to deal in coal and fuel; capital stock, $25,000. Incorporators: R. J. Buchholz, C. E. Buchholz, J. V. Koch, Jr.

Mt. Sterling, Ohio—The Barner Coal Co.; capital stock, $32,000. Incorporators: Lewis Apperson, W. C. Taylor, J. W. Clay, M. C. Clay, R. T. Judy and J. A. Judy.

Mingo Junction, Ohio—The Brettelle Bros. Co., of Mingo Junction, Ohio, has been incorporated, with a capital stock of $25,000, to mine and deal in coal. The incorporators are Thomas Brettelle, Sr., W. M. Brettelle, M. Brettelle, George L. Thompson and James Brettelle.

INDUSTRIAL NEWS

Dorchester, Va.—The Wise Coal & Coke Co. recently ordered two five-ton, 44-in. gage electric mining locomotives from the General Electric Co.

Fairmont, W. Va.—The Consolidation Coal Co. will add to its equipment two 10-ton electric mining locomotives recently ordered from the General Electric Co.

Pottsville, Penn.—A Massachusetts manufacturing firm has purchased the only loose tract of coal land lying untouched in Kline Township. The consideration was $45,000.

Huntington, W. Va.—The local plant of the American Car & Foundry Co. has received an order from the Baltimore & Ohio R.R. for the construction of 500 all-steel hopper coal cars.

Elders Ridge, Penn.—The Iselin mines of the Rochester & Pittsburgh Coal & Iron Co., recently loaded 2058 two-ton mine cars in one day. This coal-loading feat was accomplished in ten hours.

DuQuoin, Ill.—A large block of coal weighing 4000 lb. was recently taken from the Paradise mine and shipped to Cairo. It was 6 ft. 9 in. high, 42 in. square at the base and 21 in. square at the top.

Chicago, Ill.—The By-Products Coke Corp. will install one 70-hp. and three 135-hp. motors in connection with new belt conveying systems. The motors will be furnished by the General Electric Co.

Johnstown, Penn.—The Black Lick Mining Co., for 20 years operating at Big Bend, has gone into the hands of a receiver, a Philadelphia man having been named to settle the firm's financial affairs.

Big Stone Gap, Va.—The Stonega Coal & Coke Co. will place in operation in its mines four new four-ton, 250-volt, 44-in. gage electric mining locomotives recently ordered from the General Electric Co.

Roswell, Penn.—At a meeting of the stockholders of the Standard Quemahoning Coal Co. the old directors and officers were reëlected. Plans for future development of the company's fields near here were discussed.

Hoonville, Ind.—W. T. Blair has recently bought 400 acres of coal and expects soon to start operations at surface mining. Mr. Blair is said to represent Chicago and Indianapolis capitalists. The price paid for the land was $40,000.

Johnstown, Penn.—Options for 1700 acres of coal land in Indiana County, between Vintondale and Strongstown, which were taken by Dr. Charles E. Altemus, may result in the development of this large territory within the next year.

Lorain, Ohio—The United States Steel Corporation's new freighter "James A. Farrell," built at the Lorain yards of the American Ship Building Co., was given its trial trip recently and will be used in coal trade after the lake season opens.

Greensburg, Penn.—John G. Felger, of Greensburg, has been inspecting property which he owns in Sewickley Township. Tests are being made of the underlying seam of Pittsburgh coal, preparatory to sinking shafts for the mining of the coal.

Morgantown, W. Va.—J. A. Martin, owner of the Terra Alta electric-lighting plant, has sold that property to W. F. Patterson, of Waynesburgh, Penn., in exchange for 1000 acres of coal in Monroe County, Ohio. The deal involves approximately $50,000.

Pittsburgh, Penn.—The Belmont Coal Mining Co. will add to the electrical equipment in its power plant 200-kw. and 300-kw. two-unit, three-bearing motor-generator sets and switchboard. The machines have been ordered from the General Electric Co.

Mt. Pleasant, Penn.—M. F. Byers has sold his farm, which is underlaid with valuable coal, about a mile from Central, to Isaac Brownfield, of Unlontown. Mr. Brownfield tendered in payment 2050 acres of coal land in Marshall County, West Va., and $74,000 in cash.

Logan, Ohio—According to a decision recently made by the public service commission, the Hocking Valley Ry. Co. must pay the Colonial Coal & Supply Co., of Columbus, the value of 11,020 lb. of coal alleged to have been lost in a shipment from Pomeroy to Lima.

Scottdale, Penn.—A tract of 2500 acres of coal in the Ohio valley, near Wellsburg, W. Va., has been sold for $600,000. The tract was being operated by Messrs. Stauffer, Braddock & Hough under the name of the Beech Bottom Coal Co. The sale included the plant with a daily output of 1000 tons.

Pottsville, Penn.—Excavating for cellars for new dwellings on the property of S. A. Hogan, workmen discovered the outcrop of a vein of fine coal. The vein is 15 ft. thick, but being so near the surface and directly underlying Pottsville's new residential section, it will be impossible to mine it.

Dorchester, Va.—The N. Y. Mining & Mfg. Co. will increase its power-plant capacity by the addition of a 1250-kv.a. Curtis turbo-alternator with 15-kw. turbo-exciter, three 150-kv.a. transformers and switchboard. The apparatus will be supplied by the General Electric Co., which corporation will also install the plant.

Pond Creek, Ky.—The Pond Creek Coal Co., which controls a large acreage in Pike County, Ky., is reported to be arranging for a bond issue of $2,000,000 for the purpose of providing funds for the development of its properties. The company already has seven mines in operation and plans three additional openings.

Johnstown, Penn.—John Lochrie, of Windber, has taken over a lease of the 400 acres of rich coal near Dunlo, owned by Matthew Calvin and Eliza C. Smith, of Hollidaysburg. Mr. Lochrie is to mine a minimum of 2000 tons a month for one year after beginning operations and a minimum of 4000 tons after the first year of mining.

Des Moines, Iowa—Supervisors James B. Uhl, C. W. Keller and Harry Barquist have been appointed to enter into a contract with the Bloomfield Coal Co. for the leasing of the coal under the Polk County farm. A royalty of 10c. per ton has been agreed upon with the stipulation that, if the third vein is directly under the shaft of the mine, the board expects an income of $40,000 from the deal.

Earlington, Ky.—The St. Bernard Mining Co. has arranged for equipping its power station and mines with new electrical apparatus consisting of a 500-kw. Curtis turbo-alternator, a 200-kw. Curtis turbo-generator set, a 14-kw. induction motor-generator exciter set, 100-kw., 150-kw. and 200-kw. synchronous motor-generator sets, and switchboard. All the apparatus will be built by the General Electric Co., which will make the installation.

Louisville, Ky.—After recovering rapidly from the slight setback caused by high water, the coal mines on the Lexington & Eastern in eastern Kentucky and in the Letcher County field, recently opened by the Consolidation Coal Co., are increasing their output daily, and expect soon to be operating at the maximum. The Consolidation company is shipping nearly all of its Letcher County coal to Gary, Ind., for the use of the U. S. Steel Corporation's plant at that place.

Joliet, Ill.—The Laclede Gas Light Co. has awarded to the Koppers Co., of Joliet, the contract for the installation of a new $5,000,000 byproduct coke-oven plant, to be located in South St. Louis at the junction of the River Des Peres and the Mississippi. Work will start in the course of the next three weeks. The coal to be used will be brought from West Virginia fields by water in barges via the Ohio and Mississippi Rivers, and a special dock for unloading barges will be built.

Camden, Ark.—Considerable activity in the development of the lignite deposits in this vicinity would indicate that in the course of the next two years large investments will be made in mines west of this place. Local parties are planning the organization of a $1,000,000 corporation, to develop coal and clay properties in Ouachita County.

A party of Little Rock people is organizing a similar company for the development of lignite and clay properties in Ouachita and Nevada Counties.

Jenkins, Ky.—The Chesapeake & Ohio Ry. has let the contract for the construction of its 22-mile Beaver Creek extension, reaching from the mouth of Beaver Creek to Steele's Branch, Jackson County, Ky. The branch will tap a rich coal and timber section, and its completion will be followed by an industrial development similar to that which has been seen in Harlan County in the past two or three years. The cost of the line will be about $10,000 a mile, but the amount of grading and trestle work necessary is expected to run the total cost to nearly $300,000. The firm of Ballard, Herring & Severer, of Jenkins, Ky., received the contract.

Moundsville, W. Va.—The big river tipple at the Fort Pitt coal mine in Belmont County, Ohio, which was carried away by high water three weeks ago, will not be rebuilt. The company has been making but few shipments by water during the last few months and it has been decided that all will be discontinued from now on, owing to the fact that it is not considered profitable to build a new tipple in consideration of the small returns. All shipments will be made by the Cleveland & Pittsburgh division of the Pennsylvania line, which runs by the mine. It is likely that improvements will be made on the railroad tipple in order that the full production may be handled through this source without delays.

COAL TRADE REVIEWS

GENERAL REVIEW

The hard-coal companies appear to have all the business they can possibly handle as is usually the case in April when the minimum anthracite prices are in effect. There is a general shortage on all the domestic grades, with broken probably in the greatest demand; pea is the shortest of the steam sizes. The difficulty in obtaining supplies last fall has tended to stimulate an early buying this season.

Some of the Coastwise soft-coal agencies are still apprehensive over the labor situation in West Virginia, but this has not effected any tangible improvement in the market so far. Buyers generally are not responsive and usually more than small concessions are necessary to interest them. There is quite an amount of coal on hand, inland, although this is slowly moving off, but probably at low quotations; many prices are being asked and predictions into the future are confusing. The heavy consumption has undoubtedly been the controlling feature in maintaining prices, and operators continue to hold firm; it is not believed that the discounts of the smaller companies are having any material effect upon the market.

Shipments out of the Pittsburgh district into Ohio and beyond are still considerably restricted, but the Lake service is probably up to full requirements. Prices are holding well, except on small business, which is a trifle irregular and production is greater than at any time since the Lakes closed, fully 75 per cent. of full rated capacity. Order is being gradually restored out of the chaos in Ohio, and conditions are again slowly becoming normal. The movement continues uncertain, but embargoes are being lifted rapidly, and it is now possible to get rail connections to all Ohio points. Operations have been severely restricted because of the lack of transportation facilities, conditions in the Hocking Valley having been generally better in this respect than at other points.

In the Southern market there is a temporary rush of orders for steam sizes, consumers fearing that the floods may cut them off from supplies as has been the case on other occasions. The movement into Chicago is far below normal, only a few of the Illinois mines being able to ship; the main supplies for the time being are coming from the Hocking Valley district. The Terre Haute, Ind., mines, which were closed for two weeks, are again working, but many other operations are still unable to get cars; fortunately, the demand, especially for manufacturing, is also restricted.

BOSTON, MASS.

Bituminous—Reports on the labor troubles in the New River district are received here with much interest. The union seems to be gaining in membership from day to day and several of the important mines are affected. The practice of the mine-workers buying land to camp on has put a new face on the situation. Some of the agencies appear to be apprehensive of trouble but so far there have been no signs that the market has in any way improved. A good volume of coal is being sold off-shore but there is no slackening up of effort to place coal here. Buyers are not responsive and with the present state of trade it will take more than small concessions to interest them. The call for Pocahontas and New River for spring shipment will depend very largely on the outcome of the negotiations in West Virginia.

Georges Creek mines are in good shape with an ample business and a large output. There has been some hesitation on the part of the regular buyers of this grade on account of the differential asked this year over Pocahontas and New River, but it remains a popular coal.

There is only a small movement of Pennsylvania coals at tidewater this month. A good tonnage is usually moved in conjunction with anthracite, particularly from Philadelphia, but retailers are apparently confining themselves to the latter for the present. All-rail there is fair business for coals from the Cambria districts and from the better known operations in Clearfield, but otherwise there is only a light demand.

Anthracite—April is not turning out such a disappointment as was feared. The companies appear to have all the business they can handle and there are even notable shortages in sizes like broken and pea. Dock screenings are also hard to get and distributors at this end are getting more interested in hard coal as the weeks go on. Inland, there are so many that were in difficulty last year that with the spring price in their favor they are trying to get their coal forward this year as early as possible. A decided improvement can be reported in that respect over a week ago. At least one of the originating companies that stayed out of New England last year is planning to do the same in 1913, on account of a largely increased demand from the West. That situation helps keep the other shippers well supplied with orders. Dealers here have become so accustomed to entering requisitions to be filled on short notice that already some of them find themselves out of certain sizes.

Current wholesale quotations are about as follows:

Clearfields, f.o.b. mine	$1 00@1 35
Clearfields, f.o.b. Philadelphia	2.25@2 60
Clearfields, f.o.b. New York	2.55@2 90
Cambrias, Somersets, f.o.b. mines	1.25@1.55
Georges Creeks, f.o.b. mine	1.67@1.77
Georges Creeks, f.o.b. Philadelphia	2.92@3.02
Pocahontas, New River, f.o.b Hampton Roads	2 75@2.85
Pocahontas, New River, on cars Boston	3.70@3.85
Pocahontas, New River, on cars Providence	3.40@3.70

PHILADELPHIA, PENN.

Dealers here are reporting a slight improvement in the demand for anthracite, but the difference is trifling, and is undoubtedly due to the damp and unpleasant weather prevailing here for almost a week. The companies, however, still continue mining at full time, and it is understood that most of the prepared sizes are being readily taken up, but all that is moved to the retailer is not sold, by any means. Quite a number of the dealers, whose demand for a certain size, say egg, is not great, will possibly get a supply in April that will about carry them over until fall of next year, and the same is sometimes true of the other sizes, particularly buckwheat and rice. The market, from a wholesale point of view, is good, although still lacking the snap that usually characterizes April business. While some new business is reported, orders are not coming in as rapidly as they would like to see them, but they all claim to see business ahead for at least the next three or four weeks.

The bituminous situation shows little or no improvement. Cheap coals are almost a drug in the market, and the better grades are selling, in some cases, at prices that probably net the operators less than the cost of production. Many contractors are still holding out for better figures, and with the prospects fair that they will secure them, if conditions do not change.

NEW YORK

Bituminous—While there is no tangible evidence of any material improvement in the local soft-coal market, there is undoubtedly an optimistic undertone that is having a steadying and beneficial effect on the trade. This is particularly true on contract business. Consumers are showing a greater willingness to close and there has been much business signed up during the past week; in fact, the companies generally report that nearly all contracts which expired the first of the current month have been renewed, and that they are not interested in further contract business unless same presents some unusually desirable features. Prices for the new contract year showed a general increase without exception, varying from 5@15c. above last year's figures.

In the prompt market there is no pressure to sell and inquiries seem to be on the increase. Supplies at tide are rather below normal. Mines are reported to be working about two-thirds capacity, some curtailment still being evident; the railroad movement is good, and plenty of cars are available. Prices have not undergone any change, although they are probably somewhat firmer on the same basis as last week as follows: West Virginia steam, $2.55@2.60; fair grades, Pennsylvanias, $2.65@2.70; good grades of Pennsylvanias, $2.75@2.80; best Miller, Pennsylvania, $3.05@3.15; Georges Creek, $3.25@3.30.

Anthracite—There are no indications of any letup in the demand for hard coal, and it is probable that this will continue in excess of the production throughout the balance of the month, as is usually the case in April. Production is up to full rated capacity and all the tonnages are going immediately into the consumers' storage bins. The car supply is a trifle short but not sufficiently so as yet to materially affect production. The heaviest demand is centering on stove, although all the domestic sizes are about equally active; the

steam grades are also quite strong, particularly rice, and the companies are, in some instances, drawing upon their storage supplies for these grades.

Interest in the Eastern markets is being shown in the situation in the Northwest, where the supplies on the docks are almost entirely depleted. This means that Lake shipments, and those to the West generally, will be unusually heavy during the coming season, while consignments to the Eastern points will be correspondingly lighter; in fact, one company has withdrawn entirely from the New England trade, in order to concentrate its entire attention upon the Western market. We quote the nominal New York market fairly strong and active on the following basis:

	Circular	Individual—Lehigh	Individual—Scranton
Broken	$4 50	$4 45	$4 50
Egg	4.75	4.70	4 75
Stove	4.75	4 70	4.75
Chestnut	5.00	4 95	5.00
Pea	3.50	3 35@3 45	3 50
Buckwheat	2.75	2 25@2.45	2 50@2.75
Rice	2 25	1 95@2.05	2 25@2 35
Barley	1 75	1 50@1.70	1.60@1.75

PITTSBURGH, PENN.

Bituminous—Coal shippers have been securing almost full service from railroads for lake coal, but shipments to various points in Ohio and beyond are still considerably hampered. Production in the Pittsburgh district is greater than at any time since Lake shipments closed last season, and probably exceeds 75 per cent. of capacity. Prices are well maintained by leading shippers, with occasional irregularities among the small ones. Slack rarely commands a premium, now that the Lake trade has begun. We continue to quote: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in., $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—The coke market shows more stiffness than might be expected, after so serious an interruption to shipments as was caused by the floods. The regular quoting basis on prompt furnace is $2.25, this being shaded only occasionally on small lots, while on contract the operators speak confidently of obtaining $2.50. There is, however, no contract market, there being practically no inquiry even, and an actual inquiry would probably develop weak spots, as was the case in the last contract placed, some three weeks ago, when $2.25 was done for shipment to July 1. Furnaces uncovered for second-half are quite indifferent, and naturally so, as they see a constantly falling pig-iron market, and scarcely any demand. We quote: Prompt furnace, $2.25; contract furnace (nominal) $2.25@2.50; prompt foundry, $3@3.50, and contract foundry, $3@3.50, per ton at ovens. Indifferent grades of foundry coke could possibly be picked up at slightly lower figures.

BALTIMORE, MD.

The continued movement of traffic westward to await the opening of Lake business was the only feature of interest during the week. Local operators depend largely on this Western business to tide them over the dull period in the East, and the Lake trade promises to show a substantial increase this year. The Eastern situation has undergone but little change. The demand for coal is still light, the supply has not been large and the report is current that some of the smaller mines were shutting down.

More consumers renewed their contracts during the week, but there are still many who are holding out, preferring to take their chances in the spot market. In the face of the quiet market at this time optomistic predictions for future business are heard.

Spot business here is certainly not booming, due to the large supplies purchased by consumers during January and February, when it was thought that severe weather would be experienced. These consumers are still drawing on their supply, and consequently have no occasion to enter the market. The coke market is quiet, the supply being gradually reduced to meet light demand.

BUFFALO, N. Y.

There are a good many prices asked for bituminous coal and predictions as to the future of the trade differ widely. The seller who has held his prices firm and expects to continue doing so does not believe that the low prices here and there are likely to have any influence on the general trade. If a few operators want to give their coal away they certainly cannot be prevented. For all that the consumer is buying sparingly, he is not going to pay 15c. or 20c. more for coal than he has to. It is not denied that a good part of the cheap coal is low in quality, but there is enough of it that is good to keep the consumer uncertain as to the future.

There is nothing but the heavy consumption all along the line that keeps prices at all firm. There is really enough being used to enable the sellers to maintain prices, but dealers hear rumors that competitors are cutting and start doing likewise themselves, when it is quite likely they are the only ones cutting. Some time ago there was quite an amount of coal on track here, but it is now said to be sold at pretty low prices, it is believed.

Reports from the Canadian trade are favorable to a heavy movement in that direction. The industries there are well kept up and there is plenty of money available. Collections in Canada are said to be satisfactory. The Eastern trade is not so strong, but it would be good if the cheap salesman would stay away.

Pittsburgh is holding prices firmest. A big Lake trade is opening and rumors are current that some of the heavy operators refuse to make quotations to new inquirers. With such possible competitors out of the way it ought to be rather easy to keep the market firm. Quotations remain at $2.80 for Pittsburgh lump, $2.65 for three-quarter, $2.55 for mine-run, and $2.15 for slack. Coke is still rather quiet at $5 for best Connellsville 72-hr. foundry. Allegheny Valley coal is about 25c. below Pittsburgh. Side coals, such as smithing and cannels, are not much affected by other fluctuations and prices have not changed lately.

The demand for anthracite is light. March and April have not made much inroad on the supplies, so that consumers have quite an amount on hand and do not care to buy now, even at the reduced prices.

COLUMBUS, OHIO

After several weeks of demoralization, the coal trade is again showing signs of becoming normal. One of the results of the flood was a rush of small orders for domestic grades and this is having a good effect on the trade generally. There is also a fair demand for steam sizes and taking it all in all the outlook for the future is considered excellent.

Prices have strengthened materially although there has not been any special advance excepting in the small sizes; other grades are sold at the circular figures. Concessions off of the list are infrequent and most of the operators and jobbers are inclined to maintain the circular figures.

Railroad traffic is still somewhat uncertain but officials are making every effort to remedy the situation. Embargoes have been the rule and the work of shipping required calculation. But toward the latter part of the week the embargoes were gradually removed and it is now possible to reach practically every point in Ohio through some railroad or other. Springfield, O., was about the only large town where there was any great shortage of coal and this situation is now relieved. The shortage at no time amounted to a coal famine.

Operations have of course been much restricted by the lack of transportation facilities. The greatest activity is shown in the Hocking Valley because the roads were best able to handle the output from that district. Lake trade is close at hand. A number of bottoms have been loaded and will leave the ports of the lower Lakes just as soon as navigation is formally opened which will be shortly after Apr. 15. Word received from the upper Lakes shows considerable ice in the Soo, although efforts are now being made to break the ice by means of tugs. There is an extraordinary Lake demand in prospect for the summer.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawh
Domestic lump	$1 50		$1 50	$1 50
¾-inch	1.35	$1 35	1 35	1 30
Nut	1.20	....	1 25	
Mine-run	1 15	1.10	1 15	1 10
Nut, pea and slack	1 00	..	1 00	1 00
Coarse slack	0 90	0 85	0 90	0 85

BIRMINGHAM, ALA.

One interesting feature of the local coal market is the rush of orders for steam coal by some of the railroads west of the Mississippi who have contracts for Alabama coal. It is feared that the floods of last year will be repeated; at that time some of the roads were caught short of fuel on account of their inability to get coal across the flooded territory.

There is no apparent change in the domestic market since our last report. We give below schedule of prices covering Carbon Hill domestic coal for the coming season:

Month	Fancy Lump	Nut
April	$1 75	$1 45
May	1 85	1 55
June	1 90	1 60
July	1 95	1 65
August	2 00	1 70
September	2 15	1 75
October to February, inclusive	2 25	1 90

The market for both foundry and furnace coke is active and high prices are maintained. All of the producers are sold up for several months ahead and an inquiry for 100 cars for nearby shipment found no bidders although it was stated they were willing to pay $4 f.o.b. local ovens.

LOUISVILLE, KY.

The coal business in this vicinity was virtually brought to a standstill by the flood, but the railroads are slowing resuming operations again, altheugh the road beds are in a precarious condition.

The Louisville, Henderson & St. Louis which handles the large proportion of the Western Kentucky production is once more getting under operation, but the movement is still uncertain. In the same field the Illinois Central is in somewhat better condition and its movement East is fairly prompt but the service for the South is badly crippled by the floods in the Mississippi Valley. In the Eastern Kentucky fields the situation is much better. The roads generally are not so accessible to flood waters and little trouble was experienced in rapidly repairing what little damage was done.

The damage to the mines was comparatively insignificant and there will be few if any protracted shut-downs due to loss of equipment or water in the workings. The great congestion of traffic at all the important junction points appears to have been the most serious result of the flood. The service is still badly demoralized at a number of points and the work of getting cars moving again is going forward slowly. The congestion of coal is particularly accute. While the physical condition of the roads is such that there seems to be no reason for further delays there is a paralyzing confusion that seems to make the efforts of the operating departments ineffective.

Because of the large number of cars tied up and not available for use an actual shortage of equipment has developed. The Kentucky product is being called upon to supply markets which usually belong to the West Virginia operators. A prominent Kentucky operator recently shipped 30 box-cars of the best block coal to Seattle, Wash., the freight rate on which was between $10 and $11 a ton.

The heavy demand and short supply of nut and steam grades has resulted in an advance on these to as high as $1.10. Western Kentucky lump can be had from $1.10 to $1.25, domestic nut from $1 to $1.10, with nut and slack strong at 75 to 85c. and not much available.

KNOXVILLE, TENN.

Business in this district is considered fairly good for this period of the year. While the advance in prices, as compared with other states, and even with adjoining competing districts is somewhat less, still most steam contracts are being closed on an average of about 10c. higher than last year's figures and operators appear satisfied. The domestic consumption has been comparatively light due to the persistently warm weather over the past two or three months, but the steam grades are in strong demand and the surplus domestic is being diverted into the steam market.

The excessive domestic production which always occurs through May and June appears to be pretty well covered; contracts have been rather harder to close. Local operators are taking considerable pains with their preparation and this, together with a rather extensive campaign for business, and the high grade of the coal, has created a very strong and consistent demand for these fuels.

INDIANAPOLIS, IND.

Many of the mines of the state are still shut down because of inability to get cars and the movement to Indianapolis and to some of the other large cities is small. Railroads are repairing flood damage as fast as possible, but scores of bridges were carried away and the work of rebuilding will be slow. Where parts of them only were damaged, repairs will soon be made and some have already been fixed.

On account of the high water and restricted railroad service, hundreds of factories were shut down or are now working part time and this relieves the pressure for coal. The weather has not been severe and the domestic demand has not yet cleaned up stocks in retail yards, the mild winter leaving these still of ample proportions.

In the Terre Haute district, mines that were closed for two weeks during the worst of the flood and its aftermath are in operation again, as some cars are being furnished. While here and there a premium is offered, no advantage is being taken by operators or retailers of the shortage condition in particular places and summer prices prevail at the mines.

DETROIT, MICH.

There is a reverse condition existing here from last week; the consumers of steam coal seem to be all over stocked by the abundance of fuel that is arriving daily, some of the railroads being forced to auction several cars off for demurrage. They are now requiring the shippers to stop all shipments so that they can work their stocks down and clean up for the spring.

It is thought by the operators that this will give them an excellent advantage on prices for contracts in the future. Pocahontas is the only coal that is showing any strength just now, however, as retailers are very slow in the matter of stocking up on domestic soft coal.

The market is dull at present, and only those who are forced are buying coal. The following quotations for today are as follows, f.o.b. mines:

	W. Va. Splint	Gas	Hocking	Cambridge	No. 8	Pocahontas	Jackson Hill
Domestic lump.	$1.40	..	..	....	....	$2 25	$1 75
Egg.....	1.40	..	..	....	..	2 25	1 75
Nut.....	1.30	..	$1 30	....	..	..	..
1½-in. lump.....	1 15	..	..	....	..	..	..
¾-in. lump.....	1 05	$1.05	1 05	$1.05	$1 05	1 25	....
Mine-run.....	0 95	0 95	0 95	0 95	0 95	....	
Slack.....	0.75	0.75	0 75	0 75	0 75	1 00	

The coke situation here has fallen off quite materially in the last few days because of the slight demand. Connelsville is being quoted at $2.80 Semet Solvay $3, and Gas House $2.75, f.o.b. the ovens.

CHICAGO

The amount of coal available for Chicago delivery is far below normal, due to the recent floods in Ohio, Indiana and Illinois. The main source of supply at the moment is the Hocking district of Ohio, that part of Indiana north of the Wabash River and from a comparatively few mines in Illinois. Chicago dealers report a temporary rise of prices for spot coal and dimirished storage piles.

Domestic coal is being sold largely for steam-making purposes and commands mine-run prices; mine-run is bringing from $1.10 to $1.25. Retail dealers are paying $1.25 for central Illinois coal and $1.35 for the southern product. Eastern coals coming into this market include Hocking, Pennsylvania smokeless and anthracite. The coke market temporarily is strong and byproduct coke has been fairly active during the past few days at $5@5.25. A few shipments of Connellsville coke have been made and the price is firm at about $6 delivered.

Prevailing prices in Chicago are:

	Sullivan Co.	Springfield	Clinton	W. Va.
Domestic lump.	$2.47	$2.07	$2.27	....
Egg.....	2.47	....	....	$3.95
Steam lump....	$2.12 @ 2.37	1.92 @ 1.97	2.17	....
Mine-run.....	....	1 87 @ 1.92	1.97	3.30
Screenings.....	1.77 @ 1.82	1.77 @ 1.82	1 77	....

Prevailing prices for coke are: Connellsville and Wise County, $6@6.25; byproduct, egg, stove and nut, $4.45; gas house, $4.75@4.85.

ST. LOUIS, MO.

There is no change in the local situation, with the possible exception that a few of the operators are beginning to realize that they are losing money, and are asking a trifle more for coal. Franklin County coal is being sold on the local market at perhaps the lowest price of any high-grade coal.

The Standard market is still struggling along against odds. The past week has seen the price of screenings jump from 60 to 90c. on account of the poor demand for the screened sizes. With this exception there has been no change in prices.

The circular is:

	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard
2-in. lump.....	....	....	....	$0.90
3-in. lump.....	....	....	$1.25	....
6-in. lump.....	$1.20 @ 1 25	....	1 35	1.10
Lump and egg	1 25	$2.25	..	....
No. 1 nut.....	1.10 @ 1 15	..	..	....
Screenings.....	0 95 @ 1 00	..	..	$0.85@0.90
Mine-run.....	1.05 @ 1.15	..	..	0.85
No. 1 washed nut	1.35			....
No. 2 washed nut..	1.35			....
No. 3 washed nut	1.35			..
No. 4 washed nut	1.35			..
No. 5 washed nut	1 00 @ 1.05			..

OGDEN, UTAH

March finished with all the mines working every day. This increased demand for coal during the latter part of the month resulted in a production that was not expected. The first 20 days were very discouraging and had it not been for the storms that visited the West, March would have been a poor month. April is starting out well as there is not much coal in storage and also because of the reduction in quotations for shipments to Nebraska. No doubt the demand for Rock Springs coal will steadily increase until this market will again become normal. This will be a great relief to the Wyoming operators as Kansas and Nebraska have been a source of annoyance.

Prices remain unchanged as follows, with nut and slack selling below circular prices: Lump, $2.25; nut, $1.75; mine-run, $1.75; slack, $1 for Nebraska and Kansas. Lump, $2.75; nut, $2.25; mine-run, $1.85, and slack, $1, with Utah slack $1.25 for shipments to the Northwest.

PRODUCTION AND TRANSPORTATION STATISTICS

ANTHRACITE SHIPMENTS

The following is comparative statement of the anthracite shipments for March and the first three months, of the years 1912-13, in long tons:

	March		3 Months	
	1913	1912	1913	1912
Phila. & Reading	976,712	1,472,696	3,399,293	3,861,766
Lehigh Valley	829,502	1,225,019	3,066,782	3,329,391
Cent. R.R. N. J.	665,856	848,110	2,240,293	2,393,145
Del. Lack. & West.	532,247	916,824	2,217,917	2,491,221
Del. & Hudson	562,440	578,983	1,782,988	1,718,283
Pennsylvania	429,211	537,170	1,496,825	1,665,828
Erie	700,383	761,742	2,073,342	2,154,850
Ont. & Western	212,932	228,843	642,236	656,867
Total	4,909,288	6,569,687	16,919,876	18,209,351

Stocks at Tidewater at the close of March were 772,115 tons as compared with 484,270 tons on Feb. 28.

CHESAPEAKE & OHIO RY.

The following is a comparative statement of the coal and coke traffic over the lines of the C. & O. Ry., for February, and the eight months ending Feb. 28, 1912-13, in short tons:

	February		Eight Months			
Destination	1913	1921	1913	%	1912	%
Tidewater	323,469	299,459	2,391,580	22	2,605,213	22
East	220,991	190,655	1,739,089	16	1,472,804	13
West	671,742	971,416	6,109,197	57	7,456,874	63
Total	1,216,202	1,461,530	10,240,466		11,534,891	
Coke	29,643	91,579	195,343		147,616	
From connections						
Bituminous	88,546	17,650	423, 11	4	153,890	1
Anthracite	1,480	4,742	8,829	1	26,646	1
Grand total	1,335,871	1,503,501	10,867,749	100	11,863,043	100

THE CAR SITUATION

The net surplus of idle coal cars shows an increase of about 40% over the two previous statements. American Ry. Association reports surpluses and shortages of coal equipment for two weeks ended Apr. 1, as follows:

	Surplus	Shortage	Net*
New England Lines	321	0	**321**
N. Y., New Jersey, Del.; Maryland; Eastern Penn.	4,303	182	**4,121**
Ohio; Indiana; Michigan; Western Pennsylvania	1,215	554	**661**
West Virginia, Virginia, North & South Carolina	1,574	400	**1,744**
Kentucky, Tenn.; Miss.; Alabama, Georgia, Florida	1,412	150	**1,262**
Iowa, Illinois, Wis., Minn.; North & South Dakota	3,368	55	**3,313**
Montana, Wyoming, Nebraska	1,453	15	**1,438**
Kansas, Colorado, Missouri, Arkansas, Oklahoma	2,792	0	**2,792**
Texas, Louisiana, New Mexico	635	33	**602**
Oregon, Idaho, California, Arizona	3,008	0	**3,008**
Canadian Lines	127	11	**116**
Totals	20,209	1,400	**18,809**
Greatest surplus in 1912 (Apr. 25)	94,692	2,144	**92,548**
Greatest shortage in 1912 (Oct. 10)	6,491	14,897	8,406

*Bold face type indicate a surplus

FOREIGN MARKETS

GREAT BRITAIN

Apr. 4—A great improvement has taken place in the demand for all descriptions of coal. Prompt supplies are very scarce and dear, while for forward shipment values are stiffening further all round.

Quotations are approximately as follows:

Best Welsh steam	$4.80@4.92	Best Monmouthshires	$4.44
Best seconds	4.68@4.80	Seconds	4.32
Seconds	4.56@4.68	Best Cardiff smalls	3.78
Best dry coals	4.56	Seconds	3.60

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both exclusive of warfage, and for cash in 30 days —less 2½%.

FINANCIAL DEPARTMENT

Pittsburgh Coal Co.

Chairman M. H. Taylor reports under date of March 11, as follows:

Results—The total tonnage produced and handled, including coke purchased and exclusive of coal purchased by the subsidiary companies, was 18,363,417 net tons, an increase of about 14%. The gross earnings from all sources increased $382,558, or 9.46%, and the net earnings after interest charges and full depreciation were $2,025,483 (an increase of $633,545, or 45.52% on the preferred stock.

Demand caused by favorable weather conditions and the uncertainty attending the biennial miners' wage-sclae settlement materially improved tonnage and earnings for the first quarter of the year. Then followed idleness for three weeks in April, pending scale adjustment. When the mines resumed, contracting was done under sharp competition from all districts at prices at which the bulk of the production for the year was moved. This, with floods, shortage in labor and car supply, limited the advantage that otherwise would have been received under the better trade conditions of the last half of the year.

The increase in net earnings is partly due to a small increase in the average selling price of the product f.o.b. mines, and from better dock and agency returns. Labor mine costs were increased under the wage scale adjustment of Apr. 1. Practically all of the betterments on the mines for the year have been charged to operation, as has also full depreciation. Floods during the spring and summer caused severe losses in property.

The undivided earnings account now stands at $9,153,134.

Finances—The working capital Dec. 31, 1912, was $4,573,679, a net increase of $267,275. There are no outstanding obligations for borrowed money, either by this company or any of its subsidiaries, and the floating debt is chiefly for accounts payable not yet due and for paper issued by subsidiary companies for sold undelivered dock stock coal.

Mining Plants—Disposition of 77 mining plants owned at the beginning of the year is as follows: In commission either the whole or part of the year, 51; available but idle for the year, 6; operated under leases, 7; exhausted and dismantled, 5; assigned to other mines, 8; total, 77. The possible tonnage capacity of the mines in commission for the year as against the actual output shows an efficiency percentage of only 65.36%.

Pittsburgh Coal Dock & Wharf Co.—Guaranteed Bonds—To secure funds to repay the Pittsburgh Coal Co. of Wisconsin for its advances on account of Dock No. 7 construction, to enlarge dock No. 5 at Superior, Wis., and to construct a dock at Lime Island, Mich., it became necessary to transfer the dock properties at the head of Lake Superior to the Pittsburgh Coal-Dock & Wharf Co. and to retire the $1,852,000 outstanding bonds upon them as follows: Northwestern Coal Ry. Co., $794,000; Ohio Coal Co., $200,000; Pittsburgh Coal-Dock & Wharf Co., $858,000. [Of these old bonds there remained outstanding on Dec. 31, 1912, $121,000, $85,000 and $250,000, respectively.]

To do these things, an issue of bonds by the Pittsburgh Coal-Dock & Wharf Co. of Minnesota, guaranteed as to principal and interest by the Pittsburgh Coal Co. of Pennsylvania, was duly authorized in the sum of $3,500,000, dated Apr. 1, 1912, bearing 5.4% interest payable semi-annually, with sinking fund provision for their retirement at or before maturity, Apr. 1, 1938, but redeemable all or any part on any interest date at 102½. Trustee, Union Trust Co. of Pittsburgh.

The large expenditures authorized will provide modern dock facilities sufficient for storing and handling an increase over present tonnage requirements, and for some time to come, at the head of Lake Superior. Decrease in handling costs, maintenance and rentals, heretofore paid, will exceed the increase in fixed charges created based upon the same tonnage.

Midland Purchase Bonds—The Midland Coal Co. lease of Jan. 1, 1903, upon 4736 acres of coal rights and of three mining plants taken over at that time was terminated by

sinking fund bonds of Pittsburgh Coal Co. of Pennsylvania, known as Midland purchase bonds, dated May 15, 1912, $1,006,000 of which have been issued on the conveyance of the property, and the balance retained for the retirement of a prior-lien mortgage of the Midland Coal Co.

Monongahela River Consolidated Coal & Coke Co.—While practically all of the preferred and about 94% of the common shares are held, this controlled company has been independently conducted, although, for economic reasons, a portion of the operating staff of both companies is joint and it had relatively an equal year in net gain with this company. Of the issue of debenture bonds exchanged for the preferred shares, $57,500 have been acquired and canceled during the year, and we plan to retire annually hereafter such a percentage as will cancel the entire issue prior to maturity.

Montour R.R. Extension—Bonds—To insure maintenance of the present tonnage of the company, and to provide for its increase, it has become a present necessity to extend the Montour R.R. from its treminus at North Star, Penn., to the Mifflin Yards of the Bessemer & Lake Erie R.R. Co. by an extension of about 34 miles, to furnish an outlet for proposed new mine developments. A contract has been entered into between the Montour R.R. Co. and the Bessemer & Lake Erie R.R. Co., dated July 11, 1912, for a traffic exchange between the two railroad companies and a division of the rates upon it.

It is expected that the road will be in operation by July 1, 1914. To finance its cost, $2,750,000 first morgtage 50-year 5% cupon bonds have been issued, free of deductible tax, and having an annual sinking fund provision sufficient to retire all before maturity on Feb. 1, 1962. Contracts have been let for the work. Current progress will also be made in the opening up of mines along the line of the projected road, with which all the railroads of the district can be connected. While the tonnage of this company will furnish a sufficient revenue to meet all charges, there are assurances of other traffic which would add greatly to the value of the new line.

RESULTS YEAR ENDING DEC. 31, INCLUDING SUBSIDIARY CO'S

*Production in short tons:	1912	1911	1909	1909
Pittsburgh district coal	16,948,775	14,739,158	16,213,912	14,560,331

Undivided earnings	9,153,434	8,841,541
Total	103,992,712	100,497,000

x Properties owned Dec 31, 1912, consisting of coal loands, mine plants and equipment, railways, railway cars, docks on Great Lakes, etc., were: Coal lands and real estate, less allownnce for depletion of coal lands, $56,086,905; plant and equipments, $12,595,942; advanced royalties, $7,388.

Outlook—The outlook for the present year is for a material increase in net earnings, against the adverse factors of an unusually light winter use and a reduced general business demand. Since 1907, due to special conditions, all costs have steadily advanced, and the margin of gain has as steadily declined, until it is reasonable to expect an advance in the selling price of 1912, which did not represent the cost risk and value of the product.

⁂

The Central Coal & Coke Co.

According to the recent statement of this company (of Kansas City, Mo.), it has over 30 coal shafts operating in Kansas, Missouri, Arkansas, Indian Territory and Wyoming, with timber mills in Texas and Louisiana. Gross income for 1912 shows a better proportion than for the 19 months ended Jan. 1, 1912, being $1,265,279 to $1,581,164 for the earlier period. Expense, interest and depreciation have decreased from $1,086,577 for the 19 months before 1912 to $633,770 for 1912. Net earnings for 1312 are $631,508, against $494,587 for preceding 19 months. The payments of 5% dividends upon the $1,875,000 of preferred stock and of 6% upon the $5,125,000 of common stock left a balance of $230,259, compared with the balance of $93,337 for the previous 19 months.

Out of assets of $13,014,267, quick assets are $2,431,730. Current liabilities are $2,125,132, leaving a working capital of $306,598. This compared with assets for the 19 months before of $1,996,494 and liabilities of $1,260,115, making a working capital of $736,379. Decrease has been due largely to bills payable, which are $547,500 larger for the shorter period.

COAL SECURITIES

The following table gives the range of various active coal securities and dividends paid during the week ending Apr. 12:

Stocks	Week's Range—High	Week's Range—Low	Week's Range—Last	Year's Range—High	Year's Range—Low

Consolidation Coal Co.—Regular quarterly dividend of 1½% payable Apr. 30 to holders of record Apr. 15.

Pacific Coast Co.—Regular quarterly of 1¼% on the common and second preferred and 1¼% on the first preferred payable May 1 to holders of record Apr. 18.

⁂

Metropolitan Coal Co. (Boston)—This company, controlled by the Consolidation Coal Co., has recently issued $200,000 first mortgage 4½ per cent. bonds, dated Dec. 1, 1911. The issue is due Dec. 1, 1939, but callable at $105 with interest for sinking fund beginning Oct. 1, 1913. The total authorized issue is $250,000. The mortgage was made in connection with the purchase and development of the large coal plant of Geo. B. Emery, on the waterfront in Chelsea, it being proposed to build a 300-ft. pier and provide facilities for handling and storing 1,000,000 tons a year.

Hocking Valley Products Co.—This company was incorporated in West Virginia, February, 1911, as successors to the Columbus & Hocking Coal & Iron Co. and the Columbus & Hocking Clay & Brick Manufacturing Co., both of which were sold in foreclosure July, 1911. The authorized capital stock is $4,600,000, having a par value of $100. The annual sinking fund on bonds is at least 5c. per ton on coal, 15c. per barrel on oil and 25c. per 1000 on brick, and a further sum equal to the excess in dividends above 6 per cent.

COAL AGE

Vol. 3 NEW YORK, APRIL 26, 1913 No. 17

ARE you feeling rather tired and out of sorts just now? Sure! You're suffering from "Spring Fever"!

There is only one class of human beings who escape the tired feeling incident to Springtime—the poets: For them this is a season of undue activity.

If you assume that every one regrets the advent of Spring, just shadow the trail that leads to the fishing pool, and you'll go home convinced that your wits have been woolgathering. It doesn't take the boys long to discover that the outside boss isn't keeping close tab on them, while the fever keeps hold of him, and they slip off satisfied that they won't be missed.

Isn't it just barely possible that these same boys are the only ones around the camp who have found a sensible remedy for the annual tired feeling—sneak away and commune with nature while she is at her best and you are at your worst?

We wonder what would happen if every mining company should set apart one day each Spring and allow the entire camp to shut up shop and take to the woods—women, men, children, babies, dogs, mules, etc.,—that they might enjoy together a genuine old-fashioned picnic.

Think of the ideal picnic grounds that are within easy riding distance of most camps: Water, flowers, moss, trees, birds; with such a combination you can stage any kind of outdoor fun from baseball to "spooning."

Mining folk in this country display little imagination when it comes to planning amusements and recreation for themselves and their families, which explains, no doubt, their lack of community interest.

Can you picture to yourself anything better calculated to develop a community spirit than an entire camp's population being hauled to a picnic in company wagons, drawn by company mules, under the personal direction of the local superintendent, at a time when the Spring fever is first making itself felt?

Such a picnic holds out many possibilities. If all the women folk are required to furnish eatables for a general feast, good-natured discussions as to culinary usage will spring up and the rivalry promoted will have its effect on many a future bill of fare—if you consider all miners' wives ideal cooks, your digestive organs must resemble those of the proverbial can-eating billygoat.

Furthermore, think of the misunderstandings that might be cleared up during a general gathering of this kind. Isn't it reasonable to suppose that many a strike could have been avoided if opportunity had been presented to talk things over in a friendly way, spontaneously?

"All work and no play—"

Honest now! has the miners' play been given proper consideration?

A Brief Account of the Matanuska Field

By W. R. Crane*

SYNOPSIS—The Matanuska field has been exposed to less violence and volcanic heat than the Bering River field. Some of the coal is almost lignitic, but 75 per cent. is bituminous fuel. The best coal chemically is in the worst physical condition and would have to be briquetted or coked to make it acceptable to the market. A portion of the field has good coal, which could be mined at reasonable expense.

The Matanuska coal region, as commonly defined, occupies an area some 80 miles long by 5 to 10 miles wide, lying principally along the valley of the Matanuska River and extending to the eastward from a point slightly to the northeast of Knik, on Knik Arm.

The coal-bearing area is being rapidly extended until at present a considerably larger area is included in the field than was at first anticipated. Coal is now known to occur in beds of workable size to the northward along the Susitna and the Little Susitna rivers and on Willow, Caribou and Billy creeks, while to the southward similar

Fig. 1. Looking up Matanuska River, Chugach Mountains in Background

beds have been located at various points, covering considerable areas in the Chugach Mountains.

The Topography of the Field

The wide valley of the Matanuska River lies between the Talkeetna Mountains on the north and the Chugach Mountains on the south, both of which ranges are steep and rugged, having elevations ranging from 3000 to 6000 ft. See Fig. 1.

The country to the north of Knik Arm consists of lowlands, which gradually increase in elevation as the valley of the Matanuska River is approached and change into a comparatively narrow strip of rolling country with hills seldom exceeding 1500 ft., but increasing rather abruptly in height as the main ranges of the mountains are approached.

Unlike the Bering River coal field, this region is not isolated from the interior by mountains and glaciers, although to the northeast and eastward, except for a few passes, the passage to and from the region is rather difficult. However, to the northwest and westward, a continuous stretch of practically level country extends along Knik Arm and thence into a similar country adjacent to Cook Inlet. The accompanying map gives the location of the rivers and creeks in the coal field with respect to Knik Arm. See Fig. 3.

Not an Icy Wilderness but a Productive Valley

Few parts of Alaska excel the valley of the Matanuska River in favorable climatic conditions. The rainfall is abundant but not excessive, and the amount of sunshine

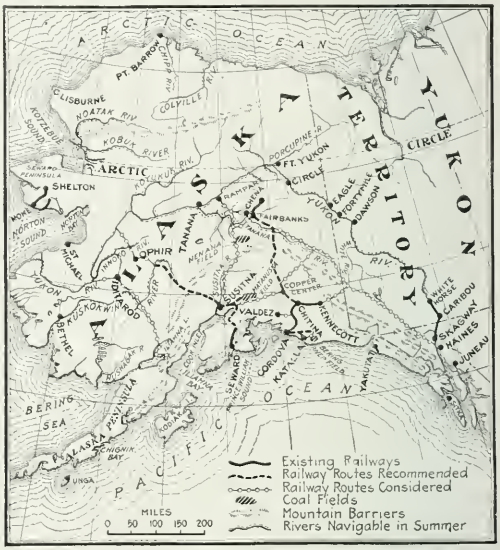

Fig. 2. The Alaska Coal Fields and the Railroads Built and Proposed

is sufficient to insure the growth and maturity of vegetation, as the luxuriant growths on the flats bordering on Knik Arm and the valley of the Matanuska attest.

Excellent pasturage for animals and a soil suitable for raising a great variety of vegetables and cereals is to be found in this locality. In the valley of the Matanuska, timber grows in great variety. The most common trees, naming them in order of their frequency, are the following: Cottonwood, birch, spruce, quaking aspen, white willow and alder; current bushes are also abundant.

The width of the bed of the Matnuska River probably averages one-half mile, although it measures a mile or more in some places. The stream gorges with precipitous walls at other points. It often consists of extensive flats of gravel and sand, through which swift mountain torrents and glacial streams are constantly cutting new channels. See Fig. 1.

No Lack of Rivers and Creeks

The principal streams tributary to the Matanuska River and entering it on the north are: Moose, Eska, Granite, Kings, Chickaloon, Hicks and Caribou, while on the south and proceeding up the river in the same order as before are: Carbon and Coal and numerous others of minor importance. These tributary streams are usually of con-

*Professor of Mining, the Pennsylvania State College, State College, Penn.

siderable volume and are, particularly in certain seasons, difficult to ford.

While the Matanuska River can be forded in a number of places, crossing it is usually a hazardous undertaking. Owing to the difficulties encountered in towing and poling river boats up the river, most of the supplies required in the field are either carried in by pack animals or are sledded in during the winter, the trail following the course of the river.

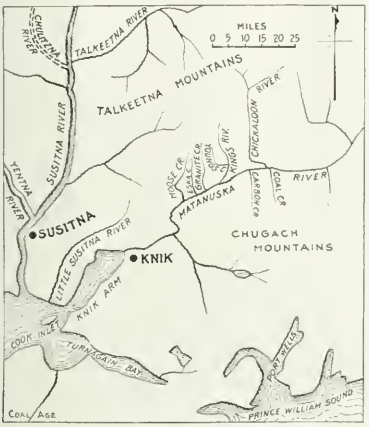

Fig. 3. The Immediate Surroundings of the Matanuska Field

is estimated that some 70 square miles are underlaid with coal. Of this area fully three-quarters, or approximately 50 square miles, contain coal of a bituminous character.

The coal areas of this field are naturally named after the various streams where coal has been found to outcrop. These streams are all tributary to the Matanuska River. The only exception is the anthracite ridge, which lies between two streams. For convenience in discussion the coals of the bituminous area can, therefore, be separated into districts according to the arrangement indicated above, namely, those along Chickaloon, Kings, Young, Eska, Moose, Carbon and Coal creeks, respectively. The last two mentioned, the combined Carbon and Coal Creeks district, lies to the south of the Matanuska and on the opposite side of the river to the Chickaloon Creek district.

The Northeastern and Southwestern Groups

This subdivision of the bituminous area by districts does not take into consideration the character of the coal, which, if followed, would require a wholly different arrangement of the districts in the field. Were the bituminous areas to be subdivided according to character of coals, the coals on Chickaloon, Carbon, Coal and Kings creeks would be placed in one group and called true bituminous coal, while the coals of Young, Eska and Moose creeks would be designated as low-grade bituminous fuels, as they are in some places considered lignitic in character.

The general physical appearance of the coals of Chickaloon and Kings creeks, when compared with those in the southwestern portion of the Matanuska coal field, would seem to indicate that there should be a greater difference in chemical properties than there actually is.

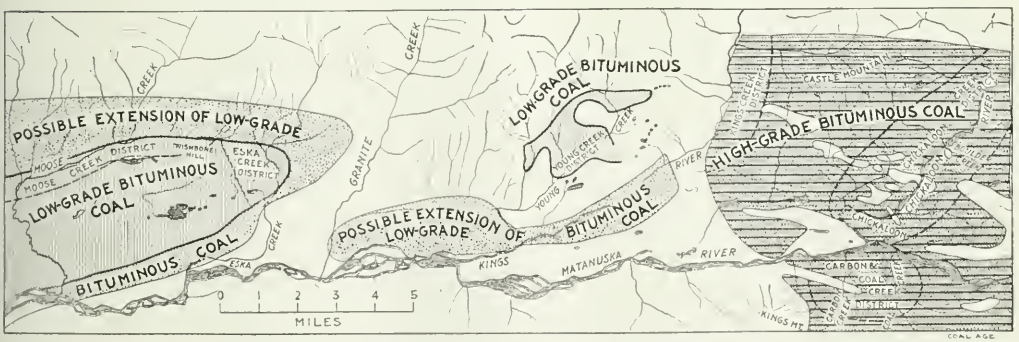

Fig. 4. Map Showing the Various Coal Districts

It is claimed that George Jammé discovered the coal in this field at a comparatively early date, although it was not until 1894 that it became generally known that coal occurred in workable quantities. While considerable work has been done in certain localities, it has been confined to exploratory work and since the withdrawal of the coal lands from entry the field has been practically abandoned.

Coal Is of Varied Grades

The area in which the various grades of bituminous coals occur, extends up the river as far as Chickaloon Creek, including particularly the region lying between and including Moose and Chickaloon creeks. Of the 300 square miles of coal-bearing formations in this field, it

Further, the rock movements evidenced by the folds, faults and igneous intrusions apparent in the upper coal field, gave every opportunity to the coals of both Chickaloon and Kings creeks and possibly to less extent Carbon and Coal creeks to assume a radically different character from those of Young, Eska and Moose creeks, where the rock movements appear to have been slight compared with those in the districts above mentioned.

The Characters of the Coals

The physical condition of the coals of the bituminous area of the Matanuska field is, as a whole, good. The coals of Chickaloon Creek and Kings Creek districts are exceptions. These are badly broken and fractured and much fine coal will be produced in their mining and hand-

ling. The rock movements responsible for the broken condition of the coals on Chickaloon and Kings creeks were much less severe in the western portion of the field, for aside from a moderate degree of folding and faulting the coal remains practically undisturbed.

The U. S. Geological Survey has made extensive tests, both chemically and physically, on the coals of this field. The results of some of these tests are given in the following table[1]:

ANALYSES OF MATANUSKA COALS

District	Total Moisture	Volatile Matter	Fixed Carbon	Ash	Sulphur	Calories	Btu.	Fuel Ratio
Chickaloon Creek	1 98	17.20	66 08	14 56	0 67	8260	14,868	3 77
Carbon and Coal Creeks	4.20	19 72	65.26	10 82	0 42	6649	11,968	3.32
Kings Creek	1 45	22.77	66.40	9 38	0.67	7419	13,354	2 91
Youngs Creek	2.50	28 32	58 82	10.36	0 58			2 08
Eska Creek	6 08	35 41	49 78	8 23	0 42	6299	11,338	1 41
Moose Creek	7 04	35 45	49 10	8 41	0 32			1 39

The chemical properties of coals determine their value and utilization while the physical properties indicate the possibility of their production and are limiting factors in their utilization. It is not, therefore, easy to say which may be the most important from the commercial standpoint, except that the first consideration is fuel value.

The Relative Availabilities of the Coals

The coals of Chickaloon Creek, Carbon and Coal Creeks, and Kings Creek districts, being in bad condition for use commercially, and readily making a coke of good quality, are naturally best suited for the production of coke. But, like the Bering River coals, they might be briquetted to advantage.

The coals of the remaining districts being hard and firm, could be mined with the production of a moderate amount of small coal, thus permitting them to be placed on the market in competition with coals of other fields. Further, the conditions under which these coals occur are no more severe nor extreme than the conditions existing in other localities, where mining is carried on both extensively and economically.

Much depends upon means of transportation both by rail and by water, if these coals are to be placed on the market in competition with other coals. However, Alaska needs fuel for local consumption, and with the assurance that a reasonably cheap fuel can be obtained, the consumption will steadily increase to the vast benefit and growth of her various industries.

How Electricity May Make Mines Safer

H. H. Clark, electrical engineer of the Bureau of Mines, in his paper on "Safeguarding the Use of Electricity in Mines" read before the Pittsburgh meeting of the American Institute of Electrical Engineers which met Apr. 18 and 19, made the following remarks relative to the hope that mines will be safer when certain electrical developments become more general and are modified to meet the needs of the situation.

"There are, however, some ways in which it seems possible for electricity to decrease the risks now attendant upon mining work. There is one piece of electrical equipment which may almost be considered as a safety device and there are three others which, by substitution for more dangerous equipment and methods, promote the safety of underground workers.

"First may be mentioned the telephone, which is of use in spreading the news of trouble, in calling aid to the injured, and in assisting in mine-rescue work after disasters. Next may be mentioned portable-electric lamps for use of miners. The development of such lamps is just beginning in the United States. At the date of this writing no device has been fully developed and standardized for insuring absolute freedom from gas ignition by lamps of this sort.

There can be no doubt, however, that in the near future some such device will be developed and then the electric lamp will become safer than the locked safety lamp, although it has not the latter's ability to detect the presence of explosive gas. The statement that the electric lamp may be made safer than the safety lamp is based upon the fact that the parts of a safety lamp may be improperly arranged and ignition of gas occur as the result. The records show that this has happened on more than one occasion.

"The greatest benefits to be derived from the electric lamp as a safety device will be in those mines where the electric lamp supplants the open-flame lamp and thereby eliminates a real fire hazard.

"Next may be mentioned the firing of shots by electrical means. There can be no doubt that the firing of shots by properly designed and operated electrical shot-firing devices and equipment is safer than firing them by fuses or other devices which ignite explosives by means of sparks or flames.

Use of Storage-Battery Locomotives

"Finally, it may be suggested that electrical development may partially remove some of the greatest dangers now confronted, by displacing trolley locomotives for those actuated by storage batteries. Main-line haulage by such locomotives can hardly be advocated at present but the gathering of coal by these motors seems to be a feasible proposition, in many cases.

"The use of storage-battery locomotives would entirely do away with the trolley wire from a large part of the mine entries which are now provided with this dangerous equipment. In addition to the greater degree of safety assured, storage-battery locomotives would be more flexible to operate than are cable-reel motors. The load factor on the generating station would be materially improved, satisfactory voltage regulation of the distributing system could be obtained with less copper, and the expense of installing and maintaining trolley wire and rail bonding would be eliminated in the entries worked by storage-battery locomotives."

He also made the following observations regarding the premature ignition of shots:

"It is not the best practice to shoot electrically under conditions that require one side of the detonating circuit to be connected to the earth, because wherever grounded systems of distribution are used unexpected differences of potential exist in the earth in the vicinity of such circuits. If, therefore, one side of the detonator be purposely grounded, an accidental ground on the other side of the detonator may enable an igniting current to traverse the detonator. Premature ignitions have been reported which seemingly have been caused by the conditions just described."

Parallel Operation of Alternators

By C. A. Tupper*

SYNOPSIS—Conditions are here enumerated, which must be complied with before two alternators may be placed at work in parallel upon a common load.

With the rapidly increasing use of electric power for coal mining, its generation and distribution as alternating current has become general; hence the matter of operating various units of a large system or systems in parallel has assumed an importance, at many plants, formerly unknown.

This is particularly true where all of the alternators are not in the same power house, serving a single mine or group of mines, but are installed in stations located at different points in an extensive area and connected by a common net-work of transmission cables.

Such interconnected systems have heretofore been more common in Europe than in America; but within a few years that condition is likely to be reversed. A discussion of the various factors to be considered in operating such units may, therefore, be of value.

When alternating-current generators are run in parallel, there are certain conditions that must be met in order to secure satisfactory operation. These are:

(a) The machines must be in synchronism. That is, the frequency of alternation must be the same for each, and the points of maximum potential of the different units must be in phase.

(b) The voltages must be approximately equal.

(c) In order to secure proper division of the load under changes in load conditions the speed regulation of the prime movers must be alike.

(d) To prevent periodic cross-currents between machines the variations in angular velocity during different parts of the revolution of the prime movers must be kept within certain limits. In waterwheel or steam-turbine-driven units the angular velocity is uniform, but with reciprocating-engine-driven generators there may be trouble, due to periodic variations in angular velocity, if the engine flywheels are not sufficiently heavy.

With belted alternators it is important that the pulleys be proportioned so as to make the speeds of the generators such that they will give exactly the same frequency; if all the machines have the same number of poles their speeds must be exactly alike. If the pulleys are not of the proper size there will be excessive belt slippage or exchange of cross-currents between the various units, thus causing fluctuations in voltage.

With engine- or steam-turbine-driven alternators the speed can be varied by adjusting the governor, and there will be no trouble from cross-currents provided the angular velocity of the engines does not vary too much, and the engine governors act properly.

When alternators are running in parallel their output (actual power) depends on the amount of power supplied by their prime movers. For example, suppose two engine- or steam-turbine-driven machines are running in parallel and that each is taking half of the total load. When the load increases there is a tendency for the speed to drop slightly, and in order for the engine governors to act and admit more steam there must be such a speed decrease.

Now the two alternators must always run in synchronism, or at the same rate, assuming the number of poles to be alike, and if the drop in speed does not result in an equal increase in the steam admission of each engine, one alternator will be supplied with more power than the other and the load will become unequally divided.

Changing the field excitation of the lightly loaded machine will not remedy matters (as with direct-current generators where the machines do not have to run in synchronism and have independent speeds). The only effect of changing the field excitation is to make a wattless current circulate between the two alternators, the actual amount of power supplied by each remaining the same.

The only way to increase the steam admission is by adjusting the engine governor, and to secure equal division of load under all conditions, the change in speed for a given change in load must be alike for each engine. When two or more alternators are run in parallel it is advisable to have an indicating wattmeter on each machine, so that the actual load will be indicated.

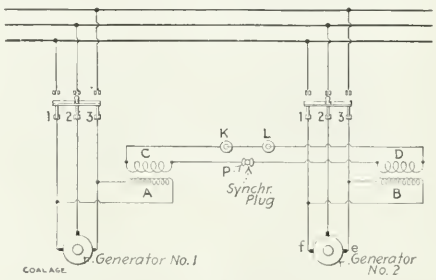

FIG. 1. DIAGRAM FOR SYNCHRONIZING TWO ALTERNATORS

In case wattmeters are not provided the load on each should be adjusted so that the sum of the currents as indicated by the machine ammeters will be a minimum for a given total current supplied to the line. If the sum of the machine currents is much in excess of the line current it shows that a wattless current is circulating between the machines.

TESTING FOR SYNCHRONIZING

The condition of synchronism is usually indicated either by incandescent lamps, which is the simplest method, or by a synchronism indicator or synchroscope, the latter now being used in most large installations. A synchroscope gives more accurate indications than lamps and has the additional advantages of showing whether the incoming machine is approaching or receding from phase and how much this variation actually is.

Fig. 1 is a diagram of the connection for synchronizing lamps. Two small transformers *A* and *B* have their primaries connected to the same phase of each generator. The secondaries *C* and *D* are connected in series through plug or switch *p*, to the lamps *K* and *L*. Assuming that cor-

*Milwaukee, Wis.

responding terminals of the primaries are connected to corresponding lines on each machine and that the two transformers are alike in every particular, corresponding secondary terminals will, at any given instant, have the same polarity when the two machines are in phase. When plug p is inserted, secondary terminals of opposite polarity are connected together; hence the two secondary voltages are in series and aid each other in forcing current through the lamps K and L, which are, therefore, bright at synchronism.

It may happen that the transformers are not wound exactly alike or that the connections have become confused; it is always advisable, therefore, to test them out to make sure that the lamps are light or dark at synchronism. To test the connections in Fig. 1, disconnect B from generator No. 2 and transfer the connections, without changing their relative position, to lines 1 and 3 of generator No. 1; A and B will then be connected to the same lines and if the lamps are bright, they will also

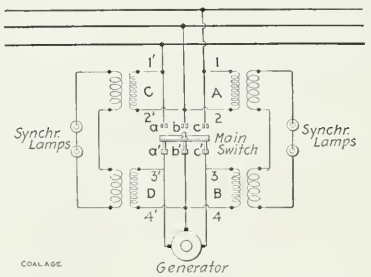

FIG. 2. TEST FOR PROPER CONNECTION TO BUSBARS

be bright at synchronism when B is connected to generator No. 2, as shown. If dark lamps are preferred, either the primary or secondary connections of one transformer must be reversed.

Another method of testing is to leave the transformer connections as they are and disconnect the main leads at e and f on generator No. 2. Both main generator switches are then closed, thus connecting both transformers A and B to generator No. 1. In synchronizing, bright lamps are to be preferred to dark.

When a polyphase alternator is first connected up it is highly important to see that all of its phases correspond with those of the busbars; if one phase only of a three-phase machine is correct, it does not follow that the other two are correct also. Two of the phases should be tested at the same time by using a pair of auxiliary transformers in addition to the regular synchronizing transformers A and B, Fig. 2. Transformer A is connected to the busbars and B to the generator. A second pair of transformers C and D is connected to one of the other phases, the connections in each case being such that the lamps are bright at synchronism.

The connections should be tested as described above to make sure that the polarity of the transformers is correct. With the main switch open and with the generator running at full voltage, both sets of synchronizing lamps should pulsate together. If they do not do so the generator leads are incorrectly connected to the machine terminals and should be interchanged so as to make the lamps pulsate together. After this test has been made, to insure that terminals a, b, c connected to the busbars correspond to a', b', c', connected to the generator, the temporary transformers C and D can be removed.

Bring each alternator and exciter up to speed and make sure that the oil rings are revolving freely. See that all resistance in both exciter- and alternator-field rheostats is out and that both field and main switches are open. Cut out resistance in exciter field and bring the exciter pressure up to normal. Close the field switch of the alternator and have all resistance in so that full voltage will not be generated in the windings.

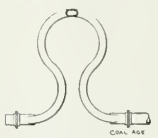
In case the machine is being started for the first time, allow it to run for an hour or two at low voltage and then gradually increase the voltage until it reaches normal; the load can then be thrown on. As the load increases it will be necessary to cut out some resistance in the field circuit in order that full voltage may be maintained, and if the load on the alternator is inductive a larger amount of resistance must be thus removed than with noninductive load.

On light loads comparatively small field excitation is required and it is advisable to run the exciter at rather low voltage and avoid wasting so much power in the field rheostat, provided the exciter voltage is not made low enough to render the operation unstable or cause sparking at the brushes, and that the exciter is not supplying current to other alternators.

A New Expansion Bend

The proper provision for expansion and contraction of steam pipelines is a subject which should receive the most careful attention in any piping layout. This is particularly true, however, when high pressure and superheat are to be dealt with. At 175 lb. pressure a superheat of 375 deg. F., causes an expansion of the pipe 2.2 times greater than is the case when saturated steam is used at the same pressure.

One of the most satisfactory expansion bends which has heretofore been produced is what is frequently termed "the lyre shape" which is equivalent to a double-offset U-bend combined with two 90° bends. The principal objection to this shape is, however, the great space which it requires, particularly in the larger sizes of pipe.



THE NEW BEND; NOTE SECTION

In order to obviate its great size and lessen the strain due to excessive expansion and contraction, a German firm has recently brought out a flat "lyre" shaped bend, the cross-section of which is somewhat elliptical in form and resembles, to a considerable extent, the ordinary Borden tube as used in the steam gage. The manufacturers of this new expansion bend claim that its compensating capacity is four times as great as that of the ordinary bend.

According to the U. S. Geological Survey, more recovery coke plants were constructed in 1909 and 1910 than at any time since 1903. In 1909, 649 such ovens were being built and 800 more were contracted for. Of the 649 ovens in process of construction in 1909, 99 were finished and working in 1910. The amount of coke produced by byproduct ovens in 1910 was 7,138,734 short tons, against 6,254,644 tons in 1909, an increase of 14.13 per cent. The output of byproduct coke ovens in 1910 was 17.12 per cent. of the total coke production. The average cost of coal used in the byproduct ovens in 1910, $2.18 per ton; the cost of that used in beehive ovens was $1.01.

The Car Hauls for a Modern Tipple

By F. R. Bogart*

SYNOPSIS—A system of six hauls which disintegrates a trip at the foot of the tipple incline, elevates one car at a time, five cars per minute, lowers the cars at the same speed and makes them up into trips of empties again.

In order to rapidly handle the output of the No. 2 colliery of the Provident Coal Co., at Fairpoint, Ohio, a system of chain car hauls was recently installed. At this plant the mine cars weigh 6000 lb. when loaded and 2000 lb. empty. These are hauled up an incline at the rate of five per minute. The incline is approximately 200 ft. long and the difference in elevation between the ground level and the tipple floor is about 47 ft. The angle of inclination is thus slightly over 14°.

There are three headings into the mine, one for the exit of loaded mine cars, and the other two for the entry of empties. The latter lie upon either side of the former, and the tipple floor is provided with four tracks.

The system consists of a feeder-haul 20 ft. long, center to center of shafts, for loaded cars at the foot of the incline; an up-haul for loaded cars 225 ft., center to center; two down-hauls for empties, each 205 ft., center to center; and two trip-maker hauls, each 20 ft., centers at the foot of the down-hauls.

A mine locomotive brings a trip of, say, 50 loaded cars, and drops them where the first car can be picked up by the hooks of the loaded car feeder. This feeder is controlled by an attendant who operates the friction clutch, starting or stopping the haul. Starting the haul, advances the trip till the second car in the train is engaged by a hook of the feeder. The chain is then stopped long enough to pull the coupling pin between the first and the second cars, whereupon it is restarted, the following car pushing the uncoupled one upon the foot of the up-haul, where it is caught by the haul hooks and drawn up the incline.

After passing over the tipple dumps, the empty cars are delivered by gravity from kickbacks to the head of the down-haul. Here they encounter a slight incline upward, just before they reach the top of which they are caught and held by one of a series of dogs until they are automatically picked up by the hooks of the down-hauls, which pull them up and over a hump, and then lower them down the incline, to be released automatically at the foot, ready for assembling into trips by the trip-maker haul.

The two trip-makers and the feeder-haul are driven from one lineshaft operated by a 35-hp. motor, and each can be operated independently of the others by friction clutches. Driven from the head of the feeder-haul, and arranged to be thrown in by a clutch, is installed a car puller, to bring up a trip of cars which may have been dropped by the locomotive some distance from the feeder.

The driving machinery of the trip-makers is arranged with a breaking-pin device to give way and protect the machinery in case a "wild" locomotive bumps into the trip while it is being pushed by these trip-makers. The two down-hauls and the up-haul are connected by shafting and gearing, and are operated by one 75-hp. motor.

Tipple and Incline up Which Cars Travel

Clutches are also employed to allow either of the down-hauls to be thrown out.

Upon one of the countershafts of the up-haul there is arranged an automatic band brake, which prevents the chain from running backward in case the current should be cut off while there are cars upon the incline.

The chain for the up-haul is composed of 18-in. pitch upset-end links with wrought-steel rigid hooks every 18 ft. upon four-roller trucks, and two-roller trucks placed midway between hooks to better support the chain. The rollers are flanged, 6 in. in diameter, and of the inclosed-oiling type.

The chains on the down-hauls are of 12-in. pitch with flat links, and with double-tumbling hooks of cast steel every 18 ft. These are also provided with four-roller trucks, and with two-roller trucks placed between. The rollers are identical with those above mentioned.

The chains for the feeders and trip-makers are 12-in. pitch links with cast-steel one-way tumbling hooks every 10 ft., provided with four-roller trucks. The rollers in this case are, however, 4 in. in diameter, but are inclosed oiling, similar to the others.

George A. Baton Co., of Pittsburgh, were the engineers for the tipple, which was erected by William B. Scaife & Sons' Co., of Pittsburgh. The car-hauls were designed and installed by the Link Belt Co., of Philadelphia.

*Engineer, Link-Belt Co., Philadelphia.

Guideless Mine Accumulator Locomotives

By J. Rechtenwald

SYNOPSIS—Description of a novel haulage system which dispenses with the services of the motorman. Comparatively low speed is used and provision is made for automatically stopping the motor when obstructions are encountered, and also for throwing the required switches. The method certainly has its limitations, and there appear to be many possibilities for failure, but there are undoubtedly numerous cases where it might be economically applied.

In the von der Heydt mine, some time ago, a hauling system with accumulator locomotives and without motormen, was installed. The construction of the locomotives in general is not greatly different from the usual accumulator locomotive, only the motorman is replaced by a device which, on meeting an obstacle, automatically disconnects the electric current, pulls the brakes electromagnetically and stops the train at once; the same device releases the brake, and switches on the current as soon as the obstacle is removed and the road again clear.

The construction and action of the arrangement is shown in Figs. 1 and 2. The feeler-like wooden frame, which protrudes over the fore part of the engine, is attached in sled-like fashion to the body of the locomotive so that when meeting an obstacle it can retreat until behind the bumper of the engine. When the wooden frame is thus pushed back, the electric current is disconnected by a switch and at the same time a short circuit is produced which sets a powerful brake on the wheels. This action occurs even if the loop is pushed back a little distance only.

The slow speed of one meter per second is used so a short application of the brake is sufficient to avoid any collision; it has been found that the motor, with a full load behind, stops readily after one meter of travel. By pushing back the protruding frame, a spring is pressed together which advances again as soon as the pressure is relieved; this at the same time switches on the current. The action of the spring is regulated by an oil buffer, so that the switching on of the motor occurs gradually; the disconnecting, however, occurs suddenly. The hoop, in its sled-like guide, is arranged so that it can be swung over the top of the battery to the other side of the

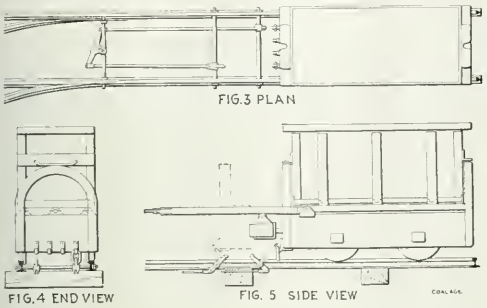
locomotive, and thus give it another direction of travel, if so desired.

The device is so sensitively constructed that a minimum pressure against the frame, for instance, running against a miner, brings the train to a sudden stop. Also if the obstacle should exert a pressure in a slanting direc-



Figs. 3 to 5. Automatic Switching Arrangement

tion, as for instance, when crossing switches or curves, the frame is easily pushed back by a parallel guide running in a chain and rolls. (See Fig. 1.) Thus any laborer, without special knowledge, can stop the locomotive immediately or give it another direction of travel. If it is to be stopped altogether, the frame has only to be pushed back and held in this position by a bolt.

The power is furnished by a side-circuit motor of two horsepower, which acts upon the axles through a double gear. (See Fig. 2.) Going down inclines this kind of motor keeps up the same number of revolutions and when miners are carried to their places or back to the foot of the shaft, a higher speed can be used; these advantages could not be obtained with a main-circuit motor.

5 in., without frame; breadth, 2 ft. 11 in.; height, 4 ft. These dimensions were selected so that the locomotive could be used wherever horses were working.

Switching Arrangement

The switches, which ordinarily have to be thrown by hand, are so arranged that the locomotive changes them automatically. The front end of the locomotive shows various hooks (see Fig. 4), on which rings are hung that engage levers, laying between the tracks which, in turn throw the switches; the different hooks are so arranged that they are exactly above the levers of the corresponding switches. Before starting the train, rings are placed on the front which will throw the switches for the track it desired the trip shall take. The switch tongues themselves are retained in the final position by springs, and when leaving the switch, are pushed into the right position by the wheels of the locomotive. The mine doors are opened in both directions, automatically by the locomotive itself, without the frame touching the door (see Fig. 6). At both sides of the door, next to the rail, are swinging posts, at bumper heights, and so fastened that when the door is closed they are directly across the rails. As soon as the bumper of the locomotive pushes the post sideways (see dotted line) the door is either pulled or pushed open by a rigid-lever transmission. After the train has passed and the door shuts itself.

There are also block stations, which prevents trains at the junction of two lines or at a crossing from running into each other. To stop one of the trains a post is fastened at the height of the frame; this is held by a blocking device with a rope and spring transmission. As soon as another train passes the switch, the post is pushed aside, and when it has left the switch, the blocking device is released, the frame of the locomotive then advancing and thus switching on the current. The various locomotives succeed each other at suitable distances, thus

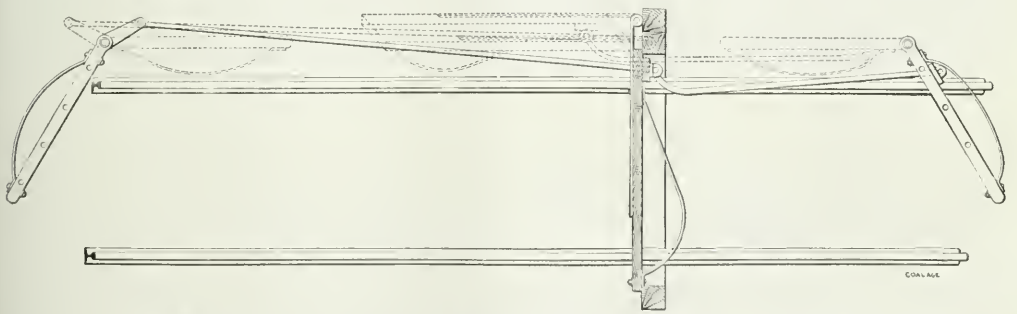


Fig. 6. Plan View, Showing Method of Operating Automatic Door

The batteries are charged by a current of 220 volts, which is developed outside the shaft. Each battery consists of 30 cells, of 2-volt discharge tension, with a capacity of 72-amp.-hr. and a radius of action of 10 km. The discharge tension of the battery is 60 volts and it is charged with a current of 30 amp. by connecting the battery to a plug with direct current. The time required for charging is three hours and the exchange of the batteries can be made by one man in two to three minutes. The weight of the locomotive, ready for use, is 2.5 gross tons. The measurements are as follows: Length, 8 ft.

furnishing a continual supply of coal. The locomotive following is always stopped by the last car of the leading train and advances automatically as soon as the latter releases the frame of the second locomotive. Each of the two locomotives, in eight-hour shifts, does about 65-ton-km. of work, with a current consumption of 0.167 kw.-hr. to 1 ton-kilometer.

The coal supply of Oklahoma is estimated to be ten billion tons. The state contains more than six million acres of coal-bearing land. Some of the land is estimated to be capable of yielding 7000 tons per acre.

What Dynamite Grade Markings Express

By F. H. Gunsolus*

SYNOPSIS—The grading of dynamite is actually based on its strength and not on its percentage of nitroglycerin. That chemical when absorbed by a body which does not aid explosion is not as powerful as when saturating bodies which are able to take part in the detonating action, such as wood pulp and nitrate of soda. Substances having much explosive force are sometimes added, guncotton for instance.

The meaning of the grade distinctions or "per cent. strength" mark on dynamite is somewhat of a puzzle to many consumers, and often a source of misunderstanding between manufacturer and customer.

Originally a 40 per cent. dynamite meant that the dynamite contained 40 per cent. of actual nitroglycerin by weight, but as modern dynamites do not always contain this proportion as marked, a short description of the modern practice in grading may be of interest. A slight knowledge of the history of the manufacture of high explosives may also help to explain the situation.

The Kiesel-Guhr Dynamite

The first dynamite manufactured by Alfred Nobel on a large scale was called "No. 1 dynamite" and consisted of 75 parts by weight of nitroglycerin and 25 parts of "kiesel-guhr," an inert infusorial earth, which is full of microscopic tubes and shells, and which has the property of absorbing three or four times its weight of nitroglycerin. This was truly a 75 per cent. nitroglycerin dynamite but it was not as strong as the 40 per cent. strength dynamites made today, which contain even less than 40 parts in a 100 by weight of actual nitroglycerin.

The kiesel-guhr acts only as an absorbent. It does not assist at all in the explosion and with it we can make only one grade of dynamite, that in which the kiesel-guhr holds nearly all the nitroglycerin it can absorb. If more nitroglycerin is added, it leaks from the dynamite to a dangerous extent, and if less than 75 per cent. is used the dynamite becomes insensitive, so much so that a mixture of 40 per cent. of nitroglycerin and 60 per cent. of kiesel-guhr cannot possibly be detonated at all. Advantage is taken of this property in the transportation of nitroglycerin for medicinal purposes. Kiesel-guhr is chemically inert. A pound of 75 per cent. kiesel-guhr dynamite will do just as much work and no more than 75/100 of a pound of pure nitroglycerin.

Active-Base Dynamites

The dynamites which are in use at present in the United States were originally known as "active-base" dynamites in contra-distinction to the kiesel-guhr dynamites which had an inert base.

At first to form active-base dynamites a crude gunpowder was substituted for the kiesel-guhr, but as the gunpowder was not a good absorbent, it was not possible to make a dynamite containing more than 30 per cent. or 40 per cent. of nitroglycerin; so a mixture of wood meal and nitrate of soda was used instead of the crude gunpowder. With these two ingredients, dynamites could be made with different proportions of absorbent to nitroglycerin, so that explosives containing as much as 75 per cent. or as little as 20 per cent. of nitroglycerin could be made, worked, packed and exploded.

A 40 per Cent. Wood Meal and Nitrate Dynamite Equal to a 75 per Cent. Kiesel-Guhr Dynamite

It was also found that with an active base like wood meal and nitrate of soda, a dynamite having only 40 per cent. nitroglycerin would develop as much power or more than a 75 per cent. kiesel-guhr dynamite. A reasonably definite proportion of wood meal to nitrate of soda existed at which an explosive was not so wet that it would leak nor yet so dry that it could not be "punched" into the paper shells.

The proportions of wood meal and nitrate were changed to accord with any change in percentage of nitroglycerin. More wood meal and less nitrate were used when the absorbent was to retain a large percentage of nitroglycerin. More nitrate and less wood meal or wood meal of less capacity for absorption, like fine-grained sawdust, were used when making a dynamite with a lower percentage of nitroglycerin.

Using these three ingredients with minute proportions of other nonexplosive substances required to stabilize the dynamite, a type of high explosive known as "straight dynamite" is made which when thoroughly incorporated out of well dried and pulverized ingredients, constitutes the standard of strength against which all other dynamites are graded.

Dynamite Containing Added Explosives

When other explosive substances are incorporated into dynamites they increase the power over the straight dynamite and it is then necessary to reduce the amount of nitroglycerin and otherwise modify the formula so that the new compound will develop the same power in actual work as the standard dynamite.

For instance, when guncotton is dissolved in nitroglycerin it makes a sticky jelly-like substance which when added to the wood meal and nitrate of soda makes an explosive much more powerful than one in which nitroglycerin alone is used.

If such an explosive were graded according to its actual content of nitroglycerin, it would be so much more powerful than the standard grade of dynamite that it would not be safe to use in work where the blasters were accustomed to using that standard grade, as it would break the material too fine and throw it too far and do much damage.

When other active ingredients in the absorbent were employed, it was found necessary to reduce the amount of nitroglycerin until the mixture developed the same strength as the straight dynamite nitroglycerin by which it was graded.

There are now many explosives in the market which contain no nitroglycerin at all, some of them being equal to a 40 per cent. straight nitroglycerin dynamite, and these are graded against the straight nitroglycerin dyna-

*Manager technical division E. I. Du Pont de Nemours Powder Co. Wilmington Del.

mite as described above. There are other powerful explosives widely used which contain only small amounts of nitroglycerin, sometimes from 5 per cent. to 10 per cent.—which, nevertheless, develop as much power, weight for weight, as 50 per cent. and 60 per cent. straight nitroglycerin dynamites. It is readily seen, therefore, that a customer should not feel that he has been injured when he finds that the dynamite he has been buying as 40 per cent. strength has actually less than 40 per cent. nitroglycerin in it.

Straight Dynamites Are Rapid in Action and Susceptible to Shock

While the straight nitroglycerin dynamites are still on the market, they alone actually contain the same percentage of nitroglycerin as the per cent. strength marked. In many ways they are distinctly inferior to later explosives containing less nitroglycerin, but having more of the other active ingredients in the absorbent. The straight nitroglycerins are too quick for much of the work to be performed and are much more sensitive to rough handling than explosives which have been developed more recently.

When a dynamite contains less nitroglycerin than the per cent. strength as marked on it, that difference is made up by other explosive substances so that a given weight of the dynamite is equal in strength, as developed in the ballistic pendulum and in active field trials, to a straight dynamite which contains that percentage of actual nitroglycerin.

Central-Station Power for Coal Mines

By C. W. Beers

SYNOPSIS—The author presents the coal-corporation view of central-station power for coal mines and declares himself in favor of its further introduction where a reasonable contract can be secured. This the central-station management opposes, not understanding the nature of mine demands, which are highly favorable for power generation. He regards 0.8c. per kilowatt-hour delivered at the substation a fair figure for 50 per cent. load factor. The power-plant officials decided that the average maximum colliery demand was half the rated power in kilowatts of all the connected consuming units, not including transformers, converters and motor-generator sets. Their bid was based on this consideration.

The purchase of central-station power by coal operators for use in and about the coal mines, appears paradoxical owing to the apparent cheapness of fuel at the mines, yet some companies have found it economical to do so, and up to the present time these companies do not regret making contracts for the purchase of power. One large coal company in the anthracite field has closed a contract with a large central station for a long term of years, and with considerable advantage to itself.

Inefficiency in the Boiler Room

A great source of loss in the present colliery steam plants today is in the boilers themselves. This is due to the fact that the firemen employed are not very intelligent and their wages are not particularly high. The result is that while fuel is comparatively cheap, little effort is made to use it economically; oftentimes the grates are ill adapted for the kind of fuel used and this is due to the fact that the fuel varies largely in quality from time to time. Draft arrangements are not always suitable, with the result that much energy goes up the stack. The boiler units are usually small in size, working at large overloads, and no arrangements are made to have them operate at their highest efficiency.

As far as the boiler losses are concerned they are subject to easy control, and one large operating company has made great strides in this direction by expending intelligent effort on the type of boiler used, the grates employed, and the quality of fuel burned.

Long steam lines poorly designed are responsible for much waste of steam. Leaks are seldom repaired, and, owing to exposed locations, the pipe covering is usually in bad condition.

From the above rough sketch of average conditions it is seen that large steam consumptions are invited, and it is a conservative statement to say that for every effective horsepower-hour used in and about the coal mines, 25 to 30 lb. (11.3 to 13.6 kg.) of fuel are burned under the boilers.

A Continual Rise in the Cost of Steam

During the last eight years, the average value of the fuel used under colliery boilers has increased in value from 35c. to 75c. per ton and it is still advancing.

Today, an ordinary boiler plant of 700 to 1000 hp. rated capacity has a steam cost of approximately 15c. per 1000 lb. (453.5 kg.) of steam generated. This figure drops to about 12c. per 1000 lb. in plants of 2000 to 3000 boiler horsepower capacity.

The correct design of a modern central-station plant for colliery operations is a rather difficult task, and it requires that the future of the mining operations be clearly forecast. This is an exceedingly difficult thing to do, and, as a result, the tendency is to curtail the initial expense as much as possible, owing to the uncertainty of future developments. Hence the plant is started on a more or less limited basis with the idea of expansion.

Variant Power Factor as Mine and Plant Grow

This is good practice, and the engineer, being eager to show good economy, installs apparatus that permits of a good load factor on the plant, and as a result shows low cost of power at the switchboard. As soon as the plant is loaded, additional apparatus must be installed. The station then will operate at a reduced load factor for some time, although there has been no reduction in the steaming expense; hence the cost per kilowatt-hour delivered to the switchboard has naturally increased.

This method produces a variation in the kilowatt-hour cost from time to time and may result in the ultimate installation of five or six machines in the plant. Idle-

Note—Paper presented at the Pittsburgh meeting of the American Institute of Electrical Engineers, Pittsburgh, Penn., Apr. 18, 1913.

time periods and idle hours during the working day require that some machines work at underload and this with full steam capacity on the boilers, hence the load factor naturally decreases, and as a result the average kilowatt-hour cost is fairly high. This condition must be so, since the boiler plant does not show a proportionate decrease in cost of steam as the load falls off. The continued acquisition of generating capacity along these lines ultimately results in a high cost per kilowatt installed.

The cost per kilowatt installed varies somewhat for each particular case and for a mining central station of two 500-kv.-a. turbo-generator units the cost per kilowatt installed was found to be $110.07. This included a 100-deg. superheater for each boiler unit (1200 boiler horsepower was divided into three 400-hp. units). Stokers were also included. The plant operation was based on a 50 per cent. load factor. The following is an estimated tabular statement of the fixed charges per kilowatt installed:

FIXED CHARGES PER KILOWATT

Item	Installation Cost per Kw.	Fixed Charges per Yr. per Kw. Installed
5 per cent. interest on station cost	110 07	5.50
10 per cent. depreciation and repairs on machinery	37.70	3.77
5 per cent. depreciation and repairs on switchboard	3.00	0.15
10 per cent. depreciation and repairs on light-arrester	0.30	0.03
10 per cent. depreciation and repairs on superheater	4.80	0.48
5 per cent. depreciation and repairs on buildings	6 00	0.30
10 per cent. depreciation and repairs on coal- and ash-handling devices	5.00	0.50
5 per cent. depreciation on boilers	42.00	2.10
Boiler repairs (800 hp. at $2.25 per year)		1.80
50 per cent. depreciation and repairs on condenser (mine water)	3.20	1.60
5 per cent. depreciation and repairs on steam piping	2 00	0.10
10 per cent. depreciation and repairs on feed-water heater	1.50	0.15
2 per cent. taxes and insurance on plant cost	110.07	2 20
Superintendence, etc.	....	0.32
Total		$19.00

On a basis of 50 per cent. load factor we would have the following operating cost per year per kilowatt:

OPERATING COST PER YEAR PER KILOWATT

Fuel at 75c. per ton	7.62
Boiler-room attendants	3.42
Power-house attendants	2 00
One general electrician, one-half time	0.75
Oil, waste, etc.	0.20
Water	2 12
	$16.11

From these figures it will be observed that there is a fixed charge of $19 per kilowatt installed, which is a constant, regardless of the load on the plant. On a basis of 50 per cent. load factor there is a yearly charge estimated at $16.11.

At this point in the argument it is well to consider these values. Under the item of fixed cost the values of depreciation and repairs may be considered high. This is not the case. It must be remembered that the plant is installed as a mining plant to suit mining conditions, and not a main central station in some city. The care exercised in preserving efficiency, etc., is in proportion to the intelligence of the help employed, hence the plant may be considered to depreciate rapidly for two reasons:

First, variations in the proposed life of the plant or additions may be required from time to time, with the result that present capacities may be hardly operated before the necessary additions are made, thus bringing about a condition of hard usage; second, obsolescence of equipment. The first reason naturally carries with it large repairs. For these reasons the above values, from which the fixed charge of $19 per kilowatt is obtained, are considered fair.

The operating costs for coal, water, labor, etc., are the real bones of contention, and at best, their estimate is simply a guess, and the nearer the load factor approaches unity the better the guess. It is at this really crucial point in the estimation of the kilowatt-hour cost, that many fail, simply because of the high value of the load factor assumed.

Load Either below or above Maximum Efficiency

The investigation of a mine load shows that on account of hoisting, locomotive, and other variable power service, the load naturally varies largely in a plant of the above rating, the variable load being such as to cause the generators to be temporarily overloaded many times during the day. Also, for many intervals in any 12-hr. period they are run at underloads, and neither condition tends toward the best economy, although the load factor based on the kilowatt-hours generated may be fairly high.

The result is that a large portion of the kilowatt-hours developed is on ascending parts of the water-rate curves of the prime movers, and, hence, we approach a condition of good load factor on a reduced steam economy. It is such conditions as these that cause the ordinary mine central station to differ from the regular city central station in which the load varies at uniform rates.

The Annual Load Factor

Another condition that tends to destroy the calculated load factor is the idle-day periods, and, when pumping must be taken care of, the absence of large quantities of water. It is estimated that 105 days per year are idle days, and naturally on these days the load factor is not nearly so good as on the regular working day, and particularly is this true if pumping is not required during a part of this time.

The fixed charge of $19 still keeps on working silently and so does a large portion of the $16.11, due to operating expenses. The only items of this charge that show any real decrease are the coal and water. Therefore, we see that while it is possible to estimate the average kilowatt cost per year at a total of $35 or $0.008 per kilowatt-hour on a basis of 50 per cent. load factor, there are conditions which are apt to change this figure considerably.

It will be observed in the original estimate of $110.07 per kilowatt installed that no reserve or emergency equipment has been included. If such had been the case, then the fixed charge of $19 would have to be considerably increased, with a resulting increase in the estimated kilowatt-hour cost.

A number of calculations on mine power plants up to and including 1500 kw. capacity resulted in a close agreement of all the figures, which may be expressed in concrete form as follows:

AVERAGE FIGURES ON POWER COSTS

Cost per kilowatt installed	$110.07
Fixed charges per kilowatt per year	19.00
Operating charges per kilowatt per year	16.11
Net cost per kilowatt-hour at switchboard	0.008
Load factor	50%

A careful study of these statements by the engineer will bring to mind the following questions: "Why must I be saddled with a fixed charge of $19 per kilowatt?" and "How can I improve the load factor within safe station limits and reduce the kilowatt-hour cost?"

Some years ago a large central station of 40,000 kw. ultimate capacity, located in a mining region, endeavored

to interest the company by which I am employed, in central-station power, but lack of understanding of mining conditions on the part of the central station always interfered.

Price 8 Mills per Kw.-Hr., 50 per Cent. Load Factor

Finally it became apparent if the power company could be induced to sell to the mining company at a rate not exceeding eight mills per kw.-hr. on a 50 per cent. load factor basis, that the proposition would be a fine solution to the above perplexing questions, and it was with this idea in view that the mining company ultimately took up the consideration of central-station power in earnest.

A close study of colliery conditions, such as the expected load factor, periods of high and light loads, peak loads, etc., indicated that if a complete understanding of conditions could be made clear to the power company a contract advantageous to all parties concerned would be considered.

Later a contract was executed to the satisfaction of all concerned in which the charge per kilowatt-hour was based on load factor only.

Before the contract was signed the following points were taken up and thoroughly discussed:

(1) On what basis current would be paid for. (2) Territory to be covered by the contract. (3) Location of meters for registering the power consumed. (4) Delivered voltage, power and point of delivery. (5) Maximum demand charges. (6) What apparatus should be considered as "connected" load and the methods of rating the same? (7) The included rating of apparatus used intermittently. (8) The method of determining load factor. (9) Pole-line charges—co-party lines. (10) Power factor. (11) Explanation of terms used. (12) What constitutes a substation.

The discussion of each of the above topics brought out the following arguments for their adoption, and at the same time illustrates the items which should be considered in any contract between a central station and a mine operator.

Power Cost Varied with Power Factor

(1) Current could be paid for, either on the "straight maximum demand basis plus cost per kilowatt-hour," or on a varying rate depending on the load factor. The latter plan was argued and adopted, because it is a simpler method of handling all charges. It eliminates errors due to wrong reading of graphic meters, and hence prevents argument as to the demand.

To the ordinary mind, it presents the idea of cheaper rates in a clearer manner than rates based on the demand system, as the only point to be observed is that the greater the load factor the less the rate; whereas the straight demand system has a tendency to curtail consumption, due to the fact that the demand power may at times be cumulative, and hence the operator may feel worried as he sees the increase on his demand chart, although his kilowatt-hours may not increase.

(2) The contract to be of benefit should be made to cover all territory that a private mining plant could ultimately cover in order that maximum results in load factor would be obtained.

Current Measured on Secondary Side of Transformers at Substation

(3) The preferred location for meters should be on the secondary side of transformers. This is not absolutely necessary if the central station installed the meters. In any event they should always be located in the customers' substation.

(4) In this case the power company agreed to deliver direct into the customer's substation, consequently it seemed fair and equitable to permit the power company to deliver the power and voltage from its nearest available lines. This particular power delivery should always be specified by letter for any particular substation; experience has proved this to be satisfactory.

If the customer was required to build his line into his own substation then he should have the privilege of determining his own voltage in order to suit his delivery requirements. This would eliminate the cost of probable transformers on the part of the customer in lieu of the investment required by the pole line.

Maximum Colliery Demand One-Half the Total "Connected" Load as Rated

(5) Under (1) it was decided to use a sliding rate per kilowatt-hour rather than a charge based on maximum demand. On what would the maximum demand be based? Certainly not on the momentary maximum starting loads of motors, as the starting peaks would scarcely be noticed on the load curve of a station of 40,000 kv.-a.; neither could a two- or three-minute peak be used on account of the difficulty of properly analyzing curves for such a time limit, as errors would naturally be introduced by the thickness of the line; neither could a five-minute peak be used, because this would tend to eliminate hoisting and this would be unfair to the central station, as much hoisting is done on a one-, two- or three-minute basis.

To settle this question the central power-plant officials visited many plants in the mining regions, and found from actual observation that the rating of the "connected" load was just about twice the average maximum demand that occurs on the plant. Experience proved this to be fairly close, hence for the term "maximum demand" a figure was used that was equal to one-half of the total "connected" load, rated in kilowatts.

(6) Since the basis of cost was load factor and since the "maximum demand" as outlined above is used in lieu of station capacity it is necessary to correctly define the "connected load."

This to consist of all direct power-consuming devices (no transformers, converters, motor-generator sets, etc.), and is equal to the sum of the nameplate ratings of all motors, or lamps, or heating devices, etc.

Exceptions. Direct-current hoists and direct-current locomotives to be rated on one hour nominal rated basis. Alternating-current hoists to be rated on their continuous basis, and where transformers are used for lighting only, then the full kilowatt rating of the transformers is used.

Reserve Equipment Reckoned as Part of "Connected Load" in Month Used

(7) Suppose reserve equipment should be installed, such as pumps, to give protection in time of floods. This equipment would be in service only a few weeks total time per year. It was considered equitable to include this apparatus only for the month during which it was used. It is reasonable to state that in a private mining plant emergency conditions are given preference, and, there-

fore, other apparatus would not be worked; for this reason it was considered that such reserve equipment should not be carried from month to month as connected load.

(8) The method of determining load factors was intimated in (6) and is as follows: Let the total manufacturers' nameplate rating of apparatus used during the month equal 500 kw. and let the total kilowatt-hours used during the month of 30 days equal 72,000; then the maximum demand is equal to 500 divided by 2, equals 250, and the average demand is equal to 72,000 divided by 30 days times 24, equals 100; therefore, 100 divided by 250 equals 40 per cent., which is the load factor. Reference to the cost curve shows the rate to be approximately $0.009; therefore, the charge for that particular month would be 72,000 kw.-hr. times $0.009 equals $648.

Power Company Builds Transmission Lines

(9) If the coal company should require the power company to build a line expressly to reach a substation, then it seems fair and equitable that the power company should be paid a rate that will represent the total investment charge on the line. However, if the coal company uses power of a value in excess of this investment charge, then no pole-line cost shall be included in the monthly bill, but if no power is used then the full investment charge is to be paid. This service was fixed at 15 per cent. of the pole-line cost.

Exceptions. If the power company should place extra customers on this line, then this 15 per cent. line charge should be prorated among the various customers in proportion to their respective "demands."

Inadvisable To Use Induction Motors

(10) At all times it is to the interest of the coal company to have the proper voltage. The installation of considerable amounts of induction machinery tends to destroy this feature, and may cause trouble to pumps, fans and hoists, hence to protect itself it is good policy on the part of the coal company to use power-factor correcting devices judiciously.

(11) In order that no errors in calculations in load factors, etc., could arise through ignorance, the power company considered it advisable to make use of definitions that clearly explain the following terms: Maximum demand. Manufacturers' nameplate rating. Load factor. Day.

(12) To suitably define the word "substation" it was determined that all operations which could be conveniently grouped under one colliery lease should be known as a substation.

Day Load Occurs Opportunely; Night Load Is Constant

From the above discussion of the elements of a power contract it is seen how essential it is that the central-station management should be made to understand colliery operations thoroughly and the conditions relating to connected loads, and in addition they should be made to appreciate the fact that the day load is highly desirable as it reduces their station losses and increases their load factor to a very high degree, and when the night loads occur that they are usually of the constant-duty kind.

Failures on the part of others to obtain satisfactory rates could, no doubt, be charged directly to this lack of knowledge on the part of the central station which is due to the failure of the mining company to coöperate properly with the central-station management.

The company with which I am connected has been operating on central-station power for about one year, and up to the present we have about 1000 kw. connected load consisting of fans, pumps, hoists, locomotives, and heaters, and provisions are being made to increase this amount in the near future by about 2500 kw. Plans are now under way to remove the present boiler plant from one of our collieries and operate entirely by power from the central station.

Observed Advantages

Since operating on central-station power, a number of features have presented themselves that make it appear a satisfactory arrangement. They are as follows:

1. Our average kilowatt cost is lower than the estimated kilowatt charges in the ratio of about 7½ to 8, and this kilowatt charge is based on delivery at our substation meters, and not at the main power-house switchboard as per the original data.

2. The company is more ready to consider additions to its power equipment, due to the fact that main power-plant costs have been entirely eliminated and do not appear in the estimate.

3. There is always a "readiness to serve" on the part of the central station and this is seldom true of the mining power plant.

4. There is absolutely no worry due to power-plant operation.

5. In case of holidays, etc., the monthly rate per kilowatt-hour will only slightly increase, which would not be the case in those plants operated by the mining company, for, in such plants, labor and fuel decrease but little.

6. As electric operations are increased, less demands are made on the colliery boiler plant with the result that coal will be sent to a ready market which otherwise would be burned under the boilers, and ultimately this will be to small amount of fuel.

7. The use of central-station power affords a remarkably cheap method of reaching isolated banks, and isolated pumping problems. Operations, such as small washeries are more or less temporary in character, and can be advantageously worked without causing the distress that might be occasioned when operated from a mine central station.

8. The service is reliable. Our service up to the present time does not total more than 15 min. delay, due to failure of supply, and these failures were directly due to lightning.

9. The effect of efficiency is not particularly noticeable, hence air gaps can be made larger, which is highly desirable in mining apparatus, as it reduces the danger of breakdown.

In the above discussion I have presented the case of mine central station vs. public-service corporation supply as it appears to me. My experience has been somewhat limited, but the longer the service is continued the more I am convinced that the purchase of power from public-service corporations offers advantages that should not be overlooked by mining corporations.

The Pittsburgh Meeting of the A. I. of E. E.

By R. Dawson Hall

SYNOPSIS—Many papers of pertinent interest to the coal industry were presented at this meeting. Some of the more important of these were published in our issues of this week and last week. This article is a complete summary of the discussion of these different articles.

The American Institute of Electrical Engineers met Apr. 18, in the English Room of the Fort Pitt Hotel in Pittsburgh, at 10 a. m., with about 150 members and guests present.

R. D Mershon, the president, made the opening address and called the attention of those present to the formation of a new technical committee on the Use of Electricity in Mines, presided over by George R. Wood of the Arcade Building, Philadelphia, Penn.

Banquet of the A. I. of E. E., Held at the Fort Pitt Hotel, Pittsburgh, Penn., on the Evening of Apr. 18

To speed up the presentation of papers the addresses of H. C. Eddy entitled "Purchased Power in Coal Mines," published in our last issue, and that of C. W. Beers, published in the present issue on "Central Station Power for Coal Mines," were read consecutively without intermediate discussion. Whatever the nature of the presentation, the parties most ready to discuss the papers were those in sympathy with the public central station. There was a disposition to regard the uptodate central station plants of the mine operators as quite small.

Thus one speaker said that the usual needs of a colliery were from 100 to 300 hp.; that as the coal used was worth $1 a ton and the load factor only about 20 per cent., he thought Mr. Beers had been too conservative in stating his case because the average mine purchasing power was expending not 8 mills per kilowatt-hour but as much as 2c. This is very true. Such small plants certainly do well to buy such power where an 8-mill rate is available.

Is an 8-Mill Rate Reasonable?

The speaker brought Mr. Eddy to his feet and he stated in reply that his company was willing to sell power for 8 mills per kilowatt-hour under reasonable conditions and Mr. Beers remarked that his company was purchasing much of its power at 5.3 mills per kilowatt-hour.

Mr. Eddy declared that many power companies would readily sell power to coal companies at less than the average year round cost at the switchboard so as to reduce the dead losses of the off-peak period. The chairman stated that most of the mines demanded today at least 300 kw. and that there were 12 or 15 alternating-current central-station plants in the field of which Mr. Beers spoke. One speaker stated there were 200 companies already using central-station power.

Shall the Coal Operator Buy or Sell Power?

Obviously if central-station power were furnished by the coal operator with up-to-date equipment and if the plant were located at an ideal spot for domestic distribution, he should be able to make as much profit in entering the business as any one. There is nothing of a magical nature in the manufacture of power, that he could not combine this with the production of coal. Every argument in favor of the central-station supplying power to the operator is of equal force and value in favor of the coal producer supplying the power consumer with electric current.

It is a certainty that the average operator today disregards the ratio of power actually used to power on the rate-plate of his apparatus; in his estimate he coolly divides the rating of his equipment in kilowatts into his daily expense, divides this by his working hours and thinks he is getting his true kilowatt-hour cost. But as

he is not using so much power for any length of time as the rate plates of his machinery indicates, he should realize that the figure he places as the cost of his hourly requirements is low. He must realize that because his generators are rated at 500 kw. he is not necessarily using that amount of power every moment of the day.

Safety in Mines

The next paper read was that by H. H. Clarke on "Safeguarding the Use of Electricity in Mines." The most interesting remarks in this paper are not for immediate publication as the institute withholds it till it can be entered in the proceedings. The greater part of the paper was of a character hardly new, (except in the manner of expression) to those who have followed the bulletins of the bureau and modern safety literature. It was designed mainly for electrical engineers whose experience was not so definitely subterranean.

Mr. Clark gave an interesting description of an explosion caused by the ignition of a canister, containing 5 lb. of powder. The explosion seriously burned several men who were in a mine car seven cars removed from a mine locomotive.

In the discussion attention was called to the dangers and lack of economy in light equipment. The use of much sand to obtain adhesion made accidents likely from the imperfect grounding of the motor, increased the resistance of the cars to traction and reduced the available voltage for the propulsion of the motor.

Mr. Clark instanced a case where three shots were connected in series to be fired by attachment to the trolley wire. The miner withdrew to fire them by electricity. He had barely left the room when one went off. He reconnected the other shots and without passing a current through the leads, another explosion took place almost as soon as his back was turned. An engineer present recalled a case in West Virginia where a miner tried to fire a shot with a battery but failed. He went back on the shot and was met by the blast which was exploded by some unknown means.

Mr. Clark did not believe that induction could be the cause of these premature explosions. He explained that the sensitiveness of detonators varied, and consequently one would be fired before the other and break the connection. He could possibly have reasonably added that the resistance might vary and the igniting effect differ.

The Portable Electric Mine Lamp

And here may be mentioned another matter which further exemplifies the injustice done electricity. Mr. Clark declared probably without ulterior meaning, that the electric lamp should be perfectly safe, because it could ultimately be made 100 per cent. efficient. We do not demand this ideal of its predecessor, the oil safety lamps; why demand it therefore of the new light unless indeed 100 per cent. efficiency is now to be considered achievable?

The British government has approved two lamps, one oil and one using electricity. The first is for general use and the second is only for the use in rescue work. The electric lamp has adaquate protection and if I mistake not is the safest but the British Home Office does not regard it with as much favor. This is largely due to prejudice.

The Bureau of Mines officials have always contended that no lamp burning oil gave a perfect assurance of safety and have regretted that the word "safety" was ever appended to the oil lamp, while a better word like "permissible" was already in the dictionaries.

When the gauze of a lamp is broken or dirty, the glass fractured or improperly sealed and the air is traveling rapidly and is explosive, when extremely gaseous atmospheres are encountered or when the lamp is held out of the perpendicular, the oil safety lamp is not reliable. Hence, when we show that a blow which breaks the bulb without immediately severing the filament, will cause a minature electric lamp to ignite gas, especially if the battery is overcharged, we do not show concurrently that the lamp is as unsafe as a safety lamp burning oil, provided the risk of breakage of the bulb and of the oil lamp glasses are equal. There are also many other ways beside breakage, whereby an oil safety lamp can explode gas, and in which it shows itself to be undesirable.

When an electric bulb is further strengthened by a heavy glass cover and arranged to go out as soon as the glass is broken, it becomes much more reliable than the oil safety lamp, however well shrouded by gauzes and glasses the latter may be. Let us remember that a suddenly exposed tungsten filament of one candlepower "frequently" ignites gas and one of a half a candlepower *may* fire it, but is "unlikely" so to do.*

The Prone Method of Resuscitation

Dr. C. A. Lauffer gave a demonstration of the prone or Shaffer method of resuscitation, and he remarked that the importance of such methods for aid in emergencies will never cease till oxygen resuscitating apparatus can be rolled up and snugly packed away in a vest pocket. There will always be accidents where pulmotors will not be immediately available. Doctor Lauffer has instructed 2000 men in the prone method and he cited the fact that the system of resuscitation had the indorsement of the National Electric Light Association. In this method, the unconscious person is rolled over till his face is downward. His head is then turned to one side, so that his mouth does not lie in the dirt or in such a manner as to prohibit breathing; the head must, however, be given a sufficiently downward inclination, so that the tongue falls naturally forward, giving freedom for respiration as soon as that function is restored. Water will naturally fall out of the victim's mouth, thus aiding in the clearing of the air passages. The arms of the patient should either be spread out or placed above his head.

Location and Duration of Shaffer Compression—The attendant then preferably straddles the patient, dropping down onto his knees. He grasps the victim with his hands, placing one on each side of the patient over the eleventh or twelfth rib. The location of this hold is all-important; made too high or too low, no good result can be obtained. Perhaps the place where the pressure should be imposed is better defined as about 6 in. above the upper line of the victim's trousers, though Doctor Lauffer is not responsible for that statement.

A gentle but firm pressure is placed on these parts of the man's body for 3 sec. The time is important and should be regulated, either by a watch, by counting three or by the attendant judging by the working or his own breathing. Rapid breathing is a strain on the normal

*The words in quotation marks are from Mr. Clark's recent report on "Ignition of Mine Gases by the Filaments of Incandescent Lamps," page 30.

human being and cannot long be sustained. It is likewise impossible to induce the frequency of respiration of a panting victim, who by drowning or shock has an even smaller ability to breathe than a normal human.

How Much Force Should Be Used

The pressure should be imposed and removed every 3 sec. till the patient recovers or is adjudged utterly beyond hope of recovery. The number of compressions and dilations thus secured should each total 12 per minute. The pumping action induced tends to discharge water from the air passages and thus aid in keeping those channels cleared for respiration.

The attendant can use his weight to effect the required action, so that a strong man is not needed, nor does it demand much energy. Unless the one injured was affected with cancer or tuberculosis before asphyxiation, there is no risk of injuring his ribs by excessive pressure. But such "living museums of pathologic ills" are not usually found among miners or linemen. Continue to press harder till you feel the ribs give way under your hands. Some victims resist the pressure unconsciously and sufficient force must be applied.

Stimulants—Doctor Lauffer did not advocate the putting of hypodermic syringes in the hands of linemen for use in cases of suspended respiration. Aromatic spirits of ammonia, applied to the nose, are helpful. So also is domestic ammonia, if the other cannot be obtained, but as the strength varies with the honesty of the manufacturer, and its age, it is well for the attendant to first try it himself and see how much it has been diluted by solution and evaporation.

As for heart stimulants, atropine is the best with strychnine the second favorite; either one or both can be given, but care must be exercised, as heart stimulation can be overdone. Digitalin, cactin and camphor in oil are all good stimulants, but present greater possibilities for harm than help if administered by amateurs.

How Long to Persevere—Doctor Lauffer stated that his students had restored six men who were injured by electrification, drowning and other forms of asphyxiation. In reply to J. S. Jenks, who remarked that he had seen men brought back to life after 1¾ hr., Doctor Lauffer stated that results had been obtained after as much as 2¾ hr. of work, but that most men revived after 20 min. One man of 57 years of age, who fell 9 ft. onto a concrete pavement, came around in one hour, sufficiently to cause him to vomit. Yet, even with the aid of a stethoscope, his breathing could not be detected when resuscitation was commenced.

Doctor Lauffer's remarks ended the morning session and the meeting, after a short recess, reassembled nominally at 2 p.m., but actually much later.

Variable-Speed Mine Fans

F. B. Crosby then read the most severely technical paper of all those presented, entitled "Alternating-Current Motors for the Economic Operation of Mine Fans." The discussion took two divergent paths: Whether Mr. Crosby's system covered all and the most desirable forms of speed-variation provisions, and whether, after all, the operator was wise in demanding variable speeds or at least whether a choice of two would not suffice for ordinary operating conditions.

Mr. Beers objected that the paper was restricted in application to large fans. It did not meet the needs of the anthracite region where the fan used is rarely more than 100 hp. and sometimes only 50. He regarded constant speed as highly desirable for regulation, but a variable speed involved, in his opinion, a variable pressure and excessive water gages were undesirable, because they are so uneconomical. He preferred to let the fan run at any even number of revolutions per minute and make up for the increased length of the headings to be driven, by increased cross-section or by additional splits. He regarded the simplicity of the squirrel-cage motor as a great element in its favor and urged its continued use in mine ventilation.

Another speaker stated that many other methods of speed regulation were available, some of which are more simple than that Mr. Crosby had outlined. All evidence to the contrary, he said that the Americans always demanded heavier machines than the foreigners. I had always supposed that all foreign machinery was proof against fire, flood, earthquake and the suffragettes, but there are apparently people of a different opinion. The foreign apparatus described was not only light, but complicated and would require expert supervision, such as was given machinery in Germany.

A speaker who appeared to have a most complete knowledge of German conditions, countered with the statement that variable-speed fan motors were being run in Germany by superannuated miners and not by trained men. Some of the stations were kept locked and were tended by a man only once a day. The German experts and operators regarded the regulating set as a great advantage, since it saved so much power, that the purchase price of the apparatus was soon returned in reduced operating costs.

Is a Variable-Speed Motor Wanted?

One speaker advocated either a two-speed motor or a variation in speed by changing pulleys. He pointed out that the variability needed was not diurnal or monthly or even yearly. There came a time when the initial speed failed to meet the requirements of the enlarged mine and then a change in pulley ratios could be made without much trouble. The "delay" could not be called "annoying" or the "method" a "make-shift," since the change had only to be made once. A belt was necessary in any event as the motor and fan could not be run at one and the same speed.

As Mr. Wood explained, the need for a variable-speed motor is more marked with a new mine than an old one, and he did not see why, when full speed was needed, the regulating set with its complications could not be entirely discarded.

But the advocates of variable speed, found a supporter who believed in a reduction of speed at night, because less air was needed when few men were in the mine. That is true, though where much gas is generated, practical men in this country are not much interested in speed reduction, though it is considered important in Germany. Strange to say, no one instanced the difference in barometric pressure as a reason for the use of variable-speed motors. This speaker further advocated arranging for a belt reduction to make up the difference between the requirements of a new and old mine; also a two-speed system to make the change in revolution from the day air current to the lesser night ventilation.

H. L. Beach had his own solution. He purchased two squirrel-cage motors made by the same firm and having exactly the same characteristics. One he installed on temporary work, and one was set up for the driving of the fan. So far the increase of speed needed to take care of the extension of the workings has been obtained by a change in the pulley ratio, but the time is arriving when the second motor will be needed and it will be used to assist in driving the fan.

Mr. Crosby declared that in his paper he did not intend to discuss ventilation. The problem of variable speed was given to him for solution and his paper was a reply to the question, "how to vary," and not to the one of, "why vary."

Low-Load Factors

J. S. Jenks then read his paper on "Central-Station Power for Mines," prefacing it with a few remarks on the impossibility of fixing (without consideration of local conditions), the proper number of mills per kilowatt-hour which the consumer should pay to the public central station. He made the statement that the load factor was often as low as 20 per cent. and might even run as low as 6 per cent. In an average of over 200 installations, it had fallen under 40 per cent. He did not, however, define "load factor."

H. M. Warren then read the paper, of which he and A. S. Biesecker were joint authors, entitled "Characteristics of Substation Loads at the Anthracite Collieries of the Lackawanna R.R. Co." The discussion turned: (1) On his definition of "load factor," which expression he chose to use to express the ratio of the average load to the rated connected loads; (2) on the fact that his "one- and five-minute peaks were measured as block peaks," and did not give the integrated kilowatts.

In the discussion there was no lack of speakers and everyone seemed to have his own way of calculating load factor, some figuring in four or more ways, according to the classification of the customer. Not one adhered to the definition which was placed upon the word for the sole purposes of the paper. Nor did the more general version of load factor meet with approval, viz., ratio of average load on the station to the rating of its included machinery.

Mills per Ton Mined or Mills per Kilowatt-Hour

The definitions given by the public central-station experts varied so much that it was no wonder Mr. Wood declared that the operator would hesitate to commit himself to a bargain with any of them except on the basis of so many mills per ton of coal mined.

Some compared the minute peak with the average monthly demand. Some took the 5-min. or 15-min. or 30-min. or the 1-hr. peak and found its relation to the average power used in determining the load factor. Again it was said that all the peaks should be integrated and further some thought that a single peak towering above all others should not be given such a prominence in figuring, so that they took the three highest peaks in the year and divided by 3 instead of a single isolated peak.

Induction vs. Synchronous Motors

The question of the induction and synchronous motors was then brought up and one speaker declared that the current supplied was the crux of the whole question. When induction motors started there was a watt-less current, and therefore even if pure current considerations did not enter into the question, the load-factor should, in any event, have a bearing on the price paid for power.

❋

The Explosion at Finleyville

Shortly after 1 o'clock, on the afternoon of Wednesday, Apr. 23, the most disastrous explosion that has happened in this country for more than a year, occurred at the Cincinnati Mine of the Monongahela River Consolidated Coal & Coke Co. Present indications show that about 100 men have been killed.

This mine is located near the Town of Monongahela, about 15 miles in a straight line south of Pittsburgh. It is one of the oldest mines in the Monongahela River Valley. The Monongahela River Consolidated Coal & Coke Co. is a subsidiary of the Pittsburg Coal Co., the latter owning practically all of the preferred and 94 per cent. of the common stock of the former. The Monongahela Co. has been for the most part independently conducted, although a portion of the operating staffs of both companies is the same for economic reasons.

The mine is a drift operation and has three principal openings. Having been in operation for such a long period of time, the workings are quite extensive. It has evidently been considered dangerous from a dust and gas standpoint, reference being found in the Pennsylvania Mine Inspector's report for 1909, where the dust was being laid by a water wagon. In later reports of the Pennsylvania inspectors the mine is also rated as gaseous.

It is ventilated by an electrically driven Capell fan, which in 1911 was furnishing 129,000 cu.ft. of air per minute, at a developed water gage of 3 in., the fan running at 157 r.p.m. The inspector's report for 1910 shows that the air was divided into twelve splits, but this was reduced to eight in 1911, a portion of the mine evidently having been closed off during the intervening period.

The ventilation in the mine, according to the Pennsylvania Mine Inspector's report for 1911, was considered good in some portions and fair in others. The report further states that the defects were not due to lack of adequate power, or the most advantageous arrangement of openings and airways, but rather to a lack of attention to details and over-splitting the air. It appears that brick and concrete stoppings were freely used, there having been some 70 installed during the year 1911, together with three brick overcasts. The slope at the second opening was enlarged at this same time, a 10-ton locomotive put in service, and a Morgan-Gardner longwall electric mining machine installed.

Up to the present moment, the information available as regards the cause of the explosion is meager and entirely unreliable. It was, however, evidently of great force, press reports stating that windows in buildings several hundred feet from the mine mouth were shattered and a 15-ton locomotive completely turned over. The fan house and fan were also seriously damaged, and the ventilation of the mine badly crippled. It is evident, however, that the explosion was not general throughout the entire mine, as some 70 men made their escape. From the information now at hand, most of the fatalities have been caused by afterdamp rather than by the force of the explosion itself. A detailed report will be published in Coal Age next week.

EDITORIALS

The Prime Need of the Workingman

The average workman does not believe that the greatest of his personal needs is efficiency. The attainment of that quality, he thinks, is a pretty problem for his employer. He admits that there may be something dishonest about loafing but it is a vice which concerns only the corporation which employs him.

The social condition will never be bettered measurably till the operative, miner or mechanic, learns that he is engaged with others in supplying the world with what it needs. If he or his fellows in other industries produce but little, the world receives a smaller proportion of its wants and, as he is part of the world, he himself suffers.

Efficiency is the humbler worker's problem; if two blades be induced to grow where but one grew before, the second blade on the stalk, from its root almost to its very tip, will fall to him. We admit he is concerned in the relative distribution of the awards of labor but he is even more interested in the bulk of that prize of which the workers as a whole get by far the larger share.

The waste of labor and material is a moral question and it is an appropriate consideration for us all. The operator who fills his mine with men, in excess of his power to supply them with cars is depriving those men of their due opportunity to make money and is withdrawing from the world a certain amount of valuable labor. The man who neglects to put his mine in such shape that work can be performed with minimum effort is wasting the limited labor of the world's markets.

On the other hand, the miner who opposes improvements in production, mining machinery and mechanical devices is endeavoring to constrict the world's output which output is destined ultimately to find its way in part into his own home.

We read of the "class consciousness of the working man" and of the "solidarity of the laboring classes." Has the workman's social consciousness and his unionism done him much good if he has not learned that the main duty of the consuming worker to the working consumer is to work as efficiently as he possibly can.

Adequate Boiler Foundations

The matter of proper and adequate boiler foundations is one which is not infrequently neglected around coal mines. This is, generally speaking, not a wilful oversight but arises from ignorance.

In laying out and building boiler foundations, they should be made sufficiently deep in the ground to strike good, solid, natural earth, and not be laid upon any filling. A layer of concrete at least 8 in. thick should be placed under the entire boiler and setting, and not merely under the side walls.

Above this layer of concrete, and up to the floor line, the foundations for the boiler may be built up of either concrete or hard brick laid in cement mortar, care should be taken, however, to make the top of this foundation, or the points upon which the boiler supports rest, perfectly level.

If proper precautions are not thus taken to have the boiler set firm and true, it is almost certain, sooner or later, to settle at one or more points, thus bringing undue strains upon the pipelines, which are connected to the steam nozzle. These in course of time may cause rupture of the steam pipes with attendant danger and possible loss of life, to say nothing of the loss in time and the inconvenience required in making repairs.

The Purchase of Power

At the vast majority of collieries, or, for that matter, in most coal-mining regions, there is one and only one source of power, and that is coal.

There are some regions, however, which are situated within the reach of transmission lines from water-power developments. There are also many power companies, and their numbers are constantly increasing, that are generating current in central power plants, transmitting it at high voltage, and selling same to the various mining companies within reach of their transmission lines.

The question of buying power from some outside company, or generating it at the mining plant, hinges upon the difference between the cost of the power as supplied and the value of the coal which would be used in generating an equal amount. Where the rate charged per kilowatt-hour is high, and the coal which may be burned at the colliery in making steam is of a low grade, possessing but a small market value, the choice would naturally go against the central power company. If, on the other hand, the outside company can furnish power at a moderate or low rate, and the output of the mine possesses a good market value, no sensible mine operator will insist upon manufacturing his own current.

Concrete Underground

The employment of concrete or reinforced concrete underground is on the increase. It has not yet, however, in this country, at least, assumed such an importance as to be a serious competitor of wood.

Although utilized to a considerable degree for the building of stoppings and overcasts, concrete in mines is not used to the extent that engineers who work only above ground might anticipate, for, although almost ideal for supporting tender roofs on haulage roads, the necessary centering and the supports sustaining the same, for a considerable period of time, necessarily block the haulageway upon which they are placed. In many instances, this fact alone precludes the employment of concrete underground.

The many and varied methods of using wood have been so successful, that operators in general are loath to adopt any substitute, the utility and adaptability of which have

not been thoroughly proved. To the actual miner, the use of timber has become almost second nature and he distrusts any change introducing marked variations in his daily routine as being either useless or unnecessary.

It is possible that, although perhaps concrete may never be a strong rival of timber for room props and similar purposes, it may become a serious competitor of steel timbering on road and haulageways, where it is desirable to make the roof support of a permanent or semi-permanent nature. Reinforced-concrete posts and beams either made separately or cast *en bloc,* possess all the advantages of the steel timbering and require no painting or other protection from dampness.

The West Virginia Strike

Governor Hatfield, of West Virginia, will have performed a great service to the coal industry in general, and to the State of West Virginia in particular, if he succeeds in settling the bitter dispute between the operators and miners of his commonwealth. Industrial history affords no more prolonged, cruel fight than has been carried on during the last year in the southern coal fields of West Virginia.

Both factions in the controversy have been virulent in their campaign; both sides have been partly wrong and partly right. Many of the operators interested in this particular field have failed to keep pace with the advances in commercial industrialism. They have wielded their power in a thoughtless, selfish manner, often extracting the maximum of service and forcing the minimum reward.

For years a few of these same operators have held the whip hand and have successfully fought down every rebellion on the part of their employees. The country affected is not easily accessible and has practically no large towns so that physical conditions favor the establishment of company stores, which latter have been frequently operated in a manner unfair to the men. Time was not so far back when a miner who was not a good spender at the company's store was discharged, and his place filled by someone less careful in the matter of handling his hard-earned wages.

Such actions as this on the part of a few coal companies aggravated the acute labor situation of the field to the breaking point, and the more humane operators of the district have paid a fearful price for the shortsighted policy of their less wise breathren.

If in future contests between labor and capital in the coal industry the miners become masters of the situation and base their subsequent conduct on the idea that might should prevail rather than right or reason, some operators will have to concede that they themselves were the exponents of such a creed, and that the men are only following the example laid down by their worthy teachers. No man should whimper at having to take some of the same medicine he has forced down the throats of others.

A great many miners are mean and selfish, seeking to force concessions from their employers without regard to justice or legal procedure. Contracts have been violated knowingly by the union officials and wage agreements have, and are, today being disregarded with impunity. However, this unfortunate condition does not furnish a justification for employers to condemn labor organizations as a whole, any more than moral laxity on the part of one individual is sufficient cause for a general condemnation of the whole human race.

Every movement, whether industrial or social, if it is to succeed, must be built on a foundation of truth and honesty. The day is near when crooked labor leaders will be as popular with their men as a cholera patient at a social tea. On the other hand, it is quite possible that the very union so many coal operators have been fighting, will eventually prove the bulwark of their defense against such dangerous anarchistic bodies as the Industrial Workers of the World, which have already, and will again, try to gain control of the miners' union.

Only a short time ago the great railroads of America were crying out bitterly against the strictures placed on their business by our federal government. A few days ago this same government appeared before our Supreme Court as the champion of the roads in an appeal against the destructive attacks of individual states. Surely times do change.

The coal industry has enough outside enemies to keep it busy. Why can we not have peace within the family? Let us encourage the union to select honest, capable leaders who will fight to the "drop of the hat" for what they consider "fair rights of the men," but who will insist that every miner strictly observe his bargain, once a contract is made, just the same as the operator is supposed to do. No other plan is fair or right, and what is not fair and honest cannot permanently succeed.

Conservation and the Consumer

During recent years we have all heard much from the public platform and popular press concerning the conservation of our natural resources. Almost without exception this expression refers to coal in the ground, natural gas either in the earth or as it issues therefrom, mineral oil in a position similar to that of the gas above described, and standing timber in the forest.

Up to the present time, regardless of what efforts have been made toward saving for future generations what might truthfully be termed the nation's birthright, no legislator has been bold enough to advocate compulsory utilization of fuel-saving apparatus by the consumer. No would-be stateman has yet unlimbered his oratorical artillery in condemnation of the pernicious waste of heat in the furnaces of antiquated and inefficient steam boilers, with which the country is all too generously dotted.

The public in general is quick to criticize the producer of the world's fuel and clamor for drastic legislation governing the mining industry. These same people evidently forget the little cook stoves in their own kitchens which utilize in actual cooking perhaps 2 or 3 per cent. of the heat evolved in the combustion of the fuel and spill the balance up the chimney in the form of hot air and gas.

It is safe to say that the small consumers of the country by employing obsolete and extravagant methods of fuel burning and heat utilization annually waste amounts of coal which in actual cash value vastly exceeds that left in the ground impossible of recovery.

The conservation of natural resources is a laudable ambition and one worthy of strong commendation. Like most other great reforms, however, its practice should begin at home.

Dangers of Taking Powder Home

By H. G. Cockill*

The picture published herewith shows a house owned by the Knickerbocker Smokeless Coal Co., at Knickerbocker No. 2 mine, Hooversville, Penn., which was blown up Mar. 9, 1913, by a keg of powder.

Mike Truckley, a Slav, preparing for work with four other boarders at 5 a.m., went into the cellar to get powder for his day's work. He stepped near the red-hot stove in order to see more clearly and began pouring the powder into his cadger. The dust of the powder blew onto the stove and the flame passed back into the keg, which exploded with great violence.

Showing Result of Powder Explosion in Miner's Home

The explosion broke the 10-in. concrete walls and completely demolished the building. Four open kegs of powder standing near-by were untouched by the explosion. Mike's sister and her child were at the door upstairs and had to be taken down over the ladder shown in the picture, as the stairs were blown down. They escaped unharmed. Two porches of the house were blown a distance of 20 ft. The injured man, Mike Truckley, was removed to the Johnstown Hospital, where he died two weeks later.

⁂

Our Front Cover This Week

The photograph on the front cover of this week's issue of Coal Age shows a No. A-1 ½-C-3 electric rotary drill in operation in mine of the New Pittsburgh Coal Co., Murray City, Ohio. This drill has met with considerable favor in bituminous mines because of its extreme simplicity. It may be readily handled by one man and is easily moved or set in position for drilling. Although especially designed for drilling coal, it can be used for drilling slate, shale, rocksalt, clay and gypsum. The drill is manufactured under patents owned by the Jeffrey Mfg. Co.

*Mining engineer, Knickerbocker Smokeless Coal Co., Hooversville, Penn.

The Shot Blew Through

By J. R. Allardyce

(Written expressly for "Coal Age.")

Old Tony Marconi, the Dago,
In the face of his room drilled a hole;
Says he, with a grin,
"I put powder in,
An' play helly-fire wi' da coal."

So he gave it six feet of a charge
And tamp'd it up tight as a gun;
Says he, "I come back
When he giva da crack,
An' maka da big pile o' mon!"

So he lit up the fuse and decamped,
To wait for the roar and the crash;
And munch'd at his ease
His garlic and cheese,
And reckon'd his labors in cash.

When the smoke rolled away from the face,
He crept back elate to the job;
But Tony felt punk
When he found not a chunk,
And he sat down and wept in the gob.

"Cara mia!" said he, "but I hear
Da big crack, an' I smella da smoke;
But I no see no coal,
An' da tamp in da hole—
Sancto Pietro! he no even broke."

And he quit the whole job in disgust,
While old Squeaky Pete with delight,
Loaded coal in the cars
Till he blink'd and saw stars,
From the shot that blew through on the right.

⁂

Mining Meetings

The meeting of the committeemen at the Pittsburgh Experimental Station of the Bureau of Mines, which was scheduled for Apr. 7, has been postponed. The object of the meeting was to make provision for the organization of the American Mine Safety Association. It is the desire to organize the 15,000 men scattered throughout the United States, who have qualified as first-aid men into a compact body.

The idea is to model this organization after the far-famed St. John's Ambulance Association of Great Britain. The first step necessary is to have the members of the American Safety Association solidify the widely scattered local branches of that institution. So few of the members of the committee were present on Apr. 7, that it was decided to postpone the meeting until such time as would be most convenient for those concerned.

⁂

The presence of blackdamp, a mixture of carbon dioxide and nitrogen, will often neutralize the effect of fire lamp on a flame. Analyses of mine gases which gave only a faint cap when tested with a safety lamp, have shown 4 per cent. of methane mixed with blackdamp. When testing with a lamp, remember that the flame is not as clear in these that have burned some time in a dusty atmosphere as in lamps which have burned but a short time in clear air.

DISCUSSION BY READERS

Education in Coal Mining

Letter No. 5—The unique suggestion of COAL AGE, that textbooks should be allowed students in examination, is a striking commentary on the system of mining education today. How true it is that system makes or mars the man. Favorable results, however, are often attained, despite the system employed; and when the results are otherwise, the system is more to be blamed, perhaps, than the capacity of the student. I have seen excellent work accomplished by a system confined to certain limits when the slightest deviation from the beaten track would produce confusion and disaster. Most unacademic systems err in their neglect of the study of principles, and this, even with the approbation of boards of education.

What, after all, is education but a knowledge of principles and their application. Therein lies the crucial test of any system. If the student is not enabled to grasp fundamentals and use them in the development or transposition of formulas, in the solution of problems, upon what does the system as a means of education rest? Here is where the function of examination lies—not in scrutinizing the mechanical results, to produce which the tools have been provided; but to ascertain, if possible, the extent of the pupil's mastery of principles and his ability to apply them efficiently in practice.

I would like to ask what is a man's efficiency, in a special branch of education, if his results are obtained by the mechanical handling of a ready-made formula? Would there be any obstacles to his acquiring the reputation of an "admirable Crichton," with accommodating textbooks at his elbow and a minimum of study and grind to his credit? What is my knowledge of the steam engine worth if it consists only in ability to substitute numerical values for the symbols in the formula

$$H = \frac{plan}{33{,}000}$$

Or, what is my conception of the mathematical relation of the sides of a right-angled triangle to one another, if it is determined by the mechanical substitution of figures in variations of the formula

$$Base = \sqrt{hyp.^2 - perp.^2}$$

No! Let us take the bull by the horns and, admitting the defects of method in our systems of teaching and taking a dose of Bacon or Descartes as a stimulant to our efforts, settle down to the production of something that will simplify instruction and yet provide a basis for a system that shall efficiently teach the essentials of the education needed in coal mining.

❖

Letter No. 6—The education of the miner is a large subject to discuss. I believe every miner ought to be educated—at least he should have a common-school education; but I cannot see how we are going to educate the miners unless we start with the boys. I believe every boy ought to be compelled to attend school until he graduates from the high school. He will then have a start in life and if he has any ambition he can advance himself in any line.

On the other hand, if a boy is compelled to work about the mines at the ages of twelve and fourteen, he will lose all ambition to study and will not realize what he has lost until later in life. He is then ashamed to start back with the boys, and continues in the same old rut as his father did before him. To avoid this embarrassment every boy should be compelled to attend school till he completes the high-school course, as the miner needs education as well as any other class of men, so that if there is any chance for his advancement he will be capable of filling a higher position.

In coal mining, there is not a greater drawback than to be without an education; but if we educate the miner who is going to mine the coal? The educated man is not going to mine coal. And again a miner cannot educate his family on the average wage of $50.00 a month. I believe we will have to educate somebody higher than the miner and have them take more interest in educating the mine workers who cannot educate themselves. The great cry in the anthracite region of Pennsylvania is, "We must educate the miner." But the great trouble is that those who have been educated seem to get above their fellowmen and forget that they ever worked as common miners. We should educate the mine officials to get nearer to their men, and then we can do something towards educating the miner. I say, however, educate the miner by all means.

MINER.

Scranton, Penn.

❖

Letter No. 7—Owing to the failure of the state legislature of Washington to pass legislation on the new code of mine laws drawn up by the commission appointed by Governor Hay, who retired from office, Jan. 1, 1913, the state of Washington is deprived of the advantage to be gained by a new code of mine laws, for another two years. As I have stated in a previous article, in COAL AGE, the present law does not require a man to hold a certificate of competency in order to serve either as mine foreman or fireboss. The Northwestern Improvement Co., the largest and most progressive coal company in the state, does, however, require that in order to hold either of these positions, a man must have a certificate which is issued by the company, and examinations for such certificates are held by this company twice a year.

At the last examination, which was held during the fore part of the present month, the same method was pursued as in the previous examinations. The applicants for fireboss were given ten questions to answer in writing with a total marking of 50 per cent. Later, they were taken to a certain entry, in a mine in which the ventilating system had been disarranged, props knocked out and

others set wrong, drop sheets misplaced, and in several places small quantities of marsh gas (CH_4) could be found. Throughout this territory, experienced and competent men were stationed to watch the men as they made their inspections.

The candidates were stationed on the main parting under the inspection of a competent man, and when all was ready, they were started in, at intervals of ten minutes. When they had completed their inspection, each candidate was required to make a written report of the conditions as he found them; and this report was compared with the report of the inspectors, and the candidate given a mark, according to the following schedule:

	Points
Handling and testing of safety lamps	10
Drop sheets and ventilation	10
Gas in all places	10
Timbering	10
General deportment	10
Total	50

I have always been an advocate of allowing candidates the use of textbooks in these examinations, as long as the questions asked do not give the applicant a direct chance to copy, although by so doing the candidate would cheat no one but himself. In conducting the last two examinations held by the Northwestern Improvement Co., I found that several good men would have failed to pass the examination had I not allowed them the use of textbooks to find the formulas for certain questions asked. Knowing these men from having been connected with them in their work around the mine, I am satisfied that they will make much better mine foremen than the younger men who have studied hard to memorize all the formulas, and who have had some engineering experience, but who still lack the necessary practical experience in mining.

It has also been my experience that men who have studied hard previous to taking an examination, in order that they might memorize the formulas, constants and other data, after securing a position as foreman, forget these formulas and data and refer at once to their textbooks whenever obliged to make calculations that will enable them to contend successfully with the various difficulties that occur in daily mining practice.

FRANK GOOD.

Roslyn, Wash.

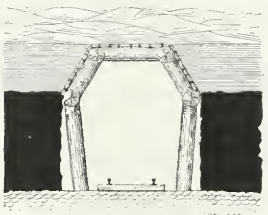
Waste of Mine Timber

The recent discussion on post timbering at the working face has called my attention to the large and in most cases unwarranted waste of timber in and around coal mines. This waste of timber is probably greater in mining than in any other industry. The unnecessary waste of timber can be greatly reduced; at the same time, the necessary waste portions can often be put to some good use, if the mine officials will give the matter proper attention. Greater consideration is given this matter in foreign countries than in America, because they have come to realize the necessity for so doing. As civilization advances and the population increases, suitable timber naturally becomes more scarce and higher in price and, for this reason, the practice of economy in its use is essential.

It is important to give all mine timber a careful inspection when it is received at the mine, as without this inspection much timber will be received that cannot be used and must be thrown aside. It is likewise important to give careful attention to the framing of timbers and avoid waste, as far as possible, by cutting down posts that are too large for the purpose. Much timber is lost in abandoned places, that could be used again if proper care be taken to recover and send it where it can be used.

Again, it is important that timber should be cut at the right time of the year and stored so that it will become seasoned. The life of mine timber is greatly increased by treating timber so as to preserve it from decay. Wood continually deteriorates under the stresses or loads to which it is subjected, and these ill effects are greatly increased by the conditions of moisture and temperature so common in mining.

Proper care should be used in placing timber, in order to secure the best service and prolong its life. In rooms, a systematic method of timbering is generally the safest plan to follow. Special conditions require special forms of framing. When mining under a week drawslate, and it is desired to maintain a permanent haulage road, it may be advisable to adopt a style of timbering similar to that shown in the accompanying sketch. In this system four longitudinal stringers are supported by two legs, two struts and a short collar or crossbar at the top. As shown in the figure, the legs of the timber frame are given a slight inclination inward, at the bottom, so as to better support the side thrust of the drawslate above the coal. The upper portion of the frame forms an arch and is lagged, as shown in the sketch. In special cases, where the roof has a tendency to cave high, it may be advisable to omit the collar, or crossbar, and extend the side struts as rafters until they meet a single stringer in the roof, which gives greater head room.



ARCHED TIMBER FRAME

Much timber can be saved by the miners and daymen engaged on pillar work, exercising suitable precaution. It often pays to set a couple of temporary props to save one timber that would otherwise be abandoned. Machines for drawing timbers are used to advantage by many companies. Much timber is lost through neglect. It is common to find posts that have been taken to working places and never used. A visit to most abandoned places will reveal many posts that should have been drawn and other timber covered by falls. It is common to find ties, wooden rails, brattice boards, etc., scattered through air courses and going to waste, because they have not been cleaned up and taken to where they could be used. Miners will often order timber sent in rather than gather the loose timber lying in the waste and left along the rib. Care should be taken to see that miners order the proper length of timber required, to avoid the waste of cutting long timbers where a shorter stick is needed.

For permanent work, when possible, steel and reinforced concrete should be used, as they have greater strength and longer life. Tile, brick or concrete stoppings, and overcasts are generally tighter and safer than those built of wood. The use of steel mine ties, in rooms and airways, will generally be found to be of advantage.

MINING ENGINEER.

Clarksburg, W. Va.

System in Timbering

It is both economical and advantageous to adopt a uniform and special method of timbering that will be suited to the particular conditions in a mine. The weight is thereby more evenly distributed over the coal face and the timber is more promptly set by the miners, because the system demands that another row of timbers must be stood at the specified distance from the face of the coal and the back timbers drawn regularly as the working face advances. If the miner fails to do this at the time, his neglect is observed by the foreman or his assistant on his first round and he is ordered to cease work on the coal till he has done the timbering as required by the regulations of the mine.

In my opinion, the miner should be held responsible for the timbering of his own working place as it advances. I believe this is a safer method to adopt than to employ a special timberman, because the miner working every day in the same place is more apt to note the changing conditions of the roof than the mine foreman or timberman, who spend but a portion of their time in one place and visit, perhaps, a hundred different working places, in the same shift. The miner should be supplied with plenty of timber of the right length so that he will have no excuse for not setting the same promptly, as the face advances.

Since the miner is not a proper judge of all the conditions that should determine where timbers ought to be placed, it is all the more important that he be required to set the timbers at the face according to some regular order or system. This system should be determined by the conditions and nature of the overlying and underlying strata; the thickness and nature of the coal; the depth below the surface; the pitch or inclination of the seam; and the method of mining the coal. When these conditions change, it will be necessary to change or modify the system of timbering, and the miner should be given proper instructions at such time.

But, after all has been said, in favor of systematic timbering, I believe that the method adopted for the working of the coal—the width of the openings and the size of pillars required is more important than even the adoption of a proper system of timbering. It must be remembered that timbering, at the working face, is only for the purpose of securing loose pieces of slate or roof against falling and to give the miner warning of impending danger and more evenly distribute the weight upon the pillars and the face of the coal. If the thickness of the pillars is too small and not made proportionate to the width of the opening, no amount of timber or system of timbering will avail to correct the evil.

Study Course in Coal Mining

BY J. T. BEARD

The Coal Age Pocket Book

MINE GASES

The gases of most importance in coal mining, together with their chemical symbols, molecular weights, densities referred to hydrogen and specific gravities referred to air of the same temperature and pressure, are the following:

Gas	Symbols	Molecular Weights	Density H=1	Spec. Gravity Air=1
Methane (marsh gas)	CH_4	16	8	0.559
Olefiant gas	C_2H_4	28	14	0.978
Ethane	C_2H_6	30	15	1.0366
Carbon monoxide	CO	28	14	0.967
Carbon dioxide	CO_2	44	22	1.529
Hydrogen sulphide	H_2S	34	17	1.1912
Oxygen	O_2	32	16	1.1056
Nitrogen	N_2	28	14	0.9713
Hydrogen	H_2	2	1	0.06926

Occurrence of Mine Gases—Aside from the oxygen and nitrogen of the air, the gases commonly occurring in coal mines are methane, carbon dioxide, carbon monoxide, and less frequently or in less quantity, hydrogen sulphide and olefiant gas. These gases are produced by the processes of decomposition or combustion constantly going on in the mine, or they emanate from the coal or other strata, where they exist as natural gases.

Occluded Gases—The gases commonly occluded in the coal formations are methane, ethane, nitrogen, carbon dioxide and oxygen. They are the result of the chemical changes that took place in the formation of the coal; or are produced by the action of acid waters on certain limestones or other carbonates. Occluded gases are held in the pores of the coal and other strata, from which they drain into the mine openings, or work upward through such pervious strata as shale and sandstone. The process is called "emission" or "transpiration" of gases.

Pressure of Occluded Gas—At times, the gas is confined in the coal or other strata by an overlying stratum of clay or impervious limerock that prevents its escape to the surface, and the presure of the gas is then often very great, varying from 500 and 600 lb. per sq.in. to four or five times that amount. This presure is manifested in different ways. As the mine workings are extended the flow of gas into the mine increases with the exposure of fresh faces of coal, except where the conditions are such as to allow the gas to drain off and reach the surface.

Effect of Faults—Fault lines and other geological disturbances of the strata have opened channels by which the gas confined in certain strata escape to other strata or into the mine workings or to the surface. For this reason, the near approach of the working face to a fault line or a disturbed condition of the strata is often accompanied by a marked change in the gaseous condition of the mine air. The percentage of gas common to the mine may then either increase or decrease depending on the location of the gas and the nature of the fault.

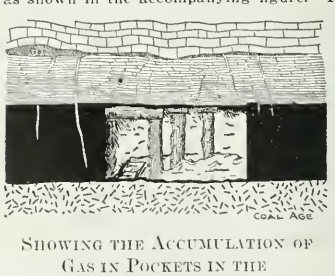
The Coal Age Pocket Book

Gas Feeders, Blowers—Any continuous flow of gas from a crack or crevice in the strata is called a "gas feeder," or simply a "feeder." The gas flowing from the crevice is known as "feeder gas."

When a gas feeder is under high pressure so that the gas issues with considerable velocity, the feeder is called a "blower" and the gas "blower gas."

Effect of Gas Pressure in Mining—The pressure of gas confined in the coal is often sufficient to splinter the coal in its effort to escape, the fine coal being thrown into the face of the miner at work. At times, the gas escapes from the coal with a peculiar hissing sound known as the "singing of the coal." The presure of gas in the roof frequently causes heavy roof falls, and gas in the floor causes the bottom to heave. In some instances, the gas pressure assists the extraction of the coal and lessens the work of the miner by helping to break down the coal.

Outbursts of Gas—In the mining of gaseous seams, it is not uncommon for gas to work in the strata as the coal is extracted. As a result, the gas often accumulates in pockets as shown in the accompanying figure. The settlement of the roof incident to the removal of the coal affords opportunity for the gas to expand and work forward toward the opening. The working of the gas in the strata is often accompanied by severe "poundings" or "bumps," due to sudden displacement of the gas. Such sounds often continue for several days previous to a sudden outburst of the gas into the mine workings. The continuance of these poundings are a sufficient warning to experienced miners to vacate that part of the mine till the strata have become more quiet by the gradual draining off of some of the gas.



SHOWING THE ACCUMULATION OF GAS IN POCKETS IN THE STRATA

In many cases, where the gas works down into the coal, either at the face or in the "ribs," as shown in the figure above, the pressure of the gas becomes distributed over a considerable surface, and is sufficiently great to throw down the coal. This is called an "outburst" of gas, since large volumes of gas and often hundreds of tons of coal are thrown violently into the opening.

INQUIRIES OF GENERAL INTEREST

Effect of Carbon Dioxide on Life and Flame

(a) What per cent. of carbon dioxide (CO_2) will cause a miner to notice that he is working in bad air? (b) What per cent. will ordinarily cause him to stop work? (c) What per cent. will cause unconsciousness, say after a half hour's work? (d) What per cent. will extinguish a miner's open lamp?

M. C. Butler.

Fairfax, Wash.

(a) The effect of carbon dioxide on the human system is not alone dependent on the percentage of this gas present, as the effect of the gas, both on life and flame, is greatly increased by the depletion of the oxygen in the air. Careful experiment has shown that when carbon dioxide is added to pure air, respiration becomes noticeably more difficult when the proportion of the gas in the air exceeeds 4 per cent. If there is 4 per cent. of carbon dioxide present, the proportion of pure air in the mixture is 100 — 4 = 96 per cent.; and since oxygen forms 20.9 per cent. of the pure air before the carbon dioxide is added, the proportion of oxygen present in this mixture is 0.209 × 96 = 20.064 per cent. In this case, therefore, the oxygen has only been depleted, by the addition of carbon dioxide, from 20.9 to 20.064 per cent.; but the presence of the 4 per cent. of carbon dioxide begins to make respiration difficult.

(b) No percentage can be stated as producing such effect as will cause a man to stop work owing to the presence of carbon dioxide in the mine air. The effect is greatly modified by the physical condition of the person, the character of work he is doing and the temperature of the air and amount of moisture present. All of these conditions greatly modify the effects of the gas on the system. As respiration becomes more difficult owing to the increasing percentages of the gas in the air, headache and nausea are produced. Some men are stronger and better able to withstand these effects and continue work longer than others; but, in general, from 6 to 8 per cent. of this gas present in the mine air may be considered sufficient to produce effects that will cause the ordinary miner to stop his work.

(c) The answer to this question must be modified by the same conditions we have just mentioned. For this reason, it can only be stated, in a general way, that from 10 to 14 per cent. of carbon dioxide present in the mine air may produce unconsciousness when breathed for one-half hour while at work.

(d) The depletion of the oxygen in the mine air increases the effect of carbon dioxide on the flame of the lamp to a much greater extent than it modifies the effect of this gas on the human system. For example, a lamp placed in a closed place, as under a bell-jar, and allowed to burn until it is extinguished, consumes some of the oxygen of the air and produces, at the same time, carbon dioxide. The depletion of the oxygen of the air and the percentage of carbon dioxide produced, at the moment the lamp is extinguished, are found to vary with the nature of the flame. A candle is extinguished when 3.2 per cent. of carbon dioxide is present and the oxygen of the air is depleted to 15.7 per cent. A lamp burning paraffin oil is extinguished when 3.0 per cent. of carbon dioxide is produced, the oxygen of the air being depleted to 16.6 per cent. The atmosphere remaining when the lamp is extinguished is called a residual atmosphere.

On the other hand, an artificial atmosphere, produced by adding carbon dioxide to pure air, will extinguish a candle flame when 13.4 per cent. of carbon dioxide is present, the oxygen being then depleted to 18.1 per cent. In like manner, an artificial atmosphere, produced by adding carbon dioxide to pure air, has been found to extinguish an oil lamp when 14.3 per cent. of carbon dioxide is present, the oxygen of the air being depleted to 17.9 per cent.

Owing to the free circulation of air in the mine, the mine air must be considered as more nearly approaching an artificial atmosphere than a residual atmosphere. It is true, however, that in portions of the mine workings that are poorly ventilated, the oxygen of the air has not been replenished as rapidly as it has been consumed and, in this case, a slightly less percentage of carbon dioxide present in the air will suffice to extinguish the lamp. Although 18 per cent. of carbon dioxide in air, under ordinary conditions, is stated as producing a *fatal* atmosphere while an oil lamp may be extinguished in air containing only 14 per cent., it is never safe to remain in an atmosphere where a lamp is extinguished. Less than 4 per cent. of carbon dioxide present in the mine air will cause the lamps to burn dim and this should warn men to seek better air.

⁂

Heat Absorbed by Air

How many B.t.u. will be required to raise the temperature of 100,000 cu.ft. of air from 35 to 54 deg. F.?

Fireboss.

Monongahela, Penn.

The first step is to find the weight of 100,000 cu.ft. of air at the given temperature (35° F.), assuming a barometric pressure of, say 30 in. of mercury. Thus,

$$100{,}000\left(\frac{1.3273 \times 30}{460 + 35}\right) = 8044\ lb.$$

Now, assume that the pressure remains constant and the air is allowed to expand freely under the stated rise of temperature. The specific heat of air, for constant pressure, being 0.2374, the heat absorbed by 1 lb. of air for each degree the temperature rises, is 0.2374 B.t.u. The rise of temperature, in this case, is 54 — 35 = 19 deg. The total heat absorbed in producing the rise of temperature, or the heat required to raise the temperature of 100,000 cu.ft. of dry air, under constant pressure, from 35 deg. to 54 deg. F., is

$$8044 \times 19 \times 0.2374 = 36{,}280\ B.t.u.$$

EXAMINATION QUESTIONS

Mensuration and Surveying

(Answered by Request)

Ques.—A certain entry is driven 9 ft. wide on the bottom, 7 ft. wide on the top and 6 ft. high, its section being in the form of a trapezoid. If this entry is half full of water—that is to say, contains half the water that it would hold if full, what is the depth of the water standing in the entry, and what is the width of the entry measured at the surface of the water?

Ans.—The area of a trapezoid is found by multiplying one-half the sum of its two parallel sides by the perpendicular distance between them; thus,

$$area = 6\left(\frac{7+9}{2}\right) = 48\ sq.ft.$$

One-half of this area, or 24 sq.ft., is the area of the cross-section of the water.

Now, observe that the width of this entry decreases 2 ft. in 6 ft. of vertical height. Therefore, calling the depth of the water x, the decrease in the width of the entry at the surface of the water will be $\frac{2}{6}$ or $\frac{1}{3}$ of x, making the width at the surface of the water $9 - \frac{1}{3}x$. The sum of the two widths measured at the bottom and at the surface of the water is then $9 + 9 - \frac{1}{3}x = 18 - \frac{1}{3}x$; and the half sum of these widths is $9 - \frac{1}{6}x$. Then, multiplying this half sum by the depth of the water x, we have for the area of the cross-section of the water

$$x\left(9 - \frac{x}{6}\right) = 9x - \frac{x^2}{6}$$

But since this area must equal 24 sq.ft., the value of x is found by solving the equation:

$$9x - \frac{x^2}{6} = 24$$

Or, multiplying through by 6 to clear of fractions, and changing the signs of all the terms, and writing x^2 first we have

$$x^2 - 54x = -144$$

Now, complete the square in the first member by adding to it the square of half the coefficient of x; or $27^2 = 729$; remembering that the same amount must be added to both sides of the equation, to preserve the equality; we have

$$x^2 - 54x + 729 = 729 - 144$$
$$x^2 - 54x + 27^2 = 585$$

The first member of this equation is now a perfect square, its square root being $x - 27$; hence, extracting the square root of each member, we have

$$x - 27 = \pm\sqrt{585} = \pm 24.187$$
$$x = 27 - 24.187 = 2.813\ ft.$$

The depth of the water is, therefore, 2.813 ft.; and the width of the entry at the surface of the water is

$$9 - \frac{x}{3} = 9 - \frac{2.813}{3} = 9 - 0.938 = 8.062\ ft.$$

Ques.—An entry measures 9 ft. on the bottom, 6 ft. at the top and is 5 ft. high. Find the depth of the water when the entry is half full.

Ans.—The area of this entry is $5\ (6 + 9) \div 2 = 37.5$ sq.ft. Since the width of the entry decreases 3 ft. in 5 ft. vertical height, and calling the depth of the water x, the decrease in width, at the surface of the water, is $\frac{3}{5}$ of $x = 0.6x$, making the width at the surface of the water $9 - 0.6x$, and the sectional area of the water

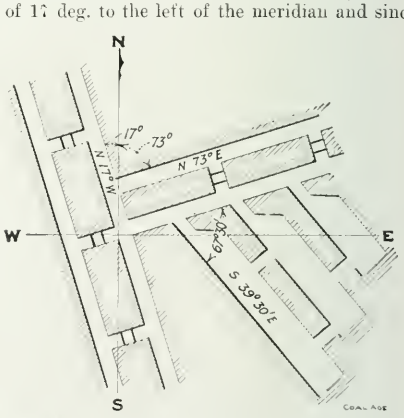
$$Area = x \times \tfrac{1}{2}\ (9 + 9 - 0.6x) = x\ (9 - 0.3x) = 9x - 0.3x^2$$

The area of the water being $37.5 \div 2 = 18.75$ sq.ft., we have

$$9x - 0.3x^2 = 18.75$$
$$x^2 - 30x = -62.5$$
$$x^2 - 30x + 15^2 = 225 - 62.5 = 162.5$$
$$x - 15 = \pm\sqrt{162.5} = \pm 12.75$$
$$x = 15 - 12.75 = 2.25\ ft.$$

Ques.—The course of the main entry in a certain mine is N 17° W: (a) What is the course of a cross-entry turned to the right at an angle of 90 deg.? (b) What is the course of the rooms turned off the cross-entry at an angle of 67° 30′ to the right?

Ans.—As shown in Fig. 2, the main entry makes an angle of 17 deg. to the left of the meridian and since the



PLAN OF MAIN AND CROSS-ENTRIES, SHOWING ROOMS

cross-entry is turned off at any angle of 90 deg. to the right of the main entry, it makes an angle of $90 - 17 = 73$ deg. to the right of the meridian. The bearing of the cross-entry is, therefore, N 73° E.

(b) Since the rooms are turned to the right of the cross-entry an angle of 67° 30′, the total angle measured from the north end of the meridian around the right, to the center line of the rooms is $73° + 67° 30′ = 140° 30′$. Since this angle is greater than 90 deg., the bearing of the rooms lies in the southeast quadrant. The angle of this bearing is measured from the south end of the meridian, and is $180° - 140° 30′ = 39° 30′$. The bearing of the rooms is, therefore, S 39° 30′ E.

COAL AND COKE NEWS

Washington, D. C.

Attorney-General McReynolds has developed a plan to govern the future administration of the Sherman act which, it is believed, may operate to change in some important particulars the present method of applying that law and would incidentally alter the mode of proceeding in the so called coal cases.

Mr. McReynolds' idea is to have the local federal legal authorities, instead of waiting for an elaborate investigation to be made by the Department of Justice, and instead of waiting for instructions from Washington, take action in all instances where they are advised that local violations of the Sherman act are being committed.

If this plan were to be followed, the effect would be that proceedings under the Sherman law would be rendered much more numerous and the amount of difficulty caused to those subject to prosecution would probably be largely increased.

Demand Coal Be Kept Dutiable

It is being unofficially stated that a strong demand is to be made by coal interests which are powerful in Congress for a restoration of rates of duty to some extent, or at all events for the insertion in the new law of a provision removing the duties on Canadian coal only in the event that Canada gives equally good treatment to America. This, however, is likely to be sharply rebutted by the New England manufacturers who have been feeling all along that they were being given but little consideration and who have recognized help for themselves in a small group of items used by them in the process of production and considerably reduced under the tariff bill or placed on the free list.

One of these was coal and there has been a strong disposition to regard the treatment of it in the act as nothing more than a bare recognition of their claims for something offsetting the heavy reductions on their goods which were carried in the act. It is therefore likely that a sharp struggle will occur before the dutiable status of coal will be altered.

Must Become Parties to the Government

According to information received by the Department of Justice it will be necessary for J. P. Morgan & Co. and the Central Trust Co., of New York, to become parties to the case of the Government against the combination of railroad and coal operators in which the Lake Shore & Michigan Southern, the Hocking Valley, and the Sunday Creek Coal Co. were involved.

This has now been held to be a trust in violation of the Sherman law under a decision of the Federal Circuit Court of Appeals at Cincinnati, Ohio. The decision holds that all persons interested in the stock of the coal company and all those holding property who are pledged to secure the dividing of the coal traffic moving over the roads in question shall be made parties to the suit of the Government. This involves the New York interests already referred to.

Coal in Our Export Trade

The Department of Commerce has compiled an analysis of the export trade of the United States which shows that ten countries take the bulk, or about three-fourths, of United States exports and among these considerable attention is given to coal and coke.

England is first in the list of countries and Canada second while in Canada's receipts of goods from the United States coal and coke rank second in value with $13,000,000. Germany is third in the list, France fourth, Netherlands fifth, Italy sixth, Cuba seventh and in Cuba's receipts coal ranks fifth with $3,000,000.

Mexico follows Cuba as eighth in the list, her receipts of coal from the United States being the seventh article of importance and amounting to about $1,500,000 annually. Japan is ninth and Argentina tenth, bituminous coal received by the latter from the United States amounting to $500,000 yearly.

Mining Institutes and Vocational Schools

According to the data which have been made public in regard to the mining institutes and vocational schools in the anthracite regions of Pennsylvania, the past season has been decidedly successful. Institutes were held at Wilkes-Barre, Scranton, Pittston, Lansford, Hazleton, Nanticoke, Shamokin, Mt. Carmel and Carbondale.

At present there are about 100 different positions in and about the mines for which special training is advisable or indispensable. In order to avoid embarrassing adult miners who dislike to show ignorance or enter classes with children the present method is to have the classes at night for men only. These have been held either three or five nights a week according to the disposition of the miners to attend.

The strong interest in the work has been quite acceptable to the mine operators as they believe it tends to bring about more efficient work and closer attention to duty on the part of the employees. Some of the coal roads have contributed largely to the expenses of the undertaking.

The President Will Not Interfere

The present understanding is that President Wilson will pursue the policy of not interfering with the men at the head of the scientific bureaus of the Government, and that in pursuance of this policy he probably will not make any changes in the Bureau of Mines or Geological Survey.

The action taken in removing the head of the Census Bureau was based on the belief that that institution had not been efficiently conducted and, curiously enough, it would seem that one of the most severe criticisms made with reference to it relates to the way in which it carried on the census of mines, particularly coal, this, however, being jointly managed by the census and the Geological Survey. There seems to be general approval for the policy of non-interference with the scientific bureaus of the Government.

PENNSYLVANIA

Anthracite

Hazelton—A recent strike of the mine workers at a colliery of the Lehigh & Wilkes-Barre Coal Co. has extended to all the operations of the corporation. Eighteen hundred men are idle. The strike was caused by the question of the wearing of union buttons.

Wilkes-Barre—Four men were killed and two fatally injured by an explosion of gas in the East Cooper slope of the Woodward mine of the Delaware, Lackawanna & Western Co. at Edwardsville, Apr. 12. Several others received burns and lesser injuries. A naked light was the cause of the explosion.

Scranton—Fire slightly damaged the breaker of the Diamond mine of the Lackawanna Coal Co. in West Scranton. The fire started in the loading shed of the building, and a serious blaze which might have destroyed the breaker was prevented by the timely discovery of the fire by two workmen employed about the breaker.

Fire believed to have been caused by children playing with matches nearly destroyed the old Mt. Pleasant washery of the Lackawanna Coal Co. at the West end of the Mulberry Street viaduct, in Scranton. The washery had been abandoned some time and was of little value.

Bituminous

Pittsburgh—Striking calkers and woodworkers employed at the marine ways of the Monongahela River Consolidated Coal & Coke Co. have been ordered to return to work or remove their tools. The striking men are demanding an increase in wages. They claim that the company has refused to meet their grievance committee.

Uniontown—Miners in this vicinity are said to be on strike owing to trouble which has arisen concerning the method of weighing.

Greensburg—The commissioners of Westmoreland County have recently fixed valuations for various coal lands for taxable purposes.

WEST VIRGINIA

Charleston—Governor Hatfield has served notice that he will arrest all persons who are caught, aiding in any way, insurrection in West Virginia.

The coal operators of Kanawha County have accepted the governor's proposal for a settlement of the miner's strike.

The miners' representatives, however, have not yet answered. It is said that the New River operators also have made peace.

A movement has been started by the United Mine Workers of America to help the miners and their families, who suffered during the recent floods. A committee has been going the rounds in this vicinity to see how many need assistance.

Morgantown—A six-week summer course will be given by the University of West Virginia department of mines to prepare men for mine foremen and fireboss positions. The course will begin June 23 and is intended to prepare miners for examinations for certificated mine positions.

The West Virginia Mining Institute will meet in this city June 24.

Clarksburg—The Consolidation Coal Co. is making its annual inspection of its coal mines in the West Virginia district.

Coal Valley—Local officers of the United Mine Workers have received word that 125 men are on strike in the Coal Valley mine in Boone County.

Wheeling—The plant of the Elm Grove Coal Co. was tied up Apr. 16 when 75 men went on tsrike. The strike is of an entirely local nature, involving the insurance policy of the company, and an early adjustment is expected.

KENTUCKY

Louisville—The Western Kentucky Coal Operators' Association met last week at the Seelbach Hotel in annual convention, for the purpose of electing officers for the ensuing year and attending to other business, mostly of a routine nature. The Association is composed exclusively of the operators of union mines in that section of the State, and representation was consequently confined to that class of the trade.

OHIO

Lisbon—The power plant and buildings of the Duquesne Coal Co., at Newhouse, a mining hamlet three miles east of this town, have been almost totally destroyed by fire.

INDIANA

Indianapolis—The Indiana Railroad Commission has not acted on the notification of some of the roads that they will raise their rate on Indiana coal, May 1, from 50 to 55c. per ton. Operators believe, however, that the higher rate will never prevail.

ILLINOIS

Springfield—It is stated on good authority that shotfirers will not be ousted from their jobs if machine mining is adopted in this section of the state. The machines will merely facilitate the undercutting of the coal, and shotfirers will still be a necessity.

Streator—The Munts Brothers have closed their operation and the 40 men employed there have sought work elsewhere. The mine will not be reopened until it has been disposed of.

MISSOURI

Kahoka—A seam of coal has been discovered on a farm a short distance south of Memphis.

KANSAS

Pittsburg—The Wear Mine No. 21 has been idle for more than three weeks, following a dispute between the miners and operators in regard to the distribution of the entries. Two hundred men have been out of work.

Fort Smith—It is reported that six men were entombed in mine No. 2 of the Western Coal & Mining Co., at Denning. An explosion wrecked the mine and set it afire. Efforts to reach the imprisoned men have met with little success.

FOREIGN NEWS

Brussels, Belgium—Between 300,000 and 400,000 miners employed in the Charleroi district are on strike for the ballot.

Hamborn, Germany—Sixteen miners were overcome by coal gas in a pit known as the "German Emperor", Apr. 16. Fire had broken out in the pit during the night.

Venezuela—Pell & Co. of New York are investigating the coal deposits of Venezuela and are proposing to engage in an extensive exploitation of them. In the same connection an examination of iron deposits in Venezuela and Colombia is being made and plans are under way to utilize the coal and iron in the establishment of an iron industry on the Caribean Sea.

PERSONALS

Judge Mitchell recently appointed Thomas Robinson receiver of the Hiawatha Coal Co., whose mine is located half a mile west of Urichsville. His bond was fixed at $5000.

The appointment was made upon the application of 65 miners, who claim they have not been paid wages earned during February.

Arthur C. Smith, formerly in charge of the office of the Bessemer Coal & Mining Co., is now connected with the St. Louis office of the Egyptian Coal & Mining Co.

Edwin M. Chance has severed his connection with the Philadelphia & Reading Coal & Iron Co., to become consulting chemist to a number of the larger anthracite and bituminous producers, and to enter into a general consulting practice in Wilkes-Barre.

James W. Turner, state superintendent of the Banner mine, which is leased by the State of Alabama from the Pratt Consolidated Coal Co., and operated by state convicts, has resigned his position, effective when his successor is appointed. His resignation has been accepted but his successor has not yet been named.

Governor Major, of Missouri, has appointed George Hill, of Bevier, as state inspector of mines. The office is a new one and pays a salary of $2000 a year and expenses. Mr. Hill has been a practical coal miner all of his life, and the governor in looking for his man wanted a practical miner from one of the largest coal-producing counties in the state.

OBITUARY

Alexander Fulton, aged 83, one of the best known and wealthiest coal operators in the anthracite region, died at Shamokin, Penn., on Apr. 15. During the early days of mining in this region, he was manager for John Jacob Astor, Franklin Delano and J. Langdon & Co. He came to the United States from Scotland in 1848.

TRADE CATALOGS

Wm. B. Scaife & Sons Co., Pittsburgh, Penn. Gasoline Storage Outfits. Welded Gasoline Tanks. 8 pp.; 7½x9¼ in.; ill.

Myers-Whaley Co., Knoxville, Tenn. Shoveling. Machines for Underground and Surface Work. 22 pp., 8x10 in., profusely illustrated. This is of especial interest to coal operators, as it describes machines which shovel the coal from the mine floor and load it into cars. The smallest machine described weighs 3 to 3½ tons, is 38 in. maximum height, consumes about 7½ hp. per minute. This machine will clean a heading or room 17 ft. in width.

CONSTRUCTION NEWS

Hillsboro, Ill.—The Clover Leaf Mining Co. has struck coal at its new air-shaft and it is understood that the work of sinking will soon be completed.

Sartell, Minn.—The Northern Pacific is planning to erect extensive coaling docks at Sartell this summer. It is intended that Sartell will be used as a coal supply depot for all through passenger trains.

Superior, Wis.—The Heyl & Patterson Contracting Co. is starting the erection of a big coal handling bridge on Northwestern dock No. 1. The company has recently completed the Island Creek dock at Duluth.

Henryetta, Okla.—The Pleasant Valley Coal & Coke Co. is sinking its No. 2 shaft north of the old 'Frisco tank on that road, about 5 miles north of town. The shaft will be 8x12 ft., 128 ft. deep, and will be built of concrete for a part of its depth.

Punxsutawney, Penn.—The P. & N. W. has started an extension of its spur that runs from Hilman into the Maderia Hill mines at Clover Run. It will be about two miles long and will tap a field of between five and six thousand acres of good coal.

Leavenworth, Kan.—It is understood that a Kansas syndicate has made an offer for the Brighton coal mine south of this city, 160 acres of land, 1200 acres of coal rights and the railroad from the mine to Lansing. It is the purpose of the syndicate to make a manufacturing center of Brighton. It is not the intention to sell any coal, but to use it for generating electric power.

Milwaukee, Wis.—The Milwaukee Western Fuel Co. and the Philadelphia & Reading Coal & Iron Co. are contemplating increasing the capacity of their docks at a cost of more than $1,000,000. The present capacity of the Milwaukee company is about 125,000 tons annually, while the capacity of the Reading company is 300,000 tons. It is expected that when the new machinery has been installed that the capacity of each will be doubled.

Grand Forks, B. C.—The Kettle Valley Ry. is building a spur to the Midway mines of the Boundary Mining and Exploration Co. As soon as this has been completed the road will use this coal for its locomotives. It is not the intention of the company to try to market any of the product, except that used by the railway, until next fall. A number of pumps, a compressor and a hoist are being installed at the mine.

NEW INCORPORATIONS

Birmingham, Ala.—The Burnwell Coal Mining Co.; capital stock, $50,000. Priestly Toulmin, president.

Birmingham, Ala.—The Wittichen Coal & Transfer Co.; capital stock, $25,000. Carl F. Wittichen, president and general manager.

Marissa, Ill.—The Marissa Coal & Mining Co.; capital stock, $2000. Incorporators: W. H. Hale, J. B. Brown and W. D. Newcom.

Frankfort, Ky.—The capital stock of the Elkhorn and Beaver Valley Ry. Co., of Ashland, has been increased from $30,000 to $130,000.

Little Rock, Ark.—The Quing Anthracite Coal Co.; capital stock, $75,000. J. T. Bullock, of Russelville, is named as agent for the company.

Dallas, Tex.—The Malkoff Lignite Co., capital stock, $10,000; purpose, mining. Incorporators: H. C. Jones, H. C. Maersch and Joseph Samuels.

Rich Hill, Mo.—The Eureka Coal Mining & Mercantile Co., capital stock, $20,000. Incorporators: F. A. Griffen, J. H. Williams and G. H. Davis.

New Straightsville, Ohio—The Calvin Essex Coal Co.; capital stock, $40,000. Incorporators: Calvin Essex, Sumner Cottingham, Fred Essex, E. R. Statler and J. A. Statler.

Chicago, Ill.—The New Enterprise Coal Co.; capital stock, $10,000; mining, treating and preparing coal for the market. Incorporators: F. C. Honnold, L. L. Dent and C. Y. Freeman.

Chicago, Ill.—The William Meusching Coal Co.; capital stock, $10,000; buying selling and dealing in coal, wood, ice, etc. Incorporators: E. A. Kimball, E. M. Kimball and J. E. McDowell.

Santa Fé, N. M.—A charter has been granted to the Superior Coal Co., capital, $25,000. Incorporators: Mrs. Elizabeth G. Kunz, Charles E. Kunz and Guy L. Rogers ,all of Albuquerque.

Huntington, W. Va.—The Big Ugly Creek Mining Co.; capital stock, $60,000; to mine coal, seek oil, gas, etc. Incorporators: A. J. Stein, G. Neace, G. J. McComas, H. E. Love and Daniel Dawson.

St. Louis, Mo.—The United Coal & Coke Co.; capital stock, $2000; to do wholesale and retail coal and coke bulsness. Incorporators: T. F. Nolde, C. E. Miller, L. C. Poon, J. P. Murphy and G. W. Hooper.

Phœnix, Ariz.—A charter was granted to the Mother Lode Gold & Copper Co., to deal in and operate minerals and mineral lands, including coal; capital, $1,000,000. Incorporators: Fred H. Larsen and M. A. Rabbitt, of Phœnix.

Mingo Junction, Ohio—The Brettel Bros. Co.; capital stock, $25,000; mining and dealing in coal and kindred products. Incorporators: Thomas Brettel, Sr., N. M. Brettel, M. Brettel, G. L. Thompson and James Brettel.

Cleveland, Ohio—The Short Creek Coal Co., of Cleveland, Ohio, has been incorporated with a capital stock of $600,000 to mine and deal in coal. Incorporators: J. J. Roby, E. B. Thomas, C. A. Niman, E. G. Hoag and L. T. Smythe.

Columbus, Ohio—The Central Pocahontas Coal Co., of Columbus, Ohio, has been incorporated with a capital stock of $100,000 to mine and deal in coal. Incorporators: J. S. McVey, S. McFadden, J. W. Miller, E. Bragunier and D. N. Postelwaite.

Phœnix, Ariz.—A charter was granted to the Golden Rescue Mining & Mercantile Co., of Phœnix; to deal in and operate mineral lands, including coal; capital, $1,500,000. Incorporators: W. G. Johnson, J. A. Jacoby, C. S. Norman and R. S. Watkins.

Phœnix, Ariz.—A charter has been granted to the Antelope Gold Placer Mining Co.; deal in and operate coal and other mineral lands in addition to gold; capital, $250,000. Incorporators: John L. Uhlik, of Octave, Ariz.; C. C. Castle, of Octave, and C. W. Trasey, of Octave.

INDUSTRIAL NEWS

New Albany, Ind.—The C. H. Menden Coal Co., formerly of Evansville, has moved its headquarters to this city.

Grove, Okla.—A bed of coal about 4 ft. across and 6 in. thick has been discovered on the John Kariho farm, 5 miles north of Grove.

Port Arthur, Tex.—Capt. W. W. Tyrrell has purchased an interest in the South Coast Coal and Fertilizer Co. with headquarters at Sabine.

Pittsburg, Kan.—Frank Pierce & Sons, of Sharpsville, have purchased 160 acres of coal land and are now making arrangements to develop the same.

Pine Bluff, Ark.—The Arkansas & Texas Consolidated Ice & Coal Company has disposed of its ice plant, street railway and light plant at Marshall, Tex.

Ashland, Penn.—The Reading Coal & Iron Co. is soon to make an effort to transplant the borough of Gilberton and more than 500 inhabitants from the present site.

Hazleton, Penn.—Many hands will be given employment when N. J. Cuyle & Co. open the new strippings at Laurel Hill for the Lehigh Valley Coal Co., east of this city.

Williamson, W. Va.—It is stated that a tract of 10,000 acres of coal land on Pond Creek, owned by Col. L. E. Tierney, will soon be leased to several well known operators.

Punxsutawney, Penn.—W. G. Wilkins & Co., Westinghouse building, Pittsburgh, have placed orders for the equipment of the power plant of the Sykesville Coal & Coke Co., Sykesville, Penn.

Pittsburgh, Penn.—J. V. Thompson, of Uniontown, has sold a tract of coal land to the Midland Steel Co. for $1,700,000, netting him a profit of nearly $1,000,000. The average price per acre was $800.

Sunbury, Penn.—A prospector has been seeking continuation of the Lykens Valley field, in lower Northumberland County. During the last year his efforts have been rewarded by striking a 5½-ft. seam.

Piedmont, W. Va.—The Franklin Coal Co., at Westernport, has recently filed a petition for receivership, and W. F. Coale, of Cumberland, has been appointed. The company alleges debts of over $16,000.

Welch, W. Va.—It is understood that the works of the U. S. Coal & Coke Co. on Tug River are again in full operation. They were shut down as a result of the car shortage caused by the recent high waters.

Mahaffey, Penn.—The Maderia Hill Coal Co. has purchased a tract of 5000 acres of coal land in the Clover Run district near this place. Operations are to begin at once and a large tipple has already been contracted for.

Freeport, Ill.—E. J. Thorne has been appointed receiver for the Fairbury Coal Mining Co., following a strike by the employees due to unpaid wages. The miners have returned to work pending the action of the receiver.

Hazard, Ky.—It is reported that several prominent coal operators have been making investigations in that vicinity, either with a view to acquiring properties or for the purpose of looking over lands which they already own.

Obersonia, Penn.—A large bed of coal has been discovered at Rocky Ridge, in the new workings of the Possum Hollow Coal & Coke Co. Special arrangements are being made to get the coal on the market. R. W. Jacobs is general manager.

Bluefield, W. Va.—The Boswell Coal Co. has recently been formed at Richlands. Thos. T. Boswell, of Baltimore, is general manager. The company has leased 23,000 acres of coal land on Coal Creek and will make extensive improvements.

Charleston, W. Va.—A tract of several hundred acres of coal land on Slab Fork near Mullens has been leased by Fayette capitalists form the Powell Lusk heirs. It is rumored that great developments will begin at once. This tract carries the famous Pocahontas No. 3 seam.

Pittsburg, Kan.—Mine No. 11 of the Cherokee & Pittsburg Coal Co., which was shut down a little more than a week ago by State Mine Inspector Francis Keegan, is again in operation. The managers have remedied the defects which caused Mr. Keegan to order the mine to be closed. The mine employs about 300 men.

Morgantown, Ky.—The Butler County Coal Co., recently incorporated, proposes immediately to begin development work on a tract of 800 acres, with a daily output of about 50 tons. The officers of the company are: J. A. Watkins, president; G. L. Drury, vice-president, and C. E. Sullivan, secretary, treasurer and manager.

Johnson City, Ill.—The Lake Creek mine, which has been idle for several years, and was recently taken over by a New York Syndicate, representing the Cotton Belt Ry., has been leased by the Consolidated Coal Co., of St. Louis, who are rapidly developing the property with a view to selling the output for railroad purposes.

McAlister, Okla.—W. E. Beatty, president of the Union Coal Mining Co. has given orders to the superintendent to open the company's mine at Adamson. The mine was closed in February for want of orders. Four hundred men will return to work and a long run is in prospect. This is one of the largest mines in the McAlister district.

Pittsburgh, Penn.—A special meeting of the stockholders of the Westmoreland Coal Co. has been called for June 16 for the purpose of voting on the proposition to increase the capital stock of the company by $1,000,000. The proceeds of the issue will be used to purchase new coal lands. This move would bring the capital up to $6,000,000.

Columbus, Ohio—Coal men in Columbus have received word that insurance on lake vessels is now in force and a good lake movement is expected from this time on. A number of vessels had been loaded before the formal opening of navigation and these moved as soon as word was received from the upper lake regions that the ice was melted.

Buffalo, N. Y.—The Noble-Williams Coal Co. has bought the property of the Outlook Coal Co., of Lackawanna County, Penn., consisting of 790 acres of partly developed anthracite land. The company proposes to mine about 300 tons of coal a day. It is controlledd by the Frank William & Co., which operates three bituminous mines in the Allegheny Valley.

Scranton, Penn.—T. P. Lewis, of Throop, has struck a 5-ft. vein of coal on a tract lying between Marshwood and the Mossic Mountain, and expects to open up one of the richest coal fields that has been discovered in this region in years. Mr. Lewis, who is foreman for the Pancoast company, owns 438 acres in that vicinity. The first seam was struck at a depth of 110 ft.

Johnstown, Penn.—The new drift at Rummel has recently sent out its first shipment of coal. The original Rummel drift was exhausted not long ago. Shortly before this, however, work was commenced on a trestle from the old hill mine to another hill across the valley. Coal is now brought from the new mine over the trestle and through the old drift to the tipple.

Pottsville, Penn.—An outcrop of virgin coal has been discovered on the property of S. A. Hogan by workmen who were excavating for a cellar. The seam measures 15 ft. in thickness and is of good quality. It will, however, be impossible to work the coal for market purposes, owing to the fact that it lies so close to the surface and in the residential section of the city.

McKeesport, Penn.—It is reported that the upper or Sewickley seam of coal, which is located 80 ft. above the Pittsburgh seam, has been discovered and opened up in North Versailles Township. This coal covers an area of several hundred acres and is easily accessible because of improved roads. It is said that the G. M. Cypher Co. is contemplating opening up this new field and operating it on an extensive scale.

Beaver Dam, Wis.—It is reported that a large coke plant is soon to locate at Mayville. The new plant will furnish employment for about 600 men most of whom will live in houses erected by the company. It is said that several furnaces will be built near the ore mines and that the gas obtained in the coke manufacture will be utilized in smelting the ore. The Mayville Coke & Gas Co. is behind the venture.

Springfield, Ohio—The Ohio Southern R.R., from Lima to Wellston, was sold recently to Henry J. Schumacher and Daniel I. Murray, representing the Central Trust Co., of New York, first-mortgage bond holders, at the upset price of $1,550,000.

The sale of the D. T. & I. from Lima north and from Wellston to Ironton was postponed to June 24, in view of the fact that there were no bids presented.

Winchester, Ky.—The Broadhead-Garrett Co. recently closed a deal for 3000 acres of Perry County coal and timber land. The tract is one of the largest undeveloped pieces of land in that part of the state, and has been sought by many investors and working companies. The consideration is said to have been in the neighborhood of $500,000. Green Garrett, of Winchester, a member of the Kentucky Railroad Commission, is president of the purchasing company.

Belleville, Ill.—Mine No. 2 of the St. Louis & O'Fallon Coal Co., at Nigger Hollow, claims the state record for the output of coal. One day recently the output of this mine was 4112 tons in six hours and fifty minutes, or 600 tons per hour. The previous state record was 4500 tons for eight and one-half hours, or 529 tons per hour. This mine uses the H. & H. automatic self-dumping cages, manufactured by the Herzler & Henniger Machine Works, Belleville, Ill.

Columbus, Ohio—The rumor that the Jeffrey Manufacturing Co., of Columbus, Ohio, is contemplating consolidation with another large concern in its line of manufacture and the removal of the larger part of the plant from Columbus has been emphatically denied recently by R. H. Jeffrey, vice-president of the concern. He says the plant will continue to operate in Columbus and, except for a slight modification of the system of the plant, there has been no particular change in the policy of the company.

DuQuoin, Ill.—The Central Illinois Utilities Co., a subsidiary of the Commonwealth Co. of Chicago, has taken over a large number of lighting plants in the Southern Illinois coal field. It is understood that it is the intention to operate them in connection with a new gas company which will have a monster plant at Marion. The gas will be made from Carterville coal with a purifier, and will be pumped to surrounding towns to the extent of 30 miles. The proposed plant will produce a big tonnage of domestic coke.

Welch, W. Va.—It is understood that the Berwind-White Coal Co. has made an offer to purchase the property and holdings of the Jed Coal & Coke Co. at a consideration of $300,000. This property has been in the hands of a receiver for the last year. The property consists of a shaft mine of Pocahontas No. 3 coal and is a part of a lease from the Pocahontas Coal & Coke Co. and the Bouvier-Iaeger Coal Land Co. The mines are adjacent to the U. S. Coal & Coke Co. The Berwind-White people expect to spend in the neighborhood of $200,000 on improvements.

Fort Smith, Ark.—A $2,000,000 deal has been consummated here whereby every mine in the Spadra field, with the exception of the Pennsylvania Mining Co., has become the property of a party of New York capitalists who are said to be closely allied with some of the railroads that traverse the Spadra field. Thirty-two mines are involved, together with 1800 miners. The purpose of the consolidation, it is understood, is to overcome the winter car shortage. Immense storage yards will be built in St. Louis, Kansas City, Little Rock and other points for summer shipments, leaving the cars available in the winter time for the scattered country trade. This will permit the operation of the mines in the summer months, which has never been done with any success in the past.

St. Louis, Mo.—All the property of the Southern Coal & Mining Co., in St. Louis and Illinois, including its several mines on the Southern Ry., has been acquired by the Southern Coal, Coke & Mining Co., with practically the same officers of the company holding these properties previously. The new company is a reorganization of the old company.

In a suit against the Watson Coal Co., of Herrin, Ill., for $29,000, for alleged damages, etc., the Mississippi Valley Fuel Co., of St. Louis, endeavored to tie up $29,000 worth of property of the Devoy & Kuhn Coal Co., claiming that Devoy & Kuhn were indebted for a large amount to the Watson Coal Co. for coal shipped under a contract.

In connection with this, the Watson Coal Co., in March, was given a judgment in the U. S. Supreme Court of about $14,000 against the Mississippi Valley Fuel Co., in a breach of contract suit.

COAL TRADE REVIEWS

GENERAL REVIEW

While the hard-coal dealers are fairly busy, they are not by any means as crowded as is usually the case at this time; as a rule they are having no difficulty in filling all requisitions, although there is coal going into storage. The situation in the wholesale trade is somewhat stronger and the originating companies as a rule are declining to commit themselves for any further deliveries at April prices; indications are that May will also be nearly as active in this department as April has been. It is becoming evident that the individuals are not cutting prices to the extent that was anticipated; this may be accounted for, however, by the fact that many of them have sold their entire summer production at the April circular.

The West Virginia labor trouble still continues to be the controlling feature in the Eastern Bituminous market. It is evident that there is a great deal of determination on both sides of the controversy, and the probabilities are that Pocahontas and New River shipments will be very materially restricted before long. The movement now is almost entirely on contracts, but as consumers are showing a disposition to take their full allotment it is evident that there is a good strong and consistent consumption. Prices in the New England markets still rule about 15c. above last year's level, but business is slow to close at these figures; consumers do not feel that the advance is justified and think that concessions will be offered later.

The Pittsburgh market developed a great deal of strength during the week due probably to a large unsatisfied demand for Lake coal. There is some shortage of railroad equipments particularly of certain descriptions, but operations are now up to about 75 per cent. capacity; local producers are watching the West Virginia labor difficulty with keen interst as a restriction of the production there will undoubtedly be reflected upon the Pittsburgh market. Conditions in this vicinity are evidently becoming steadily better in spite of the effort on the part of the consumers to depress the market; consumption is so enormous that it is taxing the capacity of the railroads, and it is tentatively conceded that the operators are in controll of the market.

It is now evident that it will be several weeks and possibly months before the movement in Ohio will again be entirely normal. There is still considerable congestion at junction points, but embargoes are being lifted in every direction, and production has probably reached 75 per cent. normal. The tidewater demand out of Hampton Road is light, but coastwise shipments are heavy, and have materially reduced the accumulated supplies; dumping at the piers has been good, and prices firm. In the Southern markets the steam coals are maintaining an unusually strong position hardly to be expected at this period of the year.

In the flood zone in the Middle West railroad yards and terminals are jammed with all kinds of freight, and the roads are making slow headway in the work of restoring conditions. The first shipments for more than three weeks over the Norfork & Western and Chesapeake & Ohio into Chicago, arrived last week. Coal at this latter point continues selling at the circular, but there is evidently a large unsatisfied demand. Screenings are somewhat stronger due to the meager production of domestic grades; prices are quite unstable and fluctuating over a large range.

BOSTON, MASS.

Bituminous—The mine workers' union is apparently confining its efforts to the New River field and is letting other districts alone for the present. A good sized sum of money is reported available for purposes of organization and for supplying necessaries to those who join and are thereby out of employment. There appears to be a good deal of determination on both sides and it is now expected that work at the New River operations will be under severe curtailment from lack of men.

It is too early yet, to say what would be the effect of a general strike in West Virginia on the market; the other fields are capable of a much increased output and unless the troubles in New River develope to serious proportions it may be that the results will be negligible, so far as prices are concerned. Buyers seem not to be disturbed over the outlook, and there is almost no change from a week ago. Sales of Pocahontas and New River are scattering, for the most part, and few contracts are being placed. There are many large orders in New England yet to be closed but purchasers feel that there will be concessions later and that conditions do not warrant higher prices than in 1912.

There has been an awakening of interest in the better grades from Pennsylvania. The differential with Pocahontas and New River is larger than usual and several buyers are experimenting with them in the hope of replacing some of the coal ordinarily taken from West Virginia, via Hampton Roads. Many have already found that certain of the coals from Cambria, Somerset and Clearfield, can be used with excellent results and from now on there is likely to be a better demand for these grades. The movement is good; the dullness early in the month has given way to a fairly strong demand, although prices remain where they were put, in order to induce April shipments.

Water Freights—Barges and large schooners are chartering at 75 to 80c., Hampton Roads to Boston, and while there is a regular demand there is no snap to the business. Steamers that ordinarily load New River, in one or two instances, have lately been diverted into Baltimore to load Georges Creek. On Long Island Sound 40c. to 45c. is the ruling rate from New York.

Anthracite—The cold weather has given an impetus to the retail demand and in some cases the originating companies are declining to commit themselves to the April price on boats entered between now and the end of the month. Broken, stove and pea are in relatively short supply and it looks as if May would prove to be almost as active in anthracite as the month just closing. The bulk of the hard-coal receipts continue to be from Philadelphia.

Current wholesale quotations are about as follows:

Clearfields, f.o.b. mine	$1 00@1.35
Clearfields, f.o.b. Philadelphia	2.25@2.60
Clearfields, f.o.b. New York	2.55@2.90
Cambrias, Somersets, f.o.b. mines	1.25@1.45
Cambrias, Somersets, f.o.b. Philadelphia	2 50@2.70
Cambrias, Somersets, f.o.b. New York	2.80@3.00
Georges Creeks, f.o.b. mine	1 67@1.77
Georges Creeks, f.o.b. Baltimore	2.85@2.95
Pocahontas, New River, f.o.b. Hampton Roads	2 75@2 85
Pocahontas, New River, on cars Boston	3.68@3.90
Pocahontas, New River, on cars Providence	3 58@3.80

NEW YORK

Bituminous—There is some very cheap soft coal being offered in the local spot market, but the volume moving is so small that these low quotations are not of great moment. There is very little demand for prompt coal, but owing to the restrictive measures of the operators there is an equally reduced supply available. Operators are showing every determination to obtain a stable and profitable figure for their product, and in some cases are restricting production entirely to contract requirements. The contracts in the local markets are now all pretty well closed up and this feature of the business has ceased to attract any further interest.

The car supply has been gradually tightening for some time, and was a trifle worse during last week. However, since the mines are not attempting to run full capacity the supply has so far been fully up to requirements. The shortage is ascribed to the large amount of equipment tied up in the flood zone, and it was stated by one company that the distribution for one day last week was only 10 per cent. the requirements. We continue last week's quotations, although there is some coal being offered at less, on the following basis: West Virginia steam, $2.55@2.60; fair grades, Pennsylvanias, $2.65@2.70, good grades of Pennsylvanias, $2.75@2.80; best Miller, Pennsylvania, $3.05@3.15; Georges Creek, $3.25@3.30.

Anthracite—The hard-coal market has developed no new features during the week. The companies have all the orders they can possibly take care of and it is clear they will not be able to fill all the requisitions for April tonnages. They are endeavoring to make as equitable a distribution of the production as possible. The demand is generally insistant on all grades, but is the most urgent on stove and rice, particularly the former.

Production at the mines is heavy, there being few interruptions to work, due to labor troubles or car supply, although there has been some slight delays occasioned by the latter. Toward the end of the week an occasional shortage develops

in the supply of open cars, but the railroads invariably catch up again over the week end so that the shortage has at no time been serious.

The local market is not quotably changed and we continue last week's prices as follows:

	Circular	Individual Lehigh	Individual Scranton
Broken	$4 50	$4.45	$4.50
Egg	4.75	4.70	4.75
Stove	4 75	4 70	4.75
Chestnut	5.00	4.95	5.00
Pea	3 50	3.35@3.45	3.50
Buckwheat	2 75	2.25@2.45	2.50@2.75
Rice	2.25	1.95@2.05	2.25@2.35
Barley	1.75	1.50@1.70	1.60@1.75

PHILADELPHIA, PENN.

There is practically little or no change in the anthracite coal trade in this vicinity. All the dealers seem to be fairly busy, although they report business is not what it should be. Most of them like to have their books crowded with orders, but now they claim they are having little or no difficulty in keeping up with those they are receiving. The demand for egg does not seem to be as brisk as would be desired, although this by no means indicates a general condition; requisitions from other points are absorbing all that is mined. The operations at the mines are still continuing at full time, with little troubles here and there on account of strikes. One of the largest companies had all of its mines tied up for some time, owing to the so called "button" decoration, which the mine workers seem to feel all the men should wear. These troubles, however, seem to be quickly adjusted now. Compared with 1911, which is the only comparison that can be made, inasmuch as the suspension was on at this time last year, all operating companies report that their tonnage is at least on a parity, but they do not look for any records to be broken.

Strange to say, notwithstanding the marked lack of snap to the trade, there does not seem to be as much cutting of prices by the individual operators as has been the case in former years. This has been commented on to some extent, but the explanation may be in the fact, that many of them have closed for almost their entire summer output, at the April circular. One very large operator claims that his tonnage for the next five months has been disposed of, although not indicating at what price such disposition had been made. Taking into consideration the fact that possibly these arrangements are being made, this may possibly explain the lack of cutting at the present time, the trade being perfectly willing to pay the present prices, if assured of obtaining them over such a long period.

The bituminous market is not distinguishing itself by any marked activity. There are consumers enough, but it is difficult to sell them, and they are driving hard bargains. Good grades of coal are holding fairly to quotations, but the medium and fair grades are going begging, in some instances. Contracts are still being held up, and the current movement at the present time is rather to the individual than the contract buyers.

PITTSBURGH, PENN.

Bituminous—The market is very strong. It is claimed that some producers have in the past week secured $1.50 for ¾-in. coal in the lake trade. A heavy business was done after the announcement of season prices, at $1.40 for ¾-in. coal, but it is understood some producers held off from contracting, expecting to do still better. There remains considerable unsatisfied demand in the Lake trade. Mine operations are the best yet this season and represent better than 75 per cent. of full capacity. Car shortage is heard of in some quarters, and flat bottom gondolas are being used in trade which much prefers hopper cars. It is claimed the railroads have not sufficient hopper cars, and some of the operators have been trying lately to make an issue with one of the leading roads, furnishing it coal for its own use in flat bottom cars when the road much prefers the hopper bottoms. Contrary to reports sent out last week from the scene of the trouble, the West Virginia labor difficulties are not settled and some operators in the Pittsburgh district expect production in that state to be curtailed all summer. The market is firm at regular prices, as follows: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in., $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—The market is showing surprising stiffness. While a little coke backed up in the region on account of transportation difficulties growing out of the floods, it seems difficult to find enough coke to resume normal shipments. Trustworthy figures of shipments week before last showed less than 400,000 tons, whereas requirements of blast furnaces involve 425,000 tons at the very least, and it is doubtful whether full shipments were made even last week. There is very little demand for prompt coke, but the market seems strong at $2.25, with very few sellers. As to second-half contracts, there is nothing but opinion, there being no active negotiation, but the operators all insist that nothing can be done under $2.50. Foundry coke remains quotable at $3@3.50 for prompt or contract, these figures referring to standard brands of 72-hr. foundry.

BALTIMORE, MD.

The movement in the local market during the past week was confined almost entirely to contracts, especially in the tidewater business. As compared with last week, there was considerably more contract coal handled over the local piers, and this willingness of the consumers to take their full allotment, has caused a more cheerful feeling in the trade. While operators have been generally optimistic, there has not, as a rule, been anything tangible upon which to base such a feeling, but the increased business during the past week makes them now feel that the dull corner in the trade has been definitely rounded. More contracts have also been renewed at the customary advance.

The small demand in the spot market is ascribed to the heavy stocking early in March, when a protracted cold spell was anticipated. The low grades are quoted in the prompt market as 70 to 80 cents; slack is active, due to a rather sharp demand from cement works in Maryland. The labor situation in the West Virginia field is causing a slight feeling of uncertainty in the local trade. A number of the coke oven plants in the state have been shut down, and will not resume until there is more life in the coke market.

BUFFALO, N. Y.

The bituminous market is quite strong and appears to be gaining in steadiness from week to week in spite of the efforts of the consumers to depress it. The amount of unsold coal is not as large as it was and there would be none at all if everybody believed in the future soundness of business. The consumption is enormous, fairly taxing the railroads to handle it. The outlook is for a continuation of these conditions for an indefinite period.

All effects of the late floods have about disappeared from this section and the railroads running into Ohio are taking care of their business about as usual. The opening of the Lakes has improved the bituminous market, for it was found that there was not tonnage enough to handle the coal stored at various points. Something like the same conditions prevailed in anthracite for the Lake trade; shippers are complaining that when they can get tonnage they are often without coal.

Reports from all points in this bituminous sales-district agree that the demand is very strong. Shippers with a good organization and good coal behind them claim that they are selling a large output at paying prices and the outlook is very much better than it was a year ago. There is a good volume moving under contract and contracting is not concluded yet, but the consumer by no means controls the market, as he has done for so many seasons past. At the same time there is no great profit to anyone.

The Lake season opened here on Apr. 12 by the sailing of one steamer light, for a coal cargo at Toledo She was followed on Apr. 16 by 31 other steamers, mostly coal laden. The upper Lake ports are not open and they may all have to wait. Lake clearances to date include 280,000 tons.

It looked early in the month as if the bituminous market was going to break, so many people were offering coal at cut prices, but Pittsburgh and the largest concerns in the Allegheny Valley held firm and now the others are following suit. Quotations are fairly strong at $2.80 for Pittsburgh lump, $2.65 for three-quarter, $2.25 for mine-run and $2.15 for slack, with Allegheny Valley and Reynoldsville about 25c. less. Coke is stronger on the basis of $5 for best Connellsville foundry. Smithing and other special coals are active, but they seldom vary in price.

COLUMBUS, OHIO

The trade in Ohio shows signs of becoming normal again, since the disastrous floods. Railroads are gradually getting in shape and embargoes are being removed in every direction. There is still considerable congestion at junction points and it will require several weeks and possibly months for traffic to become normal again.

There is a good demand for practically every grade of coal from the Ohio fields. While the domestic demand is gradually running out, still orders are coming in from unexpected sources. The recent flood caused a rush of small domestic orders and all the broken natural gas mains are not yet repaired.

Steam business continues good and in a larger volume as plants are gradually resuming operation again. Prices for steam grades are strong and inclined to advance all along the line. The prospects for the future are believed to be good and producers think that steam business will rule

strong for the coming few months at least. There is also a better demand for railroad fuel as the freight movement increases. Sales managers of many of the Ohio companies are turning their attention to railroad fuel contracts which will be awarded in a short time. Some steam contracts are expiring at this time and prices generally are higher than last year.

Lake trade is also receiving its share of attention. Since insurance on lake vessels is in force, there is much activity in that direction. Movement of cargoes has started and within a short time a large tonnage will be on the way to the Northwest. In fact it is expected that the Lake movement will tax the capacity of the coal carrying roads in the Ohio fields. The demand for tonnage from the Northwest is strong and the season is expected to be a prosperous one.

Production is gradually getting larger. In the Hocking Valley the output during the past week has been about 75 per cent. normal and the same is true of Eastern Ohio. In the Pomeroy Band, where a number of mines were flooded, the production is about 60 per cent. of the average.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1.50	...	$1.50	$1.50
¾-inch	1.35	$1.30	1.35	1.30
Nut	1.25	...	1.25	...
Mine-run	1 15	1.10	1.15	1.10
Nut, pea and slack	1.00	...	1.00	1.00
Coarse slack	0.85	0.90	0.90	0.85

LOUISVILLE, KY.

A continued spell of pleasant weather has reduced the demand for domestic grades and caused a corresponding shortage of screenings, but the steam consumption continues strong. The flood damage to the railroads seems to have been more general than was at first supposed. They are experiencing a great deal of trouble in restoring order and there is still a heavy congestion at the terminal. Belt lines are finding it difficult to move freight owing to the crowded condition of the yards and in some cases to the lack of adequate motive power. While all the roads are now handling traffic, the roadbeds, trestles and bridges are so unsafe that the train movement is considerably handicapped.

However, about the only inconvenience that is being experienced by the consumers is due to the shortage of screenings. Preferences as to quality on screenings are being disregarded because of the shortage; the Western Kentucky variety which usually sells 10 to 20c. off the Eastern Kentucky grade now readily brings 90c. and even higher, while Straight Creek and like qualities sell up to as high as $1.10 f.o.b. mines. Mine-run is rather heavy, operators being glad to obtain $1.25 to $1.35 for Eastern Kentucky grades.

HAMPTON ROADS, VA.

While there has been no heavy demand for coal at tidewater during the past week there have been some large shipments on Coastwise contracts which has considerably decreased the accumulated coal. Prices have remained firm, $2.85 being asked for spot coal. There have been some small shipments of high-volatile coals but there is little demand for this grade. The outlook is that prices will continue firm although the unrest in the New River-Pocahontas fields may have some effect on the market.

Dumpings at the three ports have been good, during the latter part of the week; a large tonnage was handled over the Sewalls Point Piers and it is expected that April dumpings there will run considerably over the March tonnage. It is rumored that one of the large shippers over these piers has acquired land at that point for the erection of a large and modern plant for the storage of steam coal; also that the contract has been let and that work on the plant will be commenced shortly.

Bids have been asked for on Government transport coal but operators have not responded on account of several of the requirements in the contract.

INDIANAPOLIS

Practically all parts of the state can again be reached with coal, although some in a roundabout way. Railroad conditions are far from normal, however, and it will be a month or two yet before that status will be reached. Shipments are still slow on all roads and a week to ten days must be allowed for the usual two to three days movement. Railroad yards at terminal and connecting points are jammed with all kinds of freight, including coal.

Under these conditions operators are not busy. With spring weather prevailing, the consumption of domestic coal has practically ended and the warm sun has cut down the needs of steam users, though, otherwise, the latter trade is about normal for the season. The floods left many of them with matters more pressing to attend to.

Not a car of Eastern coal has come to Indianapolis since the flood, Mar. 25. It is said the C. & O. has 6500 cars in Kentucky and West Virginia, ready to move through Cincinnati but held back because connecting lines in that city have been unable to accept shipments. Temporary bridges are being erected over the rivers in Indiana. The Big Four is only now getting into Chicago over its own lines. Coal prices are at summer level and run about as follows, f.o.b. mines:

No. 4 mine run	$1 10	3-inch domestic lump	$1.45
No. 5 and 6 mine run	1 05	4 and 5-inch	1.55
1½-in. steam lump	1 30	4 screenings	1.00
Nut	1 25	5 and 6 screenings	0.90
Egg	1.35	Brazil block	2.05

The f.o.b. price, Indianapolis, is 50c. higher than the above figures.

BIRMINGHAM, ALA.

The season of the year is here when the steam-coal market suffers most, but a thorough canvass of the various sales offices finds present business and the outlook better than for the past several years at this season. There is of course price cutting on the cheaper steam coals which do not find a ready market except during the period of the year when business is most active. A number of the local producers report heavy bookings of domestic orders, on which shipment is to begin at once, and continue through the entire winter season.

We give below prices of Corona coal for the ensuing season. Corona is one of the Standard coals with the domestic trade.

Month	Fancy Lump
April	$1.80
May	1.85
June	1.90
July	1.95
August	2.00
September	2.15
October to February, inc.	2.25

DETROIT, MICH.

Bituminous—The steam trade at this point is entirely featureless, and as quiet as it has been at any time during the last year. Spot business is confined entirely to small orders for filling out requirements until the new contracts go into effect. The larger buyers who failed to close up early in the season are still holding off, and no important business has been reported during the week.

The prevailing market is about as follows:

	W.Va. Splint	Gas	Hocking	Cambridge	No. 8	Pocahontas	Jackson Hill
Domestic lump	$1.50				....	$2.25	Open
Egg	1.50					2.25	Open
1½-in. lump	1 30					...	..
¾-in. lump	1 15	$1.15	1 20	$1 20	$1.20	....	
Mine-run	0 10	1.10	1 15	1.15	1.15	1.50	
Slack	0.90	0.90	0 90	0.90	0.90	1.25	

Anthracite—There is a light demand for hard coal, and the independent shippers are unable to dispose of much tonnage, with the result that they are cutting the circular prices freely. Egg and stove have been quoted down to $3.20, f.o.b. mines, with chestnut 25c. higher.

Coke—Ovens seem to be working up to a good capacity, but the demand for coke is far from strong. Connellsville is quoted at $2.75.

CHICAGO

Chicago coal dealers were agreeably surprised this week when shipments of coal via the Norfolk & Western and the Chesapeake & Ohio R.R. were received. These shipments included smokeless mine-run and they had been in transit for nearly three weeks. What little coal there is in Chicago is selling at circular prices. According to dealers, the market will absorb a large amount of coal as soon as shipments are heavier.

Prevailing prices in Chicago are:

	Springfield	Franklin Co.	Clinton	W. Va.
Domestic lump	$2 07	$2.40	$2 27	
Egg		2 40		$3.95
Steam lump	$1 82@1 87		2 17	
Mine-run	1 82@1 87	2.20@2 30	1 97	3.30
Screenings	1 62	1 95@2 00	1 62	

Coke—Connellsville and Wise County, $6@6.25; byproduct, egg, stove and nut, $4.45@4.75; gas house, $4.65@4.75.

ST. LOUIS, MO.

Screenings have been about the only coal on which there has been a change in price during the past week; Carterville screenings have gone as high $1, but the market is unsteady and they are liable to fall off to 80c. one day and be back to 95c. the next. Standard screenings are selling anywhere from 75c. to 80 and 85c., with a steady demand that is hard to supply, for the reason that there is no call for the screened domestic coal.

Carterville fell off to its lowest point during the past week, when it was offered for 95c. at the mines, for lump and egg. It is being quoted to large consumers at from $1 to $1.05, and mine-run as low as 95c. An order for 125 cars, lump, egg and nut, for immediate shipment, received quotations on all sizes at from 97½c. to $1.15.

The anthracite price cutting war still continues; one company is now selling to the retail trade at 25c. under the price that the first company made, when they announced a cut. If these people are paying the circular price they are delivering the coal without compensation for delivery. Even at that it is hard to move anthracite, on account of the poor preparation that a large tonnage has shown in this season's shipments.

There is no demand at all for smokeless, and likewise coke. The prevailing market is as follows:

	Carterville and Franklin Co.	Big Muddy	Mt. Olive	Standard
2-in. lump				$0.90
3-in. lump			$1 20	
6-in. lump	$1.15 @ 1.20		1 25	1.05
Lump and egg		$2 25		
No. 1 nut	1.05 @ 1.15			
Screenings	0.90 @ 0.95			0.85
Mine-run	1.00 @ 1.10			0.80
No. 1 washed nut	1.35			
No. 2 washed nut	1.35			
No. 3 washed nut	1.35			
No. 4 washed nut	1.35			
No. 5 washed nut	1.10			

MINNEAPOLIS—ST. PAUL

The trade in the Twin Cities and the Northwest is without any particular interest at this time. April so far has been very dull and were it not for the fact that the contract period is here business would be extremely slow. While some industrial plants are very reluctant about tieing up on contracts at this time, coal men generally predict a good summer in steam business. There is considerable spot coal to be had which is given as a reason for the holding off of some plants in signing up contracts. Wholesalers appreciate the fact that labor troubles in some fields are liable to develope and are making allowances for same in case of writing contracts over a years time.

OGDEN, UTAH

It has been customary at this time, for a number of years, for the Union Pacific, and Oregon Short Line Railroads to announce a reduction of 25c. per ton in the freight rate on lump and nut coal to take effect either May 1 or June 1 and continue for 90 days. This automatically establishes what is known as a storage period and the mine operators have coöperated with the railroad by announcing a reduction on coal for shipment during this time; this reduction, varies from 25c. to 50c. and in connection with the 25c. in freight rate makes a difference of from 50c. to 75c. to the dealer. As a change in tariff must be published thirty days before it becomes effective, it is evident that the storage period will not commence on May 1 this year, as no notices have so far been received.

PRODUCTION AND TRANSPORTATION STATISTICS

IMPORTS AND EXPORTS

The following is a comparative statement of imports and exports in the United States for February, 1912-13, and for the eight months ending February, 1911-12-13, in long tons:

	8 Months			February	
Imports from:	1911	1912	1913	1912	1913
United Kingdom	12,005	5,861	7,355	217	137
Canada	1,115,655	625,238	954,363	111,669	110,401
Japan	6,313	7,307	42,217	250	12,213
Australia & Tasmania	206,765	149,396	107,017	6,256	8,709
Other countries	4,709	1,444	3,257	529	2,809
Total	1,345,447	789,246	1,114,209	118,921	134,269
Exports:					
Anthracite	1,911,812	2,301,177	3,224,604	231,684	361,493
Bituminous.					
Canada	5,586,404	7,175,621	7,559,065	396,004	556,190
Panama	348,342	303,019	307,759	52,746	38,000
Mexico	438,853	211,374	206,908	26,072	51,692
Cuba	602,174	712,451	805,162	74,419	98,386
West Indies	340,823	442,694	402,705	67,074	73,269
Other countries	391,171	519,057	642,367	79,340	79,253
Total	7,714,367	9,664,216	9,923,966	695,655	896,790
Bunker coal	4,189,020	4,453,131	4,794,912	530,272	564,222

PENNSYLVANIA RAILROAD

The following is a statement of shipments over the P. R.R. Co.'s lines east of Pittsburgh and Erie for March, and first three months of this year and last year in short tons:

	March		Three Months	
	1913	1912	1913	1912
Anthracite	741,209	1,140,976	2,743,504	3,288,737
Bituminous	4,050,247	4,501,653	12,117,747	12,169,935
Coke	1,247,451	1,147,602	3,756,325	3,111,786
	6,038,907	6,780,231	18,617,576	18,570,458

FOREIGN MARKETS

GREAT BRITAIN

Apr. 11.—Strong conditions rule in all branches of the steam-coal trade, but new business for early shipments is considerably restricted owing to the heavy commitments already undertaken by the various collieries. For forward loading the inquiry is good.

The possibility of "nonunionist" strikes on a large scale at the end of this month is causing some anxiety.

Quotations are approximately as follows:

Best Welsh steam	$5.04	Best Monmouthshires	$4.50@4.60
Best seconds	4 80@4.92	Seconds	4.32
Seconds	4.56@4 80	Best Cardiff smalls	3.88
Best dry coals	4.56@4 80	Seconds	3.64

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days—less 2½%.

British Exports—The following is a comparative statement of British exports for March, and the first three months of the last three years, in long tons:

	March		3 Months		
	1911	1913	1911	1912	1913
Anthracite	110,805	216,151	597,551	558,004	701,516
Steam	1,104,644	4,144,761	11,054,747	9,046,223	12,609,068
Gas	208,527	833,547	2,442,009	1,938,998	2,610,246
Household	34,331	141,867	368,444	299,234	435,454
Other sorts	78,606	262,448	738,601	630,613	882,725
Total	1,536,913	5,598,774	15,201,352	12,473,072	17,239,009
Coke	55,083	76,340	251,671	277,123	282,190
Manufactured fuel	63,149	156,210	425,246	373,332	507,202
Grand total	1,655,145	5,831,324	15,878,269	13,123,527	18,028,401

COAL SECURITIES

The following table gives the range of various active coal securities and dividends paid during the week ending Apr. 19:

Stocks	Week's Range High	Low	Last	Year's Range High	Low
American Coal Products	87	87	87	87	87
American Coal Products Pref	109½	109½	109½	109½	109½

DIVIDENDS

Reading Co.—First Preferred—Regular quarterly of 1%, payable June 12 to holders of record May 27.

New Central Coal Co.—Dividend of 2%, payable May 1 to holders of record Apr. 28.

INDEX OF COAL LITERATURE

We will furnish a copy of any article (if in print) in the original language for the price quoted. Where no price is quoted, the cost is unknown. Inasmuch as the papers must be ordered from the publishers, there will be some delay for foreign papers. Remittance must be sent with order.

GENERAL

Study of the Coal and Carbonization Residues. (Zur Kenntnis der Kohlen und Verkohlungsrückstände). E. Donath and E. Bräunlich. (Reprint from Chemiker-Zeitung, No. 41, 1912.) "Oesterr. Z. Berg-Hüttenwes." Feb. 22, 1913, 5 pp. 40c.

Coal Area of South as Compared with Europe. Edward W. Parker. "Mfrs. Rec." Mar. 27, 1913, 2 pp. 25c.

South African Coal Resources. (From Report of Geol. Survey of So. Africa.) "Iron Coal Trades Rev.," Mar. 7, 1913, p. 372. 40c.

The Coal Trade of Nova Scotia in 1912. F. W. Gray. "Can. Min. Jl.," Jan. 1, 1913, pp.39-43; ill. 25c.

Mining Progress in the Transvaal in 1912. "Min. Eng. World," Apr. 5, 1913, pp. 673-4. 20c.

Principles of Mine Valuation. (Lecture in Dept. of Min., Col. Univ., Dec. 2, 1912.) Jas. R. Finlay. "Coal & Coke Op.," Mar. 20, 1913, pp. 203-5. 20c.

Labor in the Mines of Western America. H. F. Davis. "M. & S. P.," Feb. 1, 1913, pp. 210-13. 20c.

Difficulties in Mine Surveying. H. G. Henderson. "Mines & Minerals," Feb., 1913, pp. 359-60, ill. 40c.

Amortizing and Interest Charges for Coal Mines. L. C. Jones. "Coll. Engr.," Mar., 1913,, pp. 415-8. 40c.

Coal Reserves of Hungary. (Die Steinkohlenvorräte Ungarns.) K. v. Papp. "Montan. Rdsch.," Jan. 16, 1913, pp. 62-5. 40c.

Construction of Buildings to Avoid Damage by Mines. (Ueber die Durchbildung von Bauten zur Verhütung von Bergschäden). Elwitz. "Glückauf," Feb. 22, 1913, pp. 278-87; ill. 40c.

WORKING OF MINERALS

Longwall Work and the Use of Electrical Coal Cutters at the Grand-Hornu Colliery, Belgium. (Travail par Longues Tailles et Emploi des Haveuses Electriques au Charbonnage du Grand-Hornu.) C. Niederau. "Ann. Mines Belgique," 1913, pp. 112-20, ill.

The Development of New Colliery Districts, with Special Reference to the Support of the Surface. Hubert Bradshaw. "Iron Coal Trades Rev.," Mar. 14, 1913, p 417. 40c.

Moving Minerals in Thin Flat Beds. "Mines & Minerals," Jan., 1913, pp. 310-2, ill. 40c.

Mining Steep Dipping Coal. A. A. Steel. "Mines & Minerals," Jan., 1913, pp. 301-3, ill. 40c.

The Hydraulic Stowing of Goaves. Geo. Knox. (From paper read before a recent meeting of the Manchester Mining & Geological Soc.) "Min. Eng.," Feb., 1913, pp. 7-10, ill. 30c.

Mechanical Effects of Mine Working upon the Behavior of the Rock. (Die Mechanischen Einwirkungen des Abbaues auf das Verhalten des Gebirges.) A. Eckardt. "Glückauf," Mar. 8 and 15, 1913, 16 pp., ill. 80c.

How a Coal Company Gets Down to the Coal. (Brief description of method followed in opening new coal mine.) "Fuel Mag.," Mar. 19, 1913, pp. 19-20; ill. 20c.

GEOLOGY

On the Arsa Coal of Carpano in Istria. (Ueber die Arsakohle von Carpano in Istrien.) E. Donath and A. Indra. (Determination of its nature.) "Oesterr. Z. Berg.- Hüttenwes," Feb. 1 and 8, 1913, 4 pp. 80c.

Study of the Borings of Waudrez and Harmignies. (Etude des sondages de Waudrez et d'Harmignies.) O. Karapétian. (Geological Engineer's thesis at the Hainaut School of Mines.) "Rev. Univ. Mines," Liége, Belgium, Dec., 1912, pp. 230-77.

French Coalfields. Roy Ronald. "Min. Eng.," Jan., 1913, pp. 250-1. 30c.

Coal Reserves of the Rhenish-Westphalian District. (Die Kohlenvorräte des rechtsrheinisch-westfälischen Steinkohlenbezirks.) Kukkuk & Mintrop. "Glückauf," Jan. 4, 1913, pp. 1-13, diagram and map. 40c.

BLASTING, EXPLOSIVES

Development and State of the Modern Explosives Industry. (Entwicklung und Stand der Mondernen Sprengstoffindustrie). P. Loeffler. "Montan. Rdsch.," Mar. 1, 1913, pp. 193-97. 40c.

Blasting Coal on to Pans. "Mines & Minerals," Feb., 1913, p. 382, ill. 40c.

Latest Improved Mine Fuse. Schaffler electric fuse. (Neuester vervollkommneter Minenzünder.) "Z. d. Zen.-V. d. Bergbau-Betr.," Mar. 1, 1913, pp. 146-7, ill. 40c.

Correct Shot Firing. Compares electrical and time fuse methods. (Ueber rationalles Schusszünden.) T. Blum. "Montan. Rdsch.," Jan. 16, 1913, pp. 58-61, illus. 40c.

The Use of Explosives in Coal Mines. F. H. Gunsolus. "Coll. Engr.," Mar., 1913, pp. 459-60, ill. 40c.

STEAM ENGINES AND BOILERS

The Braking of High-Speed Winding Engines. G. K. Chambers. "Coll. Guard.," Jan. 17, 1913, p. 121-24; ill. 40c.

Discussion of Machinery in Uptodate Plants at Mines. (Allgemeine Betrachtungen über neuzeitige Maschinenanlagen des Bergbaues.) F. Koneczny. "Montan. Rdsch.," Feb. 1, 1913, pp. 106-8. 40c.

Simply Flywheel Calculations. Chas. W. Beers. "Coal Age," Mar. 29, 1913; pp. 478-80. 20c.

Advantages of Poor Gases for Industrial Firing. (Des Avantages qui se Rattachent à l'Emploi des Gaz Pauvres comme Combustibles pour le Chauffage Industriel.) P. Cousin. "Revue Noire," Jan. 12, 19, 26, and Feb. 2, 1913, 5 pp.

CO_2 Diagrams from Actual Practice. A. Bement. "Power," Mar. 25, 1913, pp. 409-11; ill. 15c.

The Rational Utilization of Coal. F. E. Junge. "Power," Apr. 1, 1913, pp. 445-47; ill. 15.

TIMBERING, PACKING, ETC.

Use of Timber for Mining Purposes. (Verwendung des Holzes zu Grubenzwecken.) Neumann. "Z. d. Oberschl. Berg u. Hüttenmänn. V.," February, 1913, 2 pp. 40c.

The Relation of Forestry to Coal Mining. H. A. Williamson. "Fuel Mag.," Jan. 8, 1913, pp. 21-2. 20c.

HOISTING AND HAULAGE

Standard Dimensions of Mine Rails, Ruhr District. (Einheitliche Abmessungen von Grubenschienen.) "Glückauf.," Mar. 8, 1913, pp. 364-5; 3 tables. 40c.

Diamond Crossovers for Shaft Bottoms. H. D. Easton. "Coal Age," Mar. 8, 1913, pp. 375-6; ill. 20c.

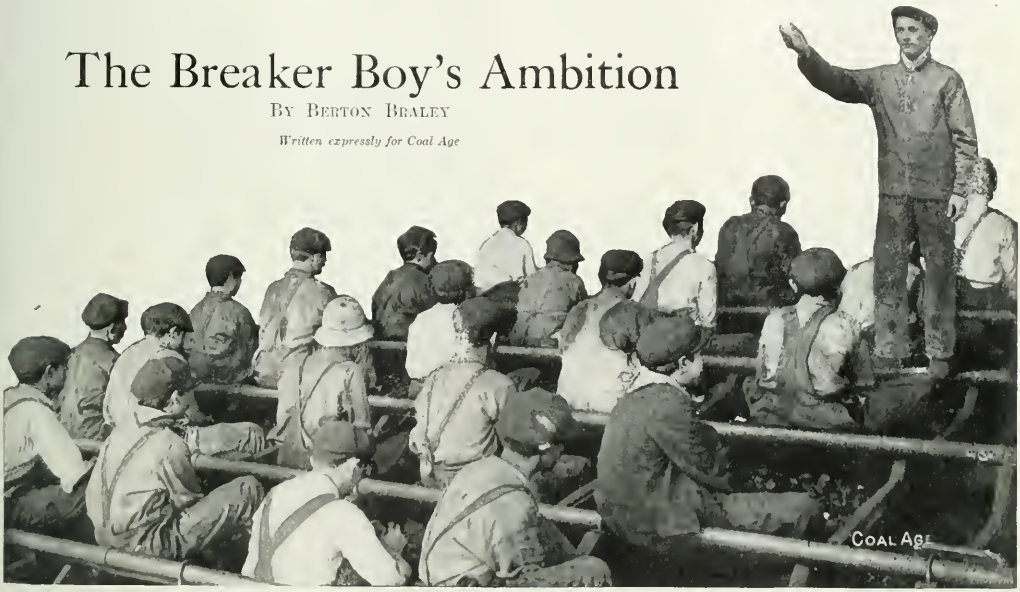
COAL AGE

Vol. 3 NEW YORK, MAY 3, 1913 No. 18

The Breaker Boy's Ambition

By Berton Braley

Written expressly for Coal Age



I'm pickin' slate in the breaker
And it isn't no fun, you bet,
Fer the dust is strong an' the shift is long
An' I'm covered with dirt an' sweat,
But I'm hopin' when I get older,
(An' I reckon of course I will)
I kin shake this mob on the breaker job
An' handle a ratchet drill.

I'm pickin' slate in the breaker,
But thinkin' of by an' by,
When I reach the age I kin ride the cage
Like a regular miner guy,
Go down with the gang of mornin's—
Say, wouldn't that strike me fine!
It's me dearest dream to work in the seam
Of an honest-to-goodness mine.

I'm pickin' slate in the breaker,
But after a while I'll be,
Way down below where the miners go
A miner—you bet, that's me!
With a light above me forehead
An' a steel drill in me hand,
I'll be too proud fer this breaker crowd,
I'm gonna be something grand!

I'm pickin' slate in the breaker
But it ain't the place I'll stay
I'm gonna be found way underground
A-drawin' a miner's pay,
An' takin' a miner's chances
(An' plenty of *them* there be)
It's me for the hole where they dig the coal,
A miner—you bet—that's Me!

A Combined Screening and Picking Table

By Frank E. Mueller*

SYNOPSIS—Probably every coal engineer has at one time felt the necessity of a combination arrangement, whereby the coal would be simultaneously screened and cleaned, and it is rather surprising that a successful arrangement for accomplishing this has never before been evolved. The device here described seems to have met the test of hard practical usage in foreign mines for a number of years and has also been advantageously applied in West Virginia.

The Pocahontas field of West Virginia has, among its various collieries, more picking, screening and washing plants than any other bituminous coal section of the United States. As each year passes, additional requirements are given the designers and builders of tipples in this section, due to the increasing demand for cleaner and better-sized coal. This demand includes shaking screens and picking tables for the larger grades of coal, such as nut, egg, and lump, and for washeries for improving the screenings.

Fig. 1. General View of the Carter Coal Co.'s Plant at Coalwood, W. Va.

The "Marcus" System in West Virginia

Great care must be exercised in the design of a tipple for this field because the Pocahontas coal, as everyone knows, breaks up very easily. It must be handled as little as possible, the screening, picking and other machinery being arranged to give the minimum breakage and at the same time be as effective as possible.

The common procedure in an ordinary screening and picking installation is to introduce a shaker screen with, say, 2-in. perforations. The coal passes over this screen onto the picking table, and is then discharged directly into railroad cars or a lowering boom. The slack from the screens passes directly to a washery, if there is one, or is conveyed to the end of the picking table to be mixed back with the picked lump coal in making picked run-of-mine; or it may be discharged directly into railroad cars.

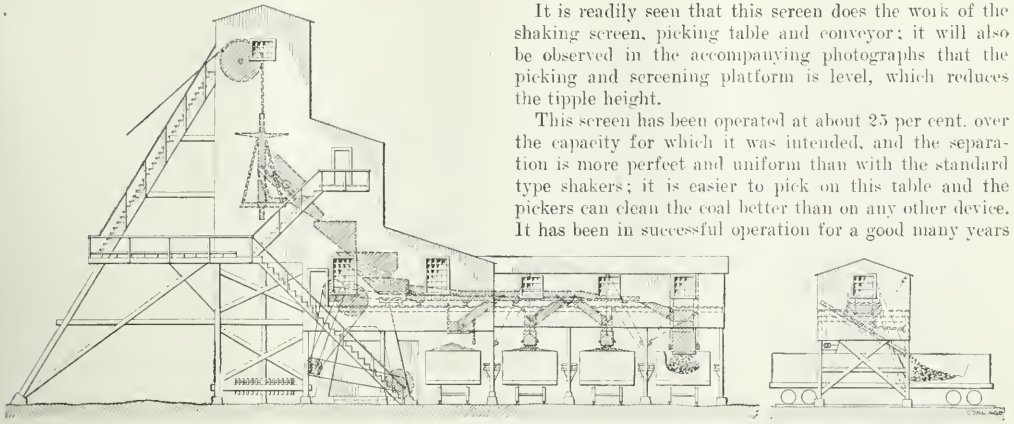
It is readily observed that a simple installation of this kind requires three units, which not only necessitates a large amount of machinery, but increased power, additional tipple height, greater attention and more maintenance, and, worst of all, a further handling of the coal, causing breakage or slack.

To overcome all these difficulties, the Carter Coal Co., at Coalwood, W. Va., have recently put into successful operation a new tipple, embodying the new "Marcus" combination screen and picking table, a brief description of the plant being as follows:

The coal, as shown in Fig. 1, is brought around the hillside to the dump house, where it is fed automatically onto a retarding conveyor, which delivers it to the "Marcus" combination screen and picking table. This screen, as shown in Fig. 2, is horizontal and comprises two decks. The upper deck, for the first 14 ft., is fitted with the 1½x2½-in. perforations; the balance of the screen, except a small portion at the end for rescreening, is comprised of a dead plate. The lower deck consists of a dead plate and simply serves the purpose of carrying the slack coal forward.

Fig. 2. Combined Screen and Picking Table

*Contract engineer, Roberts & Schaefer Co., Chicago, Ill.



It is readily seen that this screen does the work of the shaking screen, picking table and conveyor; it will also be observed in the accompanying photographs that the picking and screening platform is level, which reduces the tipple height.

This screen has been operated at about 25 per cent. over the capacity for which it was intended, and the separation is more perfect and uniform than with the standard type shakers; it is easier to pick on this table and the pickers can clean the coal better than on any other device. It has been in successful operation for a good many years

FIG. 3. THE MARION COUNTY COAL CO.'S FOUR-TRACK TIPPLE EQUIPPED WITH THE COMBINED SCREEN AND PICKING TABLE

COMBINATION SCREENING AND PICKING

This horizontal screen is given a peculiar to-and-fro motion, which effects a perfect screening of the coal, and at the same time moves forward that which has passed over the perforated plate so that it can be readily picked.

When the coal is received on the "Marcus" screen from the retarding conveyor above mentioned, the slack is removed at once, dropping below onto the horizontal dead plate. The nut, egg and lump remaining on the perforations, pass on over the dead plate, where they are picked, and then discharged directly onto a loading boom and loaded as lump coal; or they can be mixed again with the slack coal, which has also been brought forward on the lower deck, and shipped as run-of-mine. Gates have been provided in the lower deck for loading the slack on a separate track when picked lump is being prepared.

in England, Germany, Canada and other countries, and has just been introduced in the United States by the Roberts & Schaefer Co., of Chicago, Ill., who own the rights.

AN ILLINOIS INSTALLATION

The simplicity of the device and its method of installation, is shown in Fig. 3, which is the remodeled tipple of the Marion County Coal Co., at Centralia, Ill. This company originally had a three-track shaker-screen tipple, making lump, egg and screenings, a common form of tipple in use in Illinois. Within the past year, however, operators have considered the necessity of better preparing the lump and egg sizes which heretofore have been picked on the railroad cars. The installation of picking tables is now being considered and the Marion County Coal Co.

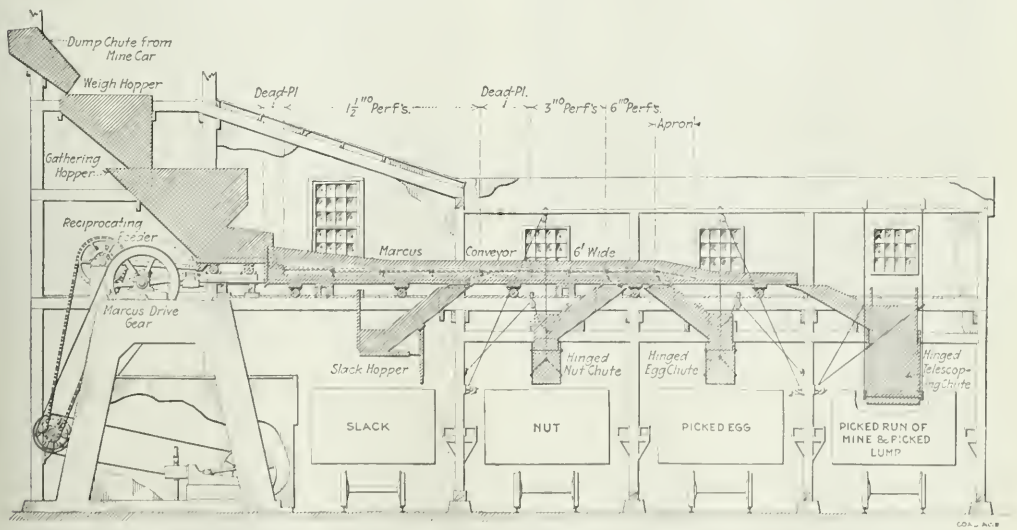


FIG. 4. AN ENLARGED VIEW OF THE "MARCUS" SCREENING ARRANGEMENT ON THE MARION COUNTY COAL CO.'S TIPPLE

is one of the first in Illinois to adopt this method in their tipple. After having carefully made an inspection of the "Marcus" installation at Coalwood, W. Va., they decided to rebuild their present three-track shaker-screen tipple, making it into a four-track plant. This could be accomplished by introducing the "Marcus" system, which also gave them the benefit of picking the lump and egg before it was discharged into the railroad cars.

The simplicity with which this device could be installed in the old tipple is readily apparent by observing Fig. 3. No change has been made in the arrangement of cages, sheave wheels, dump chutes or weigh hopper; in fact, there was sufficient height to install the screen between the bottom of the weigh hopper and the tracks, and also provide a reciprocating feeder. The coal from the self-dumping cages is discharged into a weigh hopper and then deposited in the small dump hopper, from which it is fed uniformly, by means of the reciprocating feeder onto the screen, the following sizes being prepared:

Lump over 6-in. perforation.
Egg over 3-in. perforation, through 6-in. perforation.
Nut over 1½-in. perforation, through 3-in. perforation.
Screenings through 1½-in. perforation.

The lump and egg is picked on the upper deck and by means of the valves shown, delivered to the railroad cars through the hinged and telescoping chutes; or by closing the valves, picked run-of-mine coal can be loaded on the outside track. Fig. 4 shows in an enlarged detail the arrangement.

This device has met with such favor abroad, in Canada, and in West Virginia, that the operators in this country will, no doubt, investigate it carefully, not only because of its better screening and cleaning possibilities, but owing to the fact that it eliminates the moving machinery that is necessary with screens, picking tables, and conveyors. At the same time it gives a cheaper tipple, due to its low cost, low power, maintenance and low cost of operation. Obviously a more effective cleaning can be done where the coal is handled in this way.

Coal Preparation in Eastern Kentucky

SYNOPSIS—Coal is here prepared for market in four sizes. Gravity screens, shaker screens, knocker screens, picking bands and loading booms are all used to secure effective separation and prevent degradation of lumps.

The VanLear mines, four in number, located on the Big Sandy division of the Chesapeake & Ohio R.R. in the newly developed coal field of eastern Kentucky and belonging to the Consolidation Coal Co., are worthy of more than casual notice, both on account of the machinery installed and the quality of the coal itself. This is a slabby lump bituminous, but quite hard and brittle, semi-anthracite in nature.

View along the Picking Band

The End of the Loading Boom

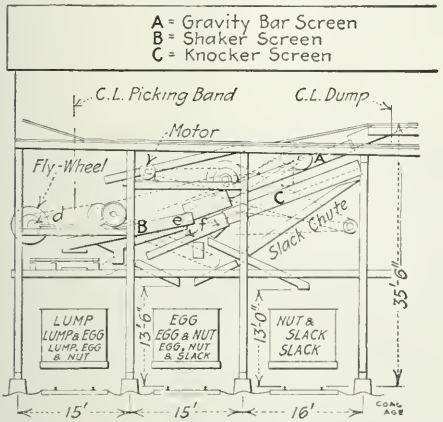
Before shipping this coal to market it is screened into four grades, the larger sizes being loaded so as to avoid as much as possible any breakage, and the utmost care is exercised in its preparation. Each of the four mines above mentioned is equipped with an extensive plant built by the Fairmont Mining Machinery Co. All conform closely to the one described and illustrated below.

The coal is first dumped from the mine cars and passes over a 3-in. gravity bar screen, set on a slope of 21 deg. On account of the large size and the flatness of some of the lumps, some fine coal tends to ride upon the larger pieces. This is dislodged by a drop of about 12 in. at the foot of the screen, which causes the lumps to either turn over or tilt. A shaker screen *B* then receives the coal, making a final separation of the lumps from the smaller sizes.

This screen is 5 ft. wide and 17 ft. long over all, the bottom being perforated with 3-in. diameter holes for 12 ft. of its length. It is set on a slope of 12 deg. and

driven by eccentrics and eccentric rods with 6 in. of a throw, the shaft making 100 r.p.m. From the shaker the clean lump coal passes onto the picking band.

The screenings from the shaker are caught in a pan attached underneath it and deflected to one side into a conveyor. This is of the scraper type set on a 32-deg. slope with a single strand of welded-steel link chain and flights 12 in. long by 8 in. deep curved slightly forward on the bottom, suspended at intervals. This conveyor delivers the screenings to the knocker screen *C* located directly below the bar screen *A*. Here the screenings from the shaker mingle with those from the gravity bar screen and pass over the knocker screens together.



Section of Screening Plant, Showing Screen Arrangement

The knocker screen *C* is pivoted at the upper end and raised at the lower end by means of offset cams on a shaft at the rate of 200 elevations per minute. The rise of the cams is 1½ in. and the return blow of the screen is taken by stout wood blocks. This screen is set on a slope of 21 deg. It is made in two decks, the bottom of the upper deck being perforated with 2½x1½-in. holes, the lower deck with ½x1¼-in. slots.

The egg coal which passes over may be dropped through a fly at *E* into a conveyor of similar construction to that previously described and elevated to the picking band, there mingling with the lump coal, or it may be loaded on track No. 2. The nut coal may either be thrown in with the egg or passed through a fly at *F* and loaded as shown.

The picking band is 3 ft. 6 in. wide, mounted on 12-in. pitch chain with 5-in. rollers every foot. It moves at a speed of 10 ft. per min. The horizontal portion of the band is 18 ft. long, allowing ample space for pickers to remove any slate from the coal.

To avoid dropping the coal into the cars a loading boom is provided, which consists of a structural-steel frame pivoted at the upper end and adjustable at the lower, and carrying guides for the picking band.

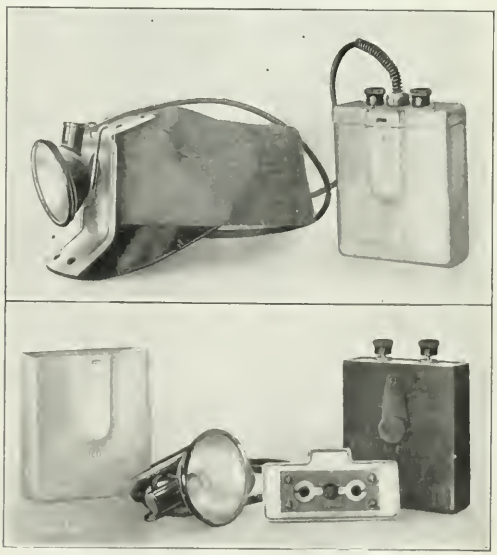
The lump coal, after leaving the shaker screen, is carried by the band and loading boom and placed either on the car bottom or on the pile in the car without appreciable breakage. The lowest slant of the boom is 22 deg. and its highest position may be horizontal, adjustment being gotten at any intermediate points as desired. Upon starting to load a car, it is used in its low position, being raised for topping out as soon as one end is filled and kept at this height until the car is loaded. By this means, a car may be trimmed without any danger whatever from a rush of coal.

The raising and lowering device for the loading boom is worthy of attention. Power is taken from the same motor that drives the picking band and is governed by means of a friction clutch located at *G*. A brake is also mounted on this same shaft. The levers are so arranged that when the clutch is thrown in, the brake is released, and, upon disengaging the clutch, the brake is at the same instant automatically applied.

The capacity of this plant is governed by the efficient capacity of the shaking screen. For good results, the average depth of coal upon this part of the apparatus should not exceed 6 in. The forward movement of the coal upon the screen is approximately 50 ft. per min. The capacity is thus 125 cu.ft. per min., or 187½ tons per hour, which is equivalent to 1500 tons per 8-hr. day.

A New Electric Miners' Lamp

By an ingenious arrangement of vent tubes, the Witherbee Igniter Co., of Springfield, Mass., has developed an acid-tight, lead storage battery, for the electric head lamp which permits of the use of free electrolite. Thus the standard construction of lead accumulators is adapted to the ordinary miners' use and the resulting gain in efficiency, life of plates and hours of service, in proportion to weight, is expected to greatly accelerate the fast growing popularity of this type of electric lamp. J. T. Jennings, electrical engineer of the Philadelphia & Reading Coal & Iron Co., placed a large number of these lamps in service over a year ago and the manufacturers acknowledge his valuable assistance in perfecting many of the details of construction of the Wico Safety Electric Lamp.



Detail View of the Lamp and Its Appurtenances

It might be called extraordinary, were it not so common an occurrence in inventions generally, that battery manufacturers have overlooked the possibility of venting a cell in the manner here employed. Two tubes are sealed into the cover of the acid chamber with their upper and lower extremities in diagonally opposite corners. A constant acid level is maintained by filling through a plug in the side of the jar, and while the battery is in the normal position, both tubes vent freely. If the battery be turned on its side, one of the tubes, of course, has its

VIEW SHOWING THE WICO LAMP IN USE

lower extremity within the acid chamber, below the acid level, but its upper extremity, projecting through the cover, is above the acid level so that none can escape. The other tube, being in the opposite position, has its lower extremity within the acid chamber, above the acid level, and is, therefore, entirely free to carry off the gases without the liquid spilling unless the battery be completely inverted, and this condition maintained; as the battery is turned from side to side, first one tube and then the other serves as the vent.

At no time are the plates uncovered, and in no position that the miner may assume, will his light be diminished. Although the capacity of the battery is more than adequate to furnish light for an entire shift, it is surprisingly small and light as a direct result of the increased efficiency. The active material of the five plates is formed in staggard grades, correctly proportioned to give the greatest capacity for weight at the desired discharge rate. The drawn aluminum housing is sufficiently stiff to resist the ordinary rough handling by miners and the connections from the battery terminals are strong and positive, spring contacts being avoided for the sake of reliability.

The latest type of bayonet-locking socket is employed to hold the tungsten bulb in the lamp, which reflects a smooth, sufficient and well diffused light and is arranged to fit on the standard oil-lamp support.

Several of the Philadelphia & Reading colliers are now equipped with the Wico Safety Lamp, and other operators are following suit. As evidence of the remarkable cleanliness of the battery, it is said that they are in great demand for candelabra equipment on hotel tables.

The Suitability of Explosives

The U. S. Bureau of Mines recently published *Bulletin* 48, dealing especially with tests which show the suitability of different classes of explosives for various kinds of work. It is one of a series dealing with tests of explosives and methods of reducing the risks involved in their use in mining.

Many explosives suitable for quarry work have proved unsuitable for use in mines or in closed workings. An explosive for use in gaseous or dusty coal mines must be so composed that its explosion temperature and the height and duration of its flame are reduced sufficiently to permit its being used with comparative safety. The nature of the gases evolved in detonation, the imperviousness of the explosives to moisture, their behavior in cold climates, their stability of freedom from chemical or physical change during warm weather, all have an important bearing upon their selection for any special work.

Practically every class and grade of commercial explosive is used in open-air work to meet varying conditions. This bulletin states the use to which each of the following explosives is best adapted: Black blasting powder, granulated nitroglycerin powder, "straight nitroglycerin dynamite," low-freezing dynamite, ammonia dynamite, and gelatin dynamite.

Black blasting powder is stated to be the best suited for work, in which a gradual pushing or heaving effort is desired, while "straight nitroglycerin dynamite" develops greater disruptive force than any of the other explosives tested. For this reason it should be employed for producing shattering effects, or for blasting very tough or hard materials.

The gelatin dynamites on detonation produced the smallest percentage of poisonous gases, but even these are far from being satisfactory in this respect. To obviate this objection, the Bureau had a special gelatin dynamite prepared, which, upon detonation, produced no poisonous gases. It is believed that this illustration of the possibility of producing an explosive of this class, that will not evolve poisonous gases, will result in its being commercially manufactured.

The bulletin closes with a table showing the relative potential energy, disruptive effort which bears a close relation to the shattering force of the explosive, the propulsive effect which corresponds to the pushing or heaving force of mine explosives of different classes and grades.

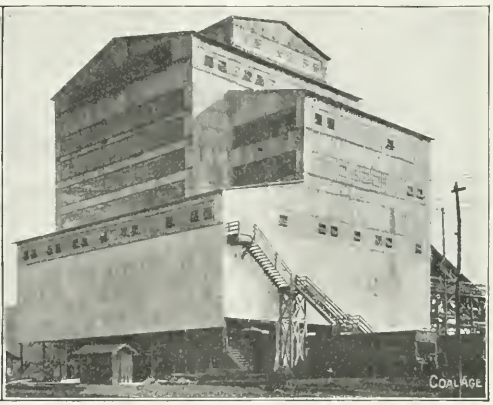
Preparation of Anthracite

By Hugh Archibald*

SYNOPSIS—A general discussion of present methods of cleaning and sizing hard coal in the anthracite field. Recent practice is quite different from the crude methods formerly used.

The means employed for the preparation of anthracite coal for market vary from mine to mine, according to the character of the coal which is being worked and the methods of development employed. When the coal, as it comes from the mines, is dry and bright, and the slate separates easily from the coal, the method known as dry preparation may be employed, in which no water is used in cleaning the coal. But when the run-of-mine coal is wet or stained so that it must be washed in order to make it look bright and so be more marketable, a strictly wet preparation may be used. In many breakers a combination of both wet and dry preparation is employed.

Chutes in an Old Breaker, Showing Crowded and Poorly Lighted Arrangement



Showing Steel- and Corrugated-Siding Construction on a Modern Breaker

In flat seams where the coal is shoveled over by the miner before it is loaded into the car, the preliminary preparation is given in the mine, the larger pieces of rock and bone being picked out by hand and stowed in the gob. Under these conditions a deduction is made from the price paid to the miner for a car of coal if there is more than a certain amount of rock in the car, this amount varying from 300 to 500 lb. In pitching seams where the coal is drawn from a battery, such a preliminary preparation is not possible to any great extent, as the coal cannot be shoveled over. In this case everything from the seam is loaded into the mine car and the preliminary cleaning is done on the surface.

Material Used in Breaker Construction

The majority of coal breakers in use, having been built for a number of years, have been constructed of wood, the older breakers being constructed with mortise and tenons, whereas in the more recent wooden structures, cast-iron shoulders and tie-rods are used. In a number of breakers which are under construction or have been built in the past few years, either steel or concrete or a combination of both have been used. The Sterrick Creek breaker of the Pennsylvania Coal Co., at Olyphant, Penn., is a large breaker which has been built out of steel with corrugated-iron siding. The same company is at present constructing a breaker known as the Underwood, near Throop, Penn., in which the pockets and foundations are made out of concrete, while the rest of the breaker is to be made out of steel.

The Lehigh Valley Coal Co.'s new breaker, at Mineral Spring, is built out of steel, the lining of the pockets and the flooring being made out of concrete. The D., L. & W. R.R. Co. has constructed a large breaker at Taylor, Penn., which is built entirely with reinforced concrete, the only steel work being the frame which carries the conveyor that lifts the coal from the shaft to the head of the breaker. This breaker is unusually steady, there being very little movement in it when all the machinery is running, a barrel of water at the top of the breaker not indicating any movement.

The Anthracite Mine Law of Pennsylvania, which was passed in 1871, required that any breakers constructed after the passage of the act should be placed a certain distance from the shaft. The purpose of this was to avoid a repetition of the Avondale disaster of 1869, when the breaker, which was located over the shaft, burned down, smothering the men in the mine from the smoke which was carried down the shaft.

This law has necessitated the handling of the coal between the shaft and the breaker. At some mines, this is done by hoisting the coal car high enough so that it can be run over a trestle directly into the breaker. A more common practice though, is to hoist the car to the surface and there dump the coal into a conveyor which lifts it to the head of the breaker.

An advantage in this is that pockets of the conveyor, holding only a portion of the coal in a car, deliver the

*Mining engineer, Scranton, Penn.

coal in a more uniform quantity than where the car itself is dumped directly at the head of the breaker, a better cleaning of the coal always being possible when it moves in a steady stream from the breaker. When the supply of coal from the mine comes from more than one source and is dumped from two points into the boot of the conveyor, the feed to the breaker is more even than when the cars from two points are dumped directly at the head.

Must Avoid Rough Handling

Coal should be handled in a breaker so that the least amount is broken into small sizes. It is stated that a reduction of 1 per cent. in the breakage amounts to a saving of $75,000 a year for one large company. As the average price of coal is about $2.40, a saving of 1 per cent. is equal to 2.4c. a ton, which can easily amount up to a large amount when the production is large. Breakage will occur as one piece of coal strikes against another or where the coal strikes against the side of the chute as it changes its direction of flow.

The coal on entering the breaker, passes over bars, either fixed or movable, or over shaking screens, so that the lump coal may be separated from that which is already broken to a more marketable size, and also to avoid passing all the coal through the rolls. The small coal is sent directly to the sizing and preparing machines.

Shaking screens are preferable to bars for making this preliminary separation, as the separation is more distinct, the reason for this being that when the coal slides down the chute and over the bars, that which should fall through, often gathers enough momentum to carry it over or may be so held by larger pieces of coal that it is carried along with them. Whereas if it is shaken free from all other pieces of coal, as will happen on a shaking screen, and given time to drop, it will pass through. The disadvantage is the power required for the screens and more complicated machinery.

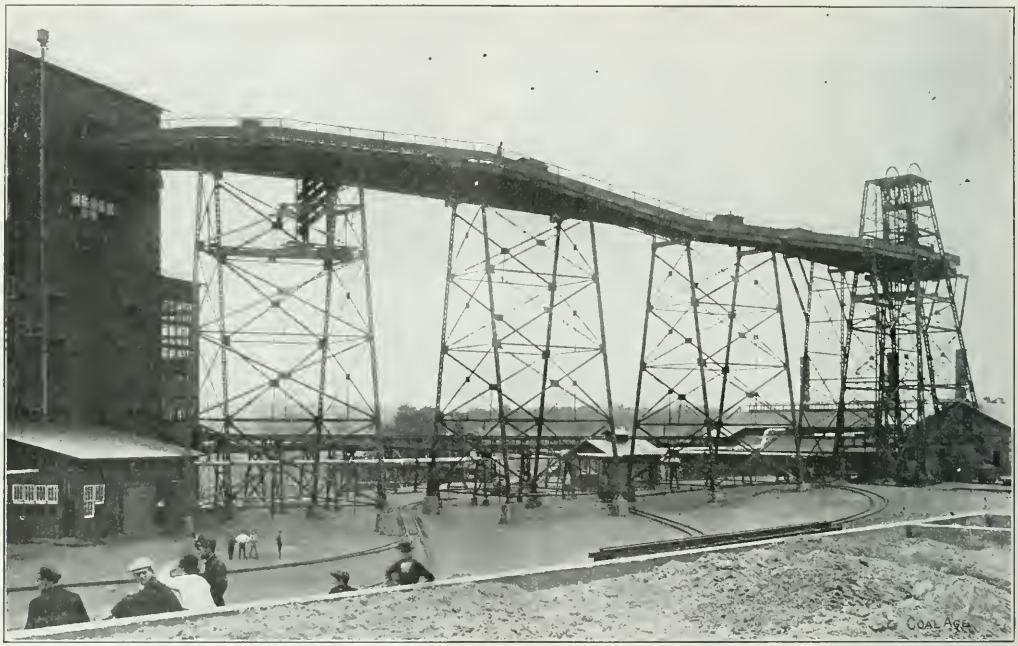
The lump coal is given a preliminary cleaning before going to the rolls to be crushed. This may be done in a picking chute or on a moving table. When it is done on a moving table, better cleaning can be accomplished as the pieces of coal do not move so fast as when sliding down a chute, and are not piled up one on the other as is likely to happen at the end of a chute.

Necessity of Careful Cleaning at the Head

Cleaning the coal at the head is important, for it is easier to pick out one large piece of slate in the beginning than to pick out a number of smaller pieces later on. Five men at the Mineral Spring breaker of the Lehigh Valley Coal Co. do most of the hand picking which is done in that breaker. In this breaker there are three picking tables on the head. Shaking screens are employed for the preliminary sizing, and these make two products, lump, which is cleaned on the center table, and steamboat and broken, which are cleaned on tables at each side. The slate which is taken out at this point, goes directly to the waste.

After cleaning on the head, the lump coal passes through rolls to be broken down to the sizes desired. In a combination wet-and-dry breaker, it is generally the product from breaking down the lump coal that is cleaned by the dry method and goes to its separate part of the breaker.

The rolls generally employed are high-speed toothed



Showing a Common Arrangement, Whereby Cars Are Taken from the Head of Shaft to Breaker

rolls, running at 900 r.p.m. Recently, however, slow-speed rolls, known as the Lloyd rolls, have come into use. In these rolls the revolutions have been reduced to 250 a minute and the saving in breakage below the desired sizes runs as high as 15 per cent. They are compound geared and the teeth are set in staggered rows and do not overlap as in the old high-speed, pointed-tooth rolls. To get the best results, rolls should be fed evenly with a sized product. Even feeding is better accomplished when moving tables are employed, as coal moving out of a chute, after being held back by a gate, travels in a mass, whereas with moving tables it falls evenly over the end of the table.

After passing through the rolls, coal is sized on shaking or revolving screens, each size being prepared separately. The sizes of prepared anthracite coal and the square holes through which they will pass are as follows: Steamboat, 5 in.; lump, 4 in.; broken, 2¾ in.; egg, 2 in.; stove, 1⅜ in.; chestnut, ¾ in.; pea, ½ in.; buckwheat, ¼ in.; rice, ⅛ inch.

In the early days of anthracite mining, no size below stove coal was prepared and the cleaning was done by hand. In those days the miner was required to rake over his coal in the chamber before loading a car and all the fine coal which passed through the rake was shoveled into the gob. The contrary is true of the present day, the smaller and cheaper sizes having increased steadily in demand, so that egg is the largest size made in some breakers. These breakers are so arranged that even egg coal can be broken into smaller sizes when there is no demand for it.

Dry Methods of Preparation

In breakers using the dry methods of preparation, the coal is first cleaned by mechanical pickers and then by hand. The mechanical pickers are of two types: the Emery picker and the spiral picker. In the Emery picker, the coal is separated from the slate as it slides down a chute in which there is a slot, the coal on account of its glassy surface, gaining enough velocity to make it jump the slot, whereas the slate being heavier and sliding at a slower rate, falls through. The spiral separator has a sheet-iron spiral which inclines toward the center down which the coal and slate slide. The coal, gaining greater velocity than the slate, is discharged over the edge by centrifugal force, while the slate remains on the spiral and is discharged in the center at the bottom.

In the modern breaker, built out of steel and corrugated-iron siding, attention is paid to lighting the inside of the breaker so that there may be plenty of light for picking the coal. In the old structures adapted to recent mines, the chutes for hand cleaning are often badly constructed and poorly lighted, the lack of daylight being made up by hanging an electric light over the picking chute in front of each boy. The hand picking of the coal is done by boys. It is avoided as much as possible nowadays; only the larger sizes are cleaned by hand. At one modern breaker, only two boys are employed on the clean coal, both of them working on egg coal after jigging. After picking, the clean coal is sent into the pockets for loading onto the cars, for shipment.

In a wet breaker the cleaning of coal is done by means of jigs, the coal being sent directly from the jigs to the pockets.

One of the hard things to eliminate in cleaning coal is flat slate. A machine has recently been devised to do this work, which can be attached to the end of the shaking screen or placed by itself in a chute. In this machine, the coal passes over a series of plates which overlap in the direction of the movement of the coal, so that as the machine moves forward, the flat slate passes back through the opening between the plates. The plates open a little at the end of each stroke in order to release any slate which may be caught between them.

Arrangement of Coal Pockets

The usual arrangement of the coal pockets is to have them parallel to the railroad track on which the loading is done. In the illustration shown of the Sterrick Creek breaker, two tracks are shown passing beneath the breaker, on both of which cars can be loaded. In contrast to this custom is the novel arrangement of the Mineral Spring breaker, where all the loading is done at one point and only one track is used. The pockets in this breaker are arranged in two opposed rows at right angles to the track, and the loading is done by means of a belt which passes through an alleyway between pockets and onto which the coal is loaded by gravity for delivery to the railroad cars. One man by a system of levers controls the gates in the pockets, the belt, and a box-car loader.

In loading by a belt, greater speed has to be given to it when the smaller sizes of coal are handled in order to throw them free from the belt at the end, and not have them stick to it, following it around. This system of loading is to be maintained in the new Franklin breaker which is being built by the same company. Another system of loading which is proposed for a breaker under construction by another company, will not have pockets in the breaker, but will have a separate track for each size of coal so as to load directly into the railroad cars.

The refuse from the breaker nowadays is generally ground up and sent back into the mines to fill up old workings. The ashes from the boiler plant are also flushed into the mines with water. The crushing is generally done with a "Williams No. 3" crusher, the largest slate sometimes being broken down in a Gates crusher.

(Problem)—The Criminal Courts in Georgia sentence a small boy to 11 years in jail for stealing a 5c. bottle of pop. How many years should the Pennsylvania courts sentence a greedy or careless miner for crossing the fireboss' dead line?

A Balanced Shaking Screen

SYNOPSIS—Double screens suspended by flexible wooden strips and driven by opposed eccentrics through resilient eccentric rods greatly reduce the noise of operation, the cost of installation and repairs, and the reflex action of the shaker upon the building.

Throughout most coal fields where the product of the mine is sized before going to market, the oscillating or shaking screen has, generally speaking, supplanted the revolving screen for sizing purposes. The principal objection to this type of apparatus has been its destructive action upon the building in which it is placed.

The third law of gravitation, which states that "for every action there is an equal and opposite reaction," holds as true between the coal screen and the structure whereby it is supported, as it does between the sun and the earth, or any other two heavenly bodies. The push exerted by the eccentric to force the shaker forward may be transmitted in the opposite direction to the timbers supporting the eccentric shaft, with the result that buildings not constructed with the especial idea in mind of resisting the action of the oscillating screens have sometimes, and not infrequently, been shaken to destruction.

Attempts have been frequently made, therefore, to counterbalance or neutralize the action of the eccentric shaft upon the building itself, and, although these were more or less successful, the heavier the screens were made, the greater and more disastrous were their effects upon the structure within which they were housed.

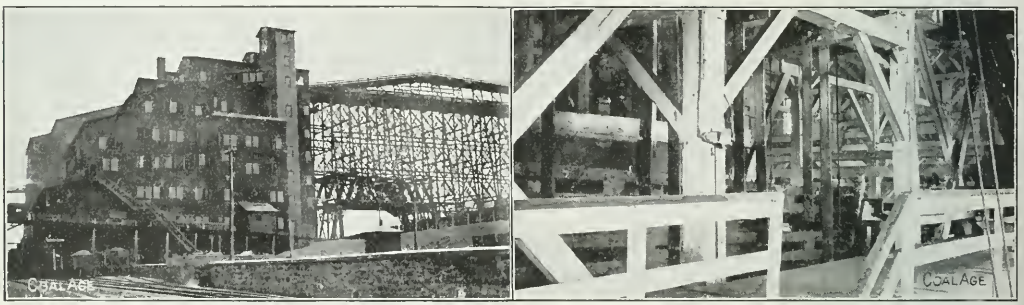
As ordinarily constructed, shaking screens are hung from above with rods provided with boxes to allow a slight rocking both at the point of suspension and point of support upon the screen. The eccentric rods were also attached to the screens in a similar manner, the points of attachment, however, being usually provided with brass boxings similar to those used upon the ordinary steam-engine connecting-rods.

Although there was comparatively little trouble experienced from heating, or undue friction, in these various boxes, great difficulty was encountered in keeping the various joints tight. It will be readily appreciated that any lost motion, either at the points of support or at the application of power, would cause a knock in the boxings which, if unattended to, would grow steadily worse, not from friction, but on account of the pounding action between the journal and box. The greater the weight of the screen itself, or of the coal carried upon it, and the more rapid its oscillation, the more severe would become any tendency to pound.

To overcome these difficulties the Wilmot Engineering Co., of Hazelton, Penn., has placed a screen on the market which is known as the Parrish flexible-arm shaker, which is in many respects decidedly different from the older type of shaking screens.

In this apparatus the framework, carrying the perforated plates by which the coal is sized, is built up entirely of wood, being thus somewhat lighter than if made of structural-steel shapes. This framework is hung from above on a series of 1x8-in. strips of seasoned ash, which are securely bolted to both the shaker proper and to the supporting beams overhead.

The backward and forward motion of the screen framework is made possible by the elasticity of these wooden hangers, and at either extreme position of the shaker they are bent and tend to force the suspended weight in the opposite direction. This serves to minimize the effect of the inertia of the screen-supporting framework.



A Colliery Where These Shakers Are Used and the Screens Themselves in Operation in the Washery

In order to obviate the necessity of connecting the eccentric rods to wristpins attached to the shaker, the elasticity of seasoned wood is again taken advantage of. One end of the eccentric rod is bolted securely to the shaker framework, while the other is bolted to the eccentric straps. Between these two ends, or points of attachment, a flat strip of thoroughly seasoned white oak is interposed and securely fastened.

In order to counteract as much as possible the action of the shakers upon the building, they are usually built double, that is, one shaker above the other, or upon the opposite side of the eccentric shaft. With this arrangement and the driving eccentrics opposed to each other, the direction of travel of the two screen-bearing frames is at all times opposite, which puts as little oscillatory shaking strain upon the building as possible.

The advantages of this construction are many. All of the principle parts except the screen plates themselves being made of wood, the shaker is light in weight and cheap to install. Renewals of either hangers or eccentric rods are not frequent, but when necessary such renewals can be accomplished quickly and at small expense by an ordinary carpenter.

Cincinnati Mine Explosion, Courtney, Penn.

By R. Dawson Hall

SYNOPSIS—A gas explosion occurred at the Cincinnati mine of the Monongahela River Consolidated Coal & Coke Co., near Courtney, Washington County, Penn., killing 96 men. The mine had been operated about three-quarters of a century and had extensive workings. Many of the men escaped through an unsuspected avenue of safety, all the provided roadways being blocked by afterdamp.

The Cincinnati mine is one of the oldest in the bituminous regions. It lays along the west or left bank of the Monongahela River, just north of the town of that name. The nearest railroad station is Courtney. A few men live in a block of wood houses between the Pennsylvania R.R. (Monongahela branch) and the river, and this block is shown in the view of the tipple. But there is no town near the mine, and the miners in general live in the many villages near-by, in Monongahela, New Eagle, Riverview, Findleyville and Gastonville, for at the Cincinnati mine the river rounds sharply against the hills and makes a steep bluff, affording little room for buildings at its base and none on its slopes.

General View of the Plant at Cincinnati Mine, Courtney, Washington County, Penn.

A Pioneer Mine

This mine and the abandoned Buffalo workings adjacent were opened almost 80 years ago. Cincinnati has been operated discontinuously since that time, having passed into many different hands, being owned at different times by the Fifth and Tradesmen's National Banks, at Pittsburgh, Robert Arthurs and C. M. Jutte & Co. At all times gas has been found, not in great quantities but sufficient to serve as a menace. At one time reports aver that the mine exploded and blew cars almost across the river, but this accident is said to have occurred 30 years ago, long before the operation came under the present ownership, and the damage was to property and not to human life. According to report, gas is occasionally found in large quantities. Nevertheless, accidents have been rare until the present disaster wiped out in one catastrophe 96 lives just at a time when the disaster seemed unlikely to occur.

The Slope Manway

When C. M. Jutte & Co. still owned the mine, Henry Louttit, being mine inspector of the district, declared that the escape of the men in case of an accident was not sufficiently provided for and insisted on a new opening on Fromans Run, a branch of Mingo Creek. The court appointed D. M. Anderson, a coal operator; Henry Cook, a miner, and George D. Jenkins, a mining engineer, to report to the court. They made an examination Oct. 13, 1893, and declared that a 20-deg. slope 550 ft. long should be constructed to connect with the surface in Fromans Run. This opening constitutes the drift marked in the illustration as Mingo manway. By this steep incline the men and mules enter the mine, and at its mouth the mule stable is located. It is a primitive adit such as a company might be expected to construct under legal necessity.

Thus there were two entries to the mine, the level main road with its rope haulage entering the hill opposite the tipple, and the manway about a mile away on a small run near the Mingo school house. By the first, the bodies were removed, and the rescuers entered the mine by the second. Five rescued mules were driven out of this opening about 70 hr. after the disaster, looking little the worse for their severe experience.

The Weather Conditions

The explosion occurred about 12:15 in the afternoon on Wednesday, Apr. 23. The temperature was about 80 deg. F., and the weather had been warm and, therefore, unfavorable for a dust explosion for several days. Since Apr. 7, the temperature had not fallen below 30 deg. F., though on Apr. 20 the temperature fell at 6 a.m. to the freezing point. The conditions did not favor a gas explosion any more than one of coal dust, for the day was

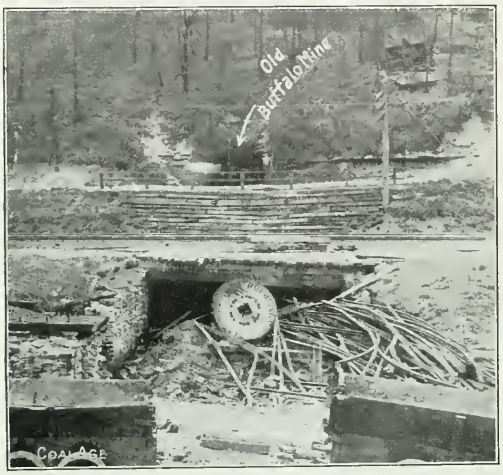
bright and the barometer did not show any marked decline. I quote the statement of the Weather Bureau:

BAROMETRIC READINGS AT PITTSBURGH STATION

Date	Hour	Inches
Apr. 20	8 a.m.	29.50
	8 p.m.	29.54
Apr. 21	8 a.m.	29.66
	8 p.m.	29.44
Apr. 22	8 a.m.	29.36
	8 p.m.	29.18
Apr. 23	8 a.m.	29.27
	8 p.m.	29.23
Apr. 24	8 a.m.	29.31
	8 p.m.	29.20

Mainly a Gas Explosion

Apparently the center of the explosion was not far from the 5th and 6th butts out of the 8th face. The accident



The Buffalo Workings Adjacent to the Cincinnati Mine. Some Think Much Gas Leaked from This Mine into the Cincinnati Workings

was probably largely a gas explosion, the violence not being greatly increased by the presence of dust. The coal is about 5 ft. thick, increasing in dips to 6 or 7 ft. Above the coal is about a foot of draw slate which is hard to maintain in place. This slate is always pulled or shot down. Thus the floor normally is covered with a certain amount of broken rock which mixes with the coal dust.

The violence of the explosion has, as is usual in such cases, been exaggerated by the press. The blast blew open the explosion doors of the fan, an illustration of which ventilator is shown in the last illustration. The doors were replaced by the fan tender, made tight with sacking and loaded with iron. The fan was in no way injured. As an evidence of violence it is said that in the mine, a locomotive was blown off the tracks.

There was, however, a great deal of afterdamp, which invaded both rooms and headings. Unfortunately, the accident occurred in a heading outby from the point where many men were working. These men were thus penned in behind the clouds of afterdamp, and many more might have perished had it not been for a fortunate circumstance.

The Unforeseen Exit

Three parallel entries formed the main approaches to the portion of the mine from which the bulk of the coal was obtained. From right to left these were No. 7, the main return, No. 8, a motor road and intake airway, and No. 9, a traveling road, also serving as an intake. Leading to the left out of these were several butt headings, each providing approach to or being prepared to provide approach to about 50 rooms. The last started was No. 21. Parallel to the face entries mentioned was No. 4 face entry, and the 15th butt heading from this entry struck across the new work not far from No. 21 butt heading. All the work in No. 4 face was nearly completed. The pillars and stumps had been largely drawn and extensive caving had taken place. Yet through No. 15 butt and No. 4 face, broken and caved as the former was, many men reached the surface.

Shipp Holmes, a colored man, was followed by 15 men into the end of No. 8 face workings and thence along No. 15 butt outward. Holmes had an unextinguished safety lamp, but the other men were in the dark, and, so five men were parted from the rest and perished. When the Boss Driver Todd discovered that Holmes had managed to reach the surface by way of the far workings of No. 4 face, he made the trip back over the ground, and finding Edward Furlong and William McDonald, brought them out.

Some Individual Experiences

Edward Furlong was a mule driver who worked in the 14th entry. Like other drivers, he collected cars from the room faces and delivered them near the mouth of the heading where it enters 8th face. From this place the cars were removed by a motor. He used an open lamp when driving down to No. 16 room. At that point he was in the habit of laying his open light down and then, taking the safety lamp in its place, would proceed down the heading.

At 12:15, on Wednesday, he was sitting at this No. 16 room, when the explosion occurred. It rolled him over a distance of about 12 ft. Picking himself up, he went to No. 8 face, and found all three face headings full of afterdamp. He tried to pass in the direction of the drift mouth but found the air terribly foul and remembering his deceased father's oft-repeated admonition, he decided

The Mingo Manway, Where the Rescuers Entered the Mine, a Steep and Narrow Slope

to go only half as far as he felt was safe so that retreat would be possible in case the air was too foul to permit his escape by the regular road. He went only a short distance and then returned to the mouth of the 14th butt entry and finally traveled as far down as butt entry 21. McDonald was with him and, as explained, he also escaped with the aid of Todd.

Many of the men were working in No. 4 face heading and the butt headings leading from it. These all escaped,

as did also some men, to the outby of the explosion. One man declared the explosion gave two distinct thuds. He was standing outside the mine foreman's shanty and after the explosion occurred he stepped inside and closed the door. As the foul air entered through the cracks around the door, he decided to leave and passed through a rear door to the intake and thence escaped.

Two Rescued after 59 Hours

The rescue of Charles R. Crall and Philip Legler aroused hope that many more men might be saved. They were located in butt entry No. 20 out of No. 8 face heading, after having been immured for about 59 hours. They were taken to the hospital, but they were soon in excellent condition and were permitted to go home. Like the other workers in the headings leading from No. 8 face they had retreated to the remote workings of the mine after the explosion, as the air in that direction was less contaminated.

In all, 96 men were killed either by shock, burning or suffocation. One man was completely decapitated, another had all the clothes burned from his body; on the other hand, some were found who had covered their heads with their coats to shut off the deadly fumes and had quietly lain down to die.

The ventilation of the mine is supplied by a Capell fan measuring 12 ft. in diameter, having a 6-ft. face and operated as an exhaust ventilator. It is driven by a continuous-current motor through gearing; this General Electric motor is rated at 525 hp. and has a speed of from 300 to 525 revolutions per minute.

Suggested Causes of the Explosion

It is early yet, before the mine inspectors have made their search and the inquest has been held, to suggest causes for the catastrophe. Some have assumed that gas entered from some of the many mines adjacent but now abandoned. The Buffalo and Garfield mines were both extensive. We show the old opening of the Buffalo mines, and the Champion or Murphy fan by which it was ventilated. In 1883, James, the father of Edward Furlong, who was rescued, was foreman of this mine. It is thought that in some way the stoppings keeping back the gas from these old mines leaked out and filled the Cincinnati mine with firedamp.

The Block of Houses Near the Cincinnati Mine and the River Tipple in the Background

There is also a disposition to blame near-by and abandoned gas wells for the catastrophe. It is said that at one time a machine cutter broke a hole into a well but fortunately no gas was found, so completely was the well exhausted or so tightly was it sealed. Some contend that the restarting of entries 5 and 6 is blameable for the accident. Report has it that these headings were closed down for a while because of the presence of gas and reopened shortly before the explosion.

Alexander McCauch, the state mine inspector, made an investigation of the mine about six weeks before the accident and found it free of gas, but those who know the mine are disposed to think that an investigation is only good for the period at which it is made, the gas generation being largely discontinuous and depending on working conditions.

Electrically Driven Mine Fan. The Explosion Doors in the Foreground Were Blown Open but the Fan Was Uninjured

The Mixed-Light System

It may be interesting to recall the mixed-light methods of the Pittsburgh district as in existence at this Cincinnati mine, because the much discussed question of their propriety will probably be revived by this disaster.

Two butt headings are driven up side by side with crosscuts between them. These are numbered, we will suppose, 14 and 15. No rooms are turned from entry 15, but they are started in regular succession from entry 14, beginning near the mouth and extending inward. The air enters at entry 15, passes to the end of that heading as far as completed and returns by entry 14. As the rooms are driven up, the pillars are drawn back and gas escapes from the broken roof. No naked lights are allowed in those rooms where pillars are being drawn or in the part of the heading from which those rooms are started. The men who are driving rooms ahead enter their working places through entry 15 and pass into entry 14 through a small door in the crosscut next above the last room where pillars are being drawn. They are forbidden to travel down to the places where the pillars are in process of removal.

In regular turn with the rooms in entry 14 rooms are turned off entry 15. That is, when *all* the rooms in the first entry are turned, a room is started from the end of entry 15 and thereafter other rooms are opened and the pillars drawn proceeding outby and not inby; that is retreating, not advancing. Thus, as the air current still continues to follow its old course, the new rooms are still all on intaking air and the pillar-drawing rooms are reached by the current which has ventilated the new rooms.

Mechanical Coal Picking

By Frank H. Kneeland

SYNOPSIS—A description of two machines which give good results. The first can be attached to any ordinary shaking screen and removes the flat slate. The second picks slate of any shape, either flat or otherwise, and is used mostly upon chestnut or larger sizes of anthracite coal, although there appears to be no good reason why it should not work with equal success upon the bituminous coal in nut, egg or lump sizes.

The preparation of coal for market, especially if it be anthracite, by no means ends with its extraction from the tenacious embrace of Mother Earth. In order to successfully meet the requirements of the consumer, it must be properly graded as to size and free from impurities, such as slate and rock.

COAL AGE

Side View of Gravity and Flat Slate Pickers. List of Parts Refers to Gravity Picker Only

For many years, the final rock separation was accomplished by employing breaker boys to hand-pick the foreign matter from the coal, although it was clearly recognized that an efficient mechanical device for this purpose would prove not only a great convenience, but a great saving as well.

For a long time all attempts at mechanical picking proved failures. Recently, however, some such machines have been placed upon the market, one of the most successful of which, manufactured by F. H. Emery & Co., of Scranton, Penn., is herewith illustrated and described.

Fig. 1 shows a side view of a shaking picker, for the removal of flat slate. The framework *A* is suspended by four rods *C* from the points *D*, is free to oscillate backward and forward, and is driven by the eccentric *E*. Mounted in this framework *A* is a series of slightly bent transverse plates, every other one of which may be rocked slightly about the adjustable axes *F*. These axes are connected to the levers *G*, which are joined at their upper ends by the rod *H*. One lever is also connected to the spring *I*.

Pivoted at *J* and connected to the rod *H* is the lever *K*, through a slot in the upper end of which passes the rod *L*, which is attached at one end to the hanger *C*. At an adjustable point on the rod *L* is placed the stop *M*, which comes in contact with the lever *K* only when the picker is in its extreme forward position.

The bottom plates of the picker are separated from each other by slots, the width of which depends upon the maximum thickness of the slate which is to be removed from the coal. This distance in each separate machine is slightly adjustable. The coal entering the picker from the receiving chute is easily jigged forward across the plates. The slate on the other hand moves with greater difficulty and instead of progressing continuously forward, passes backward through the slots between the plates.

At the beginning of each rearward movement of the picker, the rocking plates are caused to move and slightly increase the opening or width of the slot by the lever *K*, coming in contact with stop *M*. It is impossible, therefore, for a piece of slate to become caught or jammed in these openings.

A careful inspection of the refuse discarded by this machine fails to show any appreciable amount of good coal, in fact, the ordinary operation of the picker leaves less than 2 per cent. of combustible matter in the refuse, while one-half of 1 per cent. is a result not infrequently achieved.

Another device manufactured by the same company and one whose field of usefulness is even broader than that of the machine above described, is what might be termed, a stationary slate picker. This is illustrated in Fig. 2.

The crank *A* is connected by a rod to the feeder *B*, and gives it a rocking motion. *B* in turn is connected through rods and levers to the similar feeders *C*, *D* and *E*.

These feeders are semi-cylindrical and in appearance resemble nothing so much as the valves of a Corliss engine. Their rocking movement within suitable seats al-

lows the coal to enter the separate stages or passes of the machine in intermittent batches, or "volleys."

From the feeder *B* the coal moves down the plate *F*, which is set at such an angle that the coal will slide readily. Upon reaching the stone slab *G*, its momentum is checked, but it is by no means brought to a standstill. The slate also is retarded through contact with the stone slab, but to a decidedly greater extent than is the coal. The result is that the clean coal reaches the lower edge of the slab at a higher velocity than the slate, and readily jumps an opening, into which the slate drops. Of course, some coal is retarded in crossing the slab by pieces of slate; this falls through the opening with the former and enters upon the second stage of the operation. The clean coal, which has jumped the opening above mentioned, is carried off by the over-chute *H*.

Four feeders and a like number of stages and slabs are provided in this machine, and by the time that the final slab is passed, the refuse falling through the last opening contains only about 5% of coal. This can be easily led

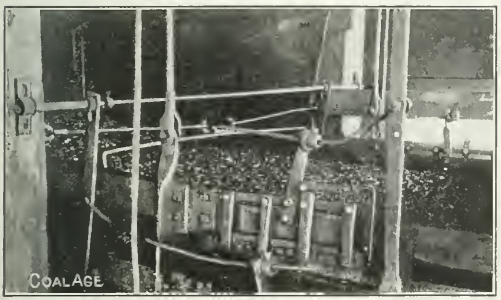

Fig. 3. Flat Slate Picker in Operation Attached to End of Shaking Screen

into a chute, where the coal may be removed by one breaker boy.

The above is the stationary picker in its simplest form. These machines can, however, be mounted in double or triple decks or in zig-zag form, depending upon the floor space and head-room available. Their work in any of the above types is practically uniform and identical.

The inclination of the various stages, as well as that of the stone slabs, will vary considerably, with different qualities and grades of coal. The width of the slot succeeding each slab is also important. Adjustments for these variations are made upon each machine.

A well known mine superintendent in the anthracite region, who has used these pickers for some time, makes the statement, that where he used to employ 40 boys to clean his coal, he now hires only 8, and if the head room in the breaker was sufficient to permit double decking of the machine, he would employ none at all, as he believes that a separation could be accomplished that would be so nearly perfect as not to warrant any hand picking whatever.

Although these machines are at present employed mostly in the preparation of anthracite, some are working successfully upon bituminous and there seems to be no good reason why it should not prove to be a cheap and efficient means of removing slate from practically all grades of this fuel, slack alone excepted.

Efficient Screens

Two efficient screens for sizing and cleaning coal are illustrated below, both being made by the Hendrick Mfg. Co., Carbondale, Penn.

Fig. 1 is designed for use in ordinary oscillating screens and is known as "Perisertread" shaker plate. It has proven effective in the proper cleaning of the smaller sizes, the perforated steps placed every 12 in. eliminating the necessity of strips of wood, angles or other shapes

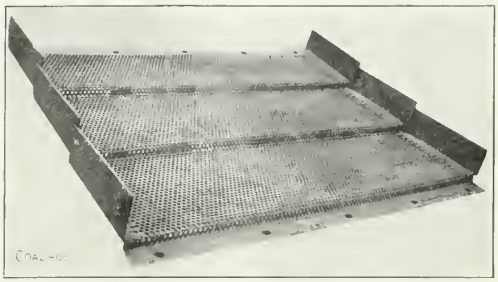

Fig. 1. Step Screen with Circular Perforations

being fastened to the screening surface to hold back or retard the mass of material passing over the shaker at the sacrifice of considerable screening area.

The steps not only retard the coal, but they also act as tumblers, as at each thrust of the eccentric, the coal rolls over at these points, causing better separation.

The increased screening surface over that of flat plates amounts to about eight per cent., and this is placed at the point where most needed, i.e., at the spot where the coal is turned over.

Another advantage gained in this construction is the strengthening of the plate by the steps, they doing away with the buckling which often occurs with light plates perforated with small holes.

The flanged-lip screen (Fig. 2) is the last screen the coal should pass over before being loaded for shipment.

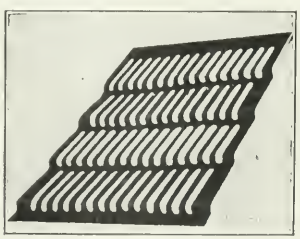

Fig. 2. Step Screen for Final Preparation of the Coal

The slots are 12 in. long, wider at the bottom than at the top, with 1½ in. of the large end of slot flanged down at the lower end.

Where these screens are used in loading chutes, they can always be depended upon to reduce the percentage of rock and slate and under-sized materials in the product that has not been eliminated by the usual screening and sizing methods. They can be manufactured in any size and to suit all conditions.

A Novel Screening Plant

By W. F. Schadel*

SYNOPSIS—The ordinary shaking screen, although admittedly efficient, has many objectionable characteristics, chief among which is its tendency to shake to pieces any structure within which it may be mounted. In the installation described this has been obviated by balancing the reciprocating parts and suspending them in a framework entirely independent of the mine tipple proper.

In the early stages of coal mining the consumer would gladly accept coal in any condition and of any quality, it being even thus vastly superior to wood and other fuels. This state of affairs, however, has been constantly changing. The consumer has gradually become enlightened, educated to the difference between good and bad fuel, between coal well prepared and that carelessly loaded, until today the average purchaser, especially the steam-coal user, is as well or better informed on the merits of the different coals as the producer.

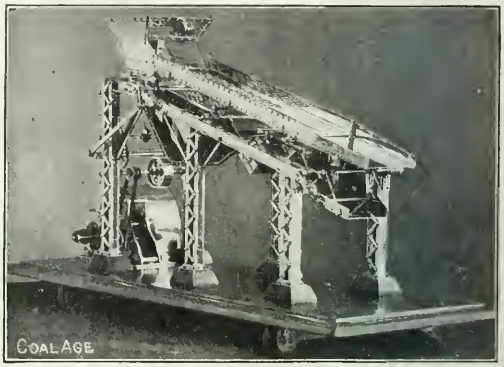
Science has taught the commercial coal consumer to test his fuel for heat value, city ordinances have compelled him to keep down the smoke nuisance, experience and his yearly balance have shown him which coal is the most economical to use and which gives the best results.

On the other hand, the domestic user perhaps does not go into the matter of heat value as scientifically as the producer of steam, but preparation is really of more importance to him than to the latter. The dealer must give him coal free from dirt and slack and if the shipper allows his product to go to the retailer in any other condition, it is the latter's loss, since he cannot sell dirt to his customers.

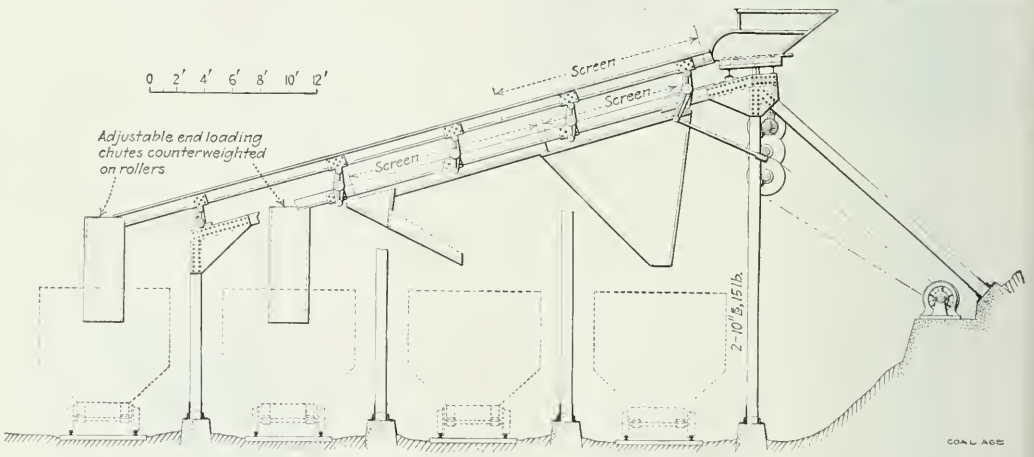
These conditions have caused a constant and increasing demand on the part of the trade for a better preparation of coal at the point of origin and have compelled the mine owner and operator to look to some means of improving the condition of the output. Various methods of screening and rescreening have accordingly been tried out with more or less success.

Shaking Screens Are Most Efficient

It is now generally conceded that the shaking screen is the most efficient means of grading coal, but the many difficulties encountered in the operation of this type of apparatus in its former crude state, have not only been expensive to those who have tried it, but have made others skeptical regarding something that they feared would be a constant source of annoyance and expense to them.



Photograph of a Working Model



Side View of Shaking Screens. Tipple Not Shown

It is a well known fact that the old-style shaker, which is hung to the tipple frame, has a destructive tendency and has even shaken tipples to pieces in a few years or even months. Much trouble with eccentrics, screen connections, etc., has also been encountered, causing delays which have possibly cost the operator in a few days of waiting for repairs the price of an entire outfit.

To say the least, it is a difficult matter to install a substantial mechanical screening outfit on truely scientific

*Wellston, Ohio.

principles in the ordinary lightly constructed, high-frame structure which is constantly deteriorating and being preyed upon by the various elements of destruction, so plentiful around a coal mine. These and other considerations have given the operator good grounds for being skeptical.

In order to overcome some of these difficulties, the Morrow Manufacturing Co., of Wellston, Ohio, have had their engineers at work for some time developing and perfecting an oscillating device which appears to have eliminated the most objectionable features of the old shaking screen and to have incorporated in its construction several features which adhere more closely to good practice in machine design. They are now installing for the Jewell Ridge Coal Corporation, at Tazewell, Va., a steel-frame self-contained shaker protected by a steel superstructure, which is entirely independent of the former.

The accompanying illustrations show the shaker which may be described as follows: The principal frame is of structural steel, the posts and top girders being built up of two 10-in. channels thoroughly tied together with steel lacing and gussets. The whole structure is well stayed laterally by angles and plates, and the principal longitudinal stiffening is effected by the two diagonal braces in the rear also built up of two 10-in. channels laced together, while the heavy double gussets also serve as bracing longitudinally.

How Shaker Is Fed

The receiving hopper is provided with a plate feeder, by means of which the coal is distributed evenly to the first screen of the apparatus. This feeder reciprocates on rollers at a speed of about 30 strokes per minute, and the feed is regulated by an adjustment which lengthens or shortens the travel of the plate. The upper and lower screens have been provided with a novel means of mounting on double arms, so that they reciprocate in opposite directions, thus reducing vibration to a minimum.

The upper or lump screen is provided with 4 perforated steel plates, each 4x6 ft., giving 96 sq.ft. of screening surface, over which the lump coal must pass. The upper end of the lower screen is provided with 12x6 ft. of perforated plate, which screens out the slack and the lower end has 12x6 ft. of a larger mesh, through which the nut passes, and over which the egg coal is carried.

This arrangement gives ample screening surface for all sizes of coal, and the plates, being inserted in sections, can be removed and changed readily if an alteration in grade is desired. Bell cranks instead of eccentrics have been employed to drive the shaker arms, and the connecting rods are provided with adjustable brass bearings similar to those commonly used on the connecting rod of a steam engine. The angular position of the drive cranks in relation to the screens tends to further break up the direction of motion and thus reduce vibration.

The lump and egg tracks are provided with receding chutes, which compensate for the difference in height of the cars furnished by the railroad. These are so arranged that picking tables and loading booms can be added at any time if desired. The other two tracks are furnished with plain chutes to convey the coal from the screens to the cars.

This whole screening structure is covered with an entirely independent steel headhouse, to which there is no possible chance of transmitting vibration. The plate feed is provided with a friction clutch, controlled from the headhouse so that the coal supply can be shut off at any time without stopping the shaker. Furthermore, the apparatus is driven by a motor which sets on its own foundation on the ground.

Preparing Coal for the Coke Ovens

By Milton J. Williams*

SYNOPSIS—Except in the immediate vicinity of Connellsville, coal must be crushed in order to make a good coke. The tendency in recent years has steadily been toward larger and heavier machines, which will handle more coal and produce a finer and more uniform pulverization.

There has been a notable change in the size of coal employed in coke manufacture during the past decade and a half. Twelve or 15 years ago the byproduct oven was little known in this country, and those making coke in bee-hive ovens at that time seldom used crushers, taking their slack or screenings and charging the ovens with coarse coal. It was not long, however, before someone discovered that great losses were incurred in coking coal in this manner, and tried a crusher. This was the beginning of what is now an important step in almost every large coking operation.

The First Crushers Made Coarse Coal

The first crushers used, produced a product ranging from 1 in. down to dust. The results obtained were encouraging, but the crude crushers used were of light construction, gave much trouble, were inaccessible for renewal or repair of parts, could not be adjusted for fine or coarse work in the same machine, and were, generally speaking, unsatisfactory.

Enterprising operators therefore began to search for a more substantial pulverizing machine, and one that would produce a finer and more uniform product. Their theory was that if 1-in. lump and finer gave better results than run-of-mine, a product ¾ in. or ½ in. and finer would give still better results.

About this time (1898) the Shawnee Coal & Coke Co., of Eckman, W. Va., secured from Milton F. Williams, of St. Louis, the first hammer crusher which he built. Within 18 months from the introduction of this machine there were in operation in West Virginia about 35 Williams' hammer crushers, most of these machines being equipped to crush to ¾ in. and finer.

It was not long, however, until all of these crushers were equipped with new cages for ½- in. to ⅜-in. crushing, and all new machines were built with ½-in. perforations. It is now seldom that coal for coking is crushed coarser than ¼ inch.

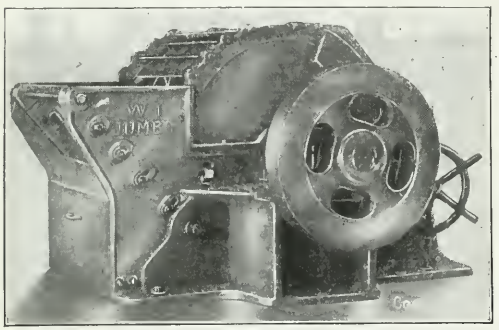
*Old Colony Building, Chicago, Ill.

These operators found that by reducing the size of their coal they were able to produce more coke per oven, and improve its texture, making it hard and firm, something that could not be accomplished without thorough pulverization. Today in many localities in Virginia, West Virginia, Pennsylvania and other coking regions, even with the bee-hive ovens, the requirements are for a product through ⅛-in. opening or finer.

Byproduct Ovens Require Fine Coal

The coal required for byproduct ovens has always been quite fine. When the Hamilton-Otto Coke Co. installed their ovens about 10 years ago, they undertook to charge them with screenings and slack, but soon found that making coke in this manner was a decided failure, as the product when exposed to the elements for but a short time disintegrated and crumbled to such an extent that it had the appearance of crushed coke.

Crushing to ¼ in. and finer gave better results, and it was not long until the byproduct operators all over this country were calling for from 70 to 90 per cent. through



Williams Jumbo Crusher. Note Substantial Construction

⅛-in. openings, and this basis of fineness has prevailed for the past four or five years. There is, of course, no good reason why an operator cannot have a product 90 per cent. through ⅛-in. openings at all times, but this means more expensive and careful attention to the crushers, as working under these conditions they must be adjusted frequently, and the coal must be reasonably dry for the best results.

Coking coal in byproduct ovens would be well nigh impossible were it not for the improved types of crushers. As for bee-hive ovens, many seams of coal are now coked, using slack and screenings. These are, however, practically all in the Connellsville region, where nature has been generous in that the product of the coal measures will produce a good coke without crushing.

Increase in Capacity of Crushers

Almost all other coking coals must, however, be crushed, in order to secure a good coke. Hence mechanical means must be employed to offset nature's neglect in those seams outside the immediate vicinity of Connellsville. In coal crushing today, there seems to be a constantly increasing demand for greater capacities and heavier weights. Twelve to fifteen years ago a crusher with a capacity of 100 tons per hour through a ½-in. openings was looked upon as a large unit. At the present time, crushers with a capacity of 200 tons per hour through ⅛ in. are considered only medium size, and not until we reach a capacity of 300 to 400 tons per hour through ⅛-in. openings is such a machine considered a large one.

In summing up the vast change that has taken place in the size of the product with which ovens are charged, it is evident that the crushing and sizing plant is one of the most important departments of any large coking operation. It is probable that many operators pay too little attention to the selection of the proper crushers as the increase in the percentage of coarse coal greatly affects the structure of the coke, and spoils many a charge that might have been a perfect product.

These conditions have been carefully studied with the result that crushers now manufactured and sold are, in most cases, machines weighing 10 to 20 tons, as compared with those of two to five tons made ten and fifteen years ago. Furthermore, the machines of today are equipped with adjustable hammers, cages and breaker plates to maintain the fineness and capacity.

If the coke operator would pay more attention to the selection of crushers, as important as this matter is to the success of his entire plant, he could save himself many thousands of dollars in equipment, reduce the amount of experimental work, and get results right from the start. Many corporation presidents, managers, superintendents, and purchasing agents have learned, however, that a crusher is an important and valuable piece of machinery and requires as much careful study and attention in installation as many other items about their plant that involve several times the outlay in money.

Germany's Coal Wealth

At the instance of the mining authorities at Bochnur, the coal deposits of the industrial districts of Right-Rhine and Westphalia have been carefully calculated. Within an area of 1532 sq.km. (about 591 sq.miles), which is now being worked, after deducting two billion tons as the amount already extracted, there remains to a depth of 1500 m. (4920 ft.) 32 billion tons of workable coal, while below the 1500-m. line there is estimated to be 10 billion tons additional.

A further area of 1728 sq.km., or about 666 sq.miles, has been opened by borings and is calculated to contain above a depth of 1500 m. a further 45 billion tons of coal. Finally, coal has been discovered in an additional area of about 2900 sq.km. (1120 sq.miles) through scattered borings, with the result that down to a depth of 1500 m. there are here deposits containing 18 billion tons, and at lower depths 151 billion tons.

Labor Conditions at Washington Mines

During the year 1912 the United Mine Workers of America organized local unions at the mines of the Carbon Coal & Clay Co., at Bayno, the Denny Renton Clay & Coal Co., at Taylor and Renton and the Puget Sound Traction Light & Power Co. (formerly the Seattle Electric Co.), at Renton. These companies, however, have refused to sign a contract with the union, and are either operating on the open-shop plan or have closed down.

Methods and Machines for Cleaning Coal

By A. Langerfeld*

SYNOPSIS—Classification of coals. Requirements in specifications for anthracite coal. Description of the different methods and machines that have been used for cleaning coal, particularly the anthracite-breaker methods and machinery. Improvements introduced to obtain a more perfect separation of coal from impure coal, bone, slate and rock. Detail description of the Langerfeld separator and recent improvements in the same. Cost of cleaning coal.

After screening and sizing coal, most of it must be further cleaned to make it marketable. That means that if there are more than certain percentages of impure coal or stone mixed with the coal, the excess must be taken out to make the coal salable.

Classification of Coals

Coal containing less than 25 per cent. of carbon is commonly classed as "rock"; that containing from 25 to 40 per cent., "slate"; from 40 to 60 or 65 per cent., "bone"; while higher percentages of carbon pass for coal of varying quality. It is common to class all coal containing sulphur, rock or other impurities as "slate." "Good bone" is that containing from 50 to 60 or 65 per cent. of carbon, while "bad bone" contains from about 30 to 50 per cent. In chestnut and the larger sizes bad bone is usually classed as slate. It is generally understood that if there is 10 per cent. of actual slate in pea coal, there must not be over 15 per cent. of bone. The same applies to all the smaller sizes.

Specifications for Anthracite Coal
