COAL AGE

Vol. 3 NEW YORK, JANUARY 4, 1913 No. 1

The End and the Means

IS anyone wise who hopes to attain the end without the means? Success in some degree is the chief object each of us is seeking. Education is the means whereby we may reach this goal of our ambition. We cannot be too well equipped for our life work, and by increased knowledge we not only earn more, but we can serve our family, our country and our generation with higher efficiency.

Education is of two kinds—one which we receive from others, and one which we give to ourselves. We refer here to the latter brand. Its office is to call forth power of every kind—power of thought, affection, will and outward action; power to observe, to reason, to judge, to contrive; power to adopt good ends firmly, and to pursue them efficiently; power to govern ourselves and to influence others; power to gain and to spread happiness.

And education should not cease when we leave school; or later, when we have succeeded in lifting our head a little above the crowd. It is no shame for a man to learn that which he does not know, whatever be his age. The two principal difficulties attending the education of people who are "on in years" is their proneness to believe the task hopeless, because of their handicap in age and their obstinate conceit.

Many people who were unknown at fifty have died famous. No one is ever beaten unless he is discouraged, and this latter feeling never helped any man over a difficulty, and never will. Despondency is a disease that saps manhood and produces complete paralysis of effort. Industry pays debts, while despair only increases them.

The conceit of age referred to above is really a species of false vanity, which is less ashamed of being ignorant than of being instructed. Pride is commendable when it dwells in a man's principles, but objectionable in his demeanor. Of course, we all agree that the man who undervalues himself will undervalue others, and he who undervalues others will oppress them.

Many old men are like old trees—past bearing themselves, they will suffer no young plants to flourish beneath them. However, this slight feeling of antipathy between youth and age is reciprocal. Young men think old men are fools, and old men know young men to be so. It is to be hoped that some day both classes will unite in the common belief that "ignorance is a voluntary misfortune, and that wisdom is to the mind what health is to the body."

An oak is not felled at one blow; Edison was not a master inventor the first day. No man was ever born wise, or was wise by chance. Wisdom is neither inheritance nor legacy. Other things may be seized on by might, or purchased with money, but knowledge is to be gained only by long continued study. Simple wishes never mined coal, and mere hoping never started a bank account. The man who cultivates hoping as an employment will find that "like our shadows our wishes lengthen as our sun declines."

When we call on our mind today for its highest efforts, and stretch it to the uttermost in our power, we have done ourselves a kindness. The mind will be all the better for it. Tomorrow we may do it again; each time it will answer more readily to our call. And it is not the quantity of study, or the amount of reading that makes us wise, but the advantage of the study to the purpose for which it is pursued. Mental, like physical faculties, are developed by exercise. It does not matter how bright a mind we have; if we do not use it, we will lose it.

Therefore, if the end of all human effort is honest success, and if this latter can only be realized through knowledge conquered by labor, then no man can afford to neglect training the mind to think and to discriminate between truth and error, which is the real object of education. The desire for knowledge, like the thirst for riches, increases ever with the acquisition of it. We should always remember that no talent comes unasked; no grace of mind stays unurged. There never was a man who reached a point where he could afford to abandon study and live altogether on his past reputation.

A Matter of Co-operation

In obedience to the whispers of the small voice within, we will state a few of our plans for this new year. Conscience forbids our working in the dark, so long as we profess to follow methods of co-operative procedure. Our aim and desire have been to judge matters from the point of view of all, and not of one. We have adhered to the belief that everything is right which tends to the happiness of mankind, and everything is wrong that increases the sum of human misery.

On the preceding page, we called attention to the necessity of gaining an education. Here we intend to outline briefly just how Coal Age can help in the accomplishment of that end. Everyone knows that even a skilled workman can't turn out a master job if his tools are lacking in completeness or quality. Preparation is half the battle. A great occasion is valuable to us, just in proportion as we have prepared ourselves to make use of it.

Last year the publishers of this paper expended more than a hundred thousand dollars getting together valuable data and printing Coal Age each week. The individual subscriber could not have purchased this same information for a penny less. Is it not the essence of wisdom, therefore, for each reader to take the fullest advantage of the opportunity offered? In other words, we are desirous of furnishing you with proper tools by way of a practical education. Resolve to spend two evenings, say six hours a week, carefully reading Coal Age, and at the end of one year you will know a lot more about actual mining than the young fellow who has just dropped in from a nearby college, with a sheepskin diploma locked up in his trunk.

We are not writing this with the idea of securing new subscribers; it is a plain talk directed solely at those readers whose $3 we have already banked. Of course, we might let it rest there, but we don't intend to. Education is one thing every man wants and is willing to pay for, but won't carry away with him. It's the same old story—with a staircase before us, we look for a rope to go down by.

Getting down to facts—The best way to determine what will be is to consider what has been. Last year we published 1776 pages of editorial matter. During the coming twelve months we will better this record both in quantity and quality. Not every page will interest each person, but if only one-half the articles appearing are read and digested, the result will be highly beneficial. Don't forget the old proverb—"A young man negligent, an old man necessitous."

The manufacture of coke will come in for greater attention this year than heretofore, and we will start a "Power Section" in our paper commencing Feb. 1. Our idea is to subdivide coal mining into its special phases, placing each department in the hands of an engineer, expert in the particular field he is to cover.

As a concrete example of what is to come, here are a few articles soon to appear: Electric Locomotive Practice; The Testing of Mine Air; Scientific Management; Early History of the Smoke Problem; Modern Strip-Pit Mining; Points from British Coal Mine Inspectors' Reports; Relation between Subsidence and Packing; Distribution of Producer Gas; Haulage Systems in European Collieries; *Series on* First Aid to the Injured; Occurrence of Coal in Alaska; *Series on* Economy in Colliery Power Plants; Compressed Air Troubles in British Mines; Strength and Size of Coal Pillars; Electric Mine-Signaling Systems; Shotfiring by Electricity; *Series on* The Preparation of Bituminous Coal; The Psychology of the Illegal Strike; Belgian Methods of Underground Development; The Engineering Aspects of Diamond-Drill Prospecting; The Use of a Refrigerating Plant for Cooling and Drying the Air in Deep Coal Mines; Modern Plans for Shaft Bottoms; Recent Developments in Byproduct Coke Ovens, and dozens of other articles now being prepared for us by coal men in all parts of the world.

In conclusion: We want you to co-operate with us, and get your money's worth. Don't be content simply to read what the other fellow says, write something yourself. There is no difference between buried treasure and concealed knowledge. We are judged, not by our intentions, but by the result of our actions.

Reducing Ventilation When Firing

By J. T. Beard

That there are always two sides to every debatable question goes without saying. The truth of this statement has been amply proved by the previous discussions in Coal Age, but by none more so than by the one just closed.

While there are doubtless still some ardent advocates of the doctrine that no mine ventilating fan should be built reversible; there are many other, equally practical, mining men who have been converted, by the last discussion, to the belief that no mine is fully equipped without this important feature.

All contend, rightly, that a reversible mine fan possesses possibilities that make for either *safety or destruction*, depending on the use to which it is put; and this, in turn, has been shown to depend on the intelligence, experience and accurate knowledge of conditions, on the part of the man in charge. But, while a few men see greater safety in excluding this feature of mine equipment from the list, because of its possible misuse; others claim that the fan should be built reversible so as to increase the chances for safety; and its use safeguarded by suitable restrictions and regulations.

We may ask: Is safety more assured by the absence of weapons of defense, on the ground that where there is no shotgun around there can be no accidental shooting? Is the theory correct that the nation's peace and safety are better assured and the chances of war minimized by the absence of the munitions of war? Most men, now, agree that it is the prevailing possibilities of action that speak for safety and success, in every sphere of life.

We are now facing another important subject for discussion. Although we do not realize it at present, there are perhaps fewer subjects fraught with greater possibilities of safety or danger, in coal mining, than the question: *Shall the normal circulation of air in the mine be reduced during the time of firing shots?*

This practise has been tried, in some mining districts, and the success claimed has won a few adherents; while on the other hand, by far the large majority of practical mining men have always considered it unsafe to reduce the air circulating in the mine, at the time of firing. In many districts, in the East and Middle West, it has been customary to speed up the fan, at such time.

The question is fairly a debatable one. Let it be understood from the start that this is not a question of high velocities, at the working face, which we all agree are both objectionable and dangerous. Neither is it a question of humidity or temperature of the mine air, except as these are incidental. It is not a question of whether the shots face the current or otherwise.

Let it be assumed that the mine, under normal conditions, is well ventilated by a current of pure air that sweeps the entire working face with a moderate velocity, sufficient for the removal of what gas, if any, is generated. Suppose, under these conditions, from 400 to 500 shots are to be fired; either by shotfirers, after the men have left the mine, or by a well-established system of rotation, in which the men fire their own shots in regular order, beginning on the last of the air, at a fixed time, and proceeding regularly against the air.

Now, ask the question: Will there be less danger of a gas or dust explosion occurring and developing into a mine explosion when the air has been short-circuited at some point, so as to reduce the circulation in the workings to a low ebb or cut it off completely? This is the question for debate.

It is the aim of Coal Age to confine the discussion of each subject, as far as practicable, to one month; except where the interest is such as to call for an extension of the time. Let every practical mining man help to decide this question, by giving his experience and conclusions.

SNAP SHOTS IN COAL MINING

Views at Anthracite Mines in Northern Pennsylvania Field

Fig. 1—Electric motor hauling trip to slope in hard-coal mine near Scranton. Shows the hard sandstone roof so common in the anthracite region.

Fig. 2—Miner and laborer working in mine at Pittston. The miner is drilling a hole preparatory to shooting.

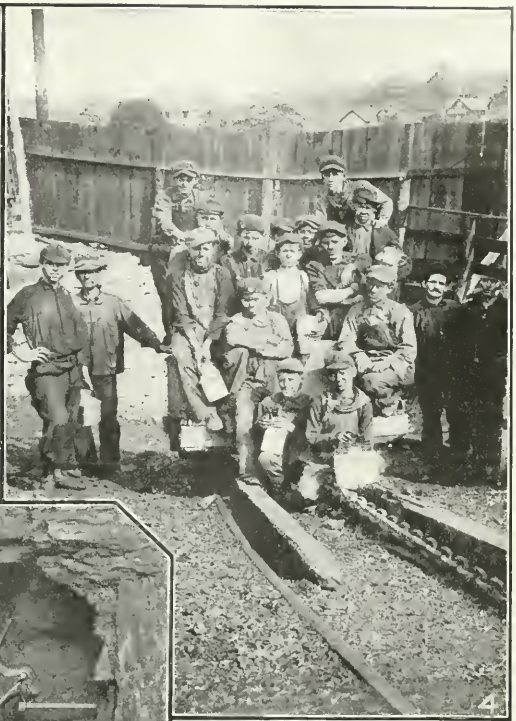
Fig. 3—Pushing cars onto cage previous to hoisting, in Erie Mine No. 6, at Dunmore. The entire bodies of the cars in the anthracite region are built to overhang the track, giving them a large capacity.

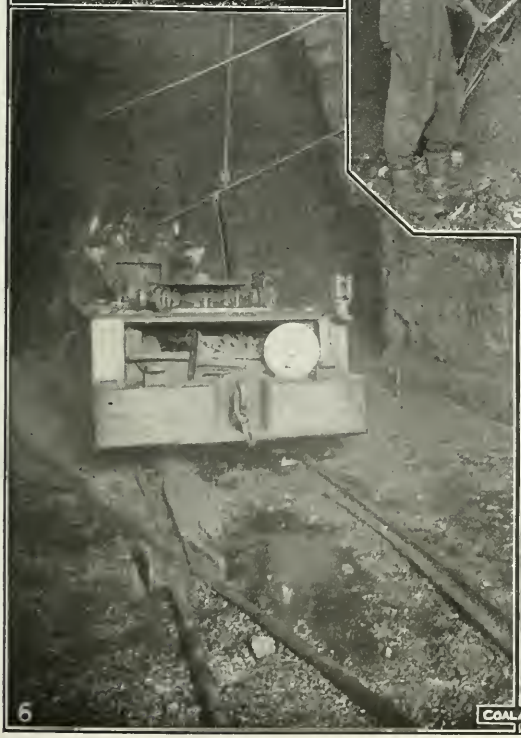
Fig. 4—Miners and breaker-boys ready to go home after a hard day's work in mine near Scranton. They hardly exhibit the "distressing effects of child labor," of which we have often read.

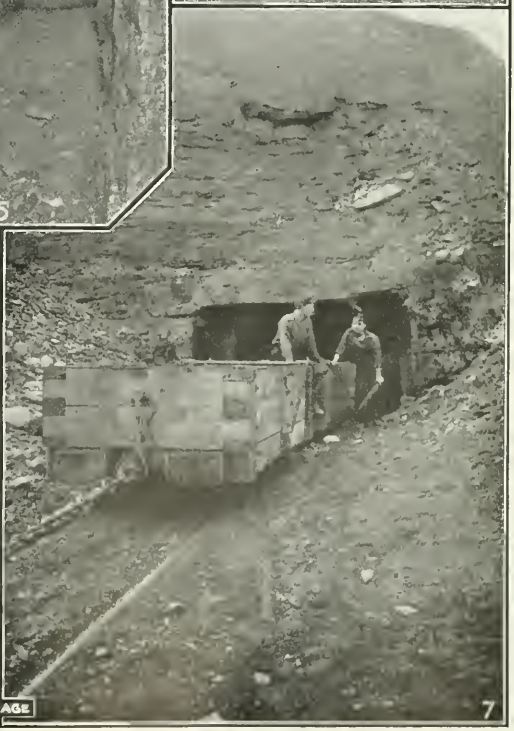
Fig. 5—Miner drilling hole at face in an anthracite mine. Practically all the coal is shot from the solid, without preliminary under-mining.

Fig. 6—Electric motor pulling trip of loads to shaft in mine at Dunmore. Exhibits method of suspending trolley wire from roof by long rod, thus avoiding use of a cross timber.

Fig. 7—Empties ready to go down slope in mine at Pittston. The drift mouths of the anthracite mines are rarely of an imposing character.







COALAGE

IDEAS AND SUGGESTIONS

When Times Are Good and Men Are Scarce

By A. W. Hesse*

When times are good, cars are scarce and so are men. When the trade is poor, men and cars are plentiful, but the mine work drags along like "a ship without a sail." For this reason, the superintendent and mine foreman are between the "devil and the deep sea," most of the time.

It was hunger that drove the Germans across the Rhine. The high cost of living and the desire to live near a city is causing a good many shifts in the mining population. Behind every such change we find an economic fact.

During these times of heavy tonnage demands, the order to rush everything is passed. Places are provided in the mine, on headings that ordinarily would not be worked until the pillars could be extracted at once. The "green" man, on the other hand, must have a solid place. Suppose you get a gang of men and place them on these headings. They labor two or three days shooting or digging the places to "death," and then the car shortage strikes you. A day or two of "no cars" and the men disappear like scared rabbits.

Either the use of that persuasive coin in some other fellow's hand, or the sight of some other mine's car allotment is sufficient to take your men away in droves; and it is done very frequently in these days.

If there is any time at which a mine superintendent longs for winter, it must be when men are scarce—in the hope that cold weather will drive in the miners for at least a few months.

To escape that scathing criticism, so freely given by conservationists, care must be taken not to overdevelop the mine. Most of us know that once a mine is established, the recovery of heading, room and pillars should be properly proportioned in order to avoid that loss of coal so frequently due to falls in standing rooms.

Quite frequently a mine is overdeveloped because of the inability of the men working therein to turn the trick of robbing. This is getting to be a very important factor. Pick miners are becoming scarce and, unless pillars can be cut by machine, the return on this work is very slow.

A remedy often resorted to when men are scarce is known as concentration. The labor must be thoroughly systematized in order to give a high production.

A driver will handle coal from eight men on a single heading much easier than he will from three men on one heading, two men on another and three men somewhere else. Likewise, a motor will make quicker trips when hauling from a concentrated operation than when running all over the mine.

There are any number of mines right now struggling along with fewer miners, notwithstanding the demand for coal, and it is safe to say that these mines will show a higher ultimate percentage of recovery than those mines in which systematic work is thrown to the winds and the mine filled with men.

It is now a question whether it is more profitable to take advantage of the present demand and run the risk of losing a quantity of coal in pillars, or to keep the work properly lined up in the hope that with a high percentage of recovery and a consistent market the returns will far offset those of the former method.

*Assistant chief engineer, Consolidation Coal Co., Fairmont, W. Va.

Inadequacy of Many Return Airways

By Francis Glover*

In these days of modern progress, when most problems seem so thoroughly understood, it is really appalling that mine explosions should come around as regularly as the "Hardy Annual." For 20 years or more, after every explosion, an inquiry has been made as to its cause, and the usual result has been to place the blame on an ignition of gas caused by a defective lamp, a blown-out shot or the negligence of someone.

Rarely has any further inquiry been made. In looking for ultimate causes, it is remarkable that the condition of the return entry has not been duly considered. For at many mines today which have a fine equipment on the surface and adequate haulage airways, you will find the other ventilating passages incapable of performing the work demanded of them without excessive resistance.

In some cases they were not large enough to carry the air when first driven, but frequently they are large enough but too crooked, and the air is much impeded in its progress. It has not appeared necessary to drive them straight because, as soon as a section is completed, the rails will be removed.

This fact not only explains why we permit the heading to be crooked, but also why it is allowed to become full of fallen rock. Once the road is torn up, it becomes impossible to clear up the heading without excessive expense. It therefore fast becomes full of a mass of broken slabs of roof, through which the air cannot find its way at any speed.

In some mines where such caves have occurred, it has been customary to break up the rock into smaller sizes, with dynamite, so that it will lie smoothly on the floor and give the air an opportunity to travel without obstruction over it. But in many mines even this is not done, and the airways not being used for haulage, traveling or piping, and so not used or open for inspection fill with rock, yet, because the airways are not explored, the reason why the air is hard to move is not easily apparent.

A larger water gage is used and much of the air is lost which would otherwise go to the face. The practice of leveling the rock by dynamite, to which I have referred, is dangerous and not to be encouraged, because

*Consulting engineer, Box 276, Ladysmith, B. C.

a body of gas in a gaseous mine might come along the heading at any time and be ignited by the open shots.

At a colliery in England, of which I was the assistant general manager for a long time, the output for the last 30 years has been from 2000 to 3000 tons per 8-hr. day. The depth of the lowest bed at the shaft is about 2250 ft., and as the present workings are about 3000 ft. from the shaft bottom and the seam is dipping 1 ft. in 7, the depth from the surface is about 2680 feet.

The bottom seam is very gassy and at different times had been ignited at most of the adjoining collieries, but at this particular mine during the whole period of 30 years, not the slightest mishap has occurred. Mueseler lamps were used, and this light, while not perhaps one of the best from an illuminating standpoint, is more than ordinarily safe, because it goes out when held a little out of the perpendicular. Thus, lamp glasses are not often cracked.

No shotfiring was allowed while the men were in the mines, and the rules and regulations were strictly enforced. All coal dust was removed from the main roads and the auxiliary gangways.

But I do not attribute the safety of that mine to any of the above conditions and safety regulatations. I have no doubt that occasionally a defective lamp *had* been used during that 30 years, and that some shots *had* blown out. Its safeness from gas explosions was due to the efficient and systematic way in which the mine was laid out and had been worked from its commencement, to its splendid airways, so designed and maintained that any gas which was liberated speedily found its way to the surface, accompanied by sufficient air to dilute it.

During my employment at this mine, one of the overmen and myself were sent to a near-by colliery, which had been working about six years, and where they had all the latest "tackle." We went to inspect a fine endless-rope haulage, which had recently been installed. On the surface, the colliery was well laid out, and there was a fine ventilating fan.

But when we got down to the bottom of the main-haulage incline, we noticed traces of gas. In the workings, we found quite a body of it and, suspecting the cause, we inspected the return airway and found it not at all what it should be. Some three or four years later this mine exploded and killed between 200 and 300 men, and everyone seemed to wonder how it happened, for the mines in that district are not subject to spontaneous combustion.

It takes two things to cause an explosion, the fire and the fuel. If you remove the fuel, the explosion cannot take place, even if the fire is applied.

Producer Gas from Low Grade Coal

It may be of interest to American firms making use of producer gas for different purposes to know that within the last two years several French inventors have taken out patents for, and are now putting into actual operation, a system of forced-draft furnaces, burning even the poorest grades of coal and coke. These furnaces are employed in the production, by a method also patented, of producer gas from low-quality coal containing up to 65 per cent. of cinders.

With one exception, however, all of these inventors have confined their experiments and operations to small "gazogènes," as these furnaces are called, producing sufficient gas to drive only low-power engines, etc. The one exception to this is a company (whose name may be had from the Bureau of Foreign and Domestic Commerce, Washington, D. C.), capitalized at $240,000, which manufactures apparatus sufficiently large and powerful to produce gas for machinery of nearly 1000 hp. per "gazogène." As a matter of fact, the inventor informs the consulate that there is no limit to the power of the machine, it being merely a matter of construction.

These "gazogènes," or producers, in addition to the generation of gas, are so constructed as to recover the ammonia and coal tar and other byproducts of coal. This is done, however, only in the larger sizes. The coal or coke used for the production of gas in these machines is not broken up or crushed in any way.

A Unique Haulage System

In these days of high-efficiency electric locomotives, which haul trips of 40 to 50 loaded mine cars at a relatively rapid speed, it seems strange that a coal mine depending entirely upon dogs for haulage trips can operate profitably, yet such is the case.

For the past 27 years, W. A. Werner has depended solely upon dogs of various breeds, from rat terriers to Newfoundlands, for haulage power in his mines, at Zanesville, Ohio. The average output of this mine is 2000 bu. (80 tons) per day, which is loaded on wagons and delivered to Zanesville. The entire output is consumed locally.

Dogs Hauling Coal from a Zanesville, Ohio, Mine

The vein is about 3 ft. in height and no roof is taken down. Some of the entries are driven to a distance of 2500 ft., and the rooms are from 300 to 400 ft. deep. Each miner mines his own coal, loads it into cars, which hold about 1800 lb. run-of-mine, and assists the dogs in hauling it to bins on the outside. The car wheels are without flanges and run upon wooden tracks. From one to three dogs haul each car, assisted by the miner, who rides on a "lazy-board," which projects behind the car. Sitting on this "lazy-board" the miner helps the dogs by pushing with his back against the car and his feet on the mine floor.

Upon reaching the bins outside, the miner tips his coal and then rides back into the mine, the dogs taking him back to the face of his coal.

The miners prefer dog haulage, as in this way they do not require anyone to assist them and can do their own loading, hauling and tipping of coal.

A Model Plant in the Coke Region

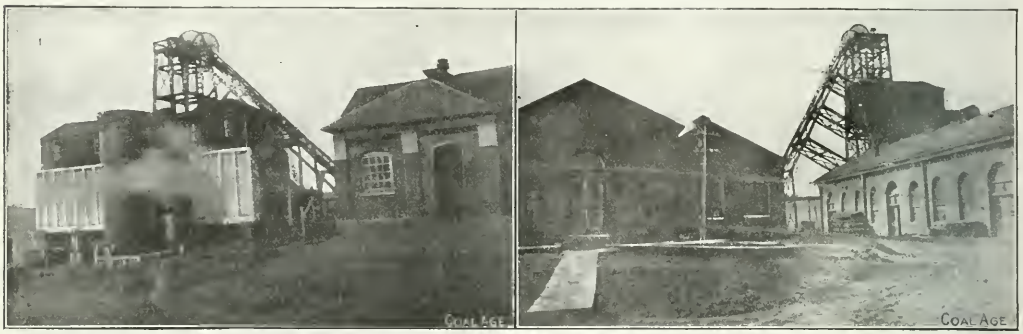
By Sim Reynolds*

SYNOPSIS—Some notes on one of the important Connellsville coke plants. It is estimated that the life of this operation will exceed that of the district as a whole. Mining is conducted along broad and comprehensive lines and unusual attention is devoted to welfare work.

East of the Monongahela River, in that part of Pennsylvania known as the Coke Region, a great deal has been done in late years to bring coal mining, coke washing, and the living conditions of the employees of these industries up to the perfection they now present. In some cases this has been a settled and persistent policy on the part of the companies, rather than any sudden outburst of zeal in coke manufacture and mining ethics, and the subject of this sketch, the Oliver-Snyder Co., is an example of this kind.

This company has been in the coke-making business for about 20 years, and it is stated on the authority of one of its chief officials that at the time recently set by an eminent mining engineer for the exhaustion of the coal in the Connellsville Region, this concern fully expects to still be engaged in the business of mining coal and making coke, so extensive are their properties. The company operates three plants known as the "Oliver No. 1," "Oliver No. 2," and "Oliver No. 3." In all they employ about 1500 men and operate 1100 coke ovens. The coal acreage consisted originally of 3300 acres, and of this perhaps only about 50 per cent. has been exhausted up to the present time.

The company's present workings are reached by three main hoisting shafts about 400 ft. in depth. Near the middle of their property there is a central pumping station which takes care of all the water made by all three mines. The power plants are practically identical, of approximately 1000-hp. capacity and equipped with Parsons' Coke-Breeze Burning System of heat-generation under the boilers. Transmission of coal to the shafts underground is by rope on the main entries, the loaded cars being gathered by horses. Ventilation of the mines is obtained by steam-driven fans of the Capell type, sizes 10x18 ft., producing now 150,000 ft. each with a 2-in. water gage. Shipments are made from all three mines over the B. & O. and the Pensylvania Lines, both systems running through the properties. The company operates 400 private cars.



Two Views of the Surface Plant at the Oliver No. 2 Mine

Welfare Work of the Company.

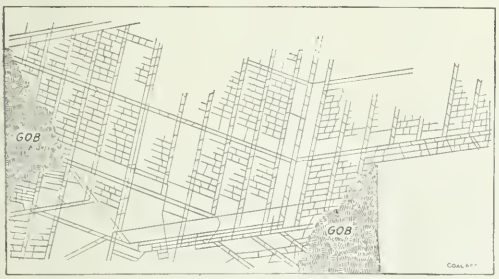
As an example of the interest the Oliver-Snyder Co.

Typical Miners' Houses at the Oliver No. 2 Mine, Oliver, Penn.

*Mt. Braddock, Penn.

shows in the welfare of its employees it may be noted that 44 miners' houses are being moved from their present site to a position where they will be totally free from the coke-smoke environment. The miners' houses owned by this company present an unusually attractive appearance, being painted a slate color and trimmed with white, with neat fences and outbuildings and ample room for gardening and grass plots. Obviously much care and thought have been given to the living conditions at these three plants, as is readily seen by the well graded streets, lined with rows of large shade trees planted years ago. This is something which costs the company owning the new mining town, practically nothing except a little trouble and thought and yet which in years to come will pay great dividends in accrued benefits to the health and happiness of the employees. Also these miners' homes are supplied with running water and electric light. One of the dwellings has been fitted up as a Y. M. C. A. building, where sociological work and a mining class is kept up under the direction of Robert Ainsley, one of the foremen of No. 2 mine.

The first aid work of the three plants, which consists of five trained crews, is managed by Clyde Brehm, Chief Electrician for the company. The managing head of



Map Showing System of Working in the Coking Region

the Oliver-Snyder Co., Mr. Fred C. Keighley, is vitally interested in all that concerns the welfare of the company's employees as well as the product of the mines, taking an active interest in the living conditions and the home life of his men, not a few of whom have been with the company as long as Mr. Keighley himself, and that is nearing the quarter century mark. This fact alone speaks well for the relations between this company and its workers.

In a celebration at Uniontown recently, termed "Old Home Week," a profile map of Oliver No. 2 Mine on exhibition there created quite a great deal of interest. This was not due alone to the excellent method of work shown, but because of the unique construction of the map. The plan of the workings had been etched out on black leather, and later traced in with white enamel. The idea originated with the General Superintendent Keighley, and the map was made under his direction. It has since been presented to the Mining Department of the School of Mines, State College, Pennsylvania.

First aid hospitals in the interior of the mines of this company are an interesting feature of their work. They are installed near the foot of each shaft, and are replete with rescue and first aid apparatus, are well lighted by electricity, have hot and cold running water, etc. Injured workmen can there receive attention before being conveyed to the surface.

Anthracite a Luxury

Anthracite coal was at one time an important factor in blast-furnace practice, but its use in that line of industry has now almost entirely ceased, according to E. W. Parker, of the United States Geological Survey, as it has been supplanted by coke made from bituminous coal. The principal demand for anthracite will be in the future, as it has been in the more recent past, restricted largely to domestic trade, for which such sizes as furnace, egg, stove, and chestnut are required. The breaking down of the lump coal, which was formerly a marketable product, for the preparation of the domestic sizes results in a much larger proportion of the small or undesirable sizes, all of which are sold at less than the cost of production. All the profits on the mining operations must be obtained from the prepared domestic sizes, for the revenue obtained from the smaller sizes, which are sold largely in competition with bituminous coal for steaming purposes, serves only to reduce the cost of the domestic sizes. The conditions under which the anthracite mines are operated, the greater depths to which the workings are carried, the consequent increased expense of mining, and the increasing cost of labor all contribute to make anthracite fuel more and more a luxury.

During recent years the anthracite operators have adopted the policy of making an allowance of 50 cents per ton from circular prices for domestic coal purchased in April of each year, with an advance of 10 cents per ton for each succeeding month until the schedule prices are restored in September. This has had a more salutary effect in steadying the anthracite trade than any other action taken by those controlling the anthracite industry. Its purpose is to encourage the purchase of coal in the spring and early summer, making the cellars of the consumers the storage places for the following winter, and at the same time to cause the mines to be operated more regularly, thus giving steadier employment to miners throughout the year.

Price of Government Maps Increased

After Jan. 1 the standard topographic maps of the United States Geological Survey will be sold at 10 cents a copy or 6 cents wholesale, an order amounting to $3 or more entitling the purchaser to the reduced rate. These maps have heretofore been sold by the Director of the Geological Survey, under authority of Congress, at 5 cents retail and 3 cents wholesale, but for some time it has been recognized that this price has been too low considering the cost of their preparation.

The Director of the Survey at Washington will be glad to furnish an index map, covering any area desired, which shows the particular quadrangles, as they are called, which have been surveyed and the corresponding maps issued for sale. This index-map circular also contains a list of special maps of the United States, of states, and of national parks, mining camps, etc., with the prices, and a list of available geologic reports on any part of the area shown.

Strip Pit Mining with Steam Shovels

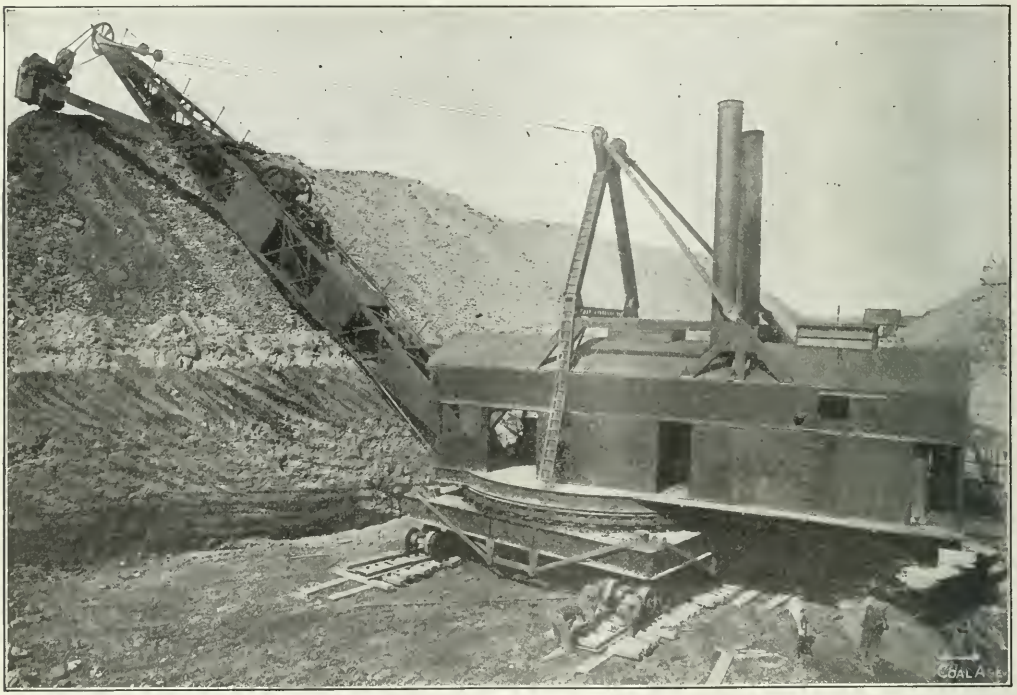
By C. M. Young*

SYNOPSIS—The recovery of coal adjacent to the outcrop is often difficult to effect in the mine, due to the disintegration of the roof, and in such areas stripping must be resorted to. Modern development in methods of stripping has also brought with it some remarkably low costs. This article describes an operation in Kansas where the largest shovel in the world is in use.

The coal fields of southeast Kansas now present a spectacular illustration of the application of machinery to mining. This is strip-pit work, in which the overburden is removed by the largest steam shovels yet constructed.

In this part of the state the coal outcrops and the strata dip gently to the west and north. Most of the coal is extracted from shaft mines, worked by the room-and-pillar method, but near the outcrop the roof is too poor to permit underground work without prohibitive expense for timbering. The coal has been worked back from the outcrop by stripping for many years, but only ordinary slip scrapers were employed until recently.

There is a considerable area of coal land, lying between the shaft mines on one side and the limits of profitable scraper stripping on the other, which can be worked by steam shovels. Within these limits the overburden will vary in thickness from about 10 ft. to 30 or 35 ft. Considerable coal has been stripped by scrapers to greater depths than 10 ft., but large quantities remain with less cover than this which will be stripped by shovels. There is coal of greater depth than 35 ft. which cannot well be handled under cover, but this is probably the limit of profitable stripping under present conditions, though an advance in the price of coal may make it profitable to strip to greater depths.



Photograph of the World's Largest Steam Shovel on a Stripping Operation in Kansas

The Marion Shovel

There are now working in the district about twenty shovels, having an average dipper capacity of about 3½ cu.yd. The most spectacular work is being done on the land of the Central Coal & Coke Co., where there are two firms operating near together under contract. One of these is now erecting the third of three Bucyrus shovels, and the other has just completed the second of two Marion shovels.

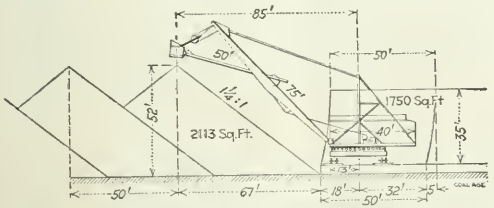
These shovels are impressive in size and capacity. The Marion machine has dimensions as follows:

Dipper capacity	5 yd
Boom	90 ft
Dipper handle	54 ft.
Height of dump above rail (boom 45°)	65 ft.
Radius of cut at 40 ft. elevation	103 ft.
Radius of cut at bottom of pit	71 ft.
Reach from pivotal center to center of dump	95 ft.
Size of hoisting engine (double)	14x16 in.
Size of rotating engine (double)	10x11 in.
Size of crowding engine (double)	9½x9 in.
Size of hoisting cable	1¼ in.
Size of boom hoist cable	1 in.
Approximate working weight	525,000 lbs.
Ballast	30,000 to 40,000 lbs

* Associate Professor of Mining Engineering, University of Kansas.

This machine was shipped in nine cars and about three weeks' time was required for erection. It is carried on four 4-wheel trucks. In this type of shovel the boom does not turn, but the upper frame carrying the machinery rests on forty-five 12-in. rollers. The Bucyrus shovels are mounted in a similar manner and this fact makes it unnecessary to turn the shovel at the end of the cut. Instead of this the whole upper part is swung around on the lower frame and digs backward on a line parallel to the first cut. The foot of the boom is vertically above one side of the roller track, so that the weight is transmitted directly to the lower frame.

To make it possible to move the machines over uneven tracks, they are provided with track equalizing devices. These are hydraulic cylinders placed at one end of the frame, and transmitting the weight from the lower frame to the trucks. They are provided with a pump and with a



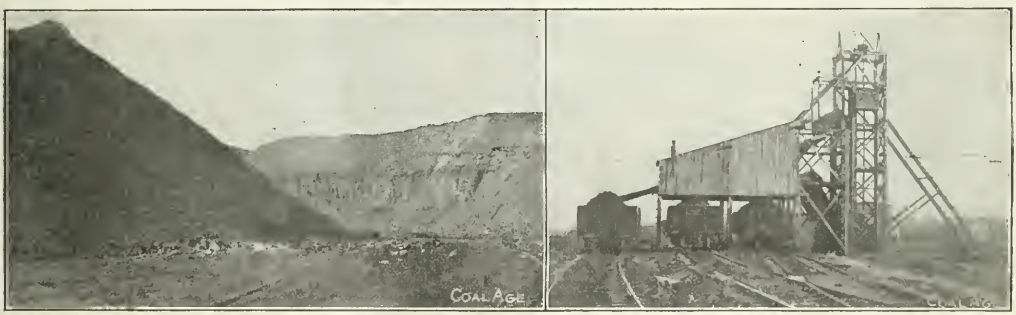
Working Range of a 3½-yd. Shovel

or 34 to 35 ft. of overburden from 50 ft. of coal, dumping 85 ft. from the center of the turntable. The position of the shovel and the cross-sectional area of the overburden and spoil bank when stripping 35 ft. of overburden are shown in the line drawing supplied by the Bucyrus company. They will dig their way to the coal on an 8 per cent. grade. Some machines are provided with electric generators and lights for night work.

It is stated that the cost of handling the ordinary overburden of the district will be from three to four cents per cubic yard. Probably these figures are slightly low, as the wage scale has been raised since they were given. The present scale is: Shovel runner, $150 per month; craneman, $110 per month; fireman, $75 per month.

The 3½-yd. shovel, removing 20 ft. of overburden, will uncover about 6000 tons per month of coal 3 ft. thick at an expense of about $1075. This does not include the handling of the coal.

The uncovered coal is easily handled. Vertical holes are drilled with augers and squibbed with 2 to 3 in. of dynamite to remove moisture. The dynamite, with lighted fuse, is dropped into the hole and the blowing out of the fuse removes danger of premature ignition of the black powder, which is immediately poured in. This is fired by a short length of fuse, which is dropped down a pipe, acting like a fuse. The coal is then loaded by hand and hauled to the tipple. The simple type of tipple



Scene in a Strip Pit About 90 Ft. Wide, and Type of Tipple Used for Screening the Coal

bypass, so that the fluid may flow from one cylinder to another or to the pump reservoir. This device permits the moving of the machine on tracks laid on the surface of the uncovered coal with almost no ballasting and without torsional strain on the frame.

One Marion machine has excavated a pit 92 ft. wide and 24 ft. deep, piling the excavated earth on the top of the bank at one side. This gives an idea of the magnitude of the machine.

The Bucyrus Shovel

The Bucyrus shovels are similar in general design to the Marion, but the company using them has not employed any of the extreme size mentioned above, though the manufacturers are prepared to build them. The largest now used in this field have 3½-yd. buckets, 75-ft. booms, and weigh about 175 tons in working condition. Assuming coal 3 to 4 ft. thick, these shovels will remove 15 to 20 ft. of overburden from 80 ft. of coal, used is shown in the accompanying photos. It is in fact little more than a frame for the screens.

One company expects to haul cars to the tipple with an endless rope. Another will lay track into the pit on a 3 per cent. grade and haul with locomotives. The tipple is located opposite the middle of the pit on the side toward which the stripping is progressing. There are several thousand acres of coal suitable for stripping and the operation as now carried on should add considerably to the output of the district.

When using rescue apparatus which contains caustic soda, remove the soda from the bag as soon as the apparatus is taken off or it will cake and have to be dissolved with warm water and a fresh supply procured. If removed at once it may be washed, dried or melted, recast and used again. India rubber regenerating and breathing bags should be washed out with warm water and thoroughly dried before the apparatus is recharged unless it is needed immediately, in which case washing is not necessary. Masks and rubber mouthpieces should be washed with soap and water, not only for cleanliness, but to preserve the rubber.

The Reforestation of Mining Areas

Special Correspondence

SYNOPSIS—In the Midlands of England, the tree found desirable for reforestation of ground which is covered with mine refuse is the black alder, which also is highly resistant to smoky atmospheres. Instead of popular interest in tree planting being confined to the setting of individual trees on land around schoolhouses or bordering on roads, it should be extended to the growth of forests planted largely for the purposes of social betterment.

The problem resulting from the general destruction of forests assumes a serious aspect in the more important mining and metal-working centers of the world. A large extension of the movement for reforestation has taken place in the Midlands of Great Britain.

Figs. 1 and 2. Fever Hospital Mound, Bilston, South Staffordshire. Planted 1907-1908. The Alders Are About 10 Ft. High. Photographed in Sept., 1912. Sycamores in Foreground Are Spindling, Owing to the Seasons Not Having Favored Their Growth

The areas adjacent to Birmingham and surrounding industrial cities are not called without reason the "Black Country," and there is no doubt that until quite recently the predominant features of the scenery were furnace slag, mine heaps and dreary looking waste lands interspersed with seething industrial activities.

Mine Waste Is Suitable Soil for Trees

To correct this, an association was formed in 1903 as a result of a public meeting held in Birmingham, to promote the reforestation of waste ground in the Midlands and particularly in the parts of Staffordshire and Worcestershire known as the "Black Country."

Once this area was forest, but at the time of the founding of the association, a large area lay wholly waste, no attempt being made to conceal the shaft dumps and spoil banks. This area, at the least computation, contained considerably more than 11,000 acres and was wholly occupied by heaps of rubbish.

In order to restore this land to its former beauty, forests were planted and developed according to the principles in practice in France, Belgium, Germany and Austria. It was found to be possible to grow thriving trees in such unpromising situations as the soil formed of mine waste, furnace slag and even the ash of burned shale.

The deterrent effect of a smoky atmosphere on the growth of trees was argued, but it was found that smoke was not so harmful as sulphur, which was emitted solely by certain industries only found in a few localities. Moreover, the increasing use of power or producer gas and the utilization of waste products of combustion in the industries of the area present a factor of hope which should become more and more predominant as economy is practiced in industrial operations.

Manner of Planting Trees

No manure or imported soil was found necessary to make the trees take root, and the only preparation made was to dig pits about 1 ft. cube, the top soil being placed at the bottom. Trees two to four years old were then planted 4 ft. apart in such pits, or 2722 trees per acre. In the older plantations the trees were spaced 5 ft. apart, or 1742 per acre, but these did not do so well as with the closer spacing.

It was found that almost all the work of planting could be done satisfactorily by unskilled labor. It was early realized that plantations, even of infant trees, were better neighbors than unsightly waste heaps, and the presence of each plantation added enormously to the value of building land in its vicinity.

The first two plantations were finished before Christmas Eve in 1904, and arrangements were pushed forward to increase the work of the association, which, it should be remarked, was supported by voluntary contributions.

Fig. 3. Fever Hospital Mound. Willows in Foreground, Alder and Wych Elm Higher Up. The Piece of Shale Ground in the Rear Has Small Alders on It, Which Are Stunted Owing to the Severity of the Wind. Photographed, Sept. 12, 1912

At the present day, there are 21 plantations with a total area of 73 acres holding about 150,000 trees.

Various methods of forestry have been attempted and experiments have been made with various species in order to determine the most suitable methods and trees for the area under consideration.

The Black Alder

Of all the trees which have been tried, the black alder has done the best. Fig. 1 shows a typical tree planted in the winter of 1907. It is now 10 ft. high. The sticks in the foreground are sycamore, planted at the same time. The white alder, as used for mine banks on the Continent, does not as yet complete on equal terms with the native tree.

It may be pointed out that the alder has three distinct advantages in this connection. In the first place it grows fast and has a high resistance to the effects of smoke. In the second place it fertilizes the soil, the action being due probably to fungoid colonies at its roots. As a third advantage, its wood is readily salable at an early age.

It will be seen that the Midland Association has had a somewhat different experience from some other forestry organizations, where it has been found that conifers, notably, Corsican pine and Sitka spruce have been the most advantageous trees to plant in reforestation schemes. Possibly the preference of other foresters has been due to the fact that conifers grow faster than oak, ash, beech or elm, and in the forester's mind, conifers always have the first place.

Birch, alder and poplars are much needed in the lumber market and are quick growers. Corsican pine and Sitka spruce are not much used in Great Britain.

Fig. 4. As Seen in January, 1912

Fig. 5. As Seen in April, 1912

Black Wagon Mound, Old Hill, South Staffordshire, England. Alders on North Side in Bare Shale, 2½ Years After Planting

although there is no reason for their being neglected. The trees actually preferred are Scotch pine instead of Corsican, and Norway spruce instead of the Sitka variety. It is proposed in the plantations under the care of the Midland Reafforesting Association to try the Corsican and Sitka varieties when they obtain an opportunity of doing so in more or less smokeless districts.

These trees, however, do not flourish very well where there is much smoke and the alder, therefore, appears to be preëminently the tree which is adaptable for planting on mine-waste heaps and in similar localities in the vicinity of large works, where there is a smoky atmosphere.

Where Timber Has a Large Money Value

Fig. 2 shows alders four years old planted 5 ft. apart. It has been found that the poplar grows freely. Under normal conditions timber is a crop which, although yielding a good profit in the course of the years, has a slow turn-over and consequently locks up much capital. With the woods of quick growth, however, and especially with a local demand, one of the great difficulties in the way of reforestation is removed.

It is reasonable to surmise that it may be possible to develop sufficient planting to enable a colliery to obtain its own supply of mine props. Alder and birch have a ready sale as young trees. In Great Britain, larch and similar wood for mine props, after about 25 years of growth, are worth $3.69 per short ton; alder for turning, of 18 to 20 years' growth, costs $6.51 per short ton.

Fig. 3 shows a general view of plantation No. 14 of the association; this was planted four years ago. In the foreground are willows, and behind are alders and wych elms. The alders on the patch of shale seen in the illustration are too small to be discernible, the slow growth being largely due to wind which strikes that point.

Reforestation as a Feature of Village Betterment

Recently the association has reached a stage where it has been publicly recognized by a municipal corporation as the proper authority to deal with waste lands and the action of the corporation has been approved by the Local Government Board. After considerable negotiation, the Town Council of West Bromwich leased, at a nominal rent, 10 acres of mine-waste heaps to the association for 21 years, with power of renewal.

On Jan. 12, 1912, an Arbor Day was held at which the mayor and many members of the Town Council, members of the association and teachers and children from the elementary schools in the town, assembled on the waste heaps and planted trees. Ultimately the area will accommodate 13,000 plants. So great was the success of this function that since that day six Arbor celebrations have been held, and another has been arranged for the coming season.

In addition to this, there have been ceremonial plantings in which children took no part because the distance was too far away from any schools. Fig. 4 shows a view of the "Black Wagon" mound at Old Hill, Staffordshire, taken in mid-winter. The view is well chosen, as by the exercise of a little imagination an idea can be gained of the desolate appearance, these pit mounds presented in the days before anything was attempted to make them attractive, while on the other hand the transformation effected when the trees are in leaf over this area can be readily imagined.

Fig. 6. Photographed in January, 1912

Fig. 7. Photographed in April, 1912

Black Wagon Mound. Fire under Foreground in Left Picture. Mostly Alders Growing on Bare Shale

Figs. 6 and 7 show the two other views of the "Black Wagon" mound. The former shows the north side, planted in 1907-8, while the latter shows the top of the mound looking north. The trees are mostly alders. The larger trees on the left were planted on Arbor Day, Dec. 17, 1909, while the smaller trees were located on January, 1908. The foreground is on fire underneath, so that there are only one or two trees growing there.

Trees Around as Well as In the Village

While it is impossible in an article of this nature to enter into all the details of this valuable scheme, it forms a useful text for an inquiry as to whether in connection with the waste lands in the United States adjacent to the mammoth iron and steel industries and mining centers, some attempt could not be made along similar lines. Arbor Day is recognized as a national institution, but it is time that attention should be focused more directly

on this phase of welfare work among our colliery and allied branches of industry.

It is pleasing to record the advance which has been made in Great Britain in this direction, an advance, the good effects of which will be felt in increasing strength as the years go on. With the example of the European nations above mentioned before us, and the widespread opinion in our own country that serious inroads are being made upon our forests by the advancing forces of industry, it is surely a wise proposal to consider whether a similar system to that described above could not with advantage be adopted here.

Storage Battery Locomotives in Belgium

Storage-battery locomotives, similar to those which run on the 1666-ft. level, have recently been installed on the 1916-ft. level in part of the workings of the Chaumonceau mine of the Amercoeur collieries, Belgium. They are housed and charged in a room constructed of iron and ventilated by a separate air current.

Separate Tracks for Locomotives and Cars

The tracks have a grade of 0.3 per cent. The locomotives run on 24-lb. rails set at 20-in. gage and the cars run on a separate track, the rails of which are 17 in. apart. Oak ties, measuring 32x6.4x3.6 in., support the tracks. The ties are set at 20-in. centers. The trips consist of 24 cars, weighing 550 lb. when empty, 1430 loaded with coal, and 2090 lb. loaded with rock.

The charging of the batteries, being done at constant potential, requires no supervision. The current is led from the surface by a cable with two conducting wires, each of about 0.11 sq.in. section. As the junctions are male and female, it is impossible to interchange the poles in charging.

Description of the Locomotives

Each locomotive is about 14 ft. long, and 43 in. wide and 47 in. high. Its weight is 13,200 lb., the storage batteries themselves weighing 6160 lb. The motor is formed of a rigid frame surmounted by a casing containing the storage batteries. The side sills, with crossbars, end at the front and back in cast-steel buffer frames. These carry the bumpers which are cushioned with hempen cords.

The battery, composed of 40 elements, is inclosed in casings lined with lead and provided inside with lead pipes to drain off the acidulated water which may be spilled from the cells.

Each locomotive is equipped with two 5-hp. series motors, the speed reduction being accomplished by gears which run in a case filled with grease.

The housing of the motor, which forms at the same time the yoke connecting the poles, is of soft steel; it completely incloses the magnets, the armature, the commutator and the brushes, thus protecting all parts from dust and moisture. This housing is in two parts, connected by hinges which afford easy access to the interior. The motors, which are placed between the wheels, rest on springs, which themselves are partly sustained by the axles and partly by the frame.

Note—Translated by E. P. Buffet from a report by M. Ledouble in the "Annales des Mines de Belgique."

Controller

The controller is of the parallel type, permitting reversal of motion and the braking is electrical. The locomotive has, moreover, a mechanical brake, operated by a ratchet crank, and it is equipped at front and back with a 16-cp. electric lamp and reflector. An ampere meter and a voltmeter indicate the current consumption and state of the battery.

The accumulators, which are made at the mine, are composed of 40 elements of six positive plates and seven negative oxide plates. A positive plate weighs about 9 lb. after pasting and 5 lb. before. The plate measures 12x8x0.4 in. The negative plate weighs about 4½ lb. before pasting and 7 lb. afterward and measures 12x8x0.28 in.

The capacity of the battery is 350 ampere-hours. The locomotive consumes about 100 amperes when running and from 150 to 180 amperes when starting. The cost of hauling is about 3.35c. per short ton per mile.

Increased Value of Ashes

Recently a Berlin inventor, S. Sborowitz, read a paper in the Exhibition Palace, in the "Spree-Athens," on a new process of his own invention, for making a new material out of ordinary coal and briquette ashes. According to his statement, this material has properties ranging from those of marble to those of india rubber, according to the method of treatment.

Sifted coal ashes, preferably those from briquettes, are mixed with water glass, copal varnish, and asbestos. The mixture is dried either in the air or by artificial heat.

To give the material the appearance of marble, the desired coloring material is added to the mass. Before drying, the material may be molded into any desired form. It is claimed, therefore, that the substance is highly resistant and may be chiseled, planed and sawed. Aside from being fire-, water- and acid-proof, it is a good insulator, and so hard that it will break marble.

It may be used for wall surfacing and for floors, for table tops, etc. It is said that a Berlin company has been formed to exploit the invention, and that 50 pfg. (12c.) per bucket of briquette ashes are being paid by this company.

Why Sulphur is Found in Coal

E. E. Sommermeier, professor of metallurgy, Ohio State University, in the introduction to his book on "Coal, its Composition, Analysis and Valuation" makes the following remarks:

"If coal contained only the constituents which were present in the original vegetable matter, it would be uniformly low in both sulphur and ash. But during the early stages of its formation and when underneath the surface of swamps or lakes, streams or rivulets carried silt and sediment over the decomposing bed of vegetation, which sediment settled down and became an integral but varying constituent of the coal.

Sulphur in solution in the water, coming in contact with salts of iron and reducing organic compounds resulted in the formation and precipitation of pyrite, while other reactions not clearly understood produced variable quantities of organic compounds of sulphur as a constituent of the coal.

The Science of Good Management

By A. J. Reef*

SYNOPSIS—The answer to the problem of the "time-and-motion" loss in any industry is the one word "system." Methods employed in the various shops today may, with but little alteration, be applied to coal mining. The bonus system may be introduced with advantage to both employer and employee.

The claim advanced by Mr. Brandeis before the Interstate Commerce Commission that the application of scientific management to the railroads of this country would result in economies of $1,000,000 a day, and that this same science of management could be applied to practically every business endeavor, has directed public attention to a new propaganda in management and a new body of specialists in engineering.

The daily press and the popular magazines, which take no notice of technical matters except of a startling nature, have given much space to this movement.

Inquiry as to what this new element in management is, tends at first to confusion, for nomenclature and definitions of essentials and statements of principles still vary even with the recognized experts, and there are even those who deny that there is anything new about it.

What is Scientific Management

The name adopted by most of its advocates is "Scientific Management," not meaning that there is a science rather than an art of management, but referring to the use of scientific methods in management as opposed to "rule of thumb" methods. These methods are largely derived from a study of the science of physics and psychology.

In popular discussion we hear much of time-and-motion studies, and nearly every one is familiar with those studies, by which unskilled workmen, under skilled direction, are enabled, without frantic exertion, to load into cars four times as many tons of pig iron per day as had been the record before. How is it accomplished? The answer is by eliminating all useless motion, wasteful expenditure of energy and by taking rest for fixed lengths of time at fixed intervals.

One hears also of routing of work and material through factories, so that one department is not waiting on another; of systematizing the giving out of tools and materials by the use of requisitions and orders on a clerk of stores; of schedules of work for each machine or operative in a shop so that the least possible time may be lost changing from one job to another; of scheduling the work of the shop crane to fit this first schedule so that a tool and operative may not be idle waiting for crane service; of systems of daily reports; of cost and efficiency records; of standards of performance; of bonus systems of payment of workers; of planning functions being segregated in a separate organization.

All these things have part in scientific management in certain cases but not necessarily all of them in one individual case.

The essence of the new idea seems to be in attacking management problems in that same scientific spirit that has heretofore prevailed in the design of automatic machinery and engineering structures—by the methods of research, experiment and detailed study.

The Principle of "Transference of Skill"

The Subcommittee on Management of the American Society of Mechanical Engineers, in its recent report on this subject says, "A basic principle in the rise of industry is that of 'transference of skill'", meaning thereby the transference of the skill of the trained craftsman to the automatic machine tool. Careful study will convince one that this principle of transference of skill together with its concomitant, division of labor, has been largely if not wholly responsible for our present era of low-cost manufacture.

For years every large manufacturing concern has employed a designing and engineering force to work out this transference of human skill to a machine. The men of this force were the best talent obtainable and well paid. They used research in all sciences, experiment and detailed study to aid them. But usually the operating department was allowed to run the machines and turn out the product as seemed best to the operative or at most to the foreman.

Application of this Principle to Management

This new idea in management is merely the application of these same methods of operation, to the workmen, as well as the machinery.

Does it sound futile? Are you sure that the laborer, skilled though he may be with the traditional art of his craft, knows and practices the best and least laborious method of performing his task?

If one were attempting to design a machine to lay brick in a wall he would not hesitate to study long on the motions necessary. He would experiment with his machine, even at considerable expense, and would not balk at continued study to improve it. It is only rational then for the man who employs a human brick-laying machine to study and experiment how to lay them in the least time and with the least expenditure of energy.

One contractor made such a time-and-motion study and by applying its results cleaned up millions. His masons, instructed by him, and with scaffolding arranged to the best advantage, laid three times as many bricks per man as those of his competitors.

This furnishes a clean cut example of skill; not traditional skill of the craft, but real skill based on scientific research and experiment.

The report, above alluded to, renames this movement labor-saving management and draws the parallel with labor-saving machinery.

The Fundamentals of Scientific Management

Fundamentally then scientific management means three things: for every oft repeated operation, study in detail of all good methods of performing it; deciding on the best method; establishment of that method in practice.

*Victor-American Fuel Co., Denver, Colo.

Many other things follow from these. To the first and second steps we may add a bit of caution. A time-and-motion study is not always necessary to the decision. Even if necessary it should not be wastefully carried beyond the stage needful to a decision; neither should it be thoughtlessly applied to an occasional operation where the total saving would not justify it. The establishment of this best method as a standard, involves many of the auxiliary features of scientific management.

If a standard method is set up, standard conditions must obtain. The arranging of work to give standard conditions for the various operations for which the standard method is being taught is frequently a problem of no mean importance. The solution, however, will carry its own collateral benefits.

Workmen dislike change and particularly dislike being taught how to do their work. To obtain the establishment of new methods, particularly when these promise to turn out more work per man, usually calls for schedules of average work and payment of bonus for performance above that.

The maintenance and carrying into effect of these matters frequently calls for systems of reports, and always temporarily and sometimes permanently for additional clerical and supervising force.

There is no question also but that it means more work for the managing force, for in order to transfer skill, the manager must first acquire skill himself.

Application of Scientific Management to Coal Mining

No particular part of scientific management is new; time-and-motion studies were made in industries a hundred years ago; profit sharing is nearly fifty years old; but the scientific spirit in management which applies this principle of transference of skill to all activities in the industry consistently is at least recent.

Can we apply it to coal mining? The laying of a room switch on an entry is an oft repeated operation and so worth considering. How long does it take a track-layer and helper to lay one? Some managers may know. How long *ought* it to take them to lay one? I doubt if any of them know, and necessarily under ordinary operating practice they cannot know, because the conditions are so variable. The men may have to cut a rail to put in the frog or they may not. They may have to carry their tools a half mile to the job or not. They may have to wait for materials to be delivered or not. Laying a room switch is not a standard operation.

What is Meant by a Standard Operation

The first step in labor saving management is to make it one. Lay the main-line track so that the joints will come right for the room frogs. This will of itself partially standardize the laying of the entry track. Give the track-layer a schedule when he reports for orders in the morning, to cover his work for the day so that there is a minimum of moving between jobs.

Knowing how much moving there is to be done a definite time allowance for it can be made. See to it that the extra driver on the preceding day or night shift has hauled to the same schedule of places the track materials needed at each. Then so far as the variables mentioned are concerned the laying of that room switch is a standard operation.

Then begin a time-and-motion study and decide and formulate in writing the best method of doing it. Determine a reasonable time to do it by this method; teach your track-layer that method until it becomes habit. Make out a schedule for him for the day based on this determined time, and the moves to be made, and by means of a bonus payment for performance according to schedule keep him up to such performance.

Right here an attendant or incidental advantage is manifest. The workman of course cannot expect to equal that schedule and obtain his bonus unless conditions are up to standard and a spur to the management to keep them so is thereby automatically provided.

Not All Operations Can Be Standardized

Admittedly there are many operations in coal mining which can not be standardized even though oft repeated. Thus, although the basic idea cannot be carried to completion, some careful study and experiment may even here prove helpful.

If the making of the time-and-motion study seems inexpedient or if it should develop that the present method is the best that can be devised, advantage may still be taken of the knowledge that can be obtained of a standard time in which the work should be performed. In this way a schedule of daily tasks may be intelligently made up and used, without any bonus system.

This will afford an easy method of detecting any soldiering on the job. With conditions really made standard and the schedule intelligently made out, based on what a man ought to do, the superintendent will have a right to insist on the schedule being completed.

Many minor points in management which can be used will develop from the attempted application of scientific management even though it be found that the system as herein outlined is not applicable in its entirety to all the various operations of the industry.

The great essential to success in applying scientific or labor-saving management lies in the scientific, experimental attitude of the managing forces toward their problems, and making all the activities of the industry their problems.

Employment of Outside Experts

A word as to the employment of experts. Scientific management is not something that can be grafted onto an industry by an outsider. It begins in the spirit of the management forces, and belief in it and enthusiasm for it must reside there continually, if its application is to succeed. Nevertheless an outsider, granted managerial ability, coming fresh to the problems of the particular industry, can frequently see far more than those who are in it every day. His point of view is different. Also the work of making time-and-motion studies is best done by one with special training and their results are best evaluated by one with experience in using them.

The whole idea is so big that its ardent advocates seem unduly enthusiastic and from some of their writings one would imagine the movement a cult or religion. Like every new movement with worth it has its fakers; but these things should not detract from the real value in "labor-saving management."

CURRENT COAL LITERATURE

Relation of Subsidence to Packing

By Geo. Knox*

SYNOPSIS—Where flushing is used instead of pack-walling to support the mine roof, the miner is exposed to less risk at his work. The roof subsides over the pillar from one-tenth to one-eighth of the depth of the seam in room-and-pillar working. With flushing, the subsidence extends over the pillar more than one-third of the depth of the seam. Flushing reduces the emission of gas and cools the workings. It costs from 9 to 21c. per ton mined. The Krupps are extracting all the coal beneath their works and protecting them by flushing.

In extracting coal seams, there are two distinct types of supports to be considered, namely: (a) those left in the mined area for regulating the subsidence of the overlying strata; and (b) the temporary support between the permanent packing and the working face for preventing any sudden movement of the descending mass from breaking off, without warning, pieces of the lower roof strata. Attention has centred largely on the need for some system for the latter type of support.

Roof Support in Rear Has Bearing on Safety at Face

After personal investigations of the methods adopted at the Courrières and other continental collieries, I am of opinion that the careful attention paid to the packing of the worked-out areas, which accompanied the systematic timbering, had quite as much effect in reducing the accident rate as the timbering at the face.

When a layer of coal is being removed, it is subject to two forces, one, that of gravity acting downwards, and amounting roughly to about 1 lb. per sq.in. for every foot the coal is below the surface, and the other acting horizontally in a direction opposite to that of the workings. If the packing is inefficient, the downward weight acts suddenly and irregularly, breaking the roof strata by a series of "slip-faults," as shown in Fig. 1, and throwing a large amount of extra pressure on the edge of the solid coal at the face.

The resultant of the two forces, to which reference has been made, acts toward the region of least resistance, the area of extraction, thus forming planes of strain projecting over the solid coal. The area of subsidence on the surface, is, therefore, always greater than the area of extraction below it, and will vary according to the rate of advance of the working face, the nature of the overlying strata, the presence of faults, etc.; but the obliquity of the resultant of the two components forming these planes seems to be determined chiefly by the efficiency of the packing (Fig. 4).

*Lecturer in mining, Wigan and District Mining College, Wigan, England

Note—Abstract of paper entitled "Relation Between Subsidence and Packing, with Special Reference to the Hydraulic Stowing of Gouves," read before the Manchester Geological and Mining Society, at a session held at Manchester, England.

Horizontal Draw

The distance that surface subsidence extends in advance of the working face (that is the amount of "horizontal draw") varies with the efficiency of the method of packing adopted. In room-and-pillar workings, where the roof is allowed to fall in as the props are withdrawn, the draw appears to be about a tenth to an eighth of the total depth; in longwall mines with good pack-walling, a quarter to a third of the depth; and where hydraulic packing is used, an even greater distance.

Where the draw is short, gravity acts freely, breaking the roof strata along the line of the coal face. Where it is increased, by the packing of the extracted area, the vertical force is partly arrested by the pressure of the horizontal force projected against the subsiding zone, which throws a greater proportion of the weight forward on to the solid coal, allowing gradual settling, with the roof unbroken (Fig. 5 and 6.)

The Change From Compression to Tension

As the coal at the face is being undercut, and the roof strata above leave the "solid" and enter the mined zone, a change of strain, from compression to tension, must take place in the rock particles. The nearer to the vertical, the line of strain approaches, the more sudden and violent will the reactions become between these forces in the roof strata at the face. To minimize this, the plane of strain should be thrown as far back as possible, as shown in Fig. 4, thereby increasing the horizontal pressure and allowing the reactions to take place slowly and evenly.

In opening out the workings in a partly packed seam, the only evidence of strain as the workings advance beyond the shaft pillar, is that of "thrusting" (Fig. 3) until a sufficiently large area has been mined to permit of the huge rock lever breaking through to the surface.

When this "first-weight" takes place, the strata will cut through at the face, up to the surface, as shown in Fig. 4. As each undercut is made, new fractures parallel to the first will be produced and the roof, instead of subsiding solidly and evenly on the packs, will probably come down in a series of jerks between the fractures.

The maximum subsidence is obtained when the packing is wholly inefficient. Under this condition it ranges from 30 to 70 per cent. of the thickest part of the seam. The minimum subsidence is from 5 to 10 per cent., this value being frequently obtained where the opened spaces are filled by flushing. When the subsidence is reduced to the lower figures and the roof strata allowed to subside gradually and evenly on the packs without fractures, better results may be expected from the application of systematic timbering than is obtained in present day practice.

With complete packing, this subsidence would also tend to prevent the drainage of large volumes of gas (and in many cases water) from the overlying strata

into the mines and thus another danger encountered in gaseous workings would be removed. Where the roof is completely packed, all the coal can usually be extracted, but even in cases where coal of a poor quality is left behind, it is impossible for gob fires to take place where flushing is used. Seams up to 40 ft. thick, in which gob fires formerly occurred with frequency when only partial packing was in use, are now being worked and completely packed by flushing without the slightest risk from gob fires.

Importance of Manner of Working

Large areas of coal have been lost through lack of attention to the cause of subsidence. Fig. 7 is an example where a series of pillars in a 9-ft. seam, covering an area measuring about 1200 yd. in length by 400 yd. in width, was rendered unworkable through the extraction of the pillars on the rise sides of the basin, allowing the strata to break to the surface, thus forming a huge rock pyramid which rested directly on the coal seam.

Fig. 8 is another example where a 6-ft seam was being worked from two different shafts towards each other. When the faces approached within 200 yd. it was found impossible to keep the strata from cutting along the faces, and filling up the roadways through the longwall.

In Upper Silesia over a hundred collieries have installed the hydraulic packing system in seams varying from 4 to 40 ft. in thickness, and have thus reduced the subsidence from 30 to 70 per cent. down to 0.3 to 7.8 per cent. of the total thickness of the seam. Spontaneous combustion (which accounted for the loss of 25 per cent. of the total area of coal) has been entirely prevented; surface damages have been considerably reduced, and a great saving effected in timber. The cost of packing varies from 9c. per short ton of coal extracted at Myslowitz, to 13c. per ton at Florentina colliery, and 14 to 16 per ton at the Kattowitz collieries.

In my opinion, the problem of safety in coal getting is largely that of regulating the subsidence of the strata and the same may be said concerning the saving of coal supplies. It is evident that the regulation of subsidence is largely determined by the efficiency of the packing used, and that the most complete system of support known is that provided by flushing.

FIG. 13 - METHOD OF WORKING BY LONGWALL AND PANELLING

It may not be altogether out of place to meet some of the more common objections against the introduction of flushing, which roughly resolve themselves under the following headings:—

Cost of Providing Packing Material

In newly opened coalfields, in the absence of a plentiful supply of material for packing, this might be a costly difficulty. Where mining has been in progress for many years, the huge refuse heaps provide a sufficient supply of suitable filling.

Where this is plentiful, it forms the cheapest and most

efficient packing material, costing in Upper Silesia from 6c. to 8c. per ton of coal raised; but where local weathered pit heaps are available the cost is said to be from 10 to 14 c. per ton.

In Essen and other thickly populated centers, the money saved in ground rents by getting rid of refuse heaps, and the saving of 7 to 9c. per ton for surface damages, reduces the total comparative cost of packing by flushing to a very small sum compared with the old system.

Where slag or other refuse has to be transported for considerable distances by rail, as at Saarbrücken, the cost may become as high as 18 to 21c. per ton—about 5c. per ton higher than for hard packing, but the difference is made up in the saving effected in the timber required.

Packing Flat and Unfavorably Inclined Workings

It is not so hard to pack flat or unfavorably inclined workings despite the accepted opinion. With a dip of 5 deg. or more (Fig. 5) and the flushing shaft on the rise side of the property, there is little difficulty experienced in carrying the packing material into the extracted area. In fact the material can be carried on a level grade a distance equal to from three to five times the pressure head according to the percentage of water used. Because of the excessive volume of water needed it is not advisable to force the material in the pipes uphill, although this is frequently done for a distance of 90 to 120 feet.

In flat seams, the flushed fill is kept in position by temporary timber dams, as shown in Fig. 6. These are raised sufficiently high across the pack area to prevent the flushed material from spreading too far forward. These boards are laid loose between two lines of props, and moved forward as the goaf becomes filled up.

Objections to Flushing Invalid

It has been objected that the use of large volumes of water underground, (a) would cause creep, (b) increase the cost of pumping, (c) be injurious to the health of the miners. It was also thought that in cold weather flushing would be difficult.

(a) Creep is the result of the movement of the rock particles in the floor from the point of greatest pressure which is under the pillar or pack, towards the point of least pressure which is the roadway or open excavation. The packs are forced by the weight of the overlying strata into the floor, the rock particles being translated horizontally towards the open roadways (Fig. 2.).

In flushing, the primary cause of creep can be reduced by the greater amount of support left in the mined area and the more even distribution of the total weight on the rock, as only a few roadways in longwall are necessary. Being usually applied to retreating methods of working, the wet floor is left behind.

As the old roadways are usually fitted with rubbish dams, and the water from the packing area is turned into them, they act as filter ponds and become silted up, thus completely packing all the mined area and reducing the tendency to creep.

(b) Where very little water is met with in the lower workings of the deep mines, the extra pumping would be a disadvantage, but the advantage already suggested, and the increased safety due to the damping of all coal dust in the vicinity of the working faces, would more than counterbalance the extra cost for pumping.

Flushing Lowers Mine Temperatures

(c) Regarding the question of health, hydraulic packing produces a cooling effect. It neutralizes the heat caused by the grinding of the coal in the pillars or of coal left in the extracted area. It prevents the rapid oxidation and heating of the fine coal dust which is produced by the crushing action of subsiding strata.

(d) There is no great difficulty in Great Britain, even in the coldest weather, in providing a water supply sufficient to make up any slight loss due to evaporation. The only other difficulty arises when the flushing is intermittent. In this case, the water in pipes near the surface is liable to become frozen when the flushing current is stopped; but this can be avoided by lowering the water in the pipes to a point where the temperature is high enough to prevent freezing.

Packing Very Thin or Very Thick Seams

In Essen, the Krupp firm is successfully extracting from underneath their railway works, railways, and large public buildings, 8 seams, varying from 20 in. to 5½ ft. in thickness. They are enabled to do this with impunity, owing to the completeness with which the workings are filled with flushed *debris*.

In Silesia, seams up to 40 ft. thick are being worked and completely packed, sometimes by panel-slicing the whole 6 thicknesses of seam and sometimes by longwall layers. Working is commenced from the bottom upwards and the goaf packed in each layer as it is extracted. The only disadvantage in thin seams, compared with thicker ones, is the frequency with which the flushing pipes have to be moved for a given amount of packing.

Maintenance of the Pipe Lines.

The greatest difficulty which had to be surmounted in hydraulic packing arose from the excessive cost of maintaining pipe lines and it has taken several years of experiment and practice to devise a suitable conduit capable of resisting the grinding action of the *debris* in the horizontal pipes.

There are practically only four types of pipe now in use, namely: (a) mild ungalvanized-steel pipes; (b) mild steel or cast-iron pipes lined with hard wood or steel (Figs. 11 and 12); (c) steel pipe lined with porcelain (Fig. 10); and (d) the Stephan system of oval steel pipes, with steel lining, or the Busch system with iron linings (Fig. 9).

Wood Lining Costs 52c. per Yard and Porcelain Pipes $3

The first system is still used in many continental mines where the plant was installed some years ago, and the second is utilized most successfully in Silesia and the Transvaal the cost of wooden lining being about 52c. per yd.; but in all new installation types (c) and (d) are adopted.

Porcelain-lined pipes will pass from 180,000 to 200,000 tons of material before they require renewal, and iron-lined oval pipes will pass 14,280 cu.yd. per hundredth inch wear of surface. The latter system would seem to be the most satisfactory yet adopted, the cost of lining being about $3 a yard.

There is a difficulty in adapting the system to mines now using hand-packing, especially where the workings are well advanced.

EDITORIALS

Watch for our statistical number next week. This special annual issue of COAL AGE will contain a complete review of all that has occurred in each state during the past year. Read it, and file it for future reference.

Special Power Number

On the first of February, the entire issue of COAL AGE will be devoted to the question of power at coal-mining plants. All of our readers are invited to contribute articles and letters adapted for publication in this special issue. If there is an uptodate power equipment at one of the mines in your vicinity, send us some photographs and a description of the most interesting points connected with this particular installation.

The Air Current a Factor in Mine Explosions

No one doubts for a moment that a strong current of air is an important factor in the initiation and propagation of a mine explosion, when the conditions in the mine are favorable for explosion of either gas or dust.

No one would essay to question the potency of a high velocity of pure intake air to augment the combustion of gas or dust in mine workings. A high velocity represents an energy that may, under favorable conditions in the confined space of mine workings, be transferred to and become a part of the energy of an explosive blast.

When, however, one reads the account of such experiences as are unfolded in the letters of Alexander McAllister, COAL AGE, Nov. 16, p. 692; Dec. 14 and 21, pp. 838 and 881; and again in this issue, p. 24, one is forced to the conclusion that the narration is simply phenomenal. It is more than remarkable. The question to be decided, and which we hope will be clearly discussed in the coming issues of COAL AGE, is: To what extent is this experience, as given by Mr. McAllister, of general application in coal mining, today?

The Mining Engineer

What constitutes a mining engineer? This question is often asked, because of the confusion growing out of many practical mining men styling themselves "Mining Engineers," after a few years' experience in making mine surveys and maps, or in planning and superintending the construction of mining plants and equipment. The idea seems to have gained some prevalence that all that is required to make a competent engineer is an experience of a certain length of time in the mines, in the line of work generally performed by the mining engineer.

The sub-committee of the Commission to revise and codify the present anthracite mining laws of Pennsylvania, in its report just made to the Commission, define the term "mining engineer" as follows:

> The term "mining engineer" means any person who is competent to survey and plot accurately the inside workings of a mine, and who has had ten years' practical experience at such work; or one who is a graduate of a school of mines or some similar institution, and who has had five years' practical experience in the mines.

While it goes without saying that there are many practical men, untrained in book knowledge and unacquainted with the theory and principles of mining but whose practical experience in the operation of mines has fitted them to successfully perform many of the duties that belong to a mining engineer, it still remains that these men are only specialists in particular lines of practical work. They are incompetent to design new machinery; plan new equipment calling for the intelligent application of known laws and principles; or to estimate accurately the efficiency of the ventilating system in the mine or the power plant on the surface. These duties require a mining engineer, who is *more* than a thoroughly practical and experienced man. He must be a man who combines in his personal equipment both the theory and the practice of coal mining.

We would suggest that the enactment into law, of such a definition of the term "mining engineer," would operate to weaken mine management and, incidentally, lower the standard of efficiency of all certified mine officials, because of the tendency, on the part of such practical engineers to eliminate theory and principles from mining examinations. The result would be to rapidly impair the conditions in the mine relative to the health and safety of the men employed and the security of property.

We would suggest that every mine examining board should include at least one graduated mining engineer of not less than five years' practical experience in gaseous mines. We cannot safely eliminate from mining practice the knowledge of the theory and principles of mining; these are essential to all branches of mining if economy and safety of operation are to be secured.

Class Legislation

All the coal-mining laws which have been passed in the United States have been written for the good of the miner. Except the provision that the operator may condemn rights-of-way over the lands of others, which is probably unconstitutional in most states, we do not recall any parts of the law which were or are favorable to the operator.

The law reads that he should do this and supply that and failing to do and supply these things, certain penalties are threatened against him and his agents. Perhaps some provisions do not cover all the dangers in the mine, some are perhaps not duly severe, some, it may be, bring too much force to bear on the foreman and too little on his employer.

But this is not the matter we have in mind. The main truth is that all the legislation hitherto passed has been in the interest of the workman and not in the interest of the operator. The laws were proposed and passed to

promote the safety, health, comfort and happiness of the miner, mainly at the expense of his employer. These laws were expected to put the mine owner to considerable expense and no one can deny that at least the charge for safety is large.

But we do not find that the workman is prepared to back up the laws provided for his sole advantage by insisting on their enforcement. He does not condemn openly those firebosses who fail to make inspections, he does not demand the discharge of men who leave mine doors open, he fails to hound those men who put in overheavy charges, who tamp with slack, who mix powders, who make tight shots in dusty mines and who fill cartridges with pipe in mouth or lamp on hat.

In fact, if men are discharged or arrested who do such things, the miners as a body go on a strike. The burden of enforcing these laws invariably is placed entirely on the operator and his officials. The workingman is either indifferent or hostile. Who cares? Not the men who are likely to be injured or killed, it is nothing to them. It is the operator's business, they think, to protect them, even though they will not obey the law.

When the first man to carry a safety lamp went into an English mine, he met a miner who, resenting the fancied foolhardiness of the stranger who would venture to carry a lamp of any kind into a mine, so gaseous that all lights were prohibited, prepared to brain him with his pick. Perhaps this British "coal hewer" had a better conception of a miner's need to enforce obedience to common sense than is found among many miners today.

The miners should be prepared to see that the law is obeyed. Morality and penalties restrain the operator, to the miner there is a third and larger restraint—personal interest. It is a foolish man who is blind to his own advantage and to his own safety.

We would expect to find that the workers who did not value safety would be driven from camp to camp as marked men and that official guardians of the miners who habitually neglected duties, they were hired to perform, would be drummed out of the society of the men whom they had betrayed and whose lives they had risked.

But we do not find any such disgust and dislike on the part of their fellows. After a while an accident occurs and then the operator and his unfaithful employee are visited with resentment. The men who have been well aware that the careless fellow was always indifferent to all laws and regulations are often over ready to blame an official who has had far less opportunity to observe the work of his subordinate than the men who make loudest complaint, and who was paying the man to do his work well, possibly not at all for the good of the company, but for the sole advantage of the men employed.

Roof Control

We publish today an article by George Knox, on the "Relation of Subsidence to Packing." It is reproduced because of the valuable facts relative to roof settlement, gob walling and flushing which it contains and not because we are impressed with the train of reasoning by which roof fracture is explained.

Perhaps the fear of the German technical training has overcome English discretion and has caused Great Britain to multiply her colleges unduly. This unhealthy growth may explain to us many of the obscurities in diction and much of the unsoundness in theory in an author who is styled lecturer in mining at an English college.

Wherever we were unable to understand what the author intended to convey, we left his wording in its pristine incoherence. Even when he talks the almost universal language of pure science, he is as hard to understand, because he is as severely involved, as our own Mary Baker Eddy of muddled memory.

Mr. Knox must surely pardon us if we do not believe that the roof breaks along the lines he suggests. We cannot grant him that peculiar tilted L fracture which he favors and we fancy he will find it hard to conjure the roof to follow the extraordinary course of breakage he has laid out for it.

He appears, from his drawings, to think that a measure will lie flat on a bed of coal and then bend down at maximum curvature along a given line. The whole theory of flexure is opposed to such a conception. All bendable bodies flex under load into continuous curves, the continuity being only broken when the elastic bodies break.

Every evidence points to the fact that a theoretical treatment of roof breakage is needed accompanied by experimental work in the mines and the stressing of rocks and models in a laboratory. The matter is one of great complexity, as the stresses vary not only with the movement of the face, but also with progressive demolition.

Before the coal in one part of the mine is even opened up, it is subject to variations of pressure due to the undulations of roof which mining in other parts of the workings create. The load on the coal must thus be greater or less than the immediate overburden provides. Where the roof, in bending, forms a trough, the burden is increased, where it forms a ridge the weight declines.

Then again comes a change when the coal tends to tear from the roof and form no longer a part of that composite beam. Later long rents form from the surface at the head of the primary undulation and underground at the center of the span. As the extension of these rents would involve their becoming wider, they cease to extend.

The beam across the opening and over the adjacent pillars becomes an arch from a structural point of view, and then various forces come into play, probably some tensions arising from the line of pressure leaving the middle third, longitudinal shears, which permit the measures to distort into such shapes that the arch can fail, overturning actions on the coal pillars and thrusts on other sections of the mine roof, causing greater subsidence in these than their own weight would occasion. Now and again, perhaps, the arch will fail a little and then the beam strains reassert themselves. Then the roof will crack further and the arch strength once more come into play.

Thus at last demolition occurs and a number of forces thus deprived of their balances tend to work havoc on other parts of the mine roof. If the nature of the roof's resistance did not change in the course of its demolition, the first break would be the last, as rapid as the failure of a girder in a testing machine.

The mine roof is in need of its Navier, Saint-Venant and Clerk Maxwell, and both theory and nomenclature call for development. The use of the word "draw," for instance, to cover both the area affected by tension and the tension itself, is even more confusing than the early indiscriminate use of "stress" and "strain."

COLLIERY NOTES AND COMMENTS

The use of animals for haulage purposes underground is generally unprofitable if the distance to be covered exceeds 2000 feet.

If an electric mine locomotive is not giving the best results, examine the overhead work, as upon the character of this work depends to a great degree the success of the locomotive.

Borehole explorations have shown that the Appalachian coal basin has an area from 50 to 75 miles wide, barren of commercial coal. This begins north of Pittsburgh and extends through Ohio, West Virginia and into Kentucky; in the latter state it is 25 miles wide.

Increasing the life of mine timbering not only saves the value of the timber, but also saves on labor needed for frequent resettings, and eliminates the worry and risk incident to such operation. Only timber so situated as to be free from the danger of crushes can be profitably treated with preservatives.

When choosing a rescue apparatus give consideration to the following points: Weight of apparatus, capacity, strength and durability, liability to derangement in use, simplicity of construction, comfort in wearing, regulation of supply, facility of communication, safeguards for return, ease in cleaning, initial cost, and cost of operation per hour.

Under no circumstances should a miner be allowed to enter his place until it has been examined. All miners and laborers, before going to their working places, should be compelled to report to the official whose duty it is to make the early morning examination. This rule should be unbreakable and if ignored should be followed by prompt dismissal.

According to George S. Rice, engineer in charge U. S. Bureau of Mines, Pittsburgh, Penn., there is an opportunity for concrete ties, if they can be adapted to the conditions in the main haulage-ways. If made light and durable, they could be used for temporary room ties and taken up and relaid like rails in another part of the mine when the room is worked out.

A great deal of unnecessary wear in the working parts of machinery could be avoided if the nature and application of the lubricants were properly studied. Too much oil should never be used, and it should be the special care of the workman to see that it is uniformly distributed and regularly applied. One dry spot on a hearing causes heat, and cutting is sure to follow.

Some time ago a fatal accident occurred, due to a miner heating his explosive in an oven. This is perhaps a much more common method of "getting the explosive into condition" than is usually suspected, and among others is that of carrying the explosive next to the body. The miner who is guilty of this habit is a walking danger, not merely to himself, but also to his companions.

The advantages and disadvantages of fixed screens used in the preparation of anthracite coal are: Advantages—(1) Low first cost. (2) Run with very little attention. (3) No power is needed to run them. (4) Large capacity. Disadvantages—(1) Do not screen the coal as perfectly as might be desired. (2) Need of additional breaker height to accommodate the pitch. (3) Breakage and loss of coal due to the drop at the lower end.

As the pressure increases with the depth of mining, so will the proportion of large coal decrease. This is clearly recognized, and it may be moderated by laying out the workings so as to take advantage of the cleavages. Also by the method of holing and packing, and by avoiding downhill falls in seams with much dip. It is further held to be especially desirable to work at a uniform rate with just sufficient pressure to help in bringing down the coal. Stopping the workings for a time is generally detrimental.

Comparing methods of working, Joseph Dickinson, a British mining expert, informed a coal-supplies commission that he favored the longwall system, but stated that there are considerations which have to be taken into account with regard to all mines. If there is no material in the seam for stowing and packing, it may be necessary to use the room-and-pillar system. As regards cost, there may not be much difference between the two systems, but on the question of the quality, the longwall method will probably produce the best coal.

The importance of accurate work in the surveying department of a coal company is obvious when it is remembered that mistakes are liable to cause great loss of mineral by bringing down the overlying strata in the vicinity of faults and loose ground, also through flooding in piercing old workings in front or overhead. Such mistakes also lead to trespass actions, the loss of coal through leaving extra-thick pillars and an increased length of haulage. Care, accuracy and attention to details should be the characteristics of a good mine surveyor.

Regarding the limit of depth in mining, Joseph Dickinson said: "Some people are talking now of 5000 ft.; I think the possibility is that it may be obtained hereafter by means of deeper shafts, and taking the men out and allowing them a little respite and time to cool; also the use of some of these cooling adjuncts. I do not know what effect an ice arrangement or liquid air will have, but compressed air, when liberated, will freeze the small valves of an air machine. We have by no means exhausted the cooling powers within reach of the collier."

Crush and upheaval naturally increase with the depth. To certain depths, varying with the degree of hardness, the increase may be moderated by increasing the proportion of pillars, and in all kinds of work by varying the direction of the working. Soft seams with slippery faces, begin to crush in narrow openings at a depth of about 500 yd.; in some instances, both in narrow and wide work, large outbursts of crushed coal occur suddenly from the unworked portions of the seam beyond. Such outbursts are often accompanied by firedamp, and may occasionally be avoided by boring in advance, or in the roof or floor.

Explosives should be handled with great care, and it is well to keep in mind the eight causes of accidents when shotfiring, quoted by Prof. Courtenay de Kalb: (1) A hole missing fire; driving a wedge near the hole two days later has been known to explode the charge. (2) Using a short fuse to hasten explosion has exploded the charge before the workmen could retreat. (3) Smoking a pipe while charging a hole. (4) Loading a hole with the aid of an iron needle. (5) Firing a charge in a hole to clear it of water, and immediately reloading. (6) Ramming a charge in a hole with an iron crowbar; also tamping a charge with an iron bar. (7) Drilling out a misfire shot with a blunt drill. (8) Forcing a cartridge in too small a hole.

The British Mine Inspector, R. A. S. Redmayne, is of the opinion that it would be advisable to eliminate safety catches, and to substitute chains in place of the rigid rods at present used for suspending the cage from the rope. He also advocates having the former systematically annealed at stated periods. Such safety catches as are now in use constitute a doubtful safeguard and may actually be a source of danger. This was shown by Inspector Walker in connection with the inquiry into the Barrow colliery shaft accident. He said: "The engineer did not run the cage at the same speed all the way down, and the safety catches partially acted with the result that the rope accumulated on the top of the cage until the weight became such as to cause the cage to drop."

The Yorkshire mine inspectors have long held the view that miners should not be allowed to keep gunpowder in their homes. Explosives should be supplied by the owners themselves, and the following case is to the point: The manager of a South Yorkshire colliery, who was bound to use a "permitted" explosive, thought the men were buying their explosives outside. He had them searched and found that they were taking in gunpowder wrapped up with their meals and in their pockets. Even the British miner is partial to this class of powder, but as is known, under certain conditions it is dangerous to use it in mines; in this particular mine it was prohibited by law. There had already been one explosion, and the result of the foolish conduct of the men might very easily have caused another.

DISCUSSION BY READERS

Carbon Monoxide Produced by Explosion of Methane

I was interested in reading the answer to the examination question, COAL AGE, Nov. 23, p. 732, which reads:

> What would be the probable composition of the explosive mixture, if the afterdamp of the explosion shows the presence of whitedamp, instead of blackdamp, and why?

The answer to this question states as follows:

> . . . . The complete combustion of the carbon requires a volume of air practically nine and one-half times the volume of the marsh gas. This proportion denotes the maximum explosive point of the firedamp. When the firedamp mixture contains a less proportion of air, the combustion is incomplete and whitedamp is formed.

Now, the complete combustion of methane in air is expressed by the formula,

$$CH_4 + 2\ O_2 + 8\ N_2 = CO_2 + 2\ H_2O + 8\ N_2$$

From this equation it is apparent that two volumes of oxygen (O_2) are required to burn one volume of methane (CH_4); or, what is the same thing, for the complete combustion of the methane, the firedamp mixture must contain 9.46 per cent. of gas and 90.54 per cent. of air.

My own experience confirms that of Dr. Broockmann's, namely, if more than 9.46 per cent. of methane is present and less than 90.54 per cent. of air, there will be no carbon monoxide (CO) formed by the explosion of the firedamp mixture, but the afterdamp of the explosion will contain some unburned methane (CH_4). Again, if more air is present and less gas than the proportions stated above, oxygen will be found in the afterdamp.

In most gas explosions in mines, dust is also present; and, as a result, carbon monoxide (CO) is found in the afterdamp of mine explosions. In one case, in my own experience, where only gas was present, a sample of the afterdamp taken for analysis did not show any carbon monoxide.

HENRY BOCK.

Denver, Colo.

[In answer to the remarks of our correspondent, we would draw attention to the discussion of the same question, in the excellent paper, "Notes on Explosive Mine Gases and Dust," by R. T. Chamberlin, being the original Bulletin No. 383, of the U. S. Geological Survey and reprinted as Bulletin No. 26 of the Federal Bureau of Mines. This bulletin, pp. 11-14, gives a full discussion of the possible composition of afterdamp. The bulletin, p. 12, refers to the apparently as yet unsettled question in regard to the combustion of methane in an atmosphere containing an insufficient amount of oxygen for the complete combustion of the gas.

As indicated in Mr. Chamberlin's bulletin, the conclusion of Dr. Broockmann that carbon monoxide *cannot* be formed by the combustion of pure methane in air, even though the quantity of air present is insufficient for the complete combustion of the gas, does not seem to have received sufficient corroboration for its general acceptance. The early experiments of Dr. J. W. Thomas, corroborated by the later experiments of the French Firedamp Commission, led by the eminent mining experts, MM. Mallard and Le Chatelier (1882), have since been further proved and endorsed by the able experiments of G. A. Burrell, chemist of the U. S. Bureau of Mines.

The experiments of Mr. Burrell are fully explained in a paper read by its author, before the Coal Mining Institute of America, Pittsburgh, Penn., Dec. 20, 1911. (COAL AGE, Dec. 23, 1911, p. 348.) We quote from this paper as follows:

> In these experiments pure methane was prepared and mixed with air in such proportion that not enough of the latter was present for the complete combustion of the methane. The mixtures were then exploded and the products of combustion examined. The most explosive proportion of methane and air contains 9.46 per cent. of methane. When the latter is increased above this figure, certain products are formed, about which there has been some disagreement. Some investigators have gone on record as saying that no carbon monoxide is formed.
>
> According to these experiments the carbon monoxide and hydrogen increase, and the carbon dioxide decreases as the methane content of the original mixture is raised.

The following is quoted from "Mine Gases and Explosions," Beard; p. 130:

> . . . . The increase of carbon dioxide and decrease of carbon monoxide, as the proportion of air to gas is increased, is shown by the following results (Thomas):
>
> Gas to air:
> 1:4.5; 10% carbon forms CO_2; 90% forms CO;
> 1:5.0; 13% carbon forms CO_2; 87% forms CO;
> 1:6.0; 20% carbon forms CO_2; 80% forms CO;

In an article entitled "Methane in Coal Dust Explosions," COAL AGE, Feb. 17, 1912, p. 609, F. I. Wilbur, another reference will be found to the claim of Dr. Broockmann. It is the opinion of COAL AGE that until further proof is presented to the contrary, it is better to place confidence in the earlier experiments of Thomas, as corroborated by the French Firedamp Commission and the U. S. Bureau of Mines.—EDITOR.]

Reducing Ventilation at Firing Time

Continued from Dec. 14, p. 838.

When the Western Coal & Mining Co. requested me to go to mine No. 15, Dec. 1, as mine foreman, the mine was a complete wreck and the miners were moving away from the place, there being less than fifty per cent. of the men left now to operate the mine. I agreed to take charge of the mine, provided I was allowed to manage the mine without any interference in using my method of preventing explosions. Myself and Inspector Gilday made an examination of the mine Dec. 1, 1912. The fan was out of commission; all the stoppings, doors and overcasts, were destroyed. We found a heavy air current circulating in the mine, 78,000 cu.ft. per min.

I employed some sixty men to build stoppings and made the repairs necessary to put the mine in working condition. When this was done I found that with the fan stopped I

had a natural circulation of 32,000 cu.ft. of air per minute, which I considered a dangerous condition. I therefore had carpenters seal up the air shaft with heavy folding doors, hung to fold down and close the upcast shaft during firing time. For this I was criticized by the mining men of that section, who claimed it would be murder to allow any person to enter the mine under those conditions. I stated through the press, at that time, that I would be responsible for any explosions at the mine and would guarantee to fire all shots.

The steam and water pipes were destroyed by the last explosion and I did not replace them. Every part of the mine contained a heavy coating of highly inflammable coal dust. The first night, I found nineteen shots in the danger zone. These shots were charged with an average of 5 lb. of black blasting powder and tamped with coal dust and fuse. I invited the critics to come to the mine and see the results. Over one hundred of them came. I closed the doors over the upcast shaft, shut down the fan, and, going down, lit those nineteen shots, at one lighting. There were no windy shots or any explosions. The mine was only 220 ft. deep, and the people on the surface claimed the nineteen shots went off in less than one minute. I fired all the shots each night and, in some cases, had twenty-five ignited at one time.

I succeeded later in hiring two men to do the shotfiring, by paying them each $8.00 per day, and agreeing to accompany them while they were performing their work. I had safety holes cut in the solid coal, in the danger zone, for the shotfirers' protection. When they had become convinced that there was no danger of an explosion, I told them that I considered the mine a fine testing station, and got them to agree for me to make some tests. This was in the month of December. The first test I made was with the doors closed and twenty-seven shots prepared as before, in the danger zone.

We next established stations at intervals of 25 ft., from the face of the entry toward the shaft bottom. At each station, we placed a timber, and nailed some fine paper to the timbers. My object was to find out how far the flame would extend under those conditions. I then placed one 25-lb. keg of Du Pont blasting powder, at the face, with a fuse attached, and covered the powder up with fine coal dust. I wished to find out if it was possible to ignite this dust and cause an explosion under these conditions. I went on top, closed the doors and spread newspapers over them and set several empty cans on top of the doors. My object was to discover if a vacuum or a pressure was caused by this method. I stationed two persons close to the fan to watch the result. The shotfirers and myself then went into the mine and ignited those twenty-seven shots and the fuse attached to the keg of powder. We retreated into the safety hole to watch the results. An explosion started as the fourth shot went off, but it stopped and the rest of the shots went off. On going to the surface we found that the cans were not moved, but the newspapers were drawn into the crevices in the doors, which showed a vacuum was created by the explosion. I opened the doors, started up the fan, and went into the mine to ascertain what had occurred there. We found the track covered with dust, 500 ft. from the face of the entry. We found the flame had extended for 275 ft. The timbers and everything showed there had been much flame.

Two days later, the superintendent instructed me to remove the doors from the top of the upcast shaft, and place doors on the main-return airway to give the same results. I refused to do this and immediately tendered my resignation. He refused to accept my resignation, but agreed to assume all responsibility if I would make this change. As I still refused, he ordered the blacksmith and carpenter to remove the doors, which was done. He then ordered the men to put a door on the main-return airway and that was done. I sent for the shotfirers and the mine committee and informed them of the change the superintendent was making. When the day's work was over and the men were hoisted the mine committee, the shotfirers and myself went into the mine to note the conditions as changed. We found a strong air current on the south side of the mine, the second south being in the danger zone. I explained the danger in that entry, and added that I would not fire a shot in this entry for $5000, under those conditions. Returning to the bottom, I asked the shotfirers to refuse to fire shots under those conditions, and told them an explosion would occur if they did. The mine committee and myself then went to the surface and I had sworn statements made by them as to the instructions I had given of this danger.

The shotfirers meanwhile held a consultation between themselves and decided to fire that entry first, to prove that I was right in my prediction. They went to the second south and lit two shots and a terrific explosion occurred. At the time of this explosion, one of the cages was resting on the bottom, the other being up at the upper landing. This cage was forced through the headframe, breaking one of the sheave wheels. The other cage was buried in wreckage, the shaft buntings and guides were blown out. At the fan shaft the fan drift and buildings were destroyed; the stairway was blown out the top of the shaft, and all means of rescue were destroyed, except the steel rope, that was attached to the cage on the bottom.

I at once procured a lamp and a wet cloth and slid into the mine by the steel cable and made direct for the second south. All stoppings, doors and overcasts were destroyed in the mine. Natural ventilation had set in, however, and I found in the center of the main south entry a small tunnel, formed by the rush of air through the gas-filled mine. When I at last succeeded in reaching the safety cellar in the second south the men were not there. I made an attempt to get further in to locate them, and heard one of them struggling. I rescued him, brought him into this air tunnel and, returning, found the other and brought him to the same place. I left them there and went to call assistance. By this time, willing hands had procured a block and tackle and lowered men with restoratives. In two hours our efforts were rewarded by the men being in a condition to be brought to the surface.

The following day, I agreed to take charge of the mine again, if allowed to seal up the upcast shaft. This was done and there were no more explosions. I held this position until the following March, 1908, when I resigned. These are but a few of the tests that were made by me on the question of reducing the ventilation at firing time.

ALEXANDER MCALLISTER,
Croweburg, Kan.

INQUIRIES OF GENERAL INTEREST

Danger Signals in Mines

The revised bituminous mine law of Pennsylvania (Art. 3, Sec. 3) requires that danger signals, in all mines, shall be uniform and of a design approved by the chief of the Department of Mines. Will you kindly inform me what kind of danger signals are required and where these can be obtained. We have been using a board laid across the track marked with chalk "Danger, Keep Out." It would seem from the reading of the mine law that this is not sufficient, at the present time.

MINE FOREMAN.

Punxsutawney, Penn.

One of the important provisions of the revised bituminous mine law is the requirement that all danger signals shall be uniform. The old bituminous law required that all dangerous places be "fenced off and proper danger signal boards so hung on such fencing that they may be plainly seen."

The difficulty is present, however, that the large class of foreign labor employed (many of whom cannot speak or write the English language) fail to understand the old signal board, or comprehend the danger it points. As a consequence, there have been many avoidable accidents due to this class of labor not being properly warned.

Another difficulty is presented in the fact that men going from one mine to another are unacquainted with the danger signals used in different places and fail to familiarize themselves with the change in methods and conditions. They are, on this account, exposed to many dangers that a uniform system of signals would avoid.

FIG. 1. DANGER SIGNAL APPROVED BY THE PENNSYLVANIA DEPARTMENT OF MINES

This matter has received the careful consideration of many mining departments. The chief of the Department of Mines in Pennsylvania draws special attention to the matter of uniform danger signals as required by the bituminous mine law, in the bituminous Report (1911), recently issued. In this report Mr. Roderick states as follows:

In compliance with this provision and after a general consultation with operators and inspectors as to the kind of danger signals that would be most suitable for all persons concerned, I approved the signal designated in the following letter, which was sent to every superintendent in the bituminous region:

Dear Sir—In accordance with Sec. 3 of Art. 3, of the Act of June 9, 1911, which demands that danger signals in all mines shall be uniform and of a design approved by the chief of the Department of Mines, I have approved a signal of which a sample is inclosed herewith. The size recommended for the signal is 10x30 in., with an oval circle in the center, 10x14 in. The word DANGER appears in the middle of the circle, in white letters. The color inside the circle is red, and the color outside is black. . . . .

The last paragraph of Sec. 1, Art. 5, reads: "The meaning of all danger signals shall be explained to the non-English speaking employees of the mine, in their several languages, by the mine foreman, assistant mine foreman, or fireboss, through an interpreter."

A sample signal should be placed at a convenient point on the surface so that the non-English speaking employees can see it and be taught what it means when placed in any entry or at the entrance to a room or the entrance to any place in the mine where such signals are likely to be found.

JAMES E. RODERICK,
Chief of Department of Mines.

Harrisburg, Penn.,
Oct. 31, 1911.

The form of signal board approved by Mr. Roderick is shown in Fig. 1, with the exception that the red back-

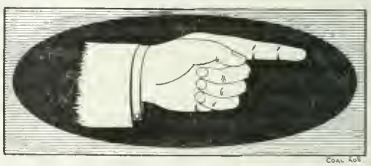

FIG. 2. UNIVERSAL SIGNAL POINTING WAY OUT OF MINE

ground within the circle is here shown in black, and the black outside the circle is hatched in the figure.

All practical mining men will heartily approve of the suggestion of "uniform danger signals." The form approved by the Pennsylvania Department of Mines appears eminently appropriate for the purpose. In this connection, we would suggest another uniform signal board, similar to the danger board just mentioned and shown in Fig. 2, consisting of the black board with the same red circle and a white hand pointing always in the direction men should take to escape from the mine. Many of the recent mine disasters have demonstrated the necessity of pointing the way of escape, at numerous points on all travelingways throughout the mine. For this purpose, a board with a hand, the index finger pointing the way out, would be readily understood by every man. As stated in Mr. Roderick's letter, a sample of the board should be placed in a conspicuous place on the surface, and its meaning fully explained to every employee and particularly to the foreigner who does not understand English. As far as possible, all signs should indicate their meaning by their form rather than by words.

The only firm we know who makes a specialty of danger and other signs for mines is the Stonehouse Enameled-Steel Mine-Signal Co., Denver, Colo. This company has made a specialty of producing indestructible signs of charcoal-rolled steel, the enameled lettering being fused on the sign at a high temperature, which renders the sign impervious to all underground conditions and enduring.

EXAMINATION QUESTIONS

State Civil Service Commission

EXAMINATION FOR MANAGER OF MINE RESCUE STATION
Springfield, Ill., Oct. 3-4, 1912.

(Selected Questions Answered by a Successful Candidate, by Request of COAL AGE*)*

Ques.—Explain the general principles upon which mine-rescue breathing appliances operate.

Ans.—The general principle of all mine-rescue appliances is to supply the wearer with oxygen and absorb the carbon dioxide and moisture contained in the air exhaled from the lungs.

Ques.—There are three different types of rescue apparatus used at the Illinois stations. Describe the construction and operation of each of these types, giving their essential points of difference. Tell which you consider the best, and why.

Ans.—The three types of apparatus in use at the rescue stations, in Illinois, are: the Draeger, Westphalia and Fluess. The principles on which the Draeger and Westphalia operate are much the same. They use the same chemicals, soda and potash, in the regenerator. Both of these types now use the helmet or the mouth-breathing attachment and deliver the same amount of oxygen per minute. The Fluess has no helmet and is confined wholly to the use of mouth-breathing attachment. The chemical used in this regenerator is caustic soda. The regenerator is equipped with a by-pass valve, which is a decided advantage over the other types, for the reason that if the reducing valve should get out of order this valve can be used to fill the breathing bag. In the latest make of the Draeger type they have added a by-pass valve.

Each type has its special advantages. Some men cannot use the mouth piece as it makes them gag. The advantages of the mouth-breathing type of apparatus are the following: They are more convenient for use when the atmosphere contains no irritating gases, as the condition of roadways can be more easily examined, and the wearer keeps cooler than when wearing a helmet.

The disadvantage of the mouth-breathing types is the absence of the protection afforded by the helmet. Helmets are better when the air contains fumes given off from fires. Men can talk to each other, which cannot be done when using mouth-breathing apparatus. The dangerous feature connected with helmets is that if the atmosphere contains no irritating gas, but will not support life, leakage is not easily detected and the wearer may be overcome. Leakage usually occurs around the face band, and is more apt to be present than in the smaller mouth-piece of the other types.

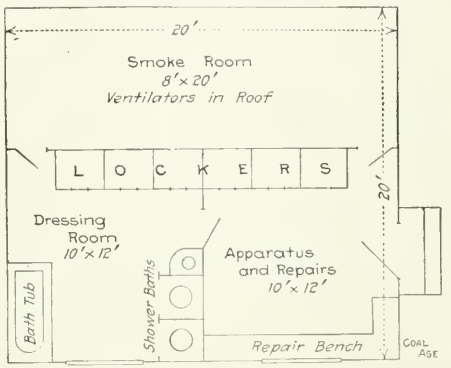
Ques.—(a) How much oxygen per minute does the average normal man require? (b) How do you determine the amount of oxygen the apparatus is furnishing?

Ans.—(a) It is estimated* that a man requires under normal conditions, when at rest, 263 c.cm. of oxygen per minute, which is increased by violent exercise about 8 or 9 times, making $8 \times 263 = 2104$ c.cm.; or, say the required amount of oxygen in mine work would be $2104 \times 0.06102 = 128$ cu.in. per min. The quantity generally stated by the manufacturers of the apparatus is 122 cu.in. per minute.

(b) Attach a measuring bag to the inhalation tube leading to the helmet or mouth-piece; then open the exhalation tube, turn on the oxygen, and note the time required to fill the bag. The volume should not be less than 2 liters (122 cu.in.) per min.

Ques.—If asked by a mine superintendent to advise him how to plan and equip a training station, at his mine; what plan of station would you suggest, and what different appliances would you advise him to get?

Ans.—I would advise him to erect a building 20x20 ft., having no less than three rooms; a room for apparatus



PLAN OF PROPOSED RESCUE STATION OR TRAINING BUILDING AT A MINE

and for making the necessary repairs; another for shower baths and lockers; and a larger room to be used as a smoke chamber. The following are the dimensions I would recommend; as shown in the accompanying diagram: Smoke Room 8x20 ft. and each of the other rooms 10x12 ft. This makes a very compact arrangement all under one roof.

The approximate cost for building and equipment, including six sets of breathing apparatus, oxygen storage tanks and pumps, electric and safety lamps, pulmotor and other necessary equipment, would be about $3000.

Ques.—What effect is produced on a man by breathing air that contains as much as 5% of carbon dioxide (carbonic acid gas)?

Ans.—The effect produced by breathing air containing 5% of carbon dioxide (CO_2) would be to cause the head to ache, and the man would soon begin to get dizzy and have pains in the back, chest and limbs, and breathe with difficulty.

*Mine Gases and Explosions—Beard, p. 184.

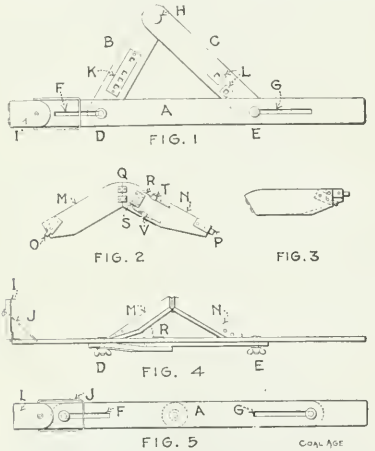
SOCIOLOGICAL DEPARTMENT

Novel First Aid Splint for Fractured Limb

By James G. Jones*

As a member of a first-aid corps in the anthracite region, I have recognized for some time the want of a combination splint which could be used for a dislocated hip. This as all first-aid men know is a difficult part to secure properly. After considerable thought, I planned and constructed a splint for use in such cases.

When first-aid squads, without this appliance, were called upon to dress a dislocated hip it was necessary to secure three splints, one about 4 ft. 6 in. long and two measuring about 3 ft. and the necessary padding. It was then necessary to turn the patient over on his side



The Jones Splint for Compound Fracture

to get the proper measurements, after which the splints were bound together and applied with the padding to keep the leg in position.

In many instances the men were compelled to waste time in hunting for old clothing and other suitable material for padding purposes. With this combination splint, less padding is needed. It is unnecessary to take the measurement of the patient's leg and hence he is not kept in suffering while splints and padding are being prepared.

The device is constructed so that the side support can be extended or shortened to any desired length and raised or lowered to the level at which the limb of the patient may be comfortable. Its most important feature is its wide range of use. While constructed principally for a dislocated hip, it can be taken apart and used for any fractured limb or fore limb. In addition it enables the first-aid men to prepare the patient promptly for transportation, thus reducing suffering to a minimum.

It can be used for either the right or left leg by reversing the rise splint as can easily be done. Where it is found that the patient must be carried any great distance without a stretcher it can be locked by tightening the bolts thus rendering it unnecessary to depend on bandages to hold the splint in place.

[Fig. 1 shows a plan of the splint as seen from above. *A* is the long or main splint and *B* and *C* are the extension splints which are made adjustable by thumb screws *D* and *E* (see Fig. 4) which pass through the slots *F* and *G*. *B* and *C* are pivoted at *H*. The main splint *A* is 4 ft. 6 in. long and at one end is a foot rest *I* which can be turned up as shown in the side view Fig. 4 and secured by the bridle wire *J* as also shown in that figure.

In limb *B* of the extension splint is a countersunk plate with four slots *K*, and in the limb *C* are two small plates carrying slots *L*. Fig. 2 shows the rise splint also consisting of two parts *M* and *N* having lugs *O* and *P* engaging in slots *K* and *L*. The two parts are hinged at *Q* and are supported by a V-shaped wire *R*, hinged at *S* and provided with extension clamps *T* and *V*. This enables the rise splint to be supported at any angle. Fig. 3 shows this splint as it appears when folded. Fig. 5 shows the whole apparatus collapsed so that it can be put away.—Editor.]

Note—Paper read before the Panther Valley Mining Institute, held at Lansford, Penn., Nov. 2, 1912.

*Mine foreman, Lehigh Coal & Navigation Co., 22 Patterson St., Lansford, Penn.

English Miners Object to Fuses

Practical miners in northern England are taking exception to some of the clauses in the recent order in regard to explosives which attended the advent of the Coal Mines Act, 1911. They argue that the use of fuses in nongaseous mines is totally unnecessary from the point of view of safety, but they admit that in wet places it is often convenient.

It is recalled that in the old days thousands of shots were fired by the home-made straws, and with practically no risk. Squibs have supplanted these and are much more effective, being the acme of safety where there is no gas present.

The present complaint is, that, to compel miners in pits free from gas to use fuses to prevent an explosion of gas, and at the same time allow them to rush about the working place with a flaring candle in their hands, is a trifle ridiculous. A deputation from the workmen presented their case to the Home Secretary, and he agreed to appoint a small expert committee to inquire into the facts.

Meanwhile the order has been modified somewhat; a fuse may be ignited in naked-light mines by a naked light, subject to certain conditions. Special provision is made in regard to shotfiring on roads where mechanical haulage is in operation up to the face and where conditions make "back-ripping" necessary.

COAL AND COKE NEWS

WASHINGTON, D. C.

It is understood that the House Democrats are being very strongly urged to place coal of all kinds upon the free list in the new revision of the tariff which is about to be taken up. The subject has been agitated for a good while and this action was urged at the time when the reciprocity bill was under consideration, but it was not possible to get from the State Department any provision for free trade in coal with Canada.

Now the suggestion is to take off the duties entirely on the ground that conditions have so radically changed as to destroy all alleged danger from foreign competition. One particular phase of the situation that is being pressed upon the politicans is the circumstance that under the proposed arrangements for selling coal in the Canal Zone, the government depots there will afford a tremnedous new demand for the American product, which will be shipped from Newport News and the terminus of the Virginian Ry. direct to the Canal Zone.

At the same time the coal shortage of the current winter and the difficulty experienced in getting an adequate supply in several parts of the country, coupled with the attempt to advance prices at a good many points which has taken an actual, although frequently veiled, form have had their effect just as they did during the coal famine in the year 1902 when Congress came very near definitely shifting coal from the dutiable to the free list.

A list of commodities is being made up by the Democrats for free-trade treatment and it is understood that this is a good deal more extensive than was the farmers' free list bill passed in the summer of 1911. Coal is one of the new items.

Petty Strikes Again

A loss to the market of 11,000 tons of coal has been caused recently by the strike of 1300 men at two Lehigh Valley Coal Co. collieries in the Pennsylvania anthracite region. In both cases the men quit work without negotiating for a settlement as provided in the agreement signed last May.

The members of the Conciliation Board, including the three labor representatives, not long ago voted in favor of a resolution condemning these strikes that are called in violation of the agreement, but interruptions are still occurring with frequency enough to reduce materially the output of coal.

At the Centralia colliery 700 men quit because of the company's requirement that three plane tenders work an hour overtime two or three days a week. The men were paid at the regular overtime rate to clean the plane after the mine closed in the afternoon, the only time when this work could be done.

The three men themselves did not object to the work, but some of their fellows protested, called a meeting of the local union Thursday, and stopped all work at the mine on Friday. The company officials learned of this decision only when the men did not start to work Friday morning.

The agreement between the mine workers and operators provides that any grievance may be taken up first with the company officials before recourse to the Conciliation Board, but in this case no notice was given even to the foreman.

The daily production at the Centralia colliery is 2000 tons, so that the strike has caused a loss of over 8000 tons.

At the Dorrance colliery, in Wilkes-Barre, where the production is 1600 tons a day, a strike of 600 men caused a loss of 3200 tons of coal. Here also the strike occurred without the attempts at peaceful settlement provided in the agreement.

PENNSYLVANIA

Anthracite

Pottsville—Snow, which fell Dec. 23 and 24, materially retarded shipments of anthracite coal. The collieries, many of them located at the bottom of steep mountains, were covered to a depth of some 12 to 15 in., greatly delaying the delivery of empty cars and the shipment of loaded ones. It is expected, however, that the situation will soon be normal again.

Wilkes-Barre—A mine fire was discovered by one of the fire bosses of the Buttonwood colliery of the Parrish Coal Co. The fire is in No. 2 East Kidney vein. Operations were suspended at noon, Dec. 16.

Hazleton—The rockmen of the Panther Creek Valley have been on strike for three weeks for a 10 per cent. wage advance. They are in the employ of contractors who are doing tunnel and other work for the Lehigh Coal & Navigation Co. This class of work does not come under the agreement signed in the spring between the coal operators and the miners.

Bituminous

Connellsville—Reports from the various trade centers are to the effect that cars are still short. In those sections where the shortage is less pronounced, the scarcity of labor is preventing operators from profiting to any great extent.

An adjustment of the wage scale of the U. S. Steel Corporation, which will result in increased earnings for its employees, has been announced. Definite statements as to the revised scale and when it will become effective, will be made later, but it is certain that an advance will be made in the near future.

Holidaysburg—James M. Dysart, formerly located in the Connellsville coke region, near Mt. Pleasant, and former general manager of the Essen Coal Co., of Pittsburgh, has presented a new Y. M. C. A. building to Holidaysburg, where he now resides.

WEST VIRGINIA

Charleston—The Kanawha Coal Operators Association has addressed a letter to the Interstate Commerce Commission, complaining about the statement accorded the Kanawha operators through the machinations of the New York Central, the Chesapeake & Ohio, and the Hocking Valley railroads, and the Sunday Creek Coal Co. interests.

Downs—Deeds for the Pittsburgh vein of coal and mining rights for about 1300 acres, located near Downs, were filed with the county clerk, Dec. 27. These deeds are made to Marcellus A. Jolliss and the total consideration is over $100,000. Although details of the deal are not to be had, it is understood that Mr. Jolliss expects later to transfer the coal to the little Kanawha Syndicate, and that the field is not to be opened until some time in the future.

Turner—The Morris Fork Coal Co. has complained to the Interstate Commerce Commission that the Coal & Coke R.R. Co., operating between Charleston and Elkins, is discriminating against it. The company charges the railroad with supplying more cars to the Davis Colliery Co., of Elkins, than to the Morris company.

Charleston—More than 4000 guns and revolvers, taken from the miners and operators in the Cabin Creek coal district, were returned to their owners, Dec. 26. Governor Glasscock has declared that he is convinced that all trouble is passed. In fact, he has granted pardons to seven of the 20 men sent to the penitentiary by the Military Commission.

Gary—Invitations have been issued for the third annual banquet of the United States Coal & Coke Co. to be held Jan. 4, for the purpose of discussing the prevention of accidents to employees.

OHIO

Columbus—A strike has been ordered by union officials at Mine No. 23 of the Hlisylvania Coal Co., at Glouster, Ohio. The cause of the strike was the discharge of three men whom the superintendent claimed were careless in their work in the mine and who endangered the lives of themselves and fellow employees.

J. W. Blower, manager of the concern, upon investigation found the men working in a room with more than 750 sq.ft. of floor space without a pillar or support. The question involved is one of considerable interest to operators and miners generally as it concerns the right of the employer to discharge for carelessness. According to Mr. Blower, the company will make more money without operating at all than by being compelled to employ careless miners.

KENTUCKY

Central City—The tipple and power house of the Nelson Creek Coal Co., near Central City, Ky., burned to the ground recently, the fire being caused by a spark from the firebox. Work will begin at once on the installation of new equipment, in order that operations may be delayed as little as possible.

Henderson—Robert M. Roll has filed suit here against the People's Mining Co. for $1750, alleging breach of contract. The plaintiff claims that he resigned his position as president of the United Mine Workers of District No. 23 in order to become the manager of the defendant's mines, and that he was subsequently discharged by the president of the company without cause.

INDIANA

Washington—C. C. Martin, president of the Davies County Coal Co., has offered a reward for information that will convict the persons who attempted to blow up the boiler of the company's mine at Black Oak. The condition of the boiler was discovered just in time to prevent the entire plant from being blown up.

Fairmount—Hundreds of cords of wood will be consumed in this vicinity during the winter in the place of coal. The clearing of the Newby woods has paved the way for many to secure their winter supply of fuel at a small cost.

Richmond—In the annual report of Frank I. Pearce, state mine inspector, he states that the production of bituminous coal is increasing steadily, while the production of block coal is decreasing.

Clinton—The Indiana Railroad Commission has declined to order the Elgin, Joliet & Eastern R.R. to operate a miners' train between Clinton and the mines of the Bunsen Coal Co., six miles distant. Other trains of this character are operated in this vicinity, the miners paying $1 per month for transportation, but in this case even if this amount was doubled, the train could only be operated at a loss.

Terre Haute—The Vandalia Coal Co., the Coal Bluff Mining Co. and the Western Indiana Mining Co. have contracted with the Terre Haute, Indianapolis & Eastern Traction Co. for electric current to be used in mining operations. The furnishing of current to these and other developments, it is believed, will not only greatly increase the output, but render the mines less hazardous in every way.

Lafayette—The Railroad Commission of Indiana issued an order, Dec. 23, fixing the freight rate for coal from Linton, Brazil and Clinton District, Indiana to Lafayette, at 65c. This order will become effective Jan. 25, 1913.

IOWA

Boone—The returns from the Mine Workers' election, District No. 13, although incomplete, show that W. H. Rodgers, of Albia, has been reëlected president for the coming year. Sam Ballantyne, of Boone, has been elected vice-president. Mr. Rodgers is quite popular with the miners of this community and has proved an efficient official in the service of the union. It is said that he ran far ahead of the other two contestants for the office.

ILLINOIS

Georgetown—There seems to be little doubt that the Bunson Coal Co. has contracted for the John F. Ashby farm, northwest of this city, and also for a portion of the farm adjoining. The purchase of this farm gives rise to the belief that it is to be used for the sinking of a new shaft at an early date.

Taylorville—The Taylor interests, of St. Louis, are preparing to take 1500 acres of coal rights in May Township, in addition to the 11,000 acres recently taken in Taylorville, Buckhart and Stonington Townships.

Springfield—A New York syndicate has purchased 30,000 acres of coal rights in Macoupin County, for $600,000, and taken an option on 280,000 acres additional, paying, therefor, $24 an acre in Montgomery, Saline, Perry, Madison and Jefferson Counties. The syndicate will sink four mines in the 30,000-acre tract.

Pekin—The Tazewell coal mine has been destroyed by fire, which is thought to have been started by particular enemies of the company.

Belleville—On Dec. 19 the Supreme Court of Illinois affirmed a ruling of Judge Bernreuter and awarded damages against a railroad company for failure to supply sufficient cars for the transportation of coal. The suit was brought by the Mulberry Hill Coal Co. against the Illinois Central R.R. Other suits of a similar character are pending.

FOREIGN NEWS

Tokyo, Japan—Over 200 Japanese coal miners are entombed and probably dead as a result of an explosion which occurred in the Ubari colliery, at Sappero, on the Island of Hokkaido, Dec. 23.

Quebec, Canada—Fire completely destroyed the coal sheds of the Nova Scotia Steel & Coal Co., on the Louise Embankment, Dec. 12. The loss is in the neighborhood of $20,000.

Cardiff, Wales—The report that 100,000 tons of American coal is being purchased by the Egyptian railroads in place of the customary Welsh supply has caused quite a sensation here.

PERSONALS

Coal men and traffic officials generally are urging the appointment of Howard Manington, formerly secretary of the Ohio Coal Operators' Association, as a member of the Ohio Public Utilities Commission.

President J. M. Fitzgerald, of the Davis Coal & Coke Co., has announced the appointment of Newell W. Roberts as assistant to the chief executive of the company. Mr. Roberts was formerly connected with the Durham Coal & Iron Co.

Joe Smith has resigned as general superintendent of the Stag Cañon Fuel Co. and leaves for Trinidad on Jan. 1 to devote his attention to his coal property there. The position will be filled by William McDermott, who has been connected with the Victor-American Fuel Co. for a number of years.

F. J. Durdan, of Pittsburgh, has been appointed Kentucky sales agent of the Monongahela River Consolidated Coal & Coke Co., succeeding Charles H. Bohmer, whose resignation takes effect Jan. 1. Mr. Durdan has been associated with the company for about a year, and was formerly sales agent of the Buffalo & Cleveland Coal Co.

OBITUARY

Martin McLaughlin, state mine inspector, at Shamokin, Penn., died in that city after a brief illness. He was prominent in Democratic politics in Northumberland County.

The funeral of A. W. Carlson a prominent coal dealer, of East Des Moines, was held at his home, Dec. 15. Mr. Carlson organized the Maple Grove Coal Co., the Maple Block Coal Co., and another enterprise known as the Delaware Coal Co. At the time of his death he was president of the High Bridge Coal Co., at High Bridge, and also of the Zimbelman Coal Co., at Boone.

CONSTRUCTION NEWS

Sartell, Minn.—The projected erection of a coal tower and water tank at Sartell has at last become a reality. Material is now being hauled to the location and work will be started soon.

Pottsville, Penn.—Work on the new Girard mammoth colliery, Raven Run, which is being rebuilt on the site of the old breaker destroyed by fire several months ago, is being pushed rapidly.

Heaverdale, Penn.—It was announced here, Dec. 20, that the large tipple owned by the Pennsylvania Coal & Coke Corporation, which was damaged by fire several evenings ago, would be rebuilt.

Osceola, Mo.—C. R. Hunt and associates plan to construct a hydro-electric plant on the Osage River, including a 14-ft. dam of reinforced concrete, to develop 4000 hp., at an estimated cost of $600,000.

Connellsville, Penn.—The National Consolidated Coal Co. will develop a large tract of coal in Barbour County, W. Va. It is proposed to erect coke ovens and enter that trade as well as the selling of coal.

Hendersonville, N. C.—Manufacturers Power Co., of Hen-

dersonville, N. C., is reported as planning to construct a dam, power house and transmission system, etc., on Green River, between Hendersonville and Saluda.

Cedar Rapids, Iowa—Among the notable improvements of the year are those of the Hawkeye Lumber & Coal Co. now nearing completion. The plant of this company has been thoroughly modernized at a cost of several thousand dollars. The yards and general surroundings have been greatly improved.

Reynoldsville, Penn.—The McConnell Coal Co., which is composed chiefly of Reynoldsville, Brockwayville and Beechwoods people, is making rapid headway at its operations above Brockwayville. Two hundred acres of land have been leased for a long term of years. Work on the tipples and the drifts has been going on for several days.

Mount Sterling, Ky.—The Kentucky Utility Co. plans extensive improvements to its electric light, power, railway, water and gas system, at Mt. Sterling, Winchester, Shelbyville, Versailles, Somerset and Elizabethtown, Ky., and is reported as expecting to build a $100,000 electric plant at Winchester, and a $75,000 plant at Somerset.

Luzerne, Penn.—Last week the new East Boston breaker, which replaces the one recently burned down, was put in operation. It is of steel and concrete construction, and unlike the old breaker, which was built directly over the shaft, this is erected several hundred feet distant from the shaft opening or mouth, to conform with the mine laws now in force.

Smith's Ferry, Penn.—The East Liverpool Traction & Light Co., and the Ohio Valley Scenic Route Ry. Co. expect to spend $2,000,000 in the construction of a big power plant, one mile north of here on Beaver Creek, at the Island Run Mines. The traction interests have leased or bought over 2000 acres of coal land in Beaver County, near the site of the coal plant.

Muscatine, Iowa—The Graving Coal Bin Co., of Chicago, has just completed its automatic coal-handling plant at a cost of $30,000. The plant is 450 ft. long, 40 ft. wide and 55 ft. high. More than ½ million feet of lumber were used, together with 1000 bbl. of concrete. Barely 3 min. are required now to load a 4-ton wagon; while, before, it required fully fifteen.

Toledo, Ohio—Final details of a contract whereby the C. W. Mooney coal lease of 25,000 acres, in Belmont and Monroe Counties, Ohio, involving nearly $5,000,000 are said to have been closed. The Captina Development Co., composed largely of Toledo capital, is the purchaser. It is said that a railroad switch to the old Correll mine, at Big Run, and a new steel tipple will be built there.

Jenkins, Ky.—Authentic information indicates that the Baltimore & Ohio Ry. Co. is planning to build a bridge across the Ohio River, at Huntington, as a part of a new line which will be built from Jenkins, Ky., to Jackson, Ohio, to connect with the main line.

If present plans are carried out eight operations will be conducted on the Jenkins side of the mountain and six on the McArthur side. It is thought that the traffic over the new road will be heavy and the Baltimore officials are pleased with the prospects.

Cowansburg, Penn.—The development of the coal lands between Yukon and Cowansburg after many years is a realty. The Pennsylvania R.R. Co. has begun work on the extension of the Yukon branch from its western terminus at Bell's Mills to Cowansburg, on the Yough branch. The railroad will follow the big Sewickley Creek and about seven miles of new roadway will be built. McMann & Simms, of Philadelphia, Penn., are the contractors. This coal is nearly all the property of the Manor Realty Co., of Philadelphia It will be developed in due time.

NEW INCORPORATIONS

Winston-Salem, N. C.—The Carolina Coal & Ice Co. has been incorporated with a capital stock of $125,000.

Cincinnati, Ohio—Cliff Coal Co., Portsmouth, Ohio, has increased its capitalization from $30,000 to $40,000.

Detroit, Mich.—The Durmond Coal & Cartage Co.; $2500. Ernest I. and Ethel M Durmond and Levi Anderson, incorporators.

Reading, Penn.—American Fuel Co.; capital, $100,000. Incorporators: T. F. Magarity, B. P. Ocheltree, M. B. F. Hawkja, Wilmington, Del.

Kansas City, Mo.—The V. McDaniel Fuel Co. has been incorporated with a capital of $4000. The incorporators are Virgil McDaniel, G. L. Stauffer and Charles Hayward.

Brooklyn, N. Y.—Greason, Son & Dalzell, Inc., deal in and transport coal of all kinds; capital, $100,000. Incorporators, J. Greason, J. L. Greason, E. T. Dalzell, Brooklyn, N. Y.

St. Louis, Mo.—The Ratican Coal & Contracting Co. has been incorporated here with a capital of $10,000, the incorporators being I. C. Muckermann, Wm. Ratican, and Peter J. Ratican.

Hillboro, Ill.—The Fayette County Coal Co. has been organized. A. J. Williford, of Nokomis, is treasurer of the company; $300,000 will be paid out immediately for 32,000 acres of coal land.

Ottawa, Ont.—Letters patent have been granted incorporating the London Land & Coal Co., of London, Ont.; capital, $2,000,000, to operate mineral and other lands and to search for coal and petroleum.

Clearfield, Penn.—Application will be made Jan. 14, by J. Boynton Nevling, Reuben F. Nevling, and Samuel E. McLarren, for the charter of an intended corporation to be called the Nevling Coal Mining Co.

Waukegan, Ill.—The Waukegan Coal Co. has been incorporated with a capital of $35,000 to deal in lumber, coal and building materials. The incorporators are Thomas McGay, W. O. McKinney, Alexander Whan, David U. Hart and J. D. Pope.

Lexington, Ky.—The Kypadel Coal & Lumber Co. recently organized with a capital of $500,000, for the purpose of acquiring coal and timber lands, has secured some 35,000 acres of land in Eastern Kentucky. No immediate development is contemplated, however.

Dover, Del.—Articles of incorporation have been filed for the Buffalo Creek, Coal & Brick Co., of Pittsburgh, Penn., to purchase, lease, hold, own, control and deal in coal and other mineral land. The capital stock is $250,000. Incorporators, Childs A. Smith, of Pittsburgh; R. D. Duranter, of McDonald, Penn.; C. E. Meyer, of Ingham, Penn.

Wheeling, W. Va.—The West Virginia Gascoloil Co., of Huntington, W. Va., has been incorporated to drill for oil or gas, mine coal, acquire mineral or timber lands, and develop them. Capital, $200,000. Incorporators, A. B. Brode, H. G. Bowles, and Frank W. Irvin, of Huntington; May B. Hess and H. H. Baker, of Hamlin, W. Va.

INDUSTRIAL NEWS

Lisbon, Ohio—Work at the new mine of the Card & Prosser Coal Co. on the old Hanna farm, near Teegarden, is now fairly under way.

Whitesburg, Ky.—The Consolidation Coal Co. is shipping from 30 to 40 cars a day out from McRoberts, consigned to the Northwest.

Scranton, Penn.—The Bittenbender Co. announces that it has just issued a complete catalog covering mine, mill, railroad and contractors' supplies.

Missoula, Mont.—O. O. Dutcher has discovered a vein of coal in Boise County which is reported to be exceptionally good and he is making arrangements to place the coal on the market.

Connellsville, Penn.—L. S. Mellinger and J. S. Bryner are busy having options on Indian Creek valley coal lands assigned to them, preparatory to turning them over to new purchasers.

Uniontown, Penn.—The big purchase of Mrs. Sarah B. Cochran, of Freeport coal in lower Tyrone township, will be developed at once. Her nephew, Frank A. Farr, is superintending the work.

Marion, Penn.—The Hillsdale Coal & Coke Co., one of Clark Brothers' interests, has opened up new mines on Horton Run, not far from Horton. The plant will be operated by electric power from the plant at Glen Campbell.

Wilkes-Barre, Penn.—Madeira, Hill & Co. have commenced transporting coal over the Lehigh Valley R.R., from their Pond Creek openings to their Harleigh breaker, a distance of about 11 miles, for preparation and shipment.

St. Louis, Mo.—The Merchants Ice & Fuel Co. has obtained a permit to build a branch office and coal and ice depot at the northeast corner of Hodiamont and Bartmer Aves. The estimated cost of the improvement is $28,000.

Manitou, Ky.—Bernheim Bros., of Louisville, who own what is known as the Talley coal field, near Manitou, are reported to have made a deal in which they purchased adjacent properties to the amount of about 200 acres. The price is not announced.

Madisonville, Ky.—It is reported here that the large block of coal properties in what is known as the Beulah coal field is to be transferred under an existing option or an extension thereof, as titles have been examined and the deal practically agreed upon.

Johnstown, Penn.—Louis J. Bradley, of Williamsport, has been in Johnstown for the past ten days conducting negotiations for coal land, and it is rumored he has secured control of a large acreage in Westmoreland County, and will start operating in the near future.

Coshocton, Ohio—Workmen, excavating for a barn on the Edward and R. R. Hanlon farm, have uncovered what is believed to be the richest vein of coal in this county. The owners of the land plan to lease it to coal operators, thus opening up an entirely new Ohio field.

Sunbury, Penn.—The season recently closed has not been a record one, owing to the fact that the water conditions were not at the best during much of the time. Thousands of tons of coal were secured, however, and there was a ready sale for all that could be mined.

Greensburg, Penn.—Over 1000 acres of Freeport coal located in Ligonier Township, near the Four Mile Run, has been sold by the farmers of that section to Franklin Byers, of Mt. Pleasant. This purchase, which is the first of the Freeport vein sold in this section, may develop this coal field.

Wilkes-Barre, Penn.—The Lehigh Valley Coal Co. is erecting a large new breaker at its Franklin Colliery in Wilkes-Barre East, which is one of the first, if not the first, colliery owned by it. It will be modern in every respect, and is estimated to cost about $200,000, or more, when completed.

Monongahela, Penn.—It has been learned that the Mongah mine of the River Coal Co., which has been shut down for the past 18 months, is to be opened up shortly after the first of the year. This mine employs over 400 men. It will be fitted out with new equipment which will cost in the neighborhood of $50,000.

Philadelphia, Penn.—The Penn. R.R. Co. is buying or condemning by right of eminent domain, a strip of land along its tracks for a considerable distance on the Sunbury Division, mainly in Conyngham Township (including some leased by the West End Coal Co.) for additional trackage and improvements. It has long needed these for its increasing trade.

Clarksburg, W. Va.—An important coal deal which has been pending for some time has just been closed, whereby Vincent E. Gocke, president of the Daniel Coal Co., has acquired from the Calvert Coal & Coke Co., of Chicago, their Byron and Robey plants. No possession will be taken of the plants until Jan. 1. The consideration is private.

Hazard, Ky.—The Buffalo Creek Coal Co. has secured the C. G Bowman tract of 2000 acres in Perry County, near Hazard, the consideration being about $75,000. The company has made arrangements for the immediate installation of equipment for mining operations, and also plans to put in saw and planing mills for the utilization of the timber on its properties.

Whitesburg, Ky.—Philadelphia and Baltimore interests recently acquired fifty acres of coal land in the Shelby Creek section, above Whitesburg, Ky., adjoining other properties owned by the same parties, at a price of a little over $7500 cash, which is said to be the highest price ever paid for land in that section. The purchasers are said to be preparing to develop their properties.

Baltimore, Md.—The Alabama Consolidated Coal & Iron Co.'s stockholders' committee has announced details of the plan it has drafted for rehabilitation of the property. It provides for an assessment of $30 a share against the preferred stockholders and $15 a share against the holders of the common stock. This would furnish a total of $750,000, divided equally between the two classes of stock.

Scotidale, Penn.—Hon. John R. Byrne and his brothers became the owners of the Mathias tract of coal, which lies in Sewickley Township, and is a part of the Yukon coal and coke development. The Byrne interests will at once begin the building of a 60-oven coke plant, it is said, and will also commence on tipple, tracks, and other improvements, it being their intention to ship coal as well as manufacture coke.

Lincoln, Ill.—The options given the Peabody interests on the coal mines in Sangamon County have expired and Mr. Peabody has been in Springfield to listen to reports of experts he has had investigating local conditions for him. Should these reports be satisfactory, Mr. Peabody was expected to have taken up the options. He has assured the Springfield people that a merger will not mean a closing down of the mines.

Ashland, Ky.—The Sara Furnace, the Martiny Iron & Steel Co., and the Ironton Iron Co., at Ashland, Ky., have been compelled to shut down owing to a lack of coke, which in turn was a direct result of the car shortage. The expected operation of the big new plant of the Kentucky Solvay Coke Co., will relieve the situation, as it will turn out enough coke to supply the local demand, as well as considerable tonnage for the outside market.

Freeland, Penn.—Dump cars and a steam shovel are on the ground and operations have been begun on the new stripping at the east end spur of the Buck Mountain vein, Drifton No. 2 colliery, of Coxe Bros. & Co., Inc., in the Lehigh region. The vein of coal is said to be about 15 ft. in thickness, lies near the surface, and is believed to crop out near the southern boundary line of the borough. It will be transported by locomotive to and prepared at No. 2 breaker of this firm.

Chicago, Ill.—The Roberts & Schaefer Co. has just been awarded a contract by the Queen & Crescent Route for two 500-ton capacity, fireproof, main-line, reinforced-concrete, Holmen coaling stations, electrically driven, for installation at Danville, Ky., and Oakdale, Tenn. Price, $37,000. These plants are to be exact duplicates of two former plants of this character of construction that this firm erected for the Queen & Crescent at Montlake, Tenn., and Ludlow, Ky.

Kingston, Penn.—Near Sugar Notch, the Pittston Coal Co. is demolishing the old breaker and building a new one of increased capacity, to cost about $30,000. The old breaker was dynamited at some parts to facilitate its removal. The concrete walls for the new are already in place, heavy lumber is on the ground and being framed, and the work is being pushed with all possible dispatch by the contractors, Messrs. Reilly & Co., of Kingston. It will scarcely be completed, however, before late next spring.

North Bend, Ore.—A new coal mine is being opened by C. A. Smith, of North Bend, and his business associates, and when in operation will be the largest coal mine in the county. Only 25 tons per day are taken out at present, but when the shaft is sunk deeper and the mine is in full operation, the output will be upward of 200 tons per day. A private railroad is used to transport the coal to deep water, where it is dumped into bunkers and stored till sold. There are about 1,000,000 tons of coal above water level at this mine.

Birmingham, Ala.—Walter Moore announces that the Panama Coal Co. will spend approximately one million dollars in the development of 35,000 acres of Black Creek coal land. Included in this development is the building of several miles of railroad for the purpose of connecting the property with the Frisco R.R., also modern equipment suited for working the Black Creek seam. It is expected that the company will be able to mine a minimum of 2000 tons of coal daily shortly after completion of the railroad spur to the mines. An average of 18 analyses of this Black Creek coal showed less than 2 per cent. ash and 15,629 B.t.u. per lb. It is equal in quality to the very best coals.

Barbourville, Ky.—Besides the Wallsend plant of the Continental Coal Corporation, near Barbourville, several other coke ovens have recently begun operations in eastern Kentucky, and turn out a product which is said to be the equal of any on the market. The Wisconsin Steel Co. is operating the largest battery of coke ovens in that region at Benham, and with a million-dollar installation turns out coke for the use of the company's northern plants, which are owned by the International Harvester Co. Ovens are also in operation in Pike County, Elkhorn district, and elsewhere in the field, and the industry bids fair to attain large proportions during the coming year.

Portland, Ore.—Much improvement is being made at the Libby mine, which is leased by George Doll. A new vein is being opened, which will greatly increase the production. The town of Libby, where the mine is situated, and which for several years was deserted, when the mine was closed down, is now quite lively.

The Beaver Hill mine, owned by the Southern Pacific interests, is undergoing some extensive development work. A new shaft is being sunk that will cost $300,000. Coal from this mine has become widely known in Portland, and is good coal for general use. The Southern Pacific owns its own coal ships and makes considerable money from the operation of this mine.

Marshfield, Ore.—The Millicoma mine on Coos Bay has been leased from the chief owner, J. A. Ward, by Portland capitalists and will be operated at once. E. H. Morgan, who examined the mine for the Portland men several months ago, will be the superintendent, and will take charge of the property at once. Mr. Ward expects to be connected with the operating company. The mine property takes in about 400 acres of land, and it is in such shape that coal in marketable quantities can be taken out at once.

COAL TRADE REVIEWS

GENERAL REVIEW

Additional stress has appeared in the anthracite market, due to the holiday suspension in the mining regions. Retailers continue short and the public is disregarding preferences in sizes and taking what can be obtained. Renewed interest is being shown in the premium coal out of New York and, while prices remain unchanged, a great deal depends on the weather. The trade has to depend on current production, which is far from sufficient to supply the demand. In some respects, however, the situation is easing off. There does not seem to be the pressure there was for egg, but pea, stove and chestnut are still quite short, and dealers can make no promises about deliveries.

In the Middle West the larger sizes appear to be getting more plentiful, and there are some cancellations, due to the milder weather, but premiums are still being well maintained. Consumers were well stocked in anticipation of a hard winter, and the trade is only about normal. In the South, the situation appears more acute; the demand continues active, and supplies are quite short.

In the coastwise bituminous trade, the last of the year developed more buying and in a larger volume. There are only small arrivals, all-rail, quantities available are scattering, and few operators can guarantee prompt shipment. Prices have reached the highest point since the depressed condition in effect during the summer and show every evidence of advancing still further. The receipts at the piers are small, and supplies generally, far short of the demand.

The appearance of real winter weather, together with a shortage, has developed an unusually strong market generally in the East. The situation could, however, hardly be otherwise in the face of these conditions; if the producers had an adequate supply of both labor and cars, they would doubtless flood the market with coal. The situation will, of course, ease off when the production does increase, but the trade generally is of the opinion that there will be no material decrease in consumption and that the high prices will hold. In the Pittsburgh district, the market has been quiet, and production relatively light due to the holiday suspension. The domestic demand has been fair, but the manufacturing quite light. In spite of the suspension over the holidays, there has still been considerable activity in Ohio. The steam business continues strong, consumers stocking against an emergency and the colder weather has brought an increased domestic demand. Prices on slack are particularly firm and some contracting is being done at a slight advance over last year's business.

Considerable surprise was occasioned at Hampton Roads, when the new circular for 1913 was announced, showing an advance of 30c. a ton over the old figures. West Virginia coals are gaining rapidly in favor for bunkering purposes, and the operators felt justified in making this increase. Railroads in the Kentucky field have apparently about satisfied their requirements, and are now taking little coal; domestic has been declining for some time, and appears to be on the verge of a break. In the Southern markets the usual holiday dullness prevails and not much buying is expected for the present; operators in this district made a special effort to lose as little time as possible over the holiday period, because of the prevailing high prices.

There has been a temporary set-back in the Middle-western market because of the holidays, but prices, as a rule, remain steady. The expected cold wave about Christmas did not materialize, and domestic is rather dull, but dealers believe that this will only be of short duration. Considerable buying has been put off until after the first of the year, and, when this appears, it will materially strengthen the market.

BOSTON, MASS.

Another small spurt has come in bituminous. The last of 1912 developed more buying, and in a larger volume. On the other hand, receipts at the loading piers are materially reduced by the holiday suspension, and prices are up at least 20 to 25c. from a week ago. This is especially true at New York, and Philadelphia shares it to a limited extent. At Hampton Roads and Baltimore there are as yet few sales of spot coal. The larger agencies are committed to loading vessels on contracts that are still effective, and the detention is only slightly improved. Of late years a large tonnage for New England has been loaded from Baltimore, and the excessive delays there, due to car shortage on the B. & O., make a serious upset in the calculations of those depending on supplies from that quarter. The quantity of coal available at other points is scattering, and values are almost sure to be higher in the next fortnight.

All-rail there is only a small movement of bituminous; $2@2.15 at the mine is the current price for fair grades from the Clearfield region. It is only the exceptional operator who can guarantee prompt service, and there is less heard about coal offering at the junction points for New England routing. The Christmas snowstorm was confined to the seaboard for the most part and apparently did not affect rail shipments, except to increase the anxiety of consumers who are running on small reserve stocks.

Hard weather on the coast has seriously interfered with arrivals. The retail dealers continue on the ragged edge for the popular sizes, and there is nothing new to report. A great deal depends on January weather; if it turns cold for a fortnight or so at a time, there will be real distress for fuel. As things have been, the public has shown a willingness to disregard preferences and get along on what sizes of anthracite could be had. There is renewed interest in premium coal at wholesale out of New York, although prices are not materially changed.

Present wholesale quotations are about as follows:

Clearfields, f.o.b. mine	$2 00 @ 2 15
Clearfields, f.o.b. Philadelphia	3.25 @ 3.40
Clearfields, f.o.b. New York	3 55 @ 3 70
Cambrias, etc., f.o.b. mine	2 15 @ 2 25
Cambrias, etc., f.o.b. Philadelphia	3 40 @ 3 60
Pocahontas New River, f.o.b. Hampton Roads	3.50 @ 3 60
Pocahontas New River, on cars Providence	4 50
Pocahontas New River, on cars Boston	4.75

NEW YORK

Anthracite—The effects of the heavy snow storm, on Tuesday of last week, have been discounted and the hard-coal trade is again back on about the same basis it was immediately preceding this. This abrupt change in weather conditions, threatened for a time, to effect a radical change in the hard-coal market and conditions during the remainder of that week were quite uncertain and rather tense. It was believed by many that the trade would prove very susceptible to this first, and rather alarming appearance, of real winter and the result was that shippers were inclined to hold all consignments available and free tonnages became quite scarce all along the line.

The tense feeling, however, has been gradually easing off since that time and is now back to approximately the same conditions in effect before. The demand has been slowing up and the situation getting easier all along the line, particularly on egg coal, the premiums on which are quite materially off; there is also little demand for chestnut. The consumption appears to be about normal and it is improbable that large premiums will again be paid in this market during the remainder of the season.

Production is quite good and it is doubtful if any large losses will be sustained as a result of the holiday suspension. These stoppages at the mines has enabled the railroads to keep the operators supplied with all the equipment they could load, which was not the case previous to this. It is probable, therefore, that the loss of time, due to the holidays, was only about the equal that which would have been sustained in any event, because of the insufficiency of cars at the mines.

We quote the New York anthracite market on the following basis, with prices generally firm in all departments:

	Upper Ports	Lower Ports
Broken	$5 00	$5 00
Egg	5 25@6 00	5 20@5 60
Stove	5 25@6 50	5 20@6 30
Chestnut	5 50@6 50	5 45@6 30
Pea	3 50	3 45@4 25
Buckwheat	1 75	2 35@2 70
Rice	2 25	1 70@1 95
Barley	1 75	1.25@1 70

Bituminous—The soft-coal situation is badly mixed up at the present time, there not being much coal available while the demand is spotty and intermittent, and confined mostly to small tonnages. There are fairly good supplies coming

in, but on the whole shipments are light. The line trade is the best feature of the business, the situation at tide being rather weak. The requirements of the trade are naturally reduced as a result of the holiday suspension in general manufacturing, but the production at the mine has likewise decreased for the same reson, and thus conditions in this respect are practically unchanged.

At the present moment it is practically a weather market. A general decline in the temperature will doubtless bring with it a jump in prices, while on the other hand, if the weather remains mild, the market will continue soft and unsteady; the car and labor supply are also important considerations that may assume serious proportions at any time.

Production in the mining regions has been quite poor. The car supply in West Virginia has been entirely inadequate, even with the curtailed work at the mines over the holidays. In Pennsylvania, however, the roads seem to have been able to keep the mines well supplied with cars. The shortage of labor in this latter district, however, is assuming serious proportions and promises to become quite acute should there be a heavy production.

New York bituminous prices are as follows:

West Virginia, steam	$3.15@3 25
Ordinary grades, Pennsylvania	3.15@3 25
Fair grades, Pennsylvania	3 15@3 25
Good grades, Pennsylvania	3.20@3 30
Best Miller, Pennsylvania	3.30@3 40
Georges Creek	3.50

PHILADELPHIA, PENN.

The inclement weather of early in the week caused additional calls on the dealers, and they are more than insistent in their desire to secure supplies of anthracite coal. Conditions are not in any way improved as to the output, for after a week of holidays, with curtailed production, certain sizes are in as short, if not shorter supply, than has been the case so far this winter. Stove and pea coal are simply impossible to obtain in sufficient quantities, and all the dealers are complaining bitterly, but it is a fact nevertheless, that the trade in this vicinity is being taken care of to the best of the ability of the companies forwarding coal to this market.

The large operators and some of the small ones, have been handicapped by lack of men, petty strikes and inadequate car supply. Large quantities of coal are coming to this market, but the demand is so heavy, and everyone so insistent, that when spread around, no one is satisfied. Egg coal seems to be in easier supply than any of the other domestic sizes, but chestnut still maintains its place as a scarce article. With two months of what is likely to be severe winter weather, the situation looks anything but promising, and a heavy snowstorm or blizzard would be likely to cause considerable discomfort, if not actual famine, if the operations of the railroads were held up for any considerable length of time.

Bituminous prices have reached what is considered the high-water mark in quotations since conditions became better the middle or latter part of the summer. Prices are anywhere from 10 to 15c. per ton over quotations of the previous week, and the supply is far short of the demand at the present time, due in a large measure to the holidays, added to insufficient car supply. As a matter of fact, the advance in prices is doubtless due to the scarcity of coal, rather than any extraordinary demand.

BUFFALO, N. Y.

The bituminous market is strong and could hardly be otherwise, so long as the car supply is so short. No doubt if the operators could have their way they would soon flood the market, no matter how great the demand might be, but as it is they are handicapped and it looks as if they would remain so for some time. The car shortage is quite as great as it has been at any time.

That there is no letting up of the stringency is shown by the report of one of the large city jobbers, that he was notified by the railroad that if he would load with fuel for the road a supply of cars would be given him next day. Of course, there was nothing to do but comply, regardless of the fact that there were plenty of customers waiting for coal.

The holiday time is not a very good one for sizing up the market, for the miners are idle a great part of the time, so that even if the factories are shut down also, it is likely that the decreased output is more than the decreased consumption. What the operator is trying to do is to evade the drawbacks and put a full capacity supply on the market in spite of everything. There is comparatively a big margin of profit in the business now and to do that would mean a large measure of success. For all the bad places in the bituminous trade, however, the general tone is very much better than it was a year ago. It is the policy of business not to be satisfied, but there are many grades of dissatisfaction for all that.

The quotations are as strong as ever. Some markets seem to find a weakness in the trade, but anything of the sort here is denied. One active jobber of bituminous and independent anthracite reports, that, for the first time in many months, he has not a single car in this vicinity subject to reconsignment. The Pittsburgh figures remain at $3 for select lump, $2.85 for three-quarters, $2.75 for mine-run and $2.50 for slack. Coke is hardly as strong as formerly, the prices appearing to have reached the top. It is still proper, however, to quote best Connellsville foundry at $6.50.

There have been a few cancelations of anthracite orders on account of the weather, but a jobber is still able to report sales of independent hard coal at $1.50 premium; the average excess is about $1.25, as last week. There is just now, very little anthracite coming this way from the mines, and prices are expected to remain pretty strong till mining is more active. Large sizes of anthracite are more plenty, and small grades shorter.

PITTSBURGH, PENN.

Bituminous—The coal market has been quiet the past week, and production has been relatively light, due to the interruption of the holiday. There has been a fair demand for domestic coal, but very little from manufacturing consumers, either for prompt or contract. Circular prices continue to be quoted as follows: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in., $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—Consumers of furnace coke were so well provided with stocks that last week's light shipments, on account of the holidays, had only a moderate effect upon the market. Prompt furnace coke sold up to $4.25, when $4 had been about the highest previously obtained. Contract business has been light, consumers objecting to paying the high prices asked, and believing the present to be an inopportune time to contract, when prompt coke is particularly scarce. It is reported that one contract has been made within the past few days for 12,000 tons a month over the first half at $3.50. We quote: Prompt furnace, $4.15@4.25; contract furnace, first half, $3.25@3.50; contract furnace, year, $3@3.25; prompt foundry, $4.25@4.75; contract foundry, $3.24@3.75, per ton at ovens.

BALTIMORE, MD.

Real winter weather conditions and a limited supply of coal were the dominating factors in the exceptionally strong market which prevailed here during the past week. The day before Christmas, this section experienced the first touch of cold weather for weeks, which was accompanied by a 3-in. snow, and such conditions have figured largely in the movement of fuel from the mines to tide water. Added to this was the expected shortage, resulting from the holiday period, in the West Virginia and other regions. One of the large local operators stated that the output from the mines of his company was considerably reduced on Tuesday. Wednesday, the mines were closed down altogether, and not more than half the miners normally employed, put in an appearance on Thursday, thus reducing the week's output of fuel to three whole days. This was the experience of practically all of the local companies.

Under such conditions, the market was naturally strong, and prices of all grades advanced from 10c. to 20c. over those of the previous week. There were rumors that one operator received $2 for low-grade coal the latter part of the week from consumers, whose stocks had run low, and who were eager for coal at any price. This was the highest price recorded during the week, but the last three days spot coal brought $1.75 and $1.80, and there were at least a half dozen customers for every ton offered.

The coal tonnage of the Consolidation Coal Co. for the year to Dec. 24 was 10,200,000 tons as compared with 9,075,000 tons for the corresponding period of last year, an increase of 1,125,000.

COLUMBUS, OHIO

While the past week has been broken by the Christmas holiday, still it has been one of considerable activity in the coal trade. Colder temperature has caused a better domestic demand and accordingly orders from retailers in Ohio, Indiana and Michigan have been more urgent. On the whole, the trade is satisfactory, when the condition of the car supply is taken into consideration and operators look for more activity in the near future.

Prices are remaining firm at the figures which have been prevailing since Dec. 1. Reports show a little softness in the Chicago market, but this condition has not affected the Hocking trade to any appreciable extent. Dealers in all sections

are fairly well stocked with domestic sizes, although in some localities stocks have run down rather low.

Steam business is still one of the strong points of the trade and there is a good demand from all lines of manufacturing. Some of the larger plants have been attempting to stock up to guard against an emergency, but they have not succeeded to any great extent because of the car supply. Concerns engaged in the iron and steel industries have been especially large purchasers of steam sizes. Some contracts expire about this time and renewals are being made, in some cases at slightly higher figures than prevailed during the previous year. There is still a good demand for railroad fuel and this branch of the trade is gaining in importance.

Production in all fields has naturally been curtailed by the shortage in cars, although it has also been affected by the Christmas holidays. In the Hocking Valley proper, the production is probably larger than in other sections in the state.

Retail trade has been rather inactive under the influence of the mild weather. Most of the larger householders have purchased their winter's supply, although there was a rush of small orders recently. Retail prices are practically unchanged.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburg	Pomeroy	Kanawha
Domestic lump	$2 00		$2 25	$2 00
3-inch	1 80	$1 50	2 00	1 65
Nut	1 50		2.00	
Mine-run	1 50	1 40	1 50	1 50
Nut, pea and slack	1 15		1 25	0 90
Coarse slack	1.00	1 15	1 10	0 75

CLEVELAND, OHIO

Prices fell off considerably on coarse coal in the vicinity of Cleveland during the past week. This break, no doubt, is due to the fact that the companies in the Pittsburgh No. 8 field have been forced to operate their mines exclusively on rail shipments during December; approximately 40% of this product was shipped via the Lakes during the summer months. The sudden placing of this tonnage in the rail market after the Lake season had a tendency to reduce coarse-coal prices.

During the early part of December operators were quoting $1.20 on Pittsburgh No. 8 run-of-mine for spot shipment and $1.10 for contract. This price has reduced considerably and consumers are now purchasing run-of-mine as low as $1.10 for spot shipment.

Slack is still the ruling factor. One 50- and one 100-car order was closed during the past week on Pittsburgh No. 8 slack at $1.20, the mines. On account of the high price of this grade, practically all of the mines are screening ¾-in. lump coal on run-of-mine orders. Slack is averaging 10c. per ton higher than run-of-mine.

The following prices per net ton f.o.b. the mines are quoted on the various coals for immediate shipment.

District	¾-in.	Mine-run	Slack
Youghiogheny	$1 40	$1 30	$1 10
Pittsburgh No. 8	1 20	1 10	1.20
Goshen No. 6	1 45	1 35	1 25
Coshocton	1 75	1 50	1 25

The production of coal between Christmas and New Years was reduced 50% on account of holiday celebrations. Mines continue to report a scarcity of railroad equipment. These conditions are bound to increase prices after the first of the year.

LOUISVILLE, KY.

The car situation has been affected by the holiday lay-off, which the eastern Kentucky miners, in particular, are taking this year as usual, despite short work during the fall. This enforced idleness at the mines is permitting cars to accumulate. It is reported that the Southeastern railroads, however, are in serious straits for coal, as initial lines have been absorbing all the fuel available. When the Louisville & Nashville and the Atlantic Coast Line, for example, have been facing a lack of fuel which made a curtailment of operations imminent, it is obvious that roads less favorably situated, with reference to the mines, must be rather badly off.

As a natural result of this condition, run-of-mine has sold, during the present week, as high as $1.75, and nut and slack has run up to $1.25, although all sorts of prices, down to 65c. have been heard. While lump is quoted at from $2.25@2.40, this is still a good deal under the high figures of November, when the car shortage was at its worst.

HAMPTON ROADS, VA.

Although interrupted by the Christmas holiday, the dumping at Hampton Roads during the past week was heavier than at any time in the past month and a half. All shippers appear anxious to clean up what old obligations are remaining, during the last few days of the old year. While the month's dumping figures are not yet available, indications point to a larger tonnage put over the local piers than during November.

During the past week, prices on bunker coal at Hampton Roads for the year 1913, were announced. Considerable surprise was expressed when it was learned that it would be advanced 30c. per ton. On the other hand, it has developed recently that good steamship coal could be purchased here for much less than at other points, and steamers were going out of their way in order to take advantage of the cheap supplies here. It is probable for this reason that the export shipments from here will soon show a rapid increase.

MEMPHIS, TENN.

Notwithstanding this territory is having one of the most open winters in its history, there is quite a scarcity of coal because the car situation has been bad for the past 60 to 90 days. The miners are having a prolonged vacation during the holidays, and it is making coal just a bit more scarce than it has been this winter.

The car situation on all the roads leading into Memphis would be very disastrous to all concerned should we have any weather demanding an unusual amount of coal. While there has been no scarcity of any particular grade, other than screenings, it has made these higher this season, than ever before.

BIRMINGHAM, ALA.

The usual holiday quietude prevails in the market for coal and coke and not much buying is anticipated until well after the new year.

Owing to the high prices now being obtained for all grades, a special effort was made by the operators to cut the loss of time, incident to the holidays, to a minimum. Many of the mines were, therefore, put into operation on Dec. 26 with a good quota of men ready for work.

Both domestic and foundry cokes are in urgent demand, and by adopting strenuous measures the coke plants were kept running full all through the holidays.

INDIANAPOLIS, IND.

The Indiana coal industry has progressed fairly well during the past week. With the exception of two holidays, the miners in nearly all the districts have worked full time. Operators say the demand is good, orders are being filled regularly and that little trouble is now experienced in securing cars for shipments. Retail and wholesale dealers report an even trade in all except anthracite coal; this has become a luxury in some markets. The Railroad Commission of Indiana has issued an order correcting and modifying rates to Lafayette and other points in the state and otherwise materially rendering assistance to the mining industry.

CHICAGO

As a result of the holiday season, there has been a temporary setback in the Chicago market, although prices, as a rule, remain steady. There is dullness throughout the domestic trade, but dealers believe there will be a resumption of brisk buying within a short time.

Hocking coal is being received in comparatively small consignments. Smokeless is stronger by from 15 to 20c. a ton than it was a week ago. Mine-run commands $1.50 and the price on lump and egg is about $2 a ton. Splint coal shipments are very light. Domestic lump is being sold for $2 at the mines. Orders for coke have lessened, although the producers have sufficient on hands to keep a full force at work for some time.

Prevailing prices at Chicago are:

	Sullivan Co.	Springfield	Clinton	W. Va.
4-in. lump	$2 87			
Domestic lump		$2 32 @ 2 57	$2 52	
Egg	2 62			$4 30 @ 4 55
Steam lump		2 12 @	2 17 @ 2 27	
Mine-run	2 07 @ 2 17	1 97	1 97 @ 2 02	3 45 @ 3 55
Screenings	1 62 @ 1 67	1 47 @ 1 57	1 57 @ 1 62	

Coke.—Prices asked for coke are: Connellsville, $6.75@7; Wise County, $6.75@7; byproduct, egg and stove, $6@6.25; byproduct, nut, $6@6.25; gas house, $6.

DETROIT, MICH.

Conditions during the past week have not varied a great deal, even considering the usual holiday dullness. Anthracite is coming in plentifully, and the fact that we have had a mild season, and that nearly everyone stocked full of the softer coals in preparation for a hard winter and a prolonged strike, the price of same is only normal.

Coke, however, is a scarce article, even in all sizes and is commanding $5 at the ovens with scant possibility of getting any large amounts.

Local market conditions are as follows:

	W.Va. Splint	Gas	Hocking	Pitts. No. 8	Jackson Hill	Pocohontas
Domestic lump..	$1 70				$2 50	$2 75
Egg..	1 70				2 50	2 75
Nut	1 60		$1 60			
3-lump..	1 40	$1 40	1 50	$1 40		
Mine-run.	1 25	1 25	1 35	1 30		1 50
Slack..	1.25	1 25	1 10	1 15		1 25

The cold wave, expected about Christmas time, failed to show up, and the market consequently continued to break. The first of the year, however, saw a slight improvement, occasioned by the demand more than anything else, inasmuch as buying has been held off until the first. It is doubtful, however, as to whether coal will again see the prices this season that it did in the fall.

The car shortage and the slow movement of coal has been the only support the market has had, and as a matter of fact, it is the only thing that is keeping the price of coal above the cost of production right now. The anthracite situation is still tense as far as chestnut is concerned, but there is plenty of the larger sizes. Coke is extremely scarce, and the price continues to advance.

The prevailing prices are as follows:

	Carterville and Franklin Co.	Trenton and Big Muddy	Mt. Olive	Standard
2-in. lump..	.....	.....	.....	$1 00 @ 1 10
3-in. lump..	.....	.....	$1 40	.....
6-in. lump..	.....	.....	1 60	1 25 @ 1.30
Lump and egg..	$1 45 @ 1.60	$2 25	.....	.....
No. 1 nut..	1 30 @ 1.50	.....	.....	.....
Screenings..	0.75 @ 0.85	.....	.....	0 55 @ 0 65
Mine-run..	1.10 @ 1.20	.....	.....	0 90 @ 1 00
No. 1 washed nut	1 50 @ 1.60	.....	.....	.....
No. 2 washed nut	1 35 @ 1 40	.....	.....	.....
No. 3 washed nut	1.15 @ 1 20	.....	.....	.....
No. 4 washed nut	1.05 @ 1 10	.....	.....	.....
No. 5 washed nut	0.85 @ 0 90	.....	.....	.....

Gas house and byproduct coke are quoted at $5.50, f.o.b. St. Louis.

OGDEN, UTAH

For the past two weeks the mines in Utah have been troubled with a car shortage, which from present indications promises to become quite severe. The Rio Grande R.R. has been putting forth an extra effort to handle the coal business tributary to its line and consequently a large percentage of its cars have gone to foreign roads and have not been returned.

Shortage of closed equipment on the Union Pacific is still acute and a very small portion of the domestic coal is being loaded in box cars. Operators are sending urgent requests to the trade to accept lump and nut in open cars. There is no relief in the labor situation and the mines are unable to reach maximum tonnage. No doubt this condition will continue throughout the remainder of the winter.

The cold weather has not affected the quotations f.o.b. mines, which are as follows:

	Wyoming	Utah
Lump	$2.75	$2.75
Nut	2.25	2.25
Mine-run	1.85	1.85
Slack	1.00	1.25

PORTLAND, ORE.

Portland is planning the installation of a system of coal bunkers for the accommodation of off-shore shipping and is now looking over the field for a satisfactory source of supply. In the past, large craft have found it advantageous to proceed to Puget Sound or British Columbia to fill their bunkers, at considerable additional expense, but the establishment of bunkering stations here will obviate this necessity. It is expected to bring the coal to the river in barges.

FOREIGN MARKETS

GREAT BRITAIN

Dec. 20—Colliery owners are still heavily booked; and they are holding firmly to quotations for all descriptions of large and small, for forward as well as prompt positions. Quotations are approximately as follows:

Best Welsh steam	$4 50	Best Monmouthshires	$4 20
Best seconds	4 26	Seconds	3 72
Seconds	4 20	Best Cardiff smalls	3 72
Best dry coals	4 38	Seconds	3.48

The prices for Cardiff coals are f.o.b. Cardiff, Penarth, or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days—less 2½%.

PRODUCTION AND TRANSPORTATION STATISTICS

Pennsylvania Railroad

Statement of coal and coke carried on the P. R.R. Co.'s lines east of Pittsburgh and Erie during November and the first 11 months, with the increase or decrease over the same period last year, in short tons:

	November	Difference	11 Months	Difference
Anthracite	916,914	— 244,373	9,275,631	—1,466,713
Bituminous	3,934,876	+ 48,512	42,162,485	+3,724,526
Coke	1,245,500	+ 332,013	12,128,463	+2,400,327
Total	6,097,290	+ 136,152	63,566,579	+4,658,140

Connellsville Coke

The "Courier" reports production in the Connellsville region as follows:

Production	Week Ending Nov 30	Dec 7	Dec 14	Dec. 21
Connellsville	218,546	214,990	212,890	228,563
Lower Connellsville	181,564	178,016	176,174	183,555

Pittsburgh Coal—Regular quarterly on the preferred of 1¾%, payable Jan. 25, to holders of record Jan. 15.

PRICES OF MINING SUPPLIES

THE MARKET IN GENERAL

The year 1913 opens far more auspiciously than did 1912. Manufacturers everywhere have orders on their books to keep them busily engaged for three or four months at least, while the prospect for new business is far better than at the same time in any year since 1907.

Iron and steel industries continue to furnish the greatest volume of orders, and the phenomenal increase in business taken by the U. S. Steel Corporation is marvelous. Every blast furnace, rolling mill, and finishing plant in the country is not only working full blast, but endeavoring to find additional men to turn out a larger product. Moreover, many of these mills are building extensive additions to care for future business.

Railroads of the country have purchased more liberally during the last month than at any time this year, and indications point to a continuation of this large amount of business for several months to come. Railway net earnings are increasing, and in good ratio. Of course, no man or corporation makes as much money as desired, but the profits of the railways are now fairly satisfactory.

Ship-building work is active, and promises to be more so. Freight rates have advanced rapidly in the last year, and even now ocean berth space is so scarce that few, if any, of the transatlantic carriers can offer cargo space for the next ten to twelve weeks. The railroads' conditions appear much the same. The shortage of cars, while not as apparent as a month ago, still exists, and in December, more cars were purchased than in any other month last year, while the railways on Jan. 1 were preparing to buy about 60,000 additional freight cars.

New terminals must be built by the railways, and additional facilities provided to take care of the enormous freight traffic.

Financial conditions have materially improved, and there is a healthy demand for money for mercantile purposes, entirely distinct from stock-market speculation.

LABOR

The differences between laborers and employers have, as a general rule, been readily adjusted, and, in fact, there have been only a few disturbances which required any outside interference. It rather prolonged strikes, the settlement of which was unnecessarily delayed by blundering on the part of the authorities.

Voluntary action on the part of the U. S. Steel Corporation in raising the wages of all of its employees after Jan. 1 seems to indicate that the officials of this corporation believe the present era of industrial prosperity will continue. It is estimated that the increased wages paid out by this company alone will amount to $5,000,000 annually.

In New York, on Dec. 30, about 75,000 garment workers went on strike. They are better organized than heretofore, and seem to have plenty of funds to carry on their campaign, backed by able leaders.

The Public Service Co., which controls a large part of the public utilities of the State of New Jersey, announced shortly before Christmas that hereafter no woman in its employ would receive less than $9 per week. On making this announcement, it stated that two-thirds of the company's female employees were affected by it.

In Boston the clerks of the New Haven railroad are striking for $2.25 per day.

IRON AND STEEL PRODUCTS

A better supply of coke in and around the Pittsburgh district, a more even distribution of cars, and the settlement of a small strike in Homestead mills all combine to make a larger production of steel products. While for the month of December, we usually present no records on account of the Christmas holidays, it is probable that in January several new high records of tonnage will be made, and it is furthermore probable that the record-breaking production which was established on several occasions in 1912 will be augmented from time to time.

Prices of steel products have changed slightly. Pig iron is practically the same as a month ago; semi-finished steel is likewise unchanged, but finished forms, such as plates and structural shapes, have been advanced $1 per ton.

Railway buying has continued in large volume. The principal transportation companies of this country bought more new equipment in December than in any month this year.

Inability to obtain shipments of bars, sheets and other finished material has caused more uneasiness than any other one thing this year.

The price of old material is considered an excellent index to the course of the market by experienced iron and steel men. The highest prices recorded in 1912 were reached around the first of November, but a month after that, prices declined with little show of resistance. During December sales was larger, but there was practically no improvement in prices. The outlook now is not especially bright.

Orders for rails placed for 1913 by railroads in 1912 will probably exceed 2,500,000 tons. The total requirements of the railroads for the present year will undoubtedly total 4,000,000, and to roll this vast quantity will tax the capacities of the mills. It is true that the rolls of the country had a capacity in the neighborhood of 5,000,000, and perhaps somewhat in excess of this, but that was several years ago, and since that time these mills have been equipped with different rolls; to change them over again would require a great expenditure.

Rails—Several good export orders came up during December, one for 100,000 tons for Brazil, which, however, was not closed. Another order of 19,000 tons for South America was accepted. Quotations are unchanged, with a continued scarcity in the lighter-weight rails, and, f.o.b. Pittsburgh, are as follows: Standard sections, 6 to 100 lb. per yd., 1.25c. per lb.; 40 to 50 lb., 1.21c.; 12 lb., 1.25c. Relaying rails in Chicago, 45 lb. subject to inspection, are held at $22 to $24 per ton. Standard sections of relaying rails in the same market are held at $24 per ton. Some of these rails can be had at points other than Chicago.

Track Supplies—A scarcity seems to exist in track bolts and prices have been moved upward. In Pittsburgh, 2.05c. per lb. is quoted. Angle bars are in plentiful supply and 1.50c. per lb. is named in Pittsburgh. In Chicago, angle bars are 1.50c.; spikes, 1.75 to 1.95c.; track bolts with square nuts, 2.30 to 2.40c.

Structural Material—Mills rolling structural shapes and track material have all the orders on their books that they can take care of for the next six months, and in spite of an advance of $1 per ton, made in the latter part of December, there seems to be no diminution in the amount of business offered. While the mills making plain material are crowded, the fabricating shops are working to the limit of capacity, and now have orders on their books which will carry them well through the summer. Of course, some rush jobs can be taken care of in the meantime, but for ordinary roof trusses and the like, there seems to be no possibility of getting material for six months, unless fancy prices are paid for it. Prices, as stated, are $1 per ton higher, ordinary angles, beams, channels and tees being quoted at 1.55 to 1.60c., f.o.b. Pittsburgh, for deferred shipments and 1.75 to 1.80c. for fairly prompt delivery. In Chicago, quotation for future shipment is 1.68 to 1.78c., and for fairly prompt delivery, 1.88 to 1.93c. The enormous buying of cars by the railroads as well as the orders by shipbuilding firms resulted in stiffening the prices of plates which are now quoted at 1.55 to 1.60c., Pittsburgh, for future delivery, and 1.75 to 1.80c. for fairly prompt. In Chciago, the price for future shipment is 1.68 to 1.73c., and for delivery in the near future, 1.88 to 1.93c.

Mine Timbers—The demand for mine timber has not been up to the expectation of the mills rolling these special shapes and the tonnage disposed of was disappointing. Makers of mine timbers, however, have sufficient stock on hand to supply the limited need, and prices are steady and unchanged at 1.50 to 1.55c., Pittsburgh.

Pipe—A revision in the list of pipe announced by manufacturers on Jan. 1, resulted in slight changes being made in the price of practically all different sizes. Most of the makers of pipe have discontinued the manufacture of merchant sizes, and all pipe will now be standard. Discounts are as follows: Steel pipe, ½-in. in large lots from the mill, black, 77½ from list; galvanized, 66⅔%; ¾- to 3-in., black, 80%; galvanized, 71½%; 2-in., black, 77%; galvanized, 68½%; 2½- to 6-in., black, 79%; galvanized, 70½. Based on these discounts, the net prices of pipe per foot are as follows, in cuts:

Size, inches	Black	Galvanized
¾	2.30	3.10
1	3.40	4.85
1¼	4.60	6.55
1½	5.50	7.70
2	7.40	10.30
2½	11.50	16.70
3	15.40	21.75

Sheets—Sheet makers are beset with many difficulties in pleasing their customers. For blue annealed sheets, 14 to 16 weeks' delay is experienced, while on the better known sizes of black and galvanized sheets, from 10 to 14 weeks, and on sheets generally used for automobile purposes, there is a delay of 12 to 16 weeks. Specifications continue larger than the mills can turn out, and the total purchase of sheets increases rather than diminishes. On Dec. 31, many long-time contracts expired, and these were taken at much lower prices. Sheet mills expect considerably better prices after the first of the year, with a volume of business fully equal to that of the last three months. In general, prices are steady without change, but small mills, which make prompt shipments, are able to command fancy prices for this accommodation.

The following table gives the price of sheets in carload lots, f.o.b. the Pittsburgh district, and also the price of small lots from store in Chicago:

	Cents per pound			
	Pittsburgh		Chicago	
	Black	Galv.	Black	Galv.
Nos. 22 to 24	2.10	2.90	2.50	3.20
Nos. 25 and 26	2.15	3.10	2.60	3.45
No. 27	2.20	3.25	2.65	3.65
No. 28	2.25	3.40	2.70	3.90

WIRE PRODUCTS

Wire—Continued efforts have been made to advance the quotations of wire, as were noted last month, but the largest manufacturers have strenuously opposed such a course, and they have been successful in their attitude. This does not mean that there is no expectation of an advance in the near future, for it is the unanimous opinion among manufacturers that an upward revision of quotations must be made before spring. Plain barbed wire is $1.75@1.80, f.o.b. Pittsburgh, and galvanized is $2.10@2.15. Annealed fence wire is $1.55@1.65, and galvanized is $1.95@2.05. All of these quotations are per 100 pounds.

Wire Rope—Some large orders have recently been placed for wire rope, and a notable export order was for 6000 ft., to be shipped to Cuba to haul 100,000-lb. cars. Samples of this rope were tested by machines, and broke under a strain of 600,000 lb. There does not seem to be the same scarcity that existed a month ago. Net prices of the sizes in most general use are quoted, f.o.b. Pittsburgh: 2-in., 57@76c. per ft.; 1¼-in., 23@32c. per ft.; ¾-in., 10@13c. per ft. All of these prices are for large lots.

Telegraph Wire—The demand for telegraph wire has been large. For lots in fair size, the wire measured in Birmingham wire gage, prices are as follows: "Extra Best Best," Nos. 6 to 9, 4½c.; Nos. 10 and 11, 4½c.; No. 12, 4⅝c.; No. 14, 5¼c.; "Best Best," Nos. 6 to 9, 3½c.; Nos. 10 and 11, 3⅝c.; No. 12, 3½c.; No. 14, 4c. Actual freight is allowed from basic points where it does not exceed 25c. per 100 pounds.

Copper Wire—Manufacturers of copper wire had a very satisfactory business all last year, and while they are somewhat behind on shipments, as a general rule these are made promptly. Prices are firm, at 18¾@19c. base, depending on the size of the order.

MINE SUPPLIES

Nails—The price of nails did not advance, but it is felt that an advance will be made within the next month or so. The following quotations are per keg of 100 lb., f.o.b. the points named: Wire nails, Pittsburgh, $1.85 base. In Chicago, the base price is $2.08 for wire nails, and in Pittsburgh, less than carload lots are quoted at $1.85. Cut nails are held at $1.80 in Pittsburgh for jobbing lots.

Bar Iron and Steel Shapes—Consumers ordering direct from the mill find it difficult, if not impossible, to secure shipments with any degree of regularity, and in consequence, much of this material is ordered from Jobbers' stocks. The prices from jobbers' store in cents per pound, f.o.b. Chicago, are as follows:

	Cents per lb.
Refined Iron:	
1 to 1¾ in., round and square	2 05
1½ to 4 in. x ⅜ to 1 in.	2 05
1½ to 4 in. x ¼ to ⅜ in.	2 25
Norway bars	3 60
Soft Steel;	
¾ to 3 in., round and square	2 05
1 to 6 in. x ¼ to 1 in.	2 05
1 to 6 in. x ¼ and ⅜ in.	2 20
Rods—⅜ and ½ in.	2 15
Bands—1½ to 6x¼ to No. 8	2 35
Beams and channels—3 to 15 in.	2 25
Angles;	
3 in. x ¼ in. and larger	2 25
3 in. x ⅜ in. and ¼ in.	2 60
1½ to 2½ in. x ¼ in.	2 35
1½ to 2½ in. x ⅜ in. and thicker	2 25
1 to 1½ in. x ⅛ in.	2 35
1 to 1¼ in.	2 40

Belting—Manufacturers of belting have all the business they can take care of for the time being, and the prospects are excellent. There has been a slight falling off in the demand for leather for other purposes, and in consequence, discounts are unchanged from last month. These discounts may be found on page 482 of the issue of Oct. 5. Net prices per foot for various widths of leather belting are as follows:

LEATHER BELTING, NET PRICE PER FOOT

Width inches	Extra heavy	Heavy	Light
1	$0.11	$0.10	$0.08
1½	0.17	0.14	0.11
2	0.23	0.19	0.15
2½	0.28	0.24	0.19
3	0.34	0.29	0.23
3½	0.40	0.34	0.27
4	0.46	0.38	0.31

Brattice Cloth—Quotations continue at a high level. In fact, prices today are on a higher basis than ever before. This is caused by a phenomenal demand for all kinds of jute products, in addition to an enormous inquiry for brattice cloth itself. Shipments are somewhat better, and deliveries can be made in shorter time than a month ago, while stocks in the United States have increased slightly. This is a relief in point of view of shipment only, for lower prices are not looked for by conservative dealers in the trade for six months to come, at least.

Packing—Prices vary within wide limit, according to the brands of various dealers, but in general, packing can be purchased at the following quotations: Asbestos wick and rope, 13c. per lb.; sheet rubber, 11 to 13c.; pure gum rubber, 40 to 45c.; red sheet packing, 40 to 50c.; cotton packing, 16 to 25c.; jute, 5 to 6c.; Russian packing, 9 to 10c.

Chain—Mills seem to have caught up with their orders, but the revision of prices announced two months ago has had no effect on the volume of inquiries and many of these will subsequently be turned into orders. Prevailing quotations per 100 lb., f.o.b. Pittsburgh, are as follows:

⅛ in.	$7.50
¼ in.	4.95
⅜ in.	3.95
½ in.	3.40
⅝ in.	3.20
½ and ⅝ in.	3.00
⅝ and ¾ in.	2.90
¾ and ⅞ in.	2.80
⅞ and 1 in.	2.70
1 to 1¼ in.	2.60
Extras for BB	
⅜ in.	1.50
½ in.	1.50
⅝ in. and larger	1.25
Extras for BBB	
⅜ and ½ in.	2c.
⅝ and larger	1.75c.

CONCRETE AGGREGATES

Portland Cement—While prices are unchanged from last month, the market is undeniably stronger. Makers of portland cement are looking forward to this year's being the most satisfactory of any in the cement industry. Eastern markets, which have been lagging behind for the last five years, are the most hopeful. There, a large amount of business is already in sight, and indications are not wanting that much more will develop, if conditions are at all favorable. All things considered, it would not be at all surprising if the price of cement should be advanced in the latter part of February, or slightly later, and revised on a basis of 10 to 20c. per bbl. higher. At present, quotations are unchanged, as stated, at $1.58 per bbl., f.o.b. Pittsburgh, subject to the regular allowance of 10c. for all bags returned. In wood, cement is quoted at $1.58 per bbl., at the same place.

Bars, Concrete Reinforcing—The inability to secure direct shipments of bars from the mills has caused many consumers to buy warehouse stocks, and in consequence, there is a premium of $4 to $6 per ton for such stock. Shipments cannot be made within three to four months on any kind of material from mill, and in some cases it is even longer.

The following quotations are named, f.o.b. Pittsburgh, for large lots from mill, also for small lots from warehouse stock:

Pittsburgh prices in cents per pound.

	Mill shipments	Warehouse stocks
¾-in. and larger	1.45@1.50	1.95@2.05
⅝-in.	1.50@1.60	2.00@2.10
½-in.	1.55@1.65	2.05@2.15
⅜-in.	1.65@1.75	2.20@2.30
¼-in.	1.95@2.05	2.45@2.55

Triangular Mesh—This form of concrete reinforcement is selling at unchanged prices, and the makers state that they are able to make delivery in a day or so after the receipt of order.

From mill in De Kalb, Ill., quotations are 18c. per 100 lb. higher. Prices are as follows, per 100 sq.ft., f.o.b. Pittsburgh district, for less than carload lots and lots of more than 10,000 sq.ft.:

No. 4	$1.23	No. 32	$2.62
" 23	2.05	" 36	1.05
" 26	1.42	" 40	3.25
" 28	1.97	" 41	2.48

Petroleum Products—Much higher prices prevail for crude oil from well. In fact, the advance in December was as rapid as any month this year. For example, Pennsylvania is now quoted at $2.07 per bbl., compared with $1.30 at the beginning of the year; Second Sand and Tiona, $1.90; Mercer black and New Castle, Corning, $1.53; Illinois, above 30 gravity, $1.08; Kansas and Oklahoma, 83c. All these prices are for the crude oil at the wells per barrel. A revision has been made in the price of kerosene, and it is now being quoted at 9c. per gal. Auto naphtha is 19¾ cents.

Paints—A further revision in the price of linseed oil brought the quotation down to 46c. per gal. in the principal market. Paints have not followed the decline, but in a general way paint is cheaper, and there are few adulterants used in the mixing of it. The amount of low-grade oils which has been used in the cheaper grades of ready mixed paints during the last few years is amazing, and the great trouble is that their imperfections do not appear for six months or so after a structure has been painted. In consequence, all bills have been paid, and there is no redress.

Spirits of turpentine is also slightly easier at 35c. to 36c. per gal. White lead in oil in 100-, 250- and 500-lb. kegs is 6½@7c. per pound. Red lead and litharge in lots of 500 lb. and over may be obtained at 7 cents.

Insulators—Prices continue with out change. Glass insulators in lots of 1000, and less than 10,000, are sold at the following price per 1000: Double petticoats, 20-oz., $33; Western Union, $30.25; No. 2 cable, $53.90; No. 4 cable, $2.10; Muncie type, 7-in., $236.50; No. 3 triple petticoat, 4½-in., $90.75.

Sheet Steel Roofing—The same scarcity which is noted in the market for ordinary sheets is felt in the corrugated-sheet market. Prices are irregular, but from store, Chicago, are as follows per 100 sq.ft. for 2½-in. corrugation, painted: No. 22, $4.75; 24, $3.75; 26, $2.85; 28, $2.50. Galvanized roofing is held at an advance of 10c. per 100 lb. over the flat sheets from which they are made. For example, 24-in. galvanized roofing in Chicago would be $3.75 per 100 lb.; 28-in. galvanized, $4.20 per 100 lb.

COAL AGE

Vol. 3 NEW YORK, JANUARY 11, 1913 No. 2

Facts and Figures.

The history of the development of America is a record of unparalleled interest, but the story of the growth of coal mining is a romance which reads like fiction.

The pinnacle of progress in the coal industry was reached in 1912, when the total production amounted to 511,964,403 short tons, having a spot value at the mines of approximately 680 million dollars. This was the largest output and highest total value ever recorded in any single year.

Nearly one-half the coal produced in the world is mined in the United States. The following figures clearly show the miraculous growth of the industry:

In 1850—11	states	produced	7,018,181	short	tons
" 1860—15	"	"	14,610,042	"	"
" 1870—21	"	"	33,035,580	"	"
" 1880—25	"	"	71,481,570	"	"
" 1890—28	"	"	157,770,963	"	"
" 1900—28	"	"	269,684,027	"	"
" 1910—27	"	"	492,647,863	"	"
" 1912—28	"	"	511,964,403	"	"

It is evident from the foregoing table that the output of coal has practically doubled every 10 years. It is likely therefore, if business continues normal, we will see either a material increase in production, or much higher prices for the tonnage mined.

The production of coke in 1912 also made a new record, bettering the figures shown in 1910 by a small margin. This important branch of the industry has shown a growth equally as remarkable as coal mining. The following summary is convincing:

In 1880 the	U.S.	produced	3,338,300	short	tons	coke
" 1890	"	"	11,508,021	"	"	"
" 1900	"	"	20,533,348	"	"	"
" 1910	"	"	40,807,204	"	"	"
" 1912	"	"	41,803,199	"	"	"

The total output of coke in 1912 had a spot value of approximately 110 million dollars, and was produced by 591 plants operating 107,000 ovens. The feature of the coke-making business was the advance in retort-oven practice. A plant of the byproduct type, comprising say 75 ovens, would cost approximately $1,000,000, while a 75-oven beehive plant costs only $65,000. The latter installation, however, will produce only about 52,500 tons annually, while the 75 byproduct ovens will show a yearly output of 400,000 tons.

Practically the only difficulty in the way of the general adoption of the byproduct oven is its first cost. Here is an important instance, then, where industrial waste of a criminal order can be eliminated only by consolidation along lines so generally condemned. Those who will look back a century hence, when "Connellsville coke" is but a name in history, will marvel at the stupidity of a nation dissipating its natural wealth into fifty miles of atmosphere. Wise men no longer predict what may be in years to come, so there is some consolation in the belief that a people of greater intelligence than ourselves will recover from the atmosphere a high percentage of what we have thrown away.

A few years ago the press and public in the United States were calling attention to the high death rate in our coal mines, as compared with European practice. A revision of opinion is now in order. Counting only those fatalities in 1912 where three or more were killed, a careful compilation shows the following: United States, 254; Great Britain, 117; Germany, 183; France, 85; Japan, 284. Considering these figures in the light of tons mined, this country does not compare so unfavorably with Great Britain, and is far ahead of Germany, France and Japan.

In fact, working in the coal mines is now about as safe an occupation as following a vocation in New York City. In our metropolis last year, 532 persons were killed on the streets. Of this number 221 were struck by automobiles, and fatalities due to this one cause are increasing at the rate of 38 per cent. annually. If we continue to improve safety conditions in our mines, these underground workings will soon be a haven of refuge for New York citizens who are not quick on their feet.

In conclusion, there is much that we of the coal industry can be proud of. Our product is the most needed of all the necessities Providence hasn't seen fit to make free, like air and water. It is the life-blood of all industry. More than two million men gain their livelihood directly or indirectly through the production and use of this mineral. Two billion dollars are expended for it, although the producer gets less than one-third of this sum, which is equal to nearly one-tenth the total income of the nation. Freighting brings in over two-thirds the gross revenue of the 350,000 miles of American railways, and coal forms nearly one-third the entire freight business of the country. It does appear, therefore, that we should feel quite pleased with our progress although it seldom pays to be entirely satisfied.

Reviews of Coal Mining for 1912

SYNOPSIS—Reports from state mine inspectors and special correspondents, giving estimates of the year's production and the outlook for 1913.

Alabama

By G. B. Allen

The general conditions in the coal industry of Alabama during 1912 have been most satisfactory and the indications are that this year's production will exceed that of any previous year, probably running to between 18,000,000 and 19,000,000 tons. In support of this prediction the advance statistics recently gathered from twelve of the largest operators in the district show material increases in tonnage during the greater portion of this year over that of 1910, which was the "banner" year.

There have been no strikes or other labor disturbances in any quarter, although here and there at certain seasons there have occasionally been slight temporary shortages of labor. A considerably larger number of men have been employed in all directions. No serious accidents have occurred, excepting one in Tuscaloosa County, where 18 men perished in a gas explosion.

There has been an increased use of permissible explosives. Mechanical haulage by electricity and gasoline motors has been made more extensive, and operators have incurred large expense for additional spraying facilities. Several large Jeffrey fans have been installed in the district.

The general trade in this state is divided into three classes, namely: steam, domestic and coke. New openings have been made in Walker, Jefferson, Tuscaloosa, St. Clair and Jackson Counties (twelve in all) and these give promise of even greater production in 1913. The Pierce Coal & Lumber Co. has already opened up some mines on the Belmont seam (in Jackson County) and will make other openings at once. This company will concentrate all its coal at one tipple, and the total output will reach approximately 1000 tons per day.

During 1912 McCormack & Ramsey, of the Pratt Consolidated Co., purchased the Newcastle properties from the Anniston Iron Corporation. Eight hundred tons are being mined daily and it is expected to greatly increase the output in the early part of 1913.

The Woodward Iron Co. absorbed the Birmingham Coal & Iron Co.; the Bonnyman-Norman Coal & Iron Co. took over the Coalmont Mine of the Helena-Cahaba Mining Co., and a small property near Brookside. These were the only consolidations of consequence.

Unfortunately there was a shortage of cars in September, October and November, and at times this was the cause of some embarrassment; the situation in this respect began to improve in December, however, and no particular complaint on this score is heard at present.

The Tuscaloosa Mineral R.R., (property of the Louisville & Nashville R.R.), operating between Birmingham and Tuscaloosa (56 miles), was opened for traffic in the spring of 1912. This line will develop a large tract of valuable mineral lands, which will naturally inure greatly to the general prosperity of the Birmingham District.

In the direction of safety, the important operators have placed several classes of well-trained helmet men in readiness for immediate service when emergencies arise. These classes have received instruction under Government supervision at the Mine Rescue Station in Birmingham, and have been awarded Government certificates of competency.

The coke production in Alabama will show an increase in 1912 over 1911 (when 2,756,697 tons were manufactured), although it is doubtful whether it will be in excess of the production in 1910, which was 3,231,399 tons. The Government work on the Warrior River is nearing completion, a number of locks having been finished. Immense deposits of undeveloped high-grade coal are accessible to this stream only, while others are accessible to both the river and the steam roads.

Practically all of this enormous tonnage for markets farther south will be transported by barges down the Warrior River, and thence by the Tombigbee and Alabama Rivers to the Gulf.

It is estimated that no other agency will contribute more vastly to the welfare of general trade conditions in Alabama than the achievement of water transportation from the rich Warrior coal fields to the Gulf of Mexico.

Colorado

By James Dalrymple*

The condition of the coal industry in the state of Colorado for 1912, has been wholesome and normal and there has been a steady increase in the production over that of 1911. The demand for coal in 1912 has greatly exceeded the production. This was due, in a measure, to the better financial conditions prevailing in the country. The operators have been seriously handicapped, however, both by a shortage of miners and a shortage of cars.

The shortage of miners may be said to be due largely to the Turkish war, which has caused an egress from the United States of many Turks, Greeks, Bulgarians and other foreigners, who follow mining as a livelihood. The shortage of cars has been greater than was ever known before and may be attributed, in part, at least, to the bumper crops. The coal industry is but one of the many great industries of Colorado, which has been hampered.

Colorado comes under a new administration early in January, 1913, at which time the legislature will convene, when it is confidently expected that our present very inadequate mining laws will undergo some much-needed changes.

The price of domestic coal was practically the same as the preceding year, with the exception of lignite coal, which suffered a slight decrease. In the matter of wages, in the southern coal field there has been an increase of about 5 per cent. In the northern field, the American Fuel Co. and the Louisville Coal & Land Co. have signed up with the United Mine Workers and, as a result, conditions have been greatly improved and the advance in wages given, which was demanded in 1910, amounts to little more than 5 per cent. The strike is still on, however in the mines of the National Fuel Co., the Rocky Mountain Fuel Co. and the Brooks-Harrison Fuel Co.

*State Inspector of Coal Mines, State Capitol, Denver, Colo.

Coal is now mined in 18 counties in this state and 90 per cent. of the mining is done by hand, while machinery is used for the remaining 10 per cent. For the latter, electrical machinery and compressed air are used.

The number of new mines started and old mines reopened is fifteen. The total number of mines in operation this year is 158. The average number of men employed during the year was 13,713.1, and the number of days worked was 186.4.

The number of fatal accidents recorded to Dec. 1, 1912, has been 92, while the non-fatal for the same period has been 291. Falls of roof still leads as the cause of fatal accidents, although there have been several gas explosions this year. The most disastrous explosion occurred in the Hastings mine, Las Animas Co., June 18, 1912, when twelve men met their death. In the Piedmont mine, also in Las Animas Co., on Aug. 29, 1912, the superintendent and the mine boss were killed by a gas explosion. A gas and dust explosion in the South Canon mine, in Garfield Co., on Oct. 1, 1912, killed two men, and the night foreman of the Simpson mine, in Boulder Co., was killed on Nov. 9, 1912, by an explosion of gas.

Black powder is used in practically all of the mines of the state, except in the coking coal mines, where permissible powder is used. It is but a natural consequence that the mining dangers are increased by the changing, shifting forces of men, although as a whole the operators and miners show a disposition to respect the law.

SUMMARY OF THE COAL PRODUCTION OF COLORADO IN 1912

Number of mines in operation	158
Tons of lignite coal produced	2,213,606
Tons of semi-bituminous coal produced	701,913
Tons of bituminous coal produced	8,327,070
Tons of anthracite coal produced	64,379
Total number of tons produced (Dec. estimated)	11,306,968

There have been but seven coke plants operating in the state during 1912 and the production has amounted to 928,917 tons, some of which has been shipped from Colorado, although the bulk has probably been used at the smelters throughout the state. A very superior grade of coke is produced here. The Sopris coke, which possesses a quality particularly adapted to the production of steel, is used exclusively at the Minnequa Steel Works, which contracts for the entire Sopris output of coke.

COLORADO COAL PRODUCTOIN FROM 1873 TO 1911 INCLUSIVE

1873	69,977	1892	3,771,234
1874	87,372	1893	3,947,056
1875	98,838	1894	3,021,028
1876	117,666	1895	3,339,495
1877	160,000	1896	3,371,633
1878	200,630	1897	3,565,660
1879	322,732	1898	4,174,057
1880	375,000	1899	4,826,939
1881	706,744	1900	5,495,734
1882	1,161,479	1901	6,210,405
1883	1,220,593	1902	7,322,923
1884	1,130,024	1903	7,775,302
1885	1,398,796	1904	6,776,551
1886	1,436,211	1905	8,989,631
1887	1,791,735	1906	10,308,421
1888	2,185,477	1907	10,965,640
1889	2,400,629	1908	9,773,907
1890	3,075,781	1909	10,772,490
1891	3,512,632	1910	12,104,887
		1911	10,197,595

Colorado

By F. W. Whiteside*

In the year 1906, the coal production of the state broke all previous records, reaching a total of 10,308,421 tons. Since that year it has fluctuated about this amount until 1910, when the highest point yet reached was attained, the total being 12,104,887 tons. In 1911, the figures dropped to 10,197,595 tons and in the past year again ascended to 10,943,153 tons, a gain of 7.3 per cent. over that of the preceding year. Of this amount only the tonnage figures of the first 11 months of 1912 have been received; a conservative estimate for the production of December was therefore added to reach the total given.

The coke production of Colorado during the past four years is shown as follows:

COKE TONNAGE IN COLORADO

Year	No. of coke ovens	No. of tons produced
1909	3240	1,076,593
1910	3164	1,190,901
1911	2764	937,952
1912	2857	969,688

Total number of coke-oven plants operating, seven; gain in 1912 over 1911, 3.3 per cent.

The total number of fatal accidents in and about the coal mines for the entire state during the past four years was as follows:

FATAL ACCIDENTS IN COLORADO

Year	In the mine	On the surface	Total
1909	89	8	97
1910	319*	4	323
1911	86	5	91
1912			92**

* 220 men were killed in the four big explosions which occurred during the year.

** Reports up to Nov 30. December reports not yet received.

The coal tonnage for 1912 is distributed as follows:

TONNAGE BY COUNTIES, COLORADO

Counties	Number of Mines Working	Tons of Coal Mined
Boulder	20	1,052,938
Delta	5	66,844
El Paso	7	340,527
Fremont	12	734,037
Garfield	3	177,205
Gunnison	8	549,608
Huerfano	29	1,897,548
Jackson	1	41,951
Jefferson	3	81,419
Las Animas	38	4,821,782
La Plata	4	121,056
Mesa	8	98,870
Pitkin	1	74,820
Routt	6	430,000
Weld	11	451,548
Total	156	10,943,153

Average tonnage per mine 70,148.4 tons.

The largest producers in 1912 were: Delagua mine, of the Victor-American Fuel Co., 625,736 tons; Frederick, Berwind and Primero, all properties of the Colorado Fuel & Iron Co., with productions of 387,312, 361,162 and 325,220 tons respectively, all situated in Las Animas County.

Place of Coal in Colorado's Mineral Industry

Assuming two dollars per ton as a fair average price, the value of the coal production for the past year amounts to $21,886,306.

The production of the most important minerals mined in Colorado is as follows: Coal, $21,886,306; gold, $18,786,000; zinc, $8,361,000; silver, $5,099,000; lead, $3,331,000, and copper, $1,165,000, which gives coal a lead of $3,100,306 over the gold production and a value of 37.3 per cent. of the entire mineral output of the state.

A number of influences affected the output of the year just concluded. While general business was better than in 1911 and the demand for coal therefore greater, there was still room for much improvement. All operators were seriously affected by the Balkan war, which took many of their most reliable men. During the busiest period of the fall season, the shortage of cars seriously impeded deliveries and made systematic mine operation impossible.

*Chief engineer, Victor-American Fuel Co., Denver, Colo.

The increase in output, though but 7.3 per cent. above that of the year preceding, is indicative of improved and more healthful business conditions, and when considered in connection with the prosperous state of business in the East, bodes well for a year of much greater activity in 1913.

❖

Illinois

MARTIN BOLT*

The coal production of Illinois reached the highest point in the history of the industry during the year ending June 30th, 1912. The total tonnage amounted to 57,685,700 tons, an increase over 1911 of 7,349,141 tons. This increase is the more remarkable when it is considered that the shipping mines, which produce 97½ per cent. of the total product, have decreased in number.

While the number of men employed and the number of days worked have increased for the year, the rate is not in proportion to the increased product. The average daily output for each man employed is 4.27 tons, while 3.87 tons was the daily average for 1911.

There has been a considerable increase in the number of mines using machines, in the number of machines in use and in tons undercut. The increase in machine mines is 13; while increase in machines themselves is 151 and in tons undercut is 5,551,760. This method of mining has steadily increased from year to year until more than 44 per cent. of the total output is mined in this way.

ACCIDENTS

The number of men killed while in the discharge of duty was 180, and 800 men were injured so as to lose 30 or more days from their employment. The increase in number of fatal casualties is in exact proportion to the increase in tonnage which is 14.6 per cent. Most of the accidents in the mines in Illinois are caused by falling coal and rock and by mine cars and motors.

There are no reports on the mines for the last half of the year 1912, except in a general way and these indicate a healthy activity in all sections where coal is produced in large quantities. The tonnage produced in the last half of 1911 was nearly 31½ million tons and there is no reason for estimating the output at less than that figure for the same period this year. It will probably reach a higher point, if the same rate of increase is maintained.

The activity is due largely to the fact that an early agreement between the operators and miners in regard to the wage scale was reached, thereby giving the operator a better opportunity to secure contracts for the year.

❖

Idaho

BY ROBERT N. BELL†

There are several scattered deposits of tertiary lignite in the state that have in no place proven of commercial value so far, and are confined to small ancient lake-bed areas and margins.

In the Teton Basin in Fremont County, a limited area of the rich coal bearing cretaceous formations of Western Wyoming extends across the Idaho state line and embraces a few townships. In one of these, at Horse Shoe Creek, some interesting coal deposits are under slow process of development and have been tested to sufficient extent to warrant the anticipation of an important local supply of desirable coal in the near future. The most extensive point of development has been on the Brown Bear claim, and all that has been done has been by the original discoverers without any outside capital.

This property has been developed by two crosscut tunnels at a total depth of 200 ft. From the bottom tunnel, entries have been run out on the seam 1000 ft. in each direction. The total extent of the development exceeds 5000 ft. on this property, during the progress of which several thousand tons of coal have been produced, and sold to the local agricultural settlers of the vicinity.

The average analysis of this coal is as follows:

Moisture	3.60%
Volatile Carbon	36.63%
Fixed Carbon	55.42%
Sulphur	0.15%
Ash	4.20%

This seam and in fact the whole series has been somewhat disturbed by vertical cross faults that cut the bed clean and displaced them in steps varying from the thickness of the seam up to 30 ft. The only serious effect of these displacements is the softening of the coal in their immediate vicinity where they carry water. The faults, however, are usually clean-cut, filled with a narrow clay gouge and when these are passed the bed continues in its usual clean and uniform condition.

The series of veins to which this 5-ft. seam belongs is traceable for over two miles along the foothill slopes by shallow surface work, and in this distance much more serious displacements along the east-west lines are in evidence.

On the adjoining Horse Shoe claim, a vein 11 ft. thick, containing 10 ft. of the same clean high-grade sub-bituminous coal and a foot of white clay in the center of it has been drifted upon by an adit entry for 500 ft.

The Horse Shoe claim has several thousand feet of similar shallow entry work on three other smaller veins, 3 ft. and over, all of which carry similar high analysis to that of the Brown Bear claim.

This coal is a blocky, lustrous black fuel, very similar to the product of the Western Wyoming mines. It works well by blasting off the solid to a loose end. It carries well and has good storing qualities, and makes a splendid steam coal, giving a long oily flame.

The property has been examined by some practical coal men, including some excellent authorities, and the minimum estimate of the resources of two 640-acre claims which have been filed upon above a drainage-tunnel site that would cut the main series at a depth of 500 ft. is 5,000,000 tons.

During the progress of its development, this property has been situated 35 miles from the nearest railroad transportation. Recently, however, a branch of the Oregon Short Line R.R. has been completed to within 10 miles of these deposits for the accommodation of the extensive agricultural interests that border the field in all directions. A survey line has been extended up to the coal

*Chief Clerk, State Mining Board, Springfield, Ill.
†Mine Inspector, Boisé, Idaho.

mines and a spur railway could be constructed on a very easy grade.

Indiana

By Frank I. Pearce*

The mining situation in Indiana during the fiscal year ending Sept. 30, 1912 was peculiar in some respects. The first half of October, the demand for coal began to improve somewhat, and from this period to Dec. 30, 1911, the mines averaged a little better than half time. A number that were closed down earlier in the year resumed operations.

From Jan. 1 to the latter part of March, demands for coal were fairly good, and the mines generally were operated better than three-fourths time. The market conditions during the latter period were strengthened somewhat, due to the wage agreement between the miners and operators, expiring on Mar. 31, and with its expiration the likelihood of a lengthy suspension of work at the mines.

All of the mines in Indiana, except one or two very small producing mines, stopped work Apr. 1, 1912, pending a settlement of the wage agreement. Work in the bituminous field was not resumed until June 1, and in the block coal field June 10, 1912.

Both wage agreements were bitterly contested, and before a settlement was finally reached it was necessary to submit them to the miners for a referendum vote. The agreements submitted to the miners were carried by overwhelming majorities, giving to the Indiana miners the highest price ever paid for mining coal.

Immediately on the signing of the wage agreements a few of the mines resumed operations, but at most of them considerable repairs and cleaning up had to be done, and as a result it took several days to restore them to their normal condition.

Production

Notwithstanding the two months' suspension pending the adjustment of the wage agreement and a number of days lost at some of the mines on account of car shortages and a number of local strikes, the total production for the year was 14,204,578 short tons. The total production of bituminous coal was 13,690,878 tons, while the tonnage of block coal reached 513,700.

A fraction over 51.8 per cent. of this was mined by machines, the electric chain cutters predominating. In only one year (1910) in the history of the state was this production excelled, when the miners of Illinois were on strike for seven months, giving Indiana the opportunity of additional markets north and northwest. These could not have been reached if the mines in Illinois had been working.

Distribution of Product

In Indiana, 8,023,701 tons of the bituminous coal were consumed during the year; 5,667,177 tons were shipped to other states. A fraction over 57.88 per cent. was consumed in Indiana. This shows an increase of about 1 per cent. in the home consumption of the yearly production over any previous year. The aggregate wages reported for the year was $13,089,001.32.

*Deputy Inspector of Mines and Mining, Indianapolis, Ind.

Cost of Production

The aggregate wages reported from the bituminous field was $12,302,947.71, making a fraction over 0.898c. per ton for the labor cost for the total production of bituminous coal. The total wages reported from the block coal field was $786,053.61, or a fraction over $1.53 per ton for the labor cost for the total production of block coal. There was a considerable increase in the labor cost per ton for total production of both the bituminous and block coal over any previous year.

There are many things which are contributing to increase the cost of producing a ton of coal and necessarily adding cost to the selling price of a ton of coal. Increased wages is an important factor. Deeper mining and increased cost of keeping the mines in proper condition, more efficient safety appliances to protect life and health, increased cost of timber and all kinds of material used in a mine all contribute to the cost of production.

Market Prices

The market prices for bituminous coal during the period from Oct. 1 to Dec. 30, 1911 (except yearly contracts) ranged from $1.00 to $1.35 per ton for mine-run bituminous coal (f.o.b. mine) and for screened block coal from $1.90 to $2.25 per ton (f.o.b. mines).

From Jan. 1 to March 30, 1912, selling prices for mine-run bituminous coal (except yearly contracts) ranged from $1.35 to $1.90 per ton (f.o.b. mine) and the the price of screened block coal ranged from $2.25 to $2.75 per ton (f.o.b. mine). The higher prices paid during this latter period, were due to the 2-year wage agreement between the miners and operators, which expired on the last day of March and with its expiration came the likelihood of a lengthy suspension of work at the mines.

From June 1 to Sept. 30, 1912, the selling price of mine-run bituminous coal (except yearly contracts) ranged from $1.15 to $1.20 (f.o.b. mines), and for screen block coal the prices ranged from $2.05 to $2.20 (f.o.b mine).

Average Wages of Employees

The total number of employees reported for the year was 21,230, an increase of 452 over the first nine months of the year 1911. Of this number 19,703 were bituminous and 1527 block-coal employees.

The total wages reported from the bituminous field being $12,302,947.71, show an average earning of $624.42 for each bituminous employee, and the total wages paid to block-mine employees being $786,053.61, show an average earning of $514.77; the aggregate wages for the state being $13,089,001.32, and the total number of employees in the state 21,230, show an average earning of $616.53 for each mine employee in the state.

Nine new mines, and other seams in seven mines already in operation, were opened up. Eighteen mines, and the seams worked by three others, were abandoned during the year ending Sept. 30, 1912.

Fatalities

During the year there were thirty-seven fatal accidents. This large loss of life we deeply deplore. We feel somewhat gratified however, with the fact that only in one year, 1899, to our knowledge, has the number of tons of

coal per fatality been excelled, and that our yearly report also shows that in 1912 fewer persons were killed per thousand employed than in any other year with the exception of 1903 and 1906.

Iowa

By L. E. Stamm*

In reviewing the coal mining industry of Iowa for 1912, it will not be possible for me to give the exact figures as to coal production, number of employees, etc., for the calendar year ending Dec. 31, 1912. This condition is due to the fact that since the establishment of the department of state mine inspection, it has been the custom as well as the law to collect all statistical data relating to the coal mining industry of the state for the fiscal year ending June 30. The law requires a report to be made to the governor biennially, just prior to the assembling of the state legislature.

Coal has been mined in Iowa since 1840, the first coal being mined several years prior to Iowa becoming a state. During the first several years that coal was produced, the output was small and was mined only for domestic use. Later, with the growth in population and the advent of the railroads in the state, the production increased each year, and considerable coal was shipped to the North and West.

For a number of years Iowa was the second largest coal-producing state west of the Mississippi river. From the time that coal was first mined until the year 1900, the output increased each year steadily until in the year 1900 the output of the state had increased to more than five million tons.

From 1900 to 1906 the production each year was more than six million tons. Since then the tonnage produced by the state has reached more than 7,000,000 tons each year until the fiscal year ending June 30, 1912, when the output was slightly under the seven million mark.

The State Geological Department is authority for the statement that the Iowa coal field contains about 19,000 square miles, possibly two-thirds of which in time may become productive. These figures do not take into consideration that portion of the most productive formation, the lower Pennsylvania (Des Moines) which is covered by the Cretaceous, and the upper Pennsylvania (Missouri) which will certainly become in part productive.

Mr. Campbell, of the United States Geological Survey, estimates the original coal supply of Iowa at 29,160,000,000 tons. Subtracting the 177,884,461 tons mined from 1840 to June 30, 1912, from the original supply, we still have left more than 4000 times the production of 1912. If the present ratio of a half a ton lost for every ton marketed continues, the supply will last nearly 2750 years at the present rate of production of about 7,000,000 tons per year.

I believe that it will be safe to say that the production for the calendar year 1912 will approximate that for the fiscal year.

The coal industry of Iowa has added much to the material wealth of the state. The mining of coal has brought manufacturing industries into Iowa because of the cheap fuel furnished. It has added to the population of the state, as the industry now gives employment to more than 17,000 people. Aside from this it provides cheap fuel which is an important item in the state's welfare.

Development work is progressing in the new mines in Marion county along the new extension of the Rock Island Railroad from Des Moines to Allerton. These new mines will add much to the output of the Second District this coming year. New mines are also being developed in Monroe and Polk counties. Owing to the warm weather which has prevailed this fall the work in mining has been but fair, but from now until March the mines of Iowa will run at their full capacity.

During the last year there have been but few labor troubles affecting the production of coal. Local strikes or difficulties were usually settled within a day or two, and none of these at any time seriously affected the output of coal. Such troubles as arose at the mines were usually caused by a difference of opinion as to the construction to be placed on the agreement between the miners and operators.

An agreement between the miners and operators of Iowa as to wages and working conditions in and around the mines of this state and extending until Apr. 1, 1914, was entered into the latter part of last May, thus giving assurance that the coal industry of Iowa will be free from serious disagreements or disturbances between the contracting parties during the life of the agreement. We therefore look forward to an increased tonnage in this state for the year 1913.

*Secretary, Iowa Mine Inspectors, Des Moines, Iowa.

Kansas

By Leon Besson*

The year ending Dec. 31, 1912, was one of the most prosperous recorded in the mining industry of the state. The coal production will exceed the output of 1911 by almost 700,000 tons, and will reach near the 7,000,000-ton mark.

The increase in production in Kansas for the year just ended can be attributed to two causes: First, the negotiating of a wage contract without any resort to strikes or shutdowns. Second, to the decrease in output of natural gas and an increase in the price of fuel oil.

There were 27 fatal accidents during the year, most of which were caused by falls of rock. This is a considerable decrease from last year.

Crawford County ranks first in point of coal production, producing more than half the output of the state. Cherokee County ranks second in the matter of coal output.

Kansas (By Special Correspondent)—The past year has been fairly prosperous in the State of Kansas. The trade was brisk during the early months of the year, due to anticipated labor troubles after the expiration of the wage agreement on Apr. 1. However, such troubles did not develop and aside from a few local strikes, the situation is quiet. The trade was materially stimulated during the last half of the year by a marked increase in the price of fuel oil and a decrease in natural-gas supply, which two fuels have been the cause of quiet business in this state for the past two years. Both steam and domestic business have been benefited by this change

*State mine inspector, Pittsburg, Kan.

in conditions, but more particularly has the demand for steam coal been stimulated. During the latter weeks of the year some fancy prices were realized for slack coal which is unusual at this period.

Steam Shovels Introduced

The year has been noted for the introduction in this state of steam shovels, which are used for "stripping" coal near the outcrop. There are now sixteen of these giant dirt movers in the Pittsburgh, Kan., field. They each have an average capacity of about 250 tons of coal per day when the coal is 3 ft. in thickness, with an average of 20 ft. of cover.

There has not been much progress made in the way of introducing mining machines in the deep shaft mines, but it is predicted that more will be done in this respect in the near future, as the growing practice of the miners of shooting the coal with dynamite will likely force the operators to the use of machines in order to get some lump coal from their product.

Fatal accidents have been few, although slight personal injuries seem to have been quite numerous.

Development of several new properties in Crawford County has commenced, and 1913 should show a good increase in tonnage unless the mild winter which marked the close of 1912 continues on into the early months of the new year.

There has been little change in ownership of properties, the largest transaction being the purchase of The Fidelity Coal & Mining Co.'s properties by The Mayer Coal Co.

The state produced considerably more than 6,000,000 short tons during the year and furnished employment to 12,000 men, with an average working time of about 220 days.

Kentucky

By C. J. Norwood*

Based on the returns for 11 months ending Dec. 1, the output of coal for the state of Kentucky will be approximately 15,500,000 tons. Estimating the production by districts, we have as follows: Western district, 7,435,500 short tons; southeastern, 4,880,900 short tons; northeastern, 3,163,100 short tons, making a total of 15,479,500 short tons.

This indicates an increase of more than 1,550,000 tons over the commercial output for 1911, and an increase of about 760,000 tons over that for 1910. The latter year held the highest record up to the year 1912.

A complete record of the mine fatalities has not yet been received. Indications, however, show that during 1912 there was a material reduction in the number of deaths from falls of roof. Five deaths from electric shock have been reported, and five persons were killed by a dust explosion in the Central mine. A gas explosion in the Coil mine also resulted in the death of five miners.

This record is as complete as it can be at the present day. The figures are made up from the monthly reports.

Maryland

By William Walters†

It is gratifying to find Maryland still in the 4,000,000 column. Business during the year 1912 has been quite favorable. There was a period of dullness in May and June, but despite the fact, there will be an increase in tonnage over 1911. The production in that year was 4,166,236 tons. The mining companies report an increase for 1912, and I estimate the total will be 4,500,000 gross tons.

The Consolidation Coal Co. will produce about 2,166,000 tons. This corporation is the largest coal company in Maryland. The Georges Creek Coal Co., Inc., reports 244,000, an increase of 66,000 tons. The Piedmont & Georges Creek Coal Co. reports 287,558, an increase over last year of 73,289 tons. The New York Mining Co. reports 265,000, a 66,000 increase. The New Central Coal Co. reports 90,731, an increase of 10,000. Likewise the Maryland Coal Co. has increased its tonnage.

The following list comprises the new coal-mining companies organized during the year: Maryland-Georges Creek Coal Co., Mertins Bros., managers; Allegheny Coal Co., Edwin Roberts, manager; Moscow Iron Co., of Barton, Oscar Batdorff, manager; and the Ajex Coal Co., with James G. Pugh, president. The latter mines are situated in Garrett County, Maryland.

Eleven fatal accidents occurred during the first eight months of the fiscal year, commencing May 1, 1912.

Montana

By J. B. McDermott*

The total tonnage produced in Montana for the year ending Oct. 31, 1912, was 3,143,799 tons, valued at $5,600,097. The number of men employed inside was 3057, and outside, 541; while the average number of working days was 195.

The number of fatal accidents was less this year than last, a total of ten against thirteen last year; but the production was the largest reported for a like period in the history of the state.

Many improvements have taken place during the past year for the betterment of the producing end of the business and there is an incentive for still greater activity along these lines. With nearly one million tons entering the state, competing for local trade, together with the fact that Montana is favorably situated to enter other fields, it looks as if there was considerable business that could be gotten with the proper endeavor.

TABLE 1. NUMBER OF COAL MINES; NUMBER OF DAYS OPERATED; COAL HAND MINED AND SHOT OFF SOLID; MACHINE MINED; VALUE OF PRODUCT AT MINES DURING 1912

County	Number of mines	Number of days operated	Hand mined and shot off solid	Machine mined	Value, selling price at mine
Valley	1	130	820		$1,927.00
Gallatin	1	138	3,687		5,588.00
Custer	1	190	4,527		13,031.00
Rhine	2	103.7	5,720.9		16,745.00
Fergus	4	213.7	4,947		11,867.50
Chouteau	2	276	10,086		24,223.50
Hill	5	194.4	16,687		38,864.22
Park	2	218.5	45,396		105,906.00
Cascade	16	191	226,054	624,803.6	1,338,975.89
Musselshell	5	200.4	732,144	201,341	1,680,273.00
Carbon	8	197.5	1,019,472	248,114	2,362,695.89
Total	47	Av. 195	2,069,540	1,074,258.6	$5,600,097.00
Total coal				3,143,798.6	

In the last published biennial report mention was made of some new properties opening up in what is known as the Roundup field. The mines were then, according to county lines, divided between Fergus and Yellowstone Counties, but are now in the baby county, Musselshell.

*Chief Inspector, Lexington, Ky.
†Chief mine inspector, Midland, Md.

*Chief coal mine inspector, Helena, Mont.

TABLE III. OCCUPATIONS OF THOSE EMPLOYED IN AND AROUND COAL MINES IN MONTANA DURING 1912.

	Rope riders	Cagers	Drivers	Laborers	Machine-men	Loaders	Boys under ground	Boys above ground	Motormen and nippers	Miners	Shot firers	Timbermen	Trackmen	Trappers	Others under ground	All above ground	Total employees
Valley										4							4
Gallatin	1			1						9					3	5	19
Custer										6					1	1	8
Blaine			2							6							8
Fergus	1									10						1	12
Chouteau	1					7				11						8	27
Hill			4			1				22			1		1	3	32
Park	2		2	5			1	2		63		1	1	1	3	16	97
Cascade	10		72	27	137	185	5	15		255	15	21	22	14	46	173	997
Musselshell	2	2	72	16	10	150	4		8	449		10	18	1	44	101	886
Carbon	11		43	58	34	220	1	12	41	703	1	51	37	3	60	233	1538
Total	28	2	195	106	181	563	11	29	49	1538	16	83	79	19	158	541	3598

The latter, instead of being a helpless infant this year, stands the second largest producing county in the state; Cascade, which for many years led in the production of coal, gave up first place to Carbon in 1909, and second place to Musselshell this year.

The labor unions throughout the state of Montana are agitating the subject of workmen's compensation and have practically agreed to adopt the Washington law as a model. This will probably be welcomed by the majority of coal-producing operators of the state.

The Madison and Missouri Rivers are being harnessed up and power lines at many points, especially along the Missouri River, are branching out and entering many towns that were prairies five years ago. Not only are the power companies supplying the rural districts with light and power, but several coal properties in Cascade County have been connected and are utilizing the power for light, haulage and pumping. In one instance electricity is being used for running undercutting pneumelectric punching machines to prepare the coal.

The following is a list of equipment used for undercutting the coal mines in Montana:

12 Ingersoll Puncher machines (Compressed air power)
26 Harrison Puncher machines (Compressed air power)
1 Sullivan Puncher machine (Compressed air power)
3 Sullivan Post Puncher machines (Compressed air power)
7 Sullivan Electric shortwall machines
11 Jeffrey Electric shortwall machines
11 Goodman Electric shortwall machines

There were less mining machines used in 1912 than in 1911, in spite of the fact that some mines are equipping with them this period and did not have them last. The decrease is accounted for by the decline of one of the larger coal mines in Cascade County, which reported 14 machines in use in 1911 and only 7 in 1912.

The number of motors in use in our coal mines in 1912 is reported as follows:

1 Whitcomb Gasoline motor
4 Goodman Electric motors
2 Jeffrey Electric motors
1 Link-Belt Electric motor
17 General Electric motors

Total 24 Electric and 1 Gasoline motors.

Rope haulage is being used in several mines in Cascade County, at 2 mines in San Coulee, and 2 mines in Stockett.

New Mexico

By Rees H. Beddow*

The law creating the office of state mine inspector became operative Sept. 13, 1912, and I was appointed inspector Sept. 25, so there has not been sufficient time since my appointment for me to become thoroughly familiar with the conditions existing at the mines throughout the state, nor to give an elaborate review of the industry for the year 1912.

*State mine inspector, Gallup, N. M.

We have 47 mines producing coal, ranging from the small country bank to large modern collieries employing hundreds of men, and equipped with the best machinery for extracting the coal, and preparing it for market, and where the latest and most improved methods of mining are adopted. On account of the favorable natural conditions, the industry has been conducted with few catastrophes or fatal accidents.

The production of the mines consists of anthracite, bituminous coal and sub-bituminous, which latter may be termed a high grade of lignite coal. Part of the bituminous coal is well suited for coking and blacksmithing. The production of each kind of coal for the year 1912, is as follows:

OUTPUT ETC. OF NEW MEXICO, 1912

Anthracite	47,892 tons
Bituminous	2,657,169 tons
Sub-bituminous	712,032 tons
Total	3,417,093 tons
Coke	400,180 tons
Number of employees in and about the mines	3,650
Number of fatal accidents	14
Number of tons of coal mined for each life lost	244,078
Number of employees for each life lost	261
Number killed for each thousand employed	3.83

There have been no explosions or catastrophes of any kind; all the fatal accidents were caused by falls of coal or slate or by mine cars and motors. Owing to the large amount of territory in the Southwest which is supplied from the mines of New Mexico, the demand for coal is good, and the greater part of the year the output is limited only by the number of miners who can be secured and by the number of coal cars supplied by the railroad companies.

Fuel oil has been a strong competitor with coal in this field, and lessened the demand by fully 50 per cent., but it seems certain that fuel oil will soon become so scarce that it will not pay to use it as a fuel. Then the output of the mines will be doubled. As we have all the different kinds of coal, of superior quality, we should be able to compete with all neighboring coal regions.

North Dakota

By J. W. Bliss

The production of lignite in North Dakota during 1912, was 545,000 tons, or 14 per cent. more than was produced in 1911 and a greater amount than has ever been mined in any one year during the history of the state.

It is to be remembered that as a coal-producing state, North Dakota is very young. Lignite cannot be shipped great distances or held in storage for other than short periods on account of its moisture content, which is comparatively high.

Furthermore, until recently, only three main lines

*Assistant State Engineer, Bismarck, N. D.

passed through the western part of the state, giving shipping facilities to but four coal-producing localities. Practically the entire lignite-bearing area was inaccessible to shipping points. Further, that portion of the state west and south of the Missouri was given over to grazing purposes, and settlers were few and far between. Now this section of the state is becoming ramified with railroads and homesteaders have taken all of the available land, and as a result lignite mining has received a considerable stimulus.

During the past year, 105 mines were operated. Some of these shipped but a portion of the fall and winter, others operate the year around, part of the time working double shifts. All of the mines are developed either on a single or double entry method of room-and-pillar work. The beds of coal vary from 3 to 19 ft. in thickness, occurring at depths of from 5 ft. to 200 ft. Where the over-burden is light the coal is mined by stripping.

As a general rule, beds of coal which are not thick enough to permit of coal to be left for the roof, are not worked by underground methods, on account of the cost of timbering. Practically all of the timber used underground consists of posts of cedar and tamarack shipped from Minnesota and Wisconsin. Local timber, such as cottonwood, elm and ash is available only in a few instances.

No Fatalities Occurred

An average of 1300 miners were employed during the winter months, while 400 was the average for the summer. The state was especially fortunate in that no fatalities occurred during the year, and very few serious or minor accidents have been reported. In none of the mines is there any explosive gas, although black damp is occasionally found, and lignite dust does not create a dangerous condition. Lignite being slightly resilient, the coal ordinarily left to support the roof usually gives ample warning of fall. Thus lignite mining is a comparatively safe occupation.

Briquetting is a subject of much interest to mine owners, and the experimental station maintained at Hebron is performing work along this line that must be of ultimate economic value to the industry.

Lignite has thus far only been used on the grate. However, it is now established beyond question that it possesses great possibilities for the manufacture of gas, while in the gas-producer engine it is especially efficient as a fuel.

Ohio

By J. C. Davies*

Reports received from all the coal-mining districts of the state point to an increase in tonnage over the year 1911. In some districts the increase will amount to 10 per cent., in some 8, while in others it may only be 5 per cent.

While the tonnage for the year may not reach that of the year 1910, which was approximately 34,500,000 tons, it will, in all probability, increase from two to three million tons over that of the year 1911, when it amounted to 30,342,039 tons.

*Chief inspector of mines, Columbus, Ohio.

Car Shortage

The tonnage for the year 1912 would undoubtedly have been much greater had the mines not been handicapped by an insufficient number of cars to move the product. The car shortage for the winter months of the year 1912, was the worst experienced in years, in fact a coal famine was threatened, which only seems to have been averted by the unusual climatic conditions, which rendered the situation less acute.

The situation became so serious that an investigation was made at the instigation of the Public Utilities Commission of the state, and while their report has not been completed, the investigation has so far developed the fact that while there was no doubt as to the existence of a car shortage, it was due largely to the inability of railroads to move them, from some cause, from one point to another after they were loaded and discharged. The output of eastern Ohio would have been much greater had it not been for this drawback. The Hocking Valley operators did not suffer to so great an extent from this cause as did those in other parts of the state.

Statistics

The number of employees in the mines of the state will not be materially changed from that in the year 1911, when it comprised some 48,000 persons.

The average time worked in the mines of the state will vary in different districts. In some it will average one-half, in others two-thirds, while in some it will amount to three-fourths of full time.

The highest price ever paid for producing the coal ready for the market was made possible by a wage agreement entered into between the miners and operators of the state for a period of two years, commencing Apr. 1, 1912, and ending Mar. 31, 1914. An increase of 5c. was granted on pick-mined, screened lump coal, and 4c. on machine-mined, screened lump coal per ton, 3½c. of which was an increase on the wages of the loaders, while the ½c. was added to the wages of the machine runner.

No important strikes occurred during the year. The wage-scale agreement which will last for a period of two years makes strikes of state-wide importance almost an impossibility.

Increase in Accidents, Many Mine Fires

Up to Dec. 27, 133 fatal accidents have been reported, which is an increase of twenty-four over the year 1911. Ninety-nine were due to falls of roof and coal, and accidents due to mine cars increased from 8 to 13.

While no explosions or mine catastrophes of any importance occurred in the mines of the state during the year, the greatest care and precaution have been necessary in order to prevent such unfortunate events on account of mine fires breaking out in many of the large mines; good judgment, however, was exercised in handling them, and one mine which is considered unusually dangerous, is now sealed up and will not be reopened until every vestige of fire has been extinguished and there is no possible danger to life or property.

Twenty violations of the mining laws were reported during the year, and fines amounting to $170 were assessed. One mine official was arrested for not supplying the required amount of ventilation; the other offenders were mine employees. Eight machine runners were prose-

cuted for not having the necessary shield on the machines, as required by law. Other offences were: Riding on mine-car trips, 3; using impure oil, 3; using steel tamping tools, 2; crossing a danger signal, 1; and conveying powder while the electric current was on the wires, 1.

The outlook for the year 1913 is exceedingly promising, especially if present conditions prevail; and if industrial and manufacturing concerns maintain their present activities, this year should be even more prosperous than 1912, and in consequence, coal, which is our prime commodity, will also increase in tonnage. The year 1912 from many standpoints was a most unusual one, and notwithstanding the fact that it was a presidential year, the coal trade did not suffer.

Oklahoma

By L. C. Snider*

All the coal in Oklahoma lies in the eastern portion of the State and the greater part of the deposit is in an area comprising parts of five or six counties in the east-central section. This main area is underlaid by seven workable seams of coal. A belt runs from this area north to the Kansas line. It has three or four beds of coal, which are mined by underground workings in the south end of the belt and stripped by steam shovels at the end near the Kansas line. The area is thus continuous with the Kansas field to the north and the Arkansas field to the east. The coal from the different seams does not vary to any great extent. All supply a good quality of bituminous coal.

The production of coal began to be recorded in 1880 when 120,947 tons were produced. The production gradually increased until 1903 when the output rose to over 3½ million tons. Since 1903 the production has remained nearly stationary at very near 3 million tons except in 1907 when it reached 3,642,658 tons, with a value of $6,253,567 the greatest output for any year up to the present. Since 1907 the yearly output has been as follows:

OUTPUT OF COAL IN OKLAHOMA

Year	Quantity	Value
1908	2,948,116	$5,976,504
1909	3,119,377	6,253,367
1910	2,646,226	5,867,947
1911	3,074,242	6,291,494

The principal causes for the lack of development during this period have been the strong competition of gas and fuel oil in adjacent territory and the mining and labor conditions which make the production cost higher than it is in other states so that coal from other fields can compete with the Oklahoma coal inside the state in spite of the difference in freight rates.

During 1912 the trade conditions have been somewhat better than in 1911 and a substantial though not a phenomenal increase is promised. From preliminary reports the indications are that the production will be in the neighborhood of 400,000 tons greater than that of 1911, which will make it between 3,400,000 and 3,500,000 tons. The value at the mine ruled a few cents less per ton than in the previous year, but the value for 1912 should be about $6,750,000 thus establishing a new high record for values.

*Geological Survey of Oklahoma, Norman, Okla.

Pennsylvania

By Frank Hall*

Pennsylvania will attain to still greater distinction this year as a coal-producing territory by reason of the fact that the bituminous output will reach the unprecedented volume of 150,000,000 net tons, the largest annual production in the history of the industry. The anthracite output may reach 85,000,000 net tons, making a total of 235,000,000 net tons.

In both regions a shortage in the car supply lessened the shipments to some extent. In the bituminous region the complaint has been loud and persistent regarding this check to trade. The inability of many of the mines to obtain sufficient labor has also tended to restrict the output.

In the anthracite region, many of the mines have reached their maximum capacity and some of them have passed beyond that point, and it may therefore be predicted that the future annual production will never greatly exceed the output of the present year. The culm banks, which have been furnishing a great deal of marketable coal of the smaller sizes, are about exhausted, and thus less coal of this grade will be marketed in the future.

Important Reduction of Accidents in Bituminous Field

In the bituminous region, the number of employees was approximately 185,000, and the number of fatal accidents in that region will total to about 450, a decrease from last year, when the number was 515. The number of days worked was about 235. In the anthracite region, the number of employees was approximately 174,000, and the number of fatal accidents will total about 600, a slight decrease from last year. The number of days worked was about 220.

The number of accidents which occur in mining operations are unfortunately increased by the rushing methods of operation which naturally result after the mines have been idle for a period of several weeks and the supply of coal approaches exhaustion. The strenuous effort made to extract enough coal to meet the demand at such times adds greatly to the hazard of an occupation that is fraught with danger even if the operations are carried on with the greatest care.

There were, however, no accidents of unusual magnitude. Several mine fires occurred, but they were only moderately destructive. Two floods of the character of cloud-bursts caused the destruction of much property in the Fifth, Seventeenth and Twenty-sixth Bituminous Districts. In addition to the property loss in the Fifth District, 18 mine employees were drowned.

The production of coke will probably reach 22,000,000 tons, the year closing with business extremely brisk and prices satisfactory. The same may be said of the coal industry, and the prospects for the coming year for both lines of trade seem to be extremely bright.

The anthracite production would no doubt have been greater had not a suspension of about seven weeks occurred during the months of April and May, pending the settlement of the differences between the miners and the operators and the signing of an agreement for the coming year. The bituminous trade was not much disturbed by strikes, although some local suspensions of activity occurred for short periods.

*Deputy to the chief mine inspector, Pennsylvania Department of Mines, Harrisburg, Penn.

Industrial Developments of the Past Year

The operators generally have been making more improvements than usual about the mines, and in accordance with the act of June 15, 1911, all inside buildings have been made incombustible. Many mines also are now equipped with the most modern and complete electrical haulage apparatus and lighting system.

One notable feature in the bituminous industry has been the recent acquisition by the Pittsburgh Coal Co. of the mines of the Monongahela River Consolidated Coal & Coke Co. and the New York & Cleveland Gas Coal Co. This addition to the present operations of the Pittsburgh Coal Co. will give it a daily capacity of 100,000 tons.

In the anthracite region two new mines were opened during the year, both in the Sixth District. In the bituminous region 46 were opened, 2 in the 2d District, 6 in the 3d, 6 in the 4th, 1 in the 5th, 1 in the 6th, 4 in the 8th, 3 in the 12th, 1 in the 17th, 6 in the 18th, 4 in the 20th, 1 in the 21st, 3 in the 23d, 3 in the 24th and 5 in the 25th.

Tennessee

By Geo. E. Sylvester*

The 1912 output is probably not materially different than for several years past. This year has been free from any general disaster, and the death rate has been materially lowered, being only eighteen from inside accidents. There was but little labor trouble during the past 12 months, although many of the mines ran on short time at various periods on account of dull season or car shortage. Business with the mines at present is good, and practically all companies are running full time.

Utah

By J. E. Pettit†

We close the fiscal year Nov. 30, 1912, with the largest increase in output of coal and coke for any one year in the history of the state. The output of coal increased 586,885 tons, or 23.46 per cent., and the coke production was augmented by 134,988 tons, or 63.56 per cent., but the extraction of hydrocarbon minerals other than coal decreased 3393.69 tons, or 9.1 per cent.

The most important reason given for the large increase in coal has been the demand for our coke. During the past year, 603,446 tons of coal were used in the manufacture of coke against 365,822 tons for 1911. The increase in the use of coal in the state for the past year is also noticeable. The amount used in 1911 was 2,124,500 tons, and in 1912, 2,466,745 tons, while our exports to neighboring states increased from 418,671 tons to 463,349 tons in the same period of time.

Increased Demand from Smelters

The distribution of coke provides some interesting figures. The Nevada smelters received 31,563 tons, against 335 tons in 1911. The Montana smelters increased their order from 86,714 tons to 135,865 tons. Idaho used 894 tons for that purpose, while Utah increased her smelter demand from 133,752 tons in 1911 to 176,426 tons in 1912.

The decrease in the output of the hydrocarbon product is due to peculiar Eastern conditions, by which its market is governed. The sale of this mineral seems to be intermittent, one month the mines are working to full capacity, the next month the forces are reduced.

We have had no labor troubles during the past year. The wages of those employed in and around the mines and coke plants remained practically the same as in the previous 12 months, and, from close observation, we are convinced that a good feeling exists between employer and employed.

The selling price of coal remained the same as in 1911; however, the market price for the hydrocarbon mineral is somewhat lower. No serious shortage of cars has been reported during the year, except in latter part of September and October.

New Developments in Utah

Three new coal properties, viz., the Willow Creek mine, operated by the Utah Fuel Co.; the Panther Cañon or Cameron mine, operated by the Castle Gate Coal Co., and the Neslen mine, operated by the American Fuel Co., have been added to the list of shippers during the past year.

The Storrs mine, being developed and equipped by the Spring Cañon Coal Co., will be shipping coal by Feb. 1. A railroad four and one-half miles in length has been built to the mine connecting with the main line of the Denver & Rio Grande R.R. Co., one-half mile west of Helper.

A new contrivance (for the Western states) in handling coal from the mine to the tipple is being installed at this mine. The coal outcrops on a bluff several hundred feet above the bed of the cañon. Because the grade is so steep that the railroad cannot approach within 3600 ft. of the mine opening, it was decided to transport the coal this distance by an aërial tramway, which is in course of erection.

It has been impossible for the state mine inspector to visit all the coal and hydrocarbon mines of the state as required by law, owing to the increase of new mines and the development of the old producers, separated as they are from one another by long distances. All the large operating mines have been visited. Those which were not inspected were mines in Iron and Uinta counties, and these are only in operation for a few months of the winter season. During the past 60 days, G. B. Smith has been employed as deputy state mine inspector.

Statistics

The coal production for 1912 was 3,088,356 tons, making an increase of 586,885 tons over that of the preceding year. The coke production was 347,356 tons, an increase of 134,988 tons. The hydrocarbon production was 33,656.31 tons, or a decrease of 3393.69 tons.

The miners used 351,505 lb. of black powder and 395,218 lb. of giant and permissible powders, a total of 746,723 lb., or about one pound of powder for every 4.13 tons of coal mined.

The men employed in and around the collieries, hydrocarbon mines and coke plants, aggregated 4063 during the year, or an increase of 265 men over those employed in 1911. The average number of days worked by the regular producing mines was 280 days.

*Chief mine inspector, Nashville, Tenn.

†State mine inspector, 501 Dooly Block, Salt Lake City, Utah.

The average amount of coal produced per man (including miners, daymen and outside men, but not including coke workers) was 770 tons. Six mine foremen's certificates were issued and three certificates were awarded to firebosses.

There were 160 accidents in and around the coal and hydrocarbon mines during the past year. Eighteen resulted fatally, 31 were serious, and 111 non-serious. Two of the fatal accidents occurred outside of the mines, one in an open rock cut, and one in an engine house.

West Virginia

By John Laing*

On account of the unsettled labor conditions in this state during the past few months and also because of the inadequacy of the car supply which has been extremely short, the production of West Virginia has been much constricted. However, as will be seen, we produced a little over five and one-half million more tons gross in 1912 than we did in the preceding twelve months. I believe that had it not been for the labor troubles and the short car supply that the production in the calendar year would have been at least 63,000,000 gross tons, but, as it is, I think we produced approximately 60,000,000.

Including superintendents, mine foremen, fire bosses, store and office clerks, there are 79,781 persons employed directly in and around the mines of this state. The mines have operated 218 days during the calendar year 1912.

Many improvements have been made at the various mines throughout the state and about 25 new mines have been opened; 38 power plants installed; 30 to 35 uptodate fans erected; 35 tipples built and 38 additional openings made at old mines.

West Virginia Only Beginning to Produce Coal

In my opinion, the development of the coal in this state is in its infancy. The next ten years will show such a marked improvement in the coal industry that the years prior to this will be almost entirely forgotten as periods of mining development in West Virginia. Furthermore, unless all signs fail, we will have the largest output of bituminous coal of any state in the Union.

The operators throughout the state report a marked improvement in the demand for West Virginia coal during the past year over that of the preceding 12 months, and the prices have advanced with the demand.

Statistics

The statistics which follow are for the fiscal year ending June 30, 1912: The total coal production during the fiscal year was 59,581,774 gross tons of coal or an increase of 5,548,588 gross tons over that of the year ending June 30, 1911, or 10.26 per cent. The coke production was 1,992,697 net tons, a decrease of 701,350 net tons under that of the year ending June 30, 1911, or 26.03 per cent.

The total value of the coal produced this year was $56,602,685.30 and the total value of the coke was $3,605,781,57. Thus the coal produced, netted the operators an average of 95c. per ton, f.o.b. cars at mines, and the coke brought an average yield to the operators of $1.81 per ton at the same point.

*Chief of department of mines, Charleston, W. Va.

During the year the mines worked an average of 224 days, employing, includ ing superintendents, mine foremen, fire bosses, store managers, store and office clerks, miners and other mine workers, a total of 79,781 persons. Of this number there were approximately 50 per cent. white Americans and 13,403 negroes, the balance being foreign labor.

Accidents

There were 409 lives lost in connection with mine operations, 392 of which number were killed inside and 17 outside the mines. There were 840 nonfatal accidents, 759 of which occurred inside and 83 outside. This shows an increase of 79 fatal accidents and 21 nonfatal accidents over the preceding year. This increase was due to explosions in the Standard Pocahontas Coal Co.'s mine (Aug. 1, 1911), the Bottom Creek Coal & Coke Co.'s mine (Nov. 20, 1911), and in the Jed Coal & Coke Co.'s mine (Mar. 26, 1912). Had it not been for these unfortunate accidents, the number of persons killed and injured by usual causes would have been reduced substantially.

Exclusive of the lives lost in the explosions, most of the fatalities were caused by falls of roof and coal. We find that 85 per cent. of them are caused from carelessness.

Rocky Mountain Coal Mining Institute

A local chapter was organized in Trinidad, Colo., Dec. 28, 1912, by a number of members of the Rocky Mountain Coal Mining Institute. The chapter is to be confined to members living in Las Animas County, Colo.

The following officers were chosen: J. S. Thompson, president; F. P. Bayles, vice-president; B. W. Snodgrass, secretary-treasurer. These, with J. E. McLaughlin and M. O. Danford, will constitute the executive committee. Other members present were W. J. Murray, D. J. Griffiths, R. McAllester, O. C. Cook, F. L. Miller and W. Morgan. It was decided to call the first regular meeting of the chapter on Jan. 25, 1913, and to notify all members residing in Las Animas County.

Large Coal Mines

There are 735 coal mines in the United States that are producing more than 200,000 short tons of coal each annually. In 1911, according to a statement by Edward W. Parker, of the United States Geological Survey, 269 bituminous mines and 168 anthracite mines in Pennsylvania produced in excess of this amount. The average production of these Pennsylvania bituminous mines was 321,773 tons and of the anthracite mines 444,697 tons. The largest anthracite mine had a production of 1,020,420 long tons (1,142,870 short tons). The largest bituminous production from one mine (a Pennsylvania operation) was 1,285,483 short tons. Thirty anthracite mines produced over half a million tons each. Illinois was second to Pennsylvania in large mines, having 93 mines which produced more than 200,000 tons; West Virginia was third, with 59; and Ohio fourth, with 38. The total production of these 735 first-class mines was 253,459,639 tons, or 51.7 per cent of the total production of the country.

Coal and Coke Production in the United States

The following tables have been compiled largely from data communicated by the several state mine inspectors, estimates having been made only where no such statistics were available, but in all cases upon the basis of good information.

PRODUCTION OF COAL IN THE UNITED STATES

States	1911 Short tons	1912 Short tons
Bituminous:		
Alabama	15,040,267	18,500,000
Arkansas	1,950,700	2,120,000
California	5,000	2,500
Colorado	10,197,595	11,300,968
Georgia	165,330	150,000
Illinois	50,336,559	(b) 57,685,700
Indiana	14,209,661	(c) 14,940,628
Iowa	(b) 7,729,674	(b) 6,820,828
Kansas	6,390,207	6,850,000
Kentucky	13,929,450	15,479,500
Maryland	4,166,236	(a) 4,300,968
Michigan	1,476,074	(a) 1,550,000
Missouri	3,760,607	3,710,992
Montana	2,913,397	(d) 3,143,799
New Mexico	3,148,158	3,369,201
North Dakota	468,700	545,000
Ohio	30,342,039	(a) 32,700,000
Oklahoma	3,074,242	3,300,000
Oregon	45,000	48,200
Pennsylvania	144,754,163	150,000,000
Tennessee	6,451,208	(a) 6,522,000
Texas	1,974,593	(a) 2,000,000
Utah	2,501,471	3,088,356
Virginia	6,864,667	(a) 8,000,000
Washington	3,550,906	3,650,000
West Virginia	59,920,207	(a) 60,000,000

Coal Mine Accidents in Washington

By D. C. Botting* and H. M. Wolflin†

The death rate in the coal mines of Washington is considerably higher than in coal-mining states of the eastern and central part of the country. At first glance the reason for this is not evident. The percentage of English-speaking miners and laborers about Washington mines is higher than in many other states, but these men, while more intelligent than the foreigners are often much more reckless and take chances which they should avoid.

The death rate per thousand employed underground was 3.19 in 1905. This figure increased to 9.17 in 1910. In 1911, it fell to 4.99, which is lower than in any year since 1905.

High Death Rate Due to Pitch

On closer study, it is seen that mining conditions are more dangerous in Washington than in most of the states with lower death rates, but it is also apparent that there are more fatalities in the coal mines of Washington than there should be. The coal beds are nearly all quite steeply inclined and there are comparatively few miners who work on a "pitch" of less than 10 or 15 deg. to the horizontal, and the large majority work on pitches of from 20 to 90 degrees.

With the exception of a few sections, which cover special phases of mining, the state laws which govern the mines are entirely inadequate, and if it were not for the humanitarian view of the situation, taken by most operators, the death rate would be even larger than it is. At the same time the fatality rate is higher than in the Vancouver Island mines, yet the conditions, although somewhat in favor of the latter, are similar.

About one-third of the fatal and one-fourth of the nonfatal accidents, in the Washington mines for the past seven years, have been due to the steep inclination of the coal beds.

It is difficult, in fact almost impossible, to make laws which will prevent those accidents which are due to the steep inclination of the coal beds. Added to the common dangers of coal mining in flat workings are many of the dangers of metalliferous mining, consequently the number of accidents may be expected to be greater than in the coal mines of the central and eastern states, where these dangers do not exist.

Difficulties of Supervision

In Washington the number of assistant foremen, firebosses, shift bosses, etc., per hundred men employed underground is not high. Because of the steep inclination of the coal beds, one man cannot visit nearly so many working places in a given time as he can inspect in a mine where the beds are flat. The result is that working places are not visited with sufficient frequency by the mine officials.

This fact, coupled with the readiness of the average Washington coal miner to "take a chance" to save a little time or work, is responsible for a great many of the miscellaneous accidents. With the passing of the pick miner and the coming of the "coal blaster," the disposition to be reckless has developed to a surprising extent.

So far as we are able to suggest, the only effective method of reducing these miscellaneous accidents is to increase the number of mine officials and enforce a closer supervision of the workmen. Such a step would, of course, mean increased cost.

⁂

During the past three and one-half years the United States Geological Survey has classified as coal land, 17,459,105 acres in the public land states, and this land has been restored to sale. The appraised value of this land, as fixed by the Survey as a result of geologic examinations, and promulgated by the General Land Office aggregates a total of $742,620,649. The minimum valuation for the same lands, at which they might have been purchased a few years ago before the policy of classification was adopted, is but $295,989,140.

Our Export Trade During 1912

By F. R. Wadleigh*

SYNOPSIS—As a result of England's great coal strike during the year, American exporters had unusual opportunities for strengthening their position in the foreign markets. While the trade benefited in a substantial manner by this abnormal condition, the activity in our own markets developed to such proportions that the attention of those interested was diverted and the full possibilities of the situation were not obtained. Mr. Wadleigh and others are of the opinion that local exporters would do better by concentrating their efforts on the markets contiguous to the United States, rather than by attempting to establish control of the Mediterranean trade.

In reviewing our exports of coal during 1912, the coal shipped to Canada may be passed over with the bare mention of the fact that 80 per cent. of our total exports are to British America. That this is so, is not due to our superior product (although it is superior), or to our better salesmanship, but simply because of location, our coal fields being nearer to the more populous parts of Canada than are its own deposits, and the imports of United States coal have grown steadily and kept pace with the increasing population and more numerous industries.

Neither should the coal shipped to Panama, amounting to approximately 488,000 tons, be considered as export coal, as it is all shipped to the Canal Zone for use on the Panama R.R., owned by the United States, and in the work of digging the Canal it does not come into any competition with foreign coals, and therefore is not an export product any more than that shipped from Hampton Roads to New England. Coals shipped to Porto Rico and Alaska come in the same category: they are not export coals, but coals shipped to our own territory.

The elimination from our export tonnage of coals shipped to Canada, Alaska and Porto Rico, enables us to consider with truer perspective and better understanding the relation that our coal exports bears to those of the world, and especially to those of Great Britain, our greatest competitor in the world's coal markets.

Bright Outlook at the Beginning of the Year

The beginning of 1912 gave bright prospects of a large increase in the shipment of American coals to foreign countries, especially to those supplied from Great Britain. Ocean freights were only slightly above normal, and the certainty of a strike of the British miners, with both sides so far apart in their demands, that a prolonged dispute seemed probable, gave good promise to the local operators of a large foreign business, and an assurance of entrance into markets hitherto impossible or at best difficult of access. "If once we get a foothold in these markets," it was said, "the British coals can never drive us out."

In 1911 determined efforts were made by the United States shippers to increase their coal exports and three or four of the large selling companies had already, that year, sent men to England and Italy to establish offices for the purpose of selling trial cargoes and making contracts for additional ones. Considerable success attended these efforts; several cargoes were sold and a few contracts for specified tonnage running into 1912 were made, but on coal for this year's delivery, with one exception (when a freighting contract was made before closing any contract for coal) no allowance, or insufficient allowance, was made for any possible advance in ocean freights; then, too, the tidewater price of United States coals was at a low point. When the sudden, and to many, unexpected, rise in ocean freights came, followed by a gradual but steady advance in the price of the local coals, caused by increased home demands, strike prospects and a scarcity of labor, the export business did not look so promising, and the same old story was repeated, to some extent; that is, when the home demand becomes strong with a fair price, the foreign business fades into the distance and is not nearly so attractive.

The Strike in Great Britain

As the British miners' strike became imminent and assured, many inquiries were received on this side for coals to replace the British product. A number of foreign shippers and buyers sent their agents over here; our coal ports became congested, the tidewater prices went up to $4.50 per ton and the prospects for a large export trade became bright. Unfortunately for us, however, we were unable to increase our output (owing to labor troubles, and the scarcity and crippling of the railroads by severe storms and floods) sufficiently to take care of this increased export demand, before the British strike was at an end, and many foreign buyers, unable to get coal here, immediately went back to the British product, so that we really obtained little permanent business in foreign countries. About the same time, New England buyers began to call for heavy shipments on contracts so that foreign business was not followed up as it would have been otherwise.

The strike of the British miners was unexpectedly brief and caused comparatively little diminution in the stocks of British coals in foreign countries; about the time we began to feel the effects of the strike, the miners were back at work, and the British shippers were straining every nerve to make up for their lost tonnage, in order to oust the United States coals from what they considered their own markets. How well they succeeded in this is largely shown by the British export figures for the eleven months of 1912, which amounted to 61,070,000 as compared with 61,236,000 tons in 1911, or a decrease in the former year of only 166,000 tons, notwithstanding the strike. The British Channel ports, Cardiff, Swansea, Newport and Port Talbot, from which nearly 50 per cent. of their coal exports come, and are those with which the United States fuels compete, showed an actual increase of 40,200 tons in exports. Part of this recovery of tonnage was undoubtedly due to the increased demand and consumption, but the fact remains that they did recover most of the tonnage lost on account of the strike.

The unparalleled rise in ocean freights hit the United States shippers to foreign countries much harder than it did the British shippers, and made it difficult, with the rise in local prices, to hold the business they had gained

*Consulting engineer, 160 Botetourt St., Norfolk, Va.

and almost impossible to get any new business. For instance, in September, notwithstanding a difference of about a dollar per ton in the tidewater prices of good Welsh and the highest grade United States coals, the delivered prices in Rio Janeiro showed nearly two dollars' difference in favor of the Welsh coal.

Our Logical Markets

It is the opinion of many, of whom I am one, that the local exporters made the mistake of putting forth their strongest efforts, and in some cases their only effort, to get increased tonnage in the Mediterranean ports. Instead, they should have attempted to displace the foreign coals in South America, our natural market, where some other lines of trade are growing, not by steps, but by leaps and bounds. This market belongs to us by right, and we will have it, if we go about obtaining it in the right way.

It is true that the difficulty of getting return cargoes for steamships carrying coals to South American ports, make these markets seem difficult of entrance, but they *can* be taken possession of, and will do us more permanent good than all of the Mediterranean business. It is, however, a long distance to Buenos Aires or Valparaiso, and much easier to go to England and Italy and France, and hundreds of agents and representatives can be found in those countries quite willing to work for United States gold, to one in Brazil or the Argentine. In addition to this a knowledge of Spanish and of the people and their ways of going business is essential to the successful salesman, whether of coal or manufactured articles.

Progress Made

Yet notwithstanding the peculiar and unforeseen conditions that arose during the past year in the export coal business, our exports did show considerable increase, and certainly did alarm the British trade to the extent of showing a hitherto unknown interest in the quality of United States coals. This is shown by inquiries from buyers and editorials in two or three of the leading British trade papers, as well as in staff letters from correspondents. These latter generally consisted in running down the quality of the United States coals, and their preparation and appearance, but they at least felt obliged to take notice of them, something they had never done before. One of the two leading English coal papers had an editorial on "The Menace of American Coals," while the other, the *Colliery Guardian* had, some time previous, called the American coals nothing but "carbonaceous dust."

We did succeed in entering into markets that had never used our coals before, and had prices remained where they were at the beginning of the year, and ocean freights not gone up, our efforts would have shown most gratifying results. Now, at the close of the year, when cars are scarce and laborers not only few, but inefficient and unwilling to work, the export market is being lost sight of and shippers are hard put to fill their home contracts. In the early months of the year foreign business was taken at as low a figure as $2.10 per gross ton f.o.b. tidewater, while now the same grade of coal is selling at $3.25 to $3.50. Yet with all this increase there is a steady stream of United States coal going to foreign countries, more than at any other time under similar conditions; the tidewater price of the best Welsh coals has also increased from $3.81 per ton in January to $4.55 in December.

Necessity of Building Vessels

Before we can hope to compete for any considerable share of export business we must build our own ships to carry it in, as is now being done in the New England trade. We must also probably establish storage depots at the most important markets accessible to us, from which small or large quantities can be shipped as required. The course of ocean freights during 1912 has been unusual and has militated against our export business. Rates advanced steadily during the year to unheard of figures, and vessel tonnage was scarce at any price. These high rates continued until December when they began to show a decline.

It would seem that this scarcity of ships and consequent high rates was due to the unusual demand for tonnage owing to the increase of business all over the world, and not to any diminution in the number of ships. Just why the December drop in freights should have come so suddenly and have been so marked, it is hard to determine, and its duration is equally difficult to foresee. General business is just as good, if not better and the shipyards have an immense amount of work ahead, the effect of which may be felt later on, and which may result in a still further lowering of rates, although the ship owners say that these will go back to the previous high levels at the first of the year. It all puts the exporter in a quandary, and the wise man will be he who makes no c.i.f. contracts, unless compelled to do so, during the coming year.

Statistics

Full statistics of our export trade during 1912 are not yet available, but we give below complete figures from the principal Atlantic ports.

With the exception of the tonnage sent to Canada, not considered in this review, and small tonnages from the Gulf of Mexico ports, these figures give our true export trade.

	1912	1911
Philadelphia	825,234	791,506
Baltimore	628,712	479,096
Norfolk	1,475,485	1,071,130
Newport News	971,336	785,763
Total	3,900,767	3,127,495

These show an increase of 773,272 tons in 1912 over 1911, or 25 per cent., not a very brilliant showing for a year that began so well, and apparently held out such promising conditions for our export coal trade, but still a rather substantial gain.

Pennsylvania Leads in Minerals

Pennsylvania far outranks all other states in the value of its mineral output. In 1911 this state contributed, exclusive of pig iron, 24.7 per cent. of the total mineral output of the United States. The reason for Pennsylvania's undisputed leadership lies primarily, according to the United States Geological Survey, in its great production of coal. It is almost exclusively the source of anthracite, and produces over one-third of the total bituminous output. Pennsylvania ranks second, next to New York, in the value of its manufactures, and stands first as a mineral producer in cement, coal, coke, pig iron, lime, mineral paints, sand and gravel, and building stone.

The Connellsville Coke Trade in 1912

SYNOPSIS—Production in the Connellsville region for 1912 crossed the 20 million-ton mark for the first time in its history. Favorable conditions prevailed throughout the year with the exception of a labor shortage which curtailed operations to a limited extent. The year closed with quotations higher than ever before. Shipments totaled 20,000,873 tons representing a value of $38,401,676.

The Connellsville coke region shipped 20,000,873 tons of coke in 1912, which, valued at the average market price of $1.92, represents a value of $38,401,676.

The Connellsville coke trade for 1912 would have been at least 10% better if there had been a man for every job. As it was, both production and output broke all records, even if they did win by a scratch. Twenty million tons was very closely approached in 1906, but never was it over-lapped until now. The value of the output was often exceeded. In 1903, for example, with an output of only 13,345,000 tons the value was over $40,000,000. In 1906 and 1907, the value of the annual output rose to $55,000,000. As recently as 1910, with an output of 18,689,000 tons, the value exceeded $39,000,000. Prices of spot coke were never higher than they are now, but the average of the year was less than $2. If the business continues at the same gait it is now going, 1913 will be by odds the biggest year in the Connellsville coke business.

Coke Ovens and Labor Supply

There has been no increase in the number of ovens in the region, though there have been some changes from beehive to rectangular types. The operators have not been able to work all the ovens they have and there has been small incentive to build more. There are now in the region 38,884 ovens as follows: Beehive, 35,399; rectangular, 3335; byproduct, 110. There were 738 additional ovens constructed during the year and 746 abandoned.

A number of mechanical coke drawers were installed during the year. The use of mining machines became more general. The installation of these machines was prompted quite as much by labor necessities as by the desire for economical operation.

The greatest handicap the Connellsville coke trade had during the year was its inadequate and uncertain labor conditions. This labor shortage was not realized until an attempt was made to fire up several thousand ovens in January, when it developed that there were not enough men to be had to operate them to their capacity.

The year 1911 closed with 26,400 ovens in blast. During January, 4000 ovens were lighted, running the active total up to 30,400. March closed with 32,000 active ovens. In the meantime, the Frick Company had announced an increase in the mining rate from $1.35 to $1.41 per hundred bushels and other labor in proportion, and the merchant operators followed suit. A few more ovens were lighted and the first week in May saw 32,663 ovens fired, but production rose only to a little over 400,000 tons weekly, as against a capacity running full of 442,000 tons. Failing to secure enough men to operate the ovens in blast the operators reversed their policy and proceeded to regulate their active ovens to labor conditions. Over 3000 ovens went out in the ensuing three months.

In August the tide turned again. Through earnest and systematic effort the labor supply was gradually improved and the year closed with 32,700 active ovens. To attract labor, the operators not only advanced wages, but many of them, notably the H. C. Frick Coke Co., made earnest efforts to further improve working conditions at their plants and to make the workmen's homes pleasant and attractive. These efforts met with so small a measure of success only because of other conditions which could not be controlled.

CONNELLSVILLE COKE STATISTICS FOR 1912.

The United States Steel Corporation hints that there is another wage advance at hand. If it extends to the Connellsville coke region it may stimulate immigration hither and improve labor conditions.

The wages now paid are as follows: Pick mining and loading room and rib coal, per 100 bushels, $1.44; pick mining and loading heading coal, per 100 bushels, $1.58; pick mining and loading wet heading coal, per 100 bushels, $1.70; drawing coke, per 100 bushels, charged, 82c.; drivers and rope riders (shafts and slopes) per full run, $2.85; drivers and rope riders (drifts), per full run, $2.80; cagers, per full run, $2.85; firebosses, per day, $3.50; tracklayers, blasters and timbermen (shafts and

Note—Abstract from the "Weekly Courier," Jan. 2, 1913.

slopes) per day, $2.85; tracklayers, blasters and timbermen (drifts), per day, $2.80; assistant tracklayers and inside laborers, per day, $2.15; dumpers and tipplemen, per full run, $2.15; levelers, per oven, 13¼c.; chargers per day, $2.15; forking cars, 40,000 pounds capacity and less, $1.75; forking cars, 50,000 pounds and 60,000 pounds capacity, $1.85; forking cars, over 60,000 pounds capacity, $2.00.

Crushed Coke and Byproduct Coal

The crushed coke business, at one time a prominent feature of the Connellsville coke trade, but recently confined almost exclusively to outside districts has taken a fresh start. In spite of the desperate demand for furnace coke during the last quarter of 1912, approximately 40,600 tons of crushed were shipped out of the Connellsville region during the year.

Crushed coke is a successful rival of anthracite as a domestic fuel where it can be laid down at competitive prices. It is prepared in similar sizes to anthracite, known to the trade as egg, stove, chestnut and pea, the sizes bearing close relation to the articles whence they get their names.

Not all Connellsville coal is made into coke in the Connellsville region. Approximately 2,000,000 tons annually are coked in the byproduct ovens of the United States Steel Corporation at Gary, Ind., Joliet, Ill., and Sharon, Penn. About one-half of this coal, or some 60 cars per day, is shipped to the Sharon ovens and the remainder goes to the western plants where it is mixed with Pocahontas coal. It was the purpose of the Steel Corporation to use a mixture of Pocahontas and Illinois coal in the Gary and Joliet ovens, and for this purpose a large area of coal was purchased in the latter field, but it was found in practise that better results, chemically, physically and commercially, were obtained by the Connellsville-Pocahontas coal combination. Connellsville coal is now being shipped from the Gates and Filbert mines which have no oven equipment, and from the coking plants at Dorothy, Bridgeport and Colonial No. 3.

The Petroleum Industry in 1912

There was no considerable change in the quantity of petroleum produced in the United States in 1912 compared with 1911. Nevertheless, according to David T. Day, of the United States Geological Survey, the year was as full of remarkable incidents as is usual in the history of this article of commerce, which depends for its statistical position more upon the chances of new discoveries and less upon trade demands than any other commodity except gold.

As a rule, the Eastern fields declined in production, because it was impossible to keep up the great output of 1911 without large additional discoveries of new pools in the older fields. The Eastern decline was, however, offset by the increase in California, where the San Joaquin Valley fields (Midway, McKittrick, Maricopa, etc.) are still at the height of the gusher stage.

It will take much time to calculate the amount of oil sold at the different prices of the year, but it is evident that the total value of the product increased markedly being about $150,000,000, compared with $134,114,752 in 1911.

An estimate of the production in 1912 and a comparison with the product in 1911 is given below:

PRODUCTION OF PETROLEUM IN THE UNITED STATES IN 1911 AND ESTIMATED PRODUCTION FOR 1912

(Barrels of 42 gallons)

State	1911	1912
California	81,134,391	87,000,000
Oklahoma	56,069,637	52,000,000
Illinois	31,317,038	28,000,000
Louisiana	10,720,420	10,000,000
West Virginia	9,795,464	11,800,000
Texas	9,526,474	10,500,000
Ohio	8,817,112	8,500,000
Pennsylvania	8,248,158	8,000,000
Indiana	1,695,289	1,200,000
Kansas	1,378,819	1,300,000
New York	952,515	700,000
Kentucky	472,458	500,000
Colorado	226,926	200,000
Other States	194,690	500,000
	220,449,391	220,200,000

Stocks—In all the fields except those of California and the Gulf there was a steady drain on stocks during the year, so that from a total of 81,789,390 bbl.—over half a year's output—on Jan. 1, the stock declined to 69,000,000 bbl. at the end of the year. This drain reflects the increased capacity of the refining plants of the United States, the greatly increased exports, and a gradual change in the general condition of the industry by which gasoline has become much more in demand, so that the trade is well satisfied with heavier grades of gasoline or naphtha. For this reason the dividing line between naphtha and kerosene has necessarily been drawn nearer to kerosene and a large quantity of oil has been distilled into the gasoline portion of the products and a less output of kerosene resulted.

On the other hand, the heavy residues which are marketed as fuel oils have come into greater demand, and owing to the over-evident effort to increase the yield of light products by splitting up these residues the supply of fuel oil has not kept up with the demand. The advent of internal-combustion engines, such as those of the Diesel type, promises still higher prices for fuel oils. The United States has been slow in the adoption of these new engines, but their general adoption abroad has pointed the way to rapid increase in their use here.

Prices

The general decline in production except in California would doubtless have been much greater but for the effort to apply laws of supply and demand by increase in price. Prices advanced so greatly during the year as to stimulate drilling, even in the old New York and Pennsylvania pools, and so checked the decline. Formerly this plan has not been so successful. In the mid-continent field also it checked the decline, so that the product will come within 4,000,000 bbl. of the maximum output (in 1910). In the Appalachian field, where higher prices and cheap methods of pumping oil wells make the decline slow in any event, the great rise in price from $1.30 to $2 per bbl. seems to have checked the normal decline and even to have effected a slight increase, which was gratifying.

Another feature tending to strengthen the position of oil in this country is the decrease in production in Russia, from 66,183,691 bbl. in 1911 to about 60,000,000 bbl. in 1912. Roumania increased its product slightly, but not sufficiently to offset the Russian decline. The chief decrease was in the old Baku field. The world's consumption of oil, according to Mr. Day, is now about a million barrels a day, the United States furnishing more than all other countries.

The Coal Markets During 1912

By A. T. Shurick

SYNOPSIS—A detailed review of trade conditions for the year 1912. The situation was abnormal in many respects, due to the protracted suspension in both the anthracite and bituminous fields, pending the fixing of the new wage scales. Anticipation of this curtailment in production caused heavy speculative buying and a temporary panicky condition, which was succeeded in midsummer by a period of extreme dullness. The markets gathered strength, however, towards the last of the year and closed firm and active in all departments.

The year of 1911 closed with the coal trade in a rather stagnant position. Some activity was noticeable the early part of December as a result of the car shortage, but with the concluding of shipments in the lake trade, the situation in this respect underwent a decided change with the result that plenty of equipment was available, and the market flooded with coal. This was further aggravated by the mild weather which caused a light domestic consumption.

The trade slumped steadily, although easily, during the course of the month but firmed at a rather low level toward the latter part, at which it held its own into the new year. This mild hardening of the market was due primarily to the cessation of work in the mining region over the holiday period, and offered only a temporary relief. The end of the year witnessed a slight activity in steam business due to an improvement in work at the steel mills.

January

The new year then opened with the market at a low level but steady. More seasonable weather appeared during the early part of January, which brought with it an increased domestic demand and a general improvement all along the line. Towards the middle of the month there was an abrupt fall in temperature, accompanied by severe storms which created a shortage in the market and resulted in the demand becoming quite heavy; requisitions became so numerous that operators were compelled to refuse further orders.

This condition continued for some two weeks, the trade reaching the strongest position it had been in so far that season. The return of mild weather again towards the close of the month, however, caused a slight easing off and more normal conditions were restored.

Consumption, which was apparently below normal at the end of the year, showed an improvement the first part of the month and became quite heavy towards the middle, responding quickly to the change in weather conditions; the reserve supplies of the consumers were drawn upon at this time. The return of milder weather toward the latter part of the month brought with it an easing off in the domestic consumption and a resumption of a more normal market. By reference to the accompanying diagrams it will be noted that no unusual features occurred during this period, as regards quotations. Prices remained at an even and rather low level, considering the time of the year, throughout the month.

The inclement weather towards the middle of the month restricted the movement materially. The transportation troubles became moderately grave during this time so that arrivals at the large consuming centers were far below normal. The heavy weather caused some losses at sea and made the coastwise movement slow and uncertain but the more equitable conditions towards the last of the month, effected a rapid change in the transportation situation and the tonnage movement became quite heavy. This increase is reflected in the rapid decrease in the surplus of idle coal cars, at this time, as shown on the accompanying diagram.

February

Contrary to expectation the return of mild weather the first part of the month did not result in any easing off in the sharp demand that appeared during the latter part of January. The large tonnages, accumulated on side tracks during the cold snap, were moved in and readily absorbed without any apparent effect. The situation, as regards anthracite particularly, became quite hard at this time, and none could be bought in the spot market. It was reported at some points that a number of steam plants were compelled to close down through the lack of sufficient fuel.

As the month advanced the demand gradually became more urgent, until the climax was reached shortly after the middle of the month, when the situation was verging on the acute. This was ascribed partially to the anxiety of the consumers over the possibility of a long shutdown in the mining regions April 1, but was more probably due to the low temperatures then prevailing.

Consumption for the month was quite heavy, and it was claimed by some that new records were established in this respect. Heavy shipments were made, but it appeared impossible for the production to keep up with the demand, and the supplies in the hands of both dealers and consumers were steadily depleted. This continued well up past the middle of the month, when a break in the weather occurred which brought with it much needed relief to the consumer. This did not, however, tend to soften the market, as supplies were uniformly low throughout the country and the demand urgent.

Prices continued fairly uniform on a somewhat higher level than during the previous month, as will be noted on the accompanying diagram. The close of the month however, marked the beginning of the sharp advance that prefaced the suspension in mining Apr. 1. At the beginning of the month quotations were ruling hard and firm, and continued to gain strength throughout the period. Toward the middle, a strong demand appeared for soft coals for storage upprposes, and these commanded good figures, finally reaching the point where they could be obtained only at fancy prices. The period closed with operators entirely in control of quotations, and with every indication of continuing so.

Coal shipments for the month were quite heavy. The large tonnages, which the severe weather in January had made it impossible for the roads to move, were now shipped in.

The car supply for the month was only fair. As will

be noted on the accompanying diagram, the surplus of idle coal cars fell sharply below that for January, but maintained the new low level throughout the month. Production during this period was undoubtedly being increased in anticipation of the expected suspension of mining Apr. 1. However, this was too remote at this time to effect any radical change, although it will be seen, by reference to the accompanying diagram of the monthly shipments of anthracite, that all the companies show a uniform, though slight, increase for the month.

March

With the prospective strike of both the anthracite and bituminous miners now only a month off, the demand became firmly established and quite insistent. It was becoming evident that there was a shortness in supplies of all kinds and in practically all parts of the country. Thus, instead of going into a protracted suspension of mining with large surplus stocks, as customary heretofore, the industry found itself with supplies low, and, in many cases, below all previous records. This was of particular significance in view of the fact that both the bituminous and anthracite agreements expired simultaneously.

It was inevitable under these conditions, that prices should experience an almost perpendicular advance which was the case, as will be noted on the accompanying diagrams. While this sharp increase in quotations tended to make the consumers cautious about purchases, the demand nevertheless continued quite strong all along the line. The activity in the market gradually increased and towards the middle of the month began to assume panicky proportions; severe weather appeared and the fear of a possible long shut-down at the mines had taken a firm hold on the consumers. There were many inquiries for April tonnages but operators refused to quote beyond Apr. 15. The situation was further aggravated by the large Trans-Atlantic steamers coaling at this end for the round trip, because of the strike in Great Britain.

Toward the last of the month the sensational advance in prices culminated at the high level of the year, as will be noted on the accompanying price diagrams. The demand became urgent in the extreme, and the general tone of the market throughout the country was uniformly panicky. The deliberations of the miners and operators had been entirely barren of any results, and it was now evident that the industry must go through a suspension of short duration at least. The market conditions were undeniably critical at this time.

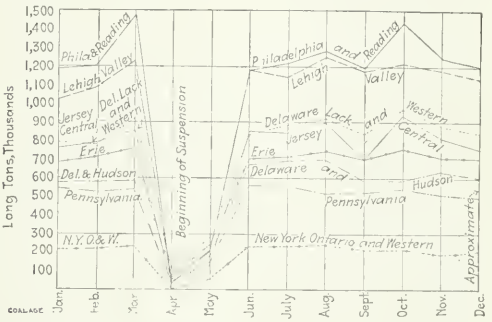
The car shortage began to ease off toward the latter part of the month, there again being a surplus on March 27. This enabled the mines to materially increase their production, and the close of the month witnessed the heaviest shipments in the history of the trade. This was particularly noticeable in anthracite. As will be seen by reference to the accompanying diagram of hard-coal shipments by the different companies for the year, these show a uniformly sharp advance for the month of March, and numerous new high records were established.

The month closed with the market in a decidedly tense condition with consumers and producers both keenly watching the results of the wage conferences, and many of the larger interests having special representatives at the meetings to assure prompt and reliable information on the situation. It was purely a strike market and interested parties on both sides were playing a waiting game.

April

The month of April opened with a general suspension in effect in practically all the organized coal fields of the country. Probably over 60 per cent. of the production was abruptly cut off. A feeling of hesitancy appeared to characterize the trade for the first few days, but reports to the effect that an agreement was being reached caused a softening in the market. As these were only tentative, however, and could not become operative in any event for some time, a heavy slump was prevented.

Prices therefore continued at the abnormally high level for from one to three weeks and it was the hope of the trade that the suspension would be of sufficient duration to permit them to work off the heavy stocks accumulated during the last of the preceding month. The



Anthracite Production by Companies During 1912

anthracite production, ordinarily quite heavy at this period of the year, was, of course, practically eliminated. Probably the most striking evidence of the effects of the suspension is shown by the rapid increase in the surplus of idle cars, which advanced from 4381 on March 27 to 46,578 on Apr. 14.

The middle of the month found the panic prices being liberally discounted in all parts of the country. Consumers showed every confidence in the belief that the referendum vote of the miners, upon which the bituminous situation hinged at this time, would be favorable, and, as a result, there was a heavy selling movement of speculative coal.

Later in the month, when it became evident that an agreement between the bituminous miners and operators had been effected, the trade was brought to an abrupt standstill. Consumers had prepared for a protracted shutdown, and the unexpected short duration of the suspension eliminated any disposition on their part to buy. A large number of dealers who had also stocked quite extensively, for speculative purposes, were compelled to throw heavy tonnages on the market, which tended to still further depress the trade. Much of this coal had been bought at high figures and wholesalers made every effort to maintain the high prices, but without much success.

The close of the month found the bituminous trade in the final stages of readjustment and approximately, on

a normal basis again. The mines were at work, though under curtailed production, which was, however, sufficient to meet requirements as most large consumers had stocked sufficiently to carry them over a 30-days' suspension and were not yet in the market. For the two weeks ended Apr. 25, the surplus of idle coal cars showed the greatest increase for the year, the total on that date being 92,548. Operators were slow in getting started at the mines and the month closed with the bituminous production far below the full rated capacity. Uncertainty in the anthracite situation still prevailed, but the harmonious sittings of the wage scale committees led to the belief that an agreement would be effected at an early date.

May

The heavy stocks, accumulated in anticipation of a prolonged suspension at the bituminous mines, had a decidedly depressing effect on the trade early in May. While some companies were still delivering on contracts, made at the high level in March, it was difficult to obtain anything more than normal prices at this time. Quotations were slowly but steadily easing off, and buyers were hesitating to purchase until they were assured that the bottom had been reached. Production was also at a low level, operators refusing to open up full blast until there was more pressure for coal. In the Middle West there was a total absence of any buying movement, and it was becoming evident that quotations must soon fall off to about the cost of production.

Later, the unprecedented action of the miners in rejecting the scale fixed by the joint committee caused some alarm and a further tightening of the situation in hard coal. This deadlock also helped the bituminous operators and, together with the opening of the lake trade, tended to check a further decline in this branch, which was now about holding its own. The situation was weak, however, and much difficulty was experienced in placing arrivals, which were again about normal.

The middle of the month saw a further relapse, due to the more general resumption of mining and consequent increase in production. Surplus stocks were still in evidence and the market was hardly in a position to absorb even normal tonnages; forced sales of demurrage coal were reported at some of the large distributing centers, and quotations again fell off. In anthracite, the situation had now become exceedingly tight and supplies quite short. Heavy premiums were being offered on every hand, and the market was in prime condition for a panic.

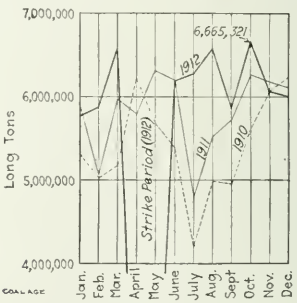
The end of the anthracite strike, toward the close of the month, was viewed with general satisfaction in trade circles. While this was accompanied by a slump in prices and a return to the usual summer lethargy, all uncertainty was, on the other hand, removed and the trade again established on a normal basis. Dealers immediately began storing up to their full capacity, in anticipation of the large shortage which must necessarily result from the long suspension in mining.

Toward the last of the month the new hard-coal circulars were announced, showing increases ranging from 15 to 50c. per ton. These advances were met with a strong protest on the part of the general public, and the demand eased up, consumers believing that little was to be gained by storing at the new quotations.

The bituminous outlook, toward the close of the month, was not encouraging. Production had been quite heavy, and with all hopes of profiting by the suspension at the anthracite mines now dispelled, it was obvious that prices could be maintained only by the most rigid curtailment. No attempts were yet being made to force the market by price cutting, but the outlook was disappointing.

June

The month of June opened up with the anthracite companies pressing their operating departments to the limit, in the endeavor to make up the shortage. The demand was not strong, however, consumers hesitating to buy at the new high prices. In bituminous, the only encouraging feature was the reports of a labor shortage in different parts of the country which, it was hoped, would effect a curtailment in production. With anthracite shipments again back to normal, the soft coals were obliged to stand on their merits and, while quotations were nominally being held, there were well defined rumors of cutting, and orders generally were scarce.



Anthracite Shipments

Opposition to the increase in prices made by the anthracite companies became stronger as the month advanced. Domestic consumers were unable to understand why the whole of the advance in the miner's wages should be added to the domestic grades, and the feeling became quite bitter at a number of points.

During the two weeks ended June 6 the surplus of idle coal cars fell sharply from 68,419 to 35,140, being the greatest decline for the year, so it is obvious that there was a large increase in production at this time.

The bituminous market was dull and quiet at the middle of the month, but not materially different from the average at that period of the year. There was no buying except at sacrifice prices, and consumers were not displaying much interest in these. The lake shipments continued to be the best feature of the market, and there was also some increase in the steel industry. On the whole the trade was not abnormally low considering the time of the year, and exhibited a rather healthy tone. Production continued to increase steadily throughout the month, as is shown by the steady decrease in the surplus of idle coal cars over this period.

Toward the close of the month, the first complaints about the small shipments of anthracite, began to appear in the East. It was becoming apparent that the Western

agencies were being favored by larger deliveries in order to get them stocked up while transportation conditions were favorable. As a result, arrivals at the Eastern distributing centers were below normal. Wholesalers were attempting to accumulate their winter stocks at the summer price level and became anxious over the situation with the result that the hard-coal trade began to assume an appearance of activity.

In bituminous, conditions were directly the reverse. The uncertainty in the political situation began to be felt with the result that the manufacting demand was showing a decided tendency to ease off all over the country. Domestic business was also slowly declining to the usual low ebb at this period of the year; consumers generally were hesitating to contract, and the trade was absolutely devoid of interest

July

A car and labor shortage developed the early part of the month which had a decidedly stimulating effect upon the trade. The former was ascribed to the remarkable activity in steel, a great deal of the coal equipment being diverted for use in this way. While the surplus of idle coal cars showed a decided reduction for the two weeks ending with July 4, it was not, however, at a low point by any means, so production was still low. The labor shortage was becoming an important consideration, and it was obvious that, if mines were working up to anything like full capacity, it would be impossible to obtain an adequate supply.

Prices took another general slump all over the country, those at Boston touching the low point for the year, as will be noted on the accompanying diagram. Cargoes were arriving at Eastern coastwise points on consignment and embargoes were being declared at some places. It was evident that prices could be maintained only by a rigid curtailment in production on the part of the operators.

The middle of the month found many of the Eastern anthracite dealers entirely out of supplies and the pressure became strong for shipments out of New York and Philadelphia. The relatively light production for June, which was announced at about this time, produced a noticeable feeling of uneasiness in trade circles. This was further increased by the urgent demand from the line and Western trade, the latter being still quite insistent upon having the first shipments.

There was an appearance of a better feeling among the Eastern bituminous dealers at this time. Although the existing conditions did not justify this, still consumers generally, had been out of the market since the suspension and it was becoming apparent that many had about reached the end of their supply, and were being forced into the market. There was also a steadily increasing consumption, along with the rapid advance in steel. In spite of this optimistic feeling, orders were more scarce than at any time during the season, and the market was so flat and dull that there was scarcely anything to report.

The position of the market was quite unique. Bituminous, normally dull at this period of the year, was down to even a lower point than usual, while the shortage of anthracite was regarded as quite serious. Dealers in the latter grade were rapidly getting farther behind on orders, and it was becoming difficult to see how they would be able to handle the heavy fall and winter business.

The month closed with low prices being quoted uniformly all over the country, although there was an effort underway in the Eastern bituminous market to maintain a higher level. Operators were, however, becoming more optimistic, shipments were more nearly down to requirements, while free consignments were seldom heard of and there were not the indiscriminate pounding of prices, so common during the preceding few weeks.

August

The first of August brought with it some tangible evidence of the improvement in bituminous, which the dealers had been looking forward to. This was general all over the country, with the possible exception of the Pittsburg district where prices broke to the low level for the year.

Deliveries generally were now only made on specific orders, and indications were that the low prices of June and July would not again be duplicated during the rest of the season. There were no longer any heavy accumulations, coal was being more closely held, and there was an entire absence of demurrage; the demand was more insistent than at any time since the suspension, and the business was on a fairly profitable basis. This was, no doubt, affected by the policy of rigid curtailment adopted by a number of the larger producers, together with a further tightening in the car supply, the surplus of idle coal equipment again showing a reduction for the two weeks ending Aug. 1.

Apparently, the only problem before the hard-coal producers at this time, was the provision of an equable distribution of their production in such a manner as to cause the least complaint. Eastern dealers were being obviously discriminated against in this respect; this was, however, to be expected, as the more remote Western points must be supplied while shipping conditions were favorable.

By the middle of the month, the bituminous market was on a strong basis, with every indication of holding its own for the remainder of the season. It was becoming apparent that the supplies in the hands of the consumers were low, as was anticipated, and while there was no heavy demand, the market was probably in a better position than normally at this period of the year.

The sales departments of the hard coalers were pushing the operating end to the limit, and it was apparent that the August production of anthracite would be heavy. President White, of the miners' union, made a visit to the anthracite field during the month, which interfered with work at the mines and caused some dissatisfaction among the producers. This was unfortunate at this time, as the shortage was becoming more serious, with stove coal almost entirely out of the market.

Bituminous operators began to foresee an active business the coming fall, and the market gradually assumed a strong, healthy tone. The possibilities of transportation troubles during the coming fall, began to be anticipated by some consumers who started accumulating surpluses; This had a further stimulating effect upon the situation.

Mining generally was becoming restricted. In the Pittsburg district the car supply was poor, with occasional

embargoes being declared on shipments from some districts, and there was an insufficiency of labor, together with frequent small strikes at the mines. The car shortage in Ohio was so pronounced that mines were being subjected to an occasional shut-down. For the two weeks ending Aug. 29, there ceased to be any surplus of idle coal equipment and a shortage of 1715 was reported for the second time during the year; this shortage was not again eliminated during the remainder of the year.

The month closed with the demand for anthracite still far in excess of the supply, and with the production being as readily absorbed as ever. Dealers were beginning to receive inquiries from the consumers, and it was evident that the winter trade would open up in earnest soon. The soft coal market closed active and firm, with prices unchanged but being much more rigidly held. Consumers were seeking to cover their requirements against a possible car shortage and the rumors of the slow movement were making them anxious.

September

The early part of September found bituminous operators becoming cautious about future commitments, and old prices being gradually withdrawn. The labor troubles in the Paint Creek field had proved another disturbing factor in the situation, deliveries were slower and consumers less inclined to be particular about quality. Production in the Pittsburgh district was now practically equal to any previous record, and would have been still heavier were it not for the insufficiency of labor and inadequate supply of equipment for loading. Manufacturing demand was increasing and shipments to the lake becoming quite large.

Inquiries for October and November deliveries of anthracite at this time, were being met with the reply that no forecast could be made as to the situation then. While every effort was being made to meet the constantly increasing demand, the Eastern dealers were becoming more concerned over the situation, and premiums were steadily advancing. By the middle of the month coastwise dealers were down to a hand-to-mouth business, and the companies were taking the stand that they could look after none but old customers.

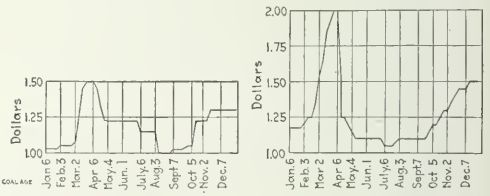
Bituminous production had become quite heavy by the middle of the month, but no surpluses were reported at the large distributing centers. Considerable of the West Virginia coals were being diverted into the Western markets which caused a shortage in the East, and arrivals were only about sufficient to meet contract obligations. Current shipments were going into immediate consumption, and no supplies were being accumulated. Prices in the Pittsburgh district were stiffer, without having experienced any advance, with the exception of domestic which had gone on to the usual winter schedule. Eastern dealers generally, claimed they had more business than they could handle, shipments were up to the maximum rate for the period, and the season showed every indication of being a prosperous one.

As the month advanced coastwise bituminous prices became more firm and there was more or less detention at all the piers. The West continued absorbing an unusually large percentage of West Virginia products, and shippers were going slow on new business. Production appeared to be only about equal to contract requirements.

Operators and jobbers in Ohio had all the business they could handle, and the inadequate car service was still curtailing production. There had been a continued heavy demand, with a limited supply, at Hampton Roads, and this finally resulted in an advance in the schedule at about this time. There was considerable business offered at good figures, which the operators were unable to take advantage of, and there was no evading the fact that there was a perceptible shortage.

The fall demand for anthracite began to open up toward the end of the month. Premiums asked in the retail trade were reaching a prohibitive level, and dealers generally were finding it easier to sell than purchase fuel. It was reported that a number of towns were practically bare of supply, and, while the clear weather caused an improvement in the coastwise movement, the scarcity at the terminals was making the loading slow.

At the close of the month it was becoming apparent that the anthracite coastwise dealers were unable to make any impression on their orders, and the trade was getting in a serious condition. The movement was being interfered with by the inadequate car supply, the demand still increasing faster than the shipments, and some consumers were being forced to substitute bituminous and coke for hard coal.



Minimum Mine-run Prices at Pittsburgh, Penn. — Boston Prices for Clearfields, f.o.b Mine

Characteristic Price Curves for the Year 1912

The close of the month, also, saw the beginning of the abrupt advance in bituminous quotations, as will be noted on the accompanying diagrams. The shortage of coal equipment had been growing steadily, although not rapidly worse through the month, which ended with the bituminous market undeniably on a firm basis in all departments.

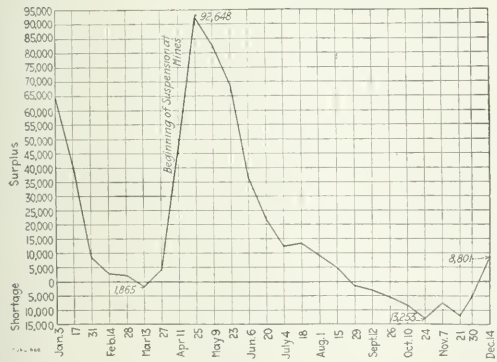
October

October opened with the bituminous market in a decidedly feverish condition. Buyers were appearing in the mining regions in the hopes of being able to pick up some loose tonnages, and the demand was urgent in all departments. The car shortage in the East has become so pronounced that operators could make no promises ahead about deliveries, and there was detention with practically all shippers. Companies were being pushed to take care of their contracts, and some began issuing instructions to their salesmen to accept no more orders. Most of the West Virginia product was still going into the Western market, and there was every indication that it would continue doing so until Eastern consumers bid up prices.

The appearance of higher temperatures toward the

middle of the month gave the anthracite dealers all over the country a welcome respite. Anticipation of the results at the closing of the heavy Western and lake trade began to be looked forward to, even at this early date. The opinion was freely advanced that the demand was abnormal by reason of many orders being placed in duplicate, and that with the appearance of these extra tonnages in the Eastern market, there was a probability of the trade experiencing a sharp recession. It was generally conceded that the operating companies were dealing with a hard situation and handling it to the best possible advantage.

The heavy demand for anthracite now began to swing onto bituminous, with the result that this branch became practically as hard as the former. There was a heavy movement of all kinds of freight, making the congestion worse and seriously affecting coal shipments particularly to tide. There were no free tonnages of the better grades to be had, tonnage consignments of all kinds were being detained, prices were correspondingly firmer, and consumers more concerned.



Surpluses and Shortages of Coal Cars During 1912

Ohio operators were now entirely at the mercy of the railroads, production was only about 40 to 50 per cent. normal, and the new circular of Oct. 1 was being maintained in every particular; manufacturers were seeking surplus tonnages and dealers were attempting to cover their requirements, but without much success. Demand and prices were improving in the South, and slightly larger tonnages going into the Northwest. Quotations continued ruling firm past the middle of the month, with requisitions insistent and the trade strong in every particular.

In spite of the assurances of the anthracite producers, it was generally believed toward the close of the month that the first appearance of severe weather would precipitate a runaway market; there was, however, some indication of an easing off in this branch, due to the mild weather. Eastern receipts of hard coal continued small, and apparently below those for the preceding few weeks and the end of the month found the dealers becoming imperative in their demand for fuel.

Toward the close of the month the scarcity of bituminous became so acute that consumers began purchasing outside of their contracts. Eastern arrivals were still curtailed due to the heavy movement West. Quality became a secondary consideration, the poorer grades took an almost spectacular advance, while operators became more cautious about future commitments. For the week ending Oct. 24 the shortage of idle cars touched the low point for the year, and it was obvious that production was heavy at this time.

Pittsburgh operators were now confining their entire attention to filling contracts and were reserved about accepting future business. There were no free tonnages of any description, and shipments were down to about 50 per cent. of normal capacity. Contracts were being freely made for the year or six months after Dec. 1 at the regular season circular adopted early in the spring, but which was so flagrantly cut in midsummer. By the close of the month sufficient tonnages had been closed to justify an advance in the circular for the year, and it was believed that this new high level would shortly be the minimum.

Eastern bituminous operators, who had contracted so freely in the spring, were, at the end of the month, becoming apprehensive over November and December deliveries. There was a dearth of steam coal in all markets, production reports for the mining regions were discouraging, while operators were evincing every confidence over the future.

November

The month opened with the anthracite operators responding to the heavy demand being made upon them to the best of their ability, but still showing little or no indication of getting ahead. The steam grades were the only easy branch of the trade and the domestic sizes were still going into immediate consumption as fast as received. Originating companies were withdrawing their Eastern fleets because of the dearth of domestic grades for shipment, hindrances and delays in both production and transportation were now the rule, and it was evident that the hard coalers would find it impossible to overcome the tremendous shortage. While the duplication of orders by the consumers had doubtless created an artificial demand, there was no doubt but that the trade was facing a strenuous situation.

The bituminous producers at the first of the month were finding it difficult to meet their contract obligations and there was no free coal in the market with the possible exception of a few odd tonnages of the lower grades. A strong off-shore demand developed which further complicated matters at the piers; detention of from one to two weeks became the rule and the situation was further aggravated by the anthracite roads withdrawing bituminous equipment for use in the hard coal regions. A number of embargoes were declared and the shortage in the Pittsburgh district reached the most serious proportions of the year. Contracts were being made at the full season circular, and mostly for the year, though occasionally for six months.

The announcement of the record-breaking production of anthracite for October was made at about this time but did not give any tangible evidence of relief. The situation was undoubtedly grave and the coast dealers who ordinarily had their full supplies by the close of navigation, Dec. 1, were beginning, towards the end of the month, to make extensive preparations for obtaining shipments throughout the season. The expected winter

demand began to get definitely under way, and, while large tonnages were being distributed, they were not sufficient to permit of the accumulation of any surpluses.

The coastwise bituminous market began to fluctuate so spasmodically toward the close of the month that it is probable there was considerable buying on speculation at that time. There was a freer movement to tide and some spot business developed, but supplies were so short that a number of companies were offering their fleets for rechartering. The Pittsburgh market was also fluctuating considerable, due to the uncertainty as to what conditions would be after the closing of navigation on the Lakes.

The car situation again tightened up toward the close of the month, there being a shortage on Nov. 21 of 12,005, this being the second greatest shortage for the year. The effects of this were quite noticeable in Ohio where the situation was probably the most acute at any time during the season. West Virginia operators were being pushed by their Western connections for final shipments before navigation closed and at the same time, the demand at the piers was so heavy that detention of from three to four weeks was quite common. The number of vessels awaiting cargoes fell off at the close of the month and more favorable weather conditions tended to lessen the anxiety of domestic consumers generally in the South, but the same uneasiness prevailed among the steam users.

The close of the month found the anthracite dealers with supplies probably shorter than they would admit to anyone except the producers. The comparatively mild weather had prevented any extensive runs on the producers and relieved what might have otherwise been a serious situation at this time. The results of the closing of lake navigation were now being eagerly anticipated.

December

The last month of the year opened with an appearance of a break in the anthracite market, the first for many months. This was due to a combination of heavier shipments into the Eastern markets and mild weather. While the situation could not be termed easy, particularly in the more remote localities, there was nevertheless a sharp decline in quotations at several points; indications were at this time that the hard-coal markets would shortly assume average normal winter proportions. Premium prices were further reduced as the months advanced and shipments continued heavy although all arrivals were going into immediate consumption. The unusually mild weather had been a great help to anthracite distributors up to this time.

Stocks of bituminous in the East were becoming shorter at the first of the month and the trade was on a firm basis, but there was an absence of pressure for coal and quotations remained conservative. Shipments to the lakes had entirely ceased shortly after the first of the month, and it was hoped that there would be an improvement in the car supply. A large proportion of the business in the Pittsburgh district for 1913 was put under contract during the first week at the prevailing circular and some large coke contracts were also let. Larger tonnages were being moved in Ohio and the situation in regard to supplies was somewhat easier. No quotations were obtainable on smokeless at Hampton Roads, the high volatiles were bringing record prices, and the movement on contracts continued heavy. Toward the middle of the month the shippers were troubled a great deal by the railroads confiscating coal *en route*. Shipments were confined almost entirely to contracts and consumers were pressing the operators for their maximum allotment of tonnages.

By the middle of the month the expected improvement in the car situation, due to the suspension of shipments to the lakes, had failed as yet to materialize; some operators reported a fair supply, but others stated that conditions were less favorable than formerly.

In the coastwise anthracite trade, reports were general, by the middle of the month, of dealers being down to the bottom of their stocks and the situation was being furthur aggravated by thick weather which was interfering with the water movement. Consumers were, however, becoming more reluctant to pay the high premiums, believing, apparently, that the diversion of the Western tonnages into the Eastern markets must shortly effect a material relief to the latter. The markets were undoubtedly much easier, but it was doubtful if they would continue so when the real winter weather appeared.

Toward the close of the month the hopes of the coastwise dealers to obtain better supplies were dispelled by a succession of storms; vessels were overdue and many barges were waiting power to move them. Premium prices, however, were now definitely established at a considerably lower level, particularly at points more contiguous to the mining regions.

The middle of the month found the soft-coal dealers beginning to anticipate the customary suspension in mining over the end of the year, at which time a slight activity was expected, and quotations for the new year were being discussed. Prices in the Pittsburgh district were down to only a slight advance over the circular but were being rigidly maintained; operators were receiving a fair allotment of cars, probably sufficient for average needs. The steam trade in Ohio gradually became more active towards the end of the year and production was quite heavy, operators getting up between 75 and 90 per cent. capacity. At the close, the car supply was fair and there were indications that a shortage was developing; it was obvious that a spell of cold weather would undoubtedly precipitate an active market. Hampton Road shippers were gradually catching up on orders, but there were still a number of vessels awaiting tonnages at the piers. The December loading greatly exceeded that for November and it was clearly evident that this point was rapidly gaining in favor for bunkering and export tonnages among these consumers.

The year closed with those bituminous operators who were not under contract getting handsome profits while a still greater advance was expected with the appearance of more winter. The demand however, was spotty and confined mostly to smaller tonnages, although all arrivals found a ready sale at relatively good prices. Supplies were undoubtedly restricted and anticipation of the loss in production due to the holidays caused consumers generally to increase their committments.

It was evident at the end of the year that the anthracite situation was swinging around to more normal conditions. There was a slight improvement in receipts and the demand at the close was strong, but with premiums being freely discounted.

Coastwise Trade Conditions in 1912

By G. G. Wolkins*

SYNOPSIS—The year was one of much anxiety and uncertainty. Many wholly independent circumstances combined to relieve situations which otherwise might have been disconcerting, if not disastrous, to the trade. The prices on Pennsylvania grades were high at the beginning and end of the year, but low during the summer. They averaged better however than in the previous twelve months. Water freights moved up and down with the demand for coal, and were on the whole unsatisfactory. The anthracite situation in New England was far from what might be desired, and the tendency toward extreme prices is something difficult for the populace to understand or the dealer to explain.

To some extent, 1912 justified expectations; it was marked by uneven prices and a surfeit of anxiety over discouraging possibilities. The early adjustment of labor troubles, in the bituminous region a day or two in advance of the expiration of old agreements, and in the anthracite field after a few weeks' suspension, deprived the year of a place with 1902, and yet it was a record twelve months for bituminous tonnage and lent zest and variety to an industry accustomed to turmoil and strife.

The collapse in both the American and the British strike situations came just in time to allow consumers to replace at low prices the reserve stocks of bituminous that had been wiped out by seven weeks of exceptional cold, and in anthracite there has been a joining of weather, of traffic, and trade accommodation that has just about enabled the average retail dealer to get along on a hand-to-mouth basis.

In January and February, for weeks at a time, rivers and inlets ordinarily open to navigation were frozen over and some loss and much inconvenience ensued. In April a high freight market and a sharp "flurry" in steam coals gave way almost at once to a state of extreme dullness. Buyers who had practically stampeded for supplies "to last until May" now found their storage filled for months to come and there was generally an utter lack of interest in bituminous from any quarter.

Shippers soon grew cautious over commitments, even the spring contract prices were gradually withdrawn, and by mid-August it was plain there need be no worry about returns for the rest of 1912. The pressure was rather toward obtaining coal than being relieved of it. A labor shortage became increasingly evident during the fall months, the Western demand went from active to brisk, and by late September the loading of all the favored coals had begun to be subject to two or three weeks' notice and in some cases indefinite delay.

Buyers have been obliged to buy outside of contracts, and those Pennsylvania operators, in the Clearfield region particularly, who from one reason or another are free of obligations at least for a part of their output, began in October to reap a harvest in fancy prices.

The lines grew tighter until the end of December, when $2@2.15 at the mine was found an easy sale, with very little question as to quality. So the year ended as it began; with a pronounced shortage of the coals on which this market usually relies, and a prospect of panic prices, "if the weather turns cold."

Pocahontas and New River

The bituminous market in New England hinges largely on the output of the Pocahontas and New River fields, and the question of whether they are in long or short supply is always a determining factor. With the exception of the dull months from April to July, three grades were in strong demand and the average price return was much higher than for 1910.

January opened with slow loading at all three of the Hampton Roads terminals and prices were firm at $2.70

for what small amounts could be had outside of contract. Early in March a season price of $3.80 on cars, Boston, was made by one of the agencies as against $3.30 the year before, although part of the increase was due to an active freight market.

The Eastern dealer or manufacturer whose old contract was expiring was obliged, in effect, to bid against the offshore trade in order to get fuel for April, May and June. The flurry then at its height soon subsided, however, and the middle of April saw the usual short-lived celerity in closing season business on price bases anywhere from $2.50@2.70. The buying power was only moderate at this time and purchases were extremely conservative.

Loading conditions improved very fast during April, but there was lack of orders and late in May recourse was had to the usual and time-worn expedients.

It was difficult, after such months as January to April,

*50 Congress St., Boston, Mass.

to get output back to an off-year basis, but when the June receipts at tidewater accumulated to such a degree that car embargoes were threatened and it was a matter either of demurrage at Norfolk or losses here, the more far-sighted interests resolved upon $2.70 ($1.30 at the mine) or nothing. A general curtailment followed. Then, with a scarcity of labor and the foreign demand already mentioned, it was but a few weeks before conditions were well on the mend.

This concerted move to send coal to tidewater only on actual orders, was perhaps the most hopeful sign of the whole season in West Virginia. It showed that at last the Pocahontas and New River producers were tiring of the old practice of throwing away great tonnages of highest grade fuel just for the sake of making a dent in the market.

Three dollars and a half, f.o.b., was the level reached in November and December and, as an outcome of the year's generally flourishing business, there is an effort on foot to try for a contract price of $3, f.o.b., and to make the coal year begin Jan. 1 rather than Apr. 1.

Georges Creek

The receipts of Georges Creek, chiefly via Baltimore, were heavier than in 1911 and this would have been a record year for the Maryland output, but for the extreme car shortage that seriously affected shipments after Sept. 1.

A number of anthracite barges were engaged in freighting Georges Creek coal at low rates and the call for Pennsylvania coals was narrowed in consequence. But when prices at Hampton Roads dropped to $2.50@2.60, much of the early advantage was lost in materially reduced consignments for June and July.

The sluggish tone of the market did not cause the Georges Creek shippers to waver on price, however, and they thus furnished an object lesson to their more southerly competitors. The price remained firm, but beginning with September, slow loading was the rule at Baltimore and receipts the last of the year were trifling.

Only limited amounts came through for loading at Philadelphia or New York and supplies of Georges Creek for this market were practically out of the question for November and December. At the close of 1912, there was almost no offering by any of the numerous shippers, but if there had been, it would have commanded $2.15 @2.25 net at the mines.

The Pennsylvania Grades

It can safely be said the Clearfield, Somerset and other bituminous districts in Pennsylvania have enjoyed a satisfactory year. While in some sections prices were for several months no higher than in 1911, not enough even to pay for the advance conceded the mine-workers, yet profits averaged much better in 1912.

During January and February receipts at tidewater were so light that spot coal of the inferior kind was marked up to $1.25 and even to $1.40 at the mine, and there it fluctuated until the preferred grades disappeared from the market in March and up to $3.25 was paid the selling agencies for anything that was known to be *en route* when a country-wide strike was supposed to be imminent. The slump was so rapid in early April that operators were slow to realize what had happened and for some weeks the lowest figures were maintained in cleaning up the speculative coal that high prices had called forth.

Quite a volume was sacrificed down to 90c. and $1.00; then with slow resumption of mining, prices swung back to normal and the market settled into an unusual dullness. There was practically nothing forwarded except on orders and there was no surplus to be absorbed. The Cambrias and Somersets again went out of the market, shippers finding their hands full to furnish contract requirements, and Aug. 15 saw quotations 5c. @ 10c. up and by Sept. 1 old prices had been withdrawn.

The contract basis for fair Clearfields was about $1.15 @ 1.20 and for Somersets $1.25 @ 1.30 or 5c. higher than 1911 on all grades. The fancy brands of Cambria commanded $1.40 in most cases. Late in September all the popular coals were well sold up and from then on there was an advancing range of price on all the Pennsylvanias, varied only occasionally by an uneven demand.

Transportation

Throughout the year water freights moved up and down with the demand for coal. The March "flurry" and the anxiety to cover tonnage before 1911-1912 contracts expired, caused a run up in rates from $1.00 @ 1.10 in February to $1.40 @ 1.50 on large vessels, Hampton Roads to Boston. With old business out of the way and the Virginia terminals catering mostly to off-shore steamers, together with a considerable amount of anthracite transportation freed from its usual service, vessel freights eased off to 70c. in May and carriers went begging. Owners preferred tying up to accepting less than 70c. A brisk demand early in September moved the current rate to 95c. and $1 with short time guaranteed for loading. Then the extreme detention at Hampton Roads and at Baltimore so discouraged vessel owners that at the end of December many had chartered into other trades.

Receipts were so light in the Chesapeake the last of the year that some of these colliers have also closed for other freighting, two at least taking grain to Europe. For the most part 1912 was a profitless year for sailing vessels.

Several small vessels took freights up to $2.00 out of New York for eastern points, in October and November.

Anthracite

New England has had a troublous year in anthracite. From Jan. 1, there was no time when more than hand-to-mouth deliveries could be had, and a more trying year to the distributor, wholesale or retail, would be hard to imagine. A prolonged season of extreme cold followed on the shortage that had been apparent since Sept. 1911. The smaller producing companies were out of business so far as the East was concerned, and to provide a climax a bitterly fought anthracite strike Apr. 1 seemed a foregone conclusion.

The "suspension" actually lasted only to May 23, but the loss of practically two of what are normally heavy months for production put the market several million tons in arrears, and 1912 ended with New England still far behind on its usual tonnage. Dealers everywhere had more than they could do to keep abreast of their trade even though every known expedient was resorted to.

New circular prices were announced June 1, with 25c. advance on all sizes as compared with prices effective the same month in 1911, or 45c up compared with April, 1911. In addition to the increased contract price on broken announced Jan. 1, 1912, $5.00 instead of $4.75 alongside Boston, an advance in pea was effective Nov. 1, making the new price $4.25 instead of $4.00 alongside Boston. In December another change was made by some of the companies shipping from New York, namely; a 15c. higher water freight on anthracite barges, or 65c. to Boston and Boston points rather than the 50c that had obtained for more than a dozen years.

All this scaling up is of great interest to the public and there are many signs of restiveness. Retail prices through New England were from 75c @ $1.50 higher than the same season in 1911. This is difficult for people generally to understand and quite as difficult for dealers to explain.

The saving factor in the whole situation was the wonderfully consistent mild weather all the later months, a circumstance that has enabled the companies to send east certain supplies that would otherwise have been directed to the big city markets. This was shown very plainly when a slightly colder day in New York practically closed the gate for consignments outside the harbor

Retailers here were therefore sparing in deliveries and conserved their small stocks. Had the weather been otherwise there is no saying what distress might have followed. Boston retail prices were advanced to $8.25 for stove and chestnut Oct. 1 and were held there through the rest of the year.

The past twelve months have fulfilled certain predictions that were freely made; that a new high figure would be reached for the volume of business and hence also for the movement of freight. Railroad equipment had not kept step with the prospect and we had our great shortage of cars.

❖ ❖

The Situation at Hampton Roads in 1912

SYNOPSIS—Dumping at Hampton Roads for 1912 exceeded that for the previous year by one and a half million tons. Trade was quite good on the whole and prices entirely satisfactory. Many improvements and additions are under way which will greatly increase the capacity of the port.

❖

Hampton Roads has experienced the most unique year in its history. Over a million and a half tons more was dumped than during any preceding year. Altogether it has been a very prosperous year for Hampton Roads shippers; no failures are recorded in the coal industry, and on the other hand, new organizations have appeared in the field, and the older ones have broadened out and grown in proportion with the gradual increase of business. The value of the coal put afloat at these ports in 1912, estimating it at $2.60 a ton, which is a fair average price, is about twenty-nine millions of dollars.

Naturally the railroads have played their part in the prosperity of the port, and made numerous improvements, purchased equipment and locomotives, and improved in other directions in order to better serve the mines located on their respective lines. Both the Chesapeake & Ohio and the Norfolk & Western have begun work on new piers during the past year, which when completed will further the efficiency of Hampton Roads as a coaling port. It is still a matter of speculation as to what effect the completion of the Panama Canal will have on the export of coal from Hampton Roads, but it is the consensus of opinion that this port will very shortly be surpassed by few in volume of business handled and by none in facilities and supply of high quality coal; these facts are already being more and more recognized by domestic as well as foreign traders and consumers.

Curtailment in the Early Part of the Year

During the months of March and April, when the light demand is felt for steam coals, and curtailments in mining are generally resorted to, local shippers found a ready market for their product, which was placed with consumers heretofore using practically none other than British coals, this stroke of good fortune being brought about by the British coal strike. Even though this strike was of only a few weeks' duration, during this period not less than a quarter million tons of steam coals moved out of Hampton Roads bought by foreign dealers for consumers, until then, using only British coals. Prices at this time ranged higher than known here for ten years. New River-Pocahontas mine-run coal being readily taken up at upward of $1 a gross ton f.o.b. the local piers. Incidentally a long sought opportunity was here given to place American coals with users of British fuels, and to better acquaint such consumers with the efficiency of the smokeless grade especially. The results in the latter respect were highly gratifying and aside from the "smalls" (as continually dwelt upon by foreign coal-trade papers), Hampton Roads smokeless coals were found as high in efficiency as the best grades of Welsh coals. (It will be noted that about this time we find the largest dumping for one month during 1912.)

During the early summer months the demand for steam coal held up remarkably well, an unusually large tonnage being moved to New England ports. While it has been

customary for a number of years to curtail shipments during the summer, the good demand for coal here obviated the necessity of such a step to any noticeable extent. As soon as the lake season opened up the greater portion of the coal from the New River-Pocahontas district was moved West. The market at tidewater not being flooded with large quantities of unsold coal, prices remained quite firm. About this time large tonnages of coke were exported from here and for a time it looked as if this feature of the business would assume proportions worthy a second consideration, but during the closing months of the year, the tonnage dumped did not measure up to expectations based on the summer performance. Nearly all the coke during the year was handled by the Norfolk & Western Ry. The Virginian Ry. handled none, and the Chesapeake & Ohio only a few hundred tons, at Hampton Roads.

Early in the fall indications pointed to a good winter business. Predictions came true, materializing earlier than expected, and by the middle of October it was difficult to obtain any quantity of standard smokeless coal at any price. The car-shortage question became serious on the Norfolk & Western, and Chesapeake & Ohio railroads about this time and continued to grow worse daily. So bad were conditions that a number of the mines only worked two and three days a week. What free coal was now on the market was eagerly taken up at prices ranging from 50c. to 75c. a ton higher than that at which most of the year's contracts were closed. This demand did not lessen to any extent, as the year came to a close, although during the early part of December (due to the moderate weather prevailing during the entire fall) the demand weakened slightly and prices seemed destined to decline somewhat, but on account of the curtailed output brought about by an inadequate car supply and insufficient labor, no accumulation of coal was effected, and consequently prices remained high; what few sales of standard smokeless coal were made, came near to the high-water mark of the year.

The high volatile (free burning) coals which had been shipped to Hampton Roads in limited quantities from time to time, on account of the light demand in the open market, were readily taken up during the stringent smokeless period by consumers who heretofore would entertain the use of smokeless coals only, but being unable to obtain these, found the Hampton Roads high-volatile coals an excellent substitute. It is well to mention here that during December, the Virginian Ry. overtook and passed the Chesapeake & Ohio Ry. in point of number of tons of coal put over their Hampton Roads piers, the Virginian's total for the month being 256,457 tons, while that of the Chesapeake & Ohio was 226,344.

Increase in Bunkering Trade

A marked increase in the bunkering business was noted during the closing weeks of 1912. This was attributed by some to the cheapness of supplies here as compared with other ports, although traffic in American waters, especially cotton from Southern ports, was unusually heavy during this period. Late in December prices for coal for steamship use during 1913 were announced, and found to be 30c. a ton higher than during the closing year.

Prices prevailing on smokeless coal during 1912 were as follows:

	High	Low		High	Low
January	$2 70	$2.50	July	$2.70	$2 45
February	2.70	2.50	August	2.70	2.50
March	5 50	2.50	September	2.80	2 50
April	4 50	2.50	October	3.25	2.60
May	3 50	2.50	November	3.25	2.60
June	2.70	2.45	December	3.55	2.60

A statement of the dumpings during 1912 over the piers at Lamberts Point, Norfolk, Sewalls Point, and Newport News, in detail follow:

Month	N. & W.	Virginian	C. & O.
January	403,881	171,806	321,210
February	413,897	190,689	308,898
March	468,883	207,552	340,521
April	571,187	166,176	475,301
May	511,785	189,689	370,885
June	424,167	174,324	290,622
July	442,818	215,637	311,751
August	423,571	223,150	332,194
September	404,016	243,272	282,492
October	406,606	239,161	275,024
November	347,255	182,242	228,373
December	361,062	256,457	226,344
Total	5,213,773	2,473,145	3,763,615

Grand total for three roads during 1912 was 11,450,533, as compared with 9,981,431 for 1911.

The Philadelphia Coal Trade

By C. B. Beers

The closing of the year 1912 ended or rather was the culminating point of one of the best seasons of business that has been enjoyed in this vicinity for several years past. In fact, it may be said to have been a banner year. It is true that scarcity of coal prevailed throughout this entire period, and that it was almost impossible to get sufficient supplies to satisfy the trade, but from the standpoint of business, it was a year never to be forgotten. It was not so much a question of securing business, for there was plenty of that, but the difficulty seemed to be that there was not sufficient of the necessary coal to go around. It is true that this condition of affairs become more apparent after the resumption of mining on June 1, but even before the strike, which lasted two months, there was no one day or week, when it could be said that there was any surplus of anthracite coal.

The beginning of the year 1912 saw the trade in a very satisfactory condition. The demand was good for all sizes, from broken to barley. On Jan. 1, 1912, there was an advance in the price of rice coal from 65c. to 85c., but it is understood that notwithstanding this increase, contracts were, as a rule, renewed at the new figure. Broken coal at tidewater was also advanced 25c. per ton.

All through the months of January and February the market readily absorbed the entire receipts of anthracite coal sent in this direction, and March found little if any coal in the yards of the dealers. Then came the first mutterings of trouble with the miners. The month of March registered the next to the largest production of anthracite coal in the history of this commodity.

Large users of the steam sizes who, as a rule, begin to be a little chary about laying in any unusual supplies at this time, utilized every inch of space they could spare for the storage of coal, some of them going to considerable expense in renting for a certain period, plots of unimproved property for the storage of additional fuel.

Dealers, as a rule, during the month of March, limit their purchases to their actual necessities, but winter extended itself well into this month, and with the prospect of strife with the miners, they were all anxious to secure supplies for possible householders who were not willing to take any chances on securing their winter requirements, having in mind the discomforts of the year 1902.

What the dealers had predicted or rather felt would be the case, came to pass. When every indication pointed to trouble with the miners, orders came in faster than they could be filled comfortably, and it is a fact, that the business in this vicinity for the month of March, 1912, far exceeded the business for any corresponding period.

Then came the suspension of work at the mines. During this time, while there was a complete cessation of production, the large companies were successful in disposing of quite a quantity of the steam sizes of coal they had in stock. The domestic sizes had been pretty well cleaned out by the demand of the winter previous.

After settlement of the strike, it was perfectly apparent that there was going to be trouble in securing sufficient supplies of coal. During the summer, while the demand was good, it was not insistent in this vicinity, and it was not until the early fall that dealers were unable to secure as much tonnage as they required. It came as welcome news to the dealers that mining operations had been resumed, but it might not have been so welcome, if they had known what difficulty and trouble they were to have in getting supplies of coal later in the year.

Early fall found the dealers very short of all sizes, and this condition continued chronic. The city of Philadelphia receives, almost without variation, about 4,000,000 tons of anthracite coal annually. It is understood, with the year ending Dec. 31, 1912, there will be a falling off in this amount of anywhere from 15 to 20 per cent., owing to the unusual situation that has prevailed since the resumption of mining. There is every indication that this dearth of supplies is likely to last well on into the spring of 1913.

Premium coal came to this city in fairly large quantities, although it is not too much to say that the amount has been probably exaggerated, isolated cases sometimes being taken as a general condition.

It was encouraging to note that the best of harmony seemed to exist among the dealers, and price cutting on any of the sizes was not heard of. Of course, it was an unusual year, but under favorable circumstances, the temptation to secure good business has sometimes resulted in the shading of figures.

With the close of the year retail prices remained: Egg, $6.75; stove, $7; chestnut, $7.25, and pea, $5.25 to $5.50.

The wholesale market enjoyed, of course, its large season of prosperity, being a reflection of the extraordinary demand prevailing, and the operators were hard pressed to know who and what to serve. However, there is every indication that the distribution of what they had was made as equitably as possible, every effort being made to see that each dealer received his fair proportion, and with the handicap of a 12,000,000 to 15,000,000 shortage staring them in the face, it was doubtless very often a difficult matter to place the output where it would do the most good.

Taking the year as a whole, it has been a very prosperous one, referring to one's peace of mind, and the balance sheet of both the wholesale and retail operator is likely to show up on the right side, and compare very favorably with any previous years.

❖ ❖

The Pittsburgh District in 1912

By B. E. V. Luty*

SYNOPSIS—Production in the Pittsburgh district during 1912 was quite heavy, but labor troubles and lack of adequate transportation facilities disturbed operations to such an extent that the year proved to be another unsatisfactory one from a financial standpoint. The most important episode of the year was the favorable decision obtained by the Pittsburgh operators in the Pittsburgh-Lake Rate case, the effects of which were, however, immediately eliminated by an equal reduction on roads in competitive fields. In the Connellsville coke regions, determined efforts on the part of both producers and consumers to control the market, resulted in spectacular fluctuations in quotations, with prices ultimately reaching the highest point in the history of the district.

❖

The Pittsburgh district coal operators, as a whole, experienced another unsatisfactory year in 1912, from the standpoint of financial results. Our review of 1911 noted that the results of that year had been unsatisfactory in this way also. The prospects for 1912 were better, and the tonnage on the whole was good. The cost of mining was increased, through the wage advance, but operators allowed for this. They made close prices and, figuring on a much larger tonnage than in 1911, expected to make a fair profit through reduction in overhead charges per ton. The unsatisfactory financial result, the disappointment in view of the expectations entertained, is attributed to the fact that, on account of short car supply and insufficient labor, operations were very intermittent and the cost of production was accordingly much higher than was anticipated. The supply of cars and labor was not uniformly bad throughout the year, but it was frequently poor, and irregularities, by disturbing plans, produced possibly worse results than would have occurred with a uniformly inadequate supply, which would have caused the plan of attack to be different.

The coal market was seriously disturbed by the unexpectedly quick settlement of the biennial wage scale, an agreement being reached between operators' and the miners' representatives at Cleveland on Friday, March 29. While the men did not return in a body until the referendum vote was completed, the suspension lasted only about three weeks. Probably the general expectation among consumers was that it would last four to six weeks, perhaps longer, and stocks had been laid in accordingly, so that the early resumption of mining found the trade with little demand. Possibly the operators were hastened in reaching a settlement by the fact that on March 1 more than a million men quitted the English coal mines, but that strike did not give the United States the demand that was expected. The wage settlement, for the two years to the end Mar. 30, 1911, was on the basis of an advance in the general mining rate of from 95c. to $1, following a similar advance made in the 1910 settlement.

*627 Oliver Building, Pittsburgh, Penn.

The year opened with circular prices on the basis of $1.15 for mine-run, and these were fairly well held in the first three months, owing to there being a demand for stocking-up purposes against the expected suspension of mining. After the settlement, circular prices were promulgated on the basis of $1.22½, but there was heavy cutting to below even the $1.15 basis, and mine-run coal for a considerable time was easy at about a dollar a ton. With a heavy lake movement, and materially increased demand from manufacturing consumers, prices began to stiffen in the summer and by September a general shortage of coal had developed. The Pittsburgh district could do little toward overcoming this, being handicapped by an insufficient supply of both cars and labor. The difficulty was as much with irregular working by the men as it was with a shortage in the actual number. In October, Pittsburgh coal for prompt shipment practically disappeared from the market, small lots commanding fancy prices. Towards the close of the Lake season one large operator named circular prices on the basis of $1.25 for mine-run, but later, on Nov. 4, the Pittsburgh Coal Co. issued quotations on the basis of $1.30, slack being 90c., nut and slack $1.05, nut, $1.25, mine-run, $1.30, ¾-in., $1.40 and 1¼-in., $1.55.

The scarcity of coal was entirely relieved at the close of the lake shipping season and the market became relatively easy, though with no serious price cutting. Operators showed a fresh determination to secure a reasonable price for coal, and allow for the contingency of irregular working in figuring the cost of production and will no doubt, consider this in the future.

An event of some importance in the Pittsburgh-Lake trade was the reduction ordered in the freight rate, to go into effect May 1, 1912. For many years the rate had been 88c. and the Pittsburgh district operators, in what was called the Boileau case, demanded a reduction to give the district a portion, at least, of the advantage which its location would give it over the West Virginia and Kentucky fields. The Commission ordered a reduction to 78c., but the railroads followed this by lowering the other rates also, so that the discrimination still remained; the operators took up the case again, in their brief No. 3853, but without avail. Upon complaint of the Pittsburgh Vein Operators' Association of Ohio, submitted Apr. 6, 1912, and decided June 6, 1912, the Commission ordered a reduction in the rate from Pittsburgh No. 3 field to Lake Erie from 85c. to 75c., to restore the former differential between the Pittsburgh district and Pittsburgh No. 8.

Connellsville Coke

From November, 1911, to December, 1912, the Connellsville coke region saw the most spectacular advance in prices in its whole history, the advance occurring chiefly in 1912. In November, 1911, furnace coke for prompt shipment could easily be secured at $1.50, and the early contracts made for the first half of 1912 were at $1.55, and $1.60, contracts for the whole year being made at $1.60 and $1.65. Toward the close of December the prompt price advanced sharply, a normal performance as shipments are usually deficient over the holidays. In January, however, the market did not recede, but reached higher levels for prompt, while contract coke sold above $1.75. In April there occurred further advances, coke becoming scarcer on account of coal shipments due to the mining suspension in the union coal mining districts, and prompt furnace coke sold at $2.50 and $2.60.

Half Year Contract Prices Mount to $3.50 Per Ton

Then a number of operators decided to market their product through a Pittsburgh brokerage firm and a price of $2.50 was asked upon second half contracts. The furnace trade immediately arose in arms and a long deadlock ensued. Finally, towards the close of July, with charges and counter charges of bad faith, the brokerage firm withdrew, taking with it a number of contracts it had made for the purchase of coke. Several of the operators thus released made an arrangement with a Uniontown brokerage firm and a period of competition ensued. A condition of great activity in the iron trade had meanwhile produced a heavy demand for coke, while the capacity of the Connellsville region, little if any increased, nominally during the three years preceding when the blast furnace capacity had been materially increased, was not fully available on account of scarcity of labor. To a disinterested observer, the conditions in August seemed to justify a $2.50 contract price much more than did those in June when that mark was set, but contracts were made in August at $2.15 and $2.25. Later, when the question of contracts for 1913 came up, the Uniontown firm sold freely at $2.50. When it was sold out the market continued to advance, and in December the contract market for 1913 was close to $3.50 for the half year and near $3.25 for the year. The nearest recent approach to such prices was in October, 1909, when for a short time the market for 1910 was $2.90 to $3, with a few contracts placed at that range.

The understanding which certain sellers attempted to maintain in the summer seems to have retarded rather than to have accelerated the advance. The final figures of the year were reached under open competitive conditions, and were caused by the very simple fact that the coke producing capacity of the country, at least with the labor supply available, was insufficient to supply the furnaces for the pig iron output for which there was an assured demand. From November, 1911, to December, 1912, the advance in prompt furnace coke was from $1.50 to $4, and in contract from $1.55 and $1.60 to $3.25 or $3.50. As about 2200 lb. of coke are needed to make a ton of pig iron, the advance in the contract price increased the cost of making iron by approximately $2; the advance in this latter over the same period was approximately $4. An advance in ore occurred, increasing the cost of making pig iron by $1 a ton. At the low point for pig iron, there was an actual loss for the average furnace, and with raw materials advanced an equivalent of $3 a ton, the $4 advance simply allowed the merchant furnace to break about even.

The circumstances all showed clearly that the coke producing capacity of the country is insufficient. The building of blast furnaces proceeded more rapidly in the five years 1907 to 1912 than the development of coke making capacity. The capacity of the Connellsville region was practically stationary, naturally enough when at the prevailing rate of output the region would be exhausted in 25 to 30 years.

Market Conditions in Ohio During 1912

By J. W. Lehman*

SYNOPSIS—The year as a whole was fairly satisfactory with an increase in production of about 10 per cent. over 1911. This result was attained despite a month's idleness in April and two periods of car shortage. Perhaps the most striking feature of the entire year was the demand for steam coal which was merely the reflection of industrial prosperity.

The year 1912 was a fairly good one in the Buckeye State both from a tonnage and a price standpoint. Although the former was not as much as in 1910, which was the banner year, but is estimated to be about 10 per cent. over the output of 1911. The estimated production during the calendar year was in the neighborhood of 33,340,000 tons.

Prices were more satisfactory from start to finish. While coal operators and jobbers did not make a large profit on their investment during the year the returns were in the main much more satisfactory than in 1911. Price cutting was less prevalent during the past twelve months and small operators and shippers were able to sell their coal without resorting to shaving quotations. The general tone of the market was healthier and the year 1913 appears with a much better outlook.

The circular put into effect Sept. 1, 1911 by Hocking Valley operators prevailed during the greater part of the year. This circular was generally lived up to although during the summer months there was some discounting from the list and some price cutting. But generally speaking, all operators who had a good grade of coal to sell could get the circular figure. Domestic lump was quoted at $1.50 and ¾-in. screened at $1.35. Mine-run was quoted at $1.15 and nut held at the same figure. The market for the fine sizes such as nut, pea and slack and coarse slack was varied and depended exclusively upon local conditions. Some small inflation occurred just previous to April 1, when large users of steam grades and many railroad companies stocked up to guard against emergencies. The two-year mining scale between operators and miners in the central competitive district expired at that time and there was considerable doubt of an early adjustment. Accordingly many of the larger manufacturing plants laid in a goodly fuel supply and the larger railroad systems stocked thousands and even hundreds of thousands of tons.

Then came the suspension which lasted a full month. In Eastern Ohio districts some of the mines resumed before the month was up, but generally speaking there was an almost complete cessation of work during April. After negotiations which lasted a week or 10 days the new scale was reached, which provided an increase of 5 cents per ton, on the pick-mine plan. Other branches of labor were given a like increase. District meetings were held and the various minor problems were mostly worked out by May 1, when mines in every district were opened. It required several weeks however for the mines to get into full operation.

*69 Rue-gery Bldg., Columbus, Ohio.

The fact of the suspension, coupled with the noticeable revival in manufacturing business after June 1, caused a good demand for all grades. Another aid was the good lake traffic as the docks of the Northwest clamored for all the tonnage possible. The extra severe winter of 1911-1912 had the effect of using all of the surplus tonnage in that section and accordingly there was an unusual demand.

The next circular was issued Oct. 1, the advance being about 10 cents per ton. This was caused by the steady demand for all grades coupled with an increasing car shortage. Domestic lump was quoted at $1.75; ¾-in. screened at $1.55; and mine-run at $1.30. Domestic nut was sold at about the same price as mine-run. The prices on the small sizes again advanced in sympathy and 95c. to $1.10 was the usual figures.

An insistent demand together with a greater scarcity of cars caused another advance Oct. 21. Instead of advancing the price a small amount, the jump was fully a quarter and domestic lump was quoted at $2.00. For ¾-in. the price was strong at $1.80 and mine-run and nut were sold at $1.50 and even higher. Fine sizes were sold on the open market at anywhere between $1.10 and $1.35.

While no special circular was issued in November prices gradually became stronger until $2.25 was the usual quotation for domestic lump and ¾-in. was quoted at $2.00. Run of mine and nut were held as high as $1.75 and even stronger. It was during this period that fine coal at some points reached the $1.50 mark and even higher.

Mild weather caused a slump from the top prices of November and by Dec. 1, the usual quotations had been decreased to the circular figures of Oct. 21. During the latter part of the year a slight improvement was noted in the car supply which coupled with the higher temperatures which prevailed caused a softening. But no great weakness developed and the market is now at the complete mercy of weather conditions and the car supply.

In the other sections quotations ranged about the same, relatively as in the Hocking field. Pomeroy Bend, which is getting to be one of the important mining districts of the Buckeye State has maintained a slightly higher schedule than the Hocking Valley. The differential is somewhere between 15 and 25 cents. The field succeeded in maintaining a $1.65 circular for domestic lump the greater part of the summer although at times some coal was sold at $1.50. But with the appearance of the car shortage, which affected Pomeroy Bend more severely than any other section, prices were jumped until in October and November they were $2.35 to 2.50 for domestic lump and $2.15 to 2.35 for three-quarter inch. Fine coal in this field ranged as high as $1.65 but that point was not maintained for any length of time.

Prices in Eastern Ohio were the last to respond to the increase in other fields towards the latter part of the season. During the early part of the year ¾-in. was quoted at $1.15 and $1.20 and mine-run as low as 95c. and $1. But with the approach of the car shortage in September

prices were strengthened, but it was later before any great increase was noted. During the period of inflation in October and November three-quarter inch was sold as high as $1.65 and mine-run up to $1.50. Course slack, the grade of fine coal produced in that field was sold up to $1.25 but soon fell to $1.10 and $1.15 where it closed the year.

While figures on the year's production are not yet available authorities are busy estimating the output of the Buckeye state. As stated above it is generally conceded that there is a slight advance, likely 10 to 12½ per cent. over the previous year. This means that the production is somewhere between 33,400,000 and 34,000,000 tons.

The largest increase in any field will be in Eastern Ohio although no great development work was done in that section. Belmont County as in previous years shows up the best in point of production with possibly Jefferson County second. In the Hocking Valley, Athens County is the leader with Perry County, second. In the Cambridge field, Guernsey County will show up well with a production estimated as over 3,000,000 and possibly 4,000,000 tons.

Generally speaking the Hocking Valley will have only a slight increase if any over the records of 1911. This is due to the insufficient car supply and to a number of petty strikes which tended to curtail the production. In Meigs County which is the whole of the Pomeroy Bend field the production is estimated at 750,000 tons which is about 10 per cent. increase over the previous year.

The records of the Toledo docks of the Hocking Valley railroad for the year 1912 in comparison with 1911 are very interesting. They show the tonnage handled from Ohio and West Virginia during the past year to be in excess of 1911, 75,000 tons. The modern dock machinery at Toledo is one of the factors of the Lake trade and aids in having the Hocking Valley R.R. act as final carrier in many coal shipments from West Virginia.

Steam prices during the coming year will be much more satisfactory to the operator. Contracts which are being renewed at this time are at a more profitable rate. The lower ones are being increased or dropped altogether and the better ones are being renewed at the old figures. In the department of railroad fuel the most radical changes are contemplated. The low railroad fuel contracts are believed to be a thing of the past in the Buckeye state and this branch of the business will be looked to for its share of profits.

Practically no development work was done in the state during the year. This is partially due to the fact that 1911 was a lean year both as to tonnage and prices and as a consequence there was very little encouragement for any new mines to be opened. But in some instances mines were enlarged and the tonnage increased which makes the net result a better output in Ohio. Very few mines were abandoned because they were worked out and the small tonnage thus lost is more than counterbalanced by increased output from other workings.

Outside of the suspension of a month in April when the wage scale was signed there was practically no labor troubles during the year. Generally speaking labor was plentiful and petty differences were not as numerous as usual. One of the largest and most important troubles was the strike ordered at the mine of the Hisylvania Coal Co. at Glouster where the right to discharge for carelessness is involved. It is expected this strike will be settled in the near future.

⁂

A Brisk Buffalo Market in 1912

SYNOPSIS—Buffalo is a center for shipments to Canada and an important port for upper Lake shipments. Some of the prices asked during the year were fictitious, the jobbers who were shipping coal being temporarily undesirous of local trade.

⁂

The history of the coal trade throughout showed little incident during the early part of the year. Bituminous coal was still dull, as it had been for the whole of the past year or two. The consumer was entirely in control of prices, on account of the light consumption and the over production. Operators complained that they were not always able to make running expenses and some old members of the Allegheny Valley operating trade became so discouraged that they declared without hesitation that they could see no future before it. With the thin seams, so expensive to work, and the price always decidedly lower than that of Pittsburgh coal, it looked hopeless. There was always quite an amount of coal land for sale, but there were no buyers among those who understood the conditions. All that saved the market and kept the mines running was the diversion of Pittsburgh coal to other points on the lakes. Moreover, higher freight rates kept the cheaply-mined West Virginia coal out of the market.

The bituminous jobber was more hopeful. He had less at stake and he always insisted on a profit, though he often worked on a margin of 5c. a ton. In order to make any showing it was necessary to handle a big tonnage and as a rule this was done. Buffalo covers a wide district, not only in this state and eastward, but through Canada, making shipments via Detroit as far west as London, Ont., and getting into Montreal in the other direction and competing with the coal from Nova Scotia. This railroad market does not cover the upper lakes, however. The rate of freight from the mines to the lakes is sufficiently above that from Pittsburgh that such trade is entirely cut off.

On the other hand, the lake movement of anthracite is largest here, having no competition as to tonnage except from Erie, Oswego and one or two minor Lake Ontario ports, which latter usually confine their shipments to ports on that lake or the St. Lawrence River, so that Buffalo ships about five-sixths of the coal which goes by water to the upper lakes.

It has been the custom of certain leading mine owners in Pittsburgh to make a Buffalo price, covering, of course, the freight rate of $1.25 from that district. The price for 1911 had been on the basis of $2.40 net for mine-run. This had been fixed to take effect on Apr. 1, 1911, and business was so dull that even the fall trade did not materially change it and the figures were still in force at the opening of April, 1912. There had been an increase

of mining wages, however, and it was felt that some return must be demanded on that score, so the Buffalo price was made $2.47½ for mine-run, with three-quarter 15, and lump 25c. higher and slack about $2, but subject to more fluctuation.

This price grew steadily stronger as consumption increased through the summer, and anthracite became scarcer, till on the week ending Sept. 20 it advanced to $2.50, with the following further fluctuations through the year: Oct. 11, $2.55; Oct. 18, $2.70; Oct. 25, $2.85; Nov. 22, $3.15; Nov. 29, $2.65 for contract; Dec. 6, $2.90.

Here is a steady advance of 40c. from the low point, which had been maintained for more than a year, or over 17 per cent. In spite of the fact that a great part of the bituminous coal had been tied up in the spring by contracts at $2.10, or so, this at once put the trade on its feet, where it will remain so long as the consumption exceeds the output. An explanation is needed of the peculiarly sharp advance made for a short time in November and the prompt decline a short time later. The prospective closing of the lakes with insufficient coal shipped by that route to last till spring caused the mines in that trade to issue price quotations which were in a sense fictitious, in order to shut off orders. Soon after the closing of the lakes a surplus was produced, and in adjusting itself the market for a short time was too low.

The Allegheny Valley market, which does not depend on the lake trade, did not show either of these fluctuations, and though its coal commonly sells at 15 to 25c. less than Pittsburgh, there was for a short time the anomalous state of the two markets which placed Allegheny Valley coal above Pittsburgh prices. There is not so very much competition between the two, as a rule, as each finds its own market.

In the anthracite trade the shortage has been so great that the year has shown many peculiarities While the larger mines made no advance in price on that account, the independent interests were released from the old arrangement of turning over their coal to the roads at 65 per cent. of the tidewater price, and they at once went into the open market and sold their coal at a premium.

Aided by a hue and cry from the daily press that "coal" was about to advance to $10 a ton, the independent operators early began to get a premium, which in some cases where quick delivery could be assured, rose to $2.50 a ton, and would doubtless have remained there but for the warm fall. On Dec. 20, the premium had fallen to $1.25, on account of the gain made on their shortage by the bigger anthracite companies. On that date a leading shipper declared that with a continuation of the mild weather he would cut out the premium entirely in ten days.

It is common for the anthracite shippers to load a large amount of coal in Buffalo harbor during the winter. The larger sizes commonly accumulate during the latter part of that season, and it is cheaper to put such coal afloat at an extra freight of 10 to 15c. a ton than to stock it, especially since it enables the lake shipments to begin in full strength on the opening of the lakes. So hard was the winter, however, that no coal could be so loaded last spring, and with a two-months' mining suspension to face, there were only 650 tons shipped by lake in April and only 39,600 tons in May, so that the resumption of mining at the end of the latter month found the lake shipments of anthracite from Buffalo about 700,000 tons behind that of former seasons. Only by mighty efforts have they been able to make up that shortage. The following figures will show that this has practically been done:

LAKE SHIPMENTS OF ANTHRACITE BY MONTHS

	1910	1911	1912
March	25,541		
April	418,638	193,325	650
May	482,289	412,694	39,600
June	430,800	590,265	440 250
July	493,450	711,539	606,885
August	522,550	573,466	713,547
September	331,190	428,280	681,421
October	426,250	470,760	759,300
November	486,300	498,650	614,600
December	21,600	38,450	68,600
Totals	3,639,368	3,917,429	3,925,003

The late start in 1911, shown by the above table, is on account of late lake opening, but the suspension of mining is responsible for the lateness in 1912.

TOTAL COAL AND COKE EXPORTS FROM BUFFALO

	Anthracite	Bituminous	Coke
1912, January	99,957	254,267	29,136
February	78,154	276,267	27,476
March	113,845	305,831	35,977
April	19,285	290,492	36,651
May	3,123	169,201	42,275

Totals, 1912	1,234,564	2,609,702	423,524
Totals, 1911	1,695,035	2,620,727	416,069
Totals, 1910	931,378	2,014,762	420,805

Birmingham, Ala.

SPECIAL CORRESPONDENCE

The coal market for the year 1912 has been a cause of much satisfaction, when the whole year is considered. All the owners of well managed mines have profited beyond their expectations and are highly optimistic in regard to the prospects for 1913.

The winter of 1911 and 1912 was about the severest ever experienced and coal business was correspondingly good. To add to this favorable situation the English strike lasted well into spring. The season was unusually cold and wet, and from the first of the year to July 1 all output records were beaten. The expectation of a strike in Pittsburgh on Apr. 1 served to stimulate the market and many users stocked up heavily for fear that the trouble might become nation wide.

During the summer months this artificial market reacted and worked a hardship on many of the mines for a short while. The car shortage has been and is still serious on some of the railroads in the district, and this reduction in tonnage during the fall and winter resulted in abnormal prices on both steam and domestic coals.

The coke market as a whole has been satisfactory and the average price a fair one. The estimated coal output of Alabama for 1912 is 18,000,000 tons which is about 2,000,000 tons higher than the record of 1910.

MONTHLY PRICES OF CAHABA FANCY LUMP DOMESTIC COAL

	1908	1909	1910	1911	1912
March	2 00	2 00	2 10	2 10	2 25
April					
May	2 25	2 25	2 30	2 30	2 35
June	2 35	2 25	2 40	2 40	2 50
July	2 50	2 50	2 55	2 55	2 60
August	2 65	2 50	2 65	2 65	2 70
September	2 75	2 75	2 75	2 75	2 85
October					
November					
December	2 75	2 75	3 00	3 00	3 00
January					
February					

These figures will be interesting to parties who are not in the coal trade and who are prone to condemn the retail coal dealers on account of high profits apparently made by them. However, in justice to the mines producing Cahaba domestic coal, it must be understood that these prices are on Fancy Lump coal, which is the cream of their product. The average price obtained for the entire output of the mines is probably less than one-half the prices quoted.

Mississippi Valley Trade in 1912

By E. J. Wallace*

The year 1912 comes to a close as a rather successful one for the operators in the high-grade fields of Williamson, Franklin, Perry, Jackson and Saline Counties. The prices for the entire year have been above the average, and while, as usual, there was a car shortage that kept the buyer and large consumer in a rather uneasy position, yet it served to keep the price for the greater portion of time above the cost of production, in a field where the supply exceeds the demand.

The threatened suspension of last spring was a stimulant to the market until the bubble burst in April, and there was a curtailing of tonnage from that time until July 1, in order to get the market in a healthy condition. From then on, however, the demand has continued to grow, and with it the price, until at the close of 1912, the Illinois operator has a better looking profit column than for the past three or four years.

The Illinois field lost considerable ground in various sections during 1912, especially in Louisiana, Texas and Arkansas, on account of the expansion of the gas and oil fields. It also lost a large tonnage in the northern markets to the smokeless coals of West Virginia, and is failing to get its proportion of the business in the extreme Northwest on account of the growing popularity of better coals from the states of Wyoming and Colorado. With all this, however, the tonnage in the Illinois field the past year will show an increase of from 8 to 15 per cent.

Very few mines during the past year have been abandoned, while a considerable number of new ones have been opened, and the producing capacities of several others have been increased from 25 to 50 per cent. There are no complete figures at this time to show what the production for 1912 has been, but it is estimated at between 55,000,000 and 60,000,000 tons. The mines of the state can produce fully 100,000,000 tons, while the market for Illinois coal cannot take care of more than a little over half that amount. The over-production has occasionally forced Illinois coals into foreign markets at a price below cost.

The year 1912 has seen the starting of a coke industry in the state, at Joliet and other points in the northern and central sections. This coke is of a byproduct nature and will be used by the United States Steel Corporation and allied companies, in their own plants with little if any going to the open market.

In the inner belt field, which embraces the counties to the east of St. Louis and within a radius of 50 miles, there has been an increased output, but on account of the irregularity of its production it is hard to estimate its amount. This field has been kept down to such an extent that it is doubtful if a majority of the operators will make any money, as they have been practically running their mines without breaking even on the selling end of the business.

In the face of these conditions, new mines are gradually being sunk and the capacities of others increased, and it is a problem as to where this tonnage will move to in the course of the coming year.

St. Louis Coal Trade

Everything considered, the St. Louis market has been unusually good during 1912, as compared with other years.

The year started discouragingly, but the severe weather that followed and the threatened suspension kept the market in a healthy condition until the controversy between the miners and operators was settled. This event had a very distressing effect upon every coal field that caters to St. Louis, for it developed so hastily that hundreds of cars of coal that were being held in storage or which were in transit from outside fields, were thrown upon the market and sold at far less than the producing cost. This kept a poor market from March to July.

Since Aug. 1 there has been a gradually growing demand, with which prices have kept pace so that by the first of October the market went as high as at any time previous to the threatened suspension of last spring. The car shortage and lack of motive power on the principal coal roads in the Illinois field (from which St. Louis draws practically its entire supply) helped keep the prices up until the close of the year.

The past year has seen a big increase in the consumption of smokeless coal and coke—at least 75% greater than 1911, and smokeless fuels will continue to grow in favor. The amount of domestic coke consumed in the St. Louis market for 1912 is estimated at 175,000 tons net. The estimated West Virginia smokeless tonnage at from 75,000 to 100,000 tons. The coke and smokeless coals have displaced a large tonnage of anthracite in 1912, on account of the scarcity of the latter. As a rule there is an annual call for about from 250,000 to 300,000 tons of anthracite, but the irregular movement this year has brought the 1912 tonnage down to perhaps 150,000 net tons.

The Arkansas semi-anthracite field contributed largely in past years to the St. Louis market, but not more than 5000 tons have moved in during 1912. No Missouri coal enters, and only during strike times is there any movement of coals from Indiana or Kentucky.

*St. Louis, Mo.

Lignite in the United States

J. A. Holmes, director of the Bureau of Mines, gives the following table to illustrate the extent of lignite deposits in the United States:

	Lignite. Sq. miles.	Sub. Lignite. Sq. miles.
Alabama	6,000	
Louisiana	8,800	
Tennessee	1,000	
Arkansas	5,900	
Texas	53,000	
North Dakota	31,000	
Montana	7,000	8,800
Wyoming		21,360
Washington		1,100
New Mexico		5,000
Colorado		5,910
Idaho		1,200
Totals	116,700	43,370

EDITORIALS

Statistics of reasonable commercial accuracy, published promptly, are of much greater value to technology and trade than are figures corrected to the last unit, which are printed six months or a year later. We are sure there is a real need for an annual statistical number such as we are publishing today. Considerable time has been spent in an effort to make this issue of COAL AGE worthy of careful attention, and we believe the approximations given in the different reviews will prove to require only slight, if any, revision.

A Suggestion to Mine Operators and State Inspectors

It is a fact that this country, of all the more civilized nations producing coal, is slowest in getting out accurate yearly production statistics. The U. S. Geological Survey, through its Division of Mineral Resources, makes an effort to fill the need for prompt and authentic coal-mining data, but the results have been unsatisfactory.

Perhaps the fault is largely with the federal officials, and undoubtedly the different state mine inspectors as individuals are greatly to blame; however, the owners and operators of mines are not above criticism. Frequently the companies delay their production returns for no reason other than negligence, and thus the work of issuing final figures showing total output is greatly hampered.

There is no reason why complete production figures for every coal company in America should not be in the hands of the chief state inspector one week after the close of the year, and the industry should have the final corrected totals before the end of January.

Then there is the matter of a common fiscal year for each and every state. In a number of cases the year closes June 30; in other instances, Sept. 30 is the time specified. Why can we not have all reports made out for the calendar year ending Dec. 31? Surely this plan would be simpler.

Every coal man in every state is vitally interested in the industry as a whole. Those inspectors who wish to improve both the efficiency and general value of their work, and at the same time gain a reputation for prompt, definite action, would do well to entertain the idea of abolishing the dilatory tactics now so prevalent. Of all abominations to the average mind, none is more abhorrent then archaic facts.

Danger from Water Hammer

The liability of long steam lines to failure through water-hammer is a source of danger not generally recognized around mines. When pumps, fan engines or similar apparatus connected to such lines are shut down, unless they are continuously drained, a large amount of steam is certain to condense in the piping. This should be gradually and thoroughly drawn off before any attempt is made to start the machinery again.

After such a period of idleness even the sudden opening of a large drain valve near the end of the line may have disastrous results. Such a procedure puts the steam and water in the pipe in motion and the latter, provided its amount is sufficiently great, acts precisely as a liquid plunger or piston and strikes any obstruction or sharp bend in its path with the force and suddenness of a blow. This action is particularly destructive to cast pipe or fittings.

A recent accident in an English colliery, which resulted in the destruction of a portion of a long steam line connected to a fan engine, was attributed to this cause. It should be mentioned also, that, in disregarding the instructions of his superior and entirely closing the drain valve while his engine was shut down, and then attempting to draw off the water quickly by fully opening this valve, the unfortunate attendant paid the penalty of his disobedience with his life. Even in coal mining it usually pays to be careful and to obey instructions.

Revision of the Pennsylvania Anthracite Code

The sub-committee of the commission appointed to revise and codify the present anthracite mining laws have recently submitted their report.

The commission appointed by Governor Tener, under the act of 1911, consisted of the folowing: Sterling R. Catlin, state senator, Wilkes-Barre; E. E. Jones, Harford; James E. Roderick, chief of Department of Mines, Harrisburg; H. C. Morgan, Scranton; Martin A. Nash, Glen Carbon; W. G. Robertson, Scranton; Peter O'Donnell, Wilkes-Barre; William D. Owens, West Pittston; William R. Reinhardt, Shamokin.

The commission organized by the election of Senator Catlin, chairman, and Peter O'Donnell, vice-chairman; William W. Hall, Wilkes-Barre, was appointed secretary and counsel. A sub-committee was then chosen to draft a suitable code for presentation to the commission for their consideration. The sub-committee consisted of James E. Roderick, Peter O'Donnell and William D. Owens.

The experience of Mr. Roderick, in the compilation of the first anthracite law (1870), and its amendment in 1885 and, later, as a member of the mine commission, appointed (1907) to revise the bituminous law, together with his knowledge of conditions as chief of the Department of Mines, rendered him capable of outlining to a large degree the work of the committee.

To say that the work of drafting such a code is gigantic, expresses but feebly the measure of the task. The difficulty of adjusting the many conflicting conditions would be and *is* superhuman, except as the several con-

tending parties, each striving for individual interests, are willing to recognize each others' rights, and enroll under a common standard, in the onward march of progress.

Carroll D. Wright, former commissioner of labor, is credited with saying that the difficulties surrounding the adjustment of interests between capital and labor are practically insurmountable, except by a mutual full recognition of the Golden Rule and the application of the principles of Christianity.

This statement, coming from one having the broad understanding of Commissioner Wright, is worthy of the most careful study and earnest consideration. Without the "mutual recognition" of the rights of another, we cannot hope for harmony; and without harmony there can be no permanent progress. Ignore the Golden Rule and it becomes impossible to frame a mining code that will be satisfactory to the operator and miner alike.

The first essential of a mining code is *equity*. The code must define clearly the responsibilities of employer and employee alike. There is no paternalism in the operation of a mine. Every man employed in the mine is responsible, to a degree, for his own safety and that of his fellows. SAFETY is the first consideration, to which the cost of operation must always be subordinate. The responsibility for safety is twofold; it does not rest wholly on the employer, but devolves alike on the employee. This division of responsibility must be clearly defined by the law governing mine operations.

The responsibility of the owner or operator ends with the provision of a recognized reasonably safe equipment and management of the mine and its operations, in conformity to the terms of an adequate mining code. The responsibility of the miner begins when he enters the mine. He must exercise reasonable care, observe proper precautions, possess a fair amount of knowledge of mining conditions, and obey absolutely the regulations of the mine and the instructions of the mine officials and fulfill all the requirements of the mining laws.

To every practical mining man nothing is plainer than the fact that every mineworker must assume certain legitimate risks common to his calling. A mining company does not run an insurance business or guarantee protection of life to employees, beyond a liability for accident due to the neglect or mismanagement of an official, or inefficient equipment.

Speaking of liability for accident, there are at least four responsible sources to which liability for accident may attach, and of these the first two are the only ones that can be said to offer a fair chance of recovery. They are as follows:

1. Neglect of government to provide adequate laws and inspection service;
2. Neglect or mismanagement of officials or inefficient equipment;
3. Neglect, carelessness or ignorance of a fellow workman;
4. Self-neglect, carelessness or ignorance.

Government that does not provide a fair degree of protection for the citizen does not fulfill the purpose of its existence, and such failure is culpable. The failure on the part of any person charged with the official management, supervision, inspection, or operation of certain work, machinery or men, to properly perform his duties, renders the corporation, company, owner, or employee liable for the results of such failure.

The law, however, distinguishes between the act or neglect of an official, for which the company is clearly liable, and that of a fellow workman, for the result of which it is generally held the employer is not responsible more than for accident due to one's own act or neglect.

What the commission will finally do with the report of its committee remains to be seen. An open session is announced to be held Jan. 14, 9:30 a.m., at which time the operators will be given a hearing. Following this, on the 15th, the miners will be heard. Little is to be expected, in the way of harmony, from these hearings. The commission will listen attentively to the presentation of each side; but to devise measures that will satisfy both parties and insure safety is a difficult problem.

One of the contemplated changes in the present law is the return to the previous system of appointing mine inspectors instead of electing them by popular vote, in each district, as has been the practice in the anthracite region since 1901. There can be no doubt, in any unprejudiced mind, that it is an unmitigated evil to expose any official whose duty is that of inspection to the caprices of a popular election. It is clear to the candid mind that such a law tends to develop an artful politician rather than a fearless inspector.

Let us get back once more to the principles of civil-service reform, and work to remove, as far as possible, the office of mine inspector from the influence and control of politics. Let us demand a high grade of intelligence, an ample mining experience and acquaintance with practical conditions in and out of the mine, and a character above reproach, of all candidates for this important office.

The qualifications we mention are rarely combined in man, and when found are not appreciated by contending parties at the polls. The strongest proof of qualification and fitness for office is efficient service, and no one knows better the character of the work performed by state inspectors than the highest state officer, who is ultimately responsible for their every act. This fact alone should recommend the appointive system to every member of the commission who seeks the best interests of mining.

COAL AGE will watch with interest the work of the commission, and will gladly voice the comments of contributors.

Spontaneous Combustion Underground

Depth from the surface is not always a determining factor in the matter of underground mine fires. An example can be given of two collieries working at identical depths and having apparently similar conditions, fires occurring frequently in one case and being unknown in the other. It is clear, however, that if a seam is predisposed to spontaneous combustion, the greater the depth, the greater the danger. The grinding action of the roof will be increased and the natural temperature of the coal will be higher at 2700 ft. than at 2000 ft.

One experimenter recently took the temperature of the strata at a depth of 2660 ft. It was 93½ deg. F. This is exactly the temperature obtained by calculation, allowing a constant temperature of 50 deg. at a depth of 60 ft. and an increase of 1 deg. for every subsequent 60 ft. The British Royal Commission on Mines has fixed the greatest workable depth of coal at 4000 ft. The temperature in such a bed would be 114 degrees Fahrenheit.

DISCUSSION BY READERS

Cost of Mining Anthracite Coal

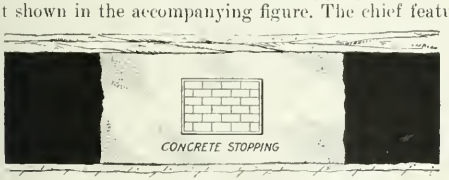
In the excellent article by Eli T. Conner, COAL AGE, Nov. 23, p. 708, he speaks of the propriety of including, in the cost of operation, the charge for coal consumed at the colliery, as is done at well managed bituminous mines. He further states that this is not done, to his knowledge, in the anthracite region.

While it may not appear in the cost sheets of any of the anthracite coal companies, yet it was once the custom with one of the then largest individual producers of anthracite coal, to always include this item in the costs, charging it up on the basis of the price of its cost at breaker. The effort was also made to use but the very small sizes, for local consumption: except in cases where locomotives, which used a larger size, were used, or in cases where there was not a sufficient amount of the smaller sizes made. In such cases the coal for the boilers was often transported from other near-by collieries where the coal was more brittle and small sizes were in excess of the requirements and brought a lesser figure in market. Mr. Conner is correct in stating that this fuel supply should be included, since these small sizes cost as much to produce, less the royalty, as the larger sizes that are sold to the trade. Moreover, no statement of the cost of operation is complete without this item of fuel.

Emergency Stoppings—A Suggestion

Referring to the question of short-circuiting the air current in a coal mine, as suggested in the recent discussion of reversible fans, it occurred to me that the following suggestion of what might be called an emergency stopping would be of value, in this connection.

For some time past I have been building, at certain principal points in the mine, a stopping similar to that shown in the accompanying figure. The chief feature



A So Called Emergency Stopping

in this stopping is that it contains a central opening from 2 to 3 ft. square, supported by a wooden frame, or pit rails may be used for this purpose. This opening is closed by brick masonry, which can be bumped out by a mine post, in case of need. By this means, the air can be quickly short-circuited without damaging the stopping. The main body of the stopping can be of concrete or of brick and masonry, as desired.

Fair Haven, Penn.

Firing Shots by Electricity

In Coal Age, Dec. 14, p. 832, Geo. M. Brown described the conditions under which a violent explosion occurred Nov. 20, 1912, in mine No. 38 of the Rock Island Coal Co., at Alderson, Okla. An electric shotfiring system was in use at the mine, the shots being fired simultaneously, by throwing a switch at the surface when all was ready. The holes were charged and tamped by shotfirers, who also connected the wires. This was the second explosion, in this mine, since the electric shotfiring system was installed.

As the system of firing shots by electricity has been adopted at a number of mines in Oklahoma, the managers of these mines are naturally concerned to know whether this method of firing shots is particularly dangerous or or whether the explosions in Mine No. 38 were the result of local conditions.

The question is: Is it safer to fire all the shots in a mine, together or at one time as a single blast, than to fire the same shots singly, at fixed intervals? A definite answer to this question can only be given with the full knowledge of the conditions in each case. There are, however, certain general features pertaining to shotfiring that should be carefully considered before a final conclusion can be reached regarding the choice of methods in firing shots.

I have often stated that, in my judgment, the presence of a concentrated dust-carrying, return-air current acted upon by a shot's flame, is sure to start a dust explosion. If this be true, it appears that the margin of safety claimed for the method of firing shots singly may be much reduced or wiped out entirely through the absence of anything to prevent the concentration of a strong dust-laden, return current at the face where the shot is fired.

On the other hand, the firing of all the shots in a mine, at one time, may have some dangerous features that are absent in firing a single shot at a time. These dangers, however, may be minimized or eliminated altogether through the prevention of the draft concentration to which I have referred, toward one point. For example, if 100 shots are fired simultaneously their combined power to produce strong draft is, of course, much greater than the draft-producing power of a single shot; but the effect on each shot is very much less. My point is that if every one of the 100 shots fired simultaneously, produced an equal effect, the draft affecting each shot would be less than, say 10 per cent. of that which would be felt by any one of these shots fired singly. Should two or more of the 100 shots fired together develop more heat than the others the greater induced draft toward them would probably still be insufficient, under ordinary circumstances, to produce explosive results.

If then the division of dangerous draft can be considered a protective feature, it would seem that the more extensive the firing area and the greater the number of

shot fired at the same time, the less would be the amount of draft affecting each shot and the more remote the danger of an explosion. From Mr. Brown's statement it appears that, in the mine above mentioned, the shots were fired in sections and not simultaneously all over the mine. This method produced a strong concentration of draft into each section as it was fired; and this may have had considerable influence in starting the explosions.

Regarding the ventilation of mine No. 38, Mr. Brown states: "The ventilating fan is always stopped when the shots are fired, but in this particular mine the natural ventilation is strong. * * * * * I believe that the natural ventilation should be stopped to prevent fresh air from traveling along the entries while the shots are being fired." I share Mr. Brown's belief in this regard. It has been shown in several instances, where dual explosions had set coal or timbers on fire, that subsequent explosions occurred at short intervals and did not cease until the mine openings were sealed air-tight. If the closing of the mine openings prevented explosions in these cases, why not in others?

About a year ago I answered an inquiry asking for my views regarding the value of emergency doors at all the mine openings and in part I gave my opinion as follows: "I believe that, under certain conditions, the use of such doors will prove a great aid in the prevention of dust explosions." When I made that statement one of the conditions I had in mind was the simultaneous firing by electricity of all the shots in a mine. If such emergency doors are used they must be substantially built and be practically air-tight; and they must be rigidly fastened so that they cannot be opened by the force of reaction. This is essential to secure sucess. Explosions have occurred with the shafts partly blocked, they occurred with the shafts nearly sealed up, they ceased to occur after the sealing was complete.

If a theory is right, it is right all the way through. If the manager of a mine, where electricity is used in firing all the shots from the surface, believes that the admission of strong draft during shotfiring time is a menace and shows his belief by stopping the fan, why should he hesitate about closing the mine openings tight at firing time, especially in view of the fact that nobody's life is placed in danger thereby and that the doors need be kept closed only for a few minutes?

JOHN VERNER.

Chariton, Iowa.

Trolley Guards in Low Coal

I was interested in the inquiry of Robert J. McTaggart, COAL AGE, Dec. 7, p. 808, in regard to suitable protection for the trolley wire, in mines. I am familiar with the conditions in Mr. McTaggart's field, and, as our own conditions are similar, and we have experienced the same difficulty, I thought the following suggestion would be helpful.

In our mines we have adopted a system that I believe to be vastly superior, cheaper, and more convenient than anything so far described. The system is in use at our Carney mine, and has proved very satisfactory. Holes are drilled in the roof and ⅝-in. expansion bolts are used to support a stirrup, as shown in the accompanying Fig. 1. This stirrup is a piece of strap iron 1x⅜ in., bent so as to provide a 4-in. hook or hanger on each arm of the stirrup. The stirrup straddles the trolley wire without touching it, and supports 4-in. pieces of yellow pine, 1 in. thick and 14 ft. long.

These wooden strips form a sufficient guard for the protection of the trolley wire. They possess the advantage that they are easily put up or removed at any

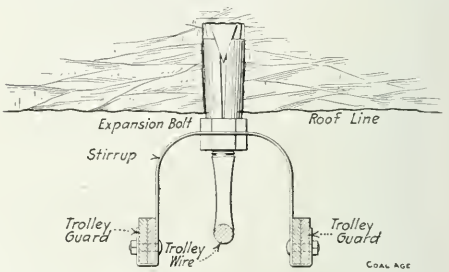

FIG. 1. SHOWING A SIMPLE FORM OF TROLLEY GUARD

time when desired. In our experience, we have found no nails or fastening of any kind necessary to hold the boards in place, although many prefer to bolt the strips to the stirrup, using a ½x3½-in. bolt for this purpose.

THOMAS FISH.

Latrobe, Penn.

Another Letter—The swinging board forms what may be called a shield for the trolley wire and serves several purposes. It has the following advantages: It is easily installed and, because of its swinging motion, the board is not as easily broken or torn down by being struck by anything passing under it.

The cut shown, Fig. 2, explains clearly the manner of hanging the boards by means of drift bolts in the roof. The drift bolts are of the ordinary expansion type having a hook at the lower end of the bolt. The eye hasps are

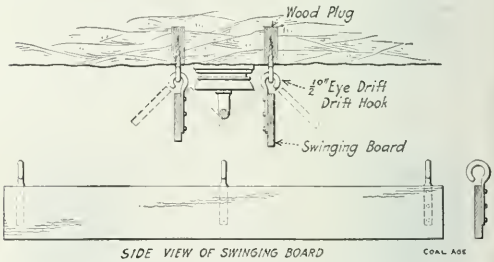

FIG. 2. A SWINGING BOARD TROLLEY GUARD

secured to the boards by ⅜x1½-in. bolts, or they may be nailed firmly to the board. These hooks should be turned outward and at right angles to the trolley wire, while the eye of the hasp is parallel to the board or wire. The hooks are first placed in position in the roof and care must then be taken to space the hasps at the same distance apart on the board. The dotted lines, in the figure, show the position to which the board swings when struck by anything passing under it. For shielding the wire on curves, shorter lengths of boards can be used.

E. J. CHRISTY, Electrician,
The Troll Mining Company.

St. Clairsville, Ohio.

EXAMINATION QUESTIONS

Illinois Examination Questions

(*Answered by Request*)

Ques.—In what time can an engine of 40 effective horsepower pump 4000 cu.ft. of water from a depth of 360 ft.?

Ans.—The weight of water to be lifted is

$$4000 \times 62.5 = 250{,}000 \text{ lb.}$$

To lift this weight of water from a depth of 360 ft. will require

$$250{,}000 \times 360 = 90{,}000{,}000 \text{ ft.-lb.}$$

With 40 effective horsepower, there will be available to lift the water

$$40 \times 33{,}000 = 1{,}320{,}000 \text{ ft.-lb. per min.}$$

The time required to raise this water is then

$$\frac{90{,}000{,}000}{1{,}320{,}000} = 68.18 \text{ min.; or 1 hr., 8.18 min.}$$

Ques.—With a water gage of 0.4 in., a fan is making 80,000 r.p.m. and producing, at this speed, 35,000 cu.ft. of air per minute. What quantity of air will this fan produce, at the same speed, under a water gage of 0.8 in.?

Ans.—Assuming the efficiency of the fan remains unchanged, the power on the air will be the same for the same speed of the fan. The power on the air remaining constant, the volume of air in circulation varies inversely as the pressure per square foot. In other words, the volume ratio is equal to the inverse pressure ratio. Calling the required volume of air x

$$\frac{x}{35{,}000} = \frac{0.4}{0.8} = \frac{1}{2}$$

$$x = \frac{35{,}000}{2} = 17{,}500 \text{ cu.ft. per min.}$$

If the fan is properly designed, the efficiency of the ventilator will be increased, under the increased water gage; and, as a result, a larger proportion of the power becomes effective on the air and a less indicated horsepower of the engine is required to produce the same speed of the ventilator; but, for a *constant* power of the engine, the volume of air in circulation may be considerably increased under the increased water gage. It is difficult to tell what any particular fan will do, under these conditions, because so much depends on the type and construction of the fan and the speed for which the fan is designed.

Ques.—There is 10,000 cu.ft. of air passing on an airway, having a rubbing surface of 24,000 sq.ft. and a sectional area of 20 sq.ft.: what is the water gage producing this circulation?

Ans.—The unit of ventilating pressure, in this case, is

$$p = \frac{ksq^2}{a^3} = \frac{0.00000002 \times 24{,}000 \times 10{,}000^2}{20 \times 20 \times 20} = 6.0 \text{ lb.}$$

The water gage corresponding to this ventilating pressure is, then

$$w.g. = \frac{6.0}{5.2} = 1.15 \text{ in.}$$

Ques.—What horsepower will an engine exert when yielding 60 per cent. of duty (efficiency 60 per cent.) and circulating 100,000 cu.ft. of air per minute, under a water gage of one inch?

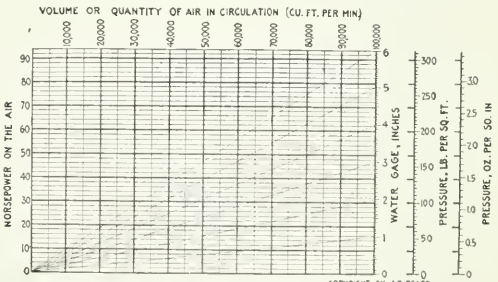
Ans.—The work performed, or the effective work per minute is

$$H = \frac{Qp}{33{,}000} = \frac{100{,}000 \times 1 \times 5.2}{33{,}000} = 15.75 \text{ hp.}$$

If the efficiency of the engine is 60 per cent., the indicated horsepower of the engine is

$$I.hp. = \frac{15.75}{0.60} = 26.25 \text{ hp.}$$

For the sake of illustration, we insert here a convenient diagram for finding the horsepower required to pass



POWER-VOLUME-PRESSURE DIAGRAM: To find the power required to pass any given volume of air against any given pressure of water gage, follow the diagonal line corresponding to the given water gage to its intersection with the vertical line corresponding to the given volume and read this point of intersection on the power scale at the left of the diagram. For example, it requires 50 hp to pass 80,000 cu. ft. of air per minute, under a 4-inch water gage or, reversing the order, 30 hp will pass about 96,000 cu. ft. per minute under a 2-inch gage. Since the power is proportional to the quantity and pressure alike, in order to deal with higher values than those given in the diagram, it is only necessary to treat these as multiples of the values given in the diagram. Thus, 100 hp. would pass 160,000 cu. ft. under a 4-inch gage, or 320,000 cu. ft. under a 2-inch gage. The horsepower in this diagram is the power on the air, which is commonly, in fan practice, 60 per cent. of the horsepower at the engine or the i.hp.

any quantity of air under any given water gage or pressure, expressed in pounds per square foot, or in ounces per square inch. In fan ventilation, the ventilating pressure is often expressed in ounces per square inch. The diagram needs no further explanation than what is given.

Ques.—A mine is producing 40,000 cu.ft. of air per minute, with 10 hp.; how many horsepower will be required to produce 60,000 cu.ft. per min., in this mine?

Ans.—The effective horsepower or the horsepower on the air varies as the cube of the quantity of air in circulation. In other words, the horsepower ratio is equal to the cube of the volume ratio. Therefore, calling the required effective horsepower, in this case, x

$$\frac{x}{10} = \left(\frac{60{,}000}{40{,}000}\right)^3 = \left(\frac{3}{2}\right)^3 = \frac{27}{8}$$

$$x = \frac{10 \times 27}{8} = 33.75 \text{ hp.}$$

This relation does not hold in regard to the indicated horsepower of the engine, since there is a change in the efficiency of the engine, as the speed of the fan is increased.

Chronology of Coal Mining in 1912*

JANUARY

Jan. 1—Virginia Iron, Coal & Coke Co. secured a $9,000,000 contract for furnishing locomotive fuel to the Boston & Maine R.R.

Jan. 4—Meeting of the Western Federation of Miners at Denver, Colo.

Jan. 5—Shops and engine house at the drift mine of the Davis Coal & Coke Co., at Thomas, W. Va., destroyed by fire. Loss, $12,000.

Jan. 7—Portion of the plant of the Galloway Coal & Coke Co., Carbon Hill, Ala., destroyed by fire. Loss, $50,000.

Jan. 10—Committee appointed by Gov. Tener to revise and codify anthracite mining laws of Pennsylvania.

Jan. 15—U. S. Supreme Court rendered decision upholding an employers' liability act as constitutional.

Jan. 16—American Federation of Coal Operators permanently organized at Chicago. The 23d annual convention of United Mine Workers of America met at Indianapolis.

FEBRUARY

Feb. 2—Breaker and colliery building of the Connell Anthracite Coal Co., Bernice, Penn., destroyed by fire. Loss, $150,000.

Feb. 6—Boiler and engine houses of the North Breeze Coal Mining Co., Breeze, Ill., destroyed by fire. Loss, $50,000.

Feb. 18—Plant of the Knickerbocker Briquette Co., Murphysboro, Ill., destroyed by fire. Loss, $100,000.

Feb. 22—Fire in No. 5 mine of the Western Coal & Mining Co., Lehigh, Okla., resulted in the death of eight men.

Feb. 29—Over 1,000,000 coal miners in Great Britain went out on strike for a minimum wage.

MARCH

Mar. 13—Anthracite operators formally rejected mine workers' demands.

Mar. 15—Officials of the United Mine Workers refused counter proposition of the anthracite operators.

Mar. 19—Interstate Commerce Commission ordered a 10c. reduction on the Pittsburgh-Lake freight rate.

Mar. 20—Conference between bituminous operators and miners opened in Cleveland, Ohio.

Mar. 29—Compromise agreement effected between bituminous operators and miners in conference at Cleveland.—Supervision of work in anthracite mines of Pennsylvania was ordered by offinials of United Mine Workers.—Bill providing minimum wage for miners became a law in Great Britain.

APRIL

Apr. 2—Complete suspension of work at anthracite mines of Pennsylvania, and at a large percentage of bituminous mines in central competitive field.

Apr. 6—Coal strike in Great Britain officially declared at an end.

Apr. 10—Bituminous miners ratified Cleveland wage scale agreement.—Conference of anthracite operators and miners opened in Philadelphia.

Apr. 18—Fifty thousand miners in Pittsburgh district returned to work.

Apr. 20—Central Pennsylvania miners and operators agreed on a two-year contract.

Apr. 25—Two-year bituminous wage scale contract formally signed at Indianapolis.

MAY

May 1—Wage scale agreement reached in Kanawha field of West Virginia.

May 2—Representative of anthracite miners refused to accept agreement reached by subcommittee of miners and operators, Apr. 25.

May 6-11—Serious rioting in various parts of anthracite field.

May 7—Illinois miners voted to accept wage scale and returned to work. Contract signed May 17.

May 11—Miners of western Kentucky voted to return to work, pending arbitration over wage scale.

May 15—Wage scale agreement for Hocking district, Ohio, signed.

May 18—Convention of anthracite miners voted to accept agreement of Apr. 25. Contract signed, May 20; general resumption of work, May 22.

May 29—Iowa miners voted to accept proposed agreement and return to work.

May 30—Wage scale contract signed for Missouri, Kansas, Oklahoma and Arkansas.

May 31—Wage scale contract signed for bituminous field of Indiana.—Miners attacked guards in Paint Creek district, W. Va.

JUNE

June 1—Striking miners evicted from company houses of Great Lakes Coal Co.

June 3—Miners on strike in Terre Haute section, Indiana, returned to work.

June 10—Wage scale agreement between operators and miners of Pomeroy Bend, Ohio, signed.

June 21—Interstate Commerce Commission denied further reductions on bituminous coal from Pittsburgh district to Great Lakes.

June 28—Fire at Twin shaft, Pittston, Penn.

JULY

July 1—Attorneys representing miners of Paint Creek district asked court for injunction to restrain coal operators from maintaining guard system.

July 8—Majority of mines of the Spadra anthracite coal field, Arkansas, started up.

July 23—Union mine of Sullivan, Ind., idle during miners' strike, resumed work.

July 25—Continental Coal Corporation opened up five new mines at Wallsend, Ky.

AUGUST

Aug. 1—Extension of the Western Maryland R.R. to Connellsville, Penn., put in operation.

Aug. 7—Girard colliery at Ravens Run, Penn., destroyed by fire. Loss, $175,000.

Aug. 9—Fifteen hundred more miners went on strike in Kanawha field, W. Va.

Aug. 12—Western Allegheny R.R. Co. placed in hands of receiver.

SEPTEMBER

Sept. 12—Experimental mine explosions conducted at Bruceton, Penn.

Sept. 20—Eight thousand men went on strike at Pottsville, Penn.

Sept 25—Several small railroads in southwestern Pennsylvania consolidated with the Baltimore & Ohio R.R.

OCTOBER

Oct. 12—Forty-five perished in fire in North Mount Lyell mines, caused by blowing out of a motor fuse.

Oct. 25—Strike in Kanawha field spreads to Solvay Collieries Co., Kingston, W. Va.

Oct. 26—First anual field day of Penn. Soc. Mine Foremen.

Oct. 29—Celebration of John Mitchell Day in anthracite region.

NOVEMBER

Nov. 2—One thousand miners employed at the No. 5 mine of the Lehigh and Wilkes-Barre Coal Co., went out on strike owing to the employment by the company of nonunion men.

Nov. 11—Mines of Lawrence County, Ohio, terminate a two-year strike and men return to work.

Nov. 13—First meeting of the Rocky Mountain Coal Mining Institute, Denver, Colo.

Nov. 16—Martial law again proclaimed in Paint Creek district.

DECEMBER

Dec. 9—December meeting of the Kentucky Mining Institute held at Lexington, Ky.

Dec. 10-11—Winter meeting of the West Virginia Mining Institute, at Parkersburg, W. Va.

Dec. 13—Remainder of troops withdrawn from West Virginia strike zone.

Dec. 18-19—Meeting of Coal Mining Institute of America at Pittsburgh, Penn.

*Accidents and explosions have been omitted.

COAL AND COKE NEWS

Washington, D. C.

Prof. Emory R. Johnson, of the Isthmian Canal Commission, in a statement this week concerning the effect of the Panama Canal on the cost of shipping coal, says that attention should be called to the fact that in trading with Pacific countries the fuel expenses of steamers engaged in the commerce of the eastern United States would be less than the expenses of steamers operated over routes between Europe and Pacific countries.

The cost of coal at Panama would be at least $1 per ton less than at Mediterranean ports and at the Suez Canal, according to his estimate, and the coal at stations along the Eastern seaboard of the United States would be fully $1 per ton less than at European stations. Relative fuel expenses via the Panama and Suez routes will work to the advantage of the Panama Canal and of the commerce of the United States carried on through that canal with Pacific countries in competition with the commerce of Europe carried through the Suez Canal to the Orient and Australia.

In considering the relation of the canal to the development of American trade, factors other than transportation facilities should receive careful attention. In fact, transportation costs and facilities, though of great importance, are only one influence affecting the volume and direction of international trade.

Professor Johnson's analysis of the situation at Panama is being read with great interest by members of Congress who have concerned themselves with the competitive side of canal operation.

A DECISION OF THE INTERSTATE COMMERCE COMMISSION

The Interstate Commerce Commission has rendered a decision in the case of the Thomas W. Gilmore Co. vs. the Chicago & Northwestern R.R. Co. This case related to carload shipments of bituminous coal to the complainants at Rose Hill, Ill., the freight charge being 20c. per net ton in excess of the charge for similar transportation to Ravenswood, Ill., a point in the Chicago switching district. On anthracite coal the charge to Rose Hill is 10c. per ton greater than to Ravenswood.

It was held that this rate situation subjects the complainants to unjust discrimination and Rose Hill to undue prejudice and disadvantage, and the differential was reduced on interstate shipments to not over 5c. per ton on coal in carload lots to Rose Hill—such 5c. to be in excess of the charge for similar transportation to Ravenswood. The decision is of some interest as an incident in the general rate controversy between anthracite and bituminous shippers.

ANTHRACITE PRODUCTION DECLINES IN 1912

According to data compiled by the government, all records for the production of coal in the United States were beaten in 1912, taking hard and soft coal together, although the production of hard coal alone fell below that of many previous years. It appears that taking the figures up to the beginning of December (those for that month not being yet available), and assuming that the month's shipments were the same as in December of last year, the total tonnage of anthracite for the year 1912 will amount to 63,781,503 tons—a smaller tonnage than for any year in the last six except 1909, when the shipments were 61,909,885 tons.

Omitting the quantity sold to the local trade and to employees, which may be estimated at about 3% of the total shipments, it would appear that the total marketable output of anthracite in 1912 was 65,694,948 tons, as compared with 72,000,000 in 1911. This does not include the coal used in the operation of the mines themselves.

Suspension of work for about seven weeks last spring is accepted as the cause for the falling off in output. The idleness of the mines during the period in question caused a loss of about 11,000,000 tons, but after the suspension, the mines were operated on a full-time basis in the attempt to make up some of this deficiency. This cut the deficit of 11,000,000 tons down to about 6,000,000.

Retail prices, it is reported, have been maintained at the regular figures by the larger companies, but premiums of from 50c. to about $1.50 per ton have been paid up to the first of January for independent coal. It is believed that the closing of navigation on the Great Lakes will now concentrate shipments in the Eastern markets, so that there will be an ample supply of coal for all consumers during the coming winter.

PENNSYLVANIA

Anthracite

Centralia—The strike, which was declared here because mine officials discharged several union men who refused to work over-time, ended Dec. 30. Fifteen hundred employees have returned to work after an idleness of two weeks.

Wilkes-Barre—Thomas Kennedy, president of the anthracite mine district No. 1., has served notice that the union miners throughout Pennsylvania would fight the proposed changes in the mining laws which are expected to come up at the coming Legislature.

On Dec. 27, miners from all parts of the anthracite region formed a meeting of the State Mine Code Commission to show their contempt for the proposed changes in the mining code. Mine leaders have brought delegations to fight against allowing the Governor to name mine inspectors instead of letting people elect them.

Four hundred employees of the Dodson No. 12 colliery of the Plymouth Coal Co. have been thrown out of employment as a result of a fire which started two weeks ago in the west plane of the Red Ash vein. The flames still remain unextinguished, although excellent headway is being made by those who are fighting the fire. Until they have been subdued, the colliery will remain idle.

The walling in of the fire in the Kidney vein of the Parrish Coal Co. is progressing so rapidly that it is expected that the 500 men thrown out of employment as a result of this fire will be back on the job in a short time.

Reading—Fire which burns stubbornly at Mt. Carmel, and which has hampered the fire fighters in their efforts to battle with the flames has destroyed about $29,000 worth of property.

Scranton—The breaker boys and a number of the outside hands at the Capouse colliery of the Scranton Coal Co. in Keyser Valley, went on strike because of the refusal of a half-dozen men and boys employed about the breaker to join the miners' union. The colliery was closed down for the day, when the boys left the chutes, laying about eight hundred men idle for the day. Within an hour after the strike had been called, the non-union men had agreed to join the union, but by that time the boys had scattered, and no attempt was made to resume work for the day.

Tamaqua—Eight of the nine miners entombed behind a barrier of coal and rock in the East Lehigh colliery for forty hours, were rescued alive standing in 4 ft. of water. One of their number had met death by drowning, and his remains were discovered soon after the rescue of the others.

Bituminous

Charleroi—The Union Supply Co. distributed more than 50,000 presents among the thousands of youngsters about the coke plants of the Connellsville region on Christmas day. Not only were the youngsters taken care of, but the poor and needy were also remembered in a suitable way.

Williamsport—Soft coal miners from central and western Pennsylvania have appeared before a committee of the Legislature and presented four bills which they would like to have enacted. One bill provides that a man has to serve two years in the capacity of laborer before being granted a certificate. This is similar to the law governing anthracite mining. Another bill prohibits electricity in gaseous mines. The third is directed against the use of machines with which to rob pillars, and the fourth has to do with certain age limits.

Pittsburgh—Director J. A. Holmes, of the United States Bureau of Mines, is quoted as saying that Pittsburgh is the proper place for the mine testing station and that he would be sorry to see it removed.

WEST VIRGINIA

Charleston—It is reported that the situation in the strike zone on Paint and Cabin Creek is again growing threatening. Outbreaks on the part of striking miners would cause little surprise at any time. The fact that no proclamation lifting martial law was issued when the troops were withdrawn two weeks ago leads many to believe that martial law is still in effect.

Notwithstanding the labor troubles in the Kanawha coal field during the greater part of the year, the coal production of West Virginia for 1912 far exceeded that of any other year. This is a statement issued Dec. 30 by Edward W. Parsons, coal statistician of the Geological Survey. The total production in the state for the year ending June 30, 1912, is reported as 66,731,587 tons.

OHIO

Columbus—A decision in the case of the Government against various railroad and coal companies handed down Dec. 30, which declares the companies guilty of restraint of trade in violation of the Sherman law, makes imperative the sale of 100,000 acres of coal land now owned by the roads involved and the Sunday Creek Coal Co., together with stock in other railroads by which the alleged monopoly was formed.

The decision further orders that the joint ownership of the Kanawha & Michigan by the Chesapeake & Ohio and the Lake Shore & Michigan Southern must be terminated.

Flushing—An explosion in the Lafferty mine of the Pittsburgh & Belmont Coal Co., near Morristown, Dec. 31, resulted in the death of one man and the serious burning of another.

INDIANA

Clifton—Deering Mine No. 1., where an explosion occurred nearly two years ago, costing the lives of two shot-firers and damaging the property, has resumed work. A new system of shot-firing, calculated to make the work safer, has been adopted. More time will be demanded of the men firing the shots. The first coal loaded out was two cars which was left from the firing of the two men who were killed.

ILLINOIS

Springfield—The governor of Illinois has appointed as members of the Illinois Mine Rescue Station Commission, Thomas Moses, General Superintendent of the Bunsen Coal Co. as one of the operators in place of the late W. W. Taylor, and J. M. Zimmerman, representing the United Mine Workers of America, in place of Charles Krallman, recently resigned.

The following members have been appointed on the Mining Investigation Commission: H. H. Stoek, J. A. Holmes, J. E. Williams, Richard Newsam, G. W. Traer, Thos. Jeremiah, Benj. Williams, Geo. McArtor, Wm. Hall.

This commission was authorized by the last session of the Illinois Legislature and was given power and authority to investigate methods and conditions of mining coal throughout the state with special reference to the safety of human lives and property, and the conservation of the coal deposits.

UTAH

Salt Lake City—Word has reached here of the discovery of quite a bed of anthracite coal in the southern part of Utah, near Cedar City.

The existence of coal in this locality has been known for some time, but it fell to the present prospectors to determine the quality and extent of the deposit.

Of late a large amount of work has been done, the main portion being confined to what is known as Tunnel No. 3. This tunnel has been cleaned out and extended until it is now approximately 180 ft. in length. It has been timbered the entire length and is in good condition.

This tunnel encountered five veins of coal, vein No. 2 measuring 18 in. of pure semi-anthracite, vein No. 3 has 4 ft. of the same quality, while veins Nos. 4 and 5 have a minimum of 5 ft. of the best kind of fuel.

If further investigation confirms the report that the coal is semi-anthracite, there is no doubt but that a ready market can be had in Utah and California. The field is located to the east of the San Pedro, Los Angeles & Salt Lake R.R., and it would be necessary to build a spur in order to open up the deposit.

At present the anthracite consumers are supplied by the Pennsylvania and Colorado mines and a good development in the intermountain territory would be welcomed and no doubt would draw its share of the trade. Such a development should also be able to successfully meet any price competition.

PERSONALS

President Walker of the Illinois section of the United Mine Workers has been selected to represent the American Federation of Labor at the British Trade Congress.

Burke H. Keeny has been appointed Western manager of the Bewley-Darst Coal Co., Bristol, Tenn., with offices at 505 Neave Building, Cincinnati, Ohio. He will thus be enabled to handle the business of the company in the states of Kentucky, Ohio, Indiana, Michigan and the West.

OBITUARY

James M. Laing, aged 43, was instantly killed at Berlin, on Cabin Creek, West Virginia, by a runaway car on an incline. Mr. Laing is a wealthy coal operator in the New River, Kanawha and Elk River districts, and is the brother of John Laing head of the state department of mines. He is survived by a wife and children.

BOOK REVIEW

CARBONIZATION OF COAL: A Scientific Review of the Formation, Composition and Destructive Distillation of Coal for Gas, Coke and Byproducts. By Vivian B. Lewes, professor of chemistry, Royal Naval College, Greenwich; 315 pp., 5½x8½, 27 ill. John Allan & Co., 8 Bouverie St., E. C. Clothboards, 7s. 6d.

This book is a reprint with considerable modification of Mr. Lewes' interesting Cantor Lectures delivered in the winter of 1911 before the Royal Society of Arts. Much of the introductory part we have published in its original form. We have also made frequent reference to it editorially, and found it necessary to dissent from some of the conclusions reached.

Mr. Lewes frankly says "Many of my views will not, I fear, be acceptable to all my readers." We cheerfully acknowledge that whether intended for us or not, it describes us to a nicety, for, to many other things we may yet take

editorial exception. But it is not an inferior book which we have to review, or it would not arouse our fighting spirit.

We are afraid that the clippings we have made from the Cantor lectures will give a false impression of the present work. Much is purely chemical, it is true, but a description of present and past coke ovens and gas retorts together fill 50 pages and in these occur most of the illustrations.

There are several pages on tar, its formation, use, and decomposition, some on coke, the nitrogen and sulphur of coal and their recovery, and a concluding chapter on modern coal gas. Every manager and engineer today should be preparing himself for the rapid introduction of byproduct ovens and for the technical skill that introduction will involve.

We are sure that all such far-sighted men will want to read this inquiry into the carbonization of coal. The reader may frequently bristle with dissent, but he will be interested, for the book is by no means dull and we owe a debt to Mr. Lewes for his willingness to propound theories which are sure to aronse dissent.

A common English fault is that of writing long sentences, which turn the reader from an analysis of the thought to a consideration of the grammatical structure. It is strange that in the land of Tyndall, there are so many offenders. We formerly classed V. B. Lewes among them, but a disintegrator seems to have gone to work at his sentences and broken them up into "prepared sizes." As a result our anticipated criticism is almost entirely disarmed.

CONSTRUCTION NEWS

Monongahela, Penn.—It is said the new plans for the improvement of Mongah mine embrace among other things a new main entry, which will be much lower than the present opening.

Duluth, Minn.—The Lehigh Valley Coal Co. is tearing down parts of a coal dock structure built several years ago at its Tower Slip plant in order to make room for modern improvements. It is understood that the present coal dock will be converted into a hard coal storage plant.

Birmingham, Ala.—The Pratt Consolidated Coal Co., one of the largest coal concerns in the southern field, has just awarded a contract to the Roberts & Schaefer Co., for the designing and building of a complete 1000-ton Stewart coal washing plant, storage bins, and steel tipple to replace the structures recently burned at their mines at Banner, Alabama. Approximate contract price $60,000.

NEW INCORPORATIONS

Portsmouth, Ohio—The Cliff Coal Co.; increase from $30,000 to $40,000.

Indianapolis, Ind.—The Pan Handle Consolidated Coal Co. has dissolved.

Peoria, Ill.—The Eastern Coal Co.; number of directors decreased from 5 to 3.

Boonville, Ind.—The Wilson-White Coal Co. has changed its name to Cypress Creek Coal Co.

Wilmington, Del.—The Electric Coal Co.; to do a general coal business; capital stock, $100,000.

Indianapolis, Ind.—The Terhune Coal & Mining Co. and the Central Coal & Mining Co. have been dissolved.

Louisville, Ky.—The Low Ash Coal Co.; capital stock, $25,000. Incorporators, C. R. Hunt, E. N. King, W. O. Alden.

Danville, Ill.—The Beech Flats Coal Co.; capital stock, $100,000. Incorporators, W. G. Hartshorn, Grant Holmes, C. J. White.

Ashland, Ky.—The Big Sandy Fuel Co.; capital stock, $10,000. Incorporators, Ralph Chatfield, V. M. Chatfield, O. P. Chatfield.

Pittsburgh, Penn.—The Fleschter Coal Co.; capital, $200. Incorporators, Alfred Fleschter, Roca Fleschter and Paul Fleschter.

Nokomis, Ill.—The Fayette County Coal Co. has been organized and will take up at once 32,000 acres of coal in this county.

New York, N. Y.—The Carter Coal Co.; capital $5,000,000. Incorporators G. L. Carter, S. R. Jennings, J. C. Stone, Johnston City, Tenn.

Ottawa, Canada—The Canadian Gazette announces the incorporation of the London Land & Coal Co., of London, Ont., capital $2,000,000.

Wilmington, Del.—Bronx Mining Co.; capital stock, $325,000. Incorporators, J. M. Frere, Jos. Zurita and C. L. Hearn, Wilmington, Del.

Astoria, Ill.—The Astoria & Woodland Coal Co.; name changed to the Eclipse Coal Mine and capital stock decreased from $2400 to $1200.

Elmore, W. Va.—Mead Pocahontas Coal Co.; authorized capital, $60,000. Dr. J. A. Wood, J. Edward Cox, J. C. Sullivan, W. G. Hubbard and E. H. Mead.

Tice, Ill.—The Coal Bank Mining Co.; capital stock, $1000; mining and marketing coal. Incorporators, J. P. Grosbill, H. V. Nelson, Mrs. M. N. Grosbill.

Mullens, W. Va.—Trace Fork Coal Co.; authorized capital, $75,000. Thos. F. Bailey, Jr., J. C. Sullivan, W. G. Hubbard, K. S. McClanahan and E. F. Hoover.

Queens, N. Y.—Home Coal Co., Inc., real estate, etc.; capital, $25,000. Incorporators are H. A. Beiler, H. W. Hach, Richmond Hill; J. C. Garbe, Woodhaven.

Montgomery, Va.—Red Eagle Coal Co. filed articles of incorporation. Capital $50,000. The home offices of the company will be located at Blocton in Bibb County.

Portland, Me.—Jaulin Alaska Mines Co.; capital $2,000,000. Promoters, Albert F. Jones, T. L. Croteau, Albert A. Richards, B. M. Maxwell, N. B. Farnham, Portland, Me.

Manhattan, N. Y.—Alaska Kougarok Co., Inc.; mines and mining rights; $200,000. Howard I. Seney, William Kennelly, Felix Valdes, 237 Lexington Avenue, Manhattan, N. Y.

Grafton, W. Va.—The Preston Fuel Co.; capital stock, $300,000. Incorporators, Buckner Clay, G. E. Price, R. M. Price, A. C. Collins, R. S. Spillman, all of Charleston.

Clearfield, Penn.—An application will be made Jan. 14 to the Governor of Pennsylvania for a charter for an intended corporation to be called the Nevling Coal Mining Co.

Tallula, Ill.—The Menard County Coal & Mining Co.; capital stock, $20,000; to mine coal, manufacture ice and deal in both. Incorporators, T. A. Tomlin, John Schome, S. O. Savage.

McAlester, Okla.—The Lane Coal Co.; capital stock, $50,000. Incorporators, S. W. Lane, Wewoka; W. J. Baber, J. Fred Miles, Tulsa; A. L. Latimer, McAlester; W. C. Ellis, Fort Worth.

Philadelphia, Penn.—Application will be made, Dec. 30, by James J. Reilly, Harold A. Schumann and L. E. Marter, for the charter of an intended corporation to be called the Schumann Coal Co.

Scranton, Penn.—Application will be made Jan. 13, 1913, by John R. Williams, Joseph W. Noble and William H. Jessup for the charter of an intended corporation to be called the Noble Williams Coal Co.

Columbus, Ohio—The Red Ash Pocahontas Coal Co.; capital stock of $10,000; to mine and deal in coal. Incorporators, W. H. Plant, Ethel M. Plant, P. W. Barricklow, Margaret M. Barricklow and E. W. Parker.

Cleveland, Ohio—The Pennington Mining Co.; capital stock, $100,000; mining and dealing in iron ore and coal. Incorporators, J. C. Merrick, G. W. Cottrell, C. C. Roads, F. W. Dellenbarger and Henry G. Dodge.

Waukegan, Ill.—The Waukegan Lumber & Coal Co.; capital stock, $35,000; to deal in lumber, coal and building materials. Incorporators, T. G. McGay, W. O. McKinney, Alexander Whan, D. Q. Hart and J. D. Pope.

Scranton, Penn.—Application will be made Jan. 21 by Archibald B. Mahon, James A. Waddell, Jno. Coyle, W. J. Welbasky and T. Ellsworth Davies for the charter of the Mining Engineering Co., of Pennsylvania. Frederic W. Fleitz, solicitor.

Altus, Okla.—A number of men of this vicinity have organized a coöperative coal company and have a mine at Blanco, south of McAlester. The name of the new company is the Tolleson Coal Co. Dr. E. A. Aberthnay is the sales director.

Pittsburgh, Penn.—The Buffalo Creek Coal & Brick Co.; capital $250,000; to purchase, take lease, hold, own and deal in coal and minerals of all kinds. Incorporators Charles A. Smith, Pittsburgh, Penn., R. Duranteer, McDonald, Penn., C. E. Meyer, Ingram, Penn.

Columbus, Ohio—The Taylor-Williams Coal Co.; capital stock of $25,000; to mine and sell coal. Incorporators, John W. Moore, S. E. Ranney, John M. Taylor, E. E. Learned and W. E. Runyan. The concern is the incorporation of a partnership which was conducted under the same name.

Florence, Colo.—The Rex Coal Mining & Mfg. Co. has filed papers of incorporation with the secretary of state for the purpose of taking over the coal mine formerly operated by the Rex Coal Co. and located on Newlin Creek. Incorporators, G. F. Stevens, M. Collins, Denver; R. M. Ramsay, A. M. Smith and E. R. Harris, Florence. It is the intention of the company to equip the mine with new and uptodate machinery as well as to provide transportation facilities for hauling the coal to market.

The company owns 160 acres of land which is underlaid by a number of excellent seams of bituminous coal.

INDUSTRIAL NEWS

Danville, Ill.—The new coal shaft belonging to Frank Woodard has been completed, and miners have begun to take out coal for the country trade.

Philadelphia, Penn.—The Pennsylvania R.R., transported 6,097,290 tons of coal and coke in November, an increase of 136,152 tons over October.

St. Clairsville, Ohio—When the total production for Belmont County for the year 1912 has been compiled it is expected that the figures will reach the 10,000,000-ton mark.

Philadelphia, Penn.—The output of the Consolidation Coal Co., for the year up to Dec. 24 aggregated 10,200,000 tons. This was an increase of 1,125,000 tons over last year.

Hazelton, Penn.—The Lehigh Valley Coal Co. took advantage of the snowstorm Dec. 27 to burn the abandoned Yorktown breaker. The structure has been replaced by a modern washery.

Newcastle, Ala.—About 250 ovens will be fired up at once by the Pratt Consolidated Coal Co. for the purpose of filling a 40,000-ton order to be delivered in the next six months. These ovens have been idle for the past 3 years.

Oak Crest, Colo.—George Campion, of Los Angeles and T. L. Darby of Denver, have been making investigations into the coal lands on Trout Creek. It is understood that arrangements will soon be made for the development of the land.

Pineville, Ky.—Two hundred coke ovens which have been idle at Straight Creek for years are being put in repair by the Continental Coke Corporation and will be operated at their full capacity. Thirty-three ovens were fired as a starter and their first coke was pulled.

Uniontown, Penn.—A tract of 655 acres of coal land in Greene County, Penn. and Wetzel County, W. Va., was sold Dec. 31 to a company of Connellsville men. The purchase price was $100 an acre. Operations will be begun at once for the development of the land.

Forrell, Penn.—The record output of coal in Mercer County in one day was broken by mine No. 7 of the Mercer Coal & Iron Co. at Stoneboro, Dec. 23, when the output for 9 hours was 1600 tons. The individual record was broken by Joseph Shasser who loaded 35 tons of coal in 8 hours.

Greensburg, Penn.—The Yukon Coal zone is developing rapidly at present. Harry Whyel Coke Co. made several purchases of coal in Sewickley township. This company now owns coal lands valued at over $100,000. A modern coal mine was constructed some time ago and the mines are running very well.

Butler, Penn.—The mines of the Great Lakes Coal Co. which have been shut down since April 1, resumed operations Jan. 2. The mines have been leased to the C. P. Munsch Coal Co. of DuBois. The Great Lakes Company had 23,000 acres of land in the Kaylor district and the plant is considered to be excellent.

Brownsville, Penn.—It is rumored that the Allicia Coal & Coke Co. is making arrangements to start operations with 200 new coke ovens, on the Fayette County side of the Monongahela River. On the Washington County side the Reliance Coal & Coke Co. is erecting 500 ovens in anticipation of a heavy coke trade.

Grand Forks, N. D.—The report of the state engineer to Governor Burke shows that there are 105 mines in operation in North Dakota, employing 2000 men. The beds of coal vary from 3 to 19 ft. in thickness and occur at depths of from 5 to 200 ft. Where the overburden is light the coal is mined by stripping.

Trinidad, Colo.—J. A. and W. H. Hardenbrook have leased the Sugar Loaf mine from P. N. Bissell, and are at work taking out some of the best coal it has produced.

J. R. Coleman, who broke into the coal business a month ago, has taken hold of the Gibbs mine and has a force of miners busy at that branch.

Hillery, Ill.—According to an unconfirmed report among the miners, another large tract of coal has been purchased near here, and a new shaft will be sunk within a short time. The Indiana Harbor Ry. Co., is said to be back of the deal and will likely put in a spur track on the northern limits of the town as soon as the mine is sunk. It is stated that the company has purchased all the mineral rights on the land in question.

Shelbyville, Ill.—It seems probable that 35,000 acres of coal land in the eastern part of Williamson County will soon change hands. This is the tract which was optioned this summer by Willard Heath, of St. Louis. After optioning the land, Heath's representative left and nothing more was heard from him until this week, when owners of the land received letters asking them at once to have abstracts made and ready for the deal to be closed.

Chattanooga, Tenn.—The Chattanooga Estates Co., which owns and is developing between 20,000 and 30,000 acres of coal and timber land on the north side of the Tennessee River, announces that it will operate freight scows by means of a tug from its property to inclines connecting with all roads leading into Chattanooga.

The work on one incline is already under way and as soon as it is completed others will be commenced. Three barges will be used and one tug.

Morgantown, Penn.—New machinery has been installed at the Rock Forge plant of the Connellsville Basin Coal & Coke Co., which has been shut down for more than a year, and the whole plant has been given a general and thorough overhauling. At present a double force of mechanics are at work putting in a new set of boilers. The ovens are being fired as fast as the coal can be supplied.

The company is short of men, but the force is being increased as rapidly as workmen can be secured.

Pittsburgh, Penn.—The Toledo & Ohio Central, which is controlled by the Lake Shore, an integral part of the New York Central Lines, is planning to compete with the Hocking Valley, owned by the Chesapeake & Ohio, in transporting coal from the West Virginia and Kentucky lines through the Toledo gateway, and has plans drawn up for new docks at Toledo.

When the docks are well under way the road will probably doubletrack its line from Toledo to Columbus.

Baltimore, Md.—It is rumored that plans are now on foot for the consolidation of the Durham Coal & Iron Co., and several other companies, representing between $12,000,000 and $15,000,000 capital. This will be one of the largest coal mergers ever put through in the South. It is said that C. H. Smith, vice-president and general manager of the Durham Company, is slated for the presidency of the new concern. Arrangements are being made to acquire about 20,000 additional acres of coal land. Extensive improvements will be made.

Birmingham, Ala.—All indications are that the Sayreton mine, operated by the Republic Company, will have the largest output in Alabama. The production of this mine is expected to exceed 360,000 tons. No. 3 mine of the Tennessee company at Ensley is expected to rank second, while the Republic mine No. 2 will probably stand third.

Other mines ranking high in the list are the Flat Top and Banner mines of the Pratt Consolidated Coal Co., and the Acmar and Margaret mines of the Alabama Fuel & Steel Co.

Steamboat Springs, Colo.—The financing of the Moffat road and the awakened interest of Denver people throughout the commercial bodies have turned the attention of the large coal interests toward Routt County.

Last week Geo. Morrison, superintendent of the Routt County Fuel Co., and John McNeill, consulting engineer of one of the largest coal using concerns in America, spent three days with Sam Adams, making a surface examination along the outcropping of the coal measures from Oak Creek through Twenty Mile Park, and as far west as the Wage and Lenox mines.

Washington, Penn.—The development of a large block of virgin coal south of Washington is believed to be assured by the closing of a deal Dec. 31, for the transfer of 2500 acres to a representative of a syndicate of Pittsburgh men. The amount involved exceeds $500,000.

It is also known that William Smith has sold 100 acres of coal and surface land east of Washington on the Baltimore & Ohio R.R. to D. L. Williams, W. S. Lockhart and Robert Young of McDonald, Penn. It is understood that the purchasers will co-operate with the Pittsburgh men in the development of the property. The price paid has not been made public.

COAL TRADE REVIEWS

GENERAL REVIEW

The open weather and consequent light demand for the domestic grades has undoubtedly proved the salvation of the anthracite trade so far this season. The situation continues to become a trifle easier each week, and while arrivals are not heavy and are going into consumption as promptly as received, it is noticeable that the consumer is not obliged to wait so long for delivery. The warm weather has undoubtedly developed a feeling of uncertainty in the market, and orders are fluctuating, but the independents are still commanding a fair premium for their product. In the Coastwise trade the storm of Jan. 3 and 4 resulted in light receipts and high retail prices are still being maintained.

The Eastern bituminous market is firm with buying on a large scale, stocks rather uneven, and demand fluctuating with the weather. An active market will be dependent upon the larger corporations, who have been relying upon districts from which shipments have been particularly bad, rather than upon the smaller consumers who appeared to be well stocked. On the whole there is a fairly large demand, and with supplies reduced and with a restricted output, due to the suspension over the holidays, prices are firm or advancing. The car supply is variously reported as both good and bad. It is stated that some roads are short, but making every effort to take care of coal consignments, while at other points the demand for equipment in other industrial branches is easing off which is helping the movement of coal. Supplies were undoubtedly reduced over the holidays, which is resulting in a temporary rush for stocks at the present time.

Demand for prompt delivery in the Pittsburgh district is relatively light, and production is again about back to normal; a fair amount of contracting was closed on Jan. 1, but most of this business here goes over until April 1. The local coke situation has eased off slightly. The softening of the domestic grades in Ohio, due to the unseasonable weather, has now disappeared and all sizes are again strong. Production at the mines has been fairly good, and the car supply much improved due to the intervention of the holidays; contracts are being renewed at slightly higher figures. The situation in the Southern market has eased off especially as regards the steam grades; a fair demand is anticipated, however, over the next two months. The order of the Louisville & Nashville Railroad, requiring all operators on their line to turn their entire output, during three days of the week, over to the company, has been rescinded, but it is doubtful if the road has acquired a sufficient supply, and the order may again go into effect at any time.

The trade in the Middlewest is described as being entirely a weather market, and the winter so far has been only an extension of the fall. At the present time supplies are plentiful, and the holiday dullness has effected a reduction in quotations; if the weather is as mild through January, as was the case in December, it is thought that summer prices will almost be reached. There is coal of all kinds on track, buyers are scarce, and a better supply of equipment on the railroads has resulted in heavy shipments. The same unsatisfactory conditions due to the mild weather, prevail in the Northwest, and operators are attempting to curtail production. Prices at this latter point are, however, being better maintained.

BOSTON, MASS.

Coal is firm with buying on a large scale and there is more inquiry for what bituminous is available. Stocks in New England are rather uneven and the demand from this territory will greatly depend upon the weather. It will also depend on loading conditions at Baltimore and Hampton Roads and if no improvement is shown, there will be an increasing call for Pennsylvania grades out of New York. The largest consumers are most likely to come into the market for spot coal. All-rail, the spot demand is not so insistent. The market in that direction does not yet justify any considerable volume of speculative coal and unless weather conditions become exceptionally hard, the call is likely to be limited at what are considered high prices.

Less anxiety over anthracite seems the rule, although there is little real occasion for it; all admit it is the influence of mild weather. The storm of Jan. 3 and 4, with its interruption to the barge movement will probably cause new anxiety over the light receipts. The almost spring like temperatures this week have reduced retail deliveries to a minimum, and this has enabled many a dealer to bear a cheerful front. Premium coal is still a ready sale at $7.35 @ 7.60 alongside Boston, and $8.25 @ 8.50 is a current price for stove coal on cars for shipment inland. The high retail prices that prevailed are still maintained and the shortage of stove coal continues the chief feature of hard-coal trade.

Current of quotations are about as follows:

Clearfields, f.o.b. mine,	$2.10	@	2.20
Clearfields, f.o.b. Philadelphia	3.25	@	3.40
Clearfields, f.o.b. New York,	3.55	@	3.70
Somersets, &c., f.o.b. mine,	2.15	@	2.25
Somersets, &c., f.o.b. Philadelphia	3.40	@	3.50
Pocahontas, New River, f.o.b. Hampton R'ds.	3.50	@	3.60
Pocahontas, New River, on cars Boston,	4.60	@	4.90
Pocahontas, New River, on cars Providence,	4.60	@	4.75

NEW YORK

Bituminous—In spite of the continued mild and unseasonable weather, the soft-coal trade is still holding its own, and if anything, becoming stronger. The effects of the curtailment in production over the holidays are now being felt, and local supplies are quite short, particularly in the better grades, which are practically unobtainable in the spot market. The conservative members of the trade believe that quotations are now approaching the high point for the season. It is thought that the next cold snap will see the maximum prices in effect, after which there will be a gradual easing off to the usual summer level.

A good car supply has been reported on practically all lines shipping the New York market. It is estimated that production in the Pennsylvania field has been up to about 75 per cent. of full-rated capacity. The labor shortage appears to be the worst feature of the industry, and the effects of this are being felt generally all over the mining districts.

New York bituminous prices experienced a further advance during the week, while anthracite has about held its own, prices now being quotable about on the following basis:

Anthracite	Upper Ports	Lower Ports	*Bituminous*	
Broken	$5 00@5 25	$5 00@5.25	West Virginia, steam.	$3 25@3 35
Egg	5 25@5 75	5 20@5 75	Ordinary grades, Penna	3 25@3 35
Stove	5 25@6 25	5 20@6 25	Fair grades, Penna	3 25@3 35
Chestnut	5 50@6 25	5 45@6 25	Good grade, Penna	3 35@3 45
Pea	3 50@4 10	3 45@4 10	Best miller, Penna	3 40@3 50
Buckwheat	2 60@2.75	2 35@2 70	Georges Creek	3 50
Rice	2 15@2.25	1 70@1 95		
Barley	1.75	1.25@1.70		

Anthracite—The hard-coal situation has become so easy that the head of one of the large local selling agencies went so far recently as to state that the unseasonable weather might cause the bottom to drop out of the market. With a shortage of 6,000,000 tons in the trade, such a view is obviously an exaggeration of the situation, but it is nevertheless pertinent as showing the better feeling which exists among the anthracite companies. The demand is still strong, but there is no doubt that warm weather is enabling the operators to rapidly catch up. There is no demand for the high-priced grades, but speculators who have acquired such are holding on firmly until the cold weather appears.

Egg coal has become so plentiful that there have been some cases of the individuals offering this down at the regular company's circular. Nut continues about normal with broken a little short. Pea is almost entirely out of the market, and rice and buckwheat are being substituted for this grade; as a result, this latter size is somewhat stronger. The market is flooded with barley, which it is almost impossible to dispose of.

PHILADELPHIA, PENN.

The second week in the new year finds the coal trade in this vicinity in practically the same position as when the year closed. As a matter of fact, the open weather has been the only salvation the dealers have had, enabling them to stave off, to some extent, the demands made on them. Taking it altogether, it may be said that the situation is a trifle easier. Every size is moving off almost as promptly as received, and the arrivals are not by any means heavy, but

householders do not have to wait quite as long to have their orders for certain sizes filled, as was the case a month or so ago. Stove and pea seem to still continue in the lead. Egg may be said to be a trifle easy, gaged by the fact that the individual operators are playing this size heavier than either stove, chestnut or pea, and quotations from them on this size are pretty close to circular; there have even been cases, it is understood, that a prompt order will take the coal at even less.

The present price of egg is almost a safe indication that this size is in fairly good supply. It is understood, however, that the large companies are having no difficulty in moving it off, although some districts are complaining that their orders for it are being shipped, while those for other sizes are ignored. The week really marked the beginning of full work at the mines, after the holidays. The output has been anything but normal, even when the collieries were reported as working, for in many cases, the full complement of men were not out.

The bituminous market shows little or no change as far as prices are concerned. The available supply, however, seems to be better, due no doubt to the fact that the mines were able to produce their normal output, but there is a ready demand just now, that is absorbing all that is sent to market.

PITTSBURGH, PENN.

Bituminous—Production of coal is almost back to normal, after the interruption of the holidays. Demand for prompt is relatively light. Shipments had been curtailed to some manufacturing consumers, on account of works being closed for inventory, but are again being resumed this week. There is little interest in contracts at this time. A fair volume of contract business was closed for various periods beginning Jan. 1 but the great bulk of this business will be for the twelve-month beginning Apr. 1. Circular prices are well maintained, and remain as follows: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾in., $1.40; 1¼in., $1.55; per ton at mine, Pittsburgh district.

A rise in the river last week permitted a good tonnage of Monongahela River coal to go down the Ohio to the various distributing points.

Connellsville Coke.—The market for prompt coke has been easier than expected, there being no particular pinch on account of the curtailment of shipments during the holidays. While as high as $4.15 and $4.25 was obtained in a very few cases for prompt furnace coke, around Christmas time, the market has dropped back to $4, where it stood before the holidays, and sales at this figure have been rather light in the past week, less than 5000 tons; in several cases operators have sold to brokers at less than this figure. There is very little inquiry for early delivery coke and it does not appear that many furnaces allowed their old contracts to expire Dec. 31 without making fresh ones. Foundry coke continues relatively scarce. We quote: Prompt furnace, $4; contract furnace, first half, $3.25 @ 3.50; contract furnace, year, $3 @ 3.25; prompt foundry, $4.25 @ 4.50; contract foundry, $3.25 @ 3.75, per ton at ovens.

BALTIMORE, MD.

The new year had an auspicious beginning for the Baltimore coal trade, and if the remainder proves to be as satisfactory, especially from the standpoint of prices, local operators will have no cause for complaint. Naturally, the supply of coal was greatly reduced, owing to the holiday, and there was a rush for fuel on the part of consumers, resulting in an exceptionally strong market. Sales of the common grades at $2 per ton were the rule rather than the exception and operators who could deliver at this price found plenty of buyers. Other grades have shown corresponding increases.

The idleness at the mines, caused by the Christmas and New Year holidays, has resulted in a marked decrease in the output and this scarcity of coal is now being felt. The mines for the past two weeks have not worked more than six full days, and it can be easily seen that such a prolonged cessation will have a pronounced effect on this and other markets. Because of this condition, consumers who managed to stock up heavily before the holidays, have been compelled to draw largely on their supply with the result that they now have little on hand. Some were able to buy at the market, but others were not.

The car supply is about the same as it was the previous week. All the roads are still short of equipment, owing to the enormous traffic which is being moved but they are making every effort to take the best possible care of coal shippers. Considerable fuel was handled over the piers here, destined for New England and other ports. The weather was cold during the week, which stimulated the demand for anthracite fuel.

The market may ease up a bit when the mines again produce their maximum output, but the trade is of the opinion that there will be no cheap coal for some time to come. Baltimore operators do not believe that there is going to be any cessation in business, and that the demand for all grades will continue brisk. The cold weather also brought increased business to the anthracite trade. Many householders found that their bins were about empty the early part of the week, and were quick to put in an additional supply.

BUFFALO, N. Y.

There is a big demand for bituminous coal and with the output still light on account of the holidays, the prices remain firm. The trade, instead of hearing that coal is offered at cut prices, steadily reports the opposite, so that the former strength certainly holds out well. Quite a block of Allegheny Valley coal sold a day or two ago for $1.85, mine-run gross, at the mine, this same quality selling last summer as low as $1 or $1.05. This difference is fairly staggering, especially if it is a real indication of the advance that business has made since that time.

Prices are not quite as high in the bituminous trade as they were a month or so ago, but they are strong enough and nobody is complaining unless it be that they are not getting out as much coal as was planned for. Still the annual reports of output coming in are satisfactory when it is figured that quite a good percentage of it has been sold for at least 30c. a ton more than it would have brought a year ago.

There is much the same complaint of car shortage, though as a rule other branches of business are not demanding so much equipment as they were a month ago, so that coal will get the benefit after a little. The railroads are likely to take even more fuel for holding if actual winter sets in so that the private consumer is not in good position to get prompt deliveries as he was last fall. Complaint that the roads are not acting fairly in taking so much coal now continues, but it is not going to be easy to change their methods.

There is a little slacking off in the price of coke, though that was expected because it ran too high for awhile. Best Connellsville is not now above $6.25 and there is some stock to be had. In the bituminous market the quotations remain firm at $3 for Pittsburgh lump, $2.85 for three-quarter, $2.75 for mine-run and $2.50 for slack, with Allegheny Valley about 25c. lower. Side coal, such as cannel and smithing, are all strong.

The warm weather has kept the anthracite dealer and consumer very anxious. One day orders will be numerous and then the sunshine will occasion a number of cancellations but when the winter shows a disposition to return, it brings the orders back again. Independent anthracite still commands a good premium.

COLUMBUS, OHIO

With lower temperatures prevailing and a continuation of active business conditions generally, the coal trade in Ohio has been fairly active during the past week. The softening in domestic sizes, which resulted from the unseasonable weather, is now passing away and strength has appeared in all grades. The demand for domestic as well as steam sizes is good and the production in Ohio fields has been fairly large during the week.

Despite the fact that the one holiday interferred, the output was about 65 per cent. of normal during the week. The car supply was much better, due to the intervention of the holidays and also to the warmer weather which aided railroads in a better freight movement. The improvement in the car supply is expected to be only temporary as the underlying conditions have not improved in the least.

One of the strong points in the market has been the steam business. Factories are demanding a large amount of fuel and this is especially true of the iron and foundry concerns. Contracts, which are expiring now, are being renewed at slightly increased figures and the low railroad fuel contracts of last year will be a thing of the past. The requisitions on the part of railroads for fuel are large.

Retailers are now in the market for more stocks since the mercury has descended. Their supplies were not large and it only required a few days of wintry weather to exhaust them in most places. As a result orders for immediate shipment are now the rule and producers are able to accommodate the dealer because of the better car supply. There is a good demand for the fancy grades of domestic coals such as splints and Pocahontas.

The bad conditions of the streets has hindered deliveries on the part of dealers. Retail prices are strong at the same level which has prevailed for several weeks.

Quotations in Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$2.00	. . .	$2.25	$2.00
2-inch	1.80	$1.50	2.00	1.65
Nut	1.50	.....	2.00	.....
Nut, pea and slack	1 15	...	1 25	1.10
Mine-run	1.50	1.40	1.50	1.50
Coarse slack	1.00	1 05	1.10	0.90

CLEVELAND, OHIO

From the viewpoint of producers and shippers of coal, 1913 will be the banner year in the coal trade. The close of 1912 ends prices 25 per cent. higher than those which prevailed a year ago. With the unprecedented and, in many cases, the unexpected increase in traffic in the many lines of business, operators have every reason to believe that prices will continue to go upward.

The speculative movement of coal to this district has slightly diminished during the past few weeks, which, no doubt, has been due to the mild condition of the weather for the past 30 days. Transportation lines are handling a large volume of business, but consumers seem to be pretty well under contract for their requirements.

The following prices per net ton f.o.b. cars at the mines are quoted on the various grades of coal for spot shipment.

District	Three-quarters	Mine Run	Slack
Youghiogheny	$1 35	$1 25	$1.10
Pittsburgh No. 8	1 20	1.10	1.20
Goshen No. 6	1 45	1 35	1 20
Coshocton	1.75	1 50	1 20

The freight rate from the Youghiogheny district to Cleveland is $1 per net ton, and Pittsburgh No. 8, 90c.; the Goshen and Coshocton coals from the middle district take a 70c. rate. The demand for Massillon domestic coal continues to hold out: $2.50 for 1¼ in. is quoted for shipment at the mines. Foundry coke is selling for $4.50, f.o.b. ovens, while $4.25 is quoted on furnace. Anthracite is extremely scarce and dealers are experiencing great difficulty, due to this shortage.

Pocahontas lump and egg is bringing $2.75, run-of-mine, $1.50, and slack, 90c., f.o.b. mines, while $2.50 is quoted on Massillon, 1¼-in. lump at the mines. Foundry coke is selling for $4.50 f.o.b. ovens, while furnace coke is going at $4.

Small dealers are experiencing difficulty in securing anthracite coal. Substitutions are made freely, and those who have not been able to secure their requirements of hard coal, have been forced to utilize soft.

Railroads are operating to their maximum capacity and are demanding heavy fuel shipments from the mines. A large Canadian Road recently purchased from 50 to 75,000 tons of Pittsburgh No. 8 fuel for shipment into Canada prior to April first. The recent cold wave did not have much effect on the market and coal men believe prices will hold out.

LOUISVILLE, KY.

As predicted last week, the situation has eased up considerably, especially in the steam coal market; although the expected break in prices has not yet materialized, the falling off in the steam grades might well be designated as such, the difference being 30 to 40c. a ton below the high figures which prevailed during the worst of the shortage. For example, Western Kentucky pea and slack is on the market at 40 and 50c., and some sales have been reported as low as 35c., f.o.b. mines, of course; and nut and slack is selling in the same district at prices running all the way from 65 to 80 and 85c., depending largely on quality and location.

Some large consumers, however, whose supplies ran low during the recent scarcity of steam grades, and who have not yet been able to stock a sufficient amount over and above their current needs to assure them of a margin of safety, are now making strenuous efforts to remedy their deficits. They are consequently taking everything in sight, in many cases necessarily at figures higher than those quoted, especially outside of their contract requirments.

Western Kentucky is figuring strongly in this feature of the market, screenings from that field being shipped to the local industries in considerable quantities, and absorbed without any trouble. The usual Christmas lay-off affected Eastern Kentucky operators, although beginning on New Year's, the men were back on the job in most cases, and half a day's run was made. The week's output was light everywhere by reason of the holidays, however, and there has been no complaint of insufficient cars.

Seasonable snows and considerably lower temperatures than ruled through December may be expected to result in a stiffer demand for all grades, especially the domestic. So mild has been the winter up to the past two weeks, that even with the scanty receipts from the mines, there has been no real danger of a shortage, with buying so comparatively slow. The worst of the winter usually occurs in January, February and March, and a brisk demand is to be expected for this and the next two months, at least, with the usual stocking by the railroads to follow that.

The Louisville & Nashville, whose recent demand for three days' output from all Eastern Kentucky mines on its lines, adhered to its promise, releasing the operators from this requirement, some time around Christmas. It may be doubted, however, whether the railroad managed to lay in sufficient supplies to last for any time, and it is, therefore, to be hoped that the present relief in the car situation is not merely temporary. In Western Kentucky the receipt of a number of the Illinois Central's long expected new cars, has had considerable to do with the relaxation of the tension in this respect, in that district.

Eastern Kentucky prices, especially on domestic grades, have been showing indications of weakening, but there is not yet much of a concession in this respect. Block is quoted at $2.25 to $2.50; lump 10 and 15c. lower; round, $1.75 to $2; nut and slack, 65 to 90c.; run of mines, $1.25 to $1.50.

The prediction is freely made by well informed operators that the trade is on the verge of a sharp break. The domestic market has been gradually declining for 30 to 60 days, on account of the continuance of mild and open weather, and this in spite of the severity of the car shortage. The supplies of local dealers, however, have in all cases been ample to tide them over this period, and consequently there has been no shortage in domestic. The market in the steam grades, which has been extremely high, is also expected to ease off somewhat, as the car situation is gradually improving; the demand of the Louisville & Nashville was responsible for a more acute condition than had existed during the entire season, but the road has about satisfied its needs. Moreover, it has been returning cars very rapidly, unloading and sending them back promptly to the mines. This made the three-day loading to the railroad no more of a hardship on the operators than was absolutely necessary.

HAMPTON ROADS, VA.

A very heavy tonnage of coal has been loaded during the past few weeks for the Panama Canal. It is understood that work there is now being pushed to the full limit. The market price on standard smokeless coal still continues upward of $3.25, with very little available.

The demand for bunker and export coal for ships' use has grown steadily during the past few months. The cost of producing and handling, the latter especially, have been increased materially by changes in railroad as well as pier charges during the year. As bunker contracts are generally made only at the first of each year, shippers were obliged to stand these new charges until time to make new contracts with ship owners.

INDIANAPOLIS, IND.

The coal trade here is a weather proposition, and so far, the winter has been merely an extension of fall. It has finally had the effect of enabling mines and dealers to catch up with consumers' demands, after the great handicap at the beginning of the season caused by the shortage following the spring shutdown and the railroad transportation troubles. The usual holiday dullness brought a reduction in the domestic grades of about 40c. a ton, and on steam grades 10c. to 15c. a ton, since Dec. 1. The weather has also had the effect of practically ending the car shortage and mines are making few, if any, complaints of lack of equipment.

If January has the same mild weather as December, the summer schedule of coal prices will be almost certain to go in effect at the mines. Values of the steam grades have not suffered like the domestic because most steam coal is under contract, and there is only small buying in the open market. The easing off in domestic prices is not yet shown by retailers' quotations because the mines are still delivering to the yards on old orders, taken at the top of the market.

The following represents closely the Indiana mine prices, Indianapolis prices being 50c. higher, to cover freight:

No. 4 mine-run	$1 10	Domestic lump 5- and 6-in.	$1 65
Nos. 5 and 6 mine-run	1 00	Screenings, No. 4	0 70
No. 4 steam lump, 1½-in.	1 25	Screenings No. 5 and 6	0 60
Nut, No. 4	1.30	Washed coal, Nos. 1 & 2	$1.75@2.00
Egg	1 40	Brazil block	2.20
Domestic lump 2½-in.	1.50		

DETROIT, MICH.

Bituminous—The coming of the new year witnesses an unsatisfactory situation in the Detroit market. Operators are reluctant about making shipments to this point, preferring to wait until the weather conditions are more favorable. They are slow to cut the prices and cause a break in

the market, at least until it has been fully demonstrated that cold weather will not appear. On the other hand the operators and jobbers of Detroit look back with great satisfaction on the year of 1912, and are now predicting with great confidence that 1913 will be a banner one in the coal business.

One encouraging feature of the holiday dullness is the fact that the prices rule firm. There has only been a slight drop in quotations and the smaller sizes are still in great demand with very little to be had. Track coal is scarce and is being disposed of with little or no difficulty as fast as it arrives. The railroads are experiencing considerable difficulty in handling cars properly, which has resulted in embargoes on nearly all of them. However, these conditions are not as severe as they were a year ago at this time. On the coarser sizes and domestic coal, the existing conditions are quite different. There seems to be considerable of this kind of fuel in stock, which it is utterly impossible to dispose of, and a number of shippers are much worried about the outcome. The fact of the matter is that the prices on this grade are ridiculously low.

Local market conditions are as follows:

	W.Va. Splint	Gas	Hocking	Pitts. No. 8	Jackson Hill	Pocahontas
Domestic lump	$1 50		$1 40		$2 40	$2 40
Egg	1.50		1 40		2 40	2 40
Nut			1 90			
3-lump	1.35	$1 35		$1 25		
Mine-run	1.15	1 15	1.15	1 20		1 60
Slack	1.10	1 10	1 10	1 10		Open

Anthracite—The hard-coal situation is being relieved quite materially, abundance of the larger sizes are arriving and the market continues to be liberally supplied. However, it is predicted that 10 or 15 days of severe weather would bring quite a change in this situation. Were severe storms to come, in all probability the big shippers would send their fuel to eastern markets, rather than take any chance of it being tied up indefinitely in and about Detroit.

Coke—Demand for coke is not so keen as it has been. However, it seems to be holding its own as to price. Semet Solvay being quoted at $4.75, gas house at $4.50 per ton, f.o.b. ovens.

CHICAGO

With the beginning of the new year a soft market is confronting Chicago coal dealers. Moderate weather and a better supply of cars are assigned as the chief reasons. Coal of almost every kind is on track and immediate buyers are few, the only exception being in anthracite. Retail dealers are receiving a comparatively scant supply and are barely able to keep even with the demands of their customers.

There has been a decided slump in the demand for splint coal. Two weeks ago dealers were kept busy obtaining supplies of this variety, but now there are many carloads remaining on track unsold. The circular price is $2, but the market is considerably below this. Smokeless market also is weak. Carterville operators are holding their high-grade domestic product for $1.75, but the low-grade coals have not sold for much under $1.50. Furnace and foundry cokes are in good demand. The price of Springfield domestic lump ranges from $1.35 to $1.60.

Mild weather has had a bearing on the general situation and retail dealers have been taking coal only on previous orders. The Western demand for anthracite continues active and it is believed that the situation will become acute before long as shipments are expected to be light for some time.

Prevailing prices in Chicago are:

	Sullivan Co.	Springfield	Clinton	W Va
4-in. lump	$2.62			
Domestic lump		$2 32	$2 27	
Egg	2 52			$3 80 @ 4 05
Steam lump	2.07 @ 2 17	2.12	2.17	
Mine-run		1.97	1.97	3.45 @ 3.55
Screenings	1.62 @ 1.67	1 47 @ 1.57	1 57 @ 1 62	

Coke—Connellsville, $6.75@7; byproduct, egg and stove, $6@6.25; byproduct, nut, $6@6.25; gas house, $6.

OGDEN, UTAH

The holidays found the mines in Wyoming and Utah shipping all the coal they were able to mine. The shortage of box cars that has been general, for the past three weeks, developed into a shortage of all kinds, and the mines in Wyoming lost a few days on this account. The shortage on the Rio Grande Railroad that has affected the mines in Utah for the past three weeks, was accompanied by a severe congestion on the road at several points and the tonnage the last week in December fell off immensely. These blockades were so severe that the railroad was unable to move the loads away or supply the mines with empties.

Weather conditions remain about the same over the Northwest, and there is a good demand for domestic coal. The shortage of anthracite coal in eastern Nebraska has increased the demand for bituminious coals and at present the shipments east of Grande Island are good.

There seems to be no excessively low temperature in any locality, the lowest reported being about 8 deg. above zero. Reports from the territory covered by the Wyoming and Utah mines show that most dealers have disposed of a large percentage of their stocks in the last two weeks and are urging the operators to place some coal in transit, anticipating colder weather in January.

ST. LOUIS, MO.

The St. Louis coal market is very quiet for this season of the year. Everybody is well stocked up and no one is buying. It was thought that the first of the year would bring changes in both weather and prices, and although the weather has been somewhat cold, it has not been enough to warrant any material change in prices.

Cold waves and snowstorms seem to circle around St. Louis, leaving the weather here moderate. Towns to the southeast are experiencing heavy storms, and trains entering St. Louis from the east are covered with snow.

Anthracite egg, stove and grate are flooding the St. Louis market, but chestnut is not moving as fast as it should.

The prevailing prices are:

	Carterville and Franklin Co.	Trenton and Big Muddy	Mt. Olive	Standard
2-in. lump				$1 00 @ 1 10
3-in. lump			$1.40	
6-in. lump	$1 35 @ 1.50		1 60	1 25 @ 1 30
Lump and egg	1.45 @ 1 60	$2 25		
No. 1 nut	1.30 @ 1.40			
Screenings	0.75 @ 0.85			0.55 @ 0.65
Mine-run	1.10 @ 1.20			0.90 @ 1.00
No. 1 washed nut	1.50 @ 1.60			
No. 2 washed nut	1.35 @ 1.40			
No. 3 washed nut	1.35 @ 1.40			
No. 4 washed nut	1.35 @ 1.40			
No. 5 washed nut	0.85 @ 0.90			

Gas house and byproduct coke are quoted at $5.50, f.o.b. St. Louis.

PORTLAND, ORE.

Colder weather has prevailed here the week past and the demand for coal for domestic purposes showed an increase. Heretofore the winter has been mild throughout the Pacific Northwest. A large order to be placed here soon is that of the Federal Government calling for 7000 tons for use in supplying power in the construction of the Celilo Canal on the upper Columbia River. Bids have been invited and will be opened in a few days by the government engineer in charge of the project. This will be one of the largest single orders for coal placed here for some time.

COAL SECURITIES

The following table gives the range of various active coal securities and dividends paid during the week ending Jan. 4:

Company	High	Low	Last
American Coal Products	90	90	90
American Coal Products Pref.	111	111	111
Colorado Fuel & Iron	34⅛	34	34⅛
Consolidatioo Coal of Marylaad	103⅞	103⅛	103¾
Island Creek Coal Pref	87¼	87¼	87¼

Lehigh Valley Coal Sales Co.—Dividend of $1.25, payable Jan. 20, to holders of record, Jan. 7.

Pacific Coast Co.—Regular quarterly 1½% on the common and second preferred and 1¼% on the first preferred, all payable Feb. 1.

COAL AGE

Vol. 3 NEW YORK, JANUARY 18, 1913 No. 3

"DO not look a gift horse in the mouth." Why? He usually has bad teeth.

Time was when nearly every position of responsibility carried with it certain perquisites, but with the gradual moral awakening in our business conscience, perquisites have fallen into disfavor, until now it requires an elastic conscience to accept most of them.

Every now and then, however, you'll run across some man in authority who is willing to accept without question the old adage about the "gift horse," and when you do, it is better not to suggest that his conscience is elastic. In this class must be placed those individuals who are willing to stand sponsor for any new organization, provided they see a "gift horse" in the distance.

Here are a few illustrations of what they sow:—

A fake "building and loan association" (there are plenty of them still in existence) was organized in a certain city which was centrally located in an important mining region. How were they to get the miners' money? Easy—they gave stock to a number of the more prominent mine superintendents and foremen, afterwards displaying the names of these men on all of their advertising circulars.

During the two succeeding years, a large number of thrifty miners followed the lead (as they supposed) of their bosses, and invested all of their savings in building-and-loan stock. In the meantime, the officials gradually became worried about the "teeth" displayed by their "gift horses;" however, the time to examine a horse's teeth is when the other fellow owns it. When the inevitable crash came, everything disappeared—except the "gift horses'" teeth; they will undoubtedly survive their masters.

In another mining town a fake industrial insurance company was started, and the same tactics were resorted to, with almost similar results. In still other communities, fake land companies, fake co-operative mining companies, fake orchard companies, fake banks, etc., were organized simultaneously, and after drifting on the customary two years, traveled the same road and shut up shop.

Don't think for a minute that large companies are the only ones that profit by the so-called "pull of prominent names." You'll find the book agents, picture agents and salesmen of all descriptions offering their wares free to ministers and other prominent people, just to get their list started. We have even known raffles to "hang fire" until the "super" accepted several numbers free and allowed his name to be artistically engraved on the sellers' lists.

You see, "gift horses" are grown in all sizes from ponies to draft horses, and serve all ages of humanity from children to the aged and infirm. In one respect, however, there is not much variation, and that is as regards teeth.

"But," says the pessimist, "everyone knows the proverb about 'a fool and his money.' Why try to protect him?" And we answer: There is not so much inclination on our part to guard the foolish and gullible as there is a desire to awaken the moral conscience of the near-owners of the "gift horses."

The most conspicuous example of discipleship to "gift horses" now in the public eye, is the prominent son of one of our most gifted authors. Whatever may be the outcome of his trial as affects himself, the incident is bringing home to all mining men the realization of the responsibility of guarding well one's name.

A man can no longer loan the use of his name to an unsafe business enterprise and hope to be held blameless afterwards if the venture brings disaster. Declarations of personal ignorance concerning the true character of the undertaking will not exonerate one. The only argument left to such a man is to defend his action on the basis of conviction that one of the perquisites of leadership is reward without responsibility.

The "gift horse" and the perquisite may not lay claim to the same identical pedigree, but they never refuse to eat from the same manger.

MORAL: Do look a "gift horse" in the mouth.

IDEAS AND SUGGESTIONS

The Fallacy of Seven Shifts a Week

By a Colorado Engineer

Any engineer or superintendent of machinery, for a large coal operation with several mines, can call to mind times without number when he has made hurry trips to a mine because some new piece of machinery "wouldn't work," or some newly installed drive "went backwards." Upon his arrival, he probably found that some little thing had been neglected, by the local force in the erection, or that some easily remediable defect existed, that took only a small amount of work and gray matter to cure. The same men can also recall that they swore at the apparent stupidity of the mine machinist or master

The stupidity was only apparent. The fact is that the local force had been working on that installation three or four shifts straight, and some of them, doubtless, for weeks previous, putting in eight to twelve shifts a week, until they couldn't be expected to have any ideas.

Furthermore, the local machinist, when physically fit, has almost, if not quite, as good ideas as the man who came down from the city office to set him straight. The conditions under which he works, however, are such as to absolutely benumb his brain and make original thought impossible. Such a run of extra shifts on the part of monthly men is often made a matter of loyalty to the company, but is mistaken loyalty at that. On the part of men paid by the hour it piles up the payroll without commensurate service. In either case the company loses.

Even seven shifts a week is one too many for the best work. Men get logy and give no more service than they would in six. Such conditions are more common in the West than in the older parts of the country, and the men themselves are largely responsible.

I myself worked on one construction job for fifteen months, seven days a week. I observed many of the men insisted on working on Sundays and would have quit had it not been permitted. The work would have gone slower on a six-day schedule, not because the men would work any slower, but because it would have been difficult to keep men on the job. The payroll was just one-sixth bigger than it would have been for the same work on a six-days-a-week basis. The company lost by working that seventh shift.

Where the Harm Is Done

Coal mines seldom run on Sunday, but certain men work almost every Sunday necessarily because machinery is idle and can be gone over for repairs. These same men frequently put in extra shifts during the week, and I never knew one of them to lay off a regular shift to catch up. That is where the harm is done. Physically they stand up under it, but mentally they are benumbed and in a position where they are incapable of keen intelligence and originality. The company loses rather than makes by such continual service.

Again, life in many camps has no distractions, except the saloon. Some men, ambitious and earnest, not caring for these attractions, live, eat and sleep with the job. It may be good for the job, but it is bad for the men. The man who has no outside interest, no recreation, begins to think in a circle, to lose perspective. The soft-handed office chap, who forgets his work at five o'clock, can come down to the mine and with a fresh mind, see and solve problems that have baffled the mind, naturally as strong, but clogged by unnatural living.

Would not companies be ahead by insisting that no man put in more than seven shifts a week, or if he does, making him lay off during the next to even up? In camps which the companies control, they should provide amusement places, aside from the saloon, not merely educational features, but billards and bowling, and moving-picture theaters. These things need not be given, they simply need to be permitted. They will pay for themselves as they do in independent communities not controlled by corporations.

The Danger in Efficiency Methods

By Pennsylvania Reader

In coal mining, as in all other industries, a large proportion of the companies have as their higher officials men who have not passed through every stage of the business before assuming their present position.

Thus by far the majority of presidents of coal-producing corporations are not men who have spent a considerable portion of their early life actually digging coal or driving a mule or picking slate. Very often they are the choice of the board of directors on account of their general executive and administrative ability. Sometimes they hold their position simply because they have the confidence of a majority of the stockholders and have average business ability. The same condition holds true with the general manager and superintendent. They, more often, are technically trained men; their actual experience in coal mining has probably been confined to more or less desultory chaining done on an engineer corps during summer vacations while at school.

When we get to the mine foreman we almost invariably find a so called practical man who has laboriously gone through all the various stages of mining up to his present position. He has mastered sufficient arithmetic, geometry, etc., etc., to enable him to discharge his duties intelligently. But his main "stock-in-trade" is not his book knowledge or the various theories which have been propounded to him. He is valuable to his employer on

account of his good common sense and judgment, his ability to handle men, and various other qualities which can be obtained at least as easily in the school of practice as anywhere else.

There are, of course, many presidents, managers and superintendents who have literally worked their way up from the bottom, but these are exceptional cases. The men who have thus succeeded have had unusual ability.

In the present day, when the daily papers, the so called muck-raking magazines, and reports of investigation committees are full of arguments for industrial efficiency, it is no more than natural that the directors of the coal industry should concern themselves with the improvement of the business over which they preside by introducing scientific management.

The first step in this process is to systematize the business completely. The manager requires numerous reports from his superintendents in order that he can point out to the latter where room for improvement exists. The superintendent, in turn, must have facts and figures on which to base his reports, so he calls on his subordinates to furnish him with daily statements. The most available man to turn to for these reports is the mine foreman, and it is just at this point that often more is lost than gained by trying to introduce modern efficiency systems.

It is always difficult to make a practical man see the advantages of any change in the established methods and the average mine foreman is no exception to this rule. The new reports he is required to make are considered by him as a mere waste of time, so that he does this part of his work half-heartedly and he is not so much concerned with accuracy as he is with getting the task out of the way.

But besides this apathy or even opposition on the part of the mine foreman, there is another more serious objection to this system of getting at efficiency figures. The mine foreman is the "man at the front." He is the man who personally directs and leads his men. The labor of which he has charge is of such a nature that it is necessary in most cases for the foreman not merely to give directions to his men as to how the work is to be carried out from day to day but, if he is to be successful, he must actually *see* the work done. This, of course, means that he must visit widely scattered points.

He may be called upon during the course of the day to see that a fall in a main haulageway is cleaned up and made safe, or that a roadway is repaired or that better ventilation is provided in a certain part of the mine or that hundreds of other jobs are duly performed. He may have men who are responsible to him for overseeing these various jobs, but after all a mine never was a success unless the "big boss" devoted a large proportion of his time to supervising the work in person.

It may happen that the foreman is conscientious and truly aims to give his superintendent the information the latter demands. We must remember that the mine boss is a self-educated man and cannot get down to any clerical work, such as is needed in making out formal reports, without his attention being taken from his regular duties, much to the detriment of the latter.

I do not mean to infer from the above that modern efficiency should not and cannot be applied to coal mining. But under the present existing conditions, with inferior grades of labor and strong overbearing pit committees, modern efficiency methods cannot start with the mine foreman. They must be initiated lower down the scale, with the diggers and daymen themselves. The modern mine foreman has not the ability nor leisure to train his men, especially when radical changes in the method of work are demanded in the interests of modern efficiency methods.

How Accidents May Be Reduced

By Joseph Northover*

Out of 490 persons killed in the mines of Pennsylvania during the year 1911, 308 met death from falls of coal, draw slate and roof rock. Thus 62.86 per cent. of the fatal accidents were caused by falls.

Systematic timbering and spragging at the working face will do much to reduce this type of fatalities. The question of when and where sprags or props should be set is one which should not be left entirely to the judgment of the individual miner. While he should be free to put up additional props when he thinks they are needed, he should not be permitted to set them more than a fixed distance apart. Experience shows that a large proportion of accidents occur from falls of apparently strong roof, in which no crevice or slip could previously be observed. Hence the roof, sides and working face can be made secure, only by timbering systematically.

The assistant foreman should not have any larger section than he can cover each and every day. No more than 75 men should be under his supervision. There should be a few special rules printed on cards in the various languages and hung in conspicuous places in the mine.

When the assistant mine foreman visits a working place and finds any workman violating the rules as set down by the company, such workman should be promptly suspended by the mine foreman for days, weeks or months, according to the nature of the rule violated.

The rules posted might be somewhat as follows:

Rule I. When undermining coal, set sprags not less than 7 ft. apart.

Rule II. Examine your working place at the beginning of every shift before you start to work.

Rule III. There shall be not less than 3 rows of props in all rooms. These shall be not more than 4½ ft. apart, and the foremost props must be set not more than 7 ft. from face.

Rule IV. Do not charge even a rock hole with both dynamite and powder.

Rule V. When you fire a blast in coal or rock, wait at least 3 min. before going to see what the shot has done.

It would be the duty of the assistant foreman to see that these rules were strictly enforced.

*Assistant foreman, Berwind-White Coal Mining Co., Seanor, Penn.

SNAP SHOTS IN COAL MINING

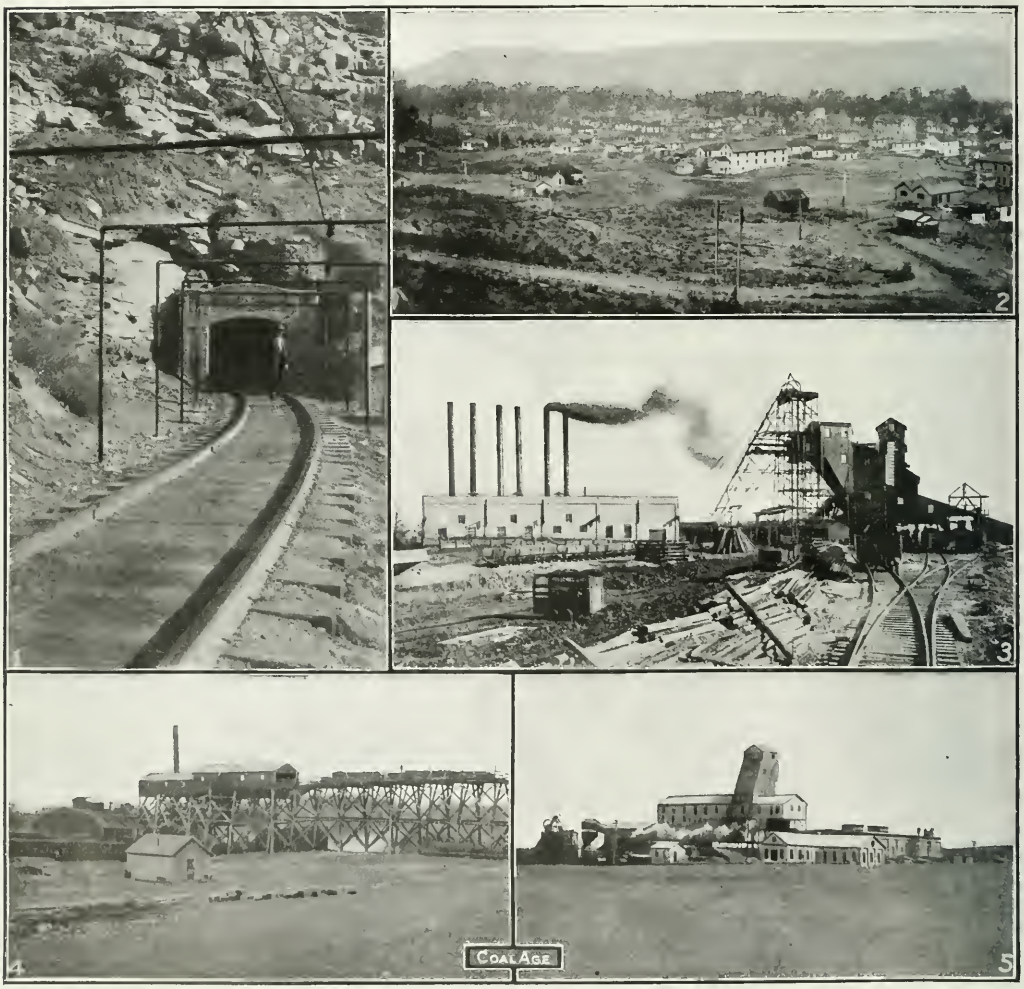
1—Concrete portal of the Willow Creek mine, Utah Fuel Co., Utah. A mine opened in 1912. Note the heavy rails for the electric locomotives.

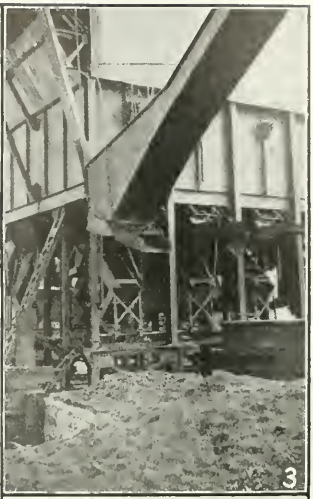
2—Village of Monarch, Wyo., where the mines of the Wyoming Coal Mining Co. are located. Most of the houses are one story high.

3—Ziegler District Colliery Co.'s Shaft North No. 1, Christopher, Ill.

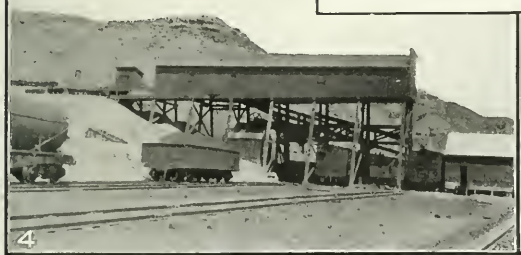
4—Roundup Coal Mining Co.'s Tipple at Roundup, Mont.

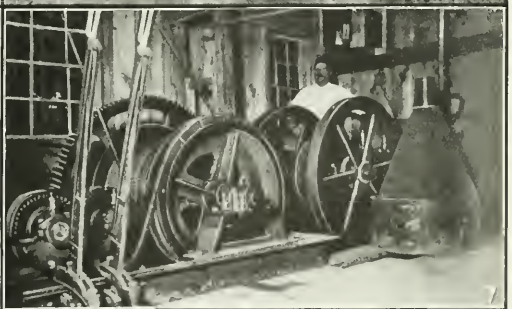
5—Headframe and Tipple at Galt Mine No. 6, Lethbridge, Alberta, Can., owned by the Canadian Pacific Ry.





1. Car-haul at the Carney Cozl Co.'s Mine at Carneyville, Wyo. Erected by Roberts & Schaefer.
2. Tipple of the Hutchinson Coal Co., at Bridgeport, O.
3. A tipple belonging to the Wyoming Coal Co.
4. Van Dyke Tipple of Central Coal & Coke Co.
5. Lorain Coal & Dock Co.'s 35-year old houses at Wheeling Creek, O.
6. Head of Short Mountain Slope, Lykens, Penn. (1) R. A. Quinn, general manager; (2) W. Auman; (3) M. Readdy; (4) C. P Kutzner; (5) C. N. Finton; (6) J. Reese.
7. Gasoline Hoist at Ratcliff Coal Co.'s Mine, Doudsleondo, Iowa.
8. Beehive Ovens of the Keystone Coal & Coke Co. at Carbon Mine, Greensburg, Penn.
9. River Tipple of Pittsburg Mining Co., Pomeroy, O.
10. Leveller at work on ovens shown in Fig. 8.





The Preparation of Bituminous Coal

By F. E. Brackett*

SYNOPSIS—This is the first of two articles on this subject. The different types of car-dumping devices are discussed, as well as the track grades, both approaching and leading from them. The slopes of bar screens and chutes for handling the various sizes of coal are also considered.

The preparation of bituminous coal for market is one of the simple problems of mining engineering. At least the process itself is simple, but it is often quite difficult to decide just what series of operations to adopt, or just how far to carry them. The present article will be confined more particularly to the engineering aspect of the business and attempt to give data of interest to those who may be called upon to lay out mine plants.

What Is Coal Preparation?

In a general sense coal preparation consists of cleaning from impurities and in sizing over screens. The first is usually carried out in the mine and in the tipple or dumphouse. The subject of washing is a specialty in itself and will not be considered here.

Such cleaning as coal otherwise receives is simply the picking out of impurities. The screening is generally done at the tipple, although coal can be "forked" in the mine.

For the present purpose we recognize two main classes —steam coals and gas coals. In physical texture the first are softer and more brittle than the latter. They produce less smoke and have a higher calorific value. On burning, the slack coal cokes quickly, forming a cover over the fire, which is easily broken with a slice bar, thus allowing a full draught through the fuel.

Slack is, therefore, nearly as good as lump coal among fuels of this class. The brittle nature and coking qualities of steam coals make sizing on screens both less effective and less important than for gas coals. We, therefore, seldom find screening carried on to any considerable extent with this class.

With gas coals, however, the conditions are quite the reverse. Their hard texture and slower coking qualities make screening advisable, and in some sections of the country where competition is strong, we find this sizing carried out with great care.

Coal is nearly always cleaned underground. Above all things the miner must be required to load a clean product. Any other policy would much increase the work at the surface and decrease the efficiency of the plant. Usually the only other attempt made at cleaning is carried out in the railroad cars. From one to several men placed there to watch the coal as it is dumped can ordinarily catch all the dirt which has passed the miner. Sometimes picking belts are installed, as in the anthracite mines, but their use has, in some cases, been found superfluous. They are not usual nor in any sense common features of bituminous plants.

The smaller grades of coal are sometimes washed for market. In coking plants the entire output is sometimes crushed and washed to remove the sulphur, and thus improve the grade of coke.

*Consulting engineer, Cumberland, Md.

It is usually thought proper to dump coal but once after it has been loaded by the miner. Thus in nearly all cases we find the mine cars brought to the surface, even though in shaft and slope mines this is sometimes quite inconvenient where large outputs are to be obtained.

It would seem that too much stress had been laid on this point. Much coal is handled eight times before it reaches the grate bars, as follows: First, from breast to mine cars; second, to railroad cars; third, to barge; fourth, to crane bucket; fifth, to storage bin; sixth, to carts; seventh, to boiler-room floor, and eighth, to grate bars. Sometimes even this schedule might be increased.

Again, the rehandling after the coal has been shipped is often much rougher than any received at the mine. For these reasons we think the colliery owner would be justified in dumping his coal from mine cars to skip, monitor or other contrivance, if he finds it convenient to do so.

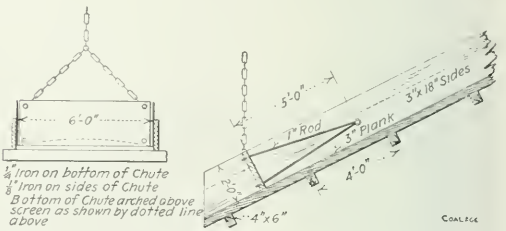


Fig. 1. A Gate Which Can Be Easily Opened or Closed

Moreover, it might be feasible by special designs to drop the coal from the skip to the railroad car more gently than it is possible to load direct from the mine car. The use of "baskets" on tipples to break the fall is a recognized advantage, but from some cause or other the use of a skip is not looked on favorably, though for reasons just given this would seem to be nothing more than a mere prejudice.

The Different Kinds of Dumps

Contrivances for dumping coal from the mine cars may be classified under three heads: bottom dumps, cradle dumps and end dumps, or tipples. These all possess their peculiar advantages, but the latter is by far the most common in ordinary use.

Gates are sometimes placed in the bottoms of mine cars, where they are to be dumped into long bins at different points. Gear equipped in this way can be discharged at any point on a track where an opening is provided, and hence for bins this is convenient. "Rope trips" can be dumped in this way without uncoupling the cable.

As bins are a necessity at coke plants and many railroad coaling stations, this method of dumping is frequently found useful. Bins can also be loaded by putting the ordinary end dump on a truck and moving same to various points, where a car is to be emptied. This, however, is tedious for a large bin and output.

Cradle dumps turn the pit wagons sideways and require no gate in the car. The form is that of a large open cylinder, in which one or more cars are placed. This cylinder slowly revolves and thus discharges the car's contents.

For loading railroad cars this arrangement has been found too slow and cumbersome for general use, but for filling bins it might prove useful, especially where several cars would be emptied at once. Like the bottom dump, it might be arranged to accommodate a rope trip without uncoupling, but for a long trip this would no doubt be too cumbersome. It is probable that the coal is deposited more gently with contrivances of this class than with any other type.

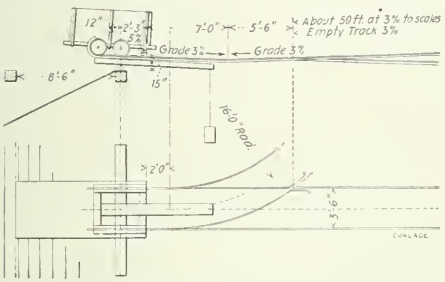

FIG. 2. A HALF TIPPLE, SHOWING TRACK GRADES

For ordinary commercial purposes—loading railroad cars—we find the end dump or tipple almost universal. This is on account of its small size, low cost and rapidity. There are a number of different types of this tipple on the market, but most of them can be classified as either "half tipples" or "through tipples."

Fig. 2 shows an efficient and cheap device of a type which since the introduction of the "through tipples" has come to be known as a "half tipple," because the car must be pulled or moves automatically backward after dumping, instead of going on through.

By arranging the grades as shown, the empty car leaves the tipple of its own accord after discharge, but sufficient momentum must exist in the car to carry it uphill to the tipple from the low point, which is 7 ft. in rear of the mechanism.

This momentum is provided by allowing about 50 ft. of a downhill run from the mine scales, as indicated. In actual practice three cars per minute have been dumped with this tipple, but delays due to non-arrival of trips, and other miscellaneous causes, much decreased this as a daily average.

Fig. 3 shows a through tipple. After being dumped, the car travels over the tipple and around the "kickback" at *B*. The "horns" which hold the car on the table while it is being dumped are opened by the action, through a special mechanism, of the next car fed to the dump. This arrangement somewhat reduces the labor requisite to the use of the half tipple and slightly increases the speed of dumping. About four cars per minute can be handled, provided there are no delays in feeding.

It is frequently claimed that this speed can be increased, though for ordinary practice it is very doubtful whether it can be materially augmented. Certainly not, if the coal is passed over a bar screen in the chute below the tipple. In fact, to screen properly this speed should be reduced a little for two-ton mine cars. There is usually far more delay in getting cars to the tipple than there is in actual dumping.

NECESSARY TRACK GRADES

The grades or slopes of the tracks below the tipple and around the "kickback" should be carefully laid out so as to prevent the empty car from attaining too great a velocity, but at the same time to make its movement prompt and certain.

To accomplish this, it would seem that the empty track grade *g* should not exceed 2 per cent., and that the total slope *b*, existing at the center of the tipple, should be between 0.0265 and 0.0320 ft., according to the amount of resistance to be encountered. For cases where there is no unusual friction, the lower value might be used, but practice usually sanctions a little higher grade. In a case where there are two extra switches, besides the one at the "kickback" to cross, and where the distance between the tracks is double width (about 16 ft.), the factor used should not be less than 0.0320.

After leaving the mine car, the coal enters the chute. If no screening is done, this is only a means of conveying the coal to the transportation car and performs no function except to break the fall and assist in trimming, so as to give the loaded car a pleasing appearance. Under these conditions the shorter the chute the better.

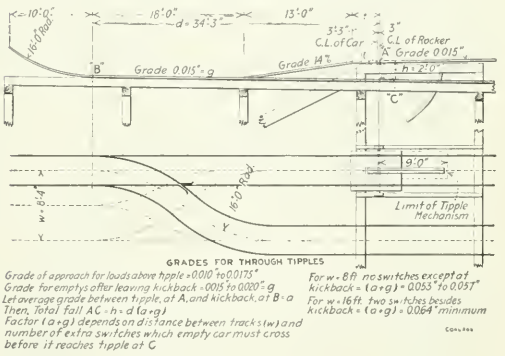

FIG. 3. A THROUGH TIPPLE AND KICKBACK

When a screen is used in the chute, this usually consists of a number of bars placed longitudinally, over which the coal passes. That portion of the chute above the screen should be long enough to spread the coal over the entire width, but not so long as to unduly increase its velocity. Sometimes this part of the chute is arched slightly on the bottom, as shown by the dotted line in Fig. 1. This materially assists in spreading the coal.

Except for an apron to aid in trimming the cars, the part of the chute below the screen can scarcely be said to perform a function, unless the coal is stopped at its lower end.

The dimensions of coal chutes no doubt are largely fixed by the capacity of the mine cars. However, with the standardization of equipment the dimensions of chutes for lump and run-of-mine coal have been quite generally fixed at 6 ft. wide and 18 in. to 2 ft. deep where screens are used. Where there are no screens, the

chutes are often made narrower and sometimes taper slightly toward the lower end. Four feet is a common width for the extremity or lip.

The narrower end assists greatly in trimming when the length of the chute lies the long way of the railroad car. By this arrangement, the best trim on the car is accomplished. Where conveyors and revolving screens are employed, the fine-coal chutes are often from 12 in. to 18 in. wide.

From 5 to 8 ft. length of chute is usually required above the screen to spread the coal. About 10 ft. of a 6-ft. chute is enough to hold, say, 2 tons of coal, or the capacity of an ordinary miné car. This, then, is about the proper length of chute below the screen. Where chutes are made of wood, lined with sheet iron, the bottoms should be covered with ¼-in. plate, while the sides may be ⅛ in. in thickness.

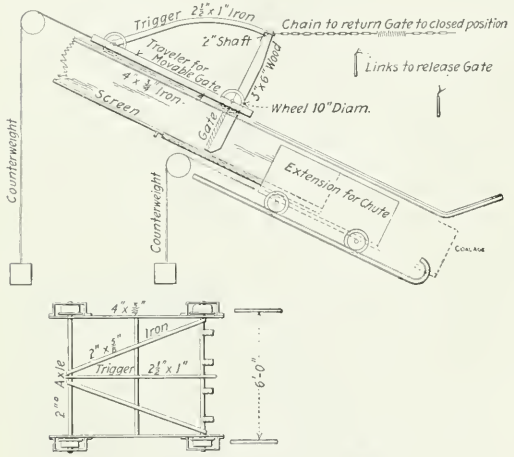

FIG. 4. A SLIDING GATE OR "MONKEY"

If the chute is a short one, the slope is not of great consequence so long as it is enough. As a rule, 25 degrees will be found sufficiently steep for steam coals. With long chutes, such as are required with screening arrangements, care should be taken to get enough slope to move the coal slowly along, but not enough to raise the velocity too high.

The following pitches have been found by trial to be about right. Some variation, however, exists between different regions. Slope or sump chutes and screens require from 5 in. to 6 in. per foot. Four and one-half inches (20°—33′) can be used for very hard, bright coals. This pitch will sometimes fail to start coal which has been stopped in the chute, even when the lining has worn bright. Nut coal will run on 6 in. per ft. or a slope of 26°—34′. The screens, however, should be pitched 8 in., or 10 in. per ft., and the chutes a little steeper than 6 in. Pea screens require about 10 in. per ft., and pea chutes at least 8 in. Slack chutes should incline 12 in. per ft., or 15 degrees.

RETARDATION NEAR END OF CHUTE

Coal is often retarded or brought to a complete standstill in the chute at the lower end, in order to permit a more thorough cleaning or for the purpose of weighing. Where the chutes are long, the coal is nearly always thus retarded, because its speed would break up the lumps too much were it allowed to enter the railroad car without check of some kind. There are various ways of stopping the coal, but the gate "monkey" and pan are the most common. A brief description will therefore not be out of place here.

Fig. 1 represents a gate of convenient form, which is easily opened and closed, and coal can be fed out at any speed necessary for a thorough inspection and cleaning. As a check on the velocity, however, it acts a little too late. The coal has already attained considerable speed, and some breakage may be expected.

The sliding gate or "monkey," Fig. 4, was designed to correct this trouble. The illustration shows an iron truck carrying the end gate for the chute. This truck is counterbalanced and controlled by a brake and a positive clutch (not shown), which holds it in its upper position. Both of these are operated through levers by the tipple man.

The weight of coal against the gate causes it to slide down the chute, until the trigger catches one of the wrought-iron loops placed for that purpose. This frees the gate, which automatically opens and releases the coal. The counterweight then returns the truck to its upper position.

The gate itself is closed by the tightening of the chain, which is fastened to the upper part of the gate frame near the point where the trigger catches it. The figure also shows an extension formed by another truck. This is a rather uncommon form of apron.

A Queer Fuel

In this country, where we have coal, wood and gas, in abundance, people hardly give the heating question a thought. But in South Africa, where there is very little fuel of any kind, they are compelled to look to other sources for their fuel. In parts of Cape Colony, it is a common sight to see little boys, ranging over the fields with a sack, picking up dried cattle dung.

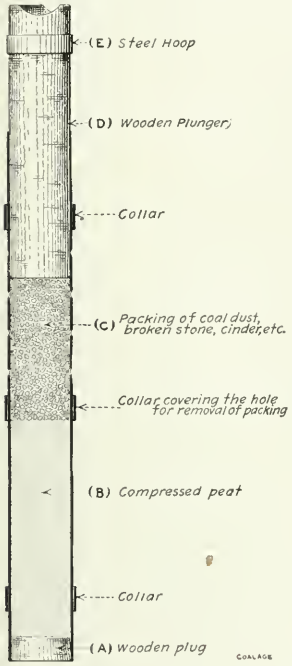
In fact this is the principal fuel supply. The farmers herd their cattle in a kraal at night, for months at a time, until their droppings have reached a thickness of several feet, and are, of course, trampled down very hard. When it is the required thickness, it is cut into square blocks and corded, very much as we cord wood in this country. When sufficiently dry it is ready for use. It lights easily and gives off considerable heat, but soon burns out, and must be replenished frequently.

Where a hillside storage of anthracite is desired, the engineer should select a slope about 300 ft. wide and 1000 ft. long, with a pitch of at least 25 deg. which ends in a level area, large enough to accommodate the desired number of tracks. If such conditions are not obtainable the expense of much digging and filling-in will have to be considered. The topography of the immediate neighborhood should be such as to permit the laying of a track, with a fair grade to the top of the storage hill and down on the other side, at a moderate cost. With this method of storage, rescreening is easy. The cost of maintenance, however, is high, as the hillside must be either concreted, paved or planked in order to insure clean coal. The cost of installing this type of plant averages $1.60 per ton of capacity, and where the hill is paved or concreted the cost is somewhat higher. The operating cost is estimated to be 10c. per ton. The percentage of breakage is high.

Metal Mine Posts

Some metal sets of the Nellen system, shown herewith, have been placed for experimental purposes at the Wérister mine, Belgium.

Each post consists of a metal sleeve of 4.8 in. diameter, split lengthwise into two parts, which are fastened together by three split collars. This sleeve is closed at the bottom with a wooden plug *A*. In it are placed one or two cylinders of compressed peat *B*, then some packing *C*, composed of coal dust, pieces of stone, cinders, etc., reaching to a point about 12 in. from the top.



When Pressure Comes on This Post it Telescopes, the Shortening Action Being Resisted by Compression of Peat

Above is inserted a wooden plunger *D* about 28 in. high, with a steel hoop *E*. The elevation of the plunger is regulated by abstracting a sufficient quantity of the packing through holes in the tube. The rail serving as a crossbar rests on the plungers of the two posts, which are held in place under it by iron shoes *F*, fastened to its base by pressure screws.

Post Gives Approximately Equal Resistance Under Unequal Subsidence

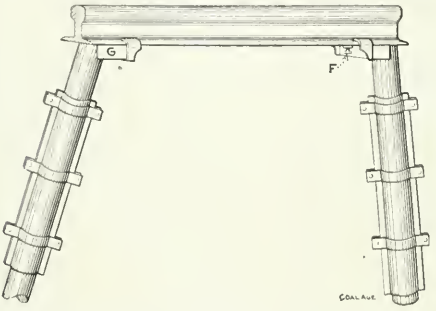
To take up the effect of the thrust, there is placed between the plunger top and the shoe, a block of compressed peat *G*. The holes in the sleeve permit the removal of packing material when the pressure is too great, thus avoiding a distortion of the frame and preserving more or less elasticity.

Unlike wooden timbers, which break, the Nellen metal posts are in this way regulated so that they give a constant support to the roof. Experiments tend to show that they resist the first pressure well. Sometimes, under its action, the sleeves tend to open, in which case more split collars are placed on them.

M. Dessard, director of the Wérister colliery, figures the cost of a metal set in place at $12.75, which compares with $1.78 for a timber set. The cost of putting up the metal set is increased by the difficulty in handling the heavy parts. Each post weighs about 103 and the crossrail about 158 lb. Furthermore, the assemblage of the parts requires some skill and takes more time than ordinary timbering.

In spite of the higher cost of the metal frame, M. Dessard thinks that its use will be economical in galleries of long life, where otherwise several successive repairs or renewals might be anticipated, due either to the pressure of the roof or deterioration of the timber.

In consequence of their being of greater size than metal supports, all-wood sets require that the galleries be made larger if an equal passage way is desired. Metal sets save about 4 or 8 in. in width and 2 in. in height. They may generally be placed farther apart than the wooden sets. Even if spaced at the same distance as wooden supports, a saving results, as, in general, intermediate timbers have to be used after the first timber sets become injured. Each replacement of the timbers in a gallery represents a cost of labor and material of about $4 per running foot.



A Three-piece Set on Nellen System, Which "Gives under Pressure" and Does Not Break

In case the galleries are abandoned, the metal post may usually be removed at little expense and used over again. It may be added that the galleries thus equipped should be easier to keep amply open. The general hygiene and safety of the workings cannot be other than improved by the use of these posts, which are likely to be adopted in all collieries where the management looks beyond first cost. The Wérister colliery proposes to use more of these sets in the future.

Note—Report of M. Beaupain in the Annales des Mines de Belgique Tome XVII, 1911. Translated by E. P. Buffet for Coal Age.

It may almost be said that good discipline in the mine will do more to reduce death rates than any discovery scientists are likely to make. The highest technical skill at the command of industry becomes inoperative where discipline is at a discount. In the same way mine rules and regulations are useless if they are not observed.

Statistics on Coal Mine Fatalities

By F. L. Hoffman*

SYNOPSIS—A brief review of coal-mine accidents during the last decade, 1902 to 1911, together with a short summary of the fatal accidents for the last thirty years, 1882-1911. It is shown that the death rate per 1000 men employed is less for 1912 than for the previous year.

The annual tabulation of coal-mine fatalities for North America is a difficult and discouraging task. It is practically impossible to obtain all returns for the several coal-equipped statistical service, and publish in the future quarterly reports on mine accidents in much the same manner as this has been done for some years by the Interstate Commerce Commission.

There are other urgent needs for reforms in the statistics of coal-mine fatalities. It requires no discussion to sustain the conclusion that trustworthy information regarding coal-mine fatalities is a matter of considerable practical importance to the coal-mining industry. The

(a) Six months only. (b) Eight months only.

mining states within a reasonable period of time after the close of the year for which the information is required. As an inevitable result, the data are deprived of the highest attainable degree of practical utility.

I first commenced the tabulation of coal-mine fatalities in 1897, at the request of the late editor of the *Engineering and Mining Journal*, Richard P. Rothwell. Since the field was new, many difficulties were met with, and these have not passed away during the intervening years. Apparently some of the coal-mine inspectors are indifferent to the requests made to them for information, and in other states the law prevents the publicity of the required facts previous to the publication of the official report.

The establishment of the Federal Bureau of Mines has done something to improve matters and it is to be hoped that the bureau will succeed in establishing a well value of the returns is in proportion to their inherent trustworthiness and comparability.

It may be seriously questioned whether, under present methods, the average number of men employed is always determined by precisely the same method, and it may be suggested that an understanding should be arrived at by all of the coal-mining states to make use of standardized methods, not only as regards the calculation of fatality rates, but also as regards many important statistical details, which at present are not available. This suggestion applies to the causes of accidents, the time of their occurrence, the age, race, nationality and precise occupation of the employed, and the killed or injured, as the case may be.

Many accidents also occur in which there is no loss of life or serious injury. The reports for the several states do not at present show the number of accidents as distinct from the number of persons killed or injured. A

*Statistician, Prudential Insurance Co., Newark, N. J.

further defect is the absence of a precise definition as to what constitutes a fatal, a serious, or a minor injury. Some time limitation must be agreed upon to make the fatalities strictly comparable for the several states. It occasionally occurs that death follows a serious injury many months after its occurrence.

For practical statistical purposes it would probably be advisable to consider all serious injuries fatal which are terminated by death within seven days of their occurrence.

All these matters require careful consideration, and no

TABLE III.—FATAL ACCIDENTS IN THE COAL MINES OF NORTH AMERICA

Comparison of 1911 with 1906-1910.

authority is in a better position to bring about the required reforms than the Federal Bureau of Mines. Its preliminary tabulation of accidents marks a promising beginning, and it is to be hoped that, in course of time, the statistical aspects of the accident problem will receive more extended consideration.

Granting a considerable degree of inherent trustworthiness to the valuable data regarding fatal accidents in coal mines, it must be admitted that the returns regarding serious and nonserious injuries are often worthless. From the point of view of employers' liability and workmen's compensation, however, the nonfatal injuries are of much greater importance than those which are terminated by death.

According to the statistics of compensation, and of proceedings under the Workmen's Compensation Act of 1906, for the year 1910, the financial consequences of mine accidents in the United Kingdom were as follows: There were 1347 fatal cases, costing companies £222,973 ($1,085,098) in compensation; the number of nonfatal cases was 166,709, for which £818,302 ($3,982,267) was paid. In addition, compensation was required to be paid to persons employed in mines on account of 3783 cases of industrial disease, to the amount of £42,507 ($206,860).

In the course of time, when the doctrine of liability for industrial diseases shall become more firmly established and enlarged, it is practically certain that compensation on this account will reach a much more impressive figure. The data are merely referred to as an illustration of the practical utility of trustworthy accident statistics, including nonfatal injuries, precisely defined, according to the nature of the injury, the part of the body injured, and the consequent duration of disablement as measured by incapacity for work.

After delaying the present discussion for several months on account of the difficulties briefly referred to at the outset, I have found it necessary to include the returns for three states as furnished by the preliminary report of the Federal Bureau of Mines. I have done so with reluctance, since the returns may be subject to future correction, but I have not been able to secure the required information from the state inspectors of mines of the three states. I only refer to these difficulties to make it clear that the long delay in publication is not my own fault or due to indifference on the part of the large majority of state inspectors of mines, who have been most courteous and prompt in furnishing the desired information.

According to the present tabulation, the number of fatal accidents in the coal mines of North America during 1911 was 2555, or 496 less than the number of fatalities during the previous year. Since the number of persons employed in mining was slightly higher, the fatality rate decreased to 3.48 per 1000 during 1911, against 4.18 in 1910. Table I gives in detail the number of fatal accidents in the principal coal-mining states of North America for each year since 1902, and a similar statement for the decade ending with 1911. Much to my regret, the returns for some of the smaller coal-mining states could not be included, particularly Alaska, Arkansas, North Dakota, Texas and Virginia.

This table shows that the largest number of fatalities (699) during 1911 occurred in the anthracite mines of Pennsylvania, followed by 515 deaths in the bituminous mines of that state, and 332 deaths in the coal mines of West Virginia.

TABLE IV.—THIRTY-YEAR RECORD OF THE FATAL ACCIDENTS IN THE COAL MINES OF NORTH AMERICA, 1882—1911.

	Number of Employees	Number Killed	Rate per 1000 Employed
1882	151,737	412	2 72

1887—91	1,415,349	3666	2 59
1892—96	1,935,832	4909	2 58
1897—01	2,197,377	6355	2 89
1902—06	3,018,695	9988	3 31
1907—11	3,578,216	13619	3 81
1882—1911	13,124,842	11308	3 15

The highest fatality rate during 1911 was 10.37 per 1000 employed, and this rate was for the state of Tennessee. This excess in the fatality rate was due largely to an explosion at Briceville, which involved a loss of 81 lives. Second to Tennessee in this respect is the state of Alabama, where the figures reached 9.20 per 1000, due largely to an explosion at the Banner mine, which caused a loss of 128 lives. The rates in detail for each state, and for each year of the decade ending with 1911, as well as for the North American coal field as a whole, are given in Table II.

According to this table the average fatality rate in coal mining in North America during the decade ending with 1911 was 3.48 per 1000 men employed. The rate attained its maximum during 1910, when it was 4.18 per 1000, and its minimum in 1903, when it was 3.16. Comparing the rate for 1911 with the rate for 1910, it is shown that there was a decrease of 0.70 per cent.

If the 1910 rate had prevailed in 1911 there would have been 510 more lives lost than was actually the case The reduction in the rate may safely be considered a gratifying evidence that improved methods of mining, the introduction of safety devices, rescue work, etc., are beginning to show results, but this cannot be entirely credited to the causes stated.

Comparing the fatality rates for 1911 with the average for the preceding five years, it appears that the rates increased in Alabama, Iowa, Kansas, Michigan, Pennsylvania (anthracite), Tennessee, Utah, Washington and Nova Scotia. This evidence of an increase in the rates of representative mining states is in itself conclusive proof that as yet the effect of improved methods of mining, the introduction of safety devices, rescue work, etc., is considerably below what might reasonably be expected. Only those who are thoroughly familiar with the underlying causes of mine accidents can fully appreciate the practical difficulties which will have to be overcome so as to bring about a material reduction in the fatality rate.

The problem will only be solved by radical improvements in mining methods, and most of all by the gradual development of a strict sense of discipline on the part of all mine employees, including the supervising officials themselves. Model mine conditions cannot be of much value as long as mine workers and mine officials continue to disregard rules and regulations, or wilfully incur risks which involve the safety of others as well as of those who are foolhardy enough to imperil themselves.

The details of changes in the fatality rates for the several states are given in Table III.

In continuation of the fatality record for previous years, I include Table IV, for a 30-year period, with a convenient summary of the returns by five-year periods. It will be noted that the decrease in the rate for 1911 did not materially change the average for the last five years, which exceeds considerably the average for the preceding 25 years of coal-mining operations in North America. The average fatality rate during this long period has been 3.15 per 1000 men employed. This rate, without question, is at least 50 per cent. in excess of that obtainable under safer mining methods with a mining population more obedient to rational rules and regulations making for safety in mine work.

Considering that the rate includes both inside and outside employees, it requires no argument to emphasize the conclusion that the rate, without doubt, represents conditions much better than they actually are. If only underground workers had been considered, the rate would probably have been not far from 5 per 1000 during the last decade.

Since the average age of coal miners in North America is probably not much over 33 years, when the normal death rate is about 9.5 per 1000, it is obvious that on account of the risk in coal-mining operations the mortality of this class of wage earners is probably increased about 50 per cent. It would, therefore, seem that much more public attention should be given to the question of accident prevention than to the subject of employers' liability and workmen's compensation.

TABLE V.—LIST OF MINING ACCIDENTS IN GERMANY DURING THE LAST 46 YEARS, 1867—1912.

Year.	Name of the Mine.	Number of Deaths.
1867.	Fundgrube Sachsen	101
1869.	Iserlohn, Ruhrrevier	101

1912.	Osterfeld, Ruhrrevier	16
1912.	Lothringen, Ruhrrevier	110

The following is a brief list of the accidents in the United States, involving the loss of five or more lives during 1911, arranged in the order of their occurrence:

1911		No. killed
Jan. 20	Gayton Mines, Richmond, Va.	5
Jan. 25	Hughestown No. 10, Pittston, Pa., Penna. Coal Co.	6
Feb. 9	Cokedale Mine, Trinidad, Colo., American Smelting and Refining Company	9
March 18	Mine No. 16, West Mineral, Kan., M., K. & T. Ry.	6
April 7	Panceast Mine, Tbroop, Pa.	73
April 8	Banner Mine, Birmingham, Ala.	128
April 24	Ott Mine No. 20, Elk Garden, W. Va., Davis Coal & Coke Co.	10
July 15	Sykesville, Pa., Cascade Coal & Coke Co.	21
Oct. 25	O'Gara Mine No. 9, Harrisburg, Ill.	8
Nov. 9	Adrian Mine, Punxsutawney, Pa., Rochester & Pittsburg C. I. Co.	8
Nov. 18	Vivian, W. Va., Bottom Creek Coal & Coke Co.	18
Dec. 9	Cross Mountain Mine, Briceville, Tenn., Knoxville Iron Co.	84

Table V is derived from German sources, and shows the more serious mine accidents throughout Germany since 1867.

During 1911 the number of deaths in disasters causing a loss of 10 lives or more was 334. It is self-evident, therefore, that the chief consideration is not the disaster which attracts national or even international attention, but the daily loss of life, due to falls of roof, mine cars and other causes more or less preventable, provided mine workers and supervising officials coöperate and work persistently toward this desired end.

Danger from shotfiring may be greatly reduced by observing the following points: (1) If possible use an electric battery for shotfiring. The handles should be detachable and the cable at least 20 yd. long. (2) Examine all working places carefully before firing. If possible remove gas and dust if present. (3) Keep all detonators in a locked can. After removing one, relock the can. (4) Never shoot from the solid. All under cutting should be at least 66 in. deeper than the shot hole. (5) Use only just enough powder to do the work where the coal is full of slips and breaks. (6) Never tamp with coal dust. (7) Remove all powder before firing. (8) Use a copper scraper and a wooden rammer. (9) Only fire one shot at a time.

Development of Coal Cutting Machinery

By Thomas W. Fry*

SYNOPSIS—This article describes briefly the inception and development of the continuous undercutting machine from the first type employing a revolving cutter-bar and cleaner-chain to the modern design, which will operate either right or left handed and is driven by a motor entirely inclosed in a flame-proof case.

For the purpose of undercutting coal, two types of machines had been developed in this country up to about 1885. These were the reciprocating or pick machine, driven by compressed air, and the breast machine, driven either by compressed air or electricity. As compared with hand work, the advent of these types mark a decided advance in the art or process of mining coal.

The reciprocating machine, or puncher, as it is commonly called, is practically the power operated equivalent of the miner's hand pick—virtually a pick engine mounted on wheels. Naturally it is much more powerful and cuts faster than by hand. It is built in various sizes, which are well designed, durable and efficient.

This type of machine will work in coal, which, owing to impurities such as sulphur and rock, cannot be economically cut by some of the other types. It is small and inexpensive in first cost, but owing to its relatively less cutting capacity compared with the larger and more powerful machines of other types, the expense of operation in labor and power per ton of coal produced is higher.

Its principal limitation is that its successful operation depends upon the skill, strength and continuous effort of the runner since it must be guided and controlled by the hands and feet, and each blow which is delivered must be placed effectively.

The Breast Machine

The breast machine substitutes for the reciprocating pick a gang of teeth or cutters, which are moved against the face of the coal, scraping or raking it from the solid. In the earlier types the cutters were inserted in a rotating bar, mounted at the front end of the machine, and as this bar was forced under the coal at right angles to the face, the bits cut a kurf equal in height to the diameter of the circle in which they rotated.

In the later machines, however, the rotating cutter-bar was dispensed with and the bits inserted in the links of an endless chain, which traveled in a horizontal plane. In this type the cutters operate only while crossing the machine at its forward end, being pushed ahead meanwhile under the coal.

Generally speaking, breast machines are more continuous in their operation than punchers, since they make an undercut, say, 3 ft. wide and 6 ft. deep, ordinarily without stopping. They are held to their work by jacks and fed forward by power instead of being guided and controlled by the strength and skill of the operator.

Both pick and breast machines make undercuts about 3 ft. and 5 ft. wide, respectively, and from 5 ft. to 7 ft. in depth. On the completion of these cuts, the machine must be moved with more or less difficulty and loss of cutting time to a position adjacent to the incision already made. This frequently involves the removal and replacement of posts for supporting the roof close to the face of the coal.

It is evident from the above that there is great advantage in a machine which, after its first undercut at one side of the room is made, will cut continuously without interruption clear across the face. Such a machine is not only more efficient in cutting capacity, but also leaves a cleaner bottom.

Continuous Coal Cutters

Development work on cutters of the continuously operating type was begun in the early Eighties and they were placed upon the market a few years later. Fig. 1 shows a top view of such a machine as built by the Diamond Prospecting Co., of Chicago, now the Sullivan Machinery Co. It will be noted that like all of the

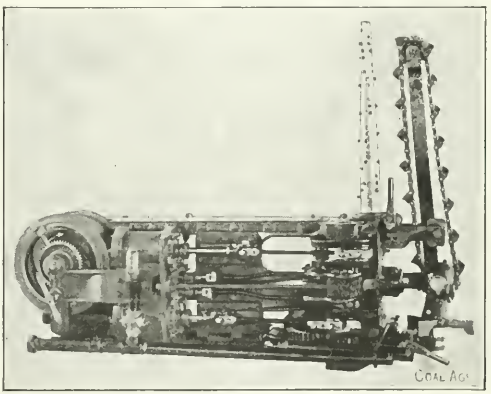

Fig. 1. Top View of First Continuous Coal Cutter

machines of that period, the cutter-bar was of the rotating type with inserted bits.

The machine was operated by compressed-air engines geared to the cutter-bar and to a drum furnished with a wire rope, the free end of which was attached to a jack set close to the face of the coal in advance of the machine. The entire mechanism could, therefore, be pulled along by means of this rope and drum.

To keep the machine close to the face, it was either mounted on rails or attached to a heavily weighted car, which was supported on sharp, edged disks or wheels which sunk into the bottom and resisted the outward thrust of the cutter-bar, which tended to force the machine away from its work. The illustration also shows the cleaner chain following the cutter-bar and provided with scrapers to clean the cuttings out of the kurf.

This machine was also provided with jacks for raising it on one side or the other, thus keeping the cutter bar down close to the bottom or raising it to pass over rocks or other impurities.

*Claremont, N. H.

The Improvements Made

Various improvements in this type of machine have been made from time to time. The first and most important of which was doubtless the substitution of the endless chain for the revolving cutter-bar. Another was the employment of a cable chain instead of the wire feed rope. The chain is not only more convenient to handle than the rope, but embodies a principle which was a pioneer invention in the method of guiding or steering the machine while at work.

The feed chain is fastened to a jack at the side of the room, extends along the face to a sprocket on the forward end of the machine body, thence to sprockets at the rear of the machine, and then to a jack at the opposite side of the room.

By tightening or loosening the chain between the machine and the rear jack, the angle of the bar supporting the cutter-chain can be varied with relation to the face of the coal, thus permitting the machine to follow irregularities therein.

Then, too, by advancing the end of the bar in the direction in which the machine is moving at the completion of its travel, the cut can be finished to the full width of the room.

By raising or depressing the feed chain in advance of the machine, the latter is made to cut higher or lower in the coal. This chain is also used in making the entering of sumping cut, and also in removing the machine from the face and loading it upon its truck for transfer to another room. All of these operations are performed by power from the electric motor or compressed-air engine.

The latest type of these machines is arranged to make its face cut either right- or left-handed. The motor is also totally inclosed in a flame-proof case, adapting it admirably for use in gaseous mines.

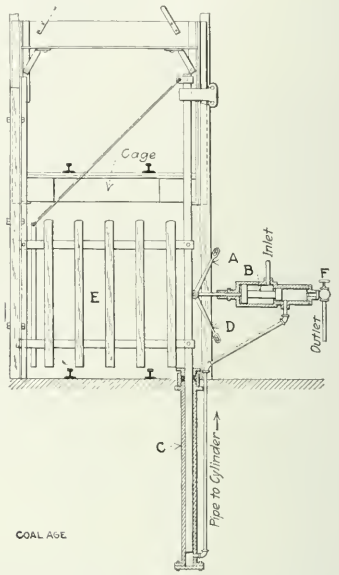
Where the local conditions will warrant the use of any chain-cutting machine, those performing a continuous cut are the most advanced and best perfected of all coal undercutters. Being far more powerful than the puncher or breast machine, their cutting capacity is proportionally greater, their expense of operation per ton of coal mined is correspondingly less and an increased output may be secured at a lower cost. Their development has extended the use of machine mining in drawing pillars and in work on steep-pitching beds, which heretofore has usually been done by hand.

An Automatic Safety Mine Gate

An automatic safety mine gate has recently been invented and patented by M. W. Harvey, of Sykesville, Penn., which, due to its simplicity and ease of manufacture, requires more than a casual notice. It consists of a cylinder approximately 6½ ft. long made of 4½ in. pipe and provided with a stuffing box at the top, inside of which works a plunger made of 4-in. pipe which has been turned down and polished to a diameter of 4⅜ in. outside.

The cylinder is placed vertically in the ground, which renders it frostproof. It may be set at either side of the gate to be operated as convenience may dictate. The gate itself may be made by bending two pieces of strap iron and bolting wood palings vertically between them.

A controlling valve, somewhat similar in principle to a piston valve on a steam engine, is provided. This is equipped with a contact for the cage in its proper position for loading. The outlet, or exhaust, is provided with a throttle valve to control the downward movement of the gate. The general arrangement can be clearly seen in the accompanying drawing.



The Gate and Operating Mechanism

The operation is as follows: When the cage is brought to position for loading from the ground, it makes contact with the lever *A*, which operates the piston valve *B*. This admits air or steam to the vertical cylinder *C*, forcing up the plunger *D* and with it the gate *E*. When the cage is moved from this position, the piston valve *B* is forced back to its original place by the pressure of the air. This releases the exhaust and allows the plunger and gate to descend. The rapidity of this descent may be controlled by the valve *F* to any desired speed.

In the ordinary operation of hoisting, the contact between the cage and the lever *A* is only momentary while the cage is passing that point. Consequently, the amount of air admitted to the main cylinder is not enough to start the plunger from its initial position, and the gate therefore remains stationary.

This gate can be easily arranged so that temporary removal of one of the guides on the opposite side from the plunger will allow it to be swung open for the loading of long rails or other material upon the cage.

One of these gates is in successful operation at a Pennsylvania coal mine, and we understand that four more are to be installed soon.

The annual loss due to the run-of-mine law of the state of Arkansas to operators and consumers is estimated to be $1,670,500; the loss to the miners is placed at $100,000, the market loss equals $1,600,000, while the loss through waste reaches $850,000. All of which gives the appalling total yearly loss of $1,220,000, due to hasty class legislation.

The New York Market in 1912

SYNOPSIS—Market conditions at New York, on the average, were satisfactory during the year. The trade in both anthracite and bituminous branches was active and profitable previous to the suspension in the mining regions. Succeeding this, however, the usual summer dullness developed in bituminous, but the fall trade was heavy and characterized by an unusually high price-level. Rather panicky conditions prevailed in the anthracite market over the last half of the year, due to the shortage as a result of the suspension, but the year closed with conditions approximately normal.

The importance of New York as a coal distributing point is probably not generally appreciated. Unfortunately no statistics covering the fuel handled there are available, but it is conservatively estimated that this runs approximately 32,000,000 tons per annum, about equally divided between anthracite and bituminous. Because of the smoke restrictions in effect, the consumption of the latter locally, amounts to less than 5,000,000 tons per annum, the remainder being shipped to New England ports or used in the bunker trade locally. It is estimated that about 12,250,000 tons of anthracite are consumed here, which is about 14 per cent. of the total production.

The First Quarter

The year opened with business fairly active. There was only a limited spot demand, but the movement was large, although not in excess of the contracts which absorbed all the arrivals without much delay. Transportation had been much better than during previous seasons at this time, and shippers were able to meet their obligations more readily than heretofore.

A demand for prompt shipment began to develop during the first month, due to the stormy weather which caused more than the usual inquiries for cargoes. However, a large number of barges had been loaded and waiting power to move them for some time, so that prices were not affected. Loading at the piers was considerably hampered by the freezing of the coal.

Congestion and accumulation of freight along the railroads retarded delivery of coal to line consumers, causing them much uneasiness over the supply and resulted in a sharp increase in the demand for rail coal. Marine transportation in the harbor and sound was quite hazardous in February, due to the ice conditions. The heavy demand and poor car supply was keeping the arrivals down with the result that local stocks were considerably below normal.

The near approach of the expiration of the agreement with the miners together with the short supply, stimulated the New York market early in March and prices advanced rapidly until even the poorer grades were being held at $2.90 to $3 f.o.b. with only small tonnages available even at these figures. The supply at the piers was extremely limited and shippers were only able to take care of their contracts.

Prices continued to advance rapidly through the month reaching the maximum about the middle, when spot bituminous was quoted as high as $4 to $5 f.o.b. It was believed at this time that the supplies were only about 50 per cent. normal and the market was apparently bordering on a panic.

The Second Quarter

The demand for bituminous became a little less urgent toward the close of the month and the market appeared to be steadying up. Prices, however, did not ease off and the change in the situation was due more probably to the hesitancy on the part of the consumers to purchase at the prevailing high prices, believing that there must shortly be a break in the market. That they were justified in this belief, is shown by the sharp decline which occurred early in April when quotations eased off to between $2.90 to $3.65 along side. The suspension in the mining regions was now in effect but there was not much anxiety apparent locally, as yet. This did not apply to anthracite, however, as the arrivals of this grade were entirely cut off and the consumers were becoming urgent in their requests for coal.

Arrivals of bituminous throughout the month were much below normal, but there was scarcely any demand due, no doubt, to the excessive storing in anticipation of a more protracted suspension at the mines. This had a decidedly depressing effect on the trade, and the market continued dull and heavy for a time.

The bituminous market gathered some strength at the same time in sympathy with the changed conditions in hard coal. This was however, more in the way of holding its own rather than making any advance. When the agreement was finally reached between the anthracite miners and operators about the middle of the month, there was a sharp flurry in the local markets.

The month of June saw little of interest in either the hard- or soft-coal markets. The larger anthracite companies reported an active business but consumers were not showing much interest in the markets due to the increased prices which the companies put in effect. The demand centered about stove coal, which was practically out of the market.

Third Quarter

The third quarter opened with the bituminous trade down at the customary low level at this period of the year. There were few transactions, but on the other hand there was no evidence of any appreciable tonnages on demurrage. The movement was confined almost entirely to contracts, any coal being sent in on consignment usually selling at prices even less than the cost of production.

Anthracite continued quite active throughout the month, with shipments considerably behind requirements. Stocks were far below normal and there was no doubt but what a decided shortage would be experienced during the coming winter. Stove was particularly short, with none of the grades easy and prices were firm with the exception of the steam sizes which were selling off in some instances.

The month of August opened with the soft-coal market about normal for that period of the year. The car shortage was quite apparent the first part of the month and there was a fair amount of contracting at average prices. Little or no coal was coming in on speculation with the

result that demurrage consignments were quite rare; it was evident that the companies were making a concerted effort to maintain better market conditions, by adopting a vigorous curtailment policy.

The strong heavy demand for anthracite continued unabated throughout the month. No stocks were being accumulated except in the steam sizes, on which a few companies were able to get ahead. The movement into New York continued slow, with little or no indication of any improvement. The shortage was most pronounced in the stove size which was practically out of the market, and by the middle of the month was bringing a premium of 25c. per ton above the circular.

The beginning of September saw a gradual but perceptible hardening in the soft-coal market. The visible supplies on hand were rather low for this period of the year and quotations began the steady advance which they were to continue for the remainder of the year. Inquiries were becoming more frequent but consumers were hesitating to enter the market because of the new high prices.

The Fourth Quarter

That there was a decidedly tense feeling in the New York bituminous market at the beginning of October was no longer to be questioned. The heavy demand at this period of the year was almost unprecedented and it appeared at this time, that the situation would be serious when the real winter trade set in. By the middle of the month nothing could be obtained under $2.85 and this only on the lower grades, Georges Creek and the better qualities being entirely out of the market.

The first of October saw little change in the anthracite trade; the prepared sizes were still short and the steam grades in rather long supply. The mines were being pushed to the limit, but production was curtailed slightly although not seriously by the lack of sufficient labor and the inadequate car supply. The large companies expressed the belief at this time that the present acute situation was brought about by the consumer attempting to acquire his entire winter supply at once.

The first of November found the bituminous market in as probably a hard a position as it had been for some years. The movement was confined almost entirely to contracts and producers were being hard pressed to meet their obligations. The trade was quite spotty at times and showed some indications of becoming softer occasionally, but supplies were short and all arrivals going into immediate consumption. The situation was relieved about the middle of the month, by the appearance of mild weather which caused the demand to lessen somewhat.

The first of December brought with it an abrupt and decisive break in the anthracite market. This was ascribed to the allotment of larger tonnages by the companies and partly to the mild weather conditions which had been prevailing. This continued well into the middle of the month, the water tonnages received by the large companies steadily reducing the premiums on the domestic grades.

Chicago Coal Trade in 1912

SYNOPSIS—The past year was fraught with many uncertainties and anxieties, but on the whole was good so far as profits were concerned. Throughout the last few months particularly, the demand for all grades of fuel, including coke, was strong and insistent, with prices ranging exceedingly high.

With the close of the year 1912, coal producers and distributors have much to be thankful for and comparatively little to complain about. It was a year fraught with many anxieties and, at intervals, gloomy predictions, but with the balancing of the books for the twelve months those in the coal trade find that it was a period of profitable dealing.

For the purpose of considering the varied features of the Chicago market, the year may be divided into four quarters as follows:

First Quarter

January—At the beginning of the year the market was technically strong, but sales were not particularly brisk. Smokeless lump and egg were selling at various figures with efforts being made to hold prices firm at $1.90 @ 2.

There was a period of severely cold weather during the week ending Jan. 13 and wholesale prices for all kinds of coal were forced to a level higher than any attained during the preceding six years. The average mine-run price was one-third higher than two weeks before. Low grade screenings doubled in value and a rise of 50c. in other sizes was not uncommon.

February—Expectation of a shut-down of the mines April 1 agitated the Chicago coal trade in the early part of February. As an outcome, a bullish influence was exerted on the market and railroads, public utility corporations, and others began acquiring surplus stocks of steam coal.

Storage buying continued to be the chief feature of the market in the latter part of the month with a break in some prices and advances in others.

March—When March arrived there was a slight recession in prices for domestic coal, but steam prices remained firm. Anthracite was a trifle weak, as a good deal of this fuel held in transit had reached the market. There was a 10 per cent. advance in coke during the first week of the month.

Second Quarter

April—Early in April what coal buyers there were bargained shrewdly with a view of beating down prices. There practically was no anthracite to be had and for some weeks the market was halting and uncertain.

May—Buying in the early days of May was done chiefly by the railroads which had supplied themselves with only enough storage coal to tide over the suspension of the mines. The coke market was active. Toward the middle of the month there was some demand from small steam users. Screenings, mine-run and steam lump all sold around $2.10 @ 2.25, f.o.b., Chicago.

June—At the beginning of this month announcement was made by the trade of an advance of 25c. a ton

in the price of anthracite. Other important events occurring about this time included the agreement reached between the Indianapolis operators and miners, the appearance of a number of contracts from the railroads and the resumption of work in Iowa.

THIRD QUARTER

July—During the first part of the month screenings remained firm, but domestic lump prices were exceptionally low. In a number of instances, this grade sold below $1 a ton, but smokeless lump and egg continued to be scarce.

August—Smokeless mine-run advanced 15c. Aug. 3, while smokeless lump and egg jumped from $1.90 to $2. There was much discussion among the trade concerning the influence on business of big crops and a car shortage. August 8 there was an advance of 10c. a ton on Franklin County coal. There was an advance of an equal amount on splint coal, while screenings fell off sharply 5c. a ton.

September—A rise in the price of Hocking Valley coal to $1.65 a ton was noted Sept. 7. Coke prices were strong and in many instances dealers were handling twice as much of this fuel as during the corresponding period in 1911.

A premium ranging from 10c. to 50c. was paid Sept. 21 for smokeless coal. The circular prices on Franklin County and Carterville coals were advanced 25c. a ton, while there was an increase of 15c. a ton in the price of Hocking. Splint was strong and 5c. a ton was added to the price of screenings.

FOURTH QUARTER

October—At the beginning of this month the Chicago coal market was on a rampage. Nearly everything that went by the name of coal could be sold at a fancy price. Some kinds of domestic lump commanded $2 while good grades brought from $2.25 to $2.75. In a number of instances prices were raised to such a level as to prevent buying. Many producers were off the market and called in their salesmen. There was an upward shoot in the price of smokeless. Mine-run, with a circular price of $1.25, sold at $1.50 in 100 carload lots and at $1.60 in lots of ten cars or less.

November—Throughout the first week orders for coal in Chicago exceeded the supply. Anthracite was exceptionally scarce and consumers bought other coals from necessity rather than from choice.

A break of from 25c. to 40c. a ton in the market for domestic coal was reported during the week ended Nov. 23. This drop was attributed to warmer weather prevailing at that time.

December—The beginning of December came with the market still strong and the demand for steam coal the greatest it had been in years. During the latter part of the first week in this month, however, there was a drop of about 25c. a ton in the price for domestic sizes of coal, due to the warm weather. The steam market continued strong. There was little change in coke quotations.

When the holiday season arrived, retail dealers and steam users did not buy coal except to satisfy immediate needs. The market was unusually quiet, but prices remained firm.

The Talking Cocoanut

"While in the government employ in the Philippines," says Sanford Jones, manager at North Yakima, "I was stationed on the Island of Basilan, which is a small island in the Sulu Archipelago. The natives of this island were so uncivilized that they did not even know the value of money, and of course had never heard of a telephone. Frequently they entertained us with their native dances, and in turn we would fill them with wonder and awe by a phonograph which we had in our outfit.

"Once we found it necessary to put up a telephone line between two buildings that were a little distance apart, using two 'Western Electric' magneto sets. I found a rather large cocoanut under a tree near the bamboo hut we were living in, and conceived the idea of making a cocoanut talk. So I emptied its contents and hung it on the outside of the house opposite the phone, and arranged it so that we could put the receiver through the grass wall and drop it into the cocoanut.

"We then invited some of the natives to see the wonderful cocoanut that we could make talk. With the aid of an interpreter at the other phone who understood their language, we had a lot of fun. Some of the natives were so frightened they left the village.

"One day a delegation of natives came and asked us to burn it, as they did not like to have so uncanny a thing around. So with great ceremony and much rejoicing we consigned it to the flames, and to this day I suppose they are telling their children about the cocoanut that could talk."

Small Tonnages in the West

By BENEDICT SHUBERT*

In the Rocky Mountain district, a large daily tonnage is rarely obtained over one dump. In comparison with the results at some of the Eastern mines, it might be inferred that the Western operator does not concentrate his work and is losing the advantages to be gained from handling a large daily tonnage at one point.

The demands of the coal trade in the West, places a handicap upon the producer not found in Eastern districts. It is true that a large tonnage can be economically taken from one opening and as economically screened, but the fact that it is necessary to load all lump and nut coal into box-cars, introduces a serious obstacle in the handling of large tonnages at one point.

For a daily tonnage of over 1800, the loading of practically all this coal into box-cars is a serious problem. The delays attendant to placing the cars and running the box-car loader in and out seriously cuts down the actual working time. The introduction of two or three box-car loaders, two extra loading tracks, the necessary storage bins and elevating machinery for handling the nut coal, together with the extra labor involved, complicates matters further and has prevented the development of large-tonnage tipples.

In a word, it is necessary to balance the economics of concentrated operation against the extra expense of loading this tonnage into box-cars so that the smaller operation is usually a better paying proposition.

Notes on Mine Gas Problems—I

By G. A. Burrell*

SYNOPSIS—The lower "explosive" limit of methane is nearer 5.5 than 6 per cent. and varies somewhat with the size and shape of the explosion vessel, kind of igniting body, degree of temperature, intensity of pressure, percentage of moisture and point of ignition. The upper limit is 12.4 per cent. But partial inflammations could be obtained below and above the limits mentioned. The presence of 10 per cent. of carbon dioxide raises the lower limit to 6.6 per cent. An explosion of 9.40 per cent. of methane was obtained, when the oxygen percentage was reduced to 14. With 12 per cent. oxygen and 6 per cent. methane a complete inflammation was obtained. Hence, J. Harger's plan of reducing the oxygen and adding to the carbon dioxide of mine air, will not entirely prevent explosions.

The limits of explosibility of fire-damp have been worked out by different investigators, and results, which in the main are in accord with each other, have been determined in their laboratories. Some discordant conclusions have been published, but these have resulted mainly from the fact that different experimenters have performed their work under different conditions. Sufficient emphasis has not always been placed upon the decided effect experimental conditions exert on the results.

The Variants on Which Explosibility Depends

The size and shape of the vessel employed, the nature of the source of ignition, i.e., whether a flame, a small electric spark, a large electric flash, the ignition of the mixture from above or below, the moisture in the sample and the temperature and pressure, all may have influence in determining the limits of explosibility of mixtures of combustible gases with air.

A partial burning takes place when the ignition temperature is reached, whether an explosive proportion of combustible gas is present or not. The extent of this burning will depend upon some of the conditions to which I have just referred.

But an explosion in the true sense of the word means a self-propagation of flame to all parts of a mixture without help from the source of combustion other than the ignition of the mixture at one point. The smallest quantity of any combustible gas which when mixed with air will enable this self-propagation of flame to take place is termed the lower limit of explosibility of the gas.

Low Explosive Limit of Methane with Air Mixtures

The low explosive limit for methane is about 5.50 per cent. methane and not 6 per cent., as is sometimes stated. Coquillon ignited methane-air mixtures in a closed vessel by means of an electric spark, and placed the lower limit of explosibility at 5.8 per cent. gas. Le Chatelier and Mallard and Boudouard have placed the limit at 6.0 per cent.

Eitner determined the lower limit of explosibility of methane to be 6.1 per cent. Clowes obtained 5.0 per cent. as the low limit of explosibility when the gas was fired from below with a flame and 6.0 per cent. as the limit when the gas was fired from above. Teclu found the lower limit of explosibility to be between 3.20 and 3.67 per cent.

The most recent values are those obtained by Burgess and Wheeler of England, who place the lower limit of explosibility between 5.50 and 5.70 per cent. No discussion of the different methods of experimentation will be given here, the idea I desire to convey being that an exact duplication of results by different experimenters has not always resulted.

In the laboratory of the bureau, an explosion could not be obtained when a mixture of methane and air containing less than 5.50 per cent. was subjected to the action of a small ⅛-in. spark from an induction coil. The latter was fed by four dry cells. The mixture was placed in a 100 c.c. spherical vessel over mercury.

An explosion could not be obtained with 0.10 per cent. less methane even when the pressure was increased from one to two atmospheres. A pronounced explosion occured when 5.50 per cent. methane was present, but the combustion was not quite complete. Analysis of the products of combustion showed, however, that only a trace of combustible gas remained unburnt. The experiment was made with a pure methane prepared by the action of alcohol and methyl iodide on a zinc-copper couple.

A Mere Flame Extension Is Not an Explosion

A number of experiments have been performed in the laboratory of the bureau in which a flame has been used as the source of ignition. In some of these experiments, a spherical flask having a capacity of one liter (61 cu. in.) has been used. Some burning followed under these conditions when as little as 4.75 per cent. methane was present and when iguition was effected from below. The burning extended as a cone about halfway to the top of the flask. Inflammation in the mixture increased with increasing percentage of methane. Of course, all mining men have noticed this behavior in mixtures of combustible gases and air.

With a very small percentage the inflammation starts as a cap on the flame. The inflammation spreads from the source of ignition as the percentage of combustible gas is increased. Finally, conditions are right for a violent projection of flame throughout the mixture. At about 5.50 per cent., the low limit of explosibility, the flame extends to all parts of the vessel, but travels with comparative slowness and can be followed by the eye. With increasing proportion of methane, the explosion becomes more violent.

A Mixture Which Propagates Flame Throughout Its Volume Should Be Said to Explode

It was observed that the partial burning in a mixture containing less than 5.50 per cent. methane depended up the several factors, such as nature of ignition, shape of container, etc., but that complete explosion could not be obtained, no matter what the experimental condition, when less than 5.50 per cent. of methane was present.

In determining the low explosive limit of methane-air

*Chemist, Gas Investigations, Bureau of Mines, Pittsburgh, Penn.

Note—Part of an article read at the winter meeting of the West Virginia Coal Mining Institute, Parkersburg, W. Va., Dec. 11, 1912.

mixtures, the products of combustion were examined to ascertain to what extent the gases had been burned. In experiments to follow, this was not done, unless otherwise stated. The term explosion will be retained to mean that the flame filled the container as far as could be seen by the eye. Inflammation will mean only a partial filling of the container by the flash. All experiments were made at atmospheric pressure.

High Explosive Limit of Methane-Air Mixtures

When the small spark from an ordinary induction coil was used as the source of ignition, no explosion in methane-air mixtures could be obtained after the methane was raised above 12.40 per cent. In these tests, a vessel having a capacity of 100 c.c. was used. When we used an electric flash, produced by breaking copper wire terminals through which a current of 220 volts and 7¾ amperes were flowing, different effects were observed. The mixtures were confined in a glass cylinder 4.5 in. wide and 12 in. high. The flash was produced in the center of the jar.

When a mixture containing 20 per cent. methane and 80 per cent. air was ignited, some inflammation occurred, extending a distance of 3 in. above the electric flash, but none was observed below it. In the presence of 15 per cent. methane, inflammation extended to the top of the jar and somewhat to the sides, but not downward. In the presence of 13.5 per cent. methane, the inflammation filled the upper part of the jar and spread downwards to within an inch of the bottom. In the presence of 13 per cent. methane, the flame seemed to fill the entire jar. Effects, about similar, were observed when a gas flame was applied from below to mixtures of methane and air.

Effect of Carbon Dioxide on the Explosibility of Methane

In explosions, as well as in flame extinction and physiological effects, the influence of carbon dioxide in mine air has usually been overestimated. Carbon dioxide always occurs in mine-gas mixtures in which explosive amounts of methane are present and there is always a greater oxygen deficiency than exists when the same amount of methane is added to air for sample laboratory experiments. The following tests show something about the explosibility of methane both in the presence of excessive proportions of carbon dioxide and when the oxygen is considerably reduced.

In the laboratory of the bureau, when 2.5 per cent. of carbon dioxide was present in a mixture, an explosion followed on the methane being raised to 5.83 per cent. With 5.0 per cent. carbon dioxide, an explosion occurred when the methane was raised to 6.25 per cent. With 10.0 per cent. of carbon dioxide present, an explosion was obtained when the methane constituted 6.60 per cent. of the total. A small spark from an induction coil was the source of ignition. The experimental conditions were the the same as those under which the 5.50 per cent. low explosive limit for methane and air was determined.

The presence of carbon dioxide narrows the explosive limits, but it will be observed that even 10 per cent. only raised the low limit to 6.60 per cent.

Effects of Reduced Oxygen on the Explosibility of Methane

A spherical flask having a capacity of one liter (61 cu. in.) was filled with a mixture containing the following gases:

AN EXPLOSIVE MIXTURE OF GASES

Gas	Percentage	Gas	Percentage
CO_2	0 03	CH_4	9 40
O_2	14 00	N_2	76.57
			100 00

When exposed to a flame from above, inflammation occurred. The flame spread downward to the middle of the flask, and out to the sides. The eye could easily follow the course of the wave. When the mixture was ignited from below with a flame, it exploded with considerable force. As far as the eye could see, the flame filled the entire flask.

Further experiments were made in which the oxygen had been reduced to 13 per cent. This mixture had the following composition.

AN INFLAMMABLE MIXTURE OF GASES

Gas	Percentage	Gas	Percentage
CO_2	0 03	CH_4	9 40
O_2	13 00	N_2	77 57
			100 00

This mixture was placed in a cylindrical vessel 4.5 in. long and 12 in. high. Two copper terminals were quickly broken to produce the flash, which took place in the center of the vessel. A current of 220 volts and 7.5 amperes was used. A flash about ½ in. long was obtained. On the breaking of the contact, the inflammation spread upward almost to the top of the jar.

With the same percentage of methane, but with 12 per cent. of oxygen, and under the same conditions of experiment, only a slight inflammation extending about 3 in. upward was obtained. But with 12 per cent. oxygen and 6 per cent. methane, the flame filled the entire top of the jar. With 15.1 per cent. oxygen and 9.4 per cent. methane, a quite violent explosion was obtained under the same conditions of experimentation.

Experiments were also performed in which a small ⅛-in. spark from an induction coil was used as the source of ignition. A mixture having the following composition exploded.

A MIXTURE WHICH EXPLODED

Gas	Percentage	Gas	Percentage
CO_2	3 92	CH_4	9 43
O_2	16.25	N_2	70.39
			99 99

Under the same conditions, a mixture in which the oxygen was slightly diminished from the foregoing, and having the following composition, did not inflame at all.

A MIXTURE WHICH WAS NON-INFLAMMABLE

Gas	Percentage	Gas	Percentage
CO_2	3.99	CH_4	9 25
O_2	15.90	N_2	70 86
			100 00

In all of these explosibility experiments, both the large electric flash and flame (flame applied from below) produced decided inflammation under more severe conditions than the small ⅛-in spark. In each case, when used, the small spark was applied near the top of the mixture. The analyses are accurate to about 0.10 per cent.

These are only a few of many experiments which have been made on explosibility of gaseous mixtures at the laboratory of the bureau. They are given as showing something about the limiting proportions at which methane ceases to be inflammable under the conditions in which it occurs in mines. Such knowledge has been es-

pecially useful to the bureau in that frequently it has been desirable to know something, before explorations have been made, about the explosive character of the atmosphere in sealed areas and in other workings in the mines where ventilation has been interrupted.

From the foregoing and from experiments to follow, we can also conclude that oxygen in mine air at one place may be diminished to such an extent that a miner's lamp will not burn, but at some point beyond, a flicker of a flame made in an attempt to relight a lamp, or the flashing of an electric spark, might precipitate an explosion if enough methane was present.

The Harger Cure for Explosions

Much interest has followed the proposal of John Harger of England[a] that the oxygen be decreased and carbon dioxide increased in mines to prevent explosions. Briefly, Dr. Harger's proposition is this: A small reduction in the oxygen percentage and a small increase in the carbon-dioxide percentage in mine air will suffice to produce an atmosphere incapable of supporting combustion and consequently one in which explosions and gob fires cannot occur.

For average mines, it is suggested that in order to start the experimental work on a large scale, the oxygen should be reduced to 20 per cent., i.e., one per cent. below normal, and a half per cent. carbon dioxide added to it. Where the conditions are more dangerous the oxygen should be further reduced, say, to 19 per cent., and the carbon dioxide increased to three-quarters of 1 per cent.

Experiments which have been performed by the bureau, some of which are here presented, indicate that the oxygen percentage will have to be reduced much below the figures mentioned by Dr. Harger to prevent all explosions. However, if all conditions are identical, the mixture will explode less violently and less completely in proportion to the decrease of oxygen percentage. As regards carbon dioxide, it appears that so much would have to be added to prevent firedamp explosions that its use for this purpose of treating normal mine air would be precluded.

Mine Gas Mixtures Containing Explosive and Other Proportions of Methane

Below are given analyses of mine-gas samples, some of which contain explosive proportions of methane. The accompanying carbon-dioxide and oxygen content are of interest in connection with foregoing experiments.

The samples were collected in the rooms of mines wherein ventilation had been interrupted for some time. Explosions have occurred in these mines.

SOME SAMPLES OF MINE AIR

Sample No.	CO_2	O_2	CH_4	N_2
1	8 28	10 50	4 49	76 73
2	0 48	17 49	9 20	72 83
3	5 81	12 95	5 67	75 17
4	1 75	17 63	7 60	73 02
5	0 34	19 46	5 79	74 41
6	0 35	18 81	7 25	73 59
7	2 00	15 64	7 37	74 99

Samples No. 2, 4, 5 and 6 are explosive. It is not believed that even an inflammation could be obtained in mixtures represented by samples No. 1 and 3.

(To be concluded in an early issue)

Experiments made in England have shown that ashes or common salt properly spread will destroy the larvae and eggs of hookworm at 77 deg. F. This is an economical method of disinfecting chambers used in place of the portable conveniences which are sadly lacking in most American mines.

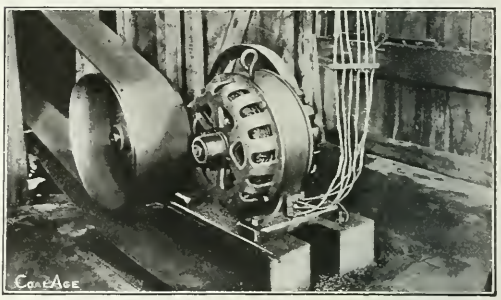
Two Speed A. C. Motor for Mine Fan Drive

An excellent example of the efficient adaptation of electricity to mine service is illustrated in the accompanying picture, which shows a two-speed, alternating current, three-phase, 60-cycle, 440-volt motor belted to a Guibal 12-ft. fan installed in the Greensburg No. 1 mine of the Keystone Coal Co., near Greensburg, Westmoreland County, Penn.

The force of miners is considerably less at night than during the daytime, and consequently it is desired to run this fan at only about one-half the speed at night that is required during the day. For this service there was selected a Westinghouse squirrel-cage type induction motor with a rating of 7½ hp. at 600 r.p.m., and 15 hp. at 1200 r.p.m.



Two-speed A. C. Motor Driving Mine Fan

The change in speed is accomplished by altering the number of poles. The stator of the motor is provided with two windings; one of which gives 6 poles, resulting in a speed of 1200 r.p.m., and the other gives 12 poles, with a speed of 600 r.p.m. The connections are changed from one set of windings to the other by the controller. This is a most efficient form of control for an installation of this kind, as the motor can be operated at low speeds and high efficiency; there being no losses in the control resistance. The motor itself is particularly well adapted to this class of service on account of its rugged characteristics, which insure great reliability of service.

Current for the operation of this machine is furnished by the West Penn. Electric Co. In order to determine the results obtained from the installation, tests were made by C. V. Elliott, electrical engineer of the lighting company, which showed the following excellent results:

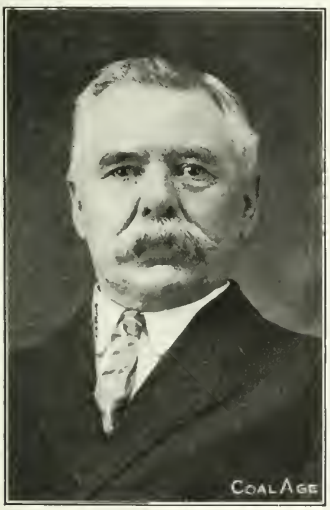
The fan is 5 ft., 6 in. wide, and the depth of blades 3 ft. 6 in. When running at 120 r.p.m., with 1.5-in water gage, or an equivalent pressure of 0.87 oz. per sq.in., 46,200 cu.ft. of air per minute were delivered. The motor in performing this work took 9.6 kw., giving an efficiency of 63.03 per cent. for the outfit. When running at half speed, or 60 r.p.m., with 0.6-in. water gage, or 0.29-oz. pressure per sq.in., 14,850 cu.ft. per minute were delivered, and an efficiency of 58.33 per cent. was obtained.

These results are particularly important as they show economy in the use of purchased power, which is becoming standard practice where alternating current is available.

WHO'S WHO—IN COAL MINING

An old myth tells how a giant, Antæus, could vanquish his adversary Hercules whenever he could touch Mother Earth and gain strength from the contact. And the theorist is never at his best in the world of practical and material things unless he has had some years at actual toil.

This is the real upbringing. This is the real royal road to achievement of which we hear so much. Yet it is one we all might travel if we would, were we not so desperately afraid of the cold, hard contact with Mother Earth and of what we are pleased to call the drudgery of toil.



THOMAS THOMAS

Thomas Thomas was born in Wales in 1860, the son of Shadrach Thomas, a Welsh miner. When the young boy was three years old, the family embarked for America. Shortly after landing, Shadrach Thomas took up his abode in Pittston and later placed the boy in the public schools.

Still later he was sent to the "pay" schools which were then so general in the anthracite region. But at nine years of age, he entered the mines as a trapper and thence he went to the breaker. At 14, he was a full-fledged driver boy. At the present time, he could not be even a trapper at that early age but different views were held in the seventies.

His first work was in the Twin shaft, the scene of a disaster caused by the heavy load of glacial drift in the Wyoming "buried valley." This crushed in the roadways and killed several men. Such an accident has never been duplicated in the anthracite region. This colliery was then owned by the Pittston & Elmira Coal Company.

Later, young Thomas became a runner and let cars down from the working faces to the levels. Then he commenced to load coal as a laborer and finally he became a miner. There were thus few places in the mine which he did not fill before he was 20 years of age. In those days there was not the multiplicity of occupations which can be found in modern mines.

In 1880, Thomas Thomas was working in the Exeter mine and having saved a little money by frugality he decided that he needed mental development and took up a course of study at the Lewisburg Academy. An education, paid for from the savings of the student, earned by some ten years of steady toil was not sought in the half-hearted way pursued by the young man who goes to school at the parental admonition, and Thomas Thomas burned the midnight oil, endeavoring to make up the deficiencies in the education of his earlier years. In 1885, he entered Lehigh University and after five years of study he graduated.

During each vacation period he went back to the mines, part of the time working on the engineering squads of the Lehigh Valley Coal Co. In 1891 he was made outside mine foreman at the old Enterprise colliery of that company. Shortly after he was transferred to the Exeter colliery, serving as general inside foreman.

In 1901, he became superintendent of the William-A and Seneca collieries. Four years elapsed before his next promotion and in November, 1905, he became division superintendent of the Lehigh division and established his headquarters at Hazelton. So well did he handle the work of this responsible position that in 1907 he was transferred to the Wyoming division, the largest under the company; there he became superintendent.

Following the promotion of F. M. Chase to the position of vice-president and general manager of the Lehigh Valley Coal Co., to succeed S. D. Warriner, it was decided to create the position of mining superintendent, and abolish the office of assistant to the general manager.

According to this plan, announcement was made Oct. 1, 1912, that Thomas Thomas was the new mining superintendent. He was given complete control of all the mining operations of the company, both inside and out. Under his charge are thirty-two collieries and several washeries scattered throughout the anthracite fields. In all, an army of 25,000 workmen is directly responsible to him.

Both educated and experienced is Thomas Thomas, but somehow neither of these qualifications, important as they are, overshadow in him that other characteristic, just as vital to success—the quality of personality. A man who has been through the mine, filled every place, worked at every job and yet has had a college experience, bridges the gap between the office desk and the mine face, the unfathomable abyss, as it seems, between the man who works and the man who, as the foolish phrase goes, "only thinks for a living."

Thomas Thomas has not forgotten the humble little cottage at Pittston, the dinner-pail days, the early walks

to the breaker, the dangers of the coal face. His interest in the miner is not the sympathy of an outsider but the clear full-faced vision of one who has but to look back in his own life to find similar experiences. The miners like to deal with men of that kind and it is to be hoped that the future may see the mines officered by more of such democratic talent, not only well trained but well experienced. It will prevent that segregation of class interests, of which the worst is to be feared.

Mr. Thomas is a pleasant, affable man who desires only to impose what he would himself be prepared to accept. And he realizes what is fair because he knows the mine from the shaft mouth to the face and the outside works from the headframe to the main railroad switch. There are not many young men who, after 11 years on the firing line, will return to their studies to put a final finish on their education.

Before such men, there opens up a large future. With bodies developed by early toil, with the mind matured by contact with men of action, made independent by the thought that they can take their place at any time in the ranks of labor, such men have a strength not usually to be found among those who have not mixed the practical with the theoretical, but have seen and probably thereafter always will see life through the spectacles of their academic education.

But above all, the feeling of the Lehigh men for Thomas Thomas is one of pride in an old friend who has "made good." Those who have known him from boyhood and knew his father before him, recognize his solid purpose and real worth. The younger men realize in him a promise that work well performed will not be forgotten and that the high places of corporational control are not beyond those, who, beginning at the bottom of the ladder, keep their eyes fixedly on the topmost rungs and their feet pressing steadily upward.

Protection of Trolley Wires

By U. U. Carr *

To safeguard employes about the mine against contact with trolley wires, as is required by the mining laws of some states, boards placed parallel to and on both sides of the conductor are claimed by many to afford an efficient and inexpensive means of protection.

*Engineer, Monongahela River Consolidated Coal & Coke Co., Pittsburgh, Penn.

Many different methods have been employed to suspend protection boards placed in this manner, and where a permanent installation is desired, the hangers shown in the accompanying cuts have proven satisfactory.

Where the usual type of trolley hanger, carried on an expansion bolt in the roof is used, Fig. 1 illustrates the method of supporting the protection boards. The iron strap is provided with a hole in the horizontal portion, into which the boss on the base of the trolley hanger fits. This strap is thus clamped between the roof and the hanger base when the latter is screwed onto the expansion bolt.

Preferably this hole should be drilled or punched the same diameter as the bolt holes and drifted to its proper size. All the perforations can be made in the strap before bending.

The boards may be joined at the hanger by making a half-notch in each, as shown in the side view of Fig. 1, or they can be spliced between hangers by butting them end to end and nailing on a batten.

They should be of sufficient width and placed low enough to extend below the point of greatest sag in the wire.

Where the trolley hangers are secured to over-head timbers, by means of lag screws, the protection boards may be carried by a similar strap, as shown in Fig. 2. In this case, holes are drilled in the strap to match the holes in trolley hanger base and the former clamped between the timber and the hanger.

These methods of supporting the protection boards have the advantage of utilizing the necessary trolley wire supports and making them perform the double duty of carrying the wire and also the boards.

If the trolley hangers are spaced more than 15 ft. apart, an intermediate strap should be provided for the boards. In cases where it is desirable to carry these protections, independently of the trolley wire supports, a hanger of round iron, shaped as shown in Fig. 3, and driven into the roof will answer the purpose. No bolts are required with this arrangement, as the boards are allowed to lap at the hangers and the thickness of two boards should fill the space in the bent portion of the hanger.

Where the roof will not permit the boards to be placed or removed from the top, this is accomplished by sliding them endwise to clear the hangers.

Each board should extend beyond or lap over the round hanger at least 3 in.

EDITORIALS

A Bituminous Trust

The people of the United States are not unalterably opposed either to trusts or to reason. Their theory of government, viewed along broad generic lines, does condemn, it is true, all amalgamations which are in restraint of trade. But they do not condemn labor unions, which are, in a real sense, trusts, and there has been a tendency to favor combinations of farmers and tobacco raisers, who seek to obtain higher prices for their produce and reduced rates for the storage of their goods.

The right to a fair compensation for services rendered to the community is thus generally recognized. Unfortunately in some cases the compensation taken by monopolists has not been fair, and in other instances, the public has set itself up as a judge when it did not understand the conditions it was endeavoring to adjudicate.

The recent increase on the price of anthracite was a case in point. This boosting of the circular rates was condemned by almost all the papers alike without careful inquiry as to what the increases actually were. Some of the reputable papers doubtless soon realized their error, but they did not care to retract their mis-statements; the others doubtless never sought the truth and would have published their diatribes in any event.

It is not now our intention to discuss the anthracite trust, but rather the prospect of creating a successful control of the bituminous-coal market after a needed change has been made in the sentiment of the electorate and in the laws on the statute books. It is useless to endeavor to harrow the mind of the average man with the misfortunes of the producer. The consumer is not disposed to be sympathetic and indeed he cannot afford to be.

An increase in the cost of coal is not a desirable end for legislation, yet this is usually the sole and declared end of those who would create a trust. The monopolist must present the public with some more logical basis for coöperation. In fact it does not appear impossible to forecast and promise that a unification of bituminous interests might lower costs of fuel.

It seems a violence to reason to declare that the cost of fuel is too high everywhere in face of the fact that many of the largest producers are in the hands of receivers. However, not only the cost of mining, but the cost of transportation as well, enter into the question, and only a large combination can hope to compel reductions in this item.

When the Standard Oil Co. found the costs of transportation on its oil were too high, it threatened to build pipe lines, and immediately obtained rebates on its own oil and even on that shipped by others. Small companies would have pleaded in vain, no, rather they would have failed to plead at all. They would have spent their time trying to reduce the pay of their pumpers and refiners or in endeavoring to harass and underbid one another.

The question of transportation, except competitively, would have been wholly overlooked, because a general reduction of all oil-transport rates with unlimited competition would not have been divided between operator and consumer. The latter would have received it all and the change would have left the producer subject to more competition by reason of the reduced expense necessary to enter the business with only the lowered freight rates to meet.

It is a fact that small profits almost invariably make narrow-minded operators, just as low wages make wooden-headed employees. The lower price of oil owes not a little to the power of the Standard Oil Co. to lower the railroad rate and of the Interstate Commerce Commission to give all the competitors of that oil company an equal transportation charge.

Just as the Standard Oil Co. threatened to build pipe lines, so could a big coal corporation compel the railroads to make needed concessions by the building of a canal or of a rival railroad. Or it could bring pressure to bear by converting all the coal into gas or electricity and transporting the product by pipes or wires to the market.

But such minatory attacks on the railroad corporations cannot be made effective by companies having small purses, though carbo-electric conversion on a small scale does not necessarily involve a large investment. To unamalgamated companies the railroad rate is fixed as by a divine fiat. The average operator would not attempt to argue with the nod of the Wall Street office.

This ability to reduce railroad rates in the hope of sharing with the consumer in the benefits of the reduction is but one of the advantages which a combination would afford. Many developments could be expected from a unified interest, which a number of jarring elements cannot hope to effect.

A Word with Our Readers

We are desirous that every subscriber to COAL AGE take an active part in discussions that occur in these pages. It is also our wish that many more of our readers would contribute articles on some phase of coal-mining and coke manufacture. Not every article received by us will be published, for it often occurs that a contributor will submit a paper of considerable merit, but which deals with a problem of only local interest or discusses a subject already covered in some recent issue.

It is certain that many more articles will be received than we can use, so there is little or no occasion for a subscriber to feel discouraged if his first attempt at authorship proves unavailing. Furthermore, articles are not judged according to the reputation or personal popularity of the contributor, but solely on the character and original value of the information contained.

One statement may be made in this connection, however, and that is concerning neatness and legibility. It is just as easy to use a little more paper and double space

all the lines, as it is to crowd the writing so that the editor must turn the manuscript over to an assistant to decipher and copy before it can be intelligently read. There is no denying the fact that a carefully written article, properly paragraphed and neatly laid out, will make a better initial impression and receive earlier editorial attention than a slovenly prepared manuscript of equal technical value.

We wish to call attention again to the fact that we will pay $20 for any five- or six-hundred-word article, suitable for publication as a "Foreword" on our first page. The subject may be ethical, technical or general—just so the meat is there.

Then there are the pages of "Ideas and Suggestions," which in a general way are sub-forewords. These little talks by our readers have proved both interesting and popular and are paid for at an unusually liberal rate.

We are sure all our subscribers have appreciated the pages of "Snap Shots" recently published, and we intend to continue this feature of our paper. Every photo which we print is paid for, and the best picture each week is awarded a prize of $5. No view shown is valued at less than $1.

On Feb. 1, the entire issue of COAL AGE will be devoted to the subject of "Power" at mines. There are dozens of modern colliery equipments deserving the attention of the industry. Send us a description of some unique power installation or efficient arrangement which has come to your notice. Help us make this "Power" number the best of its kind ever issued. Copy must reach us not later than Jan. 25.

Self Propagating Inflammation

It would be disingenuous for us to attempt to hide from ourselves, or to deny to our readers, the fact that G. A. Burrell, in making his address before the West Virginia Coal Mining Institute, purposed to make a "retort courteous" to COAL AGE and the technical press.

This purpose does him much credit, for we conceive that, with us, the Bureau of Mines is engaged in the informing of the industry. It would be negligent in the performance of its duties did it not take due exception to anything we might publish which appeared incorrect or misleading. Similarly, we have felt such a duty impending on us, which we hope we have not been disposed to shirk.

As Mr. Burrell did not fail to test the button on his foil before entering the conflict, we propose to thrust, guard and parry with equally invulnerable weapons. We desire that this reply may be taken, not as shrouded sarcasm, but in the most solemn literalness.

The section of Mr. Burrell's paper, which we reproduce today, details the percentage volumes of methane which are explosive, determining the higher and lower limits of explosibility. Made as carefully as his tests are, we shall be disinclined to cavil at his results, and shall be content merely to object to his manner of expression, which we have not hitherto followed and do not desire to adopt.

The use he makes of the word "explosion" follows neither the popular practice, the preferences of advanced scientists, nor the definitions of the dictionaries. Nor does it agree with the philology of the word. Soundless plaudits, like noiseless explosions, are alike unthinkable. Derived from the Latin root signifying "clap," the word explosion has, from the time of its first use, involved the sense of an action producing sound. In earlier years the word was used to express among other things the clamorous clappings and vociferous bellowings with which the unpopular Roman actor was driven crestfallen from the stage.

The dictionaries add to this root-meaning the idea of expansion, and term an explosion "a violent bursting expansion with noise." The public, whose unexpressed opinion constrains reluctant lexicographers, declares that "explosion" is not a synonym for "inflammation." On the other hand, the British writers, Doctor Thornton in particular, agreeing neither with Doctor Burrell nor with the vulgar herd, term "explosions" all those kinds of methane inflammations which are not mere caps on a flame.

As we have pointed out, Mr. Burrell is not so radical, and we congratulate him on his stand. Even if it is not as logical as the British view, it is more practical and gives results which are more closely consonant with the definition of an explosion as approved by popular judgments, lexicographic preferences and philologic precedents.

All inflammations probably produce sound. Helmholtz has shown that air vibrations of lower frequency than 16 per sec. fall without effect on the insensitive human ear, and we all know that sound waves of slight intensity fail to cause perceptible vibrations of the auditory nerve.

Hence, in an extremely modified sense, all inflammations are probably explosions. Even the burning of a gas jet may be made to produce musical sounds. But the judgment of most of us is that an explosion must make at least an audible sound, and not merely one which is too infrequent in vibration and too feeble in intensity to be detected by the human ear.

We have seen how widely modern writers differ from the best everyday usage in their definition of the word "explosion." Mr. Burrel takes a medium viewpoint and is sure that "an explosion, in the true sense of the word, means a self-propagation of flame to all parts of a mixture, without help from the source of combustion other than the ignition of the mixture at one point."

Why not use another term for this low limit? Does it seem desirable to use a popular word like "explosion" in such an extremely technical way? Where a body of powder or dynamite burns away quietly without detonation, we do not say it explodes; we say it burns or deflagrates. Why make a new meaning for explosion, to be applied solely to methane and similar gaseous bodies?

There were other expressions available, such as, complete, self-propagating or progressive inflammation. The English language has not broken down, nor has it been found inadequate that we should suffer ourselves to limp along with a poor philologic substitute like the word "explosion."

After all, it is a question of words and their definitions. We believe it was Lord Bacon, in his Novum Organum, who declared that disputations are as frequent over definitions as over facts. We hope that Mr. Burrell will modify his statements so that they will accord more closely with popular parlance, and declare that, on applying a light to a 5.5 per cent. mixture of methane and air, a complete inflammation or a self-propagating conflagration, and not an explosion, will result. Thus he will avoid confounding the violence of the latter with the gentle action of the former.

DISCUSSION BY READERS

Reducing Ventilation at Firing Time

Letter No. 1.—I have been much interested and startled at times in reading the phenomenal experiences of Alexander McAllister, Croweburg, Kan., as narrated in his letter, COAL AGE, Jan. 4, 1913, pp. 24 and 25. The statements set forth seem very convincing. Although such an experience is forbidden the majority of mining men, I am sure all would welcome the chance to be allowed to witness such a demonstration as Mr. McAllister cites in his letter.

The old proverb, "An honest confession is good for the soul," gives me consolation, when I say candidly, I would be afraid to perform such operations as he has described, in a gassy mine. It may be said with candor that his experience and convictions are contrary to or directly the reverse of those of practically all mining men and theorists alike, to whom we have looked and on whom we rely to furnish us facts, figures and experiences, for our guidance.

I have had nearly thirty years' experience, in all sorts of mines, having served in every capacity, but have never heard of such a scheme as that suggested. My opinion is that it would be a costly experiment to perform in a well equipped mine. I do not think the property and equipment of any mine should be jeopardized by such an experiment.

Personally, from my own experience and from that of tutors and the best authorities—men who have spent almost half a century studying mining conditions—I would condemn the practice of reducing the ventilation in a mine at firing time. I firmly believe such a method of procedure is extremely dangerous. To reduce the ventilation would increase the danger in the same proportion as to increase the quantity of explosive gas in the mine.

By reducing the ventilation, we increase the percentage of firedamp in the air, as the same quantity of gas is given off and a less quantity of air circulated. The percentage of dust is also increased and likewise the percentage of carbon monoxide produced by the explosion of powder in blasting. From these conditions it follows:

1. Percentages of gas that are not previously explosive become explosive in proportion as the volume of air is decreased.

2. Percentages of gas that are not previously explosive become explosive under the pressure of heavy blasting in a confined space where the air is dead.

3. The reduced air current will carry a large per cent. of dust, which will greatly help to propagate the flame of an initial explosion, and the danger point in respect to dust will be in proportion to the reduced ventilation.

If we knew the exact amount of gas given off in the mine, we might, with some security of feeling, estimate the quantity of air that should travel, but this is not possible. Nor can any exact estimate be made of the amount of carbon dioxide (CO_2) that would render the firedamp inexplosive. Authorities state that 1 volume of carbon dioxide (CO_2) when mixed with 7 volumes of firedamp at its most explosive point renders the latter inexplosive.

I shall watch this discussion with interest. It is an important subject, and until I was firmly convinced that I was wrong, if I were a shotfirer on my rounds and discovered a weakness in the air I would cease firing and ascertain the cause and would not commence again until conditions were normal.

The Hastings Explosion

A great deal of prominence is given in COAL AGE, Nov. 30, 1912, p. 756, to the explosion at Hastings, Colo., June 18, 1912; and it would appear from that article and the one by Mr. Verner, Nov. 16, p. 677, that the theory that damp dust or wet zones will stop an explosion is at fault.

It is difficult for me to conceive how anyone can arrive at such a conclusion, in view of the dust experiments made at Pittsburgh, Penn. In those experiments, the propagation of flame by coal dust ceased when the moisture content in the air reached 30 per cent. The coal dust, in the Hastings explosion was damp but not wet; still the writers of these articles refer to that explosion as proof that moisture cannot be depended on to stop an explosion. In reply to this statement, these writers may claim that, in the experiments at Pittsburgh, the explosion was not sufficiently under way when it reached the coal dust zone in the entry. If that line of argument is followed, then it is possible to suppose a case in which the initial force generated by an explosion of gas, or both gas and dust, would pass the flame through a zone of either stone dust or moisture, or both combined. I do not mean to say that either of these writers would dispense with moisture entirely, as a means of preventing explosions, but I think they are in error when they say that it cannot be depended on to do this.

I have worked in the Hastings mine, and know something of the conditions existing there. When there was only the upper seam working, the mine was naturally wet throughout, and small explosions that occurred failed to go further than the point of ignition. I held the opinion and expressed it to others that it was the naturally wet state of the mine that had localized these explosions. These considerations and the fact that the explosion in June, last, did not enter the main-intake airway where there was a running stream of water and where the props and everything else were saturated with moisture, leads me to the conclusion that the theory that the presence of moisture in coal dust will effectually stop the propagation of an explosion is correct.

I pointed out to Mr. Dean that there was not the least sign of an explosion on the intake; to which he replied that there was no dust being thrown into the intake from the cars, as there was on the main-haulage road. While that is true, by cars is not the only way that dust is

spread through mines. The crushing and grinding action of the overlying strata on the pillars produces a great deal of very fine dust, which is likely to be deposited all over the mine irrespective of the haulage roads; and besides, at Hastings there was one haulage road, at least, that crossed the intake, and there was also a side track from which the dust had access to the intake. I was much impressed with the amount of fine dust there was in the crosscuts and which was much disturbed when putting in new stoppings. I am of the opinion that had it not been for the running water in the intake there would have been enough of dry dust there to have carried the explosion to the surface.

The new-slope south entries do not show the same amount of moisture or standing water on the roadways that the entries of the old upper seam did, and therefore the new workings, in the lower seam, could not be expected to be immune from dust explosions to the same extent as the old mine in the seam above.

It seems probable that the greatest force of the explosion was exerted at the upper end of the main-slope side track. It was here that the cars were so badly broken up. A trip of cars standing about halfway up the slope and in the path of the explosion did not seem to be much damaged, although they were surrounded and covered with rock and loose timber. From what has been said it seems likely that the explosive force was generated from a little pocket of gas in the third south entry, and augmented, later, by dust picked up on that entry and the large side track at the end of it. From here the explosive force decreased, as is clearly shown by the fact that a man working near the top of the slope was found still alive. It is well known that a dust explosion will always travel the intake road if it can get any thing to feed on and avoid a wet road. The point of expansion referred to by Mr. Dean unfortunately is above where the man was found alive, showing that the blast had lost a great deal of its power before it reached that point.

The greater area of the road would reduce both the velocity and energy of the explosive wave, but the flame could easily have jumped across this space had conditions been favorable. Immediately beyond this point, where the area of cross-section of roadway expanded, is the last evidence of the force of the explosion, on the outby end; and here begins the naturally damp and sloppy condition characteristic of the old mine. It is here, I believe, the explosion was stopped from entering the upper seam; and I ascribe the credit for this to the very wet condition existing there. For hundreds of feet on the outby end of this point the damp conditions are very much in evidence. In some places, pools of water, from four to six inches deep, are found in the manway. When these things are considered I think it would have been a surprise to any of us had the flame of the explosion traveled beyond this point. Cases have been known where the mine was dry and dusty and the explosion traveled through the shaft from one seam to another without losing its explosive force; although there would be more room for expansion, at the shaft bottom and in the shaft, than there was in the Hastings slope.

An important factor, in connection with dust explostons, which should not be forgotten, is that, owing to the difference in the amount of energy and heat developed by different explosions, in different mines, a zone of moisture and stone dust that would stop the propagation of an explosive flame in one mine, might not stop it in another; because of the greater heat and explosive force. It is reasonable to suppose that if it required a zone of 100 yd. of moisture and stone dust to stop the propagation of flame in one mine, then it would require a zone of perhaps 200 yd. to stop the flame in another mine where the explosion had developed twice the amount of heat and energy. In the latter case, the greater velocity of the blast would carry it further into the zone, before the moisture and stone dust could cool the gases sufficiently to extinguish the flame, and the greater amount of heat in the flame would be able to convert some of the moist dust into gas, which would help to extend the explosion.

From this it is clear that a mine in which the analysis of the coal shows a high percentage of volatile combustible matter would require more attention and the stone dust and moisture have to be kept closer to the working places, than a mine in which there was less volatile matter in the coal. Referring again to the intake airway, I would like to ask: If the moisture did not stop the explosion from traversing it, what did? The flame had to cross the intake to enter the third north, and the pumper was found in the intake just below this point badly burned, which shows that the flame was there and had plenty of power behind it; but the naturally wet condition of the airway stopped it there, although it traveled up the parallel entry about a quarter of a mile further. It may be well to explain that the third-south entry is driven at right angles to the intake and main slope, so that it received little benefit from the water that was in them. This explosion was a particularly unfortunate occurrence, because the officials of the Victor American Fuel Co. had been paying a great deal of attention to the safety of their mines, by the application of adobe dust, water and other means, some of which were pointed out to me by the superintendent when he took me through the mine shortly after the explosion.

Timber for Framing

I have been asked which is the stronger, a square solid piece of timber 12 by 12 in., 20 ft. long, or six pieces of 2 by 12 in., 20 ft. long, spiked or bolted together. These six pieces make a post or stringer of the same size as the single piece first mentioned.

There is no difference in the strength of the two pieces, except what little strength may be lost by the penetration of the spikes or bolts into the wood. This slight loss in strength, however, is generally compensated by the ability to choose good clear-grained pieces of the smaller sizes. The timber is less expensive than the larger size, and the latter may contain hidden knots or imperfections in the grain that are not observed on the surface, which weaken the stick.

The combination of smaller sizes of timber is often preferred not only on account of the saving in the cost of the timber, but the pieces are more readily handled.

When a stringer is formed of several small pieces of timber bolted together, they should always be set on edge, or with the greater dimension corresponding to the depth of the beam.

MINE SURVEYOR.

Stotesbury, W. Va.

First Method—Where it is possible to cross over the stream, the following method may be used, which will give approximate results: Referring to Fig. 1, set up the instrument at *A* and sight to a point *B*. Then, by means of the 3, 4, 5 method, often called the 3, 7, 12 method, set off the right angle *OBT*. To do this, first line in the point *O*, on the line *AB*, with the instrument, making the distance *OB* 3 ft. or any multiple thereof, and place a surveying pin at *O*. With *B* as a center and a radius of

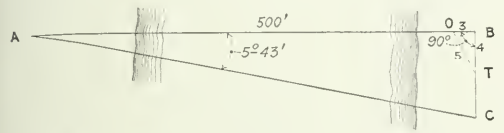

FIG. 1. METHOD OF MEASURING DISTANCE ACROSS A RIVER

4 ft., describe an arc; and with *O* as a center and a radius of 5 ft., describe another arc intersecting the first at *T*. The angle *OBT* will then be a right angle.

By the 3, 7, 12 method, the end of the tape is fastened at *O*, and the tape is then carried around the triangle *OBT* and back to *O*. The distance around the triangle *OBTO* is 12 ft. Now, holding the end and the 12-ft. mark at *O*, with the 3-ft. mark at *B*, pull out the tape with a pin at the 7-ft. mark, which will establish the point *T*, making the angle *OBT* a right angle.

With the instrument at *A*, turn off the angle *BAC* equal to 5 deg. 43 min., and line in the point *C* on the line *BC*. Now, since the tangent of 5 deg. 43 min. is 0.1, the distance *AB* will be ten times the distance *BC*. Thus, if the distance *BC* equals 50 ft., *AC* will be 10 × 50 = 500 ft.

Second Method—When it is not possible to cross to the opposite side of the stream, the following method can be used: Referring to Fig. 2, establish the line *CD* more

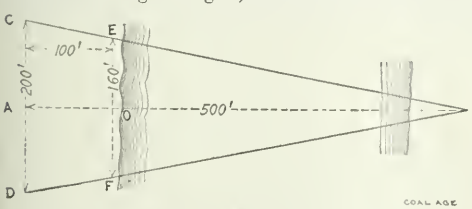

FIG. 2. ANOTHER METHOD OF SURVEYING

or less parallel to the stream, and another line *EF* parallel to the first, and at any distance *AO* from it. Now, select a well defined point or object *B*, on the opposite bank and line in the point *E* on the line *CB*, and likewise the point *F* on the line *DB*. Measure *CD* and *EF* carefully. The distance *AB* is then calculated as follows:

$$AB = \frac{CD}{CD - EF} \times AO$$

If the several distances are as indicated in Fig. 2, the calculation is as follows:

$$AB = \frac{200}{200 - 160} \times 100 = \frac{200}{40} \times 100 = 500 \text{ ft.}$$

Discharge of a Mine Siphon

A siphon pipe 4 in. in diameter and 1000 ft. long has a rise of 15 ft. and a fall of 40 feet. How many gallons of water will this siphon discharge in 24 hours?

HENRY HENNESSEY.

Stauffer, Penn.

In ordinary mining practice, the coefficient of friction of water flowing through a siphon pipe may be taken as 0.01. On this basis, the flow of water in a 4-in. siphon pipe, 1000 ft. long, rising 15 ft. and falling 40 ft., may be calculated by the following formula:

$$G = 4^2 \sqrt{\frac{800 \times 4\,(40 - 15)}{1000 + 2.08 \times 4}} = 142.4 + \text{gal. per min}$$

The quantity of water this siphon will discharge in 24 hr. is, then, 24 × 60 × 142.4 = say 205,000 gal.

In siphon work it is never safe to calculate the discharge of a siphon, by any formula, unless it is positively known that the flow of water, under atmospheric pressure, in the suction end, is equal to or greater than the discharge, under gravity, in the other end of the pipe. If the flow in the discharge end due to gravity is greater than that in the suction end due to the pressure of the atmosphere, the pipe will tend to empty itself; and sooner or later the siphon will cease to work or, in other words, will "run dry." Since it is the atmospheric pressure that causes the flow in the suction end of the siphon, and this decreases with the elevation above sea level, it is evident that a siphon that will work at sea level will often fail to work at an elevation above sea level where the atmospheric pressure is less. In order that a siphon shall work continuously, the value of the following approximate expression must be greater than zero:

$$\frac{\text{Atmos. head} - \text{suc. head}}{\text{Length of suc. end}} - \frac{\text{dischg. head} - \text{atmos. head}}{\text{Length of dischg. end}}$$

The normal atmospheric pressure, at sea level, expressed in water column, is 34 ft. Assuming the siphon, in this case, is located at sea level, the suction head being 15 ft. and the discharge head 40 ft., gives

$$\frac{34 - 15}{400} - \frac{40 - 34}{600} = \frac{19}{400} - \frac{6}{600} = 0.0375$$

This value being greater than zero, shows that the siphon will operate continuously without emptying itself, provided, of course, that both ends are submerged and other necessary conditions fulfilled.

EXAMINATION QUESTIONS

Mine Foremen's Questions

(Answered by Request)

Ques.—Two pumps are working together, the one 14x36 in., and the other 15x30 in. If both of these pumps are running at a speed of 90 ft. per min., which will throw the greater amount of water per hour; and how much will the discharge of the one exceed that of the other?

Ans.—For a piston speed of 90 ft. per min., the piston displacement of each pump is as follows:

Pump, 14x36 in.

$$\frac{90\ (0.7854 \times 36^2)}{144} = 636.17 \text{ cu.ft. per min.}$$

Pump, 15x30 in.

$$\frac{90\ (0.7854 \times 30^2)}{144} = 441.78 \text{ cu.ft. per min.}$$

Since 1 cu.ft. of water equals 7.48 gal., and assuming the water-end of each pump has an efficiency of 85 per cent., the quantity of water discharged per hour by each of these pumps is as follows:

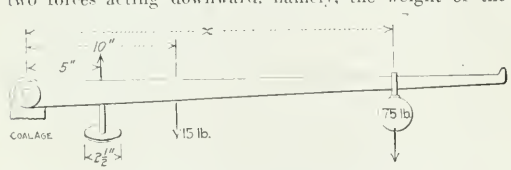
$$0.85\ (636.17 \times 7.48 \times 60) = 242{,}686 \text{ gal. per hr.}$$
$$0.85\ (441.78 \times 7.48 \times 60) = 168{,}530 \text{ gal. per hr.}$$

Difference ..... 74,156 gal. per hr.

At a speed of 90 ft. per min., the 14x36-in. pump will, therefore, throw 74,156 gal. per hour more than the 15x30-in. pump will discharge, at the same speed.

Ques.—In a ball-and-lever safety valve, the distance from the fulcrum to the valve stem is 5 in.; the diameter of the valve, 2.5 in.; the weight of the lever, including that of the valve and stem, 15 lb. and its center of gravity, 10 in. from the fulcrum. If the ball weighs 75 lb., how far should it be set from the fulcrum in order that the valve will blow off at 90 lb. per sq.in., boiler pressure.

Ans.—Referring to the accompanying figure, there are two forces acting downward, namely, the weight of the



Ball-and-Lever Safety Valve

lever and valve and the weight of the ball. The weight of the lever and valve acts through the center of gravity, which is 10 in. from the fulcrum; while the weight of the ball acts through a distance x from the fulcrum, which distance is to be determined.

These forces acting downward are balanced by a single force acting upward; namely, the total steam pressure on the valve. This force acts through the valve stem, at a distance of 5 in. from the fulcrum. The steam pressure on the valve is first found as follows:

Area of valve $= 0.7854 \times 2.5^2 = 4.9087$ *sq.in.*

Then, for a steam pressure of 90 lb. per sq.in., the total pressure on the valve is:

$$4.9087 \times 90 = 441.78 \text{ lb.}$$

At the moment when the valve blows off, there is equilibrium between the forces acting downward and that acting upward. Since the fulcrum is the center of moments about which these forces act, the sum of the moments of the downward forces must equal the moment of the upward force. Therefore, calling the distance from the fulcrum to the ball, x

$$75x + 15 \times 10 = 441.78 \times 5$$
$$x = \frac{2208.9 - 150}{75} = 27.45 \text{ in.}$$

In order that this valve shall blow off at a steam pressure of 90 lb. per sq.in., the ball must be set 27.45 in. from the fulcrum.

Ques.—If the separation doors at the bottom of a mine shaft are set open, so that the air current short-circuits at this point, passing down one shaft and up the other without circulating through the mine; will the fan run faster or slower as a result?

Ans.—The opening of the separation doors at the shaft bottom and the consequent short-circuiting of the air current, cuts out the mine resistance. As a result, a larger quantity of air is circulated by the same power applied to the fan. This means a larger volume of air is passing through the fan and the two shafts per minute. The resistance of the fan and the work lost in the fan is increased. The effective power or the power available to turn the fan will therefore be decreased, and the fan will naturally run slower. How much the speed of the fan will be decreased will depend upon the relative resisting power of the mine and that of the fan, in connection with that, also, of the two shafts and the airways connecting them.

Ques.—Does dynamite exert a greater force downward, or does it exert the same force equally in all directions?

Ans.—In the explosion of dynamite the cartridge is the center of a radiating force, which is exerted equally in all directions. The reason for the statement so often heard that dynamite exerts its greatest power in a downward direction is probably due to the fact that the cartridge or stick of dynamite is supported from below, and the force of the explosion is more in evidence in this direction, owing to the destruction of the support.

The explosion of dynamite is so sudden and violent, that it is only necessary to lay a stick of this explosive on the upper surface of a rock or boulder, and its explosion will generally break the boulder. Sometimes a handful of sand or earth is placed over the cartridge to keep it from rolling away before the explosion takes place. However, if the dynamite could be held against the under surface of the boulder or any other obstruction, its explosive force would be manifested as strongly in an upward direction as it was previously manifested in a downward direction.

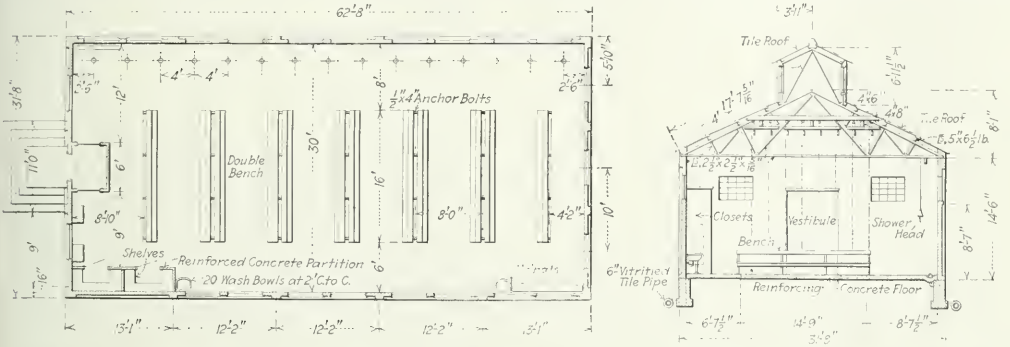
SOCIOLOGICAL DEPARTMENT

Bunsen Miners' Change and Bath House

By A. F. Allard*

The miners' change and bath house provided by the Bunsen Coal Co., at its Universal Mines, situate near Clinton, Ind., is in close proximity to the shafts, and of pivoted windows placed on each side of the monitor, running throughout the length of the building. These windows are opened and shut from the floor by a hand-operating device.

The entrance to the building is provided with an outer and inside vestibule, the men passing from the latter through swinging doorways on either side. This feature prevents cold drafts from entering the building



Plan and Sectional Elevation of Bath House of Bunsen Coal Co., Universal Mines, Clinton, Ind.

Exterior and Interior Views of Bath House at Universal Mines, Constructed of Reinforced Concrete with Steel Window Frames and Cement Tile Roof

measures 31 ft. 8 in. in width by 62 ft. 8 in. in length The floor and walls are of reinforced concrete; the roof covering is of cement tile, supported on steel trusses, and the window frames are of steel, making the building absolutely fireproof. It was designed by the Roberts & Schaefer Co., of Chicago.

At the present time, there are about 200 miners employed, out of which number about 75 per cent. make use of the bath house. Ventilation is provided by means and chilling the stripped men. A row of shower heads is located on the side opposite the washbowls, but it is not shown in the illustration of the interior. Near the entrance, two concrete closets are fitted up with shelves and hooks for the personal use of the mine managers.

The heating system consists of steam-heat coils made up of 1¼-in. pipe, in ranges of 11, supported along the side walls and the end of the building. The pipes are supplied from a high-pressure steam line and a comfortable temperature is maintained at all times. The hot-

*Chief engineer, Bunsen Coal Co., Westville, Ill.

water supply is drawn direct from a hot-water heater located in the boiler house, insuring a sufficient supply.

Along the bath side 15 shower heads are placed at 4-ft. centers and 7½ ft. above the floor. They are supplied with hot and cold water, the temperature being regulated by means of hot- and cold-water valves within easy reach of each man.

On the lavatory side there are 20 individual enameled washbowls, each supplied with a hot- and cold-water spigot. The urinal is on the same side and located at the extreme end of the house, but screened from general view by a slate partition. It is 8 ft. long and is fitted with a tank and pipes for flushing and sprinkling.

The concrete floor slopes 5 in. from the center to the gutter, permitting the water to drain off quickly. Brass bee-hive strainers placed at intervals along each gutter carry off the waste, which leads through pipes and traps to the drainage sewer. After each shift of men has used the bath house, a caretaker, paid by the company, washes down the floor, cleans the benches and wash bowls, keeping the house clean and sanitary.

Wooden benches fastened to the floor are placed in pairs back to back. They are 16 ft. long and spaced 8 ft. apart, allowing ample room for the men to walk between and around the seats. The men's clothes are suspended between the roof trusses by means of a 12-in. diameter brass ring with chain attached, operating on a pulley fastened overhead. When the clothes are hoisted into position, they are held in place by securing the chain to a padlock fastened to the back of the bench. The locks are in combination, each man carrying his own key.

Clothing thus suspended is well ventilated, and quickly becomes dry. The arrangement has an advantage over lockers placed on the floor, because no additional floor space is required. The method adopted for handling the clothing proves satisfactory to the men, enabling them to wash and change their clothing in a short time. In the view of the exterior of the bath house, another building is included on the left; the bath house can easily be distinguished by the monitor or clerestory in the roof.

Sociological Development in 1912

By R. Dawson Hall

SYNOPSIS—The work of the subsidiaries of the United States Steel Corporation has attracted much attention and will doubtless result in a great development of sociological work of all kinds. The South leads in the consideration of health, the anthracite region in the matter of institute work and first aid. The Steel Corporation leads the country in almost all forms of welfare work except in the organization of institutes.

The sociological development of 1912 is perhaps one of its most remarkable features. The work of the United States Steel Corporation at its many plants seems one of the dominant facts of the year but, as a matter of fact, the public announcement and the development of its work are about all which can be credited to the year just passed. The year before last it let an account of its plans to promote safety appear in the public press and last year it permitted the public to learn how much had been done to make its villages sanitary and picturesque.

But the greater part of the work is older than these records as the companies have been anxious to test the issue of the work before giving the public an account of it. The paper of Thomas W. Dawson at the winter meeting of the Coal Mining Institute of America best describes the work of the H. C. Frick Coke Co. Many, but by no means all, the pictures which illustrated that lecture have appeared in Coal Age. What is true of the Frick company is no less true of the United States Coal & Coke Co., another branch of the Steel Corporation.

Profits and Ethics

Suffice it to say that the Steel Trust is proving the statement of an Ohio coal operator published as a foreword that so long as we have a cut-throat competition in the coal business we cannot expect to have a truly ethical vision of the duties of operators to working men. The companies which lead today in sociologic work are the large steel corporations and the anthracite coal companies.

In relation to the first it will be recalled that at the summer meeting of the Coal Mining Institute of America, two of the officials of the Cambria Steel Co., M. J. Moore and H. S. Endsley, advocated reforms in the mining industry. The first urged the necessity for bathhouses and the second spoke in favor of making accident compensation free from the defence of contributory negligence.

Playgrounds in Colorado

But while all eyes are directed to the H. C. Frick Coke Co., due credit should be given to the Rocky Mountain Fuel Co., which is showing a commendable spirit in constructing playgrounds. We show an illustration of their mines at Superior, Colo. Careful inspection will show in the foreground a playground with a large swing and some sliding boards. Such places of recreation can be found at all the operations of the company, of which there are nine in northern Colorado and about the same number in the southern part of the state.

Only one of two houses can be seen in the picture, but this Superior camp is considered to be one of the best looking and cleanest villages in the state. There are 30 houses; some have four rooms and some five or six. There is a good boarding house with 75 rooms. All the dwellings are lighted by electricity and supplied with artesian water.

A good bathhouse supplied with hot water is provided. Fortunately, Superior has good connections, being on the main line of the Colorado and Southern railroad. The Denver and Interurban R.R. runs electric cars to Denver and Boulder every two hours. With such provisions for comfort, the Rocky Mountain Fuel Co. should have no shortage of men.

The Southern Operators Fighting Disease

In the South, a large interest has centered around sociological work. Disease which makes little headway in the colder climate of the North is rife in Southern camps,

and the Alabama Coal Operators' Association determined to cope with it and employed two experts to advise the operators as to prophylaxis and printed several pithy pamphlets on disease prevention. At the Kentucky Mining Institute, a paper was read on the hookworm.

Little on these lines has been done in the North, but it is not unlikely that the lead of the South will ultimately be followed. The H. C. Frick company has done good work by constructing concrete cesspools under their privies. In fact, the Frick company has paid as much attention to sanitary needs as to mere comforts and aesthetics.

First Aid Occupies New Territory and Intrenches Itself in Old

First-aid work has had a large development. The work of the Red Cross Society was spread so thin over so large a field of industrial work that the addition of Dr. R. N. Mackey as an assistant to Dr. M. J. Shields was

An Alley in an H. C. Frick Coke Co. Town, Showing Privy Vault

imperative. He has been doing a good work in the Southern States.

Kentucky has hitherto not been active in first-aid work but under the influence of W. L. Moss, the general manager of the Continental Coal Corporation, much is hoped from the coming year. The doctors are now at one in aiding the movement, their hostility being replaced by skillful direction since first-aid work has proved its value.

First-aid meets have been held from one end of the country to the other and have been most successful, especially in the anthracite region where there is a clear understanding as to the marking of the judges. In the bituminous region, the umpires are biassed by their private preferences as to methods. As the contestants coming from a distance have no knowledge of these preferences, a slight injustice is sometimes done in giving demerits with considerable disadvantage to a team near the lead when the final count is made.

The Debate on Methods

The time element in first-aid work is not as popular as before. Where it is still maintained, the time is made so ample that it really does not have any importance in judging the results. In some cases no limit at all is provided.

There is marked difference in view as to the relative value of elaborate and rough dressings. The Philadelphia & Reading Coal & Iron Co. is an advocate of the most careful and elaborate dressing of patients. But it must be remembered that the success of the Reading teams is due to the fact that they are well trained. It would be worse than useless to advocate such work where the men were not likely to get such continuous training or were not disposed to assimilate it.

The Coal Mining Institute of America and the Tennessee Association of Mine Foremen have each promoted first aid by holding a meet at their summer sessions and the Kentucky Mining Institute proposes to follow with one next year. The work is, however, alien to the purposes of these institutes and will probably be dropped by them after the work is well on its way. The time devoted to the reading of papers and discussion is all too short for work of any other kind to be attempted.

Doctors Differ, Yet All Are Right

The Bureau of Mines has developed a Mine Rescue and First-aid Conference which is expected to hold frequent meetings. The movement has been favorably received by the mining fraternity, but the doctors who met seem to have been obsessed with the idea that they ought not to have been there and did not become actively interested in the work at hand. This feeling is doubtless because first aid is a layman's movement.

It will take some time to overcome the unwillingness of the medical profession to assimilate it. But that acceptance will eventually take place and then the doctors will be prepared to meet and to discuss the issues as readily as they have hitherto considered other technical subjects in their medical societies. The very fact that all are not agreed is a reason for discussion. If all the practitioners of medicine and surgery had like views there would be no need for a conference. The remarkable stand is taken, however, that as no one agrees, it is well to avoid discussing the issues.

During the past year, some local hospitals have been built. One at Cle Elum, Wash., was started by the labor union. One at Pineville was built by the Continental Coal Corporation. That one has been in operation at Penn-Mary Mines for two or three years has already been noted. Evidence seems to point to a further development wherever a dense industrial population is planted in sparsely settled agricultural country where such institutions have not been provided.

Secularization of Institute Work

During the last year, the anthracite coal corporations have been taking over the institute work of the Young Men's Christian Association. This work, while conducted on a purely nonreligious basis, was not regarded by many as wholly unsectarian. For this reason, the companies believed it best before giving the movement their full support to separate the work from the association.

Whether because of the new *status quo* or from the renewed efforts of the operators, the institutes have been doing extremely valuable work. C. K. Gloman, of the Susquehanna Coal Co., has published an exceptionally useful booklet on methods to be adopted in the formation of institutes. The Panther Valley Coal Mining Institute, while perhaps not among the largest, is developing an exceptional amount of high-class literature.

All are doing a great deal to educate the younger men. Many of the classes are supplied with the textbooks of the American School of Correspondence, of Chicago, Ill., and the scholars are making remarkable progress. The Carbondale Mining School has, however, broken up, the attendance having fallen off.

The Bituminous Region Lags in Institute Work

It is to be regretted that the bituminous regions are far behind the anthracite in aggressive institute work. It should be noted here that C. L. Fay has resigned from the position he has filled most acceptably for so many years as organizer of the mining work of the Y. M. C. A. in the anthracite regions. He assures his friends that the work will not fail of success as it is now firmly supported by the coal companies and has borne enough fruit to assure the public of its value and practicability.

The school code of Pennsylvania permitting occupational schools is doing good work at Ellsworth and Nanticoke and probably in other places. E. E. Bach, of the first mentioned place, is the pioneer in such work

washhouses at the mines. Farmers in villages where roads are bad, and sidewalks unknown drift into careless ways of living and attire, which low standard is immediately raised as soon as clothing is not exposed to so much unnecessary wear and tear.

The Bureau of Mines is securing a sociologist. Consequently, we may expect, in the year to come, that the bureau will spread the good work in other states which has been started in Pennsylvania. As its good offices have taken first aid from a restricted area and made it national, so perhaps we may in a year or two find that, owing to the bureau's work, institutes will be found in almost every large camp in the Union.

A Fatal Mine Cave

The photo in a recent issue of Coal Age, showing the old Court-Wright House, at Courtdale, hanging over a cave hole, which swallowed up the heater in the cellar, sending it down out of sight into the workings of the old No. 1 slope of the Kingston Coal Co., reminds the writer

The Playground and Plant at the Industrial Mine of the Rocky Mountain Fuel Co., Superior, Colo.

of a similar but more disastrous cave in the mines at Stockton, about three miles east of Hazelton, on the night of Dec. 18, 1869. It occurred after midnight, when all were asleep, burying the house, a large double block, occupants and all; and to add to the horror of the occasion, the stoves overturned with the wreck, burning the bodies, which were never recovered. A marble slab was placed over the spot, bearing the names of the victims and dates of their births, as follows:

Elizabeth Rough,	1796
Margaret Rough,	1837
Isaac Rough,	1839
Elizabeth Rough,	1869
George Swank,	1819
William Swank,	1850

Later a neat iron fence was built about the inclosure, and within it stands several weeping willows, the mountain winds whistling in common sympathy with their drooping leaves.

In Pennsylvania a miners' compensation bill has been written by a commission appointed for that purpose and it is expected that in the coming year something will be done to enact it into law. The corporations having a firm footing are a unit in favor of some such legislation. The smaller are doubtless not so favorable, but the act will pass nevertheless and the provision will make for safety, if not for efficiency. Unless the act is carefully worded and honestly applied it will result in increased malingering.

Relation of Industry to Well Being

There has been some complaint that the miners of today do not desire to earn more than a minimum wage, that an increase of pay is always offset by a decrease of effort. If the mining villages of the country are improved so that the inhabitants of these backwoods towns can enjoy a sort of semi-urban life, it is probable that the standard of living will rise continuously with the rate of wages. Sidewalks, places of public entertainment and churches will tend in that direction and some further stimulus to pride of appearance will be derived from the building of

A "self-rescue" apparatus has been recently placed on the English markets. It is intended to be kept below ground ready for use by miners threatened by fire or bad air. Incased in this apparatus the miner could live for at least one-half hour, which would allow him to make his escape to some ventilated part of the mine.

COAL AND COKE NEWS

WILKES-BARRE, PENN.

Trouble is expected at many collieries in the anthracite field after Feb. 1. On and after this date, miners in District No. 1 are supposed to refuse to be lowered into the mines if the engineer at the colliery is not a member of the miners' union.

The decision to enforce a rule of this sort was reached at a meeting of the grievance committee of the district, which was held at Plymouth. President John T. Dempsey was not present at the meeting, and he has made a statement in which he says that such action cannot be taken because it would be in direct violation of the working agreement between miners and operators.

Despite this the miners declare they will refuse to ride on any carriage which is operated by an engineer who is not a member of the miners union. Such a decree is virtually a strike order, for the refusal to ride on a mine carriage not operated by a member of the miners' union would mean that the operation would be forced into idleness.

Mine leaders are putting forth their best efforts to prevent the men from carrying out such a threat, but the spirit of the miners just now is that every man about the colliery must be forced into their union, and this desire for a closed shop is backed by an agitation that is hard to control.

Hoisting engineers in the anthracite region have other troubles aside from those relating to the union. The proposed mine code of the state, which has been drafted and is now receiving the consideration of the mine code commission, provides that an eight-hour day be given to only those engineers at collieries where more than 200 men are employed.

The engineers have taken up the battle against proposed legislation of this sort, and are advocating that instead of placing restrictive amendments on the state law, it should be altered so as to extend to all hoisting engineers, for there are many who, besides hoisting men, rock, or coal from one vein to another, have pumps and a fan to attend.

Appeals have been made to the members of the Mine Code Commission not to wipe out the eight-hour law for all engineers, which the last legislature placed on the statutes.

A Clean Place to Eat In

Officials of the Lehigh Valley Coal Co. have erected a mess house at the Prospect Colliery for the use of all outside men. Its value will be put to a thorough test, and if it is found to be of real benefit to the men, the system will be extended to every one of the Lehigh Valley collieries. Vice-President and General Manager F. M. Chase is deeply interested in the scheme, and is watching it carefully, believing that the mess house will fill a long-felt need of the men who are employed outside at the collieries.

The mess room provides a clean place for the men to eat their meals. Sufficient room is given for all men employed on the outside. It keeps them away from the dirt and dust of the breaker, gives them comfort from bad weather, and provides the means for a pleasant chat while the meal is being enjoyed.

The rooms will be so arranged that during their noon hour the men may read and smoke, discuss any topics they desire, and get a period of rest that will be beneficial to them for the afternoon's work.

Hot and cold running water is provided, and there are benches and tables for the use of all employees.

PENNSYLVANIA

Anthracite

Pottsville—An accident at the McTurk colliery at Girardville resulted in a mine car being hoisted over the sheave. It fell and landed in the engine house. It was several days before work was resumed.

Incendiaries set fire to the barn of the Reading company at the Otto colliery, Branchdale, Jan. 3. It is believed that the object was to handicap the operation of the mine.

Scranton—T. Ellsworth Davies, the mining engineer engaged by the county commissioners to ascertain and report to them the quantity of coal in Lackawanna County that should be subject to assessment, will make his report this week. Mr. Davies, among other things, has been asked to enlighten the commissioners as to the total squeezed area in the county that is now exempt from taxation. In his report, Mr. Davies will set forth that there is between $2,000,000 and $3,000,000 of coal in the county that is being freed from taxation under the name of squeezed and unminable coal. He contends that all of this coal is not only minable, but being mined; and that coal companies are now working in places that are reported as being squeeded and worthless. In his report he will explain his reasons for declaring this coal accessible, and further will advise that the assessment value be increased from $150 to $300 per foot-acre. At the last triennial assessment the county commissioners increased the assessed valuation of coal from $67.50 to $150 per foot-acre. Appeals were filed from this valuation, but later the coal companies accepted it.

Wilkes-Barre—The strike of Lehigh Valley Coal Co. employees at Yorktown has been amicably settled and work resumed. The strike was caused on account of the miners' claim that not enough cars were furnished them under existing conditions to allow them to make a living wage. Superintendent Davies held a conference with the men and decided to abandon the hoisting of coal in No. 1 slope at Yorktown, and hereafter all coal mined in this district will be run underground to the Jeanesville operations and prepared at the Jeanesville breaker. By this plan the men can get more cars, and No. 1 Yorktown slope will be used only for the lowering of timber and hoisting of rock.

The North End Coal Co., of Scranton, proposes to take an appeal from the decree in favor of the Delaware, Lackawanna & Western Coal Co., to the Supreme Court. By the decree of the local court, the North End company was directed to forfeit leases and contracts to two tracts in North Scranton, and to pay the plaintiff $46,528.59 damages for alleged mining of coal not conveyed in the lease.

Bituminous

Washington—Martin Williams, a fireman, lost his life Jan. 9 when a flywheel on a generator engine at the mines of the Clyde Coal Co., near Fredericktown, burst. The generator is a wreck and the engine room badly damaged.

Uniontown—While drawing coke from an oven at Orient Jan. 3 workmen were horrified to find the skeleton of a man. It is thought that the man may have been murdered and thrown into the oven.

WEST VIRGINIA

Charleston—Five hundred miners of the Four States Coal Co., at Dorothy, have struck. Several mines are tied up, and among them is one which has a contract to furnish 1000 tons of coal a day to the C. & O. R.R.

Rioting has again been resumed in the Paint Creek district. A coal train was shot up and the tipple of the Standard mine of the Supplint Coal Co. was set on fire.

ALABAMA

Birmingham—The semiannual examination will be held by the State Mining Board in the auditorium of the Chamber of Commerce, Jan. 21-24, according to a statement made recently by Chief Mine Inspector Nesbitt.

Newcastle, Ala.—The Pratt Consolidated Coal Co. will fire up the Milner Iron & R.R. Co.'s coke ovens at once, for the purpose of filling a 40,000-ton coke contract, which is to be delivered within the next six months. About 250 ovens will be placed in service, after a three years' idleness. This property has been recently acquired by the Pratt company. The contract is said to involve a sum of $250,000.

KENTUCKY

Louisville—The organization of the Du Pont Coal Co. with a capitalization of $6,000,000 is expected to take place not later than Feb. 1, when the Central Coal & Iron Co. interests will be merged, it is said, with 30 smaller coal-mining companies in western Kentucky. About 20 of these smaller companies already have signed articles binding them to participate in the merger, according to reports. They will receive besides bonds securing the entire value of their property turned over, 40 per cent. of this value, as agreed upon by both sides in new stock the proposed company will issue.

The new company is said to be planning to issue $3,000,000 of stock, of which it will own 60 per cent., and $3,000,000 of bonds. This merger is supposed to be only the preliminary to the forming of a larger merger later on.

Whiteside—A new variety of smokeless bituminous coal has recently been uncovered, according to a report from Whiteside, Ky., which is said to have been used in a test at Atlanta with entire satisfaction to the smoke inspectors, no smoke consumers having been used. The coal is mined by the New Etna Coal Co., and will be placed on the market as St. Anthony coal. The supply in sight is said to be abundant.

Madisonville—With Mine Foreman H. D. Mason and a crew of expert miners in charge, United States Bureau of Mines Safety Car No. 3 is at Madisonville, Ky., for a week's stay, demonstrating the most approved methods of handling coal and of preventing accidents in mines. From Madisonville the car will proceed to Earlington and other western Kentucky points.

OHIO

Pomeroy—The floods which raged on the Ohio River recently caused practically all of the mines in the Pomeroy Bend district in Ohio to close down. One mine was operated and that was a mine belonging to the Maynard Coal Co., which was a considerable distance back from the river. Considerable damage was done to property in that mining district.

East Liverpool—There is a well defined rumor circulating in Wellsville to the effect that the Pennsylvania R.R. Co. will soon extend the Powhatan branch of the C. & P. division to a point near Martinsville, W. Va., bridge the Ohio River and extend the line through undeveloped coal fields in West Virginia.

Columbus—The United States circuit court has decided that the merger of the Hocking Valley with the Toledo & Ohio Central and the Kanawha & Michigan R.R. and other coal companies is illegal and must be dissolved.

It is expected that the Ohio state legislature will pass a bill compelling operators of coal mines to pay their men on the run-of-mine basis. The operators of the state will oppose the law with every obstacle they can invent.

INDIANA

Terre Haute—The leaders of the Mine Workers of Indiana are canvassing the vote for district officials this week. The term of office will be for two years for the first time and will begin April 1. It is generally conceded that William Houston will be elected president and that Charles Fox will be reëlected secretary.

Evansville—A fire has been raging in the Elberfield coal mine since Dec. 27. The opening of the shaft has been covered with timber and dirt to smother the fire. It is feared that the loss will be heavy. The mine employs 85 men.

ILLINOIS

Greenfield—The large coaling station buildings of the Chicago & Alton R.R. were burned Jan. 3. The origin of the fire is not known. Loss $15,000.

Streator—On Dec. 31 B. E. Parcher filed an injunction in the circuit court of LaSalle County against the Harrison Coal Co., restraining them from obstructing the flow of a small creek which runs through his land, and thence to the Vermillion River, Parcher claims that the obstruction of this creek deprives him of his right of drainage.

MISSOURI

Joplin—Six hundred and fifty miners, employed in the five mines of the Wear Coal Co., went on strike, Jan. 4, because the officials of the company refused to discharge the superintendent and the pit boss of No. 19 mine, as the men demanded. Officials of the company refuse to make any statement, except that they expect the men to return to work in a few days.

WISCONSIN

Superior—Fire, starting in the operator's cage of unloading rig No. 1, at the Carnegie coal dock, caused a damage to the apparatus estimated at $75,000.

WASHINGTON

Spokane—An extensive deposit of commercial coal has been discovered within ten miles of the heart of Spokane. The discovery has been made on a number of farms while digging wells, the workmen having cut through beds running from 10 to 20 ft. in thickness. Local and eastern capitalists have placed $250,000 on deposit in the Spokane banks to develop the find, should the pending negotiations with the owners of the land prove successful.

PERSONALS

Dr. de Holl will be succeeded by Mr. Harry M. Urban, new chief civil engineer of the Tennessee Coal, Iron & R.R. Co.

P. J. Friel, of Mahanoy City, has been appointed state mine inspector in the Shamokin district, to fill the vacancy caused by the death of Martin McLaughlin.

Henry R. de Holl, of Birmingham, Ala., assistant superintendent of the byproduct coke-oven department of the Tennessee Coal, Iron & R.R. Co., has resigned his position, effective Jan. 10, 1913, to accept the position of superintendent of the byproduct coke-oven department of the Inland Steel Co., at Chicago, Ill.

Arthur L. Ware, well known in the Kentucky and Tennessee coal fields as an engineer and machinery agent, has accepted a position with the Roberts & Schaefer Co., Chicago, and will represent them in this territory. The Roberts & Schaefer Co., through Mr. Ware, solicit the patronage of any coal companies contemplating building new plants or remodeling existing equipment.

John J. McNulty, who has been inside foreman at the Barnum Colliery of the Erie, has been transferred to the Butler Slope section of the Butler Colliery, and George V. O'Hara, who has been inside foreman on the Butler Slope workings, will have charge of the Barnum. Mr. McNulty is just recovering from injuries received in a cave in the robbing section of the Barnum Colliery.

OBITUARY

William R. Brasher, aged 33, assistant state mine inspector of Kentucky, died recently at the Norton Infirmary, in Louisville, following a surgical operation for a tumor. Mr. Brasher was brought to Louisville from Earlington, Ky., for the operation. He was unmarried, and is survived by two sisters.

CONSTRUCTION NEWS

Duluth, Minn.—The Pittsburgh Coal Co. has let contracts for two structures at its Dock No. 5, which is being rebuilt at Allouez Bay. The cost will be about $300,000.

Oak Creek, Colo.—The Yampa Valley Coal Co. is installing a plant for the manufacture of eggettes or briquettes. The machinery is valued at $50,000 and has been imported from France. It is now being erected in Denver.

Millsboro, Penn.—W. H. Flint, of Pittsburgh, has purchased a tract of 49 acres facing Black Dog Hollow and ground has been broken for a new coal plant. A modern tipple and plant will be erected, and the mine equipped with electricity.

Birmingham, Ala.—The Tennessee Coal, Iron & R.R. Co. is repairing and overhauling its Oxmoor Furnace, and will put it into blast about Feb. 1, after being idle since the fall of 1907. With this one in blast, every available furnace of this company will be at work.

Morgantown, W. Va.—The new mines of the Crucible Coal Co., near Rice's Landing, will soon be completed and it is believed that many miners will be put to work within a short time. Robert Holliday has been appointed superintendent of the Crucible company's works.

Nelson, Ky.—The Nelson Creek Coal Co., at Nelson, Ky., announces that it will rebuild its coal tipple, which was recently destroyed by fire, this time avoiding the possibility of any such mischance by making the construction fireproof. The mine has a daily output of 600 tons.

Centralia, Penn.—The Estey Coal & Mining Co., capitalized at $750,000, has been organized with the intention of starting, as soon as possible, actual development work on 500 acres of coal land recently transferred to them. The new company is an organization of Portland and Los Angeles capital.

Connellsville, Penn.—The Bellevernon Coal & Coke Co. has bought the Somers No. 1 mine, and proposes to erect 40 coke ovens. Twenty are almost completed and the others will soon be ready. The company intends to dig pillar coal for the present, as most of the solid coal has already been mined

Birmingham, Ala.—With temporary tipples and top houses in place, where the structure was burned a few weeks ago by a fire that did considerable damage, work has been resumed at the Banner mines, in the western part of the county. Something like 600 tons of coal daily will be attempted at the start.

Martin's Ferry, Ohio—The work of setting poles for the new high-tension electric power lines from the plant at Brilliant to this city is progressing rapidly. Mines between these two points will be the first to be supplied with current. A 2200-volt generator is being installed in the plant and it is expected to be in operation in a short time.

Pittsburgh, Penn.—The Cheat Haven & Bruceton Ry. has begun the construction of 8 miles of track along the bank of the Cheat River, from a junction with the Baltimore & Ohio's line in Fayette County, to Ice's Ferry, W. Va. The new railroad is backed by the Kendall Lumber Co., which has 25,000 acres of coal and timber land in the Cheat River tract. Frank Cunningham is president and chief engineer of the new road.

Bellaire, Ohio—The George M. Jones Co. is planning to develop its recently acquired territory along the Ohio & Western R.R., west of Bellaire, on an extensive scale. It has been learned that the company is planning to open at least 3 additional shafts on their property within the next year. The Pennsylvania R.R. Co. is running broad-gage cars on a siding from Wegee to the first opening, which has already been started.

Birmingham, Ala.—The Pratt Consolidated Coal Co. has leased the Montgomery County, Ala., convicts for the year 1913, paying $17 per month each in addition to maintaining and caring for them. The company will work them in their Flat Top Mine, where they will replace the Jefferson County convicts, who will be worked on the county roads after April 1, 1913. The Montgomery County convicts have for the past few years been worked on the roads and in lumber and turpentine camps.

Nashville, Tenn.—It is announced at Nashville, Tenn., that the Tennessee, Kentucky & Northern R.R., formerly known as the Overton County R.R., extending a distance of 16 miles from Algood to Livingston, Tenn., is to build south about 20 miles to connect at Sparta, Tenn., with the Nashville, Chattanooga & St. Louis Ry., and northward about 40 miles to connect with the Kentucky & Tennessee Ry. at Rock Creek, Ky., giving a short through route between Cincinnati, Nashville and Birmingham, and rendering accessible an immensely rich coal and timber section now untouched by railroads.

Knoxville, Iowa—More than $500,000 has been spent on the plant of the Indiana Consolidated Coal Co., in Dallas Township. It is estimated that the completed plant will cost little short of three-quarters of a million dollars. The shaft at the Indiana works is 200 ft. deep and has a concrete lining built around a framework of structural steel from top to bottom.

The Indiana company has 1500 acres of coal land surrounding the shaft and controls 5000 additional acres. The output of the mine will be 2000 tons a day. It is expected that everything will be ready to commence operation by Jan. 20.

NEW INCORPORATIONS

Henryetta, Okla.—The Deep Fork Coal Co.; capital stock, $10,000.

Great Falls, Mont.—The Tiger Butte Coal Co.; capital stock, $50,000.

Bonanza, Ark.—The Woodson Strickland Coal Co.; capital stock, $5000; to deal in coal.

Mount Vernon, Ill.—The King City Coal & Mining Co.; capital stock, $35,000; general mining business.

Charleston, W. Va.—The Hughes Creek Coal Co.; to increase its capital stock from $75,000 to $125,000.

Montgomery, Ala.—The Red Eagle Coal Co.; capital stock, $50,000. Home offices at Blockton, Bibb County.

Dawson, N. M.—The Vermeo Coal & Coke Co.; to change its name to the Dawson Fuel Sales Co.

Williamsburg, Ky.—The Mammoth Blue Gem Coal Co.; to increase its capital stock from $10,000 to $25,000.

Dover, Del.—The Electric Coal Co.; capital stock, $100,000; to buy, sell and deal in coal and all like products.

Toledo, Ohio—The France Coal Co.; capital stock, $10,000, to mine and deal in coal and other mineral products.

Buckhannon, W. Va.—The Welsh Colony R.R. Co.; capital stock, $5000; to own, improve and operate a railroad.

Charleston, W. Va.—The Cheat River Hydro-Electric Co. has changed its name to the Great River Hydro-Electric Co.

Wheeling, W. Va.—The California Erie Co.; capital stock, $5000; to acquire mines and mining rights, develop lands, etc.

St. Louis, Mo.—The Briquette Coal Mfg. Co.; capital stock, $100,000; to manufacture briquettes, to own and operate coal mines.

Connellsville, Penn.—The West Penn & Shenango Coal Co.; capital stock, $1,000,000; to develop western Pennsylvania tracts.

Albia, Iowa—The Monarch Coal Mining Co.; capital stock, $100,000. Incorporators, J. W. Gilschrist, B. A. Harris, H. A. Harris.

Toledo, Ohio—The France Coal Co.; $10,000. Charles L. France, H. E. Fayne, Lee J. Bronneman, G. H. France, Walter H. Jeffery.

Altoona, Penn.—Application will be made Jan. 28, 1913, by Anthony W. Smith, Alfred C. Steward and Luther E. Lewis, Richland Coal & Mining Co.

Connellsville, Penn.—Application will be made, Jan. 24, for a charter for the Connellsville Coal Co.; to mine coal, manufacture coke and sell both.

Columbus, Ohio—The Taylor-Williams Coal Co.; capital stock, $25,000. Incorporators, . W. Moore, S. E. Ranney, J. M. Taylor, E. E. Learned, W. B. Runyan.

New York, N. Y.—Buffalo Creek Coal & Brick Co.; capital stock, $250,000. Incorporators: C. A. Smith, R. D. McDonald, Pittsburgh, Penn.; C. E. Meyer, Ingram, Penn.

Connellsville, Penn.—The Consolidated Coal Co., of Baltimore, the Somerset Coal Co. and the Fairmont Coal Co. consolidate; capital stock, $31,750,000. Combined output, 10,000,000 tons a year.

Viola, Ill.—The McCraney Coal Mining Co.; to change its name to the McCraney Sand & Gravel Co., and to increase its capital stock from $10,000 to $25,000; principal office changed from Viola to Milan.

Roanoke, Va.—Hazard Coal Land Co.; capital stock, $100,000; minimum, $10,000. W. L. Brown, president, Bristol; J. B. Fishburn, vice-president, Roanoke; D. D. Hill, Jr., secretary and treasurer, Roanoke, Va.

Belington, W. Va.—The National Consolidated Coal Co.; capital stock, $2,000,000; to operate several new mines in West Virginia. A plan has also been announced to consolidate the leading southern coal companies under the name of the Consolidated Coal Co.; capital stock, $12,000,000.

Johnson City, Tenn.—A company, to be known as the Carter Coal Corporation, with a capital stock of $10,000,000, and with general offices at Johnson City, Tenn., has been organized by George L. Carter, of that place, for the purpose of developing his extensive coal holdings in Tennessee, Kentucky, Virginia and West Virginia. Mr. Carter is president of the company, J. C. Stone is vice-president, and T. F. Davis, secretary and treasurer. Most of the properties to be developed are along the Carolina, Clinchfield & Ohio and its proposed extensions to Elkhorn, Ky. The company proposes the immediate opening of mines in nine counties, with the most modern equipment. The aim of the promoters is to produce coal for the Panama Canal trade.

INDUSTRIAL NEWS

Brownsville, Tenn.—F. S. Chalfant and F. P. Stewart have bought 475 acres of coal in Luzerne Township at $55 an acre. Works will be built to employ 300 men.

Connellsville, Penn.—The Enterprise Realty Co. has sold 604 acres of coal land in Deep Valley, Springhill Township, to Fayette County parties at $100 an acre.

Frankfort, Ky.—According to the report of State Geologist J. B. Hoenig, a practically virgin coal field of fine proportions is on the eve of development along the upper Licking River.

Springfield, Ill.—The proposed merger of the coal interests of the Springfield district has been dropped for the present. Prices are considered too high for the earning powers of the plants.

Connellsville, Penn.—The outflow of Connellsville coke has awakened the upper Connellsville region into unwonted ac-

tivity. The region, in its complete collective sense, is now running full blast.

Washington, Penn.—A deal for the sale of 2500 acres of coal has just been negotiated by a syndicate of Pittsburgh men, for immediate development. The consideration exceeds one-half million dollars.

Massillon, Ohio—Valley Camp Coal Co. has purchased from the Akron Coal Co. the Columbia mine at this place. The mine will be operated as heretofore, but will be known as Valley Camp Coal Co., Columbia mine.

McDonald, Penn.—McDonald Coal Co. has bought a farm of 100 acres near Thomas Station on the Baltimore & Ohio R.R., which is underlaid with a 6-ft. bed of Pittsburgh coal. It is likely that mining operations will be begun in the spring.

Uniontown, Penn.—It is reported that J. O. Clark sold 400 acres of coal land in Braxton County, W. Va., Jan. 2, to Edward Prickell, of Pittsburgh. The consideration was $40 an acre. Clark purchased the acreage 6 years ago for $10 an acre.

Altoona, Penn.—The Bland-Cambria Coal Co., a newly organized concern, has taken over the Black coal field at Dougherty's Mines, at the terminal of the Altoona-Northern R.R., for the purpose of developing it. William H. Byers, of New York, is at the head.

Elkins, W. Va.—The Elkins mines are running as full as the scarcity of cars and men will permit. It has been officially stated that 200 men could be used up the creek, and that, while the car shortage is not so serious as during the past few weeks there is still a scarcity.

Ogden, Utah—The Lion Coal Co. has completed the connecting line between its mines and the Union Pacific R.R. The mines are located within 4 miles of Rock Springs, Wyo., and are said to embrace 600 acres of the best coal land in the district. The company has begun to ship its product.

Springfield, Ill.—It is stated that the New York Central road has purchased a tract of 30,000 acres of coal land in Montgomery County. This land will not be developed at once, but will be held in reserve for future locomotive necessities. The land is located along the line of the Big Four.

Connellsville, Penn.—L. F. Ruth is recently reported to have closed a deal for 800 acres of Greene County Coal land, which gives him nearly 2000 acres of coking coal along Dunkard Creek. The tendency toward developing Greene County coking coal is becoming more and more pronounced.

Harlan, Ky.—The Harlan Coal Mining Co. is reported to have sold to the Clover Fork Coal Co. a tract of 500 acres of land immediately adjoining the latter's tract at Kitt's. The entire consideration is said to be between $40,000 and $50,000, and to represent a good advance in the value of the land.

Wheeling, W. Va.—The miners at the Virginia Hill mine, at Lafferty, resumed work, Jan. 6, after an idleness of two weeks. It is stated that the operators notified the men that they would have to return to work or vacate the company houses. Upon the advice of their officials they returned to work.

Edmonton, Alta.—Official announcement has been made that Dr. R. Hoppe, of San Francisco, has acquired 28,160 acres of coal land in western Alberta, between Grand Prairie and the main line of the Grand Trunk Pacific R.R. Steps will be taken shortly to open the property for commercial purposes.

Fairmont, W. Va.—It is understood that a coal deal between M. A. Jolliffe and the Little Kanawha Syndicate was completed Jan. 4. As a result the holdings, recently secured by Mr. Joliffe, underlying some 1300 acres of land near Downs Station, have been transferred to the syndicate. It is understood also that the sum involved was close to $125,000.

Sharon, Penn.—The first consignment of coke arrived at the Fannie Furnace, Dec. 27, and the plant will be ready to resume operations in a short time. Officials stated that the furnace was to have been blown in Jan. 4. All the machinery has been overhauled and the plant is in first-class condition, of the Steel Corporation.

Fernie, B. C.—A snowslide has placed a damper upon operations in the Fernie, B. C., coal district. Such an occurrence is very unusual, the weather ordinarily being cold enough to prevent such a catastrophe. However, six lives were lost and seven others were fatally injured while working in the Coal Creek mines of the Crows Nest Coal Co.

Uniontown, Penn.—The Whyel Coal Co., which operates in the Yukon district, Westmoreland County, has added over 100 acres to its holdings. The latest purchase includes 3 tracts and involves a sum of $35,000.

The mines in the Sewickley field are running full time and the extensive development has given the section the title of the "million-dollar coalfield."

Martins Ferry, Ohio—Deputy Mine Inspector L. D. Devore has closed the Rush Run mine No. 3, of the Glenn's Run Mining Co., at Rush Run. Mr. Devore says he has discovered that the mining law was being violated in a number of places. The mine will remain closed until the company has complied with the law in regard to timbering and refuge holes on the main passageway.

Buffalo, N. Y.—The Sterling Coal Co., of Toronto, Ont., has bought out the Conger Coal Co., of that city, and will reorganize under the name of the Conger-Lehigh Coal Co., with R. E. Gibson, of the Conger company, president, and A. R. Gibson, acting manager. The agency of the Lehigh Valley Coal Co. will be continued and a large amount of bituminous will also be handled as before.

St. Louis, Mo.—The Santa Fé R.R. has purchased extensive coal-mining properties at Lehigh, Okla., from the Missouri Pacific R.R. Co. The property consists of more than 10,000 acres of the most productive coal land in Oklahoma. Mines now being worked are producing over 2000 tons a day. The Santa Fé management intends to open two additional shafts and increase the output to about 4000 tons a day.

Clarksburg, W. Va.—It is understood that the Righter Coal Co. has bought 136 acres of Pittsburgh coal and 86 acres of Red Stone coal along the West Virginia & Pittsburgh division of the Baltimore & Ohio R.R., 1½ miles south of Lost Creek. Grading for the sidetrack and switch is about completed, and the company expects to be shipping coal within a short time. The property will be operated on the royalty plan.

Charleston, W. Va.—The Kanawha Coal Operators' Association has addressed a letter to the Interstate Commerce Commission complaining about the treatment accorded the Kanawha coal operators by the New York Central, the Chesapeake & Ohio and the Hocking Valley Rys. It is complained that the independent operators along the Kanawha & Michigan cannot fill half their orders because they are not given cars.

Missoula, Mont.—Butler Creek Coal Co., of Missoula, Mont., has discovered a large deposit of lignite coal on their property. County Clerk F. W. Kuphal, head of the company, states that the find was made after a tunnel of 30 ft. had been dug, and the discovery leads the stockholders of the company to believe there is coal on every acre of the 1920 which they hold under lease. They expect to have the product on the market before spring.

Weleetka, Okla.—The Monitor Oil Co. is reported to have struck a 4-ft. seam of fine coal while drilling for oil at a point 3 miles northeast of here. The coal was struck at a depth of 419 ft. and is of superior quality, with a good roof and no water to contend with.

Probabilities are that arrangements will be made to mine it at once. The new find was made on the Lake Moore property, close to the railroad track.

Grand Forks, N. D.—A big effort is being made to put lignite coal on the market in such a form that it will be convenient for handling. The Northern Briquetting Co., of Minot, will at once erect a large factory for pressing lignite coal into small briquettes.

Heretofore companies have been organized with too little capital, but it is expected that the new company will be able to make an exhaustive test of the marketable qualities of the coal.

Cape Breton, N. S.—The Dominion Coal Co. has commenced to pump out the workings of the Old Victoria mine, which was closed down in 1897. The colliery produced 100,000 tons in that year, and it is expected to obtain an output as soon as the workings are unwatered. The unworked area of this colliery is chiefly submarine. The coal seam is 7 ft. thick, inclined at an angle varying from 20 to 30 degrees.

The same company also intends to open up the Emery seam at their No. 3 Colliery. The upper seam is exhausted, and the existing plant will be utilized to mine the lower seam, which is between 4½ ft. and 5 ft. in thickness. The long-wall method will be used.

Wheeling, W. Va.—It has recently become known that the Number Eight Coal Co. has purchased the old Wabash Coal Co.'s mine, north of Dillonvale. The mine has changed hands 3 or 4 times during the past 5 or 6 years, and it is stated that it has never been profitably operated. The deal includes several hundred acres of good coal, miners' homes and other physical property. The price paid has not been made public.

For several years past the Number Eight Coal Co. has been buying up coal properties in eastern Ohio. During the past year it has acquired a number of good mines and valuable coal lands in Belmont County.

COAL TRADE REVIEWS

GENERAL REVIEW

The hard-coal situation is becoming steadily easier, due to the slightly better receipts and to a lessened demand from consumers. Because of the absence of more seasonable weather, all householders have saved from one to two tons so far this season, and the combined aggregate of these small lots makes an enormous tonnage.

The future of the anthracite trade holds out excellent possibilities; in fact, it never looked better. There is just a sufficient shortness in supply to stimulate the market to a normal, or possibly a little more than normal, activity. This also keeps the buyers a little anxious and on the lookout for tonnages, which is an essential feature of a good market.

Detention in the Eastern coastwise bituminous trade is less severe, and shippers are able to promise fairly prompt loading; as a consequence, there are more sales and for larger tonnages. The demand is somewhat stronger for spot shipments on the better grades, as a result of which quotations are up slightly; consumers of these are still being compelled to fill out their requirements with the off grades. The milder weather has also relieved the car situation, and there are few complaints about slow movement.

Nearly all the river mines in the Pittsburgh district have been closed by the high water, which has also interfered with railroad operations and caused a local shortage of equipment for loading. Minimum contract prices are being well maintained and quotations on slack are firmly established at a level well over contract figures. The holidays and floods have both interfered with production to such an extent that it is difficult to form a reliable opinion on the soft-coal situation, but it seems reasonable to believe that stocks are rather low and the market consequently on a firm basis.

In spite of the unfavorable weather conditions in Ohio the trade has been fairly strong and the movement good, the unseasonable weather has had a tendency to soften the domestic grades, but the steam sizes are in heavy demand, and the consumers are attempting to obtain surpluses. The same condition as regards domestic sizes applies also to the Southern markets, where some claims are being advanced that the winter is already over. The steam market, however, is strong in every department with the railroads taking their maximum tonnage on contracts and even confiscating consignments.

The Middlewestern market is uncertain and spotty. Some appearance of real winter weather had a tendency to tighten the situation up, but increased shipments has prevented a rise in prices. The best feature in the market is the steam grades, which are relatively firm and in big demand. A heavy snowstorm in the Rocky Mountain region, with accompanying landslides and delays in transportation, has created an active demand, but prices are unchanged.

BOSTON, MASS

Pocahontas and New River, for spot shipment, are up in price from a week ago; the demand is stronger in all directions, and loading conditions at Baltimore are rather worse than heretofore. There are also more sales and for larger tonnages, as a few of the agencies are working out of the vessel detention at Hampton Roads and are in position to promise fairly prompt loading. By far the most of the clearances are still on contract, however, and it will be a long time before all the shippers have caught up on season obligations. Prices for distribution inland are on about the level that ruled last month and there is only a scattering market at the higher quotations. The shortage of Georges Creek is the most notable feature of late and several of the large corporations that ordinarily depend on that source of supply are still being compelled to buy Pennsylvania grades to keep them going, supplemented by what spot shipments can be had from Hampton roads.

The market for ordinary grades at New York has sagged a little in response to the renewed offering of Pocahontas and New River, but there are only small quantities available and the speculative business is largely confined to shippers who have sizeable contracts on which coal can be used before charges accrue.

All-rail movement has been seriously affected, not only by an increasing shortage of cars but lately by floods in southern Pennsylvania and in West Virginia. Several important groups of operations have been put out of commission and that, together with the two or three days of cold weather served to give impetus to the demand for spot coal at the transfer points; $1.75@1.95 is the market for this delivery. There is more inquiry for transportation and several charters have been made at 80c., Norfolk to Boston.

Anthracite conditions here are somewhat easier. Dealers are in better shape in the larger cities, due partly to slightly better receipts but chiefly to a slackened demand from the consumer. The New York companies are sending a better volume of coal, but all the difficulties and restrictions as to sizes and kinds still prevail. Pea has joined stove as a size that is very hard to get. The call for premium anthracite fluctuates with the weather. With the absence of any prolonged cold this market would probably squeeze by without any great distress.

Current wholesale quotations are as follows:

Pocahontas, New River, f.o.b. Hampton Roads	$3 50@$3.60
Pocahontas, New River, on cars, Providence	4.50@ 4.75
Pocahontas, New River, on cars Boston	4 53@ 4.75
Clearfields, f.o.b. mine	1 65@ 1.90
Clearfields, en route, f.o.b. mine basis	1 75@ 2.00
Clearfields, f.o.b. Philadelphia	2.95@ 3.25
Clearfields, f.o.b. New York	3.25@ 3.50
Anthracite, delivered alongside Boston	7.25@ 7.40

NEW YORK

Bituminous—The soft-coal market is practically unchanged and still continues at the relatively high level of last week. There was a slight appearance of a tendency to ease off early in the week, but this was only temporary and was immediately succeeded by a resumption of the previous hard conditions. Now that the operations in the mining regions have once again got under way, after the holiday suspension, there appears to be a little more coal offering at the mines. This is not, however, having any effect on the local situation, as the demand remains strong, and there has been considerable pressure for coal at South Amboy.

As most of the fuel contracts expire Apr. 1, there is some activity in contracting at the present time. Operators are showing a determination to procure higher prices for the next year, and are holding firmly for advances of from 10c. to 25c. over the prevailing figures. In this connection it might be stated that the selling agencies are to be complimented in the fair and equitable manner by which they have dealt with their contract customers during the past year. In spite of the relative high price level prevailing through the last few months of the year, by which the companies might have added materially to their profits by disregarding their contract obligations and entering the spot market, they have in most instances adhered rigidly to these obligations.

Both the anthracite and bituminous prices continue firm at the following relatively high level:

	Anthracite		Bituminous	
	Circular	Individual		
Broken*	$5 00	$5.00@5 10	West Virginia, steam	$3 25@3.35
Chestnut†	5 50	6 00@6 15	Fair grades, Penna.	3 25@3 35
Pea*	2 75	3 75@4 35	Good grade, Penna.	3 35@3 50
Buckwheat**	2 75	2 75@2 80	Best miller, Penna.	3 40@3 50
Buckwheat†	2 50	2 40@2 50	Georges Creek	3.50
Rice**	2 25	2 25@2 30		
Rice†	1 95	1 85@1 95		
Barley†	1 75	1 25@1 50		

* Scranton and Lehigh. ** Scranton. † Lehigh and Schuylkill.

Anthracite—Mining operations in the anthracite fields were seriously curtailed over the holiday period, and since that time by celebrations among the foreign element, coal can only now be said to have resumed in full blast. The effects of this, however, have not made any material change in the local situation, which still continues hard, and is the source of considerable anxiety, although not by any means as acute as was the case a month or two ago. In fact, the present anxiety is confined more to dealers who are loaded up with high-priced speculative coal, which they are now beginning to fear they will not be able to dispose of at a profitable figure.

Pea, stove and chestnut are in short supply and heavy demand, and are the leading features in the hard-coal market. Nut is still about normal, with egg quite plentiful and broken a trifle short. The weather still continues to be the

controlling feature in the market and pending no change in this respect a break in hard coal can hardly be looked for before March.

PHILADELPHIA, PENN.

The unusually open weather conditions that have prevailed in this vicinity, with only an occasional touch of real winter, has done more to relieve the situation as far as supplies of coal are concerned, than any other factor. It is safe to say that anywhere from one to two tons of coal have been saved each householder, and this explains why, notwithstanding the unusual demand for coal, everyone seems to be able to get a supply within a fairly reasonable time.

It has been the case, generally, all through the season that when it was absolutely necessary to have fuel, orders were filled, not promptly by any means, but without any unusual delay, except for certain sizes; the supplies received by the dealers have just enabled them to cover to this demand. A heavy snow storm or the cessation of traffic on any of the railroads centering in this city, would have soon shown to what extent this locality was in danger of discomfort or possibly a famine, as regards supplies.

There has been but one fall of snow thus far, which interfered little with deliveries, but a heavy storm, coupled with any freezing weather, is likely to bring about the condition, which the dealers have been anticipating the entire season. Supplies of stove, chestnut and pea, do not seem to be improving. Local offices of the large operators, and the individuals as well, are still besiged by the dealers, urging completion or partial fulfillment of their orders The future of the anthracite business has never looked so bright at the beginning of a new year as it does at the present time, and the dealers would consider conditions perfect, if they could only keep up to within a reasonable distance of their orders. Egg is getting to an easy stage, and is now used as a substitute for the other sizes. Shipments of the latter are contingent upon orders for the former, and even the first intimations of cutting prices on this size have been heard. One large individual operator, who ships largely to this market, indicated that their orders for egg coal were all completed, and this spells concessions, if the current production cannot be handled.

PITTSBURGH, PENN.

Bituminous—Production of coal continues to be interfered with. High water last week closed nearly all the river mines, and these are not yet again running. It also interfered with railroad operations and produced a fresh car shortage. While the weather has not been conducive to a heavy demand for domestic coal, production on the whole has been more interfered with, resulting in prices for prompt coal being established at a level measurably above the minimum contract prices. Slack has commanded a slight premium for some time, and in the past few days this has been quite heavy, small lots for spot shipment bringing $1.50, or 60c. above the contract price. Mine-run and screened coal are regularly quotable at 20c. to 30c. above circular prices, making mine-run $1.50@1.60. The anomaly of slack bringing as much as mine-run in some instances is explained by the fact of stoker-using consumers being caught short and requiring the slack. The regular minimum contract prices are being well maintained, and on contracts for six months' premium of 5c. to 10c. have been obtained in several instances in the past week. The regular minimum contract prices remain as follows: Slack, 90c.; nut, $1.05; nut and slack, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in., $1.55 per ton at mine, Pittsburgh district.

The undertone of the market is strong and operators express more confidence in the future, from the standpoint of financial results, than they have for two years or more. Demand is expected to be good throughout the year, and a heavy demand in the lake trade is regarded as assured.

Connellsville Coke—The coke market is rather dull and lifeless, and in sharp contrast with some of the predictions which were made of a special shortage. At various times since the beginning of the holidays $4 has been shaded on prompt furnace coke, the market occasionally dropping to $3.80 for a day or two. In the past few days there has been a slight stiffening, and $4 is regarded as the minimum, but there is little demand at this figure. Demand has also been light as to contract furnace coke, some furnaces which were inquiring having apparently lost interest. In the case of idle merchant furnaces, the definite statement is now made that nothing will be done unless coke can be had at lower figures, or pig iron advances. Genuine foundry coke continues scarce. Much furnace coke is being shipped on contract, and there is little, if any, really standard foundry coke available for prompt shipment. There may be 72-hour coke available, but it is likely to run high in sulphur, and as to shipment in box cars this condition is extremely difficult to meet. We quote: Prompt furnace, $4; contract furnace (nominal), first half, $3.25@3.50; year, $3@3.25; prompt foundry, $4.25@4.50; contract foundry, $3.25@3.75.

BALTIMORE, MD.

Toward the latter part of the week, the market eased off slightly due to the exceptionally unseasonable weather conditions which have prevailed. Prices, however, did not undergo much change because of the fact that there was a shortage of the coal, due to the fact that hundreds of miners did not resume work during the previous week.

One of the features of the week was the spot-line business, the demand being much greater than at tide, with slightly better prices. At the beginning of the week the $2 quotation for the low grades was well maintained, but toward the close consumers purchased in any quantity at prices ranging from $1.80 to $1.90.

The weather which has prevailed in Baltimore all through the second week of the new year, was more like summer than winter. Such conditions, however, were conducive to favorable train movements, and there was no complaint at all about slow deliveries. The car situation is far better than some weeks ago, and many of the roads are ordering additional equipment to take care of increasing business. The Baltimore & Ohio is now negotiating for 1000 additional cars.

It is stated that there was a marked falling off in the demand for anthracite, but dealers say that a cold spell will revive their business.

BUFFALO, N. Y.

The bituminous market is active and all members of the trade look for an advance in prices soon, unless the production can be increased materially. It is hard to say at present just how production and consumption will line up eventually as conditions have been so abnormal lately. The holidays cut down both, and then mining was brought to a standstill by the floods. The car shortage is still present and promises to continue, in spite of the fact that it has let up in most other branches.

Some of the jobbers are already asking an advance of 10c. to new customers and this will be general soon if present conditions hold. There is no surplus coal anywhere. In fact, the stringency in bituminous is now greater than it is in anthracite, some sections being at times in fear of an actual famine.

The lack of motive power is accountable for the shortage as much as anything. Some of the towns across the Niagara in Canada are blocked; the Toronto, Hamilton & Buffalo R.R. has for several days refused to take at Welland any coal, except fuel, for the Canadian Pacific, and other roads have since followed. Again the roads themselves have no fuel supply ahead and shippers never know where their consignments will go.

There is a heavy call this way for low-volatile coal for office-building fuel and this is made all the more active by the anti-smoke agitation, which is doing what it can to shut off coal smoke. Mayor Fuhrman, of Buffalo, in a message to the city council recommended that all the railroads entering the city be forced to electrify their passenger terminals. It would be hard, though, to cut off this class of smoke without making the abolition general.

The promise of winter weather lately added firmness to all coal prices, but that has now passed off and the rainy conditions have returned. For about the first time the coal trade is fairly welcoming mild weather. This was true of the anthracite trade only, but it is now extending to bituminous also, on account of the slow running of the railroads.

Bituminous quotations for the week were $3 for Pittsburgh lump, $2.85 for three-quarter, $2.75 for mine-run and $2.50 for slack with a strong upward tendency. Allegheny Valley prices continue about 25c. lower than Pittsburgh. Coke is active and fairly strong at $6.25 for best Connellsville foundry.

The demand for anthracite is strong, with only egg at all easy. The price of independent, for the stove sizes is from $1 to $1.25 over circular, which is the best gage of that market at present.

COLUMBUS, OHIO

There are reports of some of the larger steam users attempting to accumulate a surplus to guard against an emergency, especially an acute car shortage or congestion. But their efforts have not been very strong and surpluses are the exception instead of the rule. Dealers stocks are said to be rather light for the season of the year and lower temperatures are expected to bring about a rush of orders for immediate shipment. The Chicago market is fairly strong

which aids in maintaining quotations in the Buckeye state.

The steam trade is by far the strongest point in the market. The requirements of the larger manufacturing plants are heavy and railroads are also taking a larger tonnage to move a good freight business. There is no indication of a let-up in industrial activity and as a result steam contracts are good; renewal of contracts, which expire at this time, are being made on a slightly higher basis as a rule. At least the reign of exceedingly cheap fuel contracts on the part of the railroads is a thing of the past.

One of the best features of the trade is the good demand for the small sizes. Nut, pea and slack and coarse slack are all strong in every mining district of the state and spot orders are taken at a high figure. The supply of that sort of coal appears to be limited.

Retailers are having some difficulty in making deliveries because of the slippery condition of the streets. Retail prices are firm at the levels which have prevailed for some time.

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$2.00	.....	$2.25	$2.00
¾-inch	1 80	$1.70	2 00	1 70
Nut	1 50	.	2.00	.....
Nut, pea and slack	1 20	...	1 25	1 20
Mine-run	1 40	1.25	1 35	1.40
Coarse slack	1 00	1.15	1.10	1.00

CLEVELAND, OHIO

With the comparatively mild weather prevailing, no particular change in the market has resulted. Producers report a slight curtailment in domestic shipments, but this condition will have little effect on the market.

Present wholesale quotations are as follows per short ton f.o.b. mines:

District	Freight Rate	¾-in.	Mine Run	Slack
Youghiogheny	$1.00	$1.35	$1.25	$1.10
Pittsburgh No. 8	0.90	1.20	1.10	1 20
Goshen No. 6	0.70	1.45	1.35	1.20
Coshocton	0 70	1.75	1.50	1.30

Pocahontas coal is quite scarce. Lump and egg is quoted at $2.50; run-of-mine, $1.35, and slack, 90c. f.o.b. mines; $2.50 is quoted on Massillon 1¼-in. lump at the mines. Foundry coke is selling at $4.50 and furnace at $4 f.o.b. ovens.

While the car supply has been less stringent since the holidays, railroads continue to use every possible means to expedite the movement of their equipment. They are also impressing upon shippers the necessity of loading all cars to the fullest possible extent.

The pressing demand for steam coal coupled with the curtailed production due to high water in the vicinity of Pittsburgh and Wheeling will undoubtedly keep the market firm for some time.

BIRMINGHAM, ALA.

The temperature has been high for this season of the year, and some claim that the winter is already over and that spring will be with us within six weeks. Although prices are still firm, both the domestic and steam situation is just a bit easier. To many of the mines this situation is a great relief. There is ample business for all as the railroads are taking maximum tonnages on contracts placed in this district, and in some instances they were compelled to confiscate coal just after the holidays. This was especially true of railroad lines not touching the coal fields.

The coke market remains strong in all its departments. The iron melt in the South is breaking all previous high records and this has reflected directly in the foundry coke trade.

LOUISVILLE, KY.

There has been a substantial slump in the local market—not so much in prices, although they have naturally fallen off, as in demand. Many operators, in consequence, are simply not offering coal, rather than be compelled to take summer prices or thereabouts for their product.

This situation is largely due to the fact that the holiday lay-off permitted the accumulation of a large supply of cars. Even the largest operators have, therefore, been able to load out their entire capacity for the past week or ten days, with the result that buyers have all the coal they want, and are largely out of the market. The average industrial concern has no storage capacity to speak of, and consequently gets along on a more or less hand-to-mouth basis, taking only enough coal to answer its immediate requirements when there is a plentiful supply, and staggering along on the verge of famine when there is any shortage whatever.

Owing to the conditions noted, prices are extremely uncertain, and cover a wide range between one sale and another. Block is selling f.o.b. mines in eastern Kentucky at $2@2.25, and it is hard to say just what other domestic grades should bring at this time. Mine-run ranges between $1.10@1.25, and nut and slack has been sold as low as 60c., and on up to 80@85c. Western Kentucky prices on the steam grades are ruling as high or higher than those in eastern Kentucky, which is unusual. There is an abundance of river coal available, as has been the case all winter.

MEMPHIS, TENN.

The conditions here have changed little during the past three to four weeks, and there is a light demand on all grades of coal throughout the entire section. While there is no surplus to speak of, the prices have gradually gone lower from time to time, and now that the car situation is improving, it looks as though there will be a weak market for the balance of the season, unless weather conditions make the demand heavier and shipping conditions worse. Prices on west Kentucky coal are practically unchanged. East Tennessee-Kentucky coals have held fairly well, inasmuch as there were light stocks of this grade throughout the territory. These are now selling in the Jellico district at $2.50@2.75; Straight Creek and Holland Field, $2@2.25; Illinois 6-in. lump and egg, $1.40 per ton f.o.b. mines.

INDIANAPOLIS, IND.

Conditions have changed little within the week. Although the weather man has been predicting cold waves, none have arrived, but one is again said to be immediately ahead of us. Prices hold steady at the recent slight declines. The weather is giving retail dealers a chance to stock up as consumption has been light under moderate temperature. The car situation is, on the whole, satisfactory, and operators are not complaining. While the domestic consumption has been below the average at this season, the demand for steam grades is good. The movement of coal from the East shows some falling off. Mines are not working full time, but are averaging well.

The following represents closely the Indiana mine prices, Indianapolis prices being 50c. higher, to cover freight:

No. 4 mine-run	$1.10	Domestic lump 5- and 6-in.	$1 65
Nos. 5 and 6 mine-run	1.00	Screenings, No. 4	0.70
No. 4 steam lump, 1½-in.	1.25	Screenings No. 5 and 6	0 60
Nut, No. 4	1.30	Washed coal, Nos. 1 & 2	$1.75@2.00
Egg	1.40	Brazil block	2.20
Domestic lump 2½-in.	1.50		

DETROIT, MICH.

Bituminous—A few weeks of most discouraging weather created a congestion of both steam and domestic fuel, and caused a decided weakness in the coal market but operators are now highly elated because of the change.

There has been no improvement in the domestic trade for the past week which is attributed to the mild weather; dealers seem to be stocked to their utmost. The steam trade seems to be a little stronger and some of the large manufacturers are making inquiries as to closing of contracts.

The prevailing prices for today are as follows:

	W. Va. Splint	Gas	Hocking	Pitts. No. 8	Jackson Hill	Pocahontas
Domestic lump	$1 60	.....	$1.70	.....	$2.40	$2 50
Egg	1.60	.....	.....	.....	2.40	2.50
Nut	1.40	.....	1 60	.....	.....	.....
¾-lump	1.30	$1.30	.....	$1.30	.....	.....
Mine-run	1.15	1 15	1 20	1.20	.....	1.40
Slack	1.10	1.00	1 00	1.00	.....	1.15

CHICAGO

Anthracite coal is strong, with some premium prices being paid where dealers are running short and must have coal. All grades of steam coal, with the exception of screenings, are firm. The price of fine coal has been boosted about 10c. a ton. A drop of about 25c. a ton has been noted in prices for coke.

Prices for Hocking coal cover a wide range. Some is selling on track at $1.50, and $1.75 is being obtained for consignments in transit. There is a strong spot market for smokeless, prices ranging from $1.50 to $1.75 for mine-run. Lump and egg is quoted at from $2 to $2.25 at the mines. There are a variety of prices for splint coal. The better prepared grade is sold for delivery in the country in box cars at prices ranging from $2.10 to $2.20 at the mines. Other coal in open cars is being sold in transit at $1.75.

Prevailing prices at Chicago are:

	Sullivan Co.	Springfield	Clinton	W. Va.
4-in. lump	$2 62	.....	.....	.....
Domestic lump	.....	$2.32	$2.27	.....
Egg	2 52	.....	.....	$4 05 @ 4 30
Steam lump	2 07 @ 2 17	2 12	2.17	.....
Mine-run	.....	1 97	1 97	3.55 @ 3.80
Screenings	1.72 @ 1 77	1 57 @ 1.62	1.57 @ 1.62	.....

Prices asked for coke are: Connellsville and Wise County, $6.50@6.75; byproduct, egg, stove and nut, $5.75@6; gas house $6.

MINNEAPOLIS—ST. PAUL

During the past week the weather has been a great deal more favorable to the coal trade than at any time previous this season. However, conditions have not changed materially, and coal in nearly all grades is to be had in plenty and can be bought at a low price, considering the period of the year. Another week or two of this cold weather is what dealers are hoping for, and if it does come, conditions will be greatly changed.

Prices are uncertain and spotty on nearly all grades. Illinois screenings are selling at fairly good prices, in fact, much stronger than during the previous five or six weeks. The demand for Illinois steam lump and mine-run has been steady, with prices firm. While some of the larger Franklin County operators have been trying to hold at $2 for lump and egg, they have been practically forced by the smaller mines to sell for $1.75, and in some cases for $1.50.

Demurrage coal is reported at nearly every terminal between here and the mines and lower prices than the above have been made to move same. Reports from Illinois mines bear out the fact that the car supply is much better than heretofore.

ST. LOUIS, MO.

St. Louis experienced a sleet storm during the past week; the rain, which started in Sunday morning, turned to sleet Sunday night, and continued for a day or so. However, this did not have a tendency to advance prices on Carterville coal any, although Standard went somewhat higher Monday. On Tuesday prices on all grades went up, and continued that way throughout the week, until Saturday, when there was considerable Carterville offered at lower prices than it had been selling for all week. This was due to the operators and shippers wanting to clean up over Sunday.

However, during the week prices were made for only a day at a time, the operators and jobbers hoping that each day would see an advance, but there was no material change after Tuesday. Prices to the country trade were made for wire acceptance only.

The prevailing prices are:

	Carterville and Franklin Co.	Trenton and Big Muddy	Mt Olive	Standard
2-in. lump				$1 05 @ 1 15
3-in. lump			$1 40	
6-in. lump	$1.40 @ 1.50		1 60	1 25 @ 1.35
Lump and egg	1 45 @ 1.60	$2 25		
No. 1 nut	1 30 @ 1 40			
Screenings	0 75 @ 0.85			0 60 @ 0 65
Mine-run	1 10 @ 1 20			0 90 @ 1 00
No. 1 washed nut	1.50 @ 1.60			
No. 2 washed nut	1.35 @ 1 40			
No. 3 washed nut	1.35 @ 1 40			
No. 4 washed nut	1 30 @ 1.35			
No. 5 washed nut	0.85 @ 0.90			

OGDEN, UTAH

During the past week there has been a decided change, and winter weather is prevailing over the entire intermountain territory. The general storm made itself felt in the Northwest about Jan. 3, with a rapid drop in temperature. Seattle, Tacoma, Spokane and surrounding country experienced some real winter weather. The storm followed a southeasterly direction and California experienced the lowest temperature in years, with ice and snow at Sacramento, San Francisco and inland points.

The storm found the dealers well stocked with coal which was quickly delivered to the consumer and as the railroads have been furnishing a good supply of cars, there was a large tonnage of coal in transit. No reports of a coal shortage have been received, but judging from the way orders are being placed the supply at the various points is rapidly being exhausted and should the low temperature continue there will be a shortage of coal.

Both Wyoming and Utah quotations remain unchanged, as follows: Lump, $2.75; nut, $2.25; mine-run, $1.85, and Utah slack at $1.25 with Wyoming 25c. lower.

PORTLAND, ORE.

Portland and the Pacific Northwest had its first real cold spell this winter, but it was of rather short duration, the weather moderating in four days. However, it had the effect of increasing the demand for fuel for domestic purposes and coal dealers here were preparing to add on $1 per ton in case of an avalanche of orders. But for the moderation in the weather the rush no doubt would have followed.

From Ellensburg, Wash., comes the report that, owing to a snow blockade on the Roslyn-Clé-Elum branch of the Northern Pacific, urgent calls for coal are pouring into the mines of that section. As a result of the temporary tie-up of this line there is a shortage in many quarters, on Roslyn coal.

PRODUCTION AND TRANSPORTATION STATISTICS

ANTHRACITE SHIPMENTS

The following is a comparative state of anthracite shipments for December, 1911-12, and the totals for the year, in long tons:

	December 1912	December 1911	Year 1912	Year 1911
Phila. & Reading	1,223,880	1,238,727	12,852,386	13,265,758
Lehigh Valley	1,108,765	1,109,705	11,791,601	12,603,000
Cent. R. R. N. J	760,479	820,963	8,342,447	9,218,802

Del. & Hudson	598,969	592,922	6,361,238	7,206,731
Pennsylvania	543,361	600,803	7,435,697	8,800,179
Erie	667,532	722,093	7,435,697	8,800,179
Ont. & Western	190,539	202,966	2,213,382	2,495,476
Total	5,944,502	6,115,427	63,610,587	69,954,299

CONNELLSVILLE COKE

The "Courier" reports production and shipments in the Connellsville region for the week ended Jan. 11, as follows:

Production (tons)	Week	2 weeks	*Shipments (cars)*	Week	2 weeks
			Pittsburgh	4,189	8,437
Connellsville	223,834	436,446	W. of Pittsburgh	6,828	13,080
Lower Connellsv'le	185,630	357,222	E. of Region	917	1,814
Total	409,464	793,668	Total	11,934	23,331
Same period 1912	315,432	623,338		9,341	18,436

FOREIGN MARKETS

GREAT BRITAIN

Jan. 3—The tone of the market is very steady. Collieries appear to be heavily booked for January. Quotations are approximately as follows:

Best Welsh steam	$4.50	Best Monmouthshires	$4.20
Best seconds	4 26	Seconds	3.72
Seconds	4.20	Best Cardiff smalls	3 72
Best dry coals	4.38	Seconds	3 48

The prices for Cardiff coals are f.o.b. Cardiff, Penarth, or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days —less 2½ %.

COAL SECURITIES

The following table gives the range of various active coal securities and dividends paid during the week ending Jan. 11.

Company	High	Low	Last

Dominion Coal Co., Ltd.—Dividend No. 40 on preferred, of 3½% payable Feb. 1 to holders of record Jan. 18.

INDEX OF COAL LITERATURE

The following is a list of abbreviations used below:
A.E.G.-Ztg. = A.E.G.-Zeitung.
Am. Lab. Legis. Rev. = American Labor Legislation Revue.
Ann. Mines = Annales des Mines.
Ann. Mines Belgique = Annales des Mines de Belgique.
Austral. Min. Stand. = Australian Mining Standard.
Berg-Huttenmänn. Rdsch. = Berg- und Huttenmännische Rundschau.
Bull. Am. Inst. Min. Eng. = Bulletin American Institute of Mining Engineers.
Can. Eng. = Canadian Engineer.
Can. Min. Jl. = Canadian Mining Journal.
Chem. Eng. = Chemical Engineer.
Coll. Guard. = Colliery Guardian.
Comp.-Air Mag. = Compressed Air Magazine.
Compt. Rendus Acad. Sc. = Comptes Rendus de l'Académie des Sciences.
El. Eng. = Electrical Engineering.
El. Jl. = Electrical Journal.
El. Kraftbetr. = Electrische Kraftbetriebe und Bahnen.
Eng. Contract. = Engineering Contractor.
Eng. Min. Jl. = Engineering and Mining Journal.
Eng. News = Engineering News.
Fördertechnik = Die Fördertechnik.
Geol. Mag. = Geological Magazine.
Handel und Ind. = Handel und Industrie.
Int. Mar. Eng. = International Marine Engineering
Inst. Min. Metal = Institute of Mining and Metallurgy.
Lit. Volkswirt = Internationaler Volkswirt.
Iron Coal Trades Rev. = Iron and Coal Trades Review.
Jl. Soc. Chem. Ind. = Journal of the Society of Chemical Industry.
Jl. Ind. Engin. Chem. = Journal of Industrial and Engineering Chemistry.
Jl. Royal Soc. Arts = Journal of the Royal Society of Arts.
Jl. S. Afr. Inst. Eng. = Journal of the South African Institute of Engineers.
Kohle Erz = Kohle und Erz.
Lumière El. = Lumière Electrique.
Min. Eng. = Mining Engineer.
Mines Minerals = Mines and Minerals.
Min. Sc. Press = Mining and Scientific Press.
Min. World Eng. Rec. = Mining World and Engineering Record.
Mon. Ind. Gaz. = Moniteur de l'Industrie du Gaz et de l'Electricité.
Montan. Rdsch. = Montanistische Rundschau.
Oesterr. Z. Berg- Huttenwes. = Oesterreichische Zeitschrift für Berg und Hüttenwesen.
Portefeuille Econ. Machines = Portefeuille économique des machines.
Proc. Acad. Pol. Sc. N. Y. = Proceedings of Academy of Political Science, New York.
Proc. Am. Inst. El. Eng. = Proceedings of American Institute of Electrical Engineers.
Proc. S. Wales Inst. Eng. = Proceedings of South Wales Institute of Engineers.
Rev. Noire = Revue Noire.
Rev. Univ. Mines = Revue Universelle des Mines.
Saarbrucker Berg. Kal. = Saarbrucker Bergmanns Kalendar.
S. Afr. Min. Jl. = South African Mining Journal.
Soz.-Technik = Sozial-Technik.
Stahl Eisen = Stahl und Eisen.
Stein-Braunkohle = Stein und Braunkohle.
Tech. Rdsch. = Technische Rundschau.
Techn. Wirtsch. = Technik und Wirtschaft.
Tekn. Tidskrift = Teknisk Tidskrift.
Trans. Min. Inst. Scot. = Transactions of Mining Institute of Scotland.
Trans. Inst. Min. Eng. = Transactions of the Institute of Mining Engineers
Trans. Manchester Geol. Min. Soc. = Transactions of the Manchester Geological and Mining Society.
Ung. Mont. Ind. = Ungarische Montanindustrie und Handelszeitung.
Z. Dampfkessel-Betr = Zeitschrift für Dampfkessel und Maschinenbetrieb
Z. El. Mach. = Zeitschrift fur Elektrotechnik und Maschinenbau.

Note: We shall be glad to obtain for readers, where possible, copies of the papers referred to.

I—GENERAL

Efficiency Engineering Applied to Mining. G. A. Collins. "Am. Inst. Min, Eng." Bull. 69, p. 995-1008 2 fig.

Coal Mining Statistics, Colonial and Foreign. "Coll. Guard." vol. 104. 2706. p. 938-9. 15c.

The Results of Upper Silesian Coal Mining, in 1911. (Die Ergebnisse des Oberschlesischen Steinkohlenbergbaues im Jahre 1911.) "Stein Braunkohle." 1912. 11. p. 131. 35c.

Austrian Mines. "Min. Jl." vol. 99. 4030. p. 1115-7. (Coal is $6.65 per cent. of the mineral output of the empire, iron is 7.79 per cent. and the remainder covers the production of lead, copper, zinc and silver and gold.) 25c.

Conditions of Labor in the Mines and Similar Industries in the Prussian Mining Districts. (Die Arbeitsverhaeltnisse auf den Bergwerks- und aehnlichen Betrieben in der preussischen Oberbergamtsbezirken.) "Bergbau." 1912. 20. p. 277-8. 50c.

Successes of the Trade Union Movement in Mining. (Erfolge der Gerwerkschaftsbewegung im Bergbau.) 8 vo. 44 p. Cologne 1912. Christl. Gewerkschaftsverlag. 50c.

The Shadow of a Great Strike; The Miners' Victory. Samuel Gompers. "Am Federationist." vol. 19. 7. 1912. p. 517-29.

Consequences of the English Miners' Strike. Alms. (Die Folgen des deutschen und englishen Bergarbeiterstreiks.) "Bergbau." 1912. 25. p. 349-52. 50c.

The New Insurance Regulations for Mining Officials. (Die Neuregelung des Versicherungswesens fuer die Grubenbeamten.) "Bergbau." 1912. 39. p. 547-50; 40. p. 569-71. $7.

Workmen's Insurance and Hygienics. Hanauer. (Arbeiter versicherung und Gewerbehygiene.) "Bergbau." 1912 15 p. 211. 50c.

List of Patents Granted by the German Patent Office in 1911 (Verzeichnis der v. dem kaiserl. Patentamt im J. 1911 ertheilten Patente.) Published by the German Patent Office. 2 pts. 906 p. Berlin, Heymann, 1912. $12.

Mining Law Development. H. C. & L. H. Hoover. "Eng. Min. Jl." vol. 94. 18. p. 823-5. (The early growth of mining law gave individuals widening rights at the expense of the State; the tendency now is to restrict the individual for the good of the State.)

The New English Mining Law. H. A. Walter. (Das neue englische Grubengesetz.) "Bergbau." 1912. 14. p. 191-5 50c.

The Museum for Mining Technology at Berlin. Paul Martell. (Das Museum fuer Bergbau und Huettenwesen zu Berlin.) "Bergbau." 1912. 43. p. 601-2. 50c.

Remarks on a Few Objects Shown at the Mining Exhibition at Essen. Schultze. (Mitteilungen ueber einige auf der bergmaennischen Ausstellung zu Essen ausgestellte Gegenstaende.) "Bergbau." 1912. 27. p. 377-80; p. 390-2. 17. fig. $1.

II—GEOLOGY

The Southeastern Coalfield. The Associated Rocks and the Buried Plateau. "Coll. Guard." vol. 104. 2706. p. 940-1. 15c.

A New Stratum in the Gas-flaming Coal Section of the Ruhr Coal District. (Eine neue Schict in der Gasflammkohlen-Partie des Ruhrkohlen-Bezirkes.) "Tiefbohrwes." 1912. 12. p. 47. 50c.

Map of Workable Mineral Deposits. Evernng, H. (Karte der nutzbaren Lagerstaetten Deutschlands.) H. Baumann & F. Schuenemann, 1911. Geolog. Landesanstalt. 1912. M3. (Group: Prussia and neighboring Federal States. Pt. 1 contains sheets: Cleeves, Wesel, Muenster (Westphalia) Erkelenz, Duesseldorf, Arnsberg, Aachen, Cologne, Siegen Malmedy, Cochem and Coblenz. Two tables, introduction, and explanatory note of coloring.)

Development of the Coal Measures in the West Galician Weichsel District of the Upper Silesian Coal Region. Michael, R. (Die Entwicklung der Steinkohlenformation im westgalizischen Weichselgebiet des oberschleischen Steinkohlenbezirkes.) "Jb. d. kgl. preuss. geol. Landesanst." Lex. 8 vo. p. 159-306. 1 ill. Berlin, Geolog. Landesanstalt. 1912. $2.

III—MINING TECHNOLOGY

How Penn-Mary Coal Mine Doubled its Capacity. "Coal Age." vol. 2. p. 606-8. 7 fig. (Heat formerly wasted was utilized, excess direct electrical current converted into alternating for use in new portions of the mine.)

The Lathrop Coal Company. J. H. Williams. "Mines Min." vol. 33. 4. p. 179-81. 1 plan. 1 ill. (The new plant installation and methods of mining employed.)

Breyten Collieries, Transvaal. S. A. "S. Afric. Min. Jl." vol. 22. 1101. p. 263-5. 3 fig. (A description of mines and equipment with output of 55,000 tons per month.) 50c

Underground Layout and Working Arrangements for a New Colliery. J. Turtington. "Min Eng" vol. 16 222. p. 225-9. 4 fig.

A Recent Swedish Compressed Air Plant. Hjalmar Erikson (Eine neuzeitliche schwedische Druckluftanlage.) "Glueckauf" 1912 34 p. 1368-72 8 fig. (Description of plant for the production of compressed air, recently built by the Striber Co. for their mines.) 75c

A Stonedust Distributing Machine. "Colliery Guard." vol 104. 2710. p. 1139. 1 fig. (The apparatus employed in the Victor-American Fuel Co.'s collieries, Colorado, to cover the sides and roofs of haulage ways with stonedust and free them from coal dust.) 15c

IV—WORKING OF MINERALS

Planning Our Workings in a Mine and Various Methods of Making Levels. Graf, E. (Einteilung des Grubenfeldes

in Baufelder und die verschiedene Art der Sohlenbildung.) "Stein. Braunkohle." 1912. 17. p. 200-1. 35c.

On the Workings of Vertical Seams. Scholtze, G. (Beitrag zum Abbau stehender Floeze.) "Kohle Erz." 1912. 32 p. 801-4. 50c.

Coal Mining in British Columbia in 1911. "Coll. Gdn." vol. 104. 2706. p. 945. 15c.

Facts about Anthracite Mining. E. W. Parker. "Mines Min." vol. 33. 4. p. 202-3. (The history of the industry and development of economy in production.)

Jasper Park Colliery at Pocahontas, Alberta. "Canad. Min. Jl." vol. 33. 21. p. 750-2. 3 fig. (Development operation with plant lay-out and construction.) 40c.

Improvements at the Old Silkstone Collieries. "Coal Merch." vol. 25. 634. p. 513-4. 2 fig. (A washery capable of dealing with 1200 tons of coal in ten hours; eighty Koppers latest type of regenerative ovens and recovery plant; the output will be 3500 tons of coke per week.) 15c.

V—BORING, SHAFT SINKING AND TUNNELING

New Patterns in Deep Boring Machines and Tools. (Neukonstruktionen in Tiefbohrmaschinen und Geraeten.) "Tiefbohrwes." 1912. 18. p. 73-80. 19. p. 85-7. 23 fig.

Water Flush Percussion Method of Shaft Boring. Krecke. (Spuelschalgverfahren zum Abbohren von Schaechten.) "Glueckauf." 1912. 36. p. 1471-3. 2 fig. (Supplement to previous paper by the same author on the Stockfish Method.) 75c.

Appliances Used for Determining the Deflection of Boreholes in Shaft Sinking. (Die beim Schachtbau verwendeten Apparate zur Messung von Bohrlochsabweichungen.) "Kohle Erz." 1912. 40. p. 993-1002. 5 fig.; 41. p. 1025-32. 3 fig. (Abstract of paper read by Maurice Bodart before the Association of Old Instruments at the Liege School of Engineering, on the methods used for measuring the deflection of boreholes in sinking shafts by the congelation process through quicksands in Belgium.) $1.

Shaft Sinking in Presence of Large Inflows of Salt Water. Groeting, Heinr. (Ein Beitrag zum Schachtabteufen bei grossem Salzwasserzufluss.) "Bergbau." 1912. 42. p. 585-6. 3 fig. 50c.

Method of Thawing-out a Shaft Sunk by the Congelation Process. (Verfahren zum Auftauen eines unter Anwendung des Gefrierverfahrens ausgefuehrten Schachtes.) "Tiefbohrwes." 1912. 14. p. 95-6. 1 fig. 50c.

VI—BLASTING, EXPLOSIVES

Progress in Mine Blasting. (Fortschritte auf dem Gebiete der Minenzuendung.) "Kohle Erz." 1912. 42. p. 1089-92. 4 fig. 50c.

The Influence of Temperature and Pressure on the Combustion Speed of Fuses. Walter Snelling and Willard Cope. (Ueber den Einfluss der Temperatur und des Druckes auf die Verbrennungsgeschwindigkeit der Zuendschnur.) "Z. Schiess-Sprengstoffe." 1912. 14. p. 285-9. 15 p. 305-8. 18. p. 362-7.

Powder Which Is Soluble in Water. F. Rasching. (Wasserloesliches Schiesspulver.) "Bergbau," 1912. 29. p. 407-8. 50c.

Storage of Explosives at Mines. "Colliery Guard." vol. 104. 2707. p. 987-9. 2 tab. 15c.

Chemical Testing of Mining Explosives. J. Moir. "Chem. Tr. Jl." vol. 51. 1328. p. 457-8. 10c.

VII—TIMBERING, PACKING, ETC.

Method of Lining Shafts with Ferro-concrete Without False Work. (Verfahren zur Herstellung von Schachtauskleidungen aus Eisenbeton ohne Schalung.) "Tiefbohrwes." 1912. 17. p. 69. 3 fig. 50c.

The Preservation of Mine Timber. Max Landau. (Konservierung von Grubenhoelzern.) "Bergbau," 1912. 40. p. 563-4. 50c.

VIII—HOISTING AND HAULAGE

The Braking of High Speed Winding Engines. G. K. Chambers. "S. Afric. Min. Jl." vol. 22. 1099. p. 216. 50c.

Compressed Air Hoisting at Butte, Mont. T. T. Read. "Min. Sci. Press." vol. 105. 18. p. 554-6. 2 fig. (Hoisting shafts in a half-mile radius with central power plant and air storage system.)

Air-balanced Hoisting Engine. R. H. Carbett. "Min. Min." vol. 33. 4. p. 221-2. 2 fig. (The power developed by the descending skip compresses air to be used in hoisting.)

Winding Engine Control. "Canad. Min. Jl." vol. 33. 21. p. 734-42. 16 fig. (Apparatus controlling over-speeding and over-winding recently introduced.) 40c.

Electric Hoists at the Hecla Mine. E. M. Murphy. "Am. Inst. Ming. Eng." Bull. 69. p. 977-94. 14 fig.

Electric Hauling and Pumping in the Penn-Mary Colliery. "Coal Age." vol. 2. 19. p. 641-3. 11 fig. 1 tab.; 20. p. 674-6. 14 fig. (The steepness of the grade makes many hoists necessary; an electric larry with a reel mounted below the frame carries the rock to the end of a long dump.)

First Cost and Efficiency of Electric Main Hauling Machines. Karl Meller. (Anlagekosten und Wirkungsgrad bei elektrisch betriebenen Hauptschachtfoerder-maschinen, "Glueckauf." 1912. 42. p. 1719-21. 2 fig. 75c.

Experiments with Electrical and Steam Winding Engines. Robbert. (Untersuchungen an elektrische und mit Dampf betriebenen Foerdermaschinen.) "Z. Ver. D. Ing." 1912. 36. p. 1456-60. 5 fig. (Comparative trials of four steam and four electrical engines. Short description of plant and results. Fundamental principles affecting the consumption of energy. Results of individual trials with steam winding engines.) 50c.

Overwind Prevention in England. "Coal Age." vol. 2. 21. p. 710-11. 7 fig.

The Use of Old Wire Ropes in Timbering Roadways. J. McLuckie. "Trans. Min. Inst. Scot." vol. 35. 1. p. 37-40. $1.50.

New Cage Chains. Puetz, O. (Ein neues Soerderkorb-Zwischengeschirr.) "Glueckauf." 1912. 38. p. 1554-5. 2 fig. 75c.

Compressed Air Mine Locomotives. (Druckluft-Gruben-lokomotiven. "Z. Ver. D. Ing." 1912. 34. p. 13746. 1. ill. 6 tab. (Comparative experiments, carried out in Germany. 50c.

The Electric Locomotive Haulage with Single Phase Current at the Pit, Rosenblumendelle. (Die elektrische Lokomotivfoerderung mit einphasigem Wechselstrom auf der Zeche Rosenblumendelle.) "Bergbau." 1912. 8 p. 93-4. 50c.

Automotor Haulage Incline. Kusch, Karl. (Ein Auto-motorischer Bremsberg.) "Motan-Rdsch." 1912. 6. p. 249-51. 5 fig. (Plant at the Michaeli Colliery, Ostrau-Karwin.) 30c.

IX—SIGNALING

Wireless Telephony in Mines. O. Dobbelstein. (Drahtlose Grubentelephonie.) "Glueckauf." 1912. 40. p. 1623-8. 12 fig. (Description of installation made at the Pit Karolinenglueck, Bochum, for the purpose of determining the possibility of using wireless telephony in mines.) 75c.

Wireless Telephony in Mines. E. P. Buffet. "Coal Age." vol. 2. 19. p. 646-8. 3 fig.

Electric System Signal, Argonaut Mine. R. S. Rainsford. "Eng. Min. Jl." vol. 94. 17. p. 783-4. 4 fig.

X—LIGHTING

Prize Competition for Safety Lamps. (Preisaus-schreiben fuer Sichereitslampen.) "Stahl-Eisen." 1912. 43. p. 1791-2. 70c.

The Forerunners of the Safety Lamp. (Die Vorlaeufer der Wetterlampen.) "Bergbau." 1912. 40. p. 563. 50c.

The Safety Lamp for Gaseous Mines. A. Rzehulsa. (Die Sicherheitslamps fuer Schlagwettergruben.) "Stein . Braunkohle." 1912. 19-20. p. 233-7. 35c.

XI—VENTILATION

Ventilation of a Bituminous Coal Mine. G. W. Hamilton. "El. Jl." vol. 9. 11. p. 10,325. 1 fig. 1 tab. (A note is made that while there are set rules for the volume of air required, the application of the rules must depend on present conditions and the plan of future developments.)

Facts and Theories Relating to Mine Fans. D. M. Mowat. "Trans. Min. Inst. Scot." vol. 35. 1. p. 26-36. 1 double plate. $1.50.

Experiments in Ventilation by Means of Brattice Pipes. Arlt, W. (Untersuchungen ueber Wetterfuehrung mittels Lutten.) "Kohle-Erz." 1912. 43. p. 111-4. 50c.

Driving of Mine Fans by Three Phase Motors for Variable Speed. Sauvage. (Antrieb von Gruebenventilatoren durch Drehstrommotoren mit regelbarer Umlaufzahl.) "Glueckauf." 1912. 41. p. 1668-72. 4 fig. 75c.

XII—MINE GASES, TESTING

Causes and Prevention of Firedamp Disasters. Paul Grabein. (Die Ursachen der Schlagwetterkatastrophen und deren Verhuetung.) "Stein-Braunkohle." 1912. 16. p. 187-8. 35c.

XIII—COAL DUST

A Contribution to the History of the Coal Dust Question. v. Rosen. (Einiges aus der Geschichte der Kohlenstaubfrage.) "Bergbau." 1912. 29. p. 405-7. 50c.

A New Type of Mine Air Humidifier. "Min. Sci. Press." vol. 105. 18. p. 569-70. 1 fig. (A hollow wheel mounted on the shaft of an electric motor is fitted with water intake, spray nozzles on its periphery, and fan-blades at its back, and produces a fine water mist.)

Briquetting Tests at the United States Fuel Testing Plant, Norfolk, Virginia, 1907-8. C. L. Wright. (U. S. Bur. of Mines.) 8 vo. 42. p. 9 plates. 1912.

COAL AGE

Vol. 3 NEW YORK, JANUARY 25, 1913 No. 4

The Mine Mule

(Written expressly for Coal Age)

By Berton Braley

He sees the pleasant daylight only once or twice a year,
When they take him out to gambol on the grass;
But he cocks those funny eyes of his and waves a crazy ear,
And you bet he's wise to all that comes to pass.
He is meaner than the skinner—and the skinner's awful mean—
But he's stronger than the cable on the cage;
And of all the critters underground it's plainly to be seen
That the mule's the boy who always earns his wage!

The skinner is a driver who swears a purple streak,
But profanity is love talk to the mule;
He would kick the gentle miner to the middle of next week,
But when the skinner beats him he is cool.
For the mule he loves the skinner, and the skinner loves him back,
Though you sure would never know it by his talk;
And the mule he hauls a string of cars along the bumpy track
And very, very seldom will he balk.

But if the mule gets sulky he can tangle up the mine,
While the pit boss and the cager stand and swear;
And the cars are backed behind him in a long, unbroken line
And the skinner hops around and tears his hair.
Yet when the mule is ready he will start to work again,
And merrily he hauls the cars away;
For like that guy, Sir Galahad, he has the strength of ten
When he really wants to bring it into play.

So, here's to Mr. Long Ears with the tassel on his tail,
May he prosper like a dividend that's fat;
And when he's done with working and he hits the spirit trail,
May he go where all the saintly mules are at!
Where there isn't any mining and there isn't any coal,
And a skinner is a critter never met;
Where the only occupation is to bray with all his soul
For the mule has earned his Heaven, you can bet!

The Preparation of Bituminous Coal—II

By F. E. Brackett*

SYNOPSIS—The second and concluding article on this subject. This installment discusses gravity chutes and the different types of screens with their comparative advantages and disadvantages. Some valuable data regarding screening areas are given, together with notes and comments on the methods of sizing as practiced in different regions.

In some regions the pan shown in Fig. 1 is very popular. There are a number of different types in use, but the figure shows, perhaps, its most comprehensive form. This pan is not hinged or attached to the chute at its upper end. In its upper position it forms a continuation of the chute, but at a less grade—say 3 in. per foot. Coal entering at the upper end at a high velocity is gradually brought to rest by this change in grade and by the curve at the end of the lower part. The entire pan consists of two separate parts hinged with a bridle, like a clam shell and hung by the bridle at its upper end.

The cables by which it is suspended wind about some sheeves, or small drums, on a shaft, on which there is a band brake. By a proper arrangement of the size of the drums, any ratio of displacement between the upper and lower ends can be maintained; the figure shows a two to one ratio. If the brake be released and the lower end of the chute lowered 2 ft., the upper end will drop one foot. The entire pan is counterbalanced, so as to be held in its upper position when empty. When full of coal, the brake is released and the pan drops to the lower position shown, the "clam shell" being opened by a piece of chain attached to the end.

The whole mechanism can be mounted as a scales for weighing the coal. This arrangement checks the coal more gently than any form of gate, and also shortens the fall after it leaves the pan. It is rather doubtful though, whether this drop is less than could be accomplished by any well adjusted chute. However, where a certain amount of fall is to be neutralized and the requisite horizontal space is not available, this pan certainly does possess a decided advantage. This form of pan is more commonly hinged at its upper end and sometimes, where the main problem is to overcome height, the two parts are made of equal length and just alike. The pan then becomes a short box 10x6 ft. overall, and several feet deep, and when loaded with coal, it slides down on guides to the car, and opens up on the same principle as the one shown. The pan, as well as the monkey, requires some little time for operation, which should not be lost sight of in computing output; the plain gate is much more rapid.

The Question of Sizing

With the smaller sizes of coal carefully separated from one another, the depth of fire on the grate bars can be so adjusted that each size will get proper draught. This process of sizing can be carried on until a grade is obtained so small that it would hardly be possible to carry a fire light enough to get the proper draught, without at the same time having it so thin that holes are liable to be sucked through the fire-bed, and thus reduce the temperature of the firebox.

The minimum of useful size is about one-fourth of an inch, or at least, that is about the smallest mesh used on bituminous-coal screens. However, with mechanical stokers, even the very finest coal can be economically burned, although with these, there is no advantage in sizing below a certain limit. The harder and less coking qualities a coal has, the more advantages there are in sizing. For this reason we find the most extensive sizing plants in the anthracite region, while the least sizing is done to the soft Eastern steam coals.

In general there does not seem to be any great uniformity of practice in sizing, in the bituminous coal fields. Speaking in round figures, lump coal is such as

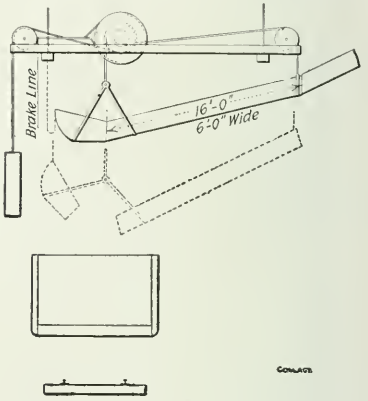

Fig. 1. Pan for Lowering Coal

passes over a 1¼-in. bar screen 12 ft. long and 6 ft. wide. Nut passes through a 1¼-in. bar screen and over a ¾-in.; slack passes through the ¾-in. screen. We do, however, find 2-, 3-, 4-, 5- and 6-in. lump on the market, as well as the various sizes of so called "egg" which these lumps produce. Also pea coal and buckwheat are sometimes made from the "throughs" of the nut screens.

Perhaps these grades are usually about as follows: Nut coal, through 1¼-in. and over 1-in.; pea coal, through 1-in. and over ¾-in.; buckwheat, through ¾-in. and over ¼-in. It would seem that the grades of lump over, say, 4-in., were really superfluous, and that one, below nut coal, was really enough at most. The sizes would then run: Domestic lump, all over 4-in.; lump, all over 1¼-in.; ¾-lump, all over ¾-in.; egg, over 1¼-in. and under 4-in.; nut, over ¾-in. and under 1¼-in.; pea, over ⅜-in. and under ¾-in.; slack, under ⅜-in. However, certain market conditions undoubtedly require further sizing, though in the majority of conditions there are usually less.

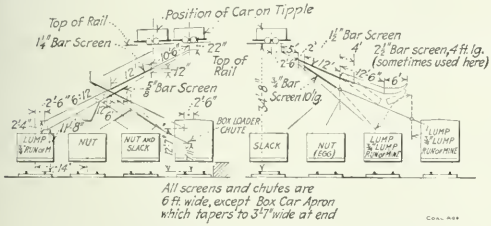
Types of Screens

There are three types of screens in use—the bar screen, the revolving screen and the shaking screen. The bar screen is the most popular, and is used to make the first

*Consulting engineer, Cumberland, Md.

or lump separation in the vast majority of cases. Everything going through the lump screen is treated either on another bar screen, or on some form of the mechanical screen. In some regions, however, the shaking screen is used to make the lump separations as well as the fine-coal separations.

Bar screens are built of a great number of bars, supported on cross pieces, notched to receive the lower edge of the bars. There is usually a little taper in the section between the top and the bottoms; this assists the fine coal in passing through and also helps hold the bar in its supporting notch. The standard lump screen, as before stated, has a 1¼-in. space between the bars, is 12 ft. long and 6 ft. wide. The slope is usually from 4½ to 6 in. per



FIGS. 2 AND 3. TYPICAL CROSS-TRACK TIPPLES

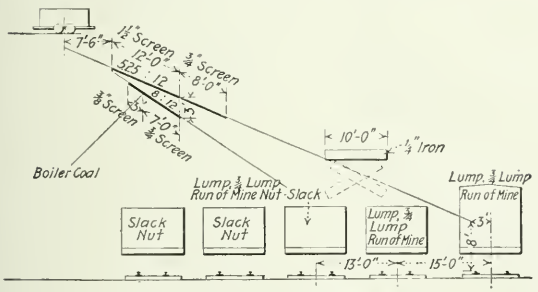


FIG. 4. TYPICAL GRAVITY-SCREEN LAYOUT

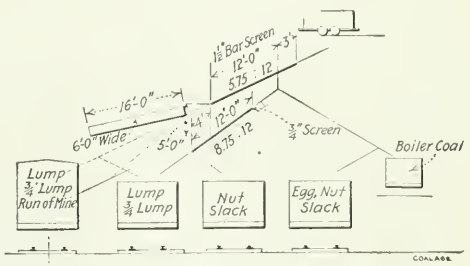

FIG. 5. A DOUBLE LUMP-SCREEN ARRANGEMENT

foot, horizontal measurement. In most cases this is the initial screen and is the only one placed in the chute.

For screening the "through," or fine coal from the lump screen, there seems to be a great diversity of plans. For 6 ft. wide the length of the nut screen has been reduced to 6 ft. without seriously impairing the results. The reason for this is, no doubt, that there is much less coal coming to this screen than to the lump screen, and as it is usually placed under the latter, much of the coal falls right through, instead of sliding along on top of a larger size, for a time. At the same time the customary size for the nut screen seems to be about the same as for the lump.

The capacity of the latter is about three mine cars per minute, or say six tons per minute of run-of-mine coal; usually two-thirds of this goes over the screen and one-third through. It would, therefore, seem that, if convenient, the nut screen could be made smaller than the lump. But since the objection to a little fine coal in the lump is not as great as a like percentage would be in the nut, it would hardly be practical to reduce the area of the nut screen to one-third of the lump screen; coal for commercial purposes, smaller than the nut size, is usually prepared on some form of mechanical screen. For use at the mine, however, smaller bar screens are sometimes placed above the nut screen, so as to take a small quantity of fine slack for boiler purposes. For the larger sizes of lump, the tendency seems to be to shorten the screen.

BAR AND REVOLVING SCREENS

In setting the bars for the bar screens, care should be taken that there is no binder over the top, at the lower end, to hold them; the upper surface of the bars at that point should be placed a little higher than the surface of the sheet iron in the chute. This is particularly important in the fine-coal screens, because small lumps catch on the binder, or on the sheet iron, and the weight of the coal is not sufficient to force the lump past. The screen thus begins to clog, even when given a heavy pitch. The lump screens do not give trouble in this way, under ordinary circumstances, because of the weight of the coal.

The bar screen cannot be replaced by a perforated metal screen, because the coal travels over it too fast to be properly screened. The wire screen is, of course, too rough. For mechanical screens, however, both wire and perforated metal give a high efficiency.

In revolving screens, the screen proper forms the periphery of a cylinder or frustum of a cone. If the form is cylindrical, the axis must be given an inclination of about 5½ deg., or about 1⅛ in. per ft., to force the material to travel through the screen; hexagonal screens sometimes replace the circular ones. The periphery of a revolving screen should travel about 200 ft. per min. There should be about 1 sq.ft. of screen surface for every ton of coal fed into the screen per day of eight hours, when the mesh is ¾ in., and with ¼-in. mesh there should be 2 sq.ft. per ton. If the coal is wet, this should be increased.

Revolving screens are sometimes jacketed; that is, two or more screens are placed concentrically on the same shaft, the inner being the coarsest, and each succeeding screen making additional separations. This reduces the space and height required for the same amount of screening. In other cases, a long cylindrical screen has coarse mesh near its discharge end and finer near the entrance end, thus making two or more through products besides the overproduct.

The disadvantage of "jacketed" screens is that the necessarily slow speed of the innermost screen reduces the capacity of the entire combination, so that if rapid work is essential, it is necessary to use large diameters; there is also some difficulty in renewing and cleaning the

inner jackets. The disadvantage of using two or more mesh of different sizes, placed one after the other on the same frame, is that all the material must pass the finer mesh, which, as a result, is rapidly worn out. Also as more work must be done, the finer mesh must necessarily be of greater area than they would be were they placed so as to screen only that which passes through the larger mesh.

Shaking screens probably possess a greater cleaning efficiency, per square foot of surface, than do the bar screens, and do not require so great a pitch. They occupy must less room and are more conveniently arranged than the revolving screen, which usually requires considerable elevating of the fine coal; the shaking screens are also particularly efficient with wet coal. The principal disadvantage of this type is that the reciprocating motion imparts a destructive vibration to the framing of the building.

For sizing bituminous coal, inclined shaking screens are extensively used in certain sections, particularly in the Middle Western states. These screens are given a shaking motion by means of cams and connecting rods, which make from 60 to 100 strokes per minute, the speed varying according to the amount of moisture in the coal; the throw of the eccentric is about 6 in. The screens are 7 ft. wide and vary in length according to the conditions on the tipple, no standard having been adopted. The average inclination at which they set is 14 deg., or 3 in. per ft., but this angle varies from 12 deg. to 15 degrees.

Screening Area Required

The necessary area depends upon the mesh principally; to screen the run-of-mine coal over a ¾-in. perforated screen for making slack, requires 0.028 sq.ft. of screen per ton of run-of-mine per day of eight hours. If the perforations are 2½ in., then 0.014 sq.ft. per ton per day are required. As with the bar screen, there seems to be some tendency to keep the fine-coal or nut screen about the same size as the lump screen, although only about one-third of the run-of-mine will pass through 1½-in. mesh. Even at three times the above figures, however, the ratio of material passing into the screen, to area of screen surface, is far below anthracite practice, where a screen for fine coal, of about ¾-in. mesh, will have about one-half square foot per ton, per 10-hr. day.

It is interesting to note that at six tons per minute, a standard 1¼-in. lump bar screen has an area of 0.025 sq.ft. per ton per 8-hour day, while the perforated shaking screen requires about 0.028 for the ¾-in. mesh. It is doubtful if these lump-screen areas could be reduced below the maximum capacity of the tipple, regardless of the actual mine output, because the rate of the flow of coal across the screen is fixed by the time of dumping a mine car. To avoid this and secure a more even distribution, feeding boxes or small bins are sometimes introduced above shaking screens, though the writer does not know of any case where these are used above the bar screens. The flow from the box is often produced by a shaking motion. For the fine coal, small bins usually exist at some point, which equalizes to a great extent the flow of the coal passing the lump screen.

For the ¾-in. nut screen, of the stationary or bar type, the usual area would be 0.075 sq.ft. per ton per day. The corresponding revolving screen would require, according to usual practice, about 1 sq.ft. per ton, and the shaking screen on anthracite, ½ sq.ft. per ton per day. It would seem rather difficult to reconcile this wide discrepancy even after making full allowance for the intermittent action of dumping.

The relation between the mesh and the area, however, is much more clearly defined than the relation between the output and the area. Thus, for shaking screens of perforated plates, when the diameter of the perforation is increased from ¾ to 2½ in., or as 3 is to 10, which is nearly four times, then the area required is reduced one-half, in other words, the areas vary inversely as the square root of the diameter of the perforation. A similar result, but more approximate, is obtained from the data on revolving screens. This same law is approximately borne out in anthracite practice.

A word might be inserted here about the bins or pockets for fine coal, usually found at bituminous plants. It is not often that these are large enough to carry

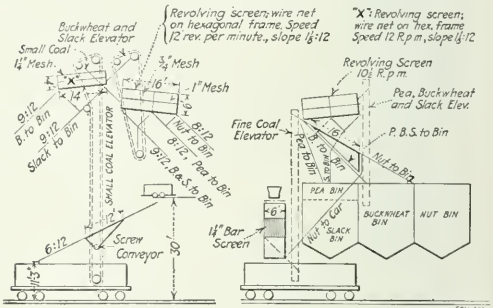

Fig. 6. End-dump Tipple Fig. 7. Fine-coal Bins

more than a few days' run, the main object being to allow a carload of the fine to accumulate before it is loaded into the car. Unless these bins are used, there must be a separate track and railroad car for every grade of coal made. With some arrangements, this is more convenient than the bins, but in other regions we find the bin plants more popular.

Tipple and Screen Arrangements

The various combinations of dumping and screening apparatus are, of course, almost endless. There are, however, two main types which will be briefly described. They are the "cross track" plant, with bar screens or shaking screens, and the "end dump" plant, with or without elevators and bins.

In Figs. 2, 3, 4, 5, 9 and 10 are shown typical plants of the "cross track" type with bar screens; Fig. 2 is a double plant consisting of two tipples or dumps and two sets of chutes and screens, one set being preferably used to load box cars. Many of the other figures represent one-half of a double plant, the second tipple and chutes being exactly or nearly the same as the ones shown. There are seldom more than two screens on the same set of chutes used in these plants. The sizing, therefore, confines itself to lump, nut and slack.

In most cases the nut screen is placed directly beneath the lump and is of about the same length and area as in Figs. 3 and 10. In other cases the nut screen is displaced or moved down the chute a little below the lump screen, as in Figs. 2 and 5. Figs. 4 and 9 show two

screens in succession on the main chute. The ¾-in. lump, produced in Fig. 4 by covering the 1½-in. screen, is not the equal of that produced by screening fine over 1½ in. and then adding the nut coal, from the ¾-in. nut screen, to the lump car. In this particular case, it would seem that the ¾-in. screen, being only 8 ft. long, was not sufficient to properly screen the coal. According to established principles and data on screens, given elsewhere in this article, it appears that if 12 ft. were sufficient for a 1½-in. lump screen, that 17 ft. would be the proper length for a ¾-in. lump screen, and not 8 ft. as shown. In the writer's experience ¾-in. lump screens, 12 ft. long, are not sufficient.

It will be noticed that by throwing the chutes across a system of tracks that each grade is conveniently loaded on a separate car with the arrangement of chutes shown in Fig. 9. The height required from top of railroad track to top of mine-car track on tipple is usually about 35 or 40 ft., according to the arrangement. Fig. 10 was laid out to obtain a maximum of convenience with a minimum height.

If shaking screens are used, a similar arrangement of tracks is still convenient. The arrangement of the screens in succession along the main chute, instead of passing lump coal over one screen only, seems more popular with the shaking screens. The reason for this is, no doubt, the increased efficiency in cleaning. This also makes the small coal chutes less complicated, and generally compacts and simplifies arrangements. The low fall required avoids the necessity of much building where height above the railroad does not already exist. Of course, there is an objection, as previously pointed out, to passing the lump coal over every screen, especially the small mesh, but advantages with this particular type seem to have overbalanced this disadvantage. These screens may and should be fed from a feeder box and not from a tipple direct.

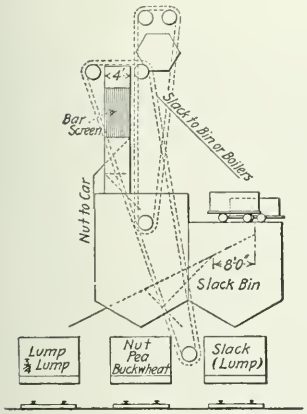

Fig. 8. A Fine-coal Loading Arrangement

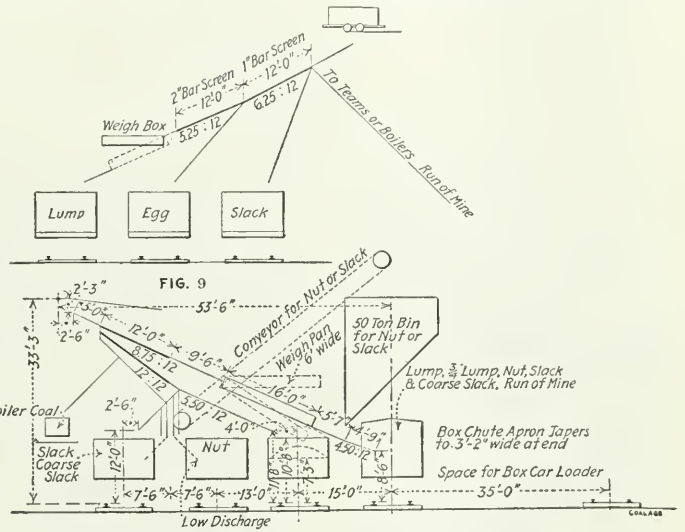

Fig. 10. A Typical Layout to Obtain the Maximum Convenience with the Least Height

The End-dump Tipple

The "end-dump" plant, with elevators and revolving screens, is shown in Fig. 6. The advantage of the end chute is to give a better turn to the cars. Some attempts have been made to turn the ends of "cross chutes" for the same purpose, so as to make them load in an endwise direction. These are called radical chutes, and if properly built, are successful but rather cumbersome. With chute and tipple or dump arranged as in Fig. 6, the point at which the fine coal leaves the pocket beneath the lump screen, makes it inconvenient to carry screening any further, or indeed to dispose of the screenings at all without elevators. Hence elevators and revolving screens are the logical accompaniment of this arrangement.

To avoid many tracks and delays of railroad cars, or waiting on railroad cars for the smaller coals, the fine coal is usually run into a series of bins, which are placed over a single track called the fine-coal track. Figs. 7 and 8 are two views of the same tipple. This is hardly typical, as it represents a combination of the two types, without any well deferred attempt to take full advantage of either. It is, no doubt, the result of the peculiar surroundings.

Before selecting any particular arrangement or preparation for a given locality, all questions must, of course, be carefully considered, the principal details being the texture of the coal, market demands and topography of the surface.

⁂

To trace the path of an explosion is a matter calling for the exercise of patience and keen observation. The following points will be found of assistance when undertaking such a task: (1) Deposits of fine dust on the faces of crossbars and timbers. (2) The abrasion of sharp projections on the pillars of coal. (3) Heavy material forced from its position and carried in a definite direction. (4) The formation of eddies of dust in the corner of timber sets and passage ways; these eddies are invariably found on the side opposite to the origin of the blast. (5) Coke dust and other materials, forced into corners of projecting sidewalls, in the same direction as the force of the explosion. (6) The bending of switches and the direction in which timbers and wagons are carried.

Last Year's Coal Mining Accidents

By R. Dawson Hall

SYNOPSIS—A large reduction in the important coal-mine disasters of the United States was effected in the year 1912. Whereas in the previous year, 444 were killed in accidents involving three or more persons, last year only about 254 men died from misadventures of like severity. The greatest disaster in the year was the explosion of the Yubari mine, and of this a brief account is given. Many of the present-day disasters result from too brief an acquaintance with fields which have unforeseen dangers.

The compilation of a list of the accidents of any year is made difficult by the fact that early reports of the smaller domestic accidents and of all foreign catastrophes are the only statements which can be obtained till the annual reports slowly appear.

When the final reports are published, from one to two years after the event occurs, the number of recorded deaths is apt to be decreased in the case of foreign accidents, owing to rescues effected or men escaping after the last report available.

Figures of domestic accidents are liable to be underestimated in our tabulation because after explosions the living victims are so badly injured that death often supervenes. When these further deaths occur, they are rarely reported except to the inspectors or the national bureau and consequently the figures published at the end of the year are frequently too low.

With this introduction, it will easily be understood why the list is only approximately correct. It may omit some important accidents, though it gives almost a complete account of the principal mine disasters in America and the British Isles. Unimportant explosions and other accidents are purposely omitted.

Larger Accidents in Coal Mines of the United States Killed 254 Men

Excluding all accidents where less than three were killed, there were 254 fatalities in our coal mines last year. Great Britain's deaths similarly calculated amount to 117 and those of Canada to 7.

The estimate made by the Bureau of Mines of the number of coal-mine workers killed in the United States during 1911 in accidents killing over two men at one time was 444. Consequently the fatalities this year show a distinct improvement even if we allow a large margin for inaccuracy in the estimate which I ha e made. The drop given is 43 per cent., quite a noticeable reduction.

A Week of Gloom

The greatest domestic mine disaster of the year was that at Jed, W. Va., where 81 persons were killed, the next that at Chant No. 2, in Oklahoma, where there were 74 victims. These accidents came within a week of each other. The first would probably not have occurred had the Jed Coal Co. supplied their men with safety lamps, as was ordered by he inspectorate. The second was probably due to the fact that the men, who were awaiting the clearing of their working place of gas, sat down where the escaping gas passed over their open lights. In fact it is a question whether Chant ought ever to have been worked as an open-light mine.

Part of the improvement in the fatality rate is due probably to our mild and damp winter. "A green Christmas makes a full graveyard." But this is not the case with the mining industry and credit must be given to the weather for its work in making the mines safer than they would otherwise have been. Though we did not have a green Christmas, the winter generally has been mild and marked by frequent rains or soft snows.

The British coal-mine death rate has only been swelled in the past year by one large catastrophe, that of Cadeby Main colliery. At this disaster, 89 persons lost their lives. Had it not been for that explosion, the British record would have been remarkable. But the frequency of mine fires seems to suggest that large disasters were only avoided by a hair's breadth.

The Lack of Precaution in English Mines

Simply as an example, I call attention to the fire at the Headly Park colliery, Feb. 26, which occurred in an oil house on the main haulage-way. For a while it threatened to duplicate the Old Hednesford disaster and it might easily have been as unfortunate as the Price-Pancoast fire. Only two days before, at St. Helen's colliery, a fire took place with 470 miners in the pit. It was only with great difficulty that they finally got out.

The German record is peculiarly bad and would appear worse if we had as complete a record of fatalities as for the United States or Great Britain, and especially if compared with the output of coal in the Empire. Six accidents caused 183 deaths.

The record may be unrepresentative of the true conditions; certainly it does not suggest that the German laws give the mine worker a superlative assurance of safety. Some close observers have been of the opinion that an excess of gold braid on the persons of all officials in charge makes it necessary in Germany to give the mines "absent treatment."

Other Disasters in 1912

France had two bad accidents; one an explosion at La Clarence colliery resulted in the death of 61 persons; the other was from a less common cause, an outburst of carbon dioxide. A Russian explosion is said to have destroyed 45 lives and a fire in Tasmania, from the blowing of a motor fuse, is said to have suffocated 42 men. This fire was, however, in a metal mine.

Little has appeared relative to the greatest catastrophe of the whole year. So little has been said of it that an account may be fitly inserted here. On Apr. 29, at 11 a.m., a violent explosion occurred at the Yubari mine, in the island of Yezo, Japan, which, not satisfied with killing all of the 278 miners and officials in the workings, destroyed the mine buildings on the outside killing 6 men and injuring 5 more.

A brisk fire succeeded the explosion and in the report made in the *Japan Weekly Mail* of May 18, the statement is made that on May 8, only 106 bodies had been recovered, so fierce was the struggle needed to combat the fire in the mine.

Reference should be made here to an explosion reported to have taken place on Dec. 23, at Sapporo, on the same island of Yezo, only about 40 miles from the ill-fated Yubari mine. The *Echo des Mines et de la Métallurgie,* of Paris, reports that of 200 miners in the workings only three have been saved. As the brief mention is unconfirmed, the figures have not been added to those in our table or in our summaries of results.

The Bad Record in Japan

Japan has probably the worst record in the world for mining disasters. It is strange because Japanese companies seem more solicitous about the care of their employees than those of any other nation. The *Nichi Nichi,* a native organ, quotes the following table as an average for five years, ended 1909.

DEATH RATE OF MINERS

	Deaths	Deaths from explosion	Percentage
Japan	2381	1209	58.8
Great Britain	5789	419	7.3
Germany	5729	589	10.3

The *Nichi Nichi* states that explosions in Japanese coal mines can be traced mostly to carelessness on the part of the miners. Match boxes carried with them into the pits often prove to be the cause of catastrophes.

Not Cognizant of Danger Till Warned

Perhaps we may congratulate ourselves not only on a lower death rate this year than last, but on the gradual movement toward safety in the mines. The fact is sometimes overlooked that it takes a certain number of years and a few disasters to exhibit the dangers of any coal field.

They nearly all look harmless enough when first opened. The danger is usually revealed by a tragedy. Nearly every new field has its peculiar dangers and until they are discovered and duly measured, accidents will happen. Until death has shown the way it remains undiscovered.

We are beginning to size up conditions in the United States with some accuracy. In Colorado, Utah, Iowa and Oklahoma, they are watching the extremely dry and

explosive dust; in the Rocky Mountains, they are learning the inflammability of dried timber; in Ohio, they are endeavoring to meet the mine-fire problem, and in West Virginia, the question faced is that of the leakage from gas wells.

The Unsolved Dangers in Foreign Countries

But foreign countries are also having to contrive answers to new problems as new parts of old fields and new regions are opened. In British Columbia, the trouble is with a roof rock which strikes fire as it falls to the ground. In India is a rock, which breaks loose so suddenly as to create terrible air blasts in its descent. In the deeper workings of Yorkshire, spontaneous combustion in gaseous mines is an ever-present menace. In Germany and France, the outbursts of carbon dioxide create a danger not known in the United States.

At the Alais mine, in southern France, the management has provided rescue chambers, so that men may have a place to which to flee when the gases escape. But such a chamber is of little use when the dust is blown clear to the surface and men are blackened with the projected coal is if they had been burned.

The recent outburst was probably not so severe as to cause the ejection of coal from the shaft mouth, but only those near the landing escaped. They became aware of the accident by the extinguishment of their lights. The shots at Alais are fired from the surface, not to prevent coal-dust explosions from killing the shotfirers, but to protect these workmen from a possible outpouring of dioxide if a crevice is laid bare.

The Explosion in Council

Safety cannot come with a bound. Both operators and men have to be convinced against their will. There is a fight against permissible explosives, safety lamps, the pocket-searcher or some other provision. When the matter is in heated discussion and is about to be settled or shelved on economic grounds, union politics or for the sake of industrial peace, a violent explosion settles the question in a peremptory fashion.

It is to be hoped that we may hereafter have the wisdom to meet the issue before it is thus forced. The evidence seems to favor the idea that eventually the United States may be a leader in the matter of safety.

The Bureau of Mines has done a great deal to enforce the teaching which has been derived from foreign accidents and to popularize the researches which have been made by alien bureaus and commissions. That instruction was preceded and has been supplemented by many ingenious devices which have been originated by clear thinkers at American mines.

There has been too much bickering as to the relative merit of the bureau's work, the labors of the technical press, the ideas imported from abroad, the talent at the mines and the efforts of the inspectorate. Certain it is, that all these factors will eventually combine to make our mines much safer.

❖

Motor rooms should, when possible, be cut out of stone rather than located in the coal seam. If this is impossible, side walls of fireclay brick should be used. No wood or other inflammable material should be used in their construction. They should be equipped with safety lamps for the detection of gas and pails of sand for use in case of fire, and also with a set of printed rules governing the treatment of persons injured by electric shock. All dust in the vicinity of motor houses should either be removed or thoroughly wet down.

A Spectacular Rescue

Special Correspondence

About noon on Tuesday, Dec. 31, of last year, a break occurred in the East Lehigh colliery at Tamaqua, Penn., which caused the death of one man and the imprisonment of eight others for 34 hours. The mine is operated by E. M. B. Shepp, C. S. Shindel and James Tinley. It is a steep slope 310 ft. deep and it is said that some 20 years ago the same number of men were entombed by an explosion of firedamp and were rescued after nine hours.

The present disaster was due to a body of water standing in the old workings above those now in operation, breaking through and flooding the latter. It appears that danger from this source had been anticipated as, apparently, a bore hole had been drilled through the pillar which failed, some ten days previous, and the water allowed to drain off. After the water ceased running in

Mine Mouth of the East Lehigh Mine

the hole it was assumed that it had all been removed, and the men were permitted to return to work in the adjoining places. It must have been, however, that the hole had simply become clogged.

The break occurred in breast No. 38, about 1710 ft. from the shaft bottom. All the men on the outside effected an escape, although with difficulty in some instances, and those on the inside were caught.

The rescuers had little difficulty in pumping the water out, but it was found that the gangway was choked with débris for several hundred feet. Tappings of the entombed men were heard on the same afternoon or evening, so systematic and determined efforts for rescuing them were undertaken. Over 200 men were employed, the gangs working up to their maximum capacity and being relieved at short intervals. Considerable care had to be exercised in this recovery work, as the conditions in the gangway were quite unsafe. It was 10 o'clock of the following night before the rescue was finally effected.

A Modern Steel Tipple in Pennsylvania

By A. Kauffman*

SYNOPSIS—A brief description of a modern steel surface equipment, having a rated capacity of 4000 tons per day. The plant is divided into two distinct units, each of which may be operated entirely independent of the other. Special provisions are made for effecting a thorough hand picking of the coal.

At Colver, 28 miles from Ebensburg, Penn., on the Cambria & Indiana R.R. is located the new mine of the Ebensburg Coal Co. just recently put into full operation. The surface arrangement at this mine consists of what may be termed a double or duplicate tipple, each a complete unit which can be run entirely independent of the other and having a capacity of loading 4000 tons of bituminous run-of-mine coal per day. The preparation of coal is second in importance only to the cost, and knowing that in order to satisfactorily clean and load this enormous tonnage, new arrangements for picking the foreign matter from the coal must be made, considerable attention was given to the picking tables, and the handling of the slack coal and refuse; also the disposal of rock coming from the mine. Fig. 6 shows diagrammatic views, and Figs. 2 and 1 a view of the approach to, and the outside of, the tipple. There is a storage capacity of 200 cars on each loaded track; the cars have a capacity of 50 tons of coal. They are brought to the foot of the feeder hauls in the tipple by electric motors in trips of from 75 to 100 cars. The motor cuts loose at this point and pushes the trip on the hauls from behind.

These feeder hauls are driven by a variable-speed motor so that a minimum capacity of four cars per minute, or a maximum of six cars per minute, can be obtained. At the head of the feeder, there is a slight incline, allowing the forward car to settle back against the trip, thus making it easy for the attendant to draw the coupling pins. The feeder haul consists of a heavy steel, Link-Belt roller chain, with forged-steel tumbling hooks to engage attachments on the bottom of the mine cars; the drive is fitted with a friction clutch to allow starting and stopping without shutting off the power.

After leaving the feeder the loaded car passes on over a track scale, which is equipped with a quick-weighing dial and then to the Phillips crossover dumps. The empty mine cars, coming from the kickback, are raised to the proper elevation by the empty car haul, which also acts as a trip maker and has a capacity of pushing 75 empty cars around a curve having a radius of 100 ft. Fig. 4 shows the two loaded car hauls in the center and the empty hauls or trip makers at each side of the tipple.

FIG. 1. GENERAL VIEW OF THE EBENSBURG COAL CO.'S TIPPLE AT CLOVER, PENN.

After the mine car has reached the dump, the coal is received by a steel hopper, the bottom of which is fitted with a reciprocating feeder to insure a uniform amount of coal being delivered to the shaking screen; this quantity is regulated by adjusting the length of stroke of the feeder plate. The shaking screen is for the purpose of separating the lump from the fine coal to facilitate the picking of the slack and bone coal from it. The large coal, which passes over the screen, is delivered to the picking band, while the fine portion, which passes through the screen is collected in a shaker chute and fed to a combined slack coal and refuse conveyor located midway between the two picking bands.

These bands are each located over the corresponding loading track, as shown in cross-section. They are of the Link-Belt overlapping corrugated apron type, 60 in. in width, and have 35 ft. of clear length for picking. Moving at a speed of 40 ft. per minute, the picking is done by men stationed along the side of the band. With practically all of the slack coal eliminated and the large lumps spread evenly over the table, an excellent opportunity is afforded the pickers to get at all the impurities; Fig. 5

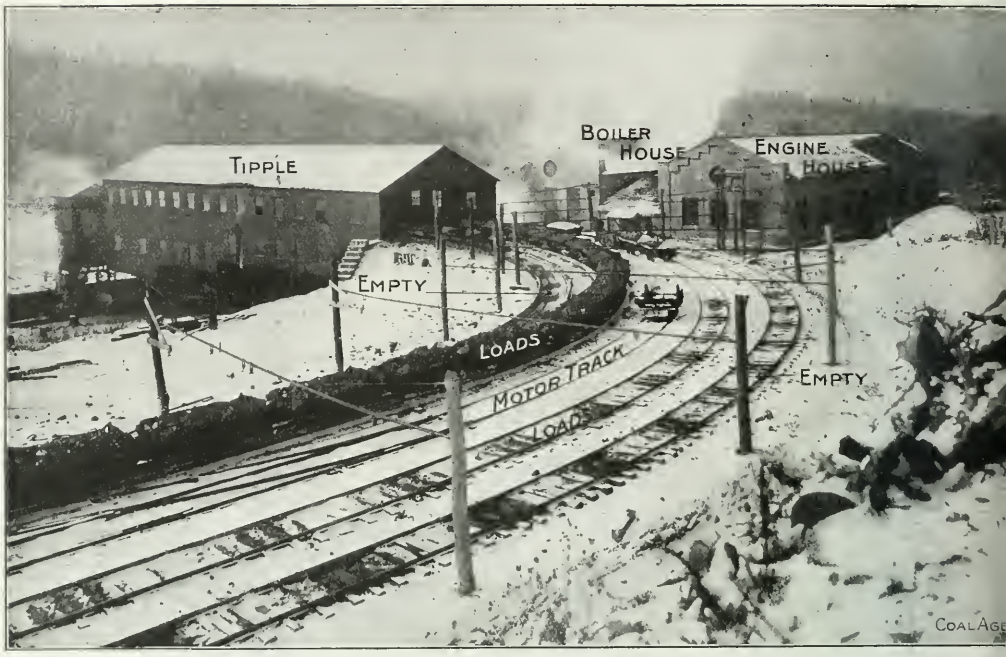

FIG. 2. MINE-CAR TRACK ARRANGEMENT, SHOWING LARGE STORAGE CAPACITY

FIG. 3. NEAR VIEW OF THE TIPPLE, SHOWING THE METHOD OF LOADING CARS

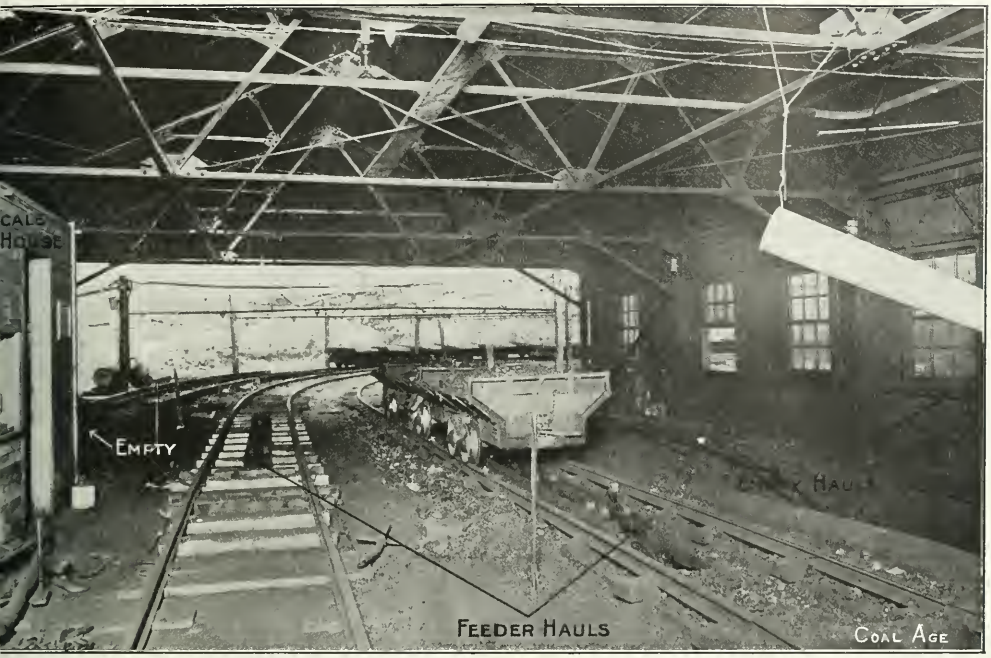

Fig. 4. View on the Tipple, Showing Car-hauls and Method of Operation

Fig. 5. Two Overlapping, Corrugated Apron Type Picking Belts, 35 Ft. Long

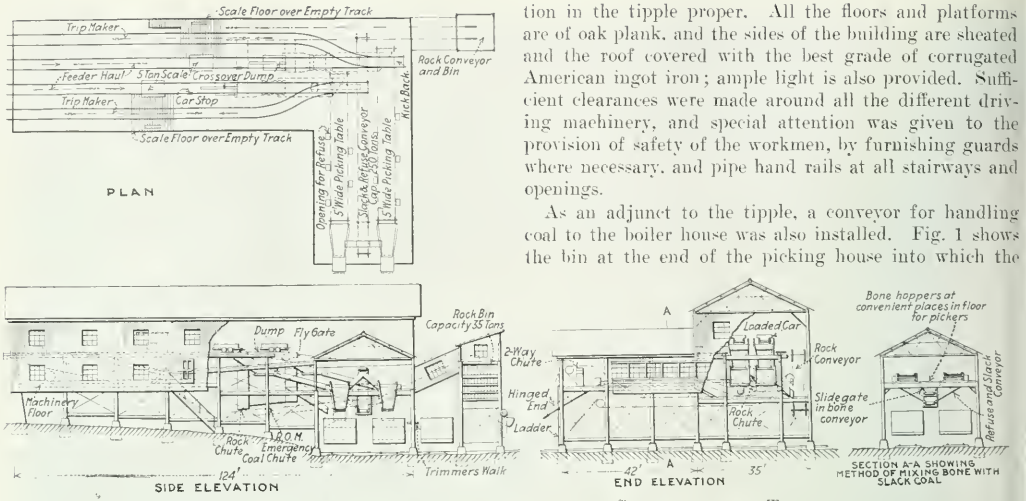

FIG. 6. DIAGRAMMATIC PLAN, ELEVATIONS AND SECTION OF THE TIPPLE

shows two 60-in. picking tables with the bone bins in the center. The conveyor in the center of the two picking tables performs a double function, in that the top run is used for carrying the slack coal from the screens to the head of the picking band, where it is mixed with the picked coal, and loaded as one, into the railroad cars.

The bottom run acts as a refuse conveyor, taking the slate and other refuse delivered to it through the chute alongside the picking tables, and carrying same to the rock conveyor located at the end of the building. The bone coal is stored in hoppers immediately above the top run of the conveyor until such time during the day when no coal is being loaded, when it is also taken by the slack conveyor to a storage bin and then on to the boiler house as described later.

DISPOSAL OF ROCK

The rock being brought out of the mine, along with the coal, the cars are naturally scattered throughout the trip, and to bypass or shunt a car to a rock dump would necessarily cause a delay in the operation of the tipple. Consequently, the rock car is brought along to the Phillips dump, a fly gate is opened in the bottom of the coal-receiving hopper, and the rock is bypassed and fed to a conveyor which takes it to the rock bin located on the outside of the passing track, as shown in Fig. 1. This conveyor is made up of two strands of Link-Belt steel strap roller chain, to which are fastened steel plates, lined with 3-in. plank, thus making a continuous moving apron. Wooden skirt boards, steel lined, form stationary sides throughout the entire length of the conveyor. The machine is electrically operated, the drive being placed at the head of the rock bin. The bin is fitted with a steam-operated Link-Belt under-cut gate (see Fig. 7), which delivers the rock to a larry and takes it to the rock dump.

The tipple is a steel structure throughout, the structural framework being well braced and stiffened to insure sufficient strength and rigidity. Particular attention was given to the design of the shaking-screen supports which are built so as to be entirely independent of any other part of the tipple, thus eliminating practically all vibration in the tipple proper. All the floors and platforms are of oak plank, and the sides of the building are sheated and the roof covered with the best grade of corrugated American ingot iron; ample light is also provided. Sufficient clearances were made around all the different driving machinery, and special attention was given to the provision of safety of the workmen, by furnishing guards where necessary, and pipe hand rails at all stairways and openings.

As an adjunct to the tipple, a conveyor for handling coal to the boiler house was also installed. Fig. 1 shows the bin at the end of the picking house into which the

FIG. 7. ROCK BIN EQUIPPED WITH A STEAM GATE

slack conveyor delivers the bone coal. From here it is fed to a two-roll crusher, the inclined conveyor delivering the crushed coal to the storage bin in the boiler house from which the stokers are fed.

The tipple was designed and the machinery furnished and erected by the Link-Belt Co., of Philadelphia and Chicago. The work of preparing for the installation of this tipple, and the opening of the new mine was under the direction of E. Dawson Coleman, formerly president of the Ebensburg Coal Co., J. Edgar Long and W. D. Kirk.

Notes on Mine Gas Problems—II

By G. A. Burrell*

SYNOPSIS—Carbon dioxide has a more dampening effect on the acetylene and oil-fed flames than nitrogen. The percentage of blackdamp present can be estimated from the brilliancy of the acetylene flame. An acetylene light in air which will extinguish a candle resembles an oil flame burning in normal air. Afterdamp, taken 1/20 of a second after an explosion, contained 8.15 per cent. of carbon monoxide and 2.55 of uncombined hydrogen. Sparrows cannot be kept in captivity; mice are too sluggish and pigeons not sensitive enough for indicators of carbon monoxide in rescue work. Inhalation of that gas does not have a cumulative effect on canaries. Natural gas is not measurably more dangerous than methane in a mine. The rapidity and uncertainty of its entrance makes its occurrence significant. Hydrogen, ethylene, ethane and carbon monoxide are not emitted by American coals.

The bureau has already called attention to the tenacity with which the acetylene flame resists extinction and to the fact that it will continue to burn in atmospheres in which the ordinary wick-fed flame is extinguished. It was found that a residual atmosphere in which an acetylene flame had been extinguished contained 11.7 per cent. oxygen and 6.30 per cent. carbon dioxide.

It was also found that when about one-half of the carbon dioxide was removed as it was formed, the acetylene flame continued to burn in a slightly greater oxygen deficiency. For this last experiment the flame was placed in a gas-tight cabinet having a capacity of 25 cu.ft. The residual atmosphere after the flame had been extinguished had the following composition:

EXTINCTIVE ATMOSPHERE FOR CARBIDE LAMP

	Sample from Middle of Chamber	Sample from Bottom of Chamber
CO_2	3 22	3 17
O_2	10 99	11 12

The bureau has noted that residual atmospheres containing about 6 per cent. of carbon dioxide, closely resemble those encountered in a mine. Where the oxygen has decreased to 11 per cent., an average of about 6 per cent. of carbon dioxide will be present. An objection has been raised to the use of the acetylene lamp, because it is only extinguished when there is grave danger that the men who are using the light will be asphyxiated by blackdamp.

The acetylene, like other flames, burns less brightly as the proportion of oxygen in mine air diminishes. It was observed at the laboratory of the bureau that when the oxygen content of air decreases to about 16 or 16.5 per cent., the flame somewhat resembles the ordinary wick-fed light when the latter burns in pure air, that is, in air containing 21 per cent. of oxygen. This indication can be used as a guide before venturing into workings filled with blackdamp and containing an even smaller proportion of oxygen.

Effect of Carbon Dioxide on Miners' Oil Lamps

The ordinary miner's lamp is extinguished when the oxygen falls to about 16.5 or 17 per cent. This extinguishment is almost entirely due to the oxygen deficiency and not to the carbon dioxide, since this constituent is rarely ever present in sufficient quantity to exert any appreciable effect when the oxygen in mine air drops to 16 or 17 per cent. When a lighted candle was placed in a bell jar filled with ordinary air it went out when the oxygen percentage fell to 16.24 per cent.

The carbon dioxide produced by the burning amounted to 2.95 per cent. When 3.22 per cent. of carbon dioxide was originally in the air, the atmosphere, after the extinguishment of the flame, contained 16.68 per cent. oxygen. When the atmosphere originally contained 13.52 per cent. carbon dioxide, the flame went out as soon as the oxygen content fell to 17.39 per cent. These analyses are tabulated below.

SOME ATMOSPHERES WHICH WILL EXTINGUISH A CANDLE

Experiment No.	Composition of Atmosphere at Beginning of Experiment CO_2	O_2	Composition of Atmosphere in Which Flame Went Out CO_2	O_2
1	0 04	21 00	2 95	16 34
2	3 22	21 13	6 51	16 68
3	13 52	20 67	16 00	17 39

A little difficulty, experienced in thoroughly mixing the atmosphere in the vessel, accounts in part for the fact that the carbon dioxide added and that produced by combustion do not exactly check.

It will be observed that the initial presence of a large amount of carbon dioxide had little effect on the flame extinguishment. These flames were extinguished in a still air; in mines, a jerk of the lamp or slight puff of air would snuff out a diminishing flame in an atmosphere containing slightly more oxygen.

Effect of Vitiated Air on the Luminosity of Miners' Lamps

J. S. Haldane† recently made an important contribution to mining literature when he determined the effect of atmospheres deficient in oxygen on the light of a safety lamp. Mine air always contains less oxygen than outside air. This deficiency in the air which is traveling through the mine may vary from 0.10 to 0.20 per cent. or even more, while at advancing faces under ordinary working conditions, the air may be depleted of 2 or more per cent. of oxygen. Doctor Haldane observed that when the oxygen percentage fell to about 19, the illumination of the lamp decreased 73 per cent. and that, roughly speaking, every diminution of 0.10 per cent. in the oxygen caused a decrease of 3.5 per cent. from the value of the light in the pure air.

Afterdamp

Two samples of afterdamp atmospheres are here presented. They are of interest as showing the large amount of carbon monoxide present shortly after an explosion.

Sample No. 1 was collected 30 min. after an explosion had occurred at the experimental mine of the bureau at Bruceton, Penn. It was taken in the main entry where the first right heading is broken off. Ventilation had been restored at that time in the main entry. Sample No. 2 was taken at the face of the first right butt entry, 100 ft. from where sample No. 1 was collected. Ventilation had not been restored in this heading.

*Chemist, Gas Investigations, Bureau of Mines, Pittsburgh, Penn.

Note—Part of an article read at the winter meeting of the West Virginia Coal Mining Institute, Parkersburg, W. Va., Dec 11, 1912. Continued from Vol. 111, p. 104.

†"Colliery Guardian," Oct. 25, 1912.

SOME SAMPLES OF DILUTED AFTERDAMP

	Sample No. 1		Sample No. 2
CO_2	0.26	CO_2	1.54
O_2	20.26	O_2	17.79
CO	0.16	CO	1.89
CH_4	0.12	CH_4	0.65
N_2	79.20	N_2	78.13
	100.00		100.00

Hydrogen was not present in these samples in quantity greater than 0.2 per cent. Samples were not obtained which were large enough to make quantitative tests for sulphurous acid. This constituent is probably mainly responsible for the eye and throat irritation caused by afterdamp. Large samples of such gases are being obtained at the Bruceton mine in order that we may study their composition.

These analyses are instructive as showing that very dangerous atmospheres may exist after an explosion in a mine in close proximity to those wherein men would not soon feel distress. The bureau found that in 0.16 per cent. carbon dioxide, a mouse only shows slight signs of weakness at the end of one hour's time. In the same atmosphere a bird showed signs of distress in 3 min. and fell from its perch in 18 minutes.

In exploring a mine containing afterdamp, a person could, by disregarding the warning of a sensitive animal like a canary, travel in a very short time from an atmosphere which would not distress him into one where collapse would quickly follow.

Automatic Gas Samplers

In order that the chemistry of the explosions in the experimental mine at Bruceton may be better studied, the bureau has lately developed an automatic mine-gas sampler to a stage of completion where it is believed samples of after-gases can be trapped at the time an explosion wave goes by and at prearranged intervals thereafter.

An analysis of a sample collected at the Altofts Experimental Station (England) $^1/_{20}$ of a second after the explosion had passed contained the following constituents:

AFTERDAMP ALMOST UNDILUTED

Gas	Percentage	Gas	Percentage
CO_2	11.25 per cent.	H_2	2.75 per cent.
O_2	1.15 per cent.	CH_4	2.95 per cent.
CO	8.15 per cent.	N_2	73.75 per cent.
			100.00

The high percentage of carbon monoxide will be noticed. The British report calls attention to the presence of oxygen as showing that an inrush of air had taken place even in the short space of time succeeding the explosion. They state that at the instant of the passage of the flame, the oxygen should have been entirely consumed. The gallery at Altofts is above ground, however, and the inrush of pure air would be quicker than in a mine where an explosion had occurred.

Use of Birds for Continued Exploration Work

The bureau has made experiments relating to the use of canaries in continued exploration work, having in mind the fact that the same animal might be used and overcome several times in the same day. It was found that even after they had been repeatedly exposed to carbon monoxide and had as often recovered, upon subsequent exposures they showed distress and collapsed and revived in about the same period of time as on the first exposure. Consequently these animals can be used again and again for all practical purposes, with the knowledge that they will not be less or more sensitive to whitedamp even after repeated exposures. No parallel can be drawn regarding the effects on men of carbon monoxide from these experiments. Men have been months recovering from severe cases of poisoning, and the after-effects have been formidable. To show how differently carbon monoxide affects men and animals, the following experiments performed by the bureau are here tabulated.

PHYSIOLOGIC EFFECTS OF CARBON MONOXIDE

Quantity of CO used—0.25 per cent.

Subject	Time Exposed	Distress	Collapse	Recovery
Canary	3 min.	2 min.	3 min.	7 min.
Mouse	12 min.	6 min.	12 min.	25 min.
Man	20 min.	1 hr.	not determined	8 hr.

Whereas the animals were left in the mixture until they collapsed, the man left the atmosphere experiencing but little discomfort at the end of 20 min. One hour later he became very sick.

Use of Sparrows for Recovery Work

The bureau has attempted to use English sparrows for recovery work in mines, but with little success, because those so far obtained have not survived captivity. Pigeons are not sensitive enough, for at the end of 11 min. in an atmosphere containing 0.25 per cent. of carbon monoxide, they showed but slight signs of distress. Mice are more sluggish and not so easily affected as canaries, but they are useful nevertheless. A mouse and a canary together would make a good combination. The usefulness of small animals for detecting bad air in mines has been so well recognized in England that the law requires them to be kept at collieries.

Escape of Natural Gas into Coal Mines

Natural gas has found its way into some coal mines with disastrous consequences. Old abandoned wells are an especial menace in that nobody knows the exact whereabouts of some of them. Natural gases of the Appalachian fields contain other paraffin hydrocarbons than methane, principally ethane. The following analysis shows the composition of the natural gas used at Pittsburgh. This gas is drawn largely from West Virginia, but some comes from western Pennsylvania.

COMPOSITION OF NATURAL GAS AT PITTSBURGH

Gas	Symbol	Percentage
Carbon dioxide	CO_2	trace (less than 0.10 per cent.)
Oxygen	O_2	0.00
Methane	CH_4	82.5 per cent.
Ethane	C_2H_6	16.0 per cent.
Nitrogen	N_2	1.5 per cent.

Carbon monoxide, hydrogen or ethylene are not contained in the gas, not even in traces.

Below are shown the explosive limits of methane-air mixtures, and Pittsburgh natural gas-air mixtures. Ignition was effected by a small electric spark from an induction coil.

LIMITS OF EXPLOSIBILITY OF METHANE AND NATURAL GAS

	Methane	Natural Gas
Low limit	5.50 per cent.	4.92 per cent.
High limit	12.40 per cent.	11.40 per cent.

Below are given the ignition temperatures of methane and ethane, determined by Dixon & Coward[1].

IGNITION TEMPERATURE

Gas	Degrees Centigrade
Methane	650–750
Ethane	520–630

It does not appear from the above that natural gas

[1] "Chemical News," Vol. 99, 1909, p. 139.

is so much more sensitive to inflammation than methane as to produce an added menace from this cause should it escape into a mine. Sudden inrushes of large bodies of inflammable gas have not always been sufficiently controlled to avert disaster. It is also fortunate that carbon monoxide is not present in the gas for its escape into a mine would produce an additional danger. Many published analyses show that natural gas contains this constituent, but the statement is erroneous. Higher paraffin hydrocarbons than methane in natural gas give to the latter its characteristic oily odor.

Inflammable Character of the Gases Present in Mine Air

The bureau has almost ready for publication a report showing the exact character of the inflammable gases present in many samples of mine air. In many textbooks, the statement is made that hydrogen, ethylene and ethane and even carbon monoxide may be present in mine air under normal conditions of operation. As far as the authors of these books are concerned, they are justified because analyses showing these constituents have been reported occasionally.

Because these gases are said to exist in mine air, the question has at times been raised regarding the application to mining conditions of experiments performed in the laboratory or in testing galleries in which methane or the nearly similar natural gas is used. In the report of the bureau, mine-gas samples are listed from about 50 mines, and the methods of examination are described.

It is shown that in no case are any of the gases mentioned present, except in some mines round the oil regions, into which natural gas may have escaped, and as a consequence other paraffin hydrocarbons than methane found. It is also proved that very small errors, which can hardly be avoided in the manipulation of many forms of gas-analyzing apparatus, may result in the reporting of one or more per cent. of combustible gases other than methane. Of course, if a careful analyst reports these gases in even a few samples, then one is justified in suspecting that they may occur in others.

Various Conflicting Definitions of Blackdamp and Firedamp

Blackdamp is still sometimes wrongfully used as if meaning carbon dioxide, instead of a mixture of nitrogen with that gas. Carbon dioxide usually plays but a small part in the combustion effects produced by the mixture. The deficiency of oxygen, which always accompanies excessive proportions of blackdamp, is the main factor in flame extinguishment in mines. On the other hand, any physiological effects produced in men when they are in atmospheres in which lamps do not burn, are largely due to the carbon dioxide. This statement has reference to atmospheres in old workings, etc., and not to those that have been vitiated by mine fires, explosions, etc., and wherein carbon monoxide might exist.

Different meanings have been attributed to the word firedamp. To some it means methane, to others any mixture of methane and air. That other gases than methane may frequently be present is sometimes stated. The writer believes the best definition to be: any inflammable mixture of methane and air. This definition is used by some at present.

Afterdamp

Sufficient data are not at hand to describe completely the constituents present in afterdamp. That the products of incomplete combustion of methane, coal dust and air can be quite complex, is shown by work already performed on single gases and air. This statement has reference to the immediate after-products of an explosion.

After a stagnant mine atmosphere has been clarified of smoke particles and easily condensible gases that irritate, a clear atmosphere can remain for a long time, containing oxygen, carbon dioxide, nitrogen, methane, hydrogen and carbon monoxide. In this atmosphere a lamp may burn fairly well, with no flame indication. Only the characteristic burnt odor will reveal to the senses the fact that there has been an explosion, but the atmosphere may be fatal because of the presence of carbon monoxide.

Largest Mine Hoist in the World

An order, for what is thought to be the largest mine hoist in the world, has been recently placed with the Nordberg Manufacturing Co., Milwaukee, Wis., in competition with both German and English bidders.

The hoist is to be used at the Inverness Railway & Coal Co.'s mine at Inverness, Cape Breton Island, and is of the Nordberg-Corliss, duplex type. The cylinders are 34 and 34x72 in., and the hoist is provided with two drums, each of which is equipped with a Nordberg axial clutch and post brake, enabling independent operation of either.

The hoist is designed for the following service: A train of 12 cars, each weighing 1150 lb., and containing one long ton of coal, must be hauled up a 10,000-ft. incline, which is 16 deg. at the surface and 35 deg. at the bottom. This makes the pull on the rope about 41,000 lb., and in view of this rope stress and the length of cable, this hoist is thought to be the largest ever constructed.

Hoists with larger cylinders have been built for the copper-mining business, notably the two Nordberg hoists at the Tamarack mines in Calumet, Mich., but these are surpassed in the present case in the two particular features mentioned.

As might be expected, the brakes, clutches, reverse and throttle are not operated directly by hand, but by auxiliary engines.

A British Coal Exporter Here

That Wales and the other British coal-producing centers fear an American invasion of their South American trade was evident from the remarks of D. A. Thomas, head of the Cambrian Combination, who is now in New York. He said he expected to remain for a month inspecting coal fields and investigating American methods of mining. His remarks follow:

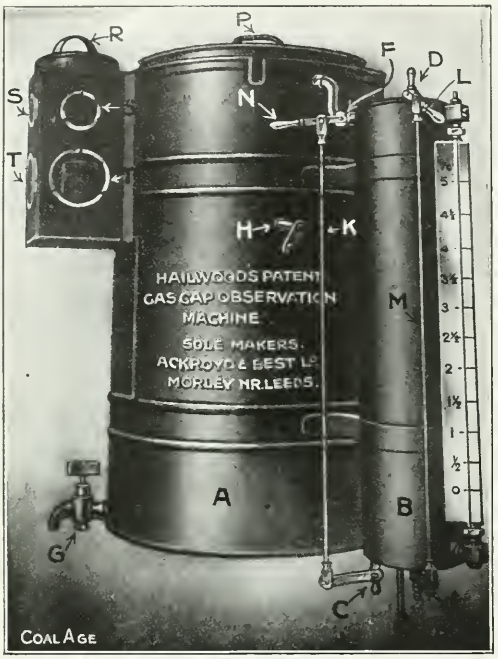
> In South Wales we produce the finest hard coal in the world, but in the cost of production we are not on a level footing with the American companies. In spite of a vast difference in carrying distance the rates in America are so much lower than ours that your coal can be delivered at the sea coast cheaper than we can do it.
>
> These factors have made the Welsh mining interests a bit fearful of their South American trade.

Mr. Thomas said that he might look over some properties with a view to purchasing them.

A New Apparatus for the Observation of Gas Caps

FOREIGN CORRESPONDENCE

Messrs. Ackroyd and Best have just placed on the market a new apparatus for use in the observation of gas caps. This appliance is illustrated herewith. It consists of a large drum marked *A* and at the right-hand side of the same is a measuring drum marked *B* and at the left-hand side, a receptacle for holding almost any kind of lamp. The lamp is placed in a water-ring seal,



AN APPARATUS FOR DETERMINING THE ABILITY OF FIREBOSSES TO DETECT FIREDAMP

so arranged that the pricker wire can be easily operated from the outside.

THE GAS MIXTURE CAN BE REGULATED AT WILL

The appliance is adapted for use with gas from the municipal mains or from high-pressure cylinders. To work the apparatus the bottom tap *C* is opened and the measuring chamber *B* filled with water. A gas tap *D* connected to either the gas service or the cylinder of compressed coal gas, is then opened.

By opening a tap *J* almost all the water is now allowed to pass from the measuring chamber, gas entering and taking its place, a little water up to the level of the zero mark being left at the bottom to form a seal. Tap *E* is then momentarily opened permitting the escape of the surplus gas so that the contents of the measuring chamber are reduced to atmospheric pressure.

Tap *F*, in a pipe which communicates between the upper part of the measuring chamber and drum *A* is then opened. Water is simultaneously allowed to reënter the bottom of the measuring drum *B* through tap *C* till it reaches the desired level, as indicated by marks at the back of the water gage connected to drum *B*. Each division on this scale represents the quantity of gas which, when passed into the chamber (which is normally full of air) adds to it one-half per cent. of gas. Thus to obtain one per cent. of gas in the drum it is only necessary to pass water into the measuring cylinder to cover two divisions of the scale.

THE CARBON DIOXIDE IS REMOVED

To allow an equivalent quantity of air to escape from drum *A*, a tap *G* in the base of same, is opened while gas is being driven into the drum and a handle *H* connected with a large mixer is rotated from time to time to blend the mixture adequately. To absorb the carbonic acid given off by the lamp, a tray of caustic soda or ordinary ground lime may be placed in the drum *A*. The lid of that drum is detachable and is closed by a water seal.

Taps *C* and *F* are coupled together by a rod *K* to ensure their working in unison. It may be mentioned that with this appliance, it is an easy matter to change very rapidly from small percentages up to 5 per cent. (a 5-per cent. cap reaching toward the top of the lamp gauze). It may also be noted that the mixing chamber is of comparatively small capacity. If a mixture containing more than 5 per cent. of gas is desired, it may readily be obtained by refilling the small chamber *B* from the mains or from cylinders and operating the machine as described above.

Working with very low percentages the gas cap would remain steady for 15 or 20 min.; when testing high percentages the cap would remain unchanged for a few minutes; the makers, however, recommend taking an average of not more than five minutes for observations of each percentage of gas. If it be desired that each cap be capable of remaining steady for more than five minutes, larger chambers are made for this purpose.

Greatest Western Coal State

Colorado leads all western states in the production of coal, according to the U. S. Geological Survey, and in 1911 was second only to California in the production of gold. Colorado is also the leading western state in the manufacture of pig iron and of coke and is the leading state in the production of tungsten ores and vanadium minerals. The total value of all mineral products of the state in 1911 was $51,958,239. The following statement shows the values of the principal mineral products in 1911:

Gold	$19,138,800
Coal	14,747,764
Zinc	4,814,562
Silver	3,958,800
Lead	2,755,890

Prof. E. W. Reiss, in an interesting paper on the fossil plants of the coal seams of England, says that the structure of coal-measure plants can be studied in microscopic preparations as effectively as that of recent plants. It is possible to form some idea of the habit of the coal-measure plants by studying their detailed structure. The wide air spaces in the cortical tissues of Calamitean roots have led to the belief that many of the coal-measure plants were rooted under water or in water-logged soil. Some plants were evidently carried by wind and water to that portion of the country where coal is now found. Fragments of marsh and nonaquatic plants are bedded close together in the coal seams.

EDITORIALS

The New Anthracite Mining Code

That the present mining laws under which the anthracite mines of Pennsylvania have been operated and are still governed are badly in need of revision is evident by the interest recently taken, by both operators and miners alike, in the report of the subcommittee to the commission appointed to revise and codify the present law. As previously announced, the commission held an open session for listening to the arguments and suggestions of coal operators, Tuesday, the 14th; and another for the same purpose on Wednesday, when the miners were heard.

It is pleasing to note the tone of conciliation on the part of the operators in their recommendations to the commission. Among those present at the session were: Col. R. A. Phillips, of the Delaware & Lackawanna Coal Co.; C. F. Huber, Lehigh & Wilkes-Barre Coal Co.; W. W. Inglis and Alexander Bryden, Pennsylvania Coal Co.; W. J. Bennett, Philadelphia & Reading Coal Co.; W. L. Allen, Scranton Coal Co., and W. G. Robertson, operator, Scranton, Penn.

The operators presented a hundred-page typewritten statement, containing many valuable suggestions. Prominent among these was the indorsement of the appointive system of choosing mine inspectors, the appointments to be made by the governor. In reference to this matter, the recommendations of the anthracite mine operators read as follows:

> In addition to the comments offered we are of the opinion that, for the benefit of the service, the change from an elective to an appointive system is to the best interest of the commonwealth, the miner and the operator. The further the position is removed from politics the better it will be for all concerned. We go further and suggest that the term of mine inspector should not be less than five years, provided he shall not be guilty of neglect.

The operators favor the acceptance of a certificate of a miner from other countries; and it was even suggested by Colonel Phillips that the provision of the present law requiring a two years' citizenship before a miner could obtain a certificate, should not be made a part of the new code. It was recommended that a board of qualified miners should be appointed to examine candidates for miners' certificates.

The operators favor a mine inspectors' examining board composed of nine citizens, proportioned as follows: Three mining engineers, three mine foremen and three miners; instead of a board of nine members, composed of four mining engineers and five miners, as suggested in the subcommittee's report.

Colonel Phillips addressed the commission at considerable length, and his remarks were well received as coming from one of long experience in the anthracite region. A gratifying feature in the work of the commission is the disposition on the part of the members to hear all parties and to profit, as far as may be, by their suggestions. It is hoped that this attitude of the commission will be rewarded by the codification of a set of mining laws that will meet the growing needs of the coal-mining industry.

Speaking of the rapid growth of electrical equipment in mines, Colonel Phillips suggested the appointment of a board of expert electrical engineers to draft a law covering the use of electricity in the anthracite mines. This is a good suggestion and it is understood, of course, that the electrical engineers so appointed would be only those thoroughly familiar with mining work and conditions in the anthracite mines.

Mr. Burrell's Address

Inexorable considerations of space compelled us to shorten our remarks relative to Mr. Burrell's address at the West Virginia Coal Mining Institute. The editor has the truly Procrustean habit of cutting us off at lengths to suit the bed in which we must lie. This will be our excuse for displaying our weary, wayworn feet and tattered sandals at the head of this editorial.

We took exception last week to the use of the word "explosion" to cover an inflammation so gentle that, to quote Mr. Burrell: "The flame travels with comparative slowness and can be followed by the eye." It is no wonder that, having entangled himself with such a definition, Mr. Burrell does not agree with us and others who believe an explosion to be both forcible and noisy. No surprise should be expressed that we have placed the low limit of explosibility somewhat higher than he favors.

But we are not disposed to pass on without a threefold commendation of Mr. Burrell. First, he has defined clearly what he means by an explosion. He has not misled people by using a word in an unusual sense without letting his hearers understand what he really means. That practice leading to much obscurity, is only too common in scientific books. Second, he has shown clearly what happens when his "lower limit of explosibility" is reached and when what he terms an "explosion" takes place. Throughout his article, no misunderstanding can arise as to his meaning.

And third, he has called attention to an important point on the scale of inflammability. It specifies a percentage volume at which heat will be generated over a large area, and at which the flame by coming in contact with dust in suspension and with the mine rib is likely to be fed till it may possibly become explosive in a real sense, due to liberated hydrocarbons. We think his so called "lower explosive point" is one, at which, perchance, under natural mine conditions, an explosion might result by reason of added methane, and other gases distilled by the heat of the flame.

E. P. Perman, of University College, Cardiff, Wales, has placed the lower limit of explosibility even lower than Mr. Burrell. To him 2.5 per cent. seems the correct figure, not 5.5, and the higher limit is 21 per cent., which is nearly twice as high as that stated in the address to which we have referred. Such results are so con-

trary to all previous figures that, at first sight, one is prone to regard them as percentages by weight instead of by volume; but the tendency in Great Britain to twist the word "explosion" explains the difficulty.

We do not feel disposed to alter our judgment regarding the canary. That bird may possibly serve the purposes of an indicator of carbon monoxide when helmets are available in sufficient quantities to make exploration work safe and efficient. But where this is not the case, the rescuers will be needlessly delayed in their work by basing their judgment of their powers of safe resistance by so susceptible a bird. In short, the canary unit is too low.

If we assume, with the Bureau of Mines, that the resistance of a canary gives the correct limit for human temerity, then why experiment with a heavy phlegmatic bird like a pigeon. It was to be anticipated that it would have a higher resistance than the bureau desires, without the corresponding advantage of lightness and lack of bulk.

Moreover, we are inclined to believe that it might not show so many intermediate signs between normal conditions and collapse as are afforded by the volatile canary, and further it would possibly be proved that "the resiliency of its nerves," if we may be pardoned for the expression, is unequal to that of the smaller bird. As Mr. Burrell believes that the canary has a power of recovery from afterdamp, as nearly perfect as desired, the pigeon could not be, in that respect, superior.

We are disposed to believe that the test has been prompted largely by the desire to placate those, within and without the bureau, who look upon the use of the canary as undignified. We are not disposed to regard the matter in that foolish light. If the canary is that animal of all animals which will note the moment for retreat or for the donning of helmets, by all means let it be used.

Because this bird is the delight of old maids and other childless women, and is dear to the hearts and replenishing to the pockets of the fortune-telling vagrant, is no reason why it should not serve to defend life. We have no patience with those who have regarded the canary as an unpractical introduction and a useless craze. Our objection has always been that the canary succumbed too easily to make it a correct index on which to base human action.

Mr. Burrell, toward the end of his address, attacked the belief that there were other gases in firedamp beside those given in any of his analyses. This conclusion is extremely interesting, as it shows, for instance, that carbon monoxide is not to be feared as a coal emanation in any of our mines and that ethane is only to be expected where gas leaks in from gas and oil wells.

But we do not believe it is safe for Mr. Burrell to deny, without examination, that such gases may be found in Europe, from which source the condemned analyses arise. In some English mines petroleum has been found, and it is needless to point out some peculiarities in European workings, among which are greater heat and depth, outbursts of carbon dioxide, excessive tendencies toward spontaneous combustion and the presence of coal in a granulated condition.

The surmise of Mr. Burrell may be correct. It is true we are not disposed to clothe analyses made many years ago with the authority of those conducted today, nor do we feel any real assurance that spectroscopic determinations are reliable, at least quantitatively. Nevertheless it is not safe to declare that because firedamp is ethaneless here, it also must be free of that hydrocarbon in the Old World.

Finally, seeing that, quite recently, M. Mahler has declared that carbon monoxide is formed by coal from Anzin, Decazeville, Azincourt and Courrières at moderate temperatures, we are disposed to think that it is unsafe to follow this conclusion of Mr. Burrell till the other side has been heard.

The Weather Bureau Mine Service

Some prominence is again given to the influence of atmospheric pressure on mine atmospheres, and the relation of the rise and fall of the barometer to mine explosions, in a circular recently issued by the Weather Bureau, at Scranton, Penn. The circular shows a laudable desire on the part of the Weather Bureau to extend their service and make it of some practical value in the operation of mines, with a view to furnish prompt information of a sudden change of barometric pressure, by telephone to the superintendent or other mine official.

It is a well established fact that mine atmospheres often experience a sudden increase in the percentage of gas, owing to the outflow of gas from large abandoned areas or other void cavities, in the mine, where gas has accumulated. This outflow of gas into the mine workings accompanies any considerable drop or fall of the barometer due to a decrease of atmospheric pressure. The effect in the mine is generally felt from 2 to 3 hr. after the fall of the barometer occurs.

Such are the practical difficulties of coal mining, with respect to the ventilation of abandoned areas, that it is impossible often to prevent the accumulation of dangerous quantities of firedamp in these workings. Such abandoned and unventilated areas are a menace to safe mining.

The equipment of most uptodate mines today includes a standard mercurial barometer, and its readings are closely watched and recorded. It is the custom of cautious mine foremen and firebosses to observe the reading of the barometer before entering the mine. The service proposed by the Weather Bureau is a responsible one and will be appreciated by the officials of those mines having no barometer at the shaft.

The circular reads as follows:

Atmospheric Pressure and Mine Explosions

It is an established fact that the pressure of the atmosphere has a direct bearing on the explosions in coal mines, in that while the pressure is high the gas in the mines is confined in pockets and the danger of an explosion is at a minimum; but, when there is a marked fall in pressure (not necessarily, however, to abnormally low pressure) causing the gas to spread from the pockets where it has been confined, the chances of explosion are greatly increased.

I am directed by the chief of the Weather Bureau to ask that you notify this office if you wish this service, and if so, that you kindly forward the name of the person or mine superintendent that should be notified, together with his telephone number, to the end that the necessary protective steps may be taken.

In this connection I wish to say that mine superintendents can obtain readings from the standard barometers in this office, for comparison with the instruments they may have in use for this purpose; also that on application to this office they can have their aneroids set to compare with weather bureau standard barometers.

WILLIAM DUDLEY,
Local forecaster in charge.

Scranton, Penn., Jan. 13, 1913.

SOCIOLOGICAL DEPARTMENT

First Aid to the Injured

By J. H. Young* and J. L. Simons†

Anyone conversant with the history of the medical profession knows that it is a long unbroken record of differences of opinion. The treatments of today are tomorrow replaced by others diametrically opposite. Upon one subject, however, all members of the medical profession agree, viz., the advisability of enlightening the general public as to the best means of alleviating suffering. For diseases and domestic accidents, well known household remedies are still and have been in use for many years.

The Origin of First Aid

Until a comparatively recent date, however, industrial and other accidents have been tended exclusively by members of the medical profession. Although for a long time it was felt that the physician could not be at or near the scene of all accidents, it was not until the Crimean war, in 1854 to 1856, that the first steps were taken in this direction. On Oct. 21, 1854, Florence Nightingale, accompanied by 34 nurses, started from England for the Crimea to organize a nursing department. Her heroic efforts in this struggle mark the beginning of professional nursing and of first-aid-to-the-injured.

In 1861 to 1865, Clara Barton performed a similar service in the American Civil War, and in 1881, in conjunction with Miss Nightingale and others, she organized the International Red Cross, which today heads all nursing and first-aid-to-the-injured movements, not only in America but throughout the civilized countries of the world.

In 1877, the St. John's Ambulance Association, of London, took steps to meet the want felt for aid in industrial accidents and arranged for holding classes in which the pupils were taught the proper methods of aiding the injured, pending the arrival of medical attendance. The movement met with signal success, and during 1877 and 1878, it was extended to include all the important towns of England.

About the same time, similar movements were started in Germany, France, Belgium and Austria. In 1879, the movement spread to Scotland, but the organization of the St. Andrew's Ambulance Association, in Glasgow, in 1882, with precisely the same object in view, removed the necessity for further activity of the English association in Scotland.

The American Movement Delayed 22 Years

Probably the first case of an American movement of this kind, among those employed in industrial pursuits, was the organization of first-aid-to-the-injured corps throughout the anthracite-coal fields of Pennsylvania. Various authorities differ in stating just where the movement originated, some giving the honor to Dr. George Halberstadt, whose endeavors along these lines with the employees of the Philadelphia & Reading Coal & Iron Co. have met with praiseworthy results, and others claim the honor for Dr. M. J. Shields, now first lieutenant, Medical Reserve Corps, United States Army, but at that time affiliated with the Delaware & Hudson Co.

Doctor Halberstadt's and Doctor Shields' movements, although differing in some small ways, are directed toward the same end. To whomsoever this honor belongs, it is an established fact that first-aid-to-the-injured in industrial plants had its beginning in America about 1899. During the past 13 years, its spread has been so great that today it is an institution recognized, not only by the anthracite-coal operators of Pennsylvania, but by the bituminous-coal companies throughout the United States, by railroads, and, in fact, by almost every industry employing large numbers of men.

Case "A," Bandaging of Simple Fracture of Lower Half of Left Leg

Case "B," Method of Supporting a Dislocated Hip

*Physician.
†Fire Inspector.
Note—Paper read at the meeting of the Panther Valley Mining Institute, Dec. 7, 1912.

The Burden of Accidents

In Great Britain alone, it has been calculated that 17,000 persons, annually, die from accidents. This, of course, represents a small proportion of those temporarily or permanently disabled. One authority calculates this number in England as 1,500,000 annually.

Lynch and Shields, judging from the incomplete records kept in the United States upon this subject, tell us that 500,000 are so disabled, every year. Accepting the figures of Lynch and Shields, which, it will be seen are low in comparison with those given for Great Britain, and considering the earning capacity of each man injured at a conservative figure of, say, $500 per year, we have an annual loss, to victims and their families, of $250,000,000.

From German statistics, which are carefully compiled, it appears that 57.95 per cent. of all accidents are due to the negligence of employees or employers, and 42.05 per cent. to the inevitable risks of the employed. Lynch and Shields estimate, from such records as are obtainable, that in this country percentages run 66 and 34 per cent., respectively. Upon the subject of inevitable risks, Sir Edward Watkin, M. P., an Englishman who has made an exhaustive study of the subject, says in a small pamphlet entitled "Is Accidental Death Inevitable": "I have at last come to the conclusion that a certain proportion of accidental deaths are as inevitable as the measles. All education in the world will not avail to stop accidents which may end fatally." We conclude therefore, that although the greater number of accidents are caused by negligence of employees and employers, that, even could all accidents from negligence be eliminated, there would still be a small number of unavoidable accidents.

The Importance of Early Assistance

A noted surgical writer has said that the fate of any injured person depends chiefly upon the acts of the rescuer into whose hands he first falls. We are in the habit of saying, when speaking of fires, that the first five minutes are the most important. The same holds good in case of accidents, the difference being that in fires the consideration is property, and in accidents it is human life, which is, undoubtedly, of vastly greater importance.

The value of prompt attendance to injuries was clearly shown during the war with Spain, and in the South African conflict. From statistics dealing with these wars, we find that the loss of life and limb has been reduced to the lowest ratio in the whole history of warfare.

There is nothing more important in the event of accidents than that some one with sufficient coolness and information should assume command and begin to set things right. Such a man will rarely fail to be recognized by those less efficient and will usually find it easy to direct them so that they render valuable assistance, or at least, do no harm to the sufferer.

The last remark brings to our minds the objections advanced by a former division superintendent to the training of first-aid men. His objection was that they would do more harm than good by the over-zealous handling of injured persons; that they would probably poke their dirty fingers into wounds, etc. This cannot happen when men are properly trained. Training is incomplete if the proper handling of wounds is omitted. We do not intend to convert first-aid men into physicians and surgeons. We purpose simply to instruct them as to what they should do and what they should not do, in endeavoring to save life, limb and suffering.

Case "C," Bandaging of Fracture at Base of Skull

Case "X," Dressing a Crushed Right Lower Leg

No Accident Is to Be Regarded as Trivial

The first principle of first aid is to do that which is understood to be helpful; the second, to do nothing which is known to be harmful. Should any doubt arise in the mind of the first-aid man concerning the nature of an injury, he is trained to regard the accident as serious until the patient is placed in the hands of a physician.

"A" was injured by having a timber fall upon his leg, causing a simple fracture of a large bone of the left lower leg. He was allowed to walk three miles across a large city to his home, where a fracture was discovered by the physician. Only good fortune prevented the fracture from being compounded and resulting in a six months' to two years' confinement with possible infection and loss of limb, instead of six weeks of practically painless disability.

"B" sustained dislocation of his hip, 55 miles from home, while working on a railroad. Fellow-workmen failed to recognize the trouble and sat him down on the pilot of an engine and thus moved him 55 miles, causing him untold suffering. Had the injury been recognized, medical attention could have been procured in five minutes.

"C" standing on a freight train entering a tunnel

was struck and was unconscious for 10 min. He was revived and the injury not being recognized by his fellow-workmen, he was allowed to walk unassisted 1½ miles to his home. He fell twice on the way and upon reaching the house fell dead from effects caused by a fracture at the base of the skull, as was discovered in a post-mortem examination. Had the injury been recognized and the proper precautions taken, "C's" life might have been saved.

A man, subject to fits, fell on "D," a four-year old girl, and she sustained a simple fracture of the thigh. She was picked up and carried in cars four miles without a dressing of any kind. The physician was not seen for two hours. Fortunately, the fracture was not compounded, but we can imagine the suffering which she must have endured.

To look at the brighter side, we will now cite three cases where nothing but the presence of mind of the first-aid man saved the patient.

"X," a boy, 15 years of age, fell under a locomotive, having his leg totally crushed to the knee. Prompt application of the tourniquet by first-aid men and proper dressing prevented loss of much blood and made it possible to operate on the patient two hours after the accident.

"Y" was run down by detached cars from a trip and had his arm and shoulder crushed. It was impossible to control bleeding by the tourniquet, but the effusion was stopped by an original dressing devised by a first-aid man, who understood the needs of the case.

"Z" was attacked and beaten by four men, with a tea kettle and stove lid, at his home, and was undoubtedly bleeding to death when a first-aid man passing the house entered, controlled the bleeding, recognized that the skull was fractured and treated the patient accordingly. "Z's" life was saved. The emergency treatment of the case was commended by the surgeon of the hospital.

The accompanying illustrations "A," "B," "C" and "X" show the proper method of dressing injuries like those of victims "A," "B," "C" and "X," respectively, referred to in this article.

Safety Boosting Banquet

On Saturday evening, Jan. 4, the United States Coal & Coke Co., at Gary, W. Va., gave its 3d annual "Safety-boosting" banquet. About two hundred persons were present.

The hall was beautifully decorated with spruce and rhododendron and was brilliantly lighted. The object of the banquet was to discuss the prevention of accidents to employees, and the decorations were arranged to impress this more forcibly upon the minds of all present. On the front of the hall, facing the guests as they entered, the slogan of the company, "Safety the First Consideration," was printed in large letters. The invitations also were decorated with safety gems, such as, "When in doubt, take the safe course." "The prevention of accidents and injuries by all possible means, is a personal duty which everyone owes, not to himself alone, but also to his fellow workmen." Even the cigars which were served bore the brand mark, "Safety First."

For the past several years the United States Coal & Coke Co. has been making special effort to reduce accidents to its employees, and while the management feels that it has not made the progress it should, the figures for the past four years show decided improvement. For the year 1912, the total tons of coal produced per fatal accident inside increased 49 per cent. over the year 1911, 104 per cent. over the year 1910, and 190 per cent. over the year 1909.

Premiums for Safety

In order to give the officials an incentive to be constantly on the lookout for dangers which might be the cause of accidents, the company gives a premium each month to its foremen and assistant foremen, who have a clear accident record, and a special feature of the banquet was the "Foreman's Honor Table," at which were seated 19 foremen and assistants who have a clear accident record of 6 months or longer, some as long as 17 months. These men, after having operated their mine sections for 6 consecutive months without an accident, receive a special premium of from $15 to $25.

Notwithstanding the marked improvement that has already been made in the prevention of accidents, it is the intention of the company to put forth a still greater effort to reduce accidents for the year 1913. Each day during the year there will be mailed to every superintendent, mine foreman and assistant mine foreman of the company a short description of some accident which has occurred during the preceding years, with a statement showing how to avoid similar accidents. This is done so that each foreman and assistant will have the question of accidents brought directly to his attention daily. These reports will also be posted at the mines each day, so that the possible causes of accidents will also be brought to the attention of the workmen as they enter the mines in the morning.

When coffee was served, the following addresses were delivered, with Edward O'Toole, General Superintendent, acting as toastmaster:

"Underground Management of Coal Mines, with a View to Eliminating Accidents to Operatives, in Actual Mining," James Booth, Mine Foreman.

"Underground Management of Coal Mines, with a View to Eliminating Accidents to Operatives in the Transportation Department," J. V. Rhodes, Mine Foreman.

"Underground Management of Coal Mines, with a View to Eliminating Accidents to Operatives from Gas and Dust Explosions," A. H. Hahn, Mine Foreman.

A short talk from the Assistant Mine Foreman's "Honor Table" on "How to Keep a Clear Accident Record," Joseph Andring, Asst. Mine Foreman.

"Inspection of Mines, with a View to Eliminating Accidents to Operatives," W. P. Kearns, Mine Inspector.

"Mining Engineering, Relative to Coal Mines, with a View to Eliminating Accidents to Operatives," H. W. Saunders, Division Engineer.

"Mechanical Engineering, Relative to Coal Mines, with a View to Eliminating Accidents to Operatives," C. H. Williams, Mechanical Engineer.

"Electrical Engineering, Relative to Coal Mines, with a View to Eliminating Accidents to Operatives," Eli Clemens, Chief Electrician.

"Superintending of Coal Mines, with a View to Eliminating Accidents to Operatives," F. A. Kearns, W. W. Harding, A. N. Harris and H. T. Graham, Superintendents.

"Statistics on Accidents," H. N. Eavenson, Chief Engineer.

Leisenring Hall

By Special Correspondent

The H. C. Frick Coke Co. built a hall in the year 1912, at its Leisenring No. 1 plant, near the large swimming pool described in our issue of Oct. 5, 1912, and illustrated on the front cover of that issue. The building, which is to be used for the amusement and recreation of its employees, measures 60x30 ft., with a 42x17-ft. side wing.

It is divided into two stories; the basement is a concrete structure and is used as a game and reading room, having installed therein a bowling alley, pool tables, punching bags and other gymnastic apparatus. This room is also used on certain nights as a reading room and school of instruction and at that time is in charge of a paid instructor.

Opening into this game and reading room is a complete lavatory for men, connected to which is a row of shower baths for the use of employees after athletic exercises. The wing of the building, opening into this room, is divided into two sections, one of which is fitted up for a complete kitchen and contains a cooking range, dishes and other utensils. This kitchen is used, in connection with the basement, as a dining room for suppers and similar entertainments.

In the other section of the wing is located a large boiler. This furnishes steam for the heating of the building and for the swimming pool adjacent, and supplies hot water to both. The story above the reading room is used for basketball and dancing, being equipped with basketball apparatus and having an alcove fitted with a piano and seats for the orchestra.

As on the first floor, the wing of the second story is divided into two sections, one of which is a complete ladies' toilet and cloak room, the other being used as a barber shop, the proprietor being the custodian of the hall. Though the two floors are connected by a stairway, access to each floor is provided by ladies and gentlemen's outside entrances.

Managed by Employees' Association

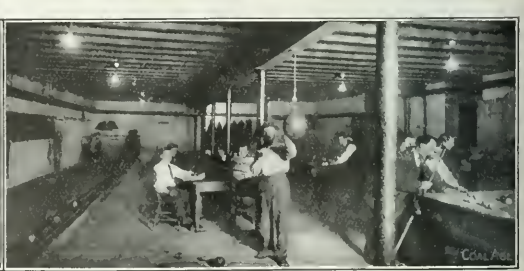
The building, which cost the H. C. Frick Coke Co. about $2500, erected, exclusive of material obtained from an old building of this size, has been put in charge of an association formed among the employees and known as the Leisenring Athletic Association. This body is required to equip and maintain the hall from its treasury.

The association membership fee as fixed by the company is $1 with a monthly assessment of 25c. per member. The present membership totals 85 employees, including members of employees' families. The association, however, is not granted the exclusive right to use the hall, all employees of the company, whether members of the association or not, having free right to its advantages and any equipment therein. The membership of the association has rapidly increased since its formation and the society has thus far received and expended about $300, most of which has been used toward the equipment of the hall. It is estimated that it will require an equal amount to complete its outfitting.

Leisenring Hall, Erected by the H. C. Frick Coke Co.

Front View of the Hall from the Swimming Pool

Room for Basket Ball and Dances, Leisenring Hall



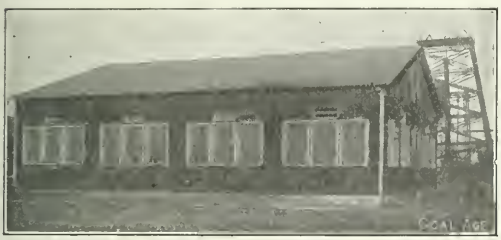
Room for Games and Reading in Same Building

No charge is made for admission to dances or basketball games, the only method used for obtaining money being the association membership, assessment fees and money derived from the sale of eatables at suppers and festivals held in this building. The work of the association is under the charge of a president, vice-president, secretary and treasurer, with executive and house committees.

The association has adopted by-laws regulating its own affairs and providing for the proper use of the hall. These relate particularly to the behavior of employees and association members while in the building. The laws are strictly enforced by the officers of the association and the custodian. The hall, which was built as an experiment, has proved a great success and is being used by old and young, men and women, native and foreign born, alike.

Club Room at Prospect Colliery

The Lehigh Valley Coal Co., under the advice of F. M. Chase, its general manager and vice-president, has installed a club house close to the breaker of the Prospect colliery. Hitherto the workers in the breaker have taken their mid-day lunch either in the dust-laden building itself or in or even under box cars. The latter did not form safe places, as it was not certain but that a shifter might at any time put the cars in motion.



Exterior View of Prospect Colliery Club House Near Wilkes-Barre, Penn.

The building measures 52x56 ft., and is well lighted and ventilated. The walls and ceilings are of cement, and have been prettily decorated by the painters. The dado is painted black, so that the diners will not disfigure the walls by contact with their working clothes.

Dining Room for Employees at Club House, Decorated in Black and White

The walls, however, above this blackened section are white, so that the rooms are light and cheerful.

The chief room of the building is the mess, club or assembly room. It measures 26x56 ft., being well lighted and heated. Benches and tables of varnished hardwood are provided. These are fastened securely to the cement floor and extend the whole length of the building, providing accommodations for about 300 men. This room will be used by the employees when eating their meals, and for conversation, reading and smoking. Appliances are on hand for heating tea and coffee, and fresh running water is on tap at all times.

On the opposite side of the building is the coat and locker room, measuring 20x26 ft. Steel lockers are provided free for each man. The wash room measures 26x27 ft., and

Interior of Mess or Assembly Room, Showing Visitors at Lunch as Guests of Officials

has hot and cold running water. Twenty enameled basins have been installed. A lavatory 8x26 ft., with urinals and closets, takes up the rest of the floor space.

The company will provide janitors free of all cost to the men to look after their club room. But the management of the building will be entirely in the hands of the employees. They will be asked to name their own committees to see that reasonable order is maintained.

Any meeting they may wish to hold may be held in the club room, as the building belongs to them. The extension of the men's club scheme depends on the degree of appreciation shown toward the new plan. If it is successful at the Prospect colliery, more club houses will be built.

While testing Draeger and Meco types of rescue apparatus, it has been discovered that the series of fine wire gages used to prevent the entrance of rust or grit, into the injector nozzle, may possibly become broken, then if small pieces of broken wires, dislodged from the gauze, fall, they may completely stop the passage and cut off the supply of oxygen. This has occurred several times while making tests. The wearer of the apparatus may fall or some other sudden jar or jerk may cause the broken wires to fall, and the man may be rendered unconscious with little or no warning that anything is wrong.

Welfare Work of the H. C. Frick Co.

By Thomas W. Dawson*

Safety, relief, sanitation and welfare, as practiced by the H. C. Frick Coke Co., a subsidiary of the United States Steel Corporation, are so closely associated that I have grouped them under "Welfare," the topic of this paper.

Bureaus of Safety

The United States Steel Corporation has a "bureau of safety" which is intended to assist in coördinating all efforts which are being made among the subsidiary companies for improving the conditions of the employees. It is not only a clearing house for everything of this sort done within the corporation, but it is also an observation station for everything of the kind done by other companies.

It is established to make sure that each subsidiary company knows the best methods adopted everywhere, and also the most successful systems tried by the corporation. The bureaus see that the companies adopt the measures which have been proved to save life.

The Origin of the Expression "Safety First"

"Safety the First Consideration" appears on all letterheads, blank forms, circulars and stationery used at the mine and general offices of the company. This slogan originated with the president of the H. C. Frick Coke Co., which has formulated 25 rules, printed them in pamphlet form, and given a copy in his own language to each workman. The first of these regulations states that:

"Strict compliance with the mining law of the state of Pennsylvania shall be the first duty of each and every employee, at all times, and under all circumstances; and, 'Safety must be the first consideration' of all superintendents, mine foremen and all others exercising authority, or charged with the direction of operations in every department; quality of product, second; and cost of production, third."

Every official and foreman of the company is continually impressed with the fact that safety is to be the first consideration, and all these officials and their subordinates are brought together as one great committee on safety; thus, the strenuous campaign, started several years ago, is being vigorously continued.

The 25 general rules of the company, printed in the various languages of the employees, are posted at conspicuous points about the mine where workmen have the best opportunity to peruse them. Pamphlets setting forth the duties of the miner and the manner in which he may protect himself against danger and giving the safety regulations for those working around machinery have been printed and generally distributed.

The sign significant of danger is the standard sign required by the mining law of the state of Pennsylvania. You will find it at all points in the mine where there is the least possibility of an accident. A similar sign, indicative of the particular danger which may be encountered, is used in and about that part of the plant situated on the surface. These signs are of substantial construction, being made of enameled steel. They have a white background, a red disk in the center, and black letters. Care is exercised to have these in use at all times.

Signs and Locks

When men are working in shafts, the "Men in Shaft" sign is placed so that by no mistake can an accident be caused by the moving of the cages. Where there are explosives, gasoline or inflammable material of any kind, you will see the danger sign indicating the same.

Should a hoisting engineer be repairing or cleaning the machinery in his charge a "Do Not Move" sign is placed at the levers. When workmen are cleaning or making repairs to the inside of a steam boiler, a "Man in the Boiler" sign is displayed. As a further precaution against accident to these men, the steam valve for the particular boiler in which they are working is locked, and one of them carries the key in his pocket, so that steam cannot be turned into the boiler while the men are within the same.

Also when workmen are repairing or cleaning coke-drawing machines, the "Do Not Move" sign is placed on the controller, and as a further precaution those men are instructed to lock the trolley wheel and carry the key until they have finished such repairs or cleaning.

A "No Clearance" sign is conspicuously displayed at all points in and about the plant where there is not clearance for a man between moving cars and buildings, tipples, yard walls and the like. Where tracks approach tipples, bridges or any other overhead obstructions which do not admit of sufficient clearance for a man standing on top of a railroad car, or a teamster sitting on his wagon when passing underneath, bridge guards or overhead warning signs are placed at a sufficient distance from these obstructions, thus giving warning of the danger ahead.

Careless Men Need Not Apply

The man seeking employment observes the sign that unless he is willing to be careful to avoid injury to himself and his fellow workmen, he is not to ask for employment, indicating that the company does not want careless men in their employ.

The sign "Safety First," printed in various languages, is displayed in all the offices, boiler rooms, power buildings, pump rooms and at the mine entrance, reminding the employee that this is to be his foremost thought. A number of these signs are illuminated. They are made of glass on both sides, so that the legend shows in two directions. They are placed at mine entrances, shaft bottoms and in other like places where they will intrude their warning on the attention of the employee and the public.

In the mine, guide signs in the various languages are posted at road junctions, and on traveling ways, indicating the safest way out of the mine.

(*To be continued in an early issue*)

*Assistant chief engineer, H. C. Frick Coke Co., Scottdale, Penn.

Note—Abstract from paper entitled "Welfare, H. C. Frick Coke Co.," read before the winter meeting of the Coal Mining Institute of America, Dec. 18, 1912.

The January meeting of the Nanticoke Mining Institute was held on Jan. 18, in the auditorium of the Susquehanna Coal Co. Papers were read by David Humphreys on "Mine Ventilation," and by Edward Curtis on "Formation of Coal." During the intervals, music was furnished by a double quartette, with Thomas Lloyd as leader.

DISCUSSION BY READERS

Reducing Ventilation at Firing Time

Letter No. 2—I first advocated slowing down or stopping the fan at Iowa mines, during shotfiring time, about n years ago. I did this after giving the matter long d careful consideration in all its bearings and fully alizing my responsibility in the premises. The practice s since become fairly general, in Iowa. Since its adopon, I have not discovered a single case giving the ghtest indication that life or property was endangered; t, on the other hand, I believe it has contributed maially to the safety of shotfirers and the protection of operty.

I had long been convinced that the presence of strong aft, at firing time, is a greater menace than the presce of dust, and later evidence has so strengthened that nviction that I not only recommended the slowing down stopping of the fan, but have since requested the comete closing of the intake openings whenever this seemed me advisable.

The following is an instance. About six years ago additional air shaft was sunk at No. 6 mine, of the noky Hollow Coal Co., in Monroe County, Iowa. The w shaft was located in the midst of live workings, conining considerable narrow work, and was about 1½ iles from the slope mouth and ¾ mile from the fan, nich was generally exhausting. A heavy door was built ar the bottom of this shaft. To prevent the entrance to the live workings of a strong, cold air current, at ing time, the shotfirers, before commencing their work, osed and locked this door, which was not opened again l all the shots had been fired. It was customary to n the fan at a greatly reduced speed for some time fore and during firing time. The only air entering e mine traveled through the main slope a distance of ½ miles before reaching the working face. Notwithnding the fact that many of the places were extremely y, owing to the absorption of moisture by the cold air tering the mine through the new shaft, and windy ots were more or less frequent, no dangerous condions developed and the shotfirers experienced no difflty in doing their work.

The matter of reducing ventilation at firing time may viewed from several angles. In a discussion of this nd, however, the question will naturally be treated rgely from a local rather than from a general standint. I believe that a broader view should be taken the matter. It is more important to investigate the ason for a proposed method or system than to discuss e method itself. Mr. McAllister's method of preventg explosions, for instance, may be objectionable under fferent surroundings, but he seemingly proved its eftiveness in his case and under most trying conditions. hether or not his method is adopted in any mine, is of s importance to the mining men of this country than at they should know and understand the reasons why proved a success in that instance.

Experimentally and otherwise, I found that explosions of fine coal occurred only with a rather intense draft, which always seemed to hasten their occurrence and increase the force of the explosion. I found that to produce a dust explosion the draft must be sufficiently intense and concentrated to pick up and carry the dust along to the flame. If this be true, it is evident that, with the fan stopped and no natural draft, the flame of a shot receives no assistance in the production of draft; and there is an increased margin of safety, because a larger flame and one of longer duration would then be required to make an explosion possible.

Mr. McAllister evidently realized the danger of a strong draft at shotfiring time. He stopped the fan and short-circuited the air; and, finding this still insufficient to stop the dangerous draft, he closed the upcast shaft by doors. The results he obtained speak for themselves.

The method of reducing ventilation at firing time will probably never meet with general approval. In mines where the shots are fired by electricity from the surface, the entire stoppage of draft when firing will probably prove the most effective means of preventing an explosion in the mine. But, much good will have been accomplished if the suggestion arouses an appreciation of the dangerous properties of draft, and the realization of the truth that the magnitude of an explosion is measured by the availability of the air supply as much as by the character and amount of the dust present.

JOHN VERNER.

Chariton, Iowa.

Letter No. 3—The question is: Shall the normal circulation of air, in a mine, be reduced during the time of firing shots? My experience has taught me that a constant supply of fresh air must be kept passing through the entries and workings of a mine, for the following reasons: 1. To remove the foul air produced in the operation of a mine. 2. To dilute and render harmless the noxious gases generated in the mine by the combustion of powder and the explosive gases coming from the coal and strata.

No two mines present the same conditions, however, and what would be an ample provision of air in one mine would prove inadequate in many other mines, working under other conditions. The question of the volume of air required in any given mine to render the workings safe and healthful must depend on the local conditions. But, the present discussion has reference particularly to reducing the normal circulation in a mine before firing shots.

While I believe the normal circulation of air should not be reduced at this time, it is also important that the air current should not be too strong, especially at the working face, where the shots are being fired. A strong air current will raise and carry more dust, which is liable to be ignited by the flame of the shots. The quantity of air passing in any district of a mine should be regulated by a competent

mine foreman in accordance with the requirements of the state mining law and the conditions in the mine. It is important, besides, to give strict attention to the cleaning up of the airways and removing the dust from the roads and spraying all dry working places.

My advice is to keep the velocity of the current at the working face normal and not allow this to be reduced when firing. I believe that it is necessary for the protection of the shotfirers, as well as the health and safety of the workmen. It is also important that all shots should be inspected by a competent person before firing, in order to prevent "shooting off the solid," or firing a "dead hole." Either of these practices is liable to cause a windy shot, which is not only dangerous but the frequent cause of mine explosions.

A. T. WADE.

St. Charles, Va.

Letter No. 4—I have read, with great interest, the debate on the reversible fan, in COAL AGE, and consider these discussions very helpful to men interested in mining.

In regard to the question concerning the reduction of air circulation in the mine, during the firing of shots, it seems to me that this will depend entirely on conditions, as some mines are gaseous, while others are free from gas. If I were firing shots in a gaseous mine, I would not, under any circumstances, want the air short-circuited or cut off, or the amount reduced. I should want air enough to dilute the gases sufficiently to make them harmless, and, also, to drive the smoke and gas out of the places where the shots are being fired.

In my experience, I have found that where the air is stopped the gas accumulates quickly, in mines generating firedamp. In such mines, I consider a sluggish ventilation or any stoppage of the fan extremely dangerous.

In a nongaseous mine, where there is a considerable accumulation of explosive dust, I deem it safer to short-circuit the air, so as to reduce the circulation to a low ebb, in the places where shots are being fired. My reason for this is that the firing of shots in a dusty mine will raise the dust; and a strong current of air will hold the dust in the atmosphere for a much longer time than a sluggish circulation. My idea is that a slow current of air will let the dust settle more quickly, and there is less danger of its being ignited, in case of a bad shot.

W. J. TYSON.

Ideal, Colo.

Letter No. 5—An experience of many years as shotfirer in mines, during which time I have closely examined 17 mine explosions and been in the mine when three explosions occurred, has convinced me that air and not coal dust is the prime factor in producing an explosion.

In proof of this claim I would refer to the many disasters that have occurred in model mines of this country and draw attention to the fact that, in the majority of cases, the explosion started in a portion of the mine where the air was at the lowest temperature and had the highest velocity. I acknowledge that at this point in the mine we naturally find the most inflammable coal dust.

In mines where the fan was reversible I have been able to prove the correctness of my conclusions, by changing the direction of the air current so that the section of the mine that gave the most trouble from windy shots was placed on the last of the air instead of being swept by a cold air current fresh from the outside. By this means the number of windy shots was greatly reduced, in every case.

It is customary, in most mines, to run the fan at practically the same velocity the year round; notwithstanding the fact that, in most cases, in the summer season we must overcome the natural ventilation due to the difference between the outside and inside temperature. In the winter season, natural ventilation generally assists the artificial ventilation in a mine, and it is at this time of the year that the most disasters occur.

I have observed, also, that the old mines with poor ventilation are almost devoid of explosions, except where a fan has been installed to increase the ventilation, or a new downcast shaft has been sunk on the inside workings of the mine to furnish more air. In the latter case, the cold air is brought directly into the midst of the blasting section. I consider any system of ventilation faulty where a cold-air current is brought directly into the workings of the mine at a high velocity.

When in the mine, at the time of an explosion, I have always noticed a heavy rush of air behind the explosive wave. In most cases, the ventilating power was overcome and reversed by this rush of air, until the recoil of the explosion took place, when the force would be exerted in the opposite direction.

I have also observed that, as the explosion advanced against the air current, the pressure on the stoppings was greater as the explosive wave approached the downcast shaft. The stoppings are first subjected to a pressure on the intake side, which is directly followed by a reverse pressure on the return side.

A careful study led me to believe that if the inrush of air behind an explosion could be prevented, a vacuum would be formed there that would soon develop a greater power than that of the explosive wave and arrest its advance. It was this that led me to build doors folding down on the top of the upcast shaft, and which were to be closed during firing time. I have referred to this in a previous letter. Following up my theory, I have endeavored, at different times, to produce an explosion under the conditions explained, but have failed.

In summing up, let me say we all agree that coal dust will explode when intimately mixed with air and subjected to a flame of high temperature. Cold air contains more oxygen per unit of volume than warm air, owing to its greater density, and this tends to increase the temperature of the flame of a blast of powder. The temperature of the flame is further increased by the additional amount of air passing, which carries the most inflammable coal dust stirred up by the firing of the shots. This causes a constantly increasing explosive condition of the air and, being acted on by the flame of succeeding shots, furnishes the combination necessary to start an explosion.

By closing the doors over the upcast shaft and short-circuiting what air is passing, we practically destroy the life-giving property of the flame—the strong air current—and reduce the temperature incident to blasting. My argument is, briefly, as follows: Should an explosion start in a mine, it will advance toward the intake opening, and the closed doors above the upcast cause a vacuum to form behind the explosion, which will soon develop force sufficient to arrest the same.

ALEXANDER MCALLISTER.

Crowcburg, Kan.

Coal Mining in Oil and Gas Fields

Some time ago a correspondent referred in these columns (Coal Age, June 29, 1912, p. 1255), to the danger arising from gas wells in coal fields. The danger mentioned is not confined to gas wells, but is common also to oil borings.

Coal, oil and gas are great natural resources. Coal must be mined; oil and gas must be produced in quantities to meet the ever-growing demands of communities. In West Virginia these industries are developing rapidly and must eventually come into serious conflict with one another. The same condition, no doubt, exists in other states. This situation given rise to many discussions, and considerable has been written on the subject; but much remains to be done before the problem can be solved and the best and safest ways to adopt rightly determined.

Coal and mineral publications, mining institutes, the U. S. Bureau of Mines and in fact, all mining men should discuss and take steps to prevent, as far as possible, catastrophes that may prove worse than even the Monongah, Marianna, or Darr explosions.

An old, abandoned well, whose location has been covered and forgotten is a menace to mining—a great, hidden danger. As has been illustrated at the Enterprise and Middleton mines, in West Virginia, and at a small country bank near Peora, W. Va., a mine may be blown up before actually cutting into such a well. The question of who is, or who should be liable for accidents of this nature may be hard to answer at the present time and under present conditions and laws.

While every uptodate mine manager strives to insure the protection of his property and the safety of his employees, and to produce a large tonnage at a low cost and recover the greatest possible amount of coal per acre mined; an unlooked for explosion may result from the mere proximity to a hidden gas well and upset the most complete plans that an efficient and capable organization could outline.

Several of the large and responsible oil-and-gas companies now realize the seriousness of the situation and consult quite generally with the coal companies affected relative to the location of proposed wells. The oil-and-gas companies will cement around the casing when the well is drilled through a coal seam. There are, however, at the present time, some companies who locate and proceed to drill their wells without making any attempt to insure the safety of the men who some day will mine coal in the vicinity of these wells.

Coal companies operating in an oil or gas field should be compelled to leave a solid block of coal around all wells whose location should be plainly marked on the mine map.

The size of such block of coal will depend on the character, inclination and thickness of the overlying strata, and other conditions relating to the mining of the coal. Many different opinions are advanced by mining men and men in the oil-and-gas business as to who is responsible for the loss of coal left unmined and the accidents that may result from gas finding its way into the mine from the well; and it is pretty hard to determine just what law of equity should be made. Many old drill men claim that cementing a well is not effective, and many old bosses say that uncovering a gas line, under which the mine pillars are being drawn, does little good, but most mining engineers take the opposite view.

In the writer's opinion, a dry hole bored for oil or gas in a producing field, should be considered and treated the same as a producing well. No wells should be allowed to be drilled through the squeezed or abandoned sections of a mine. All oil-and-gas companies should be compelled by law, to protect adjacent mines, from gas issuing from their wells, and to file with the State Department of Mines and the coal companies alike maps showing the correct location of all wells drilled in a coal field. The maps should show all oil and gas lines laid in that district. The coal companies should also place all such locations on their mine maps. Nitroglycerin magazines should never be erected over mine workings where the covering is light.

Mining Engineer.

Clarksburg, W. Va.

The Price of Coal

For some time past I have wanted to comment on the Foreword in Coal Age, Aug. 3, 1912, by the president of an Ohio coal corporation, followed by your footnote, referring to the subject of the poor returns on capital invested, received by those engaged in the production of coal. I would have written sooner, but for the pressure of other work, which prevented.

It seems strange that those who invest their labor and capital in the extraction of a mineral, a ton of which, it is safe to assume, can be made to earn $500, are scarcely able to realize a dollar on their investment. The question arises: Why is this; what is the reason?

An article in the *Technical World Magazine*, March, 1912, by George H. Cushing, gives some interesting facts and figures about buying and selling coal. He states that he buys his coal through a purchasing agent for a certain large consumer, who buys 3000 tons a day. He quotes the agent as saying that if ever the time comes when the price of coal equals or exceeds the cost of production, his company would start to operate mines of their own; adding, if there is any profit in the coal business, our stockholders want it, as we own coal lands that will last for the next 100 years.

Another large industry in Chicago owns 14,000 acres of coal land in Kentucky and 20,000 acres in West Virginia. Another Pittsburgh corporation owns practically all of the Connellsville field of Pennsylvania and has something like 200,000 acres of coal in southern Illinois. Every coal-carrying road holds a large acreage of virgin coal land, or controls the principal coal-producing companies on its lines.

This, it seems to me, is the key to the whole situation. What enables railroads and other large consumers of coal to dictate the price they pay for fuel is the private ownership of land for which they pay only a nominal tax and interest on the investment. If these coal lands were assessed at their true value, the power of these corporations to dictate the price of coal would be broken. This would seem to be the only remedy.

By the use of improved machinery or by changing the plan of working the mine, it is possible to reduce operating expenses; but the benefit, at the most, is only temporary, as sooner or later, the advantage is absorbed by the large consumers.

Special Correspondent.

Chicago, Ill.

INQUIRIES OF GENERAL INTEREST

Coal Required to Heat Water

How many pounds of bituminous coal would be required to raise the temperature of water from 45 deg. F. to 112 deg. F.; the quantity of water used being 3000 gal. per hour?

MINE SUPERINTENDENT.

Clearfield, Penn.

The weight of water used per hour is

$$\frac{3000 \times 231}{1728} \times 62.5 = 25{,}065 \text{ lb.}$$

The quantity of heat required to raise 1 lb. of water 1 deg. F. is called one British thermal unit (B.t.u.). The rise in temperature, in this case, is 112 — 45 = 67 deg. F. Therefore, the quantity of heat required to raise the given weight of water from 45 deg. to 112 deg. F., is

$$25{,}065 \times 67 = 1{,}679{,}355 \text{ B.t.u.}$$

Now, assuming 1 lb. of bituminous coal has a heating value of 14,000 B.t.u., the weight of coal required per hour is

$$\frac{1{,}679{,}355}{14{,}000} = \text{say } 120 \text{ lb. per hr.}$$

This assumes that all the heat of the coal passes into the water, which is never the case in practice. The efficiency of the heating system will depend upon the arrangement and construction. It may be assumed that the coal burned in heating the water has an efficiency of 7 per cent., if burned under a boiler. Taking the efficiency as 6 per cent., the weight of coal burned per hour would be 120 ÷ 0.06 = 2000 lb. or 1 ton per hour.

**

Pumping from Different Elevations in a Shaft or Slope

Referring to COAL AGE, Feb. 10, 1912, p. 586, it is stated, in answer to the second letter of correspondent, that it would be advisable to connect the upper sump to the suction line of the pump at the lower elevation, since by so doing the head of water due to the elevation of the upper basin above the pump becomes available to assist the pump in draining that basin.

The argument apparently is that the water from the upper sump would pass through the pump under a pressure due to the elevation of the upper sump above the pump, and this pressure would balance the corresponding head in the column or discharge pipe, whereby the water from the upper sump would be discharged to the surface as economically as if the pump were located at the upper basin.

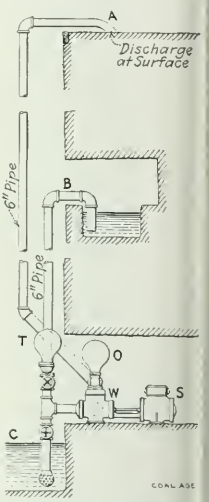
I wish to ask what effect this system would have on a reciprocating pump, as to the action of the suction valves under this pressure; and whether or not the springs controlling the valves would have to be strengthened in order to have the pump work as efficiently as when taking its water under ordinary conditions. If possible, kindly give a reference, in this regard, from someone who has a pump working under similar conditions.

M. J. BRACKEN,
Gen'l Supt., Mountain Coal Company.

Gallitzin, Penn.

The inquiry answered in COAL AGE, to which our correspondent refers, related to pumping from two different elevations, in a slope. The principle is the same whether pumping in a shaft or a slope.

The accompanying figure shows the mine pump located at the lower basin *C*, the column pipe *BC* draining the upper sump, and the discharge pipe *CA* reaching to the surface. As stated in our previous answer, there should be provided two valves, one above and the other below the point where the pipe leading from the upper basin enters the suction pipe of the pump. These valves are shown in the figure. When pumping from the lower basin, the upper valve is closed and the lower valve opened. When pumping from the upper basin, this order is reversed; the lower valve is closed and the upper one opened.



SHOWING ARRANGEMENT OF PUMP AND COLUMN PIPES

No difficulty will be experienced, owing to the pressure on the pump valves, provided the arrangement is such as to avoid a water-hammer in the pipes. This can only be prevented by placing an air chamber at the foot of the pipe conducting the water from the upper basin to the pump. In the figure, *S* is the steam end and *W* the water end of the pump. The usual air chamber *O* is placed on the water end of the pump to prevent water-hammer in the discharge pipe, by maintaining a continuous flow of water in that pipe. A similar air chamber *T* is shown at the foot of the pipe leading from the upper basin to the pump. This air chamber is connected to that pipe just above the valve, and prevents water-hammer in the pipe by maintaining a more or less continuous flow of water from the upper basin to the pump.

William Schwanhausser, chief engineer of the International Pump Co., 115 Broadway, New York City, is authority for the statement that a pump thus arranged will work without difficulty under a pressure due to the head of water on the suction end. In such an arrangement, the only factor to be considered is the inertia of the water columns, which is more or less perfectly overcome by the air chambers connected with the column pipes.

EXAMINATION QUESTIONS

Mine Foremen's Questions

(Answered by Request)

Ques.—(a) What is the angle of inclination and the percentage of grade of a slope that dips 8 in. per yd.? (b) If the slope is 1000 ft. long, measured on the incline, what is its length measured on a map drawn to a scale of 100 ft. per inch?

Ans.—(a) Since there are 36 in. in a yard, the slope dips 8 in 36. Then, calling the angle of inclination of the slope A

$$\tan A = \frac{8}{36} = 0.2222$$

$$A = 12^\circ\ 31'$$

The percentage of grade is found by multiplying the tangent of the angle of inclination by 100. Thus,

Percentage of grade $= 0.2222 \times 100 = 22.22$ *per cent.*

(b) All measurements on a mine map are horizontal distances. The horizontal distance corresponding to 1000 ft. slope measurement is found by multiplying the distance measured on the incline by the cosine of the angle of inclination. Thus.

Horz. Dist. $= 1000 \times \cos 12^\circ\ 31' = 1000 \times 0.9762 =$ 976.2 *ft.*

For a scale of 100 ft. per in., the distance measured on a map drawn to a scale of 100 ft. per inch, is then, $976.2 \div 100 = 9.762$ in., or slightly more than 9¾ in.

Ques.—A cross-heading turned off the main entry is driven due north for a distance of 150 ft., and dips 4 ft. in this distance. The coal seam rises due west 1 ft. in 6 ft. How far east or west from the center of the cross-heading will the line of strike, passing through the face of the heading, cross the main entry?

Ans.—The cross-heading, from the entry to the face, dips 4 ft. Since the seam rises 1 ft. in 6 ft., going due west, the dip of the seam is 1 ft. in 6 ft. due east. The main entry will, therefore, dip 4 ft. in going $4 \times 6 = 24$ ft.; and the line of strike passing through the face of the heading will cross the main entry 24 ft. east of the mouth of the cross-heading.

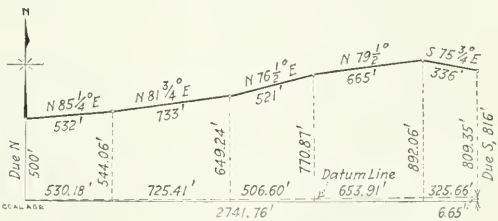
Ques.—(a) How many acres are there in the following described piece of land: Commencing at the southwest corner of the northwest quarter of section 25; thence, due N, 500 ft.; thence, N 85¼ deg. E, 532 ft.; thence, N 81¾ deg. E, 733 ft.; thence, N 76½ deg. E, 521 ft.; thence, N 79½ deg. E, 665 ft.; thence, S 75¾ deg. E. 336 ft.; thence, due S, 816 ft.; thence, westerly to the place of beginning.

(b) If the average thickness of the coal seam is 4 ft. 6 in., how many tons of lump coal can be mined from this tract, allowing 27 cu.ft. of coal, in place, per ton and 20 per cent. waste and 30 per cent. fine coal?

Ans.—(a) The accompanying figure is a plat of this survey. As shown in the figure, the closing course runs west 2741.76 ft., bearing north in this distance, 6.65 ft. The following is the traverse of the survey, showing the *northings, southings, eastings and westings of the several courses, except the closing course.

Bearing	Distance	N.	S	E	W
Due N.	500	500.0			
N 85¼ E.	532	44.06		530.18	
N 81¾ E.	733	105 18		725.41	
N 76½ E.	521	121 63		506.60	
N 79½ E.	665	121 19		653 91	
S 75¾ E.	336		82 71	325.66	
Due S.	816		816 00		
		892 06	898 71	2741 76	
			892.06		
			6 65		

An east and west line through the first station is taken as datum and the total northing of each station, above datum, is calculated by adding the northing of each consecutive course to the total northing of the previous station. The total northing of each station, as thus calculated, is shown on the diagram. The entire area of this survey is thus divided into five trapezoids and one triangle. The area of each of these trapezoids and that of the triangle is then calculated as follows:



PLAT OF SURVEY

	square feet
$\frac{500+544.06}{2} \times 530.18 =$	276,769
$\frac{544.06+649.24}{2} \times 725.41 =$	432,815
$\frac{649.24+770.87}{2} \times 506.6 =$	359,713
$\frac{770.87+892.06}{2} \times 653.91 =$	543,703
$\frac{892.06+809.35}{2} \times 325.66 =$	277,040
$\frac{2741.76}{2} \times 6.65 =$	9,116
Total area	1,899,156

The acreage in the inclosed survey is then $1,899,156 \div 43,560 = 43.6$ acres.

(b) Allowing 27 cu.ft. per ton of coal in place, and deducting 20 per cent. and 30 per cent., respectively, for waste and fine coal, leaving 50 per cent. for lump coal mined, the total tonnage that can be mined from this tract of land, the seam being 4 ft. 6 in. thick, is:

$$\frac{1,899,156 \times 4.5}{27} \times \frac{1}{2} = 158,263 \text{ tons}$$

* The northing or southing of any course is called the latitude of the course, and is calculated by multiplying the length of the course by the cosine of its bearing. The easting or westing of a course is called the departure of the course, and is calculated by multiplying the length of the course by the sine of the angle of the bearing. A course running due north or due south has no departure, and the length of the course is its latitude (northing or southing.)

COAL AND COKE NEWS

Washington, D. C.

It is now understood that Attorney General Wickersham has decided to make a further attack on the so called Hard Coal Trust, by attempting to break up the minor combinations of coal-carrying railroads and coal companies in the Pennsylvania fields, charges against which were dismissed by the Supreme Court without prejudice in its recent decision, because they were held to have been improperly incorporated in the Government's original general bill against the trust.

The work will be in charge of James C. McReynolds, of New York City, who was the Government's counsel in the anthracite trust suit. The attorney-general's idea is to get Mr. McReynolds to clear up the whole situation so far as possible by the proceding which is now contemplated. Mr. McReynolds reported to the attorney-general last week concerning the result of several weeks of study of the general situation and it is understood that he urged that the department go ahead.

The minor combinations not passed upon by the Supreme Court, but left for future consideration and possible action, were those said to have been created in 1898 by the absorption of the New York, Susquehanna & Western by the Erie; in 1901, by the acquisition by the Reading Co., which owned the Philadelphia & Reading Ry., and a coal company of similar name, of the Central Railway of New Jersey with its coal companies; in 1899, by the acquisition by the Erie of the Pennsylvania Coal Co., which is said to have been projecting a new railroad, the Delaware Valley & Kingston.

It is stated that negotiations between the Department of Justice and these concerns are under way looking for a settlement.

Alaska Coal for Testing

Eighty-eight dollars a ton for coal is the rate just paid by the Navy Department for 855 tons, and the department hopes and believes that the money has been well spent. This particular purchase of coal is in the nature of a venture and it is not likely that the Government will buy much more at the same price. But if the venture turns out well it may mean that the United States will be provided with a sufficient amount of coal to supply the entire navy for a long period of years.

The Naval appropriation bill last year contained $75,000 for the development of Alaskan coals. The only way the department could determine the efficiency of this fuel was to get a sufficient quantity of it aboard a ship and actually burn it. Alaska coal has never been brought to market. Billions of tons of it are known to exist, but as yet no means of bringing this fuel within reach of the people have been provided.

The Navy Department was instructed to determine whether there was in Alaska a coal deposit containing fuel in sufficiently large quantities and of proper quality to be regarded as a source of supply for our warships. After Congress granted the $75,000 the Department turned the technical operation of its expedition in search of coal over to the Bureau of Mines, of the Department of the Interior. It was planned to take out about 900 tons of coal from the Bering River district.

The Matanuska field is much further removed from the sea than the Bering River field. The Navy Department is not attempting to solve the Alaskan problem in its present work, but is only concerned in getting out to the seacoast a sufficient quantity to be tested. If it proves satisfactory, a better means of transportation will be devised.

Another Foreign Coal Contract

Strong interest is expressed here in the fact that the Pocahontas Fuel Co. is understood to have made arrangements by which it will furnish coal to the Austrian-Hungarian navy for several months to come. This firm already has the exclusive contract with the Isthmian Canal Commission, shipping about 500,000 tons to Panama per year and is the largest contractor for the coal used by the United States Navy.

Although the State Department is disposed to claim some merit for the progress that American coal has been making of late in the Mediterranean market it would seem that the only reason for this recent success is the high price of Welsh coal which has given American shippers the advantage.

Secretary of the Interior, Walter L. Fisher, has written a long letter to the Senate Committee on Indian affairs concerning the resolution extending the time for the appraisement of the coal lands of the Indians in Oklahoma The measure has been favorably reported to the Senate. Secretary Fisher says in part:

To work out this problem in justice to the owners of the land (the Choctaw and Chickasaw Nations), as well as the persons claiming to be owners of the improvements, I have provided in the proposed resolution that any person claiming payment for improvements must file his claim under oath within 60 days from the date of the approval of the act with the Secretary of the Interior or his authorized representative, and that if no person shall so assert a claim to the improvements on any tract, such improvements shall be sold as a part of the land.

As a conclusive rule of evidence, I also suggest that if a claim be filed by or on behalf of any person within the time allowed, and no adverse claim be filed within such time, the improvements shall be deemed to be the sole property of the person applying therefor.

It is also recommended that where there is no controversy, improvements be sold and the purchase price, except 5 per cent. to cover expenses, be paid immediately to the owner of the improvements; but that in case two or more persons claim the improvements, and one of them is a successful bidder therefor, the sale be conducted as in the case of purchases by strangers, and the proceeds deposited to the credit of the tribes, subject, however, to withdrawal on order of the Secretary of the Interior for payment to the true owner in the event that the right of ownership shall be finally established by a court of competent jurisdiction.

WILKES-BARRE, PENN.

During the year 1912, the working time for the collieries in and near Plymouth was much less than during the preceding year, due principally to the suspension which began April 1, and continued until May 23. The Avondale colliery, of the D., L. & W. Co., made the best record, showing an increase of 160 days and two hours. This mine was idle 11 months during 1911 on account of a squeeze, which almost flooded the mine.

It is expected the breaker at No. 2 D. & H. Colliery will be torn down during the present year and the coal taken out through No. 5 of the same company. Of 12 collieries whose time was examined for the year, seven worked much less time last year than in 1911. The Nottingham and Lance, of the L. & W. B. C. Co., show a net decrease of 15 days and four hours; Nos. 2, 3 and 5, of the D. & H. Co., a net decrease of 129 days and six hours; Buttonwood and Parrish, of the Parrish Coal Co., an increase of 73 days, 3½ hours; Woodward and Avondale, of the D., L. & W. Coal Co., an increase of 198 days and two hours; Gaylord and Gaylord Washery, of the Kingston Coal Co., a net decrease of 23 days; Chauncey, of the George F. Lee Coal Co., a loss of 19 days; and the Dodson, of the Plymouth Coal Co., a decrease of 128 days and seven hours. Part of this loss in the case of the Dodson, however, was caused by the fire in the Red Ash vein, which laid the mine idle from Dec. 12 to the end of the year.

PENNSYLVANIA

Anthracite

Wilkes-Barre—About 3000 employees of the Henry and Prospect Collieries of the Lehigh Valley Coal Co. went on strike, Jan. 17, because 600 workmen at the mines refused to join the union.

On Jan. 1, it was shown that several men had refused to comply with the demands of the unionists, and a canvass was made of the colliery, following which the men decided to strike. The men, however, returned to work the next morning, and appointed a committee to confer with the colliery and company officials.

Bituminous

Butler—The miners at the Cunningham coal mine went on strike recently, but enough men were found so that the mine did not lose much time.

Connellsville—Baltimore, Philadelphia, Atlanta and Toledo capitalists recently inspected the mines of the Buffalo Creek Coal & Coke Co., in Logan County, West Virginia. The company owns 6600 acres of coal and operates five openings, with a daily output of 1500 tons.

Kittanning—The bridge of the Pittsburg, Shawmut & Northern R.R. which crosses the Allegheny River about 7½ miles above Kittanning, was washed out on Jan. 8. This cuts off all connection between the mines of the Allegheny River Mining Co. on the west bank of the Allegheny with the main line of the railroad. The bridge was only partially completed when the flood came. The center span of the bridge was 400 ft. long.

Pittsburgh—An expenditure of $500,000 for the buildings of the Bureau of Mines, located in this city, is proposed by Congress. A bill appropriating $300,000 has been presented in the House.

The buildings are to occupy the new Magee site, near the University of Pittsburgh. This site is being transferred to the Government in exchange for the Arsenal property, in Lawrenceville.

WEST VIRGINIA

Moundsville—It was expected that the Panama mine, operated by the Ben Franklin Coal Co., would resume work Jan. 13. The high water still covers the low ground about the mine. It is said that the company has considerable work to do on the new machinery, which has just been placed at the mine. The management is taking advantage of the shutdown to get this work done.

The Fort Pitt mine, across the river, which closed down on account of the proximity of the water to the airshaft, was expected to resume work at the same time.

KENTUCKY

Louisville—During the past week the 40-ft. stage of the Ohio River at Louisville has caused considerable embarrassment to the Monongahela River Consolidated Coal & Coke Co. For several days the offices have been accessible only by means of skiffs, and deliveries have been, of course, impossible. In view of the weather, however, which has kept the domestic demand down to the absolutely irreducible minimum, the inconvenience has not been great.

OHIO

Columbus—Columbus shippers are very much interested in the recent ruling of the Interstate Commerce Commission establishing a rate of $1 from the Thacker and Konova fields of West Virginia to destinations in Ohio. This means that there will be competition against Ohio coal for domestic consumption in Ohio.

The 50,000 miners in the Buckeye State through the state organization will petition the Ohio General Assembly to appropriate $10,000 for the purchase and equipment of a mine rescue car modeled after the Federal car. The state mine department has safety appliances, and it is proposed to install them on the car.

INDIANA

Diamond—The McClellan coal mine No. 9, which has been in operation with fair production for the past 12 years, will be discontinued within a few days on account of excessive water, defective pipes, machinery, etc. Pillars, tools and machinery are now being removed.

The last of this month the Zellar mine No. 5, which has been running night and day, will also discontinue. With the closing of these mines a great many miners will move their families to Bunsen and West Terre Haute, where extensive collieries are being built.

Clinton—Six mines in this field resumed work, Jan. 16, following a shutdown of a week. The cause of the strike was an assessment of $1, which was levied on each man who remained away from work because the miners' train was late. The mines involved were the two Miami mines, the Jackson Hill mine and the Dering mines Nos. 5, 6 and 8. All are located on the south switch of the Chicago & Eastern Illinois R.R. The grievance is to be taken up, through the district officers.

Indianapolis—A bill to legalize the taxation of minerals in Indiana has been introduced in the state legislature by C. H. Bedwell, representative from Sullivan County. The bill was introduced because of a recent ruling of the Indiana Appellate Court that mineral is not taxable. The passage of such a measure will mean thousands of dollars annually to the coal counties of the state of Indiana.

Bills have also been introduced for the weekly payment of miners and the separation of coal inlaid and apart from real estate for assessment and taxation.

ILLINOIS

Peoria—On Jan. 16, three men were killed by a premature explosion in the Crescent coal mine, six miles west of Peoria. The explosion let down tons of earth and débris upon the men. Their bodies have been recovered.

PERSONALS

Walter Finley has resigned as general manager of the R. O. Campbell Coal Co., which operates several mines in the Eastern Tennessee field.

O. L. Stearnes has been elected president of the Tri-State Power & Milling Co. Mr. Stearnes is also a promoter of the Appalachian Power Co., of Virginia.

Governor McCreary, of Kentucky, has appointed Henry S. Sizemore, of Hopkins County, assistant state mine inspector, succeeding W. B. Brasher, who recently died.

C. J. Johnson, of Electon, Ala., has resigned his position as assistant superintendent of the Blocton Coal Mine Division of the Tennessee Coal, Iron & R.R. Co. His successor has not been appointed.

Neil McHugh, foreman at the Courtdale Colliery of the Kingston Coal Co., has been made superintendent at the Hadleigh Colliery of the Pittston Coal Co. at Sugar Notch. His successor has not yet been named by the Kingston Coal Co.

Andy Beveridge has resigned his position with the Western Coal Mining Co., with whom he has been connected for the past 35 years. For the past several years Mr. Beveridge has been superintendent of the company's plant at Jenny Lind.

Charles A. Frisbie, of Boston Hill, outside foreman at No. 2 D. & H. Colliery, has been promoted to the general outside superintendency of the company's collieries of the Hudson Division, at Scranton, to succeed the late John Bowers. He will be succeeded at No. 2 by William Steevers, of the Boston Colliery.

Harrison S. Matthews, formerly of Birmingham, Ala., and for some time previous to the receivership of the Alabama Consolidated Coal & Iron Co., vice-president and general manager of that company, has been appointed vice-president and general manager of the Western Steel Co., with headquarters at Seattle, Wash., and has gone there to reside.

G. B. Burchell, formerly general manager of the Maritime Coal, Ry. & Power Co., at Joggins Mines, Nova Scotia, has opened a consulting office at 702 Canadian Building, Montreal, Canada. He expects to spend a few months in England and on the Continent. The carbo-electric plant at Chignecto, which was under his management, was described in the Dec. 7 issue of last year.

C. Dorrance, Jr., is appointed chief engineer in charge of the Mining and Mechanical Engineers' Departments, Fuel Testing and Fuel Inspection Departments, Briquetting Plant and Chemical Laboratory, of the Lehigh Coal & Navigation Co. The mining engineer, chief mechanical draftsman, chief coal inspector and chemist will report direct to him. The title of fuel engineer has been abolished.

L. E. Patton, who has for the past several years been manager of the Birmingham office of Hickman, Williams & Co., has resigned that position and organized the Southern Fuel & Iron Co. for the purpose of doing a general brokerage business. Mr. Patton has a broad acquaintance among the producers and consumers of coal and coke and will no doubt command a good volume of business. He is succeeded at Hickman, Williams & Co. by Day Williams, who has for many years been with the St. Louis office of that company.

TRADE CATALOGS

The Keystone Bulletin No. 25. The Keystone Lubricating Co., Philadelphia. This treats exclusively of the lubrication of mining machinery, with particular reference to mine cars. This pamphlet is well worthy of study by those who have lubrication troubles or excessive bills for pit-car oil. Copies mailed free on request.

The Milburn Oxy-Acetylene Welding and Cutting Apparatus. Catalog Q. November 1912. The Alexander Milburn Co., 1120-1426 West Baltimore St., Baltimore, Md. 32 pp.; 6x9 in.; describing various sizes of welding and cutting outfits and accessories. This firm also manufactures various sizes and types of acetylene lighting outfits, including miners' lamps.

OBITUARY

Edwin L. Wolford, a prominent coal operator in Linton, Ind., died at his home Jan. 14, after an illness of several months. Mr. Wolford was president and general manager of the United Fourth Vein Coal Co., which operates in the Linton field. He is survived by a wife, daughter and three sons.

PUBLICATIONS RECEIVED

TWENTY-FIFTH ANNUAL REPORT OF THE BUREAU OF MINES, MINING AND MINE INSPECTION OF THE STATE OF MISSOURI FOR THE YEAR ENDNG DEC. 31, 1912. By Geo. Bartholomaeus, secretary of the bureau. Cloth, 6x9 in.; 160 pages; one illustration, 20 tables.

The report is replete with much information and valuable statistics relating to the production of coal and improvements in the coal mines of the state. There are three lead and zinc mine inspectors. The coal mine inspectors are: Robert Richards, Bevier; Michael Gavin, Lexington; appointed respectively Apr. 15 and Feb. 15, 1909.

STATE OF TENNESSEE, TWENTY-FIRST ANNUAL REPORT OF THE MINING DEPARTMENT. By Geo. E. Sylvester, chief mine inspector, Nashville, Tenn. Cloth, 6x9 in.; 177 pages.

This report contains a number of tables and useful information and is worthy of special attention. Following a full account of the Briceville disaster, Dec. 9, 1911, at the Knoxville Iron Co.'s Cross-Mountain mine No. 1, the report gives valuable suggestions as to the causes and prevention of mine explosions, and devotes several pages to the discussion of gas and dust in relation to explosions. The use of steam, water sprays and salt are fully discussed, together with the application of stone dust and the need of loading out the dust accumulating in the mine workings. The report further treats the subjects of mine fires, mine laws, permissible explosives and first aid in mine rescue work. Following these are full statistics relating to the production of coal in the state and a description of the coal mines.

RECENT COAL AND COKE PATENTS

Coaling Device. C. C. Leftwich, Council, Va. 1,040,703, Oct. 8, 1912. Filed June 7, 1911. Serial No. 631,772.

Ore Screen. C. O. Michaelson, Omaha, Neb. 1,040,251, Oct. 1, 1912. Filed May 20, 1911. Serial No. 628,574.

Coal-borlng Bit. With renewable cutters and auxiliary bit. George A. Moss, Plymouth, Penn. 1,040,383, Oct. 8, 1912.

Ore Bin Door. Oliver H. Dickerson, Duluth, Minn. 1,041,444, Oct. 15, 1912. Filed April 17, 1911. Serial No. 621,633.

Coal Separator. D. J. Middleton, R. M. Keefer and J. F. Ballamy. 1,040,374, Oct. 8, 1912. Filed Sept. 28, 1911. Serial No. 651,839.

Regenerative Coke Oven. Arthur Gohmann, Stettin, Germany. 1,041,457, Oct. 15, 1912. Filed Nov. 15, 1910. Serial No. 592,476.

Gas Producer. F. Merian, assignor to Forter Miller Co., Pittsburgh, Penn. 1,040,723, Oct. 8, 1912. Filed March 14, 1911. Serial No. 614,477.

Method of Making Hot Producer Gas. Emil Fleischer, Dresden-Alstadt, Germany. 1,041,058, Oct. 15, 1912. Filed Oct. 26, 1910. Serial No. 589,178.

Method of Mining Coal. J. H. Hoadley, New York City and W. H. Knight, Portsmouth, R. I. 1,040,679, Oct. 8, 1912. Filed Dec. 9, 1910. Serial No. 596,495.

CONSTRUCTION NEWS

Great Falls, Mont.—It is expected that in the early spring the Milwaukee R.R. will commence work on the survey for their proposed spur into Everson County, from Denton. The object of the spur is said to be to tap the coal deposits in the Everson field.

Danville, Ill.—The Bunsen Coal Co. is preparing to open a new mine on its property south of Danville. This mine will be the largest and best equipped of any colliery in the middle West. It is also stated that the new shaft will employ more than 600 men, when working at full capacity.

Bluefield, W. Va.—It has been learned that work has again been commenced on the survey for the tunnel of the Norfolk & Western through the Elkhorn mountain. When completed, the tunnel will be about three miles long and its grade almost level. The construction work will require about three years' time.

Holt, Ala.—The Central Iron Co., which has a blast furnace, pipe works and byproduct plant at Holt has broken ground for the erection of 20 additional ovens, thereby increasing the capacity 50 per cent. These ovens are of the Semet-Solvay type.

The Central company has recently completed a blast furnace at a cost of $325,000.

Youngstown, Ohio—It has been announced officially by the Republic Iron & Steel Co. that the new coking plant of the company would be built on 15 acres of land which the company has purchased between the Canfield branch of the Pennsylvania R.R. and Lake Erie & Eastern right of way. The contract for the ovens has already been placed with the H. Koppers Co., of Chicago. The new plant will have a capacity of 1000 tons of coke.

Portland, Ore.—The coal fields in Coos County, in the vicinity of Marshfield, will see active development during the coming summer. Considerable work is already under way and the scope will be enlarged with more seasonable weather. C. A. Smith, who is extensively interested in the manufacture of lumber on Coos Bay, is opening up a new mine on Isthmus Inlet, near Marshfield. A short spur has already been built from the Southern Pacific R.R., from Marshfield to Myrtle Point, and machinery for the mine will be hauled in soon. An electric haulage and lighting system will be installed.

From Coos Bay comes also the report that the old Beaver Hill mine of the Southern Pacific Co. is working on a new shaft and should be in good shipping condition the coming summer. This mine has shipped coal to Portland by steamer for several years, but the output has been rather limited.

NEW INCORPORATIONS

Coshocton, Ohio—The Dailey Cannel Coal Co.; capital stock, $25,000; to mine and deal in coal.

Cleveland, Ohio—The Midway Mining Co.; capital stock, $80,000; mining and marketing coal and clay.

Knoxville, Tenn.—The Hickory Coal Co.; capital, $30,000. Incorporators, N. S. Jenkins, Charles Jenkins, Brown Prosser and others.

Columbus, Ohio—The Burr Oak Coal Co.; capital stock, $35,000. Incorporators, Harry D. Shepard, Scott Dentol, Ulysses D. Beard.

Birmingham, Ala.—The Drennan Land Co.; capital stock, $100,000; to do a general land business and also mining coal and other minerals.

Page, N. D.—The Fargo Lumber & Coal Co.; capital stock, $25,000; filed Dec. 31. Incorporators, M. W. Murphy, E. F. Murphy and M. J. Murphy.

Waukegan, Mich.—Waukegan Lumber & Coal Co.; capital, $35,000; dealing in fuel and building materials. Incorporators, T. G. McGay, D. Q. Harts, J. D. Pope.

Topeka, Kan.—The Cherokee-Girard Coal Co.; capital, $30,000. Incorporators, O. S. Hubert, J. E. McFarland, O. E. Griffin, M. G. Slawson and J. O. Majors.

Trenton, N. J.—The Burns Bros. Co.; capital, $7,500,000. This is a consolidation of the coal companies known as the Burns Bros. Co., and the Curtis-Blaisdell Co.

Powhatan, W. Va.—Tierney Mining Co.; capital stock, $150,000; development of coal lands. Incorporators, E. M. Bush and E. V. Townsend, of Huntington, W. Va.

Salt Lake City, Utah—Articles of incorporation of the Ketchum Coal Co. A. T. Miller is president; F. A. Ketchum, vice president, and G. S. Payne, secretary and treasurer.

Fairmont, W. Va.—The Lehigh Coal Co.; capital stock, $150,000; mining. Incorporators, R. A. Pollock, of Massillon, Ohio; Thomas Williams, B. P. Porter, David Morrison, T. and G. D. Ewert, all of Cleveland, Ohio.

Dover, Del.—The Baker Bend Mining Co.; capital stock, $500,000; to do general mining, milling and refining of ores, metals, etc. Incorporators, Louis K. Stam, Chestertown, Md.; J. G. Gray and M. B. Hawkins, Wilmington, Del.

Cincinnati, Ohio—The Mineral Products Co., of New York City; capital stock, $100,000; minerals and mineral rights. Incorporators, Howard F. Campbell, of New York; Charles H. MacDonald, C. F. Hagedom, H. C. Humphreys and T. J. Keogh, all of Chicago, Ill.

Danville, Ky.—The Abigail Mining Co.; capital, $40,000. Incorporators, George P. Crow, John S. Van Winkle, Mitchell Taylor, Thomas Lanier and Judge B. O. Stone, all of Danville. Judge B. O. Stone and J. P. Harper will have active management of the business at the mine.

INDUSTRIAL NEWS

Laurier, Wash.—W. Pfiefer has commenced work at the Laurier mine. He expects to have two shifts working soon.

Birmingham, Ala.—A miner's safety lamp, the recent invention of Thomas A. Edison, is now on exhibition in Birmingham.

East Liverpool, Ohio—The Tri-State Electric & Ry. Co. has optioned 2000 acres of coal near the Island Run mines along Little Beaver Creek.

Pennsville, Penn.—Preparations are being made to fire the 25 ovens of the Pennsville Coke Co. at its Pennsville plant. The plant has not been run for several years.

Boonville, Ind.—Mine No. 3 has been shut down for an indefinite period because of differences between the miners and operators which could not be adjusted.

Jackson, Wyo.—A 5-ft. seam of good quality coal has been struck six miles southeast of Victor, by Cliff Bros. & Co. A tunnel had been driven 125 ft. into the hill, before the find was made.

Lancaster, Penn.—C. H. Holt and Leroy H. Holt have acquired the coal, lumber, grain and feed business at Landsville, together with the real estate occupied by the business, and a dwelling of Ezra Miller.

Du Bois, Penn.—It is stated by persons in a position to know that practically all of the holdings of the New York Central in Indiana County have been optioned by the Rochester & Pittsburgh Coal & Iron Co.

Altoona, Penn.—The mine known as No. 2, at Glen Campbell, is soon to be put in operation by Eastern capitalists. The workings were recently abandoned by the Irish Brothers Coal Mining Co., and sold with land adjoining.

Birmingham, Ala.—The Pratt Consolidated Coal Co. has begun to ship the 40,000-ton coke contract which it has made with the steel works at Monterey, Mex. The contract calls for the delivery of about 6000 tons a month.

Cleveland, Ohio—The coal men of Cleveland are getting busy and have taken options on some tonnage for Milwaukee in addition to covering a block of something more than a million tons, at 30c., for the head of Lake Superior.

Waynesburg, Penn.—W. H. Brown, of Pittsburgh, has purchased a tract of 1325 acres of coal land in Monongahela Township, from J. V. Thompson and associates, of Uniontown. It is reported that $800 an acre was paid for the land.

Sidney, N. S., Can.—The Nova Scotia Steel & Coal Co. has decided to open a new colliery at the Sidney mines. This brings the total plants of the company up to six, and increases the output from 850,000 to 1,000,000 tons annually.

Pottsville, Penn.—Weston, Dodson & Co., Inc., with operations at Morea and Kaskawilliam, announce that they are thoroughly developing their new operation in the north Mahoney region, from which they expect to ship by next autumn.

Benham, Ky.—The Wisconsin Steel Co., controlled by the International Harvester Co., has a million-dollar coke plant at Benham. This company operates the largest battery of ovens in that neighborhood, and ships its product to northern plants.

The Wallsend plant of the Continental Coal Corporation has recently begun operations. Ovens are also in blast in Pike County, in the Elkhorn district and elsewhere.

Rural Valley, Penn.—Colliery No. 2 of the Irish Bros. Coal Co., which has been abandoned for some time, is to resume operations under a different management. Considerable coal land has been bought in the vicinity recently, which will be developed in the near future.

Connellsville, Penn.—F. M. Coursin, representing a syndicate of Pittsburgh men, has purchased a tract of 2500 acres of coal in Washington County. The prices range from $200 to $300 an acre and the total sum involved is said to be in the neighborhood of $500,000.

Cumberland, Md.—The new steel coal tipple of the B. & O. R.R. in South Cumberland, has been completed, and was tested yesterday. By the aid of this modern tipple, one of the large engines was given its usual quantity of coal in exactly 32 seconds.

Butler, Penn.—There is a rumor that the Buffalo & Rochester Iron Co. will take over the coal interests held at present in Indiana County by the New York Central Road. It is expected that this will mean greater activity in the Indiana County field than ever before.

Bluefield, W. Va.—The Electric Transmission Co. has let contracts for buildings, electric machinery, boilers, etc., for the erection of a power plant at the mouth of the Lee County mines. These units represent an expenditure of $300,000. It is expected that the work will be completed by June.

Birmingham, Ala.—Eastern capitalists will soon undertake big coal development in the Birmingham district. The Panama Coal & Iron Co. has added to its holdings until now its total acreage has reached 35,000. The company already has contracts for a daily shipment of 2000 tons to South America.

Windber, Penn.—The Berwind-White Coal Mining Co. is planning several big improvements in its operating plant at Windber this year. Among these is the installation of a new turbine, at the central power house at mine No. 5, together with the addition of four boilers of the same capacity as those now in use.

Moundsville, W. Va.—The Wheeling Coal & Coke Co. has turned over the lease of 1000 acres of coal in Clay district to the Ben Franklin Coal Co. The minimum royalty is to be $12,000 per annum. The tract in question is that which is held in connection with the Panama mine.

Lock Haven, Penn.—Thirty-eight electric companies, in the counties of Lehigh and Northampton, in the anthracite region, have been authorized to combine and merge into the Lehigh Navigation Electric Co., a subsidiary of the Lehigh Coal & Navigation Co. This combination started through a plan to utilize the culm piles of the coal company.

Jenkins, Ky.—The different mines of the Consolidation Coal Co. are shipping an average of from 12 to 18 cars of coal a day and it is said this output will be practically doubled in the next few months. Coal from the McRoberts mines over the new extension of the Lexington & Eastern is now moving at a lively rate, three of the six mines being busy.

Louisville, Ky.—It is understood that both the Chesapeake & Ohio and the Norfolk & Western railways are in the market for coal cars, the former for 2000 of 70-ton capacity and the latter for 1250, of capacity not known as yet. The additional Chesapeake & Ohio equipment will give a better car supply for tidewater, as these cars cannot go west of Cincinnati or off their own lines.

Whitesburg, Ky.—The Berwind coal interests, operating the Pond Creek Coal Co.'s plants, at McVeight, are spending large sums of money in development work and the outlook is exceptionally bright in that locality for the new year. This plant is reached by the branch of the Norfolk & Western running out from Williamson, W. Va. Other plants in this field are showing unusual activity.

Boonville, Ind.—J. T. Blair, representing a Chicago coal firm, has taken options on 1200 acres of coal land for stripping purposes. He claims to be able to put the coal aboard cars for 35c. a ton. It is reported that the new company has an option on the coal lands of Dr. T. D. Scales, a prominent Democratic politician and coal operator of southern Indiana, in which the consideration is placed at $70,000.

McRoberts, Ky.—The Consolidation Coal Co.'s developments, on Wright's Fork, in the newest section of the Harlan field, have reached a point where its daily shipments over the Lexington & Eastern amount to from 20 to 30 cars. Four out of the company's seven mines are supplying this amount, and when the other three begin shipping the daily shipments of the company are expected to reach an average somewhere between 75 and 100 cars.

Louisville, Ky.—The proposed consolidation of the mines in Muhlenburg and Ohio Counties, in the western Kentucky district, appears to be considerably closer to consummation than was at first supposed. Reports from that section indicate that the representatives of the Du Pont interests on the ground are having considerable success in obtaining options on the properties desired, and it is said that a very short time will see the completion of the deal. If the plan succeeds, the holding company, which will be known as the Du Pont Coal Co., will control the greater portion of the entire output of western Kentucky, inasmuch as Muhlenberg County has for some years past produced more coal than any other county in that part of the state.

COAL TRADE REVIEWS

GENERAL REVIEW

The premiums on anthracite are gradually disappearing and the snappy condition of the trade has undoubtedly given way to what may be considered a slump. Because of the unseasonable weather conditions, and the fact that the summer reduction in the circular is now only about two months off, dealers are becoming decidedly cautious about acquiring new stocks. Consumers are certainly displaying a marked lack of interest in the trade and dealers are beginning to fear that the customary dull period in March, prefacing the April reduction in quotations, will find them overstocked. Some contracts are being renewed at last year's figures. Coastwise shipping has been interfered with by the heavy gales, and, as a consequence, loading has been rather slow.

The first break in a long time on bituminous, occurred during the past week, and there has been a generally receding market, with prices weak and materially off. While there is still a shortage in some few quarters, good-sized tonnages are being offered and large corporations are now buying at lower figures; shippers not only have free coal for sale, but are actively canvassing for buyers. The open winter has been decidedly unfavorable to consumption and operators are coming nearer meeting their contract obligations.

The floods in the Pittsburgh district have interfered with the manufacturing consumption, the mild weather has curtailed the domestic demand, and the prompt market is now quotable at only a little above the contract circular; the river mines are still idle, although they are slowly getting in operation again. However, there is a strong natural consumption, which, together with the delays in transportation, has made the accumulation of an over-supply out of the question.

The high temperatures have affected a falling off in the Ohio market, where prices are lower than at any time during the past five months, particularly on domestic, the steam grades still being fairly strong. It is entirely a weather market and it is believed that consumers have been buying in excess of their requirements for the past 60 days or more. There is a downward tendency in quotations at Hampton Roads, due to the unexpectedly heavy loading at the mines and the diverting of Western tonnages into the Eastern markets, because of the floods. The situation in the Southern markets appears to be somewhat better, there being a fair demand and prices ruling firm; coke is particularly strong, with considerable inquiries from the Western smelters.

The Middlewestern market is weak in all branches, with the exception of steam, which is only fair. The movement on the railroads has been quite free, and considerable demurrage coal has collected on tracks at various points which cannot be moved. The delayed winter has had disastrous results on this market.

BOSTON, MASS.

The week has shown a generally receding market and prices are off materially in bituminous. The Hampton Roads shippers have eased their situation so much that some of them now have coal for sale, and not only that, but are actively looking for orders. The Pennsylvania grades have sagged in consequence, and the continued mild weather and the abundant supply of water power through New England are reducing consumption to the minimum for January. There is still a shortage in many quarters, but the demand is by no means insistent and there is quite a volume of coal being offered at the various distributing points. The big corporations are still buying, but at much lower figures than a week ago. A drop of 40c. about measures the scaling down of the different grades of bituminous for consignment to this section.

Already there are signs of the approaching contract season. It is rumored that $2.85 f.o.b. Hampton Roads, is to be the initial figure for Pocahontas and New River for shipment prior to Oct. 1, and it will be interesting to see how well it carries out. The top contract price in 1912 was $2.70, but by far the most of the business was closed at $2.50@2.60; $2.85 would net $1.45 at the mines, less the selling commission.

All-rail there is much less speculative coal offering. The movement on contract seems to be fairly regular, except where there are restrictions as to kinds of cars. Some of the Pennsylvania districts have suffered from floods and empty cars in transit have been appropriated more or less by connecting lines. The Georges Creek situation is practically unchanged. Shipments are few and far between, and distributors at this end are hard to put to it to keep contractors going. In many cases they have had to admit their inability to do so, and all manner of expedients is being resorted to. Coal from Somerset County, Penn., and from West Virginia is being freely shipped to take care of Georges Creek orders.

The premium market on anthracite seems to be fading away. On rail shipments at least, egg size is quoted at only 10c. over the regular company circular and the slackness of the retail demand has about eliminated fancy-priced coal for the present. Coastwise conditions have been unfavorable of late, and gales have been the steady thing for a week or ten days. Loading continues slow and most of the dealers are getting only enough to keep them in business. There begins to be an accumulation of egg and chestnut in some places, but retailers are still taking these sizes in their eagerness to get stove and pea. It will be a long time before shipments have caught up, although at this end things are apparently easier than at any time since September.

Current wholesale prices are about as follows:

Clearfields, f.o.b. mine	$1.55@$1.85
Clearfields, f.o.b. Philadelphia	2.80@ 3.10
Clearfields, f.o.b. New York	3.15@ 3.40
Somersets, f.o.b. mine	1.70@ 1.95
Somersets, f.o.b. Philadelphia	2.95@ 3.20
Pocahontas, New River, f.o.b. Hampton Roads	3.15@ 3.35
Pocahontas, New River, on cars Providence	4.30@ 4.50
Pocahontas, New River, on cars Boston	4.40@ 4.50

NEW YORK

Anthracite—The past week has witnessed a still further easing off of the hard-coal situation here and it has now reached such a stage that the large companies are beginning to receive cancellations on certain grades. The weather conditions have certainly been most favorable to the hard-coal companies, in view of the shortage of some six million tons in production. The season is now so far advanced, that even the most abnormal weather conditions could not cause any great distress before spring.

As a matter of fact, the operators would like to see a little more activity in the market. With the reduced summer circular going into effect Apr. 1, requisitions for fuel during March are naturally cut to the lowest point possible, so that dealers have now only about one month left in which to dispose of the comparatively high-priced stocks on hand. However, it seems reasonable to believe that the next 30 days will develop some more seasonable weather. The mines are reported as working good, and the car supply is fair and all that is to be expected for this period of the year.

We quote New York prices on both hard and soft coal on the following basis:

	Anthracite		Bituminous	
	Circular	Individual		
Broken*	$5.50	$5.00@5.10	West Virginia, steam	$3.05@3.25
Chestnut†	5.50	6.00@6.15	Fair grades, Penna.	3.15@3.25
Pea*	2.75	3.75@4.35	Good grade, Penna.	3.30@3.40
Buckwheat**	2.75	2.75@2.80	Best miller, Penna.	3.40@3.50
Buckwheat†	2.50	2.40@2.50	Georges Creek	3.50
Rice**	2.25	2.25@2.30		
Rice†	1.95	1.85@1.95		
Barley†	1.75	1.25@1.50		

* Scranton and Lehigh. ** Scranton. † Lehigh and Schuylkill.

Bituminous—For the first time in over a month, there has been a slight break in the soft-coal market. While the effects of this are not yet very clearly felt at tidewater, it is, nevertheless, a fact that concessions under last week's quotations are now readily obtainable in the mining region. This applies more particularly to the lower grades and it is doubtful if the quotations on the better qualities have suffered in any way as yet. While free tonnages are obtainable at the mines, some of the large operators are quite short on their contracts at tidewater.

It is still essentially a weather market, and it is rather remarkable that it has held so good under the unusually unseasonable weather conditions prevailing through the fall and winter. This is only accounted for by the shortage in transportation facilities and, had the weather conditions been as normally, there would have been a heavy shortage at this point accompanied by the usual spectacular market.

Floods in the Pennsylvania district have handicapped operations somewhat, but not seriously. The car supply has been rather inadequate, but there is a fair amount of labor available, and, on the whole, production has been good in the region.

PHILADELPHIA, PENN.

The same unseasonable weather still continues in this vicinity, and as a consequence, there has been a decided falling off in the demand for anthracite. Egg coal is a drug on the market, and while it is understood the large companies are moving off their product, it must be in other directions. The snappy condition of the trade has undoubtedly given way to what might be almost considered a slump. Stove and pea seem to be the only sizes for which there is any demand at all; egg and chestnut cancellations are coming in thick.

It is now simply a question of the weather conditions. It is a fact, nevertheless, that the dealers are not well stocked with any particular sizes, although orders are being filled fairly promptly, that is, for stove and pea, but any sudden cold spell would be likely to bring about a sudden strengthening in the situation. The uncertainty of the weather, however, is causing the dealers to be cautious about laying in stocks of coal that they are likely to be caught with during the month of March, when the trade, as a rule, is rather stagnant.

Prices still remain at the same level, at retail, $6.75 for egg, $7 for stove, $7.25 for chestnut and $5.50 for pea. It is understood that the parties who contract for their fuel requirements at this season of the year, are, as a rule, renewing their arrangements for the ensuing year. The same prices prevailing last year are in effect, with the exception of pea, on which there has been an advance in the contract price of 50c. per ton; the price of this coal has made it practically out of reach of the majority of steam users, and most if not all of this demand has been diverted onto buckwheat, which is $1 per ton less. Pea coal is becoming, more and more a domestic fuel in this market, and the demand far exceeds the supply during most of the winter months.

PITTSBURGH, PENN.

Bituminous—River mines, which were closed on account of high water are still idle, although partial resumptions are occurring this week. The car supply is better, railroads being aided by unusually good January weather. Floods have seriously affected manufacturing operations along the rivers and have somewhat decreased coal consumption, while on account of mild weather the domestic demand is limited. Prompt coal has declined with these conditions and is quotable at but little above regular contract prices, which are well maintained as follows: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in., $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—The market has been uneventful. There has been practically no contract business, while the spot business has been light, much lighter than was expected. Practically the entire production is going out on contracts and little prompt coke is available, so that prices for this have not declined in the face of a small demand. The $4 price for prompt furnace, however, is not invariably maintained. Occasionally a consumer can buy for a shade less, while as a rule a dealer can shade the $4 price enough to make a comfortable brokerage, securing $4 from the consumer, which is usually obtainable. Foundry coke for prompt shipment is not closely quotable for the reason that there is little if any really standard foundry coke available in the prompt market. Foundries caught short must usually be content with furnace coke, sometimes selected and sometimes not, and frequently shipped in open cars. The mere shipment in box cars raises the price to $4.25 or even $4.50. We quote: Prompt furnace, $4; contract furnace (nominal), first half, $3.25@3.50; year, $3@3.25; prompt foundry, $4.25@4.75; contract foundry, $3.25@3.75.

BALTIMORE, MD.

Prevailing open-weather conditions tended to create an easier market in Baltimore during the past week, although one or two of the larger operators reported that they experienced no falling off in the demand. Prices, however, declined from 10 to 15c.; one firm was offering coal at $1.75 and appeared to have plenty on hand to meet all demands.

Local consumers appear totally indifferent to the market, realizing perhaps that weather conditions are such as to permit them to purchase in any quantities desired at a reasonable price. There was practically no spot business during the week.

The car supply appears to be adequate, the train movements are excellent and contract obligations are being carefully met. The output of the mines is also increasing, as the miners are rapidly getting back to work again.

There has been considerable activity at the local coal piers, and at least a half-dozen vessels will load here during the next ten days.

The anthracite trade is feeling the effects of the most remarkable weather conditions experienced in this section for twenty-five or thirty years. All through the week it was too warm to keep fires going in furnaces, and practically all the fuel consumed in the households was for cooking purposes.

BUFFALO, N. Y.

The weather has been doing its best to shut off the sale of coal, but other conditions are such that a moderate degree of dullness is about all that has been accomplished. There is a big natural demand and the slow movement has made it impossible for the operators to flood the market. So far they have not been able to accumulate any great amount of coal at any point and the consumer has to look for his supplies or he does not get them.

With the weather as favorable to freight movements as it could possibly be at this time of the year, and with the rush in the grain business out of the way, there is about as great a shortage of coal cars as ever. The consumption also promises to keep up as business is paying next to no attention to politics. Bituminous quotations will therefore remain rather weak at $3 for Pittsburgh select lump, $2.85 for three-quarter, $2.75 for mine-run and $2.50 for slack, with Allegheny Valley about 25c. less. The coke market holds fairly strong, the high prices remaining on account of the production about reaching its limit of late. Prices f.o.b. Buffalo are still on a basis of $6.25 for best Connellsville foundry.

There is still much water to contend with in the mining districts of the Allegheny Valley and beyond, but at present only the convenience of working certain mines is affected. The running of trains has not been interferred with for a week or more.

The anthracite shippers are getting some orders to hold or cancel former shipping directions but they are not disturbed. A single day of really cold weather would restore the demand in full. Egg coal is plenty and premiums on independent anthracite are down to 75c. on chestnut and $1 on stove.

COLUMBUS, OHIO

With high temperatures prevailing lately, weakness has developed in the domestic trade and prices are much lower than in months; in fact the past week saw the first real easing off in quotations for five months. Domestic lump and ¾-in. are particularly heavy, and the other grades have declined in sympathy with these. Retailers have unusually large stocks on hands, and as a result are not in the market at this time.

Steam business is still the strongest point in the trade. Manufacturing establishments, especially those engaged in the iron and steel industries, and the railroads are taking a large tonnage, while prices are being fairly well maintained. Renewing of fuel contracts is slow as few of them expire at this time.

The car supply is now about all that could be desired. Output in the various mining districts has been curtailed, not by a lack of cars, but rather because of a slack demand. Eastern Ohio is about the only section that reports any trouble over the supply of equipment. The Hocking Valley is well fixed and as a result, production in that district has been about 75 per cent. of normal. Eastern Ohio has produced about 65 per cent., but Pomeroy Bend's output was curtailed by the high waters which flooded a number of mines in that section. West Virginia competition was shut off, a portion of the past week, by the high waters. Both the C. & O. and the K. & M. were unable to run trains from the West Virginia fields to the Ohio side.

While the weather has been unfavorable to an active coal trade in Ohio, still the movement has been good in most lines and prices remain fairly strong. The worst feature of the trade is the growing softness in the domestic lines. This is due to the mild weather which has been prevailing and makes the retail trade rather quiet. The car supply is slightly improved and this aids the operators and jobbers to move cargoes more promptly

This softening, however, has not gone far enough to cause any decline in quotations, excepting the usual shading which is done at all times. The circular which has been in effect since Dec. 1 is pretty well maintained and complaints of price cutting are few and unimportant.

Quotations in Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1 85	...	$2 00	$1 65
¾-inch	1 65	$1 30	1 75	1 40
Nut	1 35		1 75	
Mine-run	1 35	1 15	1 25	1 25
Nut, pea and slack	1 15	...	1 25	1 10
Coarse slack	1 05	1 15	1 10	1 00

CLEVELAND, OHIO

The situation in the coal trade here is largely a weather proposition. Producers and shippers are convinced that consumers have purchased coal in excess of their requirements for the past 60 days. Buyers are fairly well fortified against a scarcity of fuel and in many cases have suspended shipments temporarily. Slack which is the ruling factor on the Cleveland market has weakened to the extent of 10c. a ton.

Quotations per net ton f.o.b. mines are as follows:

District	Freight Rate	¾-in.	Mine Run	Slack
Youghiogheny	$1 00	$1 35	$1 25	$1 05
Pittsburgh No. 8	0 90	1 20	1 10	1 05
Goshen No. 6	0 70	1 35	1 25	1 20
Coshocton	0 70	1 75	1 50	1 10

Hocking Lump which was sold at $2 in the early fall has dropped to $1.60 at the mines. Pocahontas lump and egg is quoted at $2.50, run-of-mine, $1.35, and slack, 90c. Massillon lump is going $2.50 at the mines. Prices on coke are steady at about $3.50 f.o.b. ovens for contract and $4 for spot furnace with about 50c. added for foundry grades. Production in Jefferson and Belmont Counties is at an abnormally low ebb, the high water in the rivers and tributary streams having lessened the output of the mines and tied up railroad traffic.

It will be late in the season before the Lake fleet can get coal to the docks if the mines shut down for any length of time in April, 1914. Dock companies expect to be prepared for a suspension then by carrying the maximum capacity of coal on upper lake docks at the close of 1913 season. To accomplish this a large volume of bituminous and anthracite will be shipped via the Great Lakes this year.

The following letter, signed by C. W. Galloway, general manager of the Baltimore & Ohio R.R. was mailed to all mine operators recently: "The movement of freight tonnage throughout the United States is the heaviest known. On account of the extreme car shortage it is necessary that greater efficiency than ever before be secured from freight equipment. Careful checks of cars received from mines underloaded with coal, have shown that equipment is not being loaded to its full physical carrying capacity. Will you not kindly coöperate with us by loading cars to full limit. Every ten cars so loaded means a car saved."

HAMPTON ROADS, VA.

Prices of New River-Pocahontas coal have had a downward tendency during the past week owing to the warm weather, the unexpectedly heavy loading at the mines and partly to the diversion of considerable Kanawha gas and splint coals from the West to tidewater. This latter was due to the interruption to westbound traffic by the collapse of a bridge over the Guyandotte River, on the Chesapeake & Ohio Ry., near Huntington, West Virginia.

The New England market seems to be taking no coal except for contract requirements and but few spot sales have been made. $3.15@3.25 f.o.b Hampton Roads, is about the ruling price at present and sales have been made at both those figures. A cargo (5000 tons) of Kanawha coal was sold for New England at $3, but this grade is now offered at $2.82.

The car supply at the mines has been somewhat better than during the past ten days, which may be ascribed naturally to the light loading during the holidays and also to the better movement by the railroads The Virginian Ry. has been doing exceptionally well in this respect; on Jan. 10, some 410 cars were loaded, the heaviest day's loading they have ever had.

A new harmony movement was started by this road last week when all representatives of coal sales agencies at Norfolk, were invited to luncheon by the company to discuss various questions of handling their coal at tidewater. It is proposed to have similar meetings once every month, a plan that might advantageously be followed by the other railroads.

The United States Navy has recently closed contracts for the next six months' supplies of New River-Pocahontas coals at $3 per gross ton f.o.b. Hampton Roads, an advance of 30c. over last year's price. The export and bunkering business continues fairly heavy, the respective tonnages for the week being 58,832 and 9929 tons.

LOUISVILLE, KY.

The unusually mild weather which is again prevailing, is another cause for the present slow market. While this factor does not enter to a great extent into the demand for steam grades, it is responsible for a rapid movement, which would be impossible even in normal winter weather. Heavy rains and resulting floods throughout the state have done some damage to mining equipment, bridges and the like, and if they become such as to interfere seriously with operations the market will doubtless show a stiffer trend.

Altogether, the mines are practically at a standstill for lack of domestic orders, and while the steam demand is fairly good, the market on those grades has also dropped off to a noticeable degree. Some mines are face to face with the proposition of selling their coal at unduly low prices, or going on short time. In the absence of a season of real wintry weather, which has been almost totally lacking so far, the only thing which will operate to restrain this tendency from working a still further demoralization of the market is the closing down of some mines by the floods.

BIRMINGHAM, ALA.

There is no material change in the situation since our report of last week. There seems to be plenty of demand and good prices rule on all grades of coal. The volume of business in all lines in the South was never as large as it is at present. Recent statistics show that a smaller percentage of Alabama iron is being shipped out of the state than at any time in the history of the iron business.

The market for both foundry and furnace coke is firm. There has been considerable inquiry from the West for smelter coke, and although none of the ovens have large tonnages for nearby shipment, some business was placed with the local manufacturers.

We can quote standard furnace coke at $3.50@3.75, and foundry coke from $4@4.25, f.o.b. local ovens. Nut, domestic coke can be had in small shipments at from $2.75@3 Birmingham district.

CHICAGO

As a result of the unusual weather conditions, the Chicago coal market, in almost all branches, is weak and retail dealers are ordering little coal.

According to reports from various sources, their storage capacity is taxed to the limit on account of slack business; excepting coke, there is not a branch of the domestic trade that is not suffering from lack of business. A great deal of anthracite still remains in the hands of the dealers, many of whom are cancelling orders previously placed. On this account, the market has eased off to a considerable extent. There is practically no demand in Chicago at the present time for Hocking and splint coal. Hocking domestic lump is selling at $1.50 a ton, f.o.b. the mines, when up to car service in Chicago, with shipments in transit being quoted at $1.75.

The car supply has been much better than was expected. Shipments to market, as a rule, are free and scarcely any complaints are being registered against the railroads. The steam trade continues to be satisfactory.

Prevailing prices in Chicago are:

	Sullivan Co.	Springfield	Clinton	W Va.
4-in. lump	$2 62			
Domestic lump	...	$2 32	$2 27	...
Egg	2 52			$3.80 @ 4 05
Steam lump	...	2 12	2 17	...
Mine-run	2 07 @ 2 17	1 97	1 97	3 55 @ 3.65
Screenings	1 72 @ 1 77	1 57 @ 1 62	1 57 @ 1.62	...

Coke—Connellsville, $6.50@6.75; byproduct, egg, stove and nut, $5.75@6; gas house, $6.

DETROIT, MICH.

Bituminous—The market here is controlled entirely by the weather conditions. Prices are gradually dropping and unless there is colder weather, there will be a lot of demurrage collected for track coal that cannot be moved. The car supply is unusually good. Contract fuel is coming along more readily now so that spot coal is not monopolizing the cars; steam coal is not in much demand on the larger sizes. Slack holds very firm, although the demand is not as great as it has been. There is no demand whatever for domestic coal; all the dealers seem to be loaded to their utmost capacity and in a few cases on demurrage, it has been offered

or the freight, but was promptly refused. Every operator selling as much as possible, for almost any price that can be secured.

The following are local quotations, f.o.b. mines:

	W.Va. Splint	Gas	Hocking	Pitts. No. 8	Jackson Hill	Pocahontas
omestic lump	$1.40		$1.40		$2.00	$2.00
gg	1.40		1.40		2.00	2.00
ut	1.30		1.30			
lump	1.15	$1.15	1.10	$1.10		
ine-run	1.00	1.00	0.90	0.90		1.25
ack	1.10	1.10	1.00	1.00		1.05

Anthracite—Anthracite is coming in in large quantities, but there is still a light demand for it. However, prices remain firm and it is being quoted about 50c. per ton above circular on all sizes.

Coke—This product has taken a decided slump and there is little or no demand for it. Connellsville is being quoted at $4.25; Semet Solvay, $4.25, and gas house at $4 f.o.b. oven.

ST. LOUIS, MO.

Prices hit the bottom of the market the past week, on account of the failure of winter to put in its appearance, as had been promised. Practically every coal got down to summer prices again, with the exception of the finer grades for steam; as the domestic sizes eased off the steam grades went also.

The present week will no doubt see slightly better quotations, as weather conditions are inclined to be more favorable, and it is likely that, for the balance of the month coal will continue to gradually increase.

The demand for anthracite chestnut still exceeds the supply, and coke is very scarce, while smokeless, though strongly in demand, is very little heard of, account of the shippers not being able to furnish enough cars. All kinds of coal is moving very slowly, especially when connection has to be made to some delivering line.

The prevailing market has been:

	Carterville and Franklin Co.	Trenton and Big Muddy	Mt. Olive	Standard
n. lump				$0.95 @ 1.00
n. lump			$1.30	
n. lump	$1.30 @ 1.40		1.50	1.15 @ 1.20
mp and egg	1.40 @ 1.55	$2.00		
o. 1 nut	1.15 @ 1.25			
reenings	0.80 @ 0.90			0.55 @ 0.60
ne-run	1.10 @ 1.15			0.90 @ 1.00
o. 1 washed nut	1.50			
o. 2 washed nut	1.50			
o. 3 washed nut	1.40			
o. 4 washed nut	1.20			
o. 5 washed nut	0.85			

MINNEAPOLIS—ST. PAUL

A number of the smaller operators in this field were forced to cut prices in order to pay wages and other expenses or go under. This condition has been quite discouraging to Illinois men to say the least, as the break in Franklin County coal, which is the leader, has had a tendency to weaken all other Western coals. Carterville district is bringing from $1.50@1.75 for the best domestic grades, although some has been sold as low as $1.40. Springfield coal is selling for from $1.35@1.50 lump.

SPOKANE, WASH.

Cold weather prevailing in Spokane has caused a heavy run on the coal stocks of the city, but there is not any danger of a famine. Shipments from the east and west are being delayed by landslides, and washouts, but Canada coal is coming in and is meeting all demands. No raise in price is anticipated for some time.

	Crows Nest	Wyoming Northern	Wyoming Southern	Utah	Montana	Roslyn
mp		$6.45	$7.20	$7.20		
mp and egg					$6.35	
rnace	$6.00					
g		5.95	6.85	6.85		
ne-run	5.00					$5.00
ek	4.50					
reened domestic						6.25

PRODUCTION AND TRANSPORTATION STATISTICS

VIRGINIA RAILWAY

Total shipments of coal over this road for November of 1912 were 316,504 net tons, as compared with 338,518 for the month previous.

CONSOLIDATION COAL CO.

Production of the Consolidation company for the year to Jan. 1 last, was 10,342,000 tons, as compared with 9,210,000 for 1911, showing a gain of 1,132,000 tons. With the heavy tonnage now being obtained in the Elkhorn field, production for the current year will show a still more rapid increase.

THE CAR SITUATION

For the first time since Aug. 15 of last year the American Railway Association again reported a surplus of coal equipment on Dec. 31, the following being a comparative summary of the last six reports:

Date	Number idle (net)	Decrease	Including Box	Flat	Coal
Dec. 31, 1912	17,058	51,450	†11,018	1,330	8,087
Dec. 14	†34,392	2,009	†30,818	†816	†8,801
Nov. 30	†36,401	14,711	†33,241	†1,463	†5,179
Nov. 21	†51,112	57	†38,465	†3,217	†12,005
Nov. 7	†15,169	*1,188	†43,831	†3,613	†7,599
Oct. 24	†49,981	*18,402	†38,177	†3,837	†13,253

* Increase † Net shortage.

CONNELLSVILLE COKE

The "Courier" reports production and shipments in the Connellsville region for the week ended Jan. 18, as follows:

Production (tons)	Week	3 weeks	*Shipments (cars)*	Week	3 weeks
			Pittsburgh	4,582	13,019
Connellsville	237,289	773,735	W. of Pittsburgh	7,151	20,231
Lower Connellsv'le	192,539	549,761	E. of Region	929	2,743
Total	429,828	1,323,496	Total	12,662	35,993
Same period 1912	395,185	1,018,523		11,271	29,707

SOUTHWESTERN TONNAGE

The following is a comparative statement of the Southwestern production for July and August, 1911 and 1912:

State	July 1911	July 1912	Change	August 1911	August 1912	Change
Missouri	173,809	176,125	+2,316	186,852	213,603	+26,751
Kansas	374,137	337,367	—36,770	400,820	408,947	+8,127
Arkansas	120,790	126,224	+15,434	139,762	172,090	+32,328
Oklahoma	157,633	201,959	+44,326	257,773	232,768	—25,005
Totals	826,369	841,675	+15,306	985,207	1,027,408	+42,201

FOREIGN MARKETS

GREAT BRITAIN

Jan. 10—At present there is a strong demand for all qualities of large and small. Tonnage arrivals are substantial, and chartering is very active. Quotations are as follows (approximately):

Best Welsh steam	$4 56	Best Monmouthshires	$4 20
Best seconds	4 38	Seconds	4 08
Seconds	4 26	Best Cardiff smalls	3 48
Best dry coals	4 38	Seconds	3 12

The prices for Cardiff coals are f.o.b. Cardiff, Penarth, or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days —less 2½%.

ORIENTAL MARKETS

Japan, Nov. 28 1912—A fair amount of business has been done on this market during the past fortnight and some contracts of considerable importance have been settled on private terms, whilst there is still a certain amount of enquiry going on amongst native dealers for forward business for next year.

The coal-market in Japan is very firm and prices are ruling about 20 sen higher all round; Stocks of all grades have sunk very low at Japan shipping ports. Stocks on the spot are up to the average and prices are firm at quotations.

Manchuria—Quite a brisk business has been done and in spite of the daily output having reached 5000 tons it is all being consumed on the spot or has been contracted for export.

Kaila—Although there is a certain amount of enquiry not much actual business has been done; contractors are still holding off on the chance of a decline of freights but these appear to be as strong as ever. Stocks remain small.

Quotations remain unchanged as follows: Lump, $2.75; nut, $2.25; mine-run, $1.85; slack, $1.

SPANISH IMPORTS

Spanish imports of coal for 10 months to Oct. 31, 1912, were 1,866,627 tons, as compared with 1,724,107 tons in 1911. Coke imports for the same periods were: 287,700 and 269,842 tons, respectively.

FINANCIAL DEPARTMENT

The Pacific Coast Co.

Besides controlling the Pacific Coast Steamship Co. and several railroad companies, this corporation owns all the securities of the Pacific Coast Coal Co. This latter concern owns the Franklin mines, aggregating 3850 acres at Franklin, Wash.; the Black Diamond mine with 4670 acres at Black Diamond, Wash.; the Newcastle mine with 2520 acres at Newcastle, Wash.; and the South Prairie mine, with 1140 acres at Burnett, Wash. Company also owns coal-handling plants at Seattle, Tacoma, San Francisco, Portland, Juneau and Nome, Alaska.

During the last two years the company has paid 6% dividends on both the common and second preferred stock and 5% on the first preferred. The report for the fiscal year ending June 30, 1912, showed: Gross from steamships and colliers, $4,181,147, and net, $143,389; railroads, gross, $761,775, and net, $554,254; coal department and miscellaneous, gross, $2,553,990, and net, $388,868.

The gross earnings of all departments were $7,496,912; operating expenses and taxes, $6,410,401, making net earnings $1,086,511, to which are added $28,579 other income, bringing the total net up to $1,115,090. Interest on bonds amounted to $250,000; depreciation special reserve, $103,430; dividend on first preferred (5%), $76,250; dividend on second preferred (6%), $240,000; dividend on common (6%), $420,000. This leaves a balance surplus for the year of $25,410.

Gross earnings of the coal department amounted to $316,731; operating expenses, $214,198, making the net earnings $102,533; all these accounts show a decrease during the year. The total output of the mines was 709,262 tons, including 16,116 tons from mines under development; this shows a decrease of 28,493 tons over that of the previous year. The amount of coal sold at all depots was: From company's mines, 671,290 tons; other domestic coal, 12,129 tons, foreign coal, 68,616 tons, making a total of 752,035 tons, or a decrease of 81,769 tons below last year.

The decreased output and sales is ascribed partly to depressed business conditions and partly to the competition of California fuel oil which has been selling quite cheaply during the past year. A large number of steamers have been converted into oil burners and a number of railroads are now using fuel oil on their Pacific Coast divisions.

The Lehigh Valley Coal Co.

President E. B. Thomas, of this company, has the following remarks to make regarding the year's operations, ended June 30, 1912:

The suspension of mining operations for practically both the months of April and May, during which time the company was deprived of any revenue from its property, naturally made a serious reduction in the year's income. The agreement with the mine workers expired by limitation on the 31st day of March, and, while negotiations for a new agreement were in progress, the mines remained idle. An agreement was finally reached in the latter part of the month, which gave to the mine workers a substantial increase in wages and mining was, therefore, promptly resumed.

The total net income of the company from all sources, after deducting charges for royalties, sinking funds, improvements to the property and interest on the funded debt, amounted to $1,162,241, a decrease of $350,603, as compared with the previous year.

The total production of anthracite coal from the lands owned, leased and controlled by the Lehigh Valley Coal Co. and affiliated companies, including that mined by tenants, was 8,224,317 gross tons, a decrease of 796,889 tons, or 8.83%, as compared with the preceding year.

The percentage of sizes above pea produced by the mining operations of the company was 67.67%, an increase of 2.10%.

The bituminous coal mined from the Snow Shoe lands amounted to 280,084 gross tons, an increase of 43,154 tons.

To offset in some measure the constantly increasing cost of mining, which is every year becoming more serious, owing to the greater depth and extension of the underground workings, with the attendant increase in the length of the underground haul, heavier expense for pumping and ventilation and legislation adding directly to the cost of operation, it has been necessary to continue making substantial expenditures for improvements and betterments to the property. Expenditures for such purposes during the year, deducted from income, amounted to $487,456, an increase of $42,779 over the preceding 12 months.

By appropriate court proceedings the Locust Mountain Coal & Iron Co. has been dissolved, the charter surrendered and its capital stock, all of which was owned by your company, canceled, thus obviating the necessity of maintaining that separate corporation with its attendant expense. Prior to its dissolution, the real estate of that company, consisting of certain coal lands in Columbia, Schuylkill and Northumberland Counties, Pennsylvania, from which your company has been mining under lease for many years, together with all its personal property of every description, was conveyed to the Lehigh Valley Coal Co. for a nominal consideration.

On March 1, 1912, this company redeemed and canceled the $10,537,000 certificates of indebtedness issued in 1905 to the Lehigh Valley R.R. Co. for moneys advanced to it by that company for capital expenditures; $3,037,000 of the said certificates of indebtedness were paid off in cash and the balance, $7,500,000, was taken up by the issuance in lieu thereof to the Lehigh Valley R.R. Co. of a similar amount of 50-year debenture obligations, maturing March 1, 1962, and bearing interest at the rate of 4% per annum, payable on March 1 and Sept. 1 of each year. At the time this transaction was consummated the arrearages of interest on the certificates of indebtedness were paid to the Lehigh Valley R.R. Co. at the rate of 4% per annum. That amount of the interest which accrued prior to the present fiscal year was charged to profit and loss and the balance deducted from this year's income. In addition, the income account of this fiscal year has also been charged with the accrued interest on the debenture obligations.

There were outstanding at the close of the previous fiscal year $1,292,500 short term notes given for the acquisition of property; $200,000 of these notes have been paid off during the year, leaving $1,092,500 of such obligations outstanding at this time.

COAL SECURITIES

The following table gives the range of various active coal securities and dividends paid during the week ending Jan. 18:

Company	High	Low	Last
American Coal Products	94	94	94

Monongahela Cons. C. & C. Co.—Dividend of $3.50 on the preferred, payable Jan. 25.

COAL AGE

Vol. 3 NEW YORK, FEBRUARY 1, 1913 No. 5

Power at Coal Mines

IN the past there seems to have been a more or less general opinion that the cost of power generated and used at a colliery was so low as to be unworthy of serious consideration. This condition of affairs was probably due to the fact that the coal used for generating the steam was considered to have little or no value, because it was taken direct from the mine, and further, it is likely in many instances, that no accurate records were kept of the amount of fuel used, or the actual cost of steam generation. If it had been necessary to purchase the coal, the value of the power used would probably have been considered from an entirely different point of view.

The Delaware, Lackawanna and Western Railroad Co. is a leader in the matter of economy at colliery power plants. The modernization of the D. L. & W. stations, and the high efficiency to which this company's equipment has been brought, are due principally to the engineering skill of its electrical expert, H. M. Warren. We, therefore, commend this foreword, written for us by Mr. Warren, to every COAL AGE reader who is interested in the important problem of "Power at Coal Mines"—*Editor.*

In later years however, conditions have changed. The various costs of mining and preparing coal have, for well-known reasons, constantly increased, and as a result the value of the fuel has followed along the same lines. It is not at all surprising, therefore, that in the endeavor to check, so far as possible, the increasing cost of operation, the cost of power generation should receive its due consideration.

When the cost of steam generation is not considered of any great importance, it follows that the economy of the engines or other apparatus using steam as a motive power, can hardly be given serious consideration. As a result of this line of thought, the first cost of the equipment for generating and using steam would naturally be considered the most important item.

The old equipment, therefore, consisted of the simplest type of boilers, namely, the well-known "cylinder boiler;" steam pipe lines either bare or inadequately covered, simple engines, and pumps of the slide-valve type. This combination gave first, an extremely inefficient generating plant; second, an inefficient transmission, and third, an inefficient steam-driven equipment. The line of procedure along which improvements have been made, is approximately as follows:-

The old boilers have been eliminated, and in their place we now see modern plants containing water-tube boilers, designed with special reference to the conditions under which they must operate. The chief considerations in this connection are (1) the type and size of furnace, and (2) the selection of grates, which latter should burn the desired fuel efficiently and at a high rate of combustion. The first, in order that the water evaporated per pound of coal may be high; the second, that the capacity of the boiler may be increased as much as possible, in order to keep down the fixed charges on the equipment.

As a means of increasing the rate of combustion, it is customary to use some of the various schemes of producing forced draft, the particular method used depending upon conditions. Open type feed-water heaters raise the temperature of the feed water to approximately 210 deg., and, in some instances, economizers are used to effect a further saving, and increase the feed-water temperature to a still higher point.

In the more recent installations steam turbine-driven centrifugal boiler-feed pumps have taken the place of the feed pump of the customary direct-acting type. This change is due to the simplicity and low cost of maintenance of the centrifugal equipment, as well as

the elimination of the pulsating water pressure that may occur with a direct-acting outfit. Some few plants are provided, and others are being equipped with superheaters, as a means of increasing the economy of the steam-driven equipment, and the elimination of a large amount of condensation that is bound to occur in the various steam lines. I believe that the use of superheaters designed for a moderate degree of superheat, will receive more serious consideration for boiler plants of this kind in the future, than they have in the past.

Thus we have the generating outfit designed and installed with particular reference to the conditions under which it is to operate.

The steam lines used to transmit power are of improved construction, and particularly well protected by some good heat-insulating material. The steam-driven power equipment purchased during recent years has been of a more or less improved type, such as compound, and in some instances, triple expansion pumps and engines of the Corliss or non-releasing four-valve type, simple or compound as might be desired. The pumps and engines, where conditions warrant, are operated condensing.

For the generation of electric power, it has now become quite customary to use steam turbine-driven generators, operating condensing where possible. In a few instances exhaust steam turbine-driven generators are in use. These units generate the power from exhaust steam, which had formerly been wasted by being allowed to blow directly to the atmosphere. Where the supply of exhaust steam is intermittent, such as the exhaust of hoisting engines, some form of heat accumulator or regenerator is necessary to absorb heat, while the engines are operating, and give it up while they are at rest, acting as a sort of heat "fly-wheel." The use of this type of equipment will increase rapidly in the future.

Electric power is transmitted various distances, and used for several purposes, for which steam was formerly employed, and in addition, furnishes power for lighting and portable equipment, such as electric locomotives, coal-cutting machines, and also electrically-operated coal and rock drills.

As the object of installing efficient equipment is to produce economical results, the mere installation of such an equipment is not sufficient. It is equally important that it be kept in such condition continually as to produce the highest practical economy, and in addition, no power should be wasted. Therefore the organization should be such, and it should be someone's duty to see, that the equipment is kept up and operated in such a manner as to insure the best results. It is entirely practicable to do this, but the situation must be handled in some systematic manner, and accurate records must be kept to show the actual operating costs, including all charges, from month to month.

The boiler plant records should show the amount of water evaporated, and the coal burned per month, the cost of labor and material for operation, also the same items for maintenance. It is likewise advisable to have a constant record of the boiler feed-water temperature, and the steam pressure. The record of the water pumped into the boilers may be kept by a Venturi or some other type of recording instrument. The coal may be either weighed, or measured by passing through a coal meter.

To maintain efficiency, careful attention must be paid to the method of firing. The amount of coal in the ash must be kept at a minimum. Gas analyses and stack temperatures should be made, to see that proper combustion is taking place, and that an excessive amount of air is not entering through the boiler settings; also that the baffles of the boilers are in good shape, and do not permit the short circuiting of the gases.

Waste of steam through leaky joints or drains should be avoided, and the steam-using equipment should be kept in efficient condition. There should be a frequent inspection to see that everything is in good order, and that losses are not occurring through open drains. The equipment should be indicated to insure proper setting of the valves.

Probably one of the best, if not the best method of discovering the use of excessive amounts of steam in various equipment, is to install a steam meter in the steam line, and take indicator cards of the equipment at the same time. This will give the rate of steam combustion per indicated horse power per hour, which in a great many instances will be surprising.

Take for example, a steam line leading down a shaft. The steam meter is placed in this line, and a record obtained for 24 hours. During this period the various equipment taking steam from this line is indicated, and the number of hours of operation recorded; thus the steam consumption per i.hp. used during the 24 hours, may be obtained. Such information is more valuable than any data that can be obtained by the use of indicator cards only. With this data available, it is a comparatively easy matter to determine what should be done in order to improve conditions.

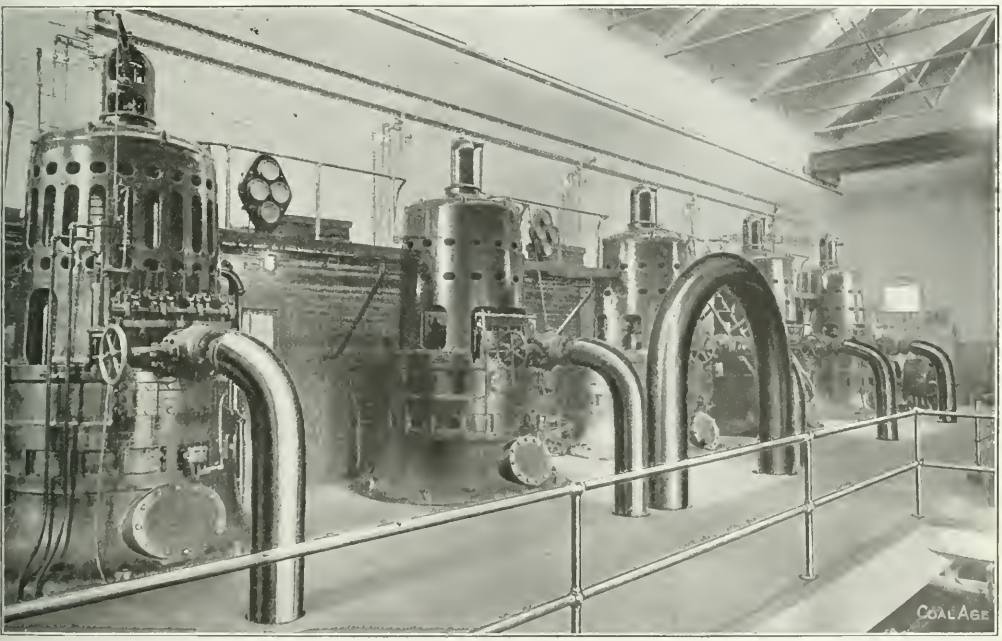
In conclusion, "Power at Collieries" is an important subject, and as such, should receive careful consideration. All equipment should be designed for the purpose intended, and each installation should be maintained so as to operate at as high an efficiency as is practicable.

A Large Anthracite Power Plant

By Frank H. Kneeland

SYNOPSIS—A plant which is neat in external appearance and efficient in operation. The boilers are all of the water-tube type, fed by centrifugal turbine-driven pumps. The prime movers of all the generating units are steam turbines operating condensing, mine water being utilized for this purpose.

In coal mining, as in many other industrial activities, two general types of power plants appear to exist. These are, first, the plant which is designed and constructed in its entirety at once, and, second, the plant which is started with few or small units, and which from time to time has been augmented and added onto until the final result is perhaps many times the magnitude of the original installation.



Interior of Power House, Showing the Vertical Turbo-generators Also Electrically Driven Exciter

Of these two, the former is usually the more efficient. In such installations the end may be clearly perceived from the beginning, and the amount of necessary material, together with the desired head room, side clearance and other circumstances conducive to the greatest possible convenience, may be readily foreseen and calculated to a nicety.

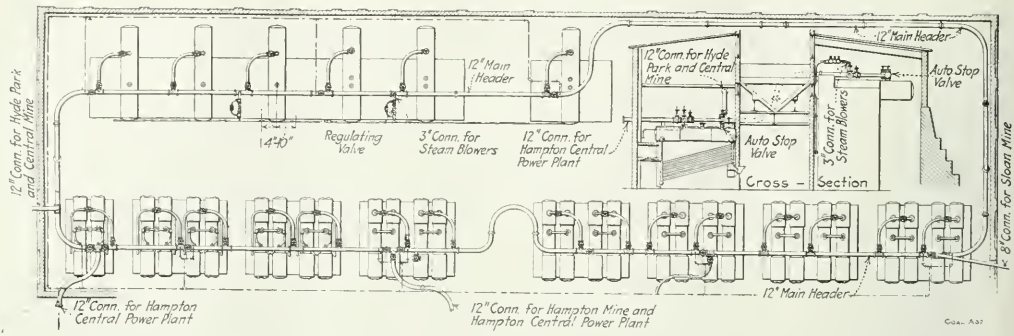
Unfortunately, however, such plants as these are the exception rather than the rule, particularly where power is strongly centralized and generated in large quantities. The ever-increasing demand for fuel, and the constantly growing applications of power to mining purposes, has rendered it difficult to accurately predict the ultimate requirements of any colliery or group of collieries. The result has been that plants which were at first deemed adequate for all possible requirements have been first overloaded, then added onto, again overloaded and again added to, until, in their final shape, they greatly exceed the magnitude with which they started.

In such cases, no matter how efficient the plant may be thermodynamically, it is seldom arranged for the greatest possible accessibility and convenience, and both the first cost and the attendance are usually higher than when the ultimate magnitude of the entire installation may be foreseen from its first inception.

There are, however, some notable exceptions to the general rule. Some instances exist wherein a plant, even though it be composed of a series of additions to the original equipment, presents not only an efficient whole, but also a neat and convenient appearance. The Hampton plant of the Coal Department of the D. L. & W. R.R. Co., near Scranton, Penn., may be justly regarded as a good example of such an installation. Although several additions to the equipment have been made from time to time, the plant as it exists today is both convenient and efficient.

Size and Arrangement of Boiler Plant

Exclusive of the main flues and economizers, the boiler house at this plant is 244 ft. 10 in. long by 75 ft. 7 in. wide. It is constructed of brick with steel roof trusses



Internal Arrangement of Boiler House, Exclusive of Flues, Economizers, Fans, Pumps and Other Auxiliaries

and concrete floors. The building contains 15 Babcock & Wilcox boilers of 313 rated hp. each. One of these is set singly and the balance in seven batteries of two boilers each. There are also six 2-drum Stirling boilers of 630 hp. each placed in battery.

The two types of boilers are arranged facing each other on opposite sides of a single firing alley of ample width to allow easy manipulation of slice bars, hoes and other firing tools.

It should be noted also that placing the 2-drum Stirling boilers in battery not only decreases the cost of the boiler settings, but also diminishes the heat radiation losses to a minimum.

Nos. 1 and 2 barley coal is used as fuel. This is first dumped from railroad cars into a pocket outside of the building. From here it is elevated and transported to an overhead bunker above the firing alley by means of a belt conveyor provided with an automatic tripper. Suitable downcomer pipes lead from the bunker to the Parsons distributors, with which each boiler is provided. Another series of these pipes also carries the coal to the floor in the middle of the firing alley, so that a supply for stoking the boilers by hand is always convenient.

The Parsons spreaders above mentioned handle about 70% of the fuel requisite for operation. The balance, or 30%, is hand fired.

A draught pressure of about 2 in. of water is maintained under the grates by means of two forced draught fans 16 ft. in diameter and 5 ft. wide, direct-connected to steam engines operating at approximately 200 r.p.m. On the Stirling boilers, Parsons steam blowers are used in place of the forced-draught fans. After leaving the Babcock & Wilcox boilers the flue gases are passed through Green fuel economizers. For this purpose two induced-draught fans, 18 ft. in diameter by 7 ft. long, direct-connected to steam engines and driven at approximately 140 r.p.m., are employed. The suction at the intake of these fans is about 2½ in. of water.

Ash Disposal and Water Feed

The ashes are flushed from the pits below the grates into the old workings of the mine through a borehole. Feed water is supplied to the boilers by two 5-in., 4-stage centrifugal pumps, each having a capacity of 500 gal. per minute. These are direct-connected to and driven by steam turbines. A 12x24-in. reciprocating plunger pump is also provided and held as a spare.

Feed-water regulators are used on all boilers, and automatic governors are provided for the turbines, maintaining a difference of pressure between pump and boilers of about 30 lb. This apparently large difference is probably necessitated, in part at least, by the interposition of the small number of economizers, through which the water for all the boilers must be forced in order to enter them.

External View of Boiler and Engine House, Showing a Portion of the Lawn

Regulating devices are also placed upon the engines driving the draft fans. By these means a boiler pressure of 150 lb. is maintained at practically a constant value.

The feed water used is drawn from the hot well of a surface condenser. It passes first into a 6000-hp. Cochrane feed-water heater, which it enters at a temperature of from 60 to 100° F., varying according to the season of the year and the conditions of operation. The water leaves the heater at a temperature slightly in excess of 200° F., passes through the pump, and enters the economizers. It normally leaves the latter at a temperature of about 240° F.

It should be borne in mind in connection with this latter temperature of the water that the supply for all of the boilers is forced through the economizers, which are subjected only to the gases from the Babcock and Wilcox boilers. This adequately accounts for the comparatively low final temperature of the water.

By means of a venturi meter all the water entering the boilers is measured and permanent records of its amount kept.

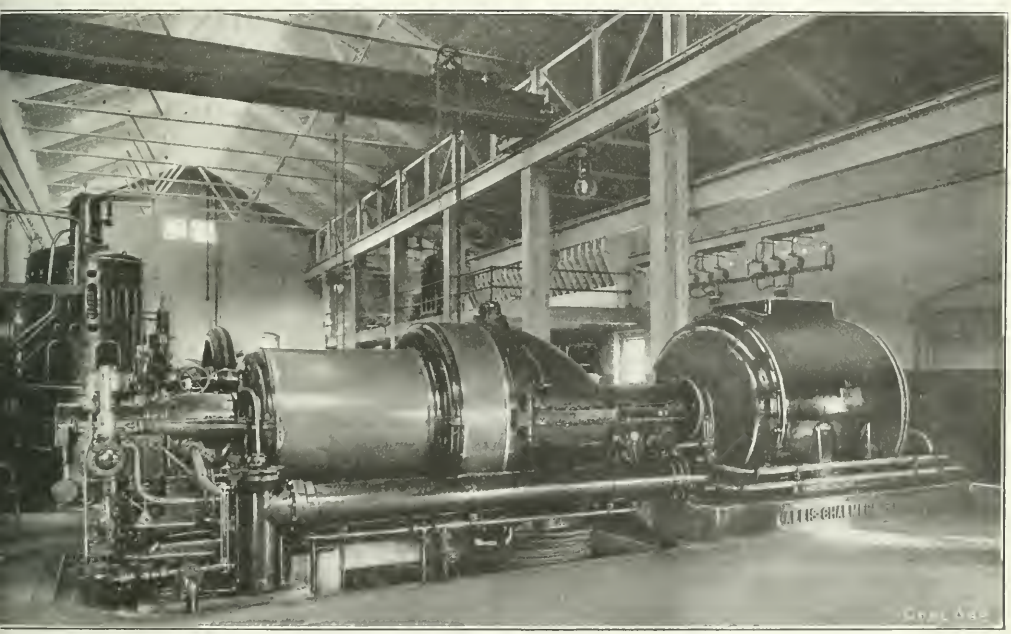
Four steam lines, ranging from 8 in. to 12 in. in diameter, and from 1200 ft. to 3800 ft. in length, radiate from the boiler house to the various collieries supplied from it. A double steam line also leads to the power plant. A Dodge steam-flow meter is installed in the boiler-house office, and connected to each of these lines in such a way that the quantity of steam in any of them may be continuously measured.

All of these steam lines are extra heavy, including all fittings and bends. In the lines which have been installed more recently, 40-ft. lengths of wrought-steel pipe have been employed, which are provided with Vanstone joints. These pipelines are carried upon supports composed of old steel T-rails. All are carefully covered and painted. The water piping, with the exception of the necessary expansion joints, is extra heavy cast iron.

The Generating Equipment

At this plant the generating units are located in a building distinct from the boiler house. The two are separated by a distance short enough to be convenient, but long enough to avoid the dust and dirt existing in the boiler room.

The power house proper contains five vertical, Curtis turbo-generators of 500 kw. capacity each, operating at a voltage of 2300 and a frequency of 60 cycles. There are also two Allis-Chalmers 2000-kw., 2300-volt, 60-cycle, horizontal turbo-generators in the same room. Four of the vertical turbines and the two horizontal machines use



Another View of Power-house Interior, Showing Horizontal Turbines, Traveling Crane, Etc.

barometric condensers. The other turbine exhausts into a surface condenser.

Mine water is employed for cooling purposes in the former machines, and as this is strongly acid, all pipes, as well as the condensers themselves, are wood-lined. In the surface condenser fresh water is used, which is then fed to the boiler plant.

The five Curtis turbines have two dry vacuum pumps so connected to the condensers as to be available for either or all of these machines. Each of the 2000-kw. turbines has its own dry vacuum pump, but these are cross-connected, so that either pump will serve either turbine, or rather its condense

The large machines are also provided with home-made automatic vacuum breakers to prevent water from backing up into the machines, should the condensing equipment by any mischance be flooded.

One engine-driven exciter is provided for starting up

and for emergency, while a motor generator set is employed for ordinary or continuous excitation.

A 10-ton electric crane spans the main part of the building, and serves all machines both on the main floor and basement (where the dry vacuum and condenser circulating pumps are located), except the outboard bearings of the large units. For these a smaller crane is provided.

The switchboard is located on the main engine-room floor, and is both compact and convenient. Transmission is accomplished at 2300 volts in all lines except that to the D. L. & W. shops, where 4600 volts are employed.

This plant is frequently called upon to develop 12,000 hp. It supplies current to 15 mines for lights, locomotives, pumps, rock crushers, breakers, drag lines, etc. It also furnishes current to a water shaft and approximately 1000 kw. to the D. L. & W. shops, yards, offices, etc.

The Pleasant Surroundings

It requires more than good equipment to make an efficient plant. The human element enters into power generation to a degree not ordinarily recognized by coal operators. To obtain satisfactory results, not only must the equipment be of the best, but good morale must exist within the operating organization.

Much has been done around this plant to render pleasant the environment of the men employed. Most conspicuous are the well kept lawns and flower beds, with which the buildings are surrounded. Of course, grass and flowers have no direct connection with the combustion of fuel or the generation of energy, but a little care and pains expended upon the grounds around almost any power station is practically certain to find a reflection in the increased care and pride the workmen take in the daily operation of the machinery intrusted to their keeping.

Hydraulic Stowage in Westphalia

From a British consular report it appears that hydraulic stowage of wastes in Westphalian coal mines is increasing from year to year, and that in the near future the majority of the coal mines may be compelled to adopt this system. In the old days the plan was to produce as much coal as possible at the least expense. In recent years, however, surface damages and claims for compensation are getting more frequent as the value of coal land rises. As a result, a system of hydraulic stowing has been adopted to support the surface, prevent buildings from cracking and railways from subsiding.

The ideal material is sand. In Westphalia this is not available. Instead a mixture of pit waste, blast-furnace slag and ashes is ground down and well mixed, and then flushed down the pipes with water. In many instances the pillars of coal which formerly had to be left to support railways and buildings have been dispensed with. In fact, there are places where the coal is being worked from under the town by this system with no dangerous results.

The pipes used for hydraulic stowing are items of considerable expense. They consist of an outer shell of steel or wrought iron with a cast-iron lining. The diameter is usually about 7 in.

Where sand can be used hydraulic stowage is cheap and is said not to amount to more than 12c. per ton, but in cases where more expensive material has to be mixed and ground down before use the cost of stowage rises to 24c. per ton of coal. It is maintained that with hydraulic stowage the expenses for pit-timber are reduced and the total coal output per annum increased.

Song of the Coal Miner

(Written expressly for Coal Age.)

By Berton Braley

Down in the hole where it's dark as pitch,
An' wetter'n we care to say,
We cut an' shoot to make 'em rich—
The fellers that pay our pay;
They drops us down in a rattlin' cage
A thousand feet er so,
An' there we work in the dust an' murk
Makin' the profits grow.

What if we do "take five"*
What if we do "take ten"*
The men that didn't ain't alive,
They're part uv the "might-uv-been."
We aim to do what's fair,
We think we do what's right,
But we'd rather be LIVE lazy men
Then under a tombstone white.

We gotta look out when the "cap" turns blue,
We gotta "shoot down the back."
'Er while we're drillin' a hole er two
The roof uv the room may crack,
An' then it's "Dig the poor devil out
An' take him up to the top."
Fer the wife may sigh an' the children cry,
But the Mine—the Mine can't stop.

Down in the deep black hole
There's allus the chance to take,
Uv a "missed hole" found er a "fall uv ground"
Er a ladder that will break.
So what if we do "take five"
An' what if we do "take ten,"
We'd rather be lazy an' alive
Than dead as we "might-uv-been."

We puts in timbers an' takes 'em out
In crossent, entry er raise;
Soldierin' sometimes, there's no doubt
But them is natural ways.
We takes our lives in our hands each shift
For never a guy can tell,
But what he will pick in a powder stick
That'll blow him all to hell.

So what if we do "take five"
An' what if we do "take ten,"
We're here today, alive,
Not part uv the "might-uv-been."
There's better men than us
That tried to outwork a mule,
But we'd rather be LIVE in a coal mine here
Than dead in a graveyard cool.

*"To take five" or "take ten" means to rest for five or ten minutes

Barometric Condenser Installation

SYNOPSIS—In the barometric condenser, the condensing water and condensate flow out of the cooling chamber without being pumped. A vacuum of 25 in. can be obtained without the use of an air pump as the air is entrained by the falling water in the condenser, but a pump must be used if as complete a vacuum as 28 in. is desired. Too much water should not be used in high-vacuum work or the condenser will be choked and the air and water to be handled will be increased without corresponding advantage.

One of the largest mining central stations in this country is located at Homer City, Indiana County, Penn., about 45 miles from Pittsburgh. The power station is one of a number of plants throughout western Pennsylvania, owned and operated by the Rochester & Pittsburg Coal & Iron Co., and is a fair example of the modern tendency of generating power at one mine and distributing it through high-tension lines to other operations.

Convenience for Obtaining Coal Locates Plant

In building the plant, due consideration was given to alternative locations. The installation could be placed near the coal supply or convenient to water. As it was necessary to install pumps for the cooling water, regardless of the site chosen, and a pipeline was the only additional equipment rendered necessary by a choice of a location convenient to the coal supply, the plant was located at the mine shaft. This greatly reduced the cost of handling the coal. The loaded cars, on being brought to the ground level, are run directly into the boiler room and emptied into the coal bunkers.

Description of Power Plant

The power house is built of brick with concrete foundation and occupies a space of 100x150 ft. It is an imposing building and the twelve steel stacks and three condenser exhausts can be seen for miles.

The prime movers consist of two General Electric Co. 3000-kw. horizontal turbo-generators, and an Ingersoll-Rand two-stage air compressor. Space has been reserved for a third turbo-generator of 3000 kw. The exhaust of the two turbines is condensed by two Wheeler barometric condensers, with 48-in. exhaust elbows, vacuum

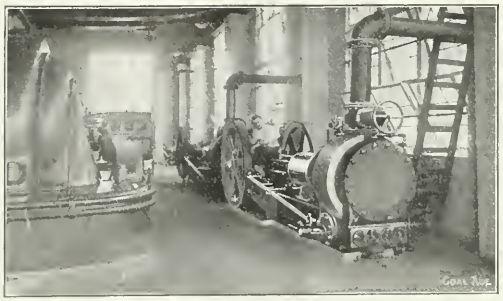

Fig. 2. A Dry-vacuum Pump Removing Air from the Exhaust Steam and the Condensing Water

breakers and 24-in. automatic exhaust relief valves. The two large turbine condensers may be seen at the left in Fig. 1.

A Wheeler rotative dry-vacuum pump of the tandem type removes the air and uncondensed gases from each condenser, even with high cooling-water temperature. The exhaust piping is of riveted steel, which is quite unsuitable for high-vacuum service and it is probable that if this could have been kept perfectly air-tight, unusual results might have been obtained.

Excessive Use of Water in Barometric Condensing

However detrimental this leakage was to the maintenance of a high vacuum, the loss was undoubtedly small compared to that resulting from the undue excess of injection water which was fed to the condensers at all times. Barometric condensers will not operate at their best with more than a minimum amount of water, yet in nearly every case where the initial operation of the condenser has been left to the engineer of a plant, the mistake has been made of using too much water, with the result that the throat of the condenser is constantly choked.

Formerly, for engine work and reasonably cold water, the amount of injection water used was rarely considered. But with large high-vacuum condensers for warm water, the quantity used is very important; first, because of the cost of pumping and second, on account of the quantity

condenser. This may be seen in Fig. 2. At the bottom of the exhaust pipe, near each turbine, a 5½x8x7-in. direct-acting suction valveless hotwell pump and hotwell, handles the condensate not carried by the exhaust into the condenser.

A 28-inch Vacuum Obtained

Each outfit was designed for 54,000 lb. of steam per hour and to give a vacuum of 28 in. using 4340 gal. of water per min. at 70 deg. F. With 25 per cent. less water and without the air pump, the same amount of steam can be handled and a 26-in. vacuum provided. The official test proved that a much better vacuum than this could be continuously maintained.

A Wheeler condenser with elbow, vacuum breaker, 10-in. relief valve, 7x16x14-in. tandem rotative dry-vacuum pump, and 5½x8x7-in. hotwell pump, furnishes vacuum to the air compressor. This unit is designed for 10,000-lb. steam, a 27-in. vacuum receiving water at 70 deg. F., and may be seen at the extreme right of Fig. 1.

Two motor-driven DeLaval pumps of 5000-gal.-per-min. capacity are installed at the cooling-water supply, which is about 1200 ft. from the plant.

In order to start up the condensers one of the main turbines must be run noncondensing for a time to furnish power to the pumps.

The table gives a number of test readings on units Nos. 1 and 2. A glance at the vacuum readings shows what favorable results may be obtained from this type of of air to be handled, a large part of which comes from the cooling water.

The Operation of the Condenser

Fig. 3 is a sectional view of the Wheeler barometric condenser, showing the water distribution and how the steam and water are mingled. The condenser is a pear-shaped shell with a large opening at the top for exhaust steam and an opening at the side for cooling water, while at the bottom connection is made to the barometric column which discharges the water to the atmosphere without a tail pump.

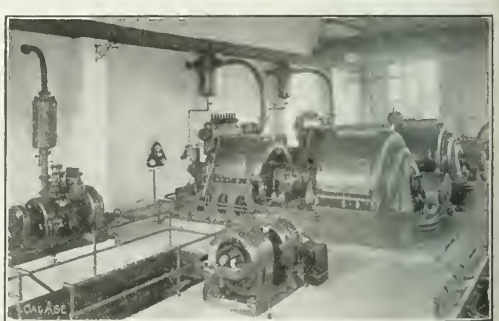

Fig. 3. Interior of the Luzerne Power House, Showing Turbo-generators and Turbo-exciters

The water entering near the top flows into the annular reservoir with vertical slots in its inner wall, through which the water falls in a large number of streams in the direct path of the steam, causing partial condensation and heating of the water. The water is then collected upon the tray immediately beneath, from which it splashes upward to some extent, causing further condensation, and heating of the water. Finally the stream flows through the multitude of small holes in this collecting tray, falling in a rain to the bottom of the condenser, and condensing the remainder of the steam.

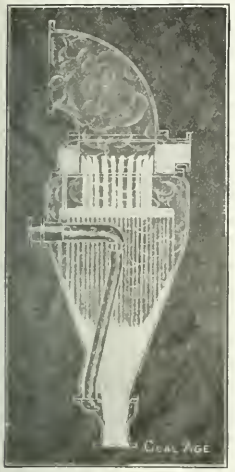

FIG. 4. SECTION SHOWING CONDENSER AT WORK, EJECTING AIR AND CONDENSING STEAM

CONDENSER ITSELF EJECTS AIR FROM "VACUUM"

For high-vacuum work the air is withdrawn by a vacuum pump (see Fig. 2) which is connected to the air-outlet nozzle at the left center of Fig. 4. The arrangement of the air intake within the condenser may be plainly seen.

For moderate vacuums an air pump is unnecessary, since the water falling down the condenser shell entraps air and carries it out by ejector action. Air is also supplied to the neck of the ejector by the air pipe shown.

Several times during the initial run of the outfits at Homer City, the condensers were operated without the air pumps and in all cases, fair working vacuums of 25 in. and 26 in. were recorded. The average vacuum obtained is 27.75 in., which corrected, is 28.75 inches.

⁂

Low Pressure Turbines

The term "low-pressure turbine" refers to machines which utilize exhaust steam at about atmospheric pressure by expanding it to a lower pressure maintained by means of a condenser.

The only costs chargeable against the low-pressure turbine are interest depreciation and maintenance of the turbine and condensing apparatus. They, therefore, furnish the most economical method of increasing plant capacity where the main engines are operated noncondensing, or, for furnishing power for live rolls or lighting in rolling mills and mines where exhaust steam from rolling mill or hoisting engines is available.

Where the exhaust steam from a single engine running intermittently, such as in hoisting, is to be used for operating a low-pressure turbine, continuous operation of the latter is made possible by use of a steam regenerator, or heat-storage reservoir which consists of a plain cylindrical tank partly filled with water, which condenses the excess exhaust steam not used by the turbine when the engine is running, and re-evaporates it, owing to a slight drop in pressure in the regenerator when the supply of engine steam is deficient.

In large plants having a number of noncondensing engines, the installation of a central low-pressure turbine plant with the exhaust lines from the isolated engines, all discharging into a single header in the station, the average flow will be sufficiently uniform so that the heat storage in the exhaust mains may be adequate, thus rendering a regenerator unnecessary.

When sufficient exhaust steam is constantly available for operating the low-pressure turbine, the simple design without a governor is preferable.

⁂

A New Mechanical Stoker

The Sanford Riley Stoker Co., Ltd., Worcester, Mass., is placing on the market a new automatic stoker which, in many ways, is an improvement over all its predecessors. It is of the underfeed type, with self-dumping features, and is the only underfeed stoker that has such a mechanical movement of the fuel-bearing surfaces, that the movement of the fuel and ash down the slight incline results in a continuous rather than a periodic cleaning.

For a year the Riley stoker has been tested out in a large electric-light plant, with conspicuous success. It has been operated under the severest conditions of actual service, and has been subjected to numerous tests to determine its efficiency and capacity. As a result of these tests, final improvements have been introduced and parts standardized.

Like all other underfeed stokers, the Riley is smokeless, even when forced to far beyond the normal capacity of the boiler. Unlike other types, however, it is without dead plates, the entire surface within the furnace being live fire surface. The makers claim that this stoker takes up less room than other types. It has been made thoroughly rugged in every part, but at the same time protected by shearing pins, so that serious obstruction in the fuel can cause no damage to the mechanism.

⁂

West Virginia Examinations

There were 41 persons who were successful in passing the state examination for mine foreman and firebosses, held at Clarksburg, W. Va., Dec. 17 and 18, 1912. The names of the successful candidates are as follows:

First grade—Elkin Reed, Simpson; O. C. Straight, Clarksburg; Roscoe Summers, Gypsy; John M. Matheney, Mt. Clare; L. K. Richard, Lewis; Jno. Oldroyd, Clarksburg; Scott Sturm, Worthington; James Cummings, Reynoldsville; S. D. Conner, Gypsy; Jno. A. Rutter, Gypsy; Clyde Van Pelt, Wilsonburg.

Second grade—Homer Yates, Grafton; M. L. Gett, Enterprise; W. H. Folf, Hutchinson, P. J. Smallridge, Weaver; Jesse M Lutman, Forbes Road; Linnie H. Harvey, Clarksburg; Thomas McCormick, Clarksburg, Marvin S. Miller, Fairmont; Frank Trader, Everson; P. O. Satterfield, Hutchinson; J. B. McCloud, Gypsy; J. H. Yoder, Shinnston; Howard Conner, Clarksburg; J. W. Bernard, Clarksburg; Allen Watson, Monongah; Richard Adcock Reynoldsville; Guy Russell, Interstate; A. J. Powell, O'Neil, John Charry, Viropa Ira Ernest Bales, Barrackville; John J. McElroy, Fairmont; J. B. Greynolds, Raynesville; E. W. Freeman, Enterprise; Dave Malone, Morgantown; W. D. Walker, Blaine; Thomas L. Price, Mt. Clare; Peter McCormick, Clarksburg; H. C. Saunders, Everson.

Firebosses—Wm. Leeper, Farmington, Matthew Conners, Grant Town.

⁂

Lignites may be profitably used in: (1) Gas producers. (2) Specially constructed boilers. (3) Briquettes. The U. S. Reclamation Service has a boiler at Williston, N. D., which burns lignite untreated, shortly after it is taken from the mine. When lignite is to be used for briquetting it should be thoroughly crushed, then dried until it contains not more than from 5 to 10 per cent. of moisture, then compressed while still warm

Central Station of Clinchfield Company

By W. H. Easton*

SYNOPSIS—The Clinchfield Coal Corporation, of Dante, Va., has gone through the evolutionary process common to many large coal producers. The company has abandoned its small power plants and replaced them by one central station and five substations, some of which are situated over eight miles from the point at which the power is produced. Thus the water problem has been met and the cost of generation and transmission reduced. The business of producing power and of extracting coal are thus kept distinct and both are in charge of men best fitted to handle them.

The mines of the Clinchfield Coal Corporation, with headquarters at Dante, Va., are interesting for many reasons but are especially noteworthy because of their system of developing and transmitting power.

In starting the earlier development, each operation had its own power plant which was situated as advantageously as possible to the water supply. These plants supplied direct current and operated with as high an efficiency as is possible for this type of installation.

Replacement of Scattered Units by Central Power Plant

The management never questioned the advantages of the use of electricity. The superiority of electric power for operating locomotives, pumps, fans, hoists and other mine machinery was regarded as sufficiently demonstrated. When, however, the development work was well under way and broader plans were formulated for the company, it became evident that great economy could be secured by doing away with the isolated power plants, efficient as they were as compared with ordinary steam plants, and operating all the company's mines from one central power station.

One of the most important considerations that led to the change was the question of water supply. Fig. 1 shows the character of the country in which the company's operations are located. It is typical coal country, where, as every miner knows, the water supply is usually not satisfactory. The rains drain off very rapidly and the rivers vacillate between conditions of flood and low water. Moreover, as much of the coal first developed lay high in the hills, it was difficult to locate the power houses immediately adjacent to the operations, which is necessary in order to secure good economy with a direct-current plant.

The Advantages of Having Only One Plant Which Can Be Placed in Charge of Competent Men

Another consideration of great importance was that of greater reliability. At a central power plant there is nothing to be done but to keep power on the lines. At the mines all thought of power is eliminated; there is nothing to interfere with the getting out of coal. Consequently, there is practically no loss of time because of the failure of the power, and the coal-mining operations can be carried on with greater effectiveness. The result is greater and cheaper production.

Proper boiler water was also hard to obtain at some of the mines, and bad boiler water meant heavy repair expenses and, what is even more serious, occasional shutdowns. In fact, all maintenance expenses could be greatly reduced by centralizing the power supply, as all machinery can be given better attention and kept constantly in the best operating shape.

For these reasons, the Clinchfield corporation established a central power station at Slemp, Va., on Dumps Creek. The generating equipment consists of two 1250-

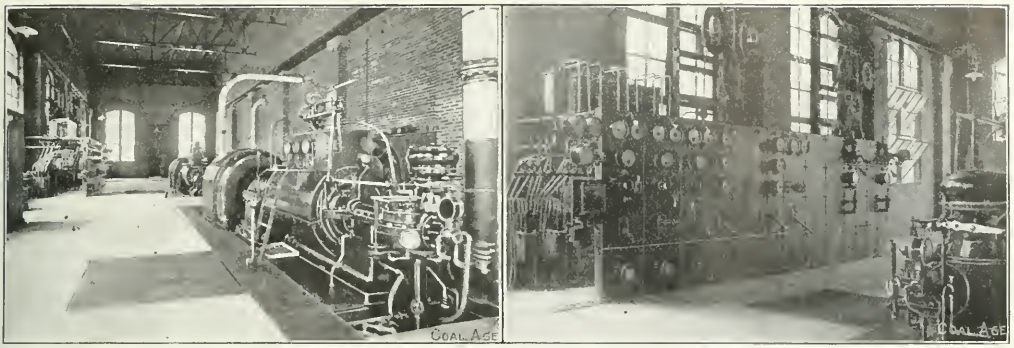
Fig. 1. View, Typical of the Country in Which the Clinchfield Coal Corporation Is Operating. Inclined Plane of One of the Laurel Mines in Foreground

kv.-a. Westinghouse turbo-generators, which develop three-phase, 60-cycle power at 6600 volts and have an overload capacity of 1560 kv.-a. each. Fig. 2 shows the interior of this plant. Fig. 3 shows the switchboard.

Substations at Slemp, Laurel and Dante

The power is transmitted at present to five substations, one near the power house at Slemp, one at Laurel, some three miles distant, and the other three are located on the Dante group of operations, eight miles away. Thus all the power required for the Dante and Laurel operations is supplied from a single power house. The addition of two more substations is contemplated and the apparatus for them was included in the original contract with the Westinghouse Electric & Manufacturing Co.

*Pittsburgh, Penn.



FIGS. 2 AND 3. CENTRAL POWER PLANT OF CLINCHFIELD COAL CORPORATION, AT SLEMP, VA. FIG. 2 SHOWS TWO WESTINGHOUSE TURBO-GENERATORS, 1250 KV.-A., 6600 VOLT, 3 PHASE, 60 CYCLE. FIG. 3. ILLUSTRATES THE SWITCHBOARD

This scheme of power distribution lends itself readily to expansion and it is probable that the future development will justify the addition of a 2000- or 3000-kv.-a. unit for distribution at either 6600 volts or some higher voltage, such as 23,000 or 33,000. This higher voltage will enable power to be transmitted economically to more remote Clinchfield properties as they are developed for an increased tonnage.

The substations are comparatively simple installations. Fig. 4 shows the end of the Laurel substation, Fig. 5 the exterior. They can be placed almost anywhere and are independent of water. The main feature of their equipment is a motor-generator set, the one at Slemp being shown clearly in Fig. 6.

Each set consists of a 6600-volt alternating-current Westinghouse motor which drives a 300-hp. Westinghouse generator delivering direct current at 275 volts. Thus the high-voltage alternating current transmitted from the power house is transformed into low-voltage direct current, suitable for driving locomotives, pumps, fan motors, lights, etc., at the mine.

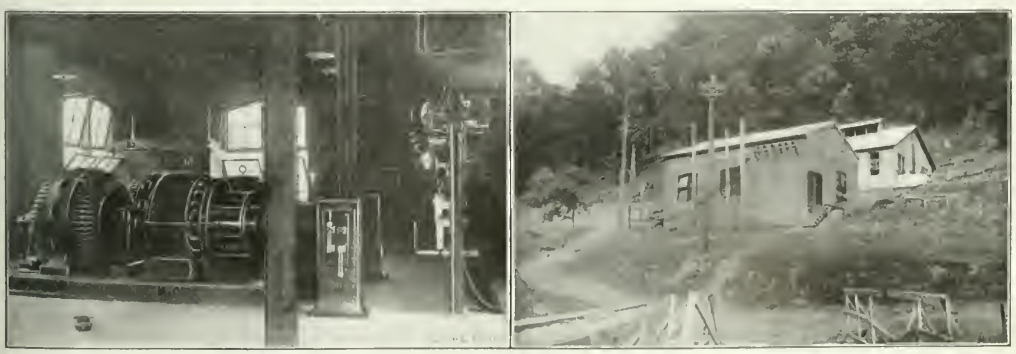
The substation requires little attention. The motor-generator set runs practically continuously and an attendant is needed only to see if everything is running properly. If power is not wanted the motor is stopped and all expense for current ceases; starting up is simply a matter of throwing a switch and full power is immediately available.

THE ADVANTAGES OF PURCHASED POWER

This system of power distribution is unquestionably the most advantageous for companies in the position of the Clinchfield corporation. Companies operating single or widely separated mines can secure its most important advantages by purchasing power from power-supply companies if such are operating in the vicinity.

It is often difficult for a mine operator to see that he can in many cases actually buy power cheaper than he can make it himself when apparently he is getting his fuel for nothing. But his fuel should be figured at the cost which it would bring if sold.

Furthermore, while he is making his own power, his attention is centered on the power house because trouble there means shutdowns and loss of production; but with central-station power, he transfers this responsibility to those whose whole business it is to carry it, leaving him to the uninterrupted business of mining coal. Records go to prove that central-station power is more reliable than that from private plants. The operator substitutes his power house with its engineers and firemen and its need for good and abundant water, for a small substation that requires minimum attendance and no water supply.



FIGS. 4 AND 5. INTERIOR AND EXTERIOR OF LAUREL SUBSTATION OF THE CLINCHFIELD COAL CORPORATION

He can shut down his plant with little expense and start up instantly, as far as power is concerned. He can obtain increased power quickly and at less cost than is involved in building additions to his power plant. His power is at all times ample so that production does not lag. If his operations become so extensive that the voltage drop in the direct-current lines becomes too great, he

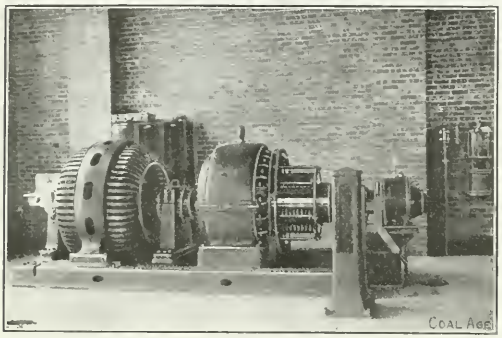


FIG. 6. WESTINGHOUSE MOTOR-GENERATOR AT SLEMP SUBSTATION, 300 KW., 275 VOLT, D. C. GENERATOR, DRIVEN BY 6600-VOLT SYNCHRONOUS MOTOR

is easily able to run high-tension lines to the proper points and install other substations, in the mine if need be.

In any case, it is well worth while for every mine situated to obtain centralized power to estimate its present costs and those of operation with purchased power, thus obtaining assurance that it is on the most economical basis possible.

An Automatic Feed Regulator in Coal Cutting

It is admittedly true that the coal cutter is a difficult portion of electrical mine equipment to keep in proper repair. This is due to the hard work which it has to perform, and frequently to the class of attendant in whose care it is placed.

The ordinary machine runner is more concerned with the amount of coal secured than with technical considerations as to overloads on electrical equipment. Hence the coal cutter is not infrequently worked at a rate which imposes, even under normal cutting conditions, a severe test as to its continuous reliability.

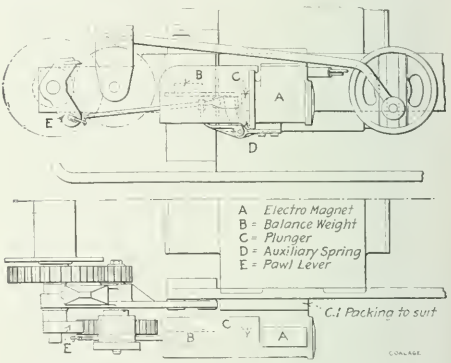
When, in addition to this, it is remembered that it is the rule rather than the exception to find the face varying as regards the nature of the material to be cut, it is evident that a very serious additional strain is thrown on the cutter from time to time, which, unless the speed of the cutting is regulated in accordance with the excess demand, is very liable to work serious results.

The inevitable consequence is frequent and excessive overloads, which culminate in exasperating trouble, both electrical and mechanical. Under the severe conditions frequently met with, breakdowns and stoppages are numerous and the constant burning out of fuses or the tripping of cut-outs is annoying and sometimes positively dangerous.

It is interesting, therefore, to note that an automatic feed regulator has been successfully introduced by the British firm known as the Diamond Coal Cutter Co., of Wakefield. This contrivance is illustrated herewith. The regulator consists of an electro-magnetic device which, the moment that an excess of current is taken by the motor, stops the forward travel of the machine by lifting a pawl from its ratchet wheel. This does not stop the cutting action, but automatically adjusts the rate of travel to suit the conditions, allowing the cutter to advance the moment it has overcome the difficulty.

It will be seen that overloads, such as have been mentioned, may be caused by some extra hard material being met with in cutting, by the picks becoming blunt, by the men attempting to make the machine travel at too fast a speed, or by neglecting to use the shovel. Overloads due to any of these causes are automatically corrected if this feed regulator is employed.

In actual practice it has been found that under the most unfavorable conditions of working the armature breakdowns have been reduced by fully 70% and the output of the machine has been considerably increased, due to the longer total cutting time, resulting from the avoid-



DIRECT-CURRENT REGULATOR APPLIED TO DIAMOND MACHINE

ance of stoppages. Moreover, the gate-end fuses, which formerly blew frequently during every shift, were renewed only at intervals of several weeks.

The figure shows a direct-current regulator applied to a Diamond two-motor machine. The solenoid *A* is in series with the armature circuit, and at a predetermined current value draws in the plunger *C* against the weight *B* and the auxiliary spring *D*. The working current can be adjusted by moving *B* along the bar. When the plunger is drawn into the solenoid, the pawl attached to *E* is lifted and the machine ceases to travel forward until the current falls again to normal, when the plunger is released, the pawl once more drops into place and the machine is again put in motion.

For alternating-current machines the principle is the same, although the arrangement is slightly different. A shunt relay across one phase is employed, which interrupts the main circuit. The instrument is especially valuable for machines of this type, since the starting current involved brings the regulator into operation and allows the motor to start comparatively light.

It will readily be perceived, therefore, that a valuable addition has been made to this important portion of mine equipment.

Economy in Colliery Power Plants

By Sydney F. Walker*

SYNOPSIS—Description of a peculiarly effective electrical installation in Great Britain. Accumulators are used for storing the surplus power when running the electric plant under a light load, and by means of a novel arrangement, a similar conservation of steam is obtained. The plant presents a striking combination of the old and new.

With the increased cost of the working of collieries in the United Kingdom, owing partly to the increased depths of the seams, and largely to the greater cost of labor, colliery managers have found it necessary to look into all possible means of saving money. Owners in the United Kingdom are notoriously conservative; they move slowly in the adoption of a new plant, regardless of how large a saving it promises to effect, but when one pioneer has successfully carried out some improvement, every colliery of any standing generally follows suit. Thirty years ago, boilers at collieries generated steam at 30 lb. pressure; a little later they ventured to 50 lb., then to 80 lb., and now 150 lb. is quite common, while pressures of 200 lb., with water-tube boilers, may be found at many collieries. While the demand for steam is constantly increasing, and the boilers are at the same time gradually approaching the point where they have to be replaced, considerable economy is effected by doing away with the low-pressure type and installing others generating steam at 150 pounds.

There have been cases, however, where the low-pressure boilers were still in good condition, and where the management hardly felt justified in facing the expense of installing others of the higher-pressure type. The economy in a great many cases would hardly pay for the cost of making the change. One such case, on a large scale, was that of two collieries at Hucknall Torkard, in Nottinghamshire, England. These were about two miles apart, and each had its battery of boilers carrying steam at 30 lb. pressure. Those at the one colliery were dismantled, and the whole of the work at both plants is now performed by the one battery at the other colliery.

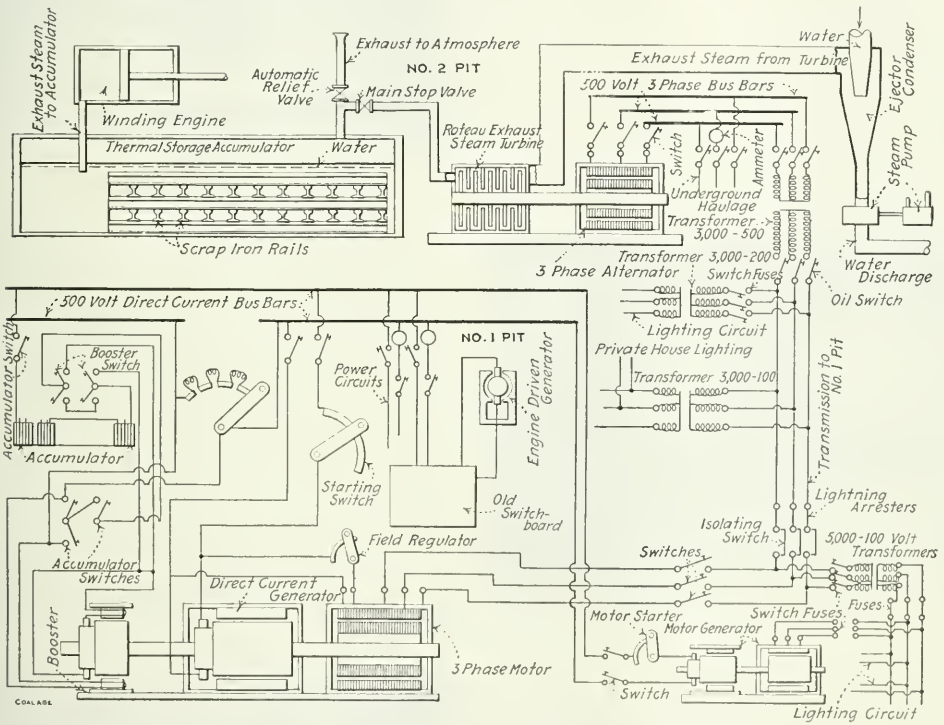


Fig. 1. General Plan, Showing Layout at Hucknall Collieries

Inefficiency of the Old Plants

In the early days, and up till quite recently, the steam used by the winding engine was considerable. Until 15 years ago, little thought was expended upon the steam consumption of the engines, at a colliery or, for the matter of that, at industrial works of any kind. The one thing needful was that the engine should work, and if more steam was required, more boilers had to be provided. With the increased cost of working the collieries referred to, the competition that has arisen in all industries, and perhaps more than all, with the general im-

*Bloomfield Crescent, Bath, England

provement which has taken place in engineering work during the last 30 years, the question of steam consumption by engines came up for examination.

It will be remembered that feed pumps of boilers were found to be exceedingly wasteful, using the equivalent of 10, and sometimes 15 lb. of coal per horsepower-hour. As to the steam used by hoists, it was found that they were even more wasteful, 11 lb. of coal per horsepower-hour being quite a common consumption. And that did not tell the whole tale. The hoisting engine was frequently supplied by its own set of boilers, placed as close as possible to the engine house. As is well known, however, it only works for from 8 to 10 hr. a day, under the recent Eight Hours Act, with an occasional hoist for men, timber or supplies during the remaining 16 hours.

At the Hucknall collieries, what was previously a loss, has been turned into a source of economy. The exhaust steam from the engine is employed to supply a Rateau exhaust-steam turbine, which drives a three-phase generator. The current developed is employed for working the machinery at the colliery, and the whole of the plant, including the hoist at the other colliery, by the aid of currents transformed to 3000 volts, and transmitted on overhead wires from the one colliery to the other. There is a railway between the two collieries, and the pole transmission line, carrying three copper wires, insulated

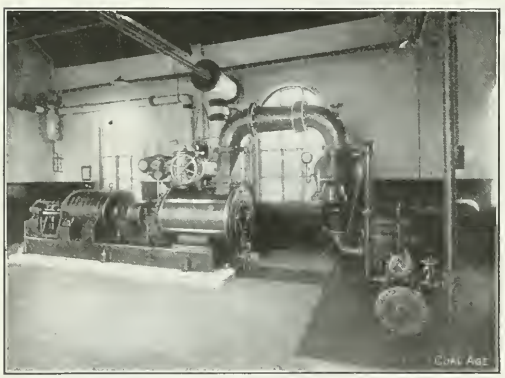

FIG. 2. THE EXHAUST TURBO-GENERATOR AND EJECTOR

with ordinary telegraph insulators, is fixed by the side of the road.

THE ARRANGEMENT OF THE POWER STATION

The installation is at what may be termed the power station, or the lower colliery, known as No. 2; the other mine is 1¼ miles up hill. There is, firstly, a thermal storage reservoir consisting of an old boiler, half filled with old iron rails, located outside of the engine house in which the turbine runs; the exhaust steam from the is about half full of water, the remainder of the steam is condensed to water, the boiler gradually becoming partially filled, and the old iron rails heated. When the boiler is about half full of water, the remainder of the steam is sometimes condensed to water, and sometimes merely delivered into the steam space between the water and the top of the boiler. It may be mentioned that the old iron boiler is merely a shell, and it is only exposed to a pressure of 2 lb. above the atmosphere or, say, 16.7 lb. absolute.

FIG. 3. EXTRA HEIGHT, THREE-PHASE TRANSMISSION LINE

The turbine takes steam from this old boiler, as long as there is any there to supply it, and when this fails, as when the hoist has been standing for some little time, live steam is fed to the turbine, through a reducing valve. Fig. 1 shows diagrammatically the arrangement of the thermal reservoir, the delivery of steam to it from the engine, from it to the turbine, and from the boiler to the turbine, when the supply of exhaust steam fails; it also shows the electrical system at the No. 2, and at the No. 1 pit.

When the engine is hoisting rapidly, and the quantity of steam going into the thermal reservoir is large, the storage capacity of the water and the old iron rails comes into play. The water is raised to a higher temperature, together with the old iron rails, while the pressure of the steam slightly increases. When the steam is not coming so fast, the rails, and the water, give up a portion of the heat which they have stored, and the pressure within the steam space being lowered, evaporation takes place on the surface of the water, steam being

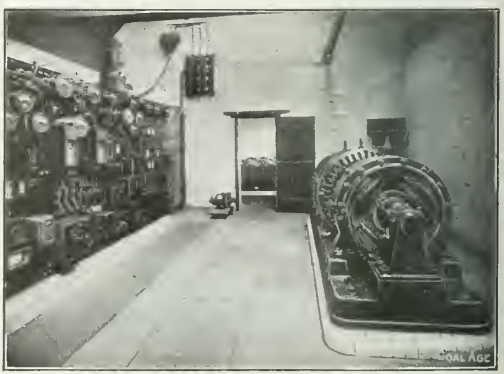

FIG. 4. VIEW OF SUBSTATION AT THE No. 1 PIT

ormed, and thus furnishing the supply required by the rbine.

The hoisting engine usually is shut down at about 11 m., the fires under the boilers being banked, and the rbine and turbo-generator also shut down. The cur-

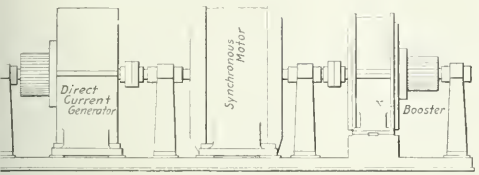

Fig. 5. Motor-generator and Booster at No. 4 Pit

nt required for work during the night, at both col-eries, and at the electric-light system, is supplied from battery of electrical accumulators fixed at the other lliery.

The Electrical System

The arrangement of the electrical system is shown Fig. 1. In the first place the steam turbine drives a ree-phase turbo-alternator, furnishing current at 500 lts. Fig. 2 shows the turbo-engine house at the No. 2 , and Fig. 3 the overhead transmission line between two pits. As mentioned before, the current at 500 lts is employed for lighting, pumping and haulage, at the mine where the turbine is fixed. For the power required at the upper colliery, where the boilers have been taken out, and where the only power is electricity, the 500-volt three-phase current is transformed to 3000 volts, three-phase, and carried by the transmission wires mentioned above, to the upper colliery. There the surplus energy, of the exhaust steam from the hoisting engine at the lower olliery, is stored in an electrical accumulator. It will be remembered that alternating currents cannot be employed to charge accumulators, and therefore the three-phase current has to be converted to continuous current, before the accumulators can be charged.

This is accomplished by the aid of what is called a synchronous three-phase motor, taking the 3000-volt system from the overhead transmission wires and converting it into mechanical power, the axle of the alternating-current motor being connected to the axle of a 500-volt continuous-current generator. The power from the continuous-current generator is employed to charge a storage battery fixed in a room close to the transformer house. Fig. 5 shows the arrangement of the motor generator and booster and Fig. 4 is a view of the substation in which the motor generator is housed, and of the accumulator house adjoining. But there was another problem to be solved. The continuous current from the motor generator is employed at the upper colliery for various work, such as driving mining machines, haulage, pumping, workshop motors of various kinds, together with electric lights for the surface, offices, etc. The cur-

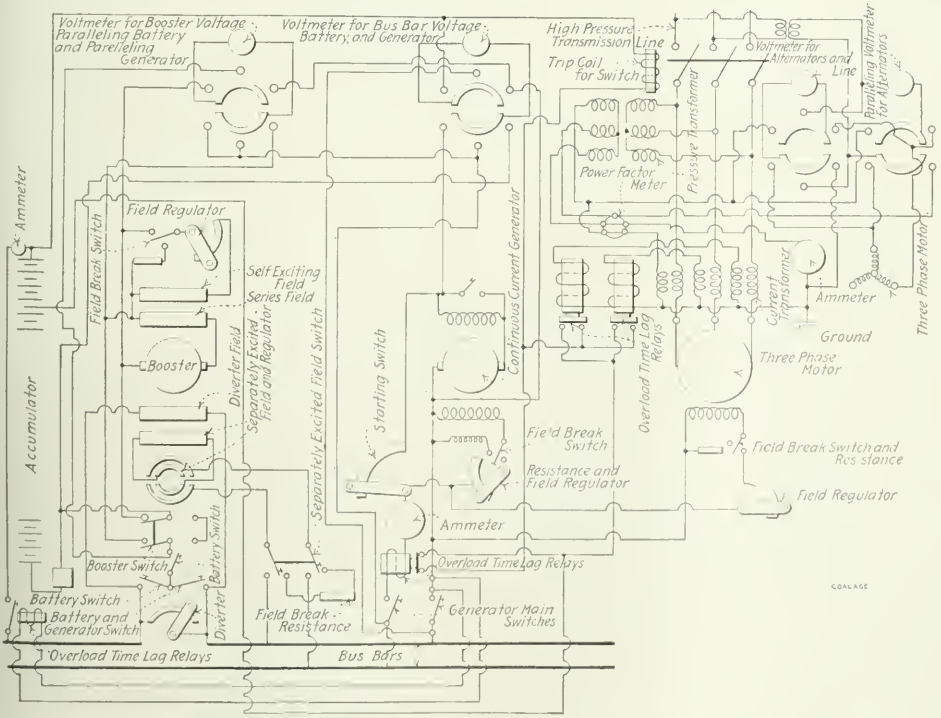

Fig. 6. Diagram Showing Arrangement of Accumulator, Three-phase Motor, Continuous-current Generator and Booster, with Connections and Measuring Instruments

rent from the generator side of the motor-generator is taken primarily to work the motors about the colliery, and any surplus energy that comes to the upper colliery from the thermal storage at the lower one, is stored in the electrical accumulator.

But, in all cases where there is a varying demand for energy, and where storage is attempted, there must be some arrangement for give and take. The thermal storage reservoir at the lower colliery, it will be remembered, takes up all the exhaust steam that is delivered to it, pass-

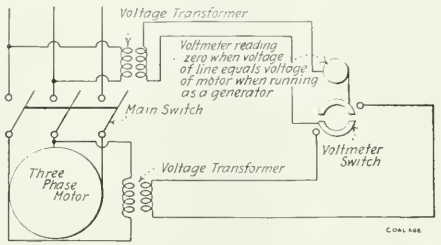

Fig. 7. Method of Connecting Three-phase Motor at Night

ing on the surplus energy to the overhead transmission wires. It also gives up stored energy when the exhaust steam is short.

The "Reversible Booster" System

In the electrical storage battery a similar arrangement holds. The problem at the upper colliery is similar to that at electric generating stations for small towns. No matter how carefully the number of engines and generators are regulated to the load, there was always some surplus energy wasted before the adoption of the method to be described. There were also always times when, unless the plant was running con-

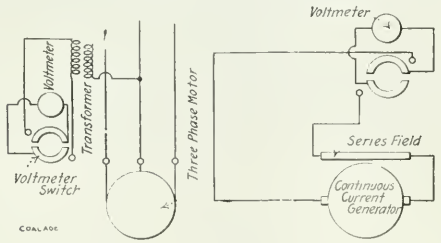

Fig. 8

Fig. 9

siderably over the average requirements, that there would be a shortage of power.

What is called the "reversible booster" system met the difficulty. The "reversible booster" takes the surplus current from the generators, or rather from the "busbars," converts it to the pressure required for charging the accumulator, and on the other hand when the demand for current is above that which the generators running can supply, the "reversible booster" delivers the current required to make up the difference, from the accumulator, re-converting it to the "busbar" pressure in the process.

A little explanation again is here necessary. When charging electrical accumulators, a pressure of about 30 per cent. above that which the accumulator itself will deliver when discharging, is required. The individual lead accumulator cell furnishes, when discharging, a pressure of from two volts downward, the pressure decreasing as the discharge proceeds. While being charged, gases are generated by electrolysis, in the dilute sulphuric acid in which the lead plates are immersed, and the presence of these gases increases the pressure between the plates of the accumulator to 2½ volts per cell. In addition, each accumulator offers a certain electrical resistance to the passage of the charging current.

When a current is passed through the accumulators to charge them, it must be of sufficient pressure to overcome this back pressure, which the accumulator itself is furnishing, and also to overcome the resistance of each individual cell. This leads to the 30 per cent. or so, increased pressure required by the charging current. If an accumulator is charged, and allowed to stand for a few minutes after the charging current is cut off, it commences to deliver current at about 2 volts. When, however, current is taken from it during the process of charging, it would be at the pressure of 2½ volts, and therefore would be unsuitable for performing the work that is being done by the current delivered by the generators themselves.

The difficulty is met by the "reversible booster" reconverting the 2½ volts to 2 volts, and delivering it at that pressure to the busbars. The accumulator then acts as another generator connected in parallel with those running. In practice, there is a variable see-saw between the accumulator and the generators. At certain times of the day the accumulators are receiving a large quantity of current, and at others they are receiving only a little; again at times they are discharging small quantities, but at others, when lighting and power are required together, comparatively heavy discharges are taken from the accumulator.

System at the Hucknall Collieries

At the Hucknall collieries, a reversible booster is fixed with its axle forming part of a mechanical system in

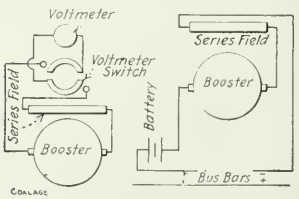

Fig. 10

Fig. 11

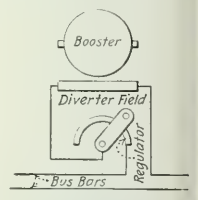

Fig. 12

which are arranged the synchronous motor and the continuous-current generator. Fig. 5 shows this, and Fig. 6 the arrangement for charging the accumulators.

All surplus steam, up to a certain point, is converted, at the lower colliery, into electricity, and transmitted to the upper colliery. This electricity furnishes all the power that is required at the upper colliery and any surplus that remains is delivered to the accumulator. The accumulator itself helps to make up any deficiency of power at the lower colliery. It was mentioned above, that the boiler and hoisting engine at the lower colliery is shut down at about 11 p.m. and a certain amount of power was required after that time. After the boiler and hoisting engine are shut down at the lower colliery, the

current from the accumulators at the upper colliery is transmitted to the lower one, being first transformed through the motor generator, and through the reversible booster, into three-phase alternating currents at 3000 volts.

It will be remembered that every continuous-current generator also acts as a motor, if required, and a synchronous alternating-current motor will act as a generator if required; consequently when current is no longer coming from the lower colliery to the synchronous motor, power is delivered from the electrical accumulator to the continuous-current generator, driving it as a motor, assisted by the reversible booster. The synchronous motor then becomes a three-phase generator, and delivers an alternating current at 3000 volts to the overhead transmission line. At the lower colliery, the 3000-volt, three-phase currents are transformed down to the 500 volts at which the colliery service is worked. The lights for the houses are supplied by special transformers, arranged for the purpose, furnishing current at 100 volts. These lighting transformers take power from the three-phase generator at the lower colliery while it is running, and from the synchronous motor, working as a generator, at the upper colliery, when the generator at the lower one is standing. Figs. 7 to 16 are parts of the diagram given in Fig. 6. They represent the details of the arrangement.

The Haulage System at the Lower Colliery

The working of the haulage system at the lower colliery, where the exhaust-steam turbo-electrical generating station is, will probably be interesting, inasmuch as it is a conversion from a steam drive to an electric. The colliery where the plant is installed is an old one, having been working something like half a century. The haulage underground is worked by two endless ropes, which were driven, before the installation of the exhaust-steam plant, by a pair of simple cylinder horizontal engines, furnishing together about 80 hp., and supplied with steam by a boiler near the pit, working at low pressure. At the time this plant was put in, it was the common practice to take steam underground. In the North of England, in the counties of Durham and Northumberland, where the most advanced practice was usually to be found, it was a common thing for steam to be taken considerable distances in-bye, and the working of a haulage plant by steam engines, near the pit bottom, exhausting into the upcast shaft, was also quite common.

At the Hucknall colliery, the haulage extended about 1½ miles on one side of the pit bottom, and for about half a mile on the other side. There was also a small rope arranged to haul the trams round the shaft bottom. The engine and boilers were taken out, and the 60-hp., three-phase, induction motor installed; this motor was guaranteed to be capable of giving 100 hp. for four hours without undue heating. The two endless ropes were driven from a single shaft, by the aid of clutches in the usual way, the driving shaft taking power from the motor by means of a series of belts.

Some careful tests were made of the power required to work the haulage plant, and it was found, as in other cases, to be less than the sum of the two powers required for the two ropes working separately. The smaller quantity of power required, and the reason, is perhaps best seen by taking the case of a large engineering works, with a number of machine tools. Going through the works, it will be found that perhaps one machine is standing, while the man looking after it is setting a tool; another machine perhaps will be taking only a light cut; a third may be taking its full cut, and so on, the result being that only the smaller quantity of power mentioned above is required.

The running costs of the plant at Hucknall are quite low indeed, so low, in fact, that the manager of the colliery stated that he would not like it to be known for business reasons.

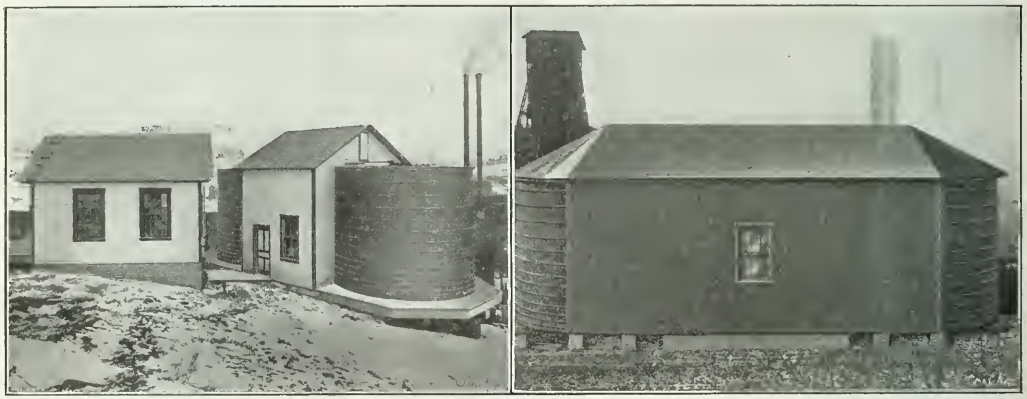
Feed Water Purification at Mines

Special Correspondence

SYNOPSIS—The feed waters encountered in mining regions are frequently both scaling and corroding in their nature. If used in their raw or untreated state, even though heated to a considerable extent before being forced into the boilers, much trouble and expense is liable to be incurred. A system of water softening and purification is here described which has been successfully installed at many mines.

In many steam power plants in coal-mining regions, particularly those which draw their boiler-feed water from sources which have been contaminated with mine drainage, considerable difficulty has been experienced from either scale or corrosion, or both. The fear of the expense and danger arising from these causes is strongly evidenced by the large number of boiler compounds, purifying devices, skimmers, filters, etc., which are upon the market.



Feed-water Purification Plants at Burgettstown, Penn. (at the Left) and at De Lancy, Penn. (on the Right)

The Origin of Scale

Incrustation and corrosion can nearly always be traced to the iron, lime and magnesia salts in solution in the water, or in some cases to the free acid which it carries. The physical character of the scale depends upon the acids combined with the iron, lime and magnesia, upon the type of boiler in use and the rate, temperature and pressure at which it is operated.

To overcome the waste and expense due to the operation of boilers with water containing one or more of these impurities, many methods and devices are in use, nearly all of them depending upon sound mechanical or chemical theory. But many of these devices fail to perform in the fullest measure what is expected of them, or are at best only partially successful due to improper application or to the fact that effort is directed against the effect rather than the cause.

A water, which to the eye seems to be absolutely clear, one which is known to be perfectly good and safe for drinking purposes, may contain so great a proportion of scale-forming material as to be extremely undesirable for boiler-feeding purposes; likewise a stream which near its source shows good analysis, and not enough foreign matter to cause any trouble in a boiler, at points lower down, due to contamination from outside sources, may show both scaling and corroding properties to a marked degree.

To decide on the suitability of a water for boiler-feeding purposes, an accurate analysis is essential. This should be complete and be carefully made by a chemist who, if possible, is a specialist on boiler-feed waters.

An analysis of the scale in the boiler is of practically no value in determining the character of the water from which the scale was deposited. This is due to the fact that incrustation is a precipitation resulting from reaction between some of the substances in solution, as well as to the heat and concentration, so that the original character of the impurities and their amount in the water in question is not always apparent from the scale.

Objectionable Sources of Supply

Mine waters, creeks and streams fed with mine drainage are objectionable on account of the free sulphuric acid and corrosive sulphate of iron and alumina as well as the other scale-forming substances which they carry in suspension.

The sulphates of iron and alumina in such supplies act in the boiler exactly like sulphuric acid, inasmuch as they are dissociated by heat, the acid being thus set free, and the iron and alumina precipated as sludge or scale.

The sulphuric acid liberated as well as that introduced in the free state with the feed water immediately attacks the metal of the boiler, forming iron sulphate, which the heat decomposes, freeing the acid and forming iron hydrate, which gives the water the characteristic color of iron rust.

The acid liberated by the reaction due to heat is constantly repeating its destructive action upon the metal. Sulphuric acid is nonvolatile; consequently its amount in the contents of the boiler is constantly being increased

by the quantity introduced with the feed, either as free acid or that combined with the iron or alumina. The destruction of the metal of the boiler may be said to be almost in direct ratio with the concentration of the acid which is contained therein.

Other corrosive acids and substances are often present in boiler supplies. Water which drains through swamps or marshes wherein there is much decayed vegetable matter often contains enough organic acid to cause severe and dangerous pitting. But in the mining regions sulphuric acid is the most common, and is also the most destructive to the piping, heaters, boilers, etc.

Scale Shortens a Boiler's Life

The effect of scale on the heating surface tends to shorten the life of any boiler. That over heating results from scale is certain. As a rule, the metal is not of such a quality as to stand continued overheating, and portions of the tubes eventually show the characteristics of cast iron in their structure. This condition is not uniform throughout the entire boiler, but is more evident in those parts which are exposed to the greatest heat.

The actual thickness of incrustation seems to have less to do with crystalization than the nature of the scale and the furnace temperature, which in turn is dependent on the rate at which the boiler is operated.

The second condition, the failure of tubes by blisters or blowouts, is more common in some types of boilers than in others, and as a rule is chargeable to the insulating effect of irregular deposits of scale, sludge or oil from which local overheating results. This condition is, of course, aggravated by the furnace gases impinging more directly on certain parts of the tubes than others, thus bringing about unequal heating and a tendency to drive the water away from the tube walls.

That scale and corrosion affect the life of the entire steam plant, as well as increase the maintenance cost, is self-evident. The full efficiency of the various devices installed to increase the economy of the steam plant, as well as that of the individual boiler, will not be reached therefore as long as any scale is allowed to form, or any boiler is permitted to be fouled with oil or sludge.

The attempt to prevent scale in the boiler by having it deposited in some auxiliary, such as a feed-water heater and purifier, is one of the most common methods of attacking the feed-water problem. It is a known fact that raising the temperature of water reduces the solubility of some of the substances in solution; but this does not justify this method of precipitation for purifying all boiler feeds.

Any attempt to make the open feed-water heater perform two separate functions, savors of a make-shift, since as its efficiency as a purifier increases, its efficiency as a heater diminishes. The mere fact that scale is deposited upon its walls or pans does not justify it being called a purifier any more than to call a boiler by the same name, for the reason that scale is deposited upon its walls or tubes.

The large number of nostrums and mechanical devices put into use indicates that the steam users realize how irrational it is to expect an economical purification of feed water to be accomplished in either boiler attachments or auxiliaries, or in the boiler itself by making use of various compounds.

Conditions of Greatest Efficiency

The condition under which the most economical and efficient boiler operation can be obtained is with the use of clear, soft, noncorroding, nonscaling feed water. The problem, therefore, before the mine operator who has at his command only a supply of objectionable water is that of purifying and softening the boiler feed before it enters either the heater or boiler.

The process of softening and purifying water deals with the problem in the manner perscribed by the chemist, by the use of proper reagents which neutralize corrosive acids and change the soluble salts of lime, magnesia and iron into insoluble precipatates which can be removed by sedimentation and filtration. These can easily be accomplished in apparatus designed with all the chemical and mechanical requirements kept constantly in view.

The impurities in a water of average hardness (say 20 grains per gallon) only represents about $^1/_{100}$ of 1 per cent. by weight. This being the case, it becomes of vital importance that an exact weight of the reagent be mingled with a measured volume of the water in order to produce complete chemical reaction (in which time is also a factor). The use of sludge from previous softening to aid sedimentation, and perfect clarification by filtration are also important features which must be considered in order to obtain results that will compare favorably with a natural soft water.

The operation of a softening and purifying system requires only the exercise of common sense and ordinary care.

It is possible with a properly designed and operated system of this kind to eliminate or neutralize any acids, to completely remove all permanent hardness, to reduce the remaining scale-forming substances to less than three grains per U. S. gallon, and to produce a clear effluent.

Any water-softening system that fails to give these results is either faulty in design or improperly operated.

The cost of water purification will, of course, depend upon the amount of the reagents required, and these in turn upon the quantity and kind of impurities. It is readily understood that it costs more to remove 25 grains of carbonate of lime than it does to remove 10 grains, not because the method is any different, but because a greater quantity of reagent is required to bring about the precipitation.

Two Types of Water Softeners

There are two types of water-softening and purifying apparatus in use, the continuous and intermittent. With the continuous system the introduction of the reagents depends upon a proportional feeding device, and hence adjustment must be made in the quantity of the chemicals introduced to meet every variation or change in the water. This being the case, an error must necessarily occur, whenever the quality or quantity of the water varies.

On the other hand, in the intermittent type, measured amounts of water are treated, and the exact quantity of reagent is determined by weight. It is possible, therefore, to accurately treat any water, no matter how it may vary in quality or in quantity.

No automatic arrangement to adjust the quantity of reagents to the impurities of various kinds in water has yet been invented, nor is it probable that one will ever be devised. Therefore, this vital function of the process

must be performed by the operator, and the care and intelligence with which it is done practically determines the efficiency of the system when there are no faults in design.

Any softening effect will improve a bad boiler feed, but to obtain the best results, accurate treatment, which means careful attention, is absolutely essential.

The water-softening and purifying apparatus manufactured by William B. Scaife & Sons Co., and known as the We-Fu-Go system, may be considered as a typical example of the intermittent purification process. Such a device renders its owner independent of uncertain weather conditions or surface supply, as water from any source can be utilized.

The Essential Elements of the System

This system consists essentially of two or more treating and settling tanks, equipped with mechanical stirring devices operated by power, a small reagent or chemical-mixing tank with mechanical stirring device and a jet or other pump for introducing the reagents into the treating tanks, and a filter.

The treating or reaction tanks are filled alternately with water. While a tank is filling, the reagents are introduced and thoroughly mixed with the incoming water by means of the mechanical stirring device consisting of a specially designed paddle revolved by power from an available line shaft, an engine or a motor.

The paddle not only mixes the reagents with the water, but at the same time stirs up from the bottom the sludge of preceding purifications. This sludge held in suspension in the water, hastens the chemical reaction and causes the new finely divided precipitates to form large wooly flakes, heavy enough to settle quickly as soon as the water stops moving.

The mixing device is the simplest and most efficient that can be constructed. With reasonable care it will not get out of order. It does not have to be frequently cleaned to keep it in working condition, and requires but very little power.

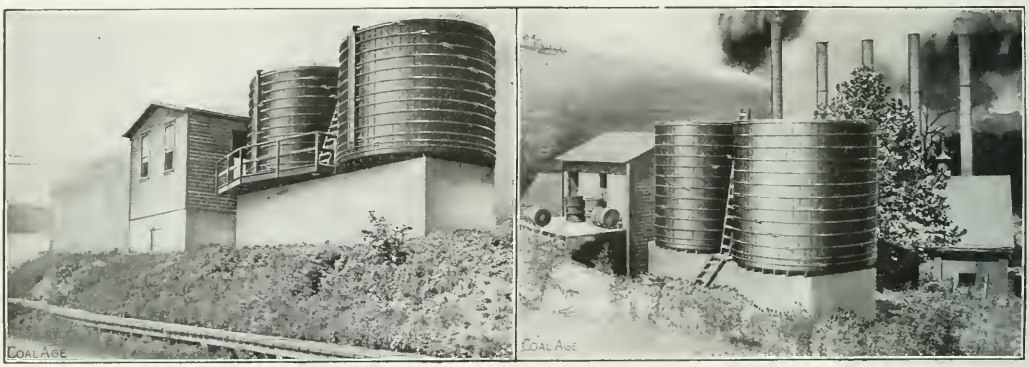
After a tank is filled the stirring device is stopped, and the water permitted to stand, in order to allow the precipitates to settle to the bottom. The softened water is removed by means of a hinged floating outlet pipe, arranged to rise and fall with the level of the water, so that the latter is always drawn from the top.

The water near the surface being the cleanest, carries the least amount of floating sludge through the outlet pipe to the filter bed. Therefore, the latter can be run the longest possible time without being cleaned. The rate of flow through the filters is automatically controlled, so that they are supplied with water as fast as it is drawn from them. Either pressure or gravity filters may be used.

While one tank is being filled, treated and settled, the other is supplying pure water; and by the time it is emptied the first tank is ready for use. In this way a constant supply of accurately treated, clear water is always available.

Pipe Connections Located in Tank Bottom

Pipe connections through which the tanks are filled, and also those which carry away the sludge are placed in the bottom. The washing of the settling tanks needs only be done once a week, or when the sludge becomes deep enough to interfere with the rotation of the paddles.



Two We-Fu-Go Feed-water Purification Systems. The One on the Left is Located at Oakdale, Penn., and that at the Right at Noblestown, Penn.

To clean out these tanks it is only necessary to open the valves to the sewer and start the stirring device which mixes up the sludge, this being soft enough to go through the pipe into the sewer.

The results accomplished with this apparatus are the following:

Accurate chemical treatment, thorough mixture of the reagents with the water, accelerated and complete chemical reaction, rapid sedimentation and perfect clarification.

With a properly softened water there will be no scale formed in heaters, pumps, pipelines or other auxiliaries, because the salts of lime and magnesia will have been removed to a point below their normal solubility. So that at the higher temperature that may be obtained without concentration, no accumulation of scale will occur.

Neither will such a water form scale or cause corrosion in the boiler. Incrustation cannot take place even with indefinite concentration, for the small amount of lime and magnesia salts left in the water are of such a character that when precipitated as a result of concentration in the boiler, only a slight sludge is formed.

WHO'S WHO—IN COAL MINING

Edwin Ludlow was born at Oakdale, Long Island, N. Y., and graduated from the Columbia School of Mines in 1879. In order to put the test of practical usage, on his long years of theoretical training, he engaged with the United States Engineer Corps under his brother, the late General William Ludlow. This early work included the surveying of various rivers and harbors on the New Jersey coast from Shrewsburg south, and on the Delaware River from the city of Trenton to Delaware Bay.

At the end of two years, young Ludlow found himself in charge of the hydrographic work of the department, the highest position in the service open to civilians at that time. While casting about for a new field with greater possibilities, he was offered a position in Mexico, which appealed to the adventurous side of the man, and he accepted. Accordingly, the year of 1881 found him, in company with two other engineers, one servant and one pack animal, engaged on the reconnaissance of the Mexican National R.R. from Laredo, Tex., to Mexico City. Some eight months were consumed in covering this eight hundred miles of mesquite- and tarantular-infested country, and our modern engineer, accustomed to elaborate camp equipments, will appreciate the hardships entailed by such a meager outfit. Added to this, the party ultimately arrived at their destination, only to find that the company was in financial straits, which necessitated the discontinuance of all further activities for the time being.

EDWIN LUDLOW

Returning to the States, Mr. Ludlow made his *debût* in the coal industry as assistant superintendent of the Mineral Railroad & Mining Co., one of the anthracite subsidiaries of the Pennsylvania R.R. Co., with headquarters at Shamokin, Penn. Being a novice at this new vocation and obsessed with an insatiable desire for first-hand knowledge of the real practical issues, he spent much of his time, dinner pail in hand, underground. At the end of two years, young Ludlow was appointed superintendent of the Union Coal Co., which concern had just leased two of the Mineral Co.'s collieries and, in 1885 when Major Stearns was made general manager of all the coal properties of the Pennsylvania R.R. Co., Ludlow was promoted to the superintendency of the Mineral Co. During his four years' incumbency of this position he was actively engaged in carrying out an extensive development propaganda, under the direction of Major Stearns, and incidentally he installed the first water-tube boilers and chain conveyors used in the anthracite regions.

In 1889, Mr. Ludlow was asked to take charge of the development of what was then a virgin coal field in the Indian Territory, now Oklahoma. Preliminary geological studies of the district had been made by H. M. Chance and Ludlow's instructions were to extend the known areas of workable coals, see that the line of the Choctaw Coal & Ry. Co., then being constructed, was located in the most advantageous position for working same, and develop mines to provide a large tonnage for the road. The field was some eighty miles in length and during the early constructive period Mr. Ludlow made a buckboard his headquarters, spending only sufficient time at the office to place orders for the supplies required at the rapidly-building camps. To step into another man's shoes and follow out tried and approved methods of procedure requires a certain ability sometimes, but to tackle the many problems incident to developing a new field on a large scale, and at the same time build up a working organization from the ground, requires an executive ability and a capacity for original thinking that probably few engineers possess. The present-day importance of the district he opened stands as a monument to the success which attended his efforts.

After ten years at the Oklahoma mines, Mr. Ludlow was again called upon for pioneer work, this time in Mexico. At the head of an American concern he was the original operator in the now well known Sabinas field in northern Coahuila, and in three years transformed a bare desert into a thriving and attractive mining camp, incidentally putting his company on an earning basis of six hundred thousand dollars per annum. Handicapped by unfavorable mining conditions, a meager supply of trained assistants, and forced to draw his labor from an inexperienced race of people, accustomed to the intermittent work of ranch life, the ability of the man was put to a severe test. Nor were his problems confined entirely to the operating end. New markets had to be created, steam consumers prevailed upon to install fireboxes suitable for using the inferior local product and today an important railroad system and many large industries rely exclusively upon this district for their fuel.

The evident success of the American company attracted new capital to the field, and other mines were rapidly opened up which ultimately developed into important competitors of Mr. Ludlow's company. His mining problems were, at the same time, becoming more complex at the increased depths, and in order to effect greater economies, and provide funds for sinking a 900-

ft. shaft (the deepest coal shaft in Mexico) he installed what is today the most modern battery of Koppers waste-gas ovens on the American continent.

Ability such as Mr. Ludlow's was, obviously, too rare to be confined to the relatively small operations on the frontiers of civilization and it was inevitable that he must eventually gravitate to the large mining districts of the East. In 1910 he was chosen vice-president and general manager of the New River Collieries Co., and, although only with that concern about one year, his work in this field was particularly effective and brought the results which the company had been seeking for a number of years.

In March of last year Mr. Ludlow accepted a position with the Lehigh Coal & Navigation Co. as vice-president, in charge of the mines. At the time of his appointment to this position the late W. A. Lathrop said of him: "Mr. Ludlow brings to his new situation a long experience with mining problems and management and the company is to be congratulated upon having secured his services." A more tangible tribute to his ability, however, was made by William C. Potter, vice-president of the Guaranty Trust Co., who said: "He has that rare combination of technical and executive ability which is in such great demand today."

Edwin Ludlow is essentially a man of contradictions. Debonair, blasé, almost Chesterfieldian in manners, a member of New York's most exclusive clubs, and an epicurean of no mean discernment, he is none the less at home in the mines, will answer to the call of "grub-pile" in a cow-camp, with the avidity of the normal "puncher" and then show the latter a few of the fine points in throwing a "diamond-hitch." He is by all instincts and training an Eastern man, while a handsome loving cup, presented him in the West, speaks eloquently of his popularity there. No more princely host or thorough disciplinarian exists. A man of quick decisions, tempered however, by a full appreciation of human failings, he has invariably won a loyalty and an *esprit de corps* among his men that is all too rare. Incisive in his orders, he inspires an immediate confidence that has stood him in good stead during the inevitable mine disasters, when directing his men at the face, where he prefers to be.

A Modern Power Plant

The Lehigh Coal & Navigation Co. is building a power house at Hauto, seven miles above Mauch Chunk, which will transmit current at 110,000 volts anywhere within a radius of 175 miles. The power house is being built of brick, the operating room being 180 ft. long, and the boiler room 385 ft. long and 70 ft. wide. The dam will be 1700 ft. long, and the height of its embankment 31 ft. The width at the base is 150 ft., and 15 ft. at the top. Broad Mountain and Nesquehoning Mountain form the sides for the new reservoir, which, when completed, will entirely cover the old L. C. & N. dam.

The boilers are of the water-tube type, having a capacity of 1000 hp. each. The water will be taken from the reservoir and, after passing through the turbines, it is to be condensed and returned through an open canal to a point midway in the new reservoir. The water will circulate through the reservoir until it again reaches the intake tunnel, when it will go into the plant to be used again.

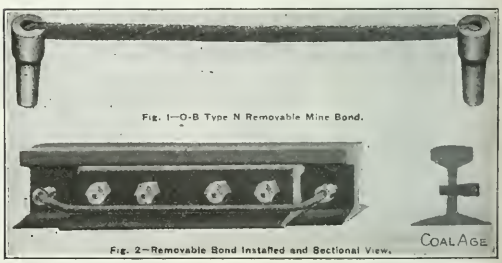
Three turbo-generators of 1000 kw. each are to be installed at the beginning. A three-phase current will be generated at a voltage of 11,000 volts, which will pass through step-up transformers until it has reached the transmitting voltage of 110,000 volts. Galvanized steel towers will be used for supporting the cables of the transmission line. The towers will be 78 ft. 6 in. high, and will be spaced about 600 ft. apart.

A New Bond for Butt Entries

In coal mines, the haulage tracks in cross headings or butt entries are used for only a comparatively short time before they are taken up and removed to new workings. In order to meet this condition, the Ohio Brass Co. recently designed their type N removable mine bond for the exclusive purpose of bonding temporary tracks.

This bond differs from compressed terminal bonds, in that it may be readily removed without injury when the temporary tracks are taken up and it can be used over and over again.

Before putting the type N removable mine bond on the market, the makers placed a number in actual service in mines and kept a careful record of their performance and have proved conclusively that they are much



Improved Type of Bond for Use in Coal Mines

more efficient than channel pins, which have hitherto been largely used for bonding temporary work.

Briefly, this bond consists of two tapered steel terminals joined together by a flexible copper cable (Fig. 1). This cable is headed and soldered into the terminals, which are tinned all over. The taper has been carefully worked out so that when the bonds are first installed they need only be driven in a short distance. The next time they are used they are driven in a little further, and so on.

Application is extremely rapid, as the bonds are simply driven into holes drilled in the rails by a few taps of a hammer, no special tools being required.

A standard $\frac{5}{8}$-in. drill is used to bore the hole in the web of the rail, and the bond terminals broach this hole so that it conforms to the taper of the bond.

The design of the bond is such that it will go around the fish plate (Fig. 2), thereby making it unnecessary to remove the generally rusted fish-plate bolts in order to install the bond. This feature makes inspection or removal much easier.

As previously stated, this bond is designed exclusively for temporary tracks, while on main-line haulages the compressed terminal type of bond should be used.

EDITORIALS

High Fan Efficiency

A great majority of the fans and blowers used in the ventilation of coal mines are sold under guarantees of performance. Unfortunately, however, it is seldom that the means and methods to be employed in the acceptance tests are mentioned in the contract. Almost invariably, if properly set up, in accordance with the instructions of the builders, these machines measure up to their specifications.

It is not at all uncommon to read of ventilating fans, even of the disk type, having an efficiency of 70 to 80 per cent., or even higher, while some manufacturers appear to have no hesitancy whatever in guaranteeing such high performances.

Almost invariably, also, the acceptance trials are conducted with the aid of an anemometer, the shortcomings of which are well known. So unsatisfactory and inaccurate may these instruments become, particularly when used in strong air currents, that it is believed by some engineers that results obtained from their use are, or rather may be, quite as unreliable as a guess.

In an article appearing in *Engineering News*, Vol. 65, p. 558, A. H. Anderson says: "A simple centrifugal blower with six radial vanes has an efficiency of about 40 per cent. A later type having a large number of narrow vanes has an efficiency of about 60 per cent." These figures closely corroborate determinations made by Prof. R. C. Carpenter.

W. G. Walker, in experiments on disk fans of uniform size and speed, but varying shape and angle of blades, found efficiencies ranging from 4.7 per cent. to 43 per cent. All of the above, it should be remembered, were laboratory tests conducted in a most careful and scientific manner.

If approximately 60 per cent. is the best that can be obtained from a centrifugal blower when on the testing floor under the most favorable conditions, it is hardly natural to expect better results when in operation at the mine. The careful mine owner or engineer may well look askance therefore, at the extremely high efficiencies guaranteed by some fan builders.

⁂

The Strength of Law

The strength of law is in the approval of the citizens. Never was an act passed which served its purpose, if the people were opposed to its execution. The law must be accompanied by the right sentiment or it will be only a job for the public printer.

When a man is killed, the common cry is, "Lynch the murderer," but in more civilized communities it is changed to "Apply the law." Everyone who saw the crime gives evidence; the whole community hopes that the criminal will not escape.

If such a sentiment backed the mining law, if the thought of everyone was to let the law be enforced, we would not have so many accidents. It would be dangerous to violate the mining code. The inspector would find witnesses at hand to testify against the violator. He would not have them slip away and leave him with a weak case when the matter came to court.

The change is coming. It will be before long as easy to put men in jail for neglecting to take precautions as to incarcerate them for "stealing cars" or appropriating picks. An act, which puts in danger a mine full of men, has not as great a justification as can be brought forward for changing checks or sawing the mark off a pick handle.

No man who committed such a petty theft would have his fine paid by the union, although at present there are those who claim that the penalty which is imposed for a violation of the mining law, is often paid from union funds. This is an evil feature in the attitude of labor. It is not what is known as "solidarity of the working classes." It permits the criminal to injure his brother man. Surely men are not banded together for the purpose of having the careless injure others who are innocent of wrongdoing.

In fact, we should not be satisfied with the law alone. The man who steals cars has to move away from the place where he committed the act; the disapprobation of the community makes the journey necessary, and the man who jeopardizes a mine should find it best to leave, and in fact, as mining is essentially an occupation where the careless usually injure more than themselves, the man should be compelled by some provision of the law to enter a life work where his folly and dishonesty of purpose could no longer constitute an offence against his fellow men.

⁂

The Central Power Station Idea

During a a comparatively recent period of time, the idea of the central power station has been rapidly gaining headway. It has been found that power losses, even over transmission lines of considerable length, are less costly than are fuel freight rates for the same distance.

Already we have hydro-electric developments supplying current to large coal-producing areas, and steam- or gas-power stations projected in the heart of coal-mining regions, where the fuel as taken from the ground possesses, as an article of commerce, its first and least value.

In the present state of power engineering, it is idle to hope that unit efficiency or even any approximation hereto, can ever be attained in any thermo-mechanical or thermo-electric plant, as a certain amount of heat energy is invariably wasted in any process involving fuel consumption. But, since heat losses are inevitable, it would appear to be the part of wisdom to permit these losses to take place only at the point where the fuel involved represents the least possible outlay in actual time and money.

A Fan Question

We publish, in the Discussion department this week, a criticism of our answer to a recent examination question, by one of our readers, at his special request. The criticism is an honest one, although as we have tried to show, in a brief editorial note following the criticism, the correspondent misjudges the conditions involved in the question.

When a criticism or other contribution is evidently in error we do not publish the same except upon the special request of the correspondent; and then only when the question involved is an all-too-common mistake, which we hope to correct, in a measure, by a free and open discussion.

In the present case, the point of issue is the reduction of the air volume caused by an increase of water gage, for the same speed of the fan. Our correspondent says the air volume is always "proportional to the speed of the fan, irrespective of the water gage."

The point to be impressed, here, is that the water gage, in mine ventilation, may be increased in two ways:

1. By increasing the speed of the fan.
2. By increasing the mine resistance.

In this question, the increase of gage, *for same speed of fan*, can only be due to an increase in the resisting power of the mine, which means a less air volume, less work lost in fan, slightly greater fan efficiency and less power required to produce the same speed of fan.

Slack

The problem furnished by the absence of demand for slack is likely to be severe so long as such a large number of coal corporations still burn run-of-mine coal. It would pay the mining companies to get together and engage a capable canvasser who would watch new installations in the cities and urge the introduction of uptodate slack-burning and self-feeding boilers. We believe that an energetic campaign might be made which would double the demand for slack and make the price such that the extreme care in preparation and mining might be relaxed.

However, the man who undertook to press the claims of slack on the attention of the smaller consumer would have to keep silent about the conditions at many of the mines which he represented. He would not be able to fortify his claim by showing how much his companies were saving by their use of small sizes and the reduction of stoking labor.

The Harger Plan

We think the Harger plan, as originally laid out, was sufficiently discredited by the public before Mr. Burrell made his address at Parkersburg, W. Va. Nevertheless, we do believe that it may ultimately be found available in connection with shotfiring from the surface. When no one is in the mine, it will be possible to fill the workings with carbon dioxide and oxygen-depleted air, so that the only things which are likely to burn will be explosives which contain their own oxygen. In this way both mine fires and explosions will be prevented.

When the mine is entirely depopulated, its atmosphere can be made so foul as to be destructive to life. The short time during which this condition will be maintained will involve less cost than 10 hr. of lesser air pollution.

Electricity in Coal Mining

It is probable that in no branch of human activity does the power of electricity meet with a more diversified field of usefulness than in coal mining. Although all of the applications of this form of energy to mining processes may be divided into four great classes or divisions, viz.: the production of light, the distribution of power, the transmission of intelligence and the initiation of chemical reactions, the number and variety of the operations performed by its aid are scarcely less than legion.

Let us consider for a moment what manipulations in the mining and preparation of coal are, or rather may be, accomplished by means of this power. First the coal is undercut by electrically operated machines. Next the shot holes are bored by electrically driven augers. After the powder charges have been properly placed and made ready they are fired by electric detonators.

The coal is then loaded into mine cars by electric-shoveling machines. The cars are hauled to the shaft bottom by electric locomotives, controlled by an electric signal system, where an electrically operated cager counts them off and places them upon the cage.

The attendant then presses an electric button and the engineer on the surface receives the signal to start the electric hoist.

During the upward travel of the cage an electric tachograph makes a permanent record of the time, duration and rapidity of the hoist and warns the engineer by a visible or audible sign if the safe speed limit is being exceeded.

Upon arrival at the pit bank an electric ram pushes the loaded car off and an empty one upon the waiting cage. After removal from the mine car through the medium of an electrically driven dump, the coal passes first to electric shaker or revolving screens and thence to electrically impelled picking tables and loading booms.

Finally, after the mine product has been safely deposited in the railroad car, by means perhaps of an electrically driven box-car loader, the tipple foreman calls up the superintendent over the telephone and informs him that a certain railroad car of a certain number has been properly loaded with such and such a grade and is ready to be turned over to the transportation company for delivery.

In the above, only the processes wherein the coal is directly involved have been considered. No mention whatever has been made of the very common and important, although perhaps somewhat subsidiary uses for electricity, such as lighting, ventilation and drainage, to say nothing of the employment of electric head- or safety-lamps by the individual miners.

We can only view the future in the light of past experience. So rapid has been the progress of electricity in the ten or twenty years which are immediately behind us that its ultimate future utility is difficult even to conjecture. Yet, the basic principles underlying all electrical achievements and inventions are extremely simple—so much so, in fact, that we are often deceived and misled by their lack of complexity.

The wise operator, therefore, will rather encourage than discourage an inquiring spirit and a tendency to experiment with things electrical on the part of his employees, even though to him the experiments in question may appear to be crude, puerile or even silly.

Resolution

Upon the recent retirement of Richard Newsam, as irman of the Illinois State Mining Commission, the owing resolution was unanimously adopted and made art of the records of the commission. The resolu- but feebly expresses the high esteem in which Mr. vsam, familiarly known as "Uncle Dick," was held very mining man in the state

The honored chairman of this Commission, Mr. Richard vsam, having announced that on account of his nearly e score and ten years, and the need of conserving his ewhat impaired health, he has felt it his duty to re- from this body, we, the members of the Mining In- igation Commission of the State of Illinois, do hereby e on record our appreciation of his services to the min- mine owners and mining interests of this state.

t is his honor that in the early years of mining in this e, when the methods of mining were crude and primi- , and when scientific knowledge of mining was rare and e valued, he, with a public spirit unusual in those days, lied himself to the betterment of mining conditions and increase of scientific knowledge, and made of himself of the most important factors in the subsequent mining gress in the state.

As chairman of the State Mining Board, he labored to e the standard of technical mining knowledge among ectors, mine managers, examiners and others connected the operation of mines, with the result that the stand- of efficiency in Illinois from being among the lowest is among the highest in the civilized world.

As chairman of the State Mining Investigation Commis- , created in the shadow of a great mining disaster, he e freely of his time, his knowledge, his ripe experience in ing matters, and his rare personal qualities in the guid- e and direction of a deliberative body, with such purpose the labors of the Board resulted in the production of t has been pronounced to be the best code of mining s ever formulated in any state or country.

And all this he was able to do without advantage of demic or collegiate training. An English miner, inured he use of the pick from early years, having entered the es at the age of eight years, a man whose school was pit, and whose university was contact with great minds ough the printed page by candle light, he was yet able qualify himself to be the leader in the application of nce to the mining industry, and make of himself an hority in that science.

Most of all, he is to be honored for his devotion to public rice, and the unstinted giving of time and energy to its rest, at a time when most other men were mainly con- ed with making money. For many years, especially in latter years of his busy life as a coal operator, he has ndrawn his working power from a business where it d have been coined into dollars and given it freely to service of his fellow men, especially in making min- conditions in this state healthier and safer to life and for those who must earn their livelihood in the bowels he earth.

The state needs such men. The patriotism of the future s for heroes who will serve their country in the strife stress of industry rather than on the field of battle and age. Because Richard Newsam has been a pioneer ng such modern patriots, this Commission honors him as of the great leaders of the mining industry in the State Illinois and places on record this public testimony of its rd and esteem.

⁂

New Coal Operation in Kentucky

Special Correspondence

ork has begun on the entry of the first large coal ation in Perry County, and is being pushed ahead the object of driving a double heading during the er months, while outside work is impracticable. The olidation Coal Co. has had work under way for more a year in Letcher County, which lies to the east of y, and on the head of the North Fork of the Ken- River, but this is the first active step toward de- the resources of Perry County.

It is being installed by the Kentucky Jewel Coal Co., and the plant will be located about one mile east of Hazard. It is the purpose of the company to put in a plant with a capacity of 800 to 1000 tons daily. As soon as spring opens, work will commence on the branch railroad, tipple, incline and attendant buildings, and it is the expectation of the management to be shipping coal by midsummer. The seam to be operated is known as No. 7 in the correlation of the Kentucky Geological Survey, and contains 5 ft. of a high grade of splint coal.

The Slemp Coal Co., which is headed by C. V. Slemp, J. C. C. Mayo and J. N. Camden, is lessor to the Kentucky Jewel Coal Co. The officers of the latter are Dr. Samuel Bennett, of Middlesboro, president; J. C. Smith, of Chicago, Ill., vice-president; Dr. D. O. Foley, of Jellico, Tenn., secretary and treasurer, and H. E. Bulloch, of Pineville, general manager. Mr. Bulloch is moving his family to Hazard this week, and will have personal charge of the operation.

⁂

Rocky Mountain Coal Mining Institute

A chapter was organized in Walsenburg, Colo., Jan. 13, 1913. Joseph Ball was chosen temporary chairman, and Lewis Hufty, temporary secretary. Others present were D. A. Stout, Charles H. Pete, John Shaw and John Neish. Permanent officers will be elected at the first regular meeting, Jan. 25.

⁂

Power Factor Conditions

A fact not always appreciated is that the demands upon a generator increase as the power factor decreases. The power factor, of course, is determined solely by the load and not by generator conditions. Machines are rated in kilovolt-amperes, this rating being the product of the current and voltage output.

The prime mover driving the generator has its energy expressed in either horsepower or kilowatts. In order to successfully match generators and prime movers, it is necessary to know the maximum outputs of both, and the operating power factor, so that a generator, the limiting capacity of which matches the limiting capacity of the engine, can be chosen. The kilowatt capacity of a generator is equal to the kilovolt-ampere capacity only when the machine operates at 100 per cent. power factor, a condition which practically never exists with present-day commercial loads.

⁂

Direct Current Turbo Generators

A small line of direct-current generators arranged for direct connection to steam turbines, the complete outfit, entirely self-contained, is made in capacities ranging from 25 kw. to 150 kw. The compactness, absence of reciprocating parts, simplicity and reliability, make these sets desirable for many applications where a small direct-current machine is required. For exciter sets in large central stations, or for small isolated plants, they prove exceedingly desirable.

⁂

When installing a spray locate it in the center of the roadway near the roof and in such a way that the water will be discharged in the direction in which the air travels. One spray box is sufficient for each 5000 cu.ft. of air supplied per minute. A pressure of from 15 to 20 lb. per sq.in. is necessary to run a spray.

DISCUSSION BY READERS

Reducing Ventilation When Firing

Letter No. 6—The coal-dust problem has been discussed from time to time by good authorities, and much valuable information deduced, relative to the presence of this dangerous element in mines. Coal dust is now quite generally recognized as one of the important factors in propagating an explosion. Likewise, a few exponents of the practice of reducing the ventilation in mines, at shotfiring time, have urged this as a means of preventing mine explosions; but, in most cases have failed to give good reasons for their opinions. These advocates have been, for the most part, content with recounting their personal experiences, as proof of their contention.

I have been waiting patiently for someone to ascribe the danger of explosion to the explosibility of powder smoke when mixed with air; but so far no one seems to have made any allusion to this important phase of the question. On account of the close connection between the two subjects, I am compelled now to discuss both the explosibility of powder smoke and reduction of ventilation during shotfiring, at the same time.

The idea seems to be prevalent, in many minds, that black powder and dynamite do not give off explosive gas when used in blasting. While powder manufacturers admit that this is not true, they generally claim that the explosive gases generated are due to the incomplete combustion of the powder. However this may be, any miner of several years' experience when doing his own shotfiring, or any shotfirer who has used squibs instead of fuse will tell you of many instances where they "fired the powder smoke" in going back too soon after shots had exploded. With this suggestion any thinking man can readily realize the danger that may exist in a mine filled with powder smoke, provided a sufficient amount of oxygen is introduced into the smoke to make an explosive mixture.

During the past year it has been the writer's unpleasant experience to have investigated five explosions in mines. In each case the investigation showed that it took at least two shots to start the trouble. We invariably found that a bad or windy shot produced a dangerous atmosphere for the shots following. In one instance, our examination showed that a heavy dynamite shot, laid about four feet on the solid, had been fired in the place adjoining that in which the explosion started. This shot did not do its work, but blew the tamping; and the force of the wind was very apparent where it had traveled out through the crosscut into the adjoining place. The shot that had been fired in this place was a good shot, charged with black powder, and did its work nicely. Although this shot had no appearance of being overcharged yet it was here that the fire started.

Some may say that the first shot stirred up the dust, which the second shot ignited. This, however, was almost impossible, as after the heat of the explosion had passed over it we found the dust and fine coal still wet enough to squeeze into a ball, in the hand. No gas of any kind had been encountered, in either place, before the explosion; and none was found after the explosion; although, by reason of the stoppings being blown out, the circulation in these places was practically stopped. Our conclusion was that the second shot ignited the gas produced by the blownout shot; and, as the fire traveled only about 300 ft., we decided that this gas furnished practically all the material for the explosion. Had the mine not been in good condition an extensive and violent explosion would likely have resulted.

As stated previously, I believe the volume of air in circulation to be closely concerned in the explosibility of powder smoke. Another instance of a violent explosion that came under my observation, gave sufficient evidence that, here also, powder smoke was the sole explosive agent. The mine was an unusually wet one; the entries were muddy their entire length, and considerable trouble was experienced in keeping the rooms dry enough to allow the men to work. The ribs in both the entries and rooms were always wet, which puts dust out of the question, for there was none. The coal seam was near the surface, the shaft being only 40 ft. deep. Not a trace of explosive gas had ever been found in any of the workings, or in any of the neighboring mines.

The mine foreman, in this mine, was a staunch advocate of reducing ventilation at firing time. He had instructed the engineer how fast to run the fan, which was just fast enough to hold the smoke back sufficiently to allow the shot firers to keep ahead of it. However, on the evening of the explosion the shotfirers had been firing about 30 min. when they came out of the mine and asked the engineer to speed up the fan, as the smoke was bothering them. He refused to do so, as he would not disobey the instructions of the mine foreman. He suggested that the men wait a short time and allow the smoke to clear up. They did not do this but went over to the fan house and opened up the throttle, giving the fan full speed. They then returned to their firing and in a few minutes the explosion occurred killing them both. The mine was badly wrecked and there was considerable evidence of flame. The speeding up of the fan increased the supply of oxygen, which rendered the powder smoke explosive and a shot ignited the mixture.

At another time, when opening a new mine, we had for some time a number of light explosions, which, at times, were strong enough to damage the tipple. We tried shutting down the fan and had no further trouble. This was nine years ago and, from that time to the present, the mine has worked steadily, but the fan is always stopped at firing time. Some of the workings are now over a mile from the shaft. It might be argued that sufficient air was kept circulating to keep the mine free from smoke there would be no danger from that source, but this could not be done in this mine.

To those who have observed the action of shots underground, when at close range, the ideas I am advancing will appear very reasonable. I once had an opportunity to watch the explosion of a black-powder shot in a room

he fire extended from the face about 75 ft. and seemed fill the entire room. Upon examination, it was found ie shot had worked nicely. It was not thought to have en overcharged. It occurred to me that, after so much re in the room, there could not be much oxygen left in ie air; and the question was suggested: If an explosion ould originate in an adjoining room, what would be ie result, by reason of this atmosphere from which ractically all of the oxygen must have been burned. ven, supposing that the room was full of fine-coal dust, ould an explosion be propagated through it, in the abnce of oxygen?

The argument is that the reduction of air supply is aid in the prevention of an explosion, because of the ck of sufficient air to form an explosive mixture. The ason that this is harder to control in winter than in mmer is because the natural ventilation in a mine, in inter, makes it almost impossible to limit the supply oxygen unless all intake openings are closed.

I realize that these remarks will meet with some severe iticism; but if they arouse a lively discussion on the bject they will have served their purpose. It may be aimed that the reduction in the percentage of oxygen in e mine atmosphere, by the flame from shots, would not ake any appreciable difference in the explosive mixtures used by blasting. In answer to such a claim, hower, I would ask that careful investigation be made as the necessary reduction in the percentage of oxygen in der to render the most explosive mixtures harmless.

C. W. Waterman,
Genl. Supt., The Fleming Coal Co.

Pittsburg, Kan.

⁂

Letter No. 7—Referring to the matter of reducing ventation by slowing down the fan at firing time, allow me say that my experience of 35 years in the mines, in ery capacity from trapper to superintendent, has taught that this is a dangerous practice. Mr. McAllister, in several letters, has described practices that every good ining man must condemn as unreasonable. I would ither try such methods myself nor recommend them to iers. The operators in Indiana think more of their operty than to allow such a method to be adopted and e shotfirers here would not risk their lives in the mines, they knew that the fan was not in good condition and nning at its normal speed.

It is the general practice, in our district, to speed up the n before beginning to fire shots. Suppose, for example, 20-ft. fan is run commonly at a speed of 40 r.p.m. dur the day. At firing time, its speed would probably be reased to 60 r.p.m., especially in mines where gas is nerated in any quantity. It appears to me unreasonable at mining men of experience should recommend firing om 100 to 300 shots, in a mine without any air in circlation. Our doctrine is that the fan should be run conuously for 24 hours of the day, with an increase in veity of, say 25 per cent, while shotfirers are at work. At the present time, I am firebossing at the Wizard ne, and I am certain not one of our shotfirers would go o the mine to perform this work, if the fan were to be t down. Not only this, but the superintendent would allow such a practice. We believe in good ventilan; air-tight stoppings and overcasts; withdrawing the n from the mine in case the fan is stopped or in case of explosion; keeping on hand a good supply of safety lamps; and the examining of every shot before firing.

I always advise our miners never to leave a shot to be fired that they would not like to shoot themselves. My advise to shotfirers is to make a personal examination themselves and be sure that the fan is running at its proper speed before going into the mine to fire shots.

John Sutton.

West Terre Haute, Ind.

⁂

Letter No. 8—Referring to the criticism of Mr. McAllister's article on "Reducing Ventilation When Firing," Coal Age, Jan. 4, p. 24, by R. Z. Virgin, Jan. 18, p. 111, it seems to me that both of these men are in error. Mr. Virgin's criticism is seemingly based wholly on the assumption that the ventilation was merely reduced in quantity; while Mr. McAllister, it seems to me, has sought to make it plain that he advocates closing the mine tight and thus completely shutting off the ventilation.

Assuming that Mr. McAllister's article refers to the complete stoppage of ventilation when firing, it should be headed "Stopping" instead of "Reducing Ventilation When Firing." Taking that meaning, it is obvious that this will produce or establish a condition in the mine that will be unfavorable to explosion. When oxidation continues in still air, the percentage of oxygen in the air is decreased while the percentage of carbon dioxide is increased, which produces an atmosphere that will exert a retarding influence on any explosion that might be started. As the oxygen in the air is reduced, the nitrogen remaining is in excess; and this excess of nitrogen will likewise act to still further retard explosion. Admitting these facts, one can readily see that there is something, in the narration by Mr. McAllister that is worthy of consideration.

Mr. Virgin divides his argument under three heads. His first point, which seems to me to be absurd, states:

> Percentages of gas that are not previously explosive become explosive in proportion as the volume of air is decreased.

According to this argument, the *minimum* volume of air will produce a *maximum* explosive mixture, which, it seems to me, is contrary to all teaching.

His second point states:

> Percentages of gas that are not previously explosive become explosive under the pressure of heavy blasting in a confined space where the air is dead.

Now, "dead air" is, as I understand it, air devoid of the life-sustaining element, oxygen. In such air, certainly there could be no explosion.

The third point states: "The reduced air current will carry a large percentage of dust, etc." But still air will carry no dust. Water is said to carry a weight of material in proportion to the sixth power of its velocity. Applying the same principle to air, a reduced velocity would carry much less dust than a current of high velocity.

John Rae.

Hanna, Wyo.

[Referring to the above, if the firedamp mixture contains an excess of air, a reduction of the air volume, for the same flow of gas in the mine, would cause the mixture to approach the maximum explosive point, which is evidently Mr. Virgin's meaning.

"Dead air" in ventilation generally relates to a stagnation of the air current in the mine, it does not refer to any deficiency of oxygen in the air.

The third point stated by Mr Virgin contemplates the dust being raised by the force of the blast, and in this case a greater weight of dust will permeate a given volume of air.—Editor.]

Yield of Fan under Increased Gage

Referring to Coal Age, Jan. 11, 1913, p. 77, the question is asked: What quantity of air will a fan produce, at a constant speed, when the water gage is increased from 0.4 to 0.8 in., the original volume of air being 35,000 cu.ft. per min., under the lower gage? In answer to this question, it is stated that the volume of air is reduced to one-half of the original amount, or 17,500 cu.ft. per minute.

I beg to say that my experience in making many air measurements has proved that the same speed and efficiency of the fan gives the same quantity of air, regardless of the water gage against which the fan is operating. The yield of a fan is so much per revolution, up to a reasonable speed. The yield of the fan for a speed of 80 r.p.m. given in this question, is 35,000 ÷ 80 = say, 440 cu.ft. per revolution. The fan certainly will not produce less air per revolution because it is harder to turn; but it may take more power to produce the same speed under the increased gage.

In my experience, I have found that the quantity of air a fan will produce, at a normal tip speed, say a mile a minute, is proportional to the number of revolutions per minute. Thus, in this case, taking 440 cu.ft. per revolution as a base of calculation, this fan would yield as follows:

At 40	r.p.m.	17,600 cu.ft.
At 60	r.p.m.	26,400 cu.ft.
At 80	r.p.m.	35,200 cu.ft.
At 100	r.p.m.	44,000 cu.ft.

I know you will gladly correct this if the answer is in error.

Joseph Virgin.

Bancroft, W. Va.

[The experience of our correspondent is at variance with that of most fan engineers. By the terms of the question the water gage is increased and the speed of the fan remains unchanged. There are two ways in which the water gage in a mine may be increased; namely, by increasing the speed of the fan, or by an increase in the resisting power of the mine. Since the speed of the fan, in this case, is unchanged, the increase of water gage here must be due to an increase in the resisting power of the mine.

In practice, any increase in water gage due to an increase in the resisting power of the mine reduces the quantity of air in circulation in the mine and passing through the fan, for the same power on the air, according to the equation $U = Qp$.

As the pressure per square foot is increased, in the mine, as indicated by the water gage being increased from 0.4 to 0.8 in., or doubled, the quantity of air circulated by the same power is only one-half of the original quantity.

There is, however, under these conditions, a slight increase of efficiency in the fan. The quantity of air passing through the fan being less, the work lost in the fan is less, which increases its efficiency; and the effective power or the power exerted to turn the fan is increased, which makes the fan run faster, under the increased water gage. To maintain the same speed of fan, under these conditions, it will be necessary to reduce the power applied to the fan shaft.

Therefore, a slightly less power is required to produce the same speed of fan when, owing to the increased resisting power of the mine, the quantity of air in circulation is reduced. The ventilator, under these conditions, is more efficient; that is to say, a larger proportion of the power is made effective on the air. This is not to say, a larger volume of air is circulated per unit of power. The volume of air circulated per unit of power depends solely on the resisting power of the mine, which is independent of the ventilator, but controls the quantity of air circulated and the water gage.

The condition that our correspondent evidently has in mind is the increase of air volume due to an increase in the speed of fan, for the same conditions in the mine. In that case, it is true, approximately, that the volume of air is in proportion to the speed of the fan. Practically, the fourth power of the speed ratio is equal to the fifth power of the quantity ratio. In other words, the quantity increases in a slightly less ratio than the speed increases.—Editor.]

The Miner's Certificate Law

I was pleased to see, in last week's editorial pages, the suggestion of Col. R. A. Phillips that the requirement of the present anthracite-mine law, demanding a two-years' citizenship of all miners before they could receive a miner's certificate, be dropped from the new law.

This requirement of the old law has debarred the better class of miners, from the soft-coal regions and the West, as well as from Wales, England and Scotland, from settling in the anthracite region. The result is that these men go West or South, or find their way into Canada, often reaching British Columbia. Others give up mining and go to farming. The anthracite-mine law, in this regard, has stopped the immigration into the anthracite field, of practically all the English-speaking miners, whose numbers are growing less and less, here, year by year.

Does any person of judgment think that any of these English-speaking miners from the old world are less qualified to receive a miner's certificate; or that an old experienced miner from the West or from the soft-coal regions, in any state, is not rightly entitled to stand an examination in the anthracite field of Pennsylvania, and, if successful, to receive a miner's certificate?

The conditions in the anthracite field, at the present time, call for a change in this law; so that any miner who has worked from two to ten years in any coal mine and gives his affidavit to this effect would be eligible for examination, and, if successful in passing the examination, should receive a miner's certificate, giving him the right to mine coal in the anthracite mines of Pennsylvania.

One of the baneful effects of the present law has been to almost depopulate some small towns and mining districts, and to close many English schools and churches. The English-speaking miners will not generally swear to an untruth, preferring rather to go back to where they came from than to labor for two years for men who probably know less of coal mining than themselves. I hope the commission appointed to revise the anthracite mining law will carry out Col. Phillips' suggestion and change the law in this respect. I was glad to know that the Wilkes-Barre Mining Institute recently voted unanimously in favor of the repeal of this portion of the law.

D. W. Evans.

Wilkes-Barre, Penn.

INQUIRIES OF GENERAL INTEREST

Mule Haulage in Mines

For some time past the driver bosses and firebosses, in our mine, have been discussing the question: Why is it that a mule or an electric locomotive cannot pull as great a load when attached to the car by a long chain or rope, say 10 or 20 ft. long, as when a shorter chain, say from 2 to 4 ft. in length, is used? We have agreed to submit this question to COAL AGE for their explanation.

CHARTER SUBSCRIBER.

Scranton, Penn.

Before attempting to answer a question of this kind, it is well to consider some of the conditions affecting problems of a similar nature. It is a matter of common observation that a mule, haulage engine or locomotive is able to haul a greater load, once started, than what the same power is able to start. It is well known that a trip of loaded cars is more easily started when loose chain or link couplings are used between the cars than when stiff couplings are employed. The obvious reason for this is that, in the first case, the load is started in sections or one car at a time, and it is necessary to overcome the inertia of a single car only; while, in the second case, the inertia of the entire loaded trip is opposed to the moving force, at the start.

A haulage engine often takes advantage of the slack in the haulage rope to start a heavy trip, which it can easily handle when once started, but the inertia of which is too great for the maximum steady pull the engine can exert. Experience has proved that a belt-driven fan runs smoother than one direct-connected, owing to the sag of the belt compensating largely for the irregularities of the engine and the load. For a similar reason, an air chamber is attached to a pump. The compression of the air in the chamber assists the action of the pump by maintaining a continuous flow of water in the discharge pipe, during the period when the pump is reversing its stroke. By this means, the pump is relieved of the burden of overcoming the inertia of the water column, at the beginning of each stroke; and water-hammer, in the pipe, due to the sudden arrest of the water, is avoided.

We have mentioned the foregoing conditions more for the sake of information and because of their indirect bearing on the question in hand. We understand the question asked by our correspondent relates to the ability of a mule to haul a greater load with a short chain than with a longer chain, after the load has been started. There are two conditions affecting the answer to this question: 1. The sag and swing of a long rope interferes with the steady pull necessary for the movement of the load and is annoying to the mule. 2. A short chain exerts a downward pull on the mule that enables him to maintain a firmer foothold on the road. When a short chain is used, the driver usually stands with one foot on the car and one foot on the chain, supporting himself by placing one hand on the mule and holding to the car with the other hand. In this position, the weight of the driver, on the chain, exerts a compensating influence on the irregularities of motion between the mule and the car, which is similar to the effect produced in the operation of a belt-driven fan.

In reply to the question, therefore, we would suggest that the most important factor, in the use of a short chain, is the downward pull exerted on the mule, which enables him to maintain a better footing on the road and the compensating connection between the mule and the car, afforded by the driver standing with one foot on the short chain. The short chain also acts to steady and control the motion of the car. Moreover, the weight of the driver on the chain destroys the tendency of the pull to lift the car from the track.

Extracting the Fifth Root

Will you kindly extract the fifth roots of 3 and 9, respectively, according to the method explained in COAL AGE, Sept. 7, 1912, p. 333.

ASSISTANT FOREMAN.

California, Penn.

Find two numbers whose fifth powers include the given number; the fifth power of the one being greater and that of the other less than that number. Thus, to extract the fifth root of 3, proceed as follows:

$$2^5 = 2 \times 2 \times 2 \times 2 \times 2 = 32 \text{ (high)}$$
$$1^5 = 1 \times 1 \times 1 \times 1 \times 1 = 1 \text{ (low)}$$

Since the given number, 3, lies between 1 and 32, its fifth root will lie between 1 and 2. Therefore, the required root is 1 plus a decimal.

To find the first decimal figure, proceed as follows:

$$2 \times 2 \times 2 \times 2 \times 1 = 16 \text{ (high)}$$
$$2 \times 2 \times 2 \times 1 \times 1 = 8 \text{ (high)}$$
$$2 \times 2 \times 1 \times 1 \times 1 = 4 \text{ (high)}$$
$$2 \times 1 \times 1 \times 1 \times 1 = 2 \text{ (low)}$$

The last product being less than the given number, add the several factors together and divide by 5. Thus,

$$\frac{2 + 1 + 1 + 1 + 1}{5} = \frac{6}{5} = 1.2$$

Therefore, the fifth root of the given number is 1.2, which is correct to the first decimal.

To find the second decimal figure, proceed as follows: Divide the given number by the fourth power of the root thus far found, and add the quotient to four times the said root, and divide the sum by 5. The quotient will be the fifth root of the given number, to two decimal places. Thus,

$$\frac{3}{1.2^4} = \frac{3}{2.0736} = 1.447$$

$$\frac{(4 \times 1.2) + 1.447}{5} = 1.24$$

Therefore, $\sqrt[5]{3} = 1.24+$, which is correct to two decimal places.

The fifth root of 9 is found, in the same manner, and is $\sqrt[5]{9} = 1.37$.

EXAMINATION QUESTIONS

Power in Mining

Ques.—Define the term *power*, as used in mining.

Ans.—As used in mining, the term *power* relates to the rate at which mechanical energy is exerted. Power is exemplified by a given force acting through a given distance in a given time; or a given force moving at a given rate of speed or velocity. The expression of power, therefore, depends on three elements or factors; namely, force, distance and time.

Ques.—What is a horsepower?

Ans.—A horsepower is an adopted standard for the measure of power. It is the power exerted when a weight of 33,000 lb. is lifted through a vertical distance of one foot in one minute. This power is expressed as 33,000 ft.-lb. per min. The same power (one horsepower) is exerted when a weight of 330 lb. is lifted through a vertical distance of 100 ft. in one minute, or 10 ft. in six seconds; or a weight of 55 lb. lifted 10 ft. in one second. The same rate of work is performed, per unit of time, and the same power exerted, in each case.

Ques.—Explain the difference between work and power.

Ans.—Work is performed when a force is exerted through a given distance, irrespective of time or velocity. Power is exerted when that work is performed in a given time. Power is work performed per unit of time. Work is expressed in foot-pounds, while power is expressed in foot-pounds per minute or per second.

For example, 100 lb. lifted through a vertical distance of 10 ft.; or 10 lb. through a distance of 100 ft.; or 1 lb. through a distance of 1000 ft.; represents a certain work performed, which is expressed by *1000 ft.-lb.* To perform this work in one minute will require ten times the power necessary to perform it in 10 min.; thus it requires a greater power to perform the same work in less time, the power varying inversely as the time.

Ques.—Disregarding friction, what power is required to hoist 100 tons of coal per hour, from a shaft 500 ft. deep?

Ans.—The work performed, in this case, is

$$100 \times 2000 \times 500 = 100{,}000{,}000 \text{ ft.-lb.}$$

This work is performed in one hour. The work performed per minute, or the power exerted, is, therefore,

$$\frac{100{,}000{,}000}{60} = 1{,}666{,}666+ \text{ ft.-lb. per min.}$$

This corresponds to a horsepower of

$$\frac{1{,}666{,}666}{33{,}000} = 50.5 \text{ hp.}$$

Ques.—Disregarding friction, what horsepower will be required to pump 300 gal. of water per minute, from a shaft 400 ft. deep?

Ans.—The weight of 1 gal. of water is practically 8⅓ lb. The weight of water lifted is, therefore, in this case,

$$300 \times 8\tfrac{1}{3} = 2500 \text{ lb. per min.}$$

The work performed in raising this water 400 ft. is then

$$2500 \times 400 = 1{,}000{,}000 \text{ ft.-lb.}$$

Since this work is performed each minute, the required effective horsepower is

$$\frac{1{,}000{,}000}{33{,}000} = 30.3 \text{ hp.}$$

Ques.—A boiler is to be run under a pressure of 100 lb. to the square inch; to what hydrostatic pressure should this boiler be subjected in order to test its safety?

Ans.—The hydrostatic test is not applied to boilers to determine the degree of safety. It is applied for the purpose of showing any leaky joints or revealing other structural defects in the workmanship. For this purpose it is customary to subject a new boiler to a hydrostatic pressure 50 per cent. in excess of the proposed working pressure. For a working pressure of 100 lb. per sq.in., a new boiler should be subjected to a hydrostatic test of, say, 150 lb. per sq.in.

To determine the safety of a boiler it must be subjected to a rigid inspection by a competent man, and must fulfil the requirements determined by a computation based on the strength of the material and manner of construction of the boiler. To subject a boiler to a hydrostatic test exceeding 50 per cent. of the proposed working pressure would, generally, strain the parts of the boiler and weaken its condition. The hydrostatic test is regarded as a test of workmanship, rather than a test for safety.

Ques.—Explain the advantage of a duplex over a single hoisting engine, in mining.

Ans.—A duplex engine is one having two cylinders. In such an engine, the cranks on the main shaft are set at right angles to each other, so that the engine has no "dead center." This is an important feature in a hoisting engine, in mining, where it is necessary that the engine shall be able to start promptly and pick up its load without difficulty. This cannot be done with a single engine if the crank happens to be on dead center, or near that point. In hoisting practice, it is customary to calculate the size of the engine required to perform a certain work, on the basis of a single cylinder. This always gives an excess of power, which is important in hoisting.

Ques.—For what reason should a boiler have a good water circulation?

Ans.—The principal reason for this requirement is to provide an even distribution of the heat throughout the bulk of the water, in the boiler, and thus accomplish a more uniform generation of steam and avoid likewise any unnecessary strain on the parts of the boiler due to alternate expansion and contraction arising from a change in temperature. In other words, a good water circulation maintains a uniform condition in all parts of the boiler.

Ques.—What weight of coal, per horsepower per hour, will be required in operating a tubular boiler, in common coal-mining practice?

Ans.—In mining practice, an ordinary tubular boiler will require from four to six pounds of anthracite, or from five to seven pounds of bituminous coal, per horsepower per hour, depending on the quality of the coal and the manner of firing.

COAL AND COKE NEWS

Washington, D. C.

The Senate has passed a bill extending the time for the survey, classification and appraisement of the surface of the segregated coal and asphalt lands of the Choctaw and Chickasaw Nations in Oklahoma, which contains the following provisions among others:

That the act of Feb. 19, 1912 (Thirty-seventh Statutes at Large, page 67), as amended and supplemented by Section 18 of the act of Aug. 24, 1912 (Thirty-seventh Statutes at Large, page 518), is hereby amended to provide that the survey, classification, and appraisement of the surface of the segregated coal and asphalt lands of the Choctaw and Chickasaw Nations shall be continued in the manner prescribed in said acts, except as otherwise provided herein, and shall be completed not later than eight months from the date of the approval hereof, such appraisement and classification to be made by the appraisers appointed by the President Nov. 25, 1912, or by their successors in office, at a compensation of not to exceed $15 per day each, with allowance for actual and necessary expenses, including transportation, not to exceed $5 per day each, to be determined by the Secretary of the Interior.

Sec. 2. That said survey, classification, and appraisement shall be made under such regulations in such manner as may be prescribed by the Secretary of the Interior, and the disposal of said lands, including purchases by holders of coal or asphalt leases, may be proceeded with when and as the appraisement of the several tracts shall be completed.

A bill reading in part as follows has been introduced in the House by Representative Foster and referred to the Committee on Public Buildings and Grounds:

That the Secretary of the Interior be, and he is hereby, authorized and directed to enter into a contract or contracts for the erection and completion of fireproof laboratories and other buildings suitable and necessary for the investigations of the Bureau of Mines, on a site hereinafter provided, in the city of Pittsburgh, Penn., within the total limit of cost hereinafter fixed.

That the said laboratories and other buildings shall be constructed under the supervision of and in accordance with plans and estimates to be approved by a board consisting of the Supervising Architect, the Chief of Engineers of the Army, and the Director of the Bureau of Mines, and shall be so constructed as to cost, complete, with the necessary railroad sidings, approaches, plumbing, lighting, heating, ventilating and hoisting apparatus, and other necessary appurtenances, not to exceed the sum of $500,000, of which amount the sum of $300,000 is hereby appropriated and shall be immediately available for the preparation of plans for said laboratories and other buildings and for carrying forward construction work; and the Secretary of the Interior is hereby authorized to employ, without regard to civil service laws or regulations, and to pay for, out of this appropriation, such architectural or other technical services as may be recommended by the above board to aid in the preparation of the plans and specifications and to supervise the construction work herein provided for.

Concerning Alaska Coal Lands

Senator Jones, of Washington, has offered the following bill in the Senate relating to the establishment of coal-land titles in Alaska:

That every person who located or entered, or attempted in good faith to locate or enter, any coal land in Alaska under the coal-land laws of the United States prior to Nov. 12, 1906, and whose location or entry thereof has been suspended, contested, denied or canceled by the United States, is hereby authorized, at any time within one year from the date of the approval of this act, to bring a suit in equity against the United States, in any court of competent jurisdiction in the district where the land is situate, to quiet his title thereof; and if, upon the trial of such cause, it shall be found by the court upon the evidence that the said locator or entryman has complied with the coal-land laws of the United States up to the time of the suspension, contest, denial, or cancellation of his location or entry, such location or entry shall be reinstated by order of the court, and the locator or entryman may thereupon complete said entry by making the proof required to the court

A bill of similar character has been offered in the House by Delegate Wickersham, of Alaska, but this measure contains the following proviso in addition to the main text:

That either the locator or entryman so bringing said suit or the United States may appeal said cause in the manner provided by the laws relating to appeals from said court, that if the final decree of the said courts shall be in favor of the said locator or entryman a patent shall be issued in the usual form, conveying the said land to the said locator or entryman; that if the final decree of said court in said cause shall be in favor of the United States, the said locator or entryman shall be held to have no right to or equity in said land, and his location or entry shall be canceled and held for naught.

WILKES-BARRE, PENN.

Three men were buried beneath a rush of coal and rock in the East Lehigh Colliery, at Tamaqua. A 15-ft. gangway leading to the place where the men were working is filled for several feet with caved material, and several days will probably be required to reach the men. Nine men were entombed in this mine three weeks ago, eight of whom were rescued after being imprisoned for 40 hours.

Anthracite Strikes

Strikes are on at four collieries in the anthracite-coal region. In Nanticoke nearly a thousand men are out of work as a result of a dispute between the workers and the Susquehanna Coal Co. The men claim that the company ordered representatives of the union off the company's property, and they are determined that this action shall be repealed. Until it is they say they will remain idle.

The breaker hands at the West End Colliery are on strike at Mocanaqua. The trouble arises from the time of blowing the first whistle in the morning. The first whistle is not blown until 7.15, and the men and boys are not paid for the extra quarter of an hour.

At the Lytle and Pine Hill Collieries, both subsidiary interests of the Pennsylvania R.R. Co. west of Pottsville, the rockmen have gone on strike. They claim they are not receiving the full wages decided by the agreement entered into between the miners and operators last spring. A request for an increase of 10 per cent. has been refused by the company.

The Meeting of the Conciliation Board

At a meeting of the conciliation board, held in Wilkes-Barre, the Lehigh & Wilkes-Barre Coal Co. was ordered to pay its contract miners 61c. per yard for cutting top clod 4 in. and over in thickness. The company claimed that they were supposed to pay only when the thickness exceeded 6 in. All back claims are also to be paid to the men. The same company agreed to have two kinds of explosives at the Lance Colliery for the men to determine which is the better for their work.

The employees of the No. 7 Colliery of the Susquehanna Coal Co., who have been on strike because the company refused to allow the grievance committee to examine the union buttons of the men, were ordered back to work. The board has never made a ruling on this question, and it was decided that the men should return to work, and present their case in a proper form at a later date.

The grievance of the contract miners of the Hollenback Colliery of the L. & W. B. C. Co. was ordered sent to the umpire by President Dempsey. The miners want 20c. per foot for mining rock, and the company offered 13c. The umpire will decide the question. Relative to the grievance of the employees of the South Wilkes-Barre Colliery of the L. & W. B. C. Co., the board decided to take further testimony, and probably render a decision at the next meeting.

The contract rock miners of the Laflin Colliery of the D. & H. Co. presented a grievance in which they declared that they received only a 5 per cent. increase following the recent award, though the coal miners received the full 10 per cent. The case will be given further attention by the board at the next meeting. A grievance was presented by the contract miners of the Seneca Colliery of the L. V. C. Co., at Pittston. The men ask 50c. per foot for removing rock and bone. The miners from the Drifton district ask for 61c. a foot for removing impurities in the vein. These cases will also be discussed further at the next meeting

Mine Caves

Wilkes-Barre and Scranton have been the scenes of serious mine caves during the week. Twenty houses were damaged in West Scranton by a surface disturbance caused, it is claimed, by a cave in the workings of the People's Coal Co. The cave affects properties on Lafayette St. to Price, North Main St. and North Hyde Park Ave.

The workings of the Hillside Coal & Iron Co., at Cork Lane, Pittston, settled and caused considerable damage, affecting several houses and breaking the water pipes of the Spring Brook Water Co. Officials of the company have warned the residents to be on the lookout for more caves as the workings are still settling.

Fully a score of houses on North Pennsylvania Ave. and Wyoming St., between Chester and Ralph Sts., in Wilkes-Barre, were damaged by a surface disturbance caused by mining operations at the Dorrance Colliery of the L. V. C. Co. The majority of the properties are not affected seriously.

PENNSYLVANIA

Anthracite

Seminole—There was a strike at the Shawmut mine a short time ago and no coal was mined for a period of four days. The disagreement is said to have arisen from the fact that some of the employees were working longer hours than prescribed by the union. The matter has been settled, however, and the men have returned to work.

Tamaqua—Little hope is entertained by the rescuers at the East Lehigh colliery for the safety of the three men entombed Jan. 22. It is believed that they were caught in the fall of top rock and killed instantly. The character of the débris which must be removed indicates that it may be a week before the bodies will be reached.

Harrisburg—The State Railroad Commission has recommended that the rate per ton for coal from the Clearfield region to Lancaster and points between Harrisburg and Lancaster should not exceed $1.40 per gross ton. This ruling was made in the complaint of the Manufacturers Association of Lancaster against the charges made by the Pennsylvania R.R. on bituminous coal.

Fredericktown—The bursting of a flywheel on a generator engine at the mines of the Clyde Coal Co. resulted in the total wrecking of the generator and serious damage to the building. A large piece of the wheel tore a hole in the roof and smaller fragments tore through the wall. The generator supplied light and power to the mines, and as a result of the accident these latter will have to be shut down. The cause of the accident is unknown.

Nanticoke—Seventeen men had a narrow escape from death at the No. 4 Slope of the Susquehanna Coal Co. at Nanticoke, when a trip of three cars in which they were riding to the surface broke loose and ran down the slope. Seven of the men were injured, three seriously. The accident was caused by the rope, in some unknown manner, becoming detached from the cars as they were ascending a slope about 4500 ft. in length. The cars were derailed after traveling downward about 200 ft., and the ten men who remained in the cars were injured considerably less than the seven who jumped from the trip when they discovered their danger.

Bituminous

Charleroi—Five hundred miners employed in the Jumbo mine of the Pittsburgh Coal Co., near McDonald, have gone on strike because the company officials refused to discharge three nonunion men employed at the mine.

WEST VIRGINIA

Charleston—District No. 17 of the United Mine Workers wound up its convention here by the passing of resolutions denouncing a martial law regime.

ALABAMA

Birmingham—The Alabama Consolidated Coal & Iron Co.'s Searles Mine, which has been idle for several months, will be put into operation at once. The entire output of approximately 1000 tons per day has been sold to the Tennessee Coal, Iron & R.R. Co., and will be made into coke in their new by-product ovens at Corey.

OHIO

Coshocton—Thirty miners, who were entombed in the Tyndale mine No. 1 of the Columbus Coal & Mining Co., have been rescued through the airshaft. Several of the men were faint from exhaustion and foul air.

Columbus—A hearing on the merits and demerits of the antiscreen bill, which provides that miners must be paid on the mine-run rate in the Buckeye State, will be held during the coming two weeks before the Senate committee on mining. The bill which was introduced in the Ohio legislature by Senator Green is bitterly opposed by operators in every mining section of the state. The passage of the bill will mean a long fight between miners and operators Apr. 1, 1914, when the present mining scale expires.

Operators gathered at Dennison, Ohio, recently and claimed in case the bill became a law all of their operations which are valued upward of $2,000,000 will be dismantled.

INDIANA

Princeton—The Princeton Coal Co.'s mine has been shut down until fans can be installed at the bottom of the air shaft. The mine, worked at 440 ft., is one of the deepest in the state. Two hundred miners are employed.

Terre Haute—Fifteen hundred miners who struck in the Clinton field, returned to work, pending negotiations by their officials for redress of their grievances, chief of which was alleged unsatisfactory train service to and from the mines.

FOREIGN NEWS

Germany

Berlin—In Haselbach, near Altenburg, a burning subterranean coal deposit has just been discovered. The whole town stands above the burning coal field. For some time several of the larger houses of the place had to be repaired because of the mysterious cracks in the walls. Finally the architects decided to drill into the ground to ascertain the cause. They came upon the burning coal field less than seven yards under the surface.

PERSONALS

W. M. Whitmore, a coal dealer of Dayton, O., is seriously ill at his home.

John P. White, of Oskaloosa, Ia., president of the United Mine Workers of America, has been reëlected president of the organization over A. Bradley, of Mt. Olive, Ill. Frank J. Hayes, of Collinsville, Ill., was reëlected vice-president. He had no opposition. Edwin Perry, of Oskaloosa, Ia., was reëlected secretary-treasurer by a large majority. On the auditing and credentials committee John J. Mosson, of North Lawrence, Ohio; Albert Neutzling, of Glen Carbon, Ill., and William Dondaldson, of Dubois, Penn., were elected. Three tellers were elected: William Young, South Fork, Penn.; Thomas Paskell, Shawnee, Ohio; Thomas Holiday, Granville, Ill. Twenty-one candidates were in the race for delegates to the American Federation of Labor. The following were elected: John P. White, John Mitchell, Spring Valley, Ill.; Frank J. Hayes, Collinsville, Ill.; John H. Walker, Springfield, Ill.; William Green, Coshocton, Ohio; Duncan McDonald, Springfield, Ill.; Adolph Germer, Belleville, Ill. The newly elected officers will be installed early in February.

BOOK REVIEW

ANNALES DES MINES DE BELGIQUE—Tome XVII 4-me livraison, 1912. 366 pp., 6¼x10 in. Paper. L. Narcisse, 4 rue de Presbytère, Brussels.

This section of the government mining annual contains "The Iron Ore Problem in Belgium," by A. Delmer, "The Coefficient of Safety of Hoisting Ropes," by F. Herbst, republished from "Gluckauf," "Ankylostomaisis in the Sicilian Sulphur Mines" from the "Rassegna Mineraria," "General Rules for the Use of Electric Machines and Transformers (except Locomotives) Adopted by the Belgian Committee of Electro-Technology, Session of Feb. 20, 1912."

This is followed by the statistical section, relating to the mining and metallurgical industries and to boilers, engines, etc. Reports are made on underground haulage by storage-battery locomotives, mechanical coal cutting, lining a shaft with reinforced concrete, safety forms used during shaft sinking, a method of hauling excavated earth from a spoil pit for use in flushing, a bucket for removing earth, installation of electric signals at shafts and Nellen's elastic metal mine posts. The book is completed by a series of cross-sections of strata in the Hainault coal basin.

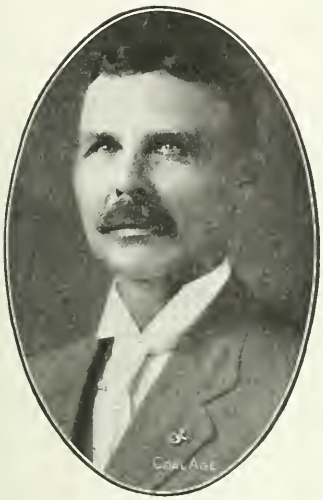
PUBLICATIONS RECEIVED

FIRST ANNUAL REPORT OF THE STATE MINE INSPECTOR OF NEW MEXICO, FOR THE YEAR ENDED NOV. 30, 1912. By Rees H. Beddow, state coal mine inspector, Gallup, New Mexico. Paper, 6x9 in.; 35 pages.

The report is the first made under the law regulating the operation of mines for New Mexico, approved June 13, 1912, and made operative 90 days later. Rees H. Beddow was appointed the first state coal mine inspector, succeeding Jo. E. Sheridan, who was mine inspector under the federal government.

The report is a brief summary of the 52 coal mines in the state, 33 of which reported to the mine inspector, 16 failed to make any report and three other mines are reported not working. Beside the usual statistical tables, the report contains a brief summary of mine inspections made by former Mine Inspector Sheridan, from July 15 to Oct. 30, 1912. The report also contains the New Mexico mining law

OBITUARY



EDWARD L. WOLFORD

Edward L. Wolford, probably one of Indiana's most prominent coal miners, died at his home Jan. 12. A strange coincident arises in the fact that his death occurred within a few hundred feet from the spot where he was born July 7, 1861.

The history of his life is interesting. After receiving his early education, Mr. Wolford was attracted by the mining business in the locality of Linton, Ind. His executive ability soon drew attention to himself as a wizard in organization and development.

In 1892 he entered the Island Valley Coal & Mining Co., acting as treasurer until the business closed out. His next position was that of secretary of the South Linton Coal Co., of which concern he was also a prominent stockholder and general manager.

Mr. Wolford was one of the original promoters and organizers of the Black Creek Semi-Block Coal Co., and was secretary-treasurer of this company until the time of its merger in 1906. When the Linton Coal Co. was organized Mr. Wolford became general manager. Later in the organization of the United Fourth Vein Coal Co., he demonstrated his keen executive ability and won for himself the respect of all in the coal mining business.

Through the achievements of Mr. Wolford this company effected the consolidation of 6 other companies, together with itself, at a capital stock of $1,000,000. Mr. Wolford became president and general manager of this concern and remained in that capacity until the time of his death.

He is survived by three sons and a daughter.

CONSTRUCTION NEWS

Johnstown, Penn.—The Fallen Timber Coal Co.'s new tipple is almost completed and it is expected that coal will be shipped within a few days. The company will employ about 150 men.

Rankin, Ill.—The new $12,000 coal dock, of the L. E. & W., is now completed. It is built entirely of steel and is run by a 12-hp. gasoline engine. It is the only one of its kind on the system

Miller Grove, Ill.—The new coal chutes which were being erected by the Fairbanks Morse Co., at a cost of $45,000, have been completed and the machinery for hoisting the coal has been installed. This newest chute is said to be the best of its kind on the Frisco System.

Duluth, Minn.—Various coal companies at the head of the Lakes are making preparations for the enlarging of their coal docks and many contracts have already been let for the same. A contract has been let recently for a new dock for the Berwind Fuel Co., which will have a capacity of 800,000 tons.

Townsend, W. Va.—A large power plant is now in the course of construction on the south side of the Kanawha, at Cabin Creek Junction. The foundation has been laid and practically all the frame work is complete. The West Virginia Power Co. is said to be the chief company promoting the new enterprise.

Morgantown, W. Va.—A company of Ohio coal operators is preparing to open up a tract of 140 acres of the Pittsburgh seam of coal just below Lowsville, together with a 90-acre tract of the Sewickley coal at Rivesville, along the Buchanan & Northern R.R. An uptodate mining plant is being installed at Watts, and it is reported that the Ohio firm will mine the coal on a royalty basis.

Franklin, Penn.—The Pennsylvania Southern R.R. proposes to construct eight miles of new track, which will cut the distance between Franklin and Clarion from 60 to 39 miles. Valuable coal deposits are being developed along this line, and it is stated on good authority that a new coal company, having 2000 acres of the best coal land in Clarion County, is being organized, with offices in Franklin.

Scottdale, Penn.—It is expected that the Hecla-Baggaley line of the West Penn Railways Co. will be completed by June 1. Most of the lesser surface grading has been done and work on the larger cuts has been started. Steel for the bridges is being delivered and ties and rails have been ordered. This road will furnish train service for nine coke towns, with a population of 15,000 or more, which are now virtually cut off.

Pittsburgh, Penn.—It is rumored that within the next three years 10,000 new coke ovens will be built in this territory, to meet the constantly increasing demand for coke from the Connellsville region. A secondary purpose is said to be to offset the number of ovens that have been abandoned because of exhaustion of coal in that region.

The Pittsburgh-Buffalo Co. has planned for 250 new ovens near Marianna, and the Pittsburgh-Westmoreland Coal Co. is contemplating the addition of many hundred ovens in its 20,000-acre holding.

NEW INCORPORATIONS

Henryetta, Okla.—The Summers Coal Co.; capital stock, $50,000; to develop coal lands.

Knoxville, Tenn.—The Hickory Creek Coal Co., capital stock, $30,000; to develop coal lands.

Ottumwa, Ia.—The Trio Coal Co.; capital stock, $10,000; to mine and sell coal and operate coal mines.

Middlesboro, Ky.—The Mingo Coal Co.; capital stock, $1500. Incorporators: John Reese, Mollie Reese and Mossie Reese.

Williamsburg, Ky.—The Bank Coal Co.; capital stock, $6000; to purchase or lease coal lands and engage in operating.

St. Louis, Mo.—The Briquette Coal Manufacturing Co.; capital stock, $100,000. Incorporators: J. Carlton O'Neal, D. E. O'Neal and Virgil Turpin.

Phoenix, Ariz.—The Black Pine Mining Co.; capital stock, $1,000,000; to deal in coal and the byproducts thereof, together with other minerals.

St. Louis, Mo.—The Ratican Coal & Contracting Co.; capital stock, $10,000. Incorporators: I. C. Muckerman, Wm. Ratican and P. J. Ratican.

Kansas City, Mo.—The V. McDaniel Fuel Co. has been incorporated here, with a capital of $4000, by V. McDaniel, G. L. Stauffer and Charles Hayward.

Bloomington, Ill.—The Meadow Grain & Coal Co.; capital stock, $12,100; to deal in grain and coal. Incorporators: John Streid, Andrew Baller, and Emanuel Oyer.

Ernukila, Penn.—Application will be made by George C. Miller, Dennie D. Mallory, Gordon F. Proudfoot, John B. Moorhead and James S. Carmichael, Pensy Coal Co.

Austin, Tex.—The Libby Manufacturing Co., capital stock, $50,000, to mine and sell lignite coal. Incorporators, L. C. Libby, W. H. Seay, P. M. Fleming. Principal office at Mount Pleasant, Titus County.

Scranton, Penn.—Charters were granted by the state department in Harrisburg to the Noble-Williams Coal Co. and the George D. Fuchs Co., both incorporated by Scranton men and both capitalized at $5000.

Cleveland, Ohio—The Balkan Mining Co., mining and dealing in iron ore and coal, etc.; capital stock, $300,000. Incorporators: G. W. Cottrell, C. G. Roads, I. L. Evans, Henry G. Dodge and Gustav von den Steinen.

Hamilton, Ohio—The Hamilton-Otto Coke Co., of Hamilton, Ohio, has been incorporated with a capital stock of $700,000, to mine and deal in coal and coke. The incorporators are J. C. Thomas, E. M. Peters, E. C. Seimer, John W. Linfert and Robert Ramsey.

Fairmont, W. Va.—The Karnak Coal Co.; capital stock, $150,000; to develop coal and other mineral lands in Pawpaw district, Marion county. Incorporators, David Morrison, J. W. Hayward, C. T. Porter, and G. D. Ewert, of Cleveland, O., and M. T. Porter, of Lakewood, O.

New York, N. Y.—The Socorro Mining & Milling Co.; capital stock, $2,000,000; to engage in all kinds of mining. Incorporators: J. L. Kauffman, B. Abbott, C. E. McMahon, M. A. Lynch, and G. H. Fitzgerald. Principal offices at 165 Broadway, and chief works to be located in Socorro County, New Mexico.

Sugarcreek, Ohio—The Sugarcreek Clay Product Co., of Sugarcreek, Ohio, has been incorporated with a capital stock of $40,000, to mine and deal in clay, coal and brick and other clay products. The incorporators are Amra Hotchstetler, J. M. Hotchstetler, E. E. Weaver, W. B. Hochstetler, and J. F. Zahner.

Charleston, W. Va.—The Thomas Coal Co.; capital stock, $50,000; the production and selling of coal, oil and timber. Incorporators: D. C. Thomas, Classton, Penn.; J. W. Blower and E. B. Graham, of Columbus, O.; L. G. Worsten and H. D. Wilson, of Atherton, O. The principal office and chief works are at Seng, Logan county.

Joplin, Mo.—A company was organized here comprised of Webb City and Oklahoma mining operators for the purpose of drilling virgin land north of Hattonville, Okla. A lease on 500 acres near that city was taken by A. D. Hatten, a local operator. Local members of the company, A. D. Hatten, T. F. Coyne, and A. J. McInturff, will leave in a few days for their property near Hattonville

INDUSTRIAL NEWS

Connellsville, Penn.—A New York syndicate has purchased 30,000 acres of coal in Macoupin County, Illinois, for $600,000.

Harlan, Ky.—The Harlan Coal Mining Co. is reported to have sold to the Clover Fork Coal Co. a tract of about 500 acres of land.

Somerset, Penn.—Lloyd G. McCrum has opened the Operator's Special Agency for coal and coke trade in the Shafer Block, Somerset, Penn.

Cantine, Ill.—The washer of the Lumaghi Coal Co., of St. Louis, which was recently destroyed by fire, with a loss of $50,000, will be rebuilt at once.

Chicago, Ill.—The fifth conference of the Western Electric prize salesmen at Hawthorne was held at the Hotel LaSalle during the week of Jan. 6.

Birmingham, Ala.—Margaret No. 3, the new mine being opened up by the Alabama Fuel & Iron Co., at Margaret, Alabama, will be ready to ship coal by Feb. 1.

Holden, W. Va.—The U. S. Coal & Oil Co. will add to the equipment of its mines six 6-ton electric mining locomotives, which have been ordered from the General Electric Co.

Windber, Penn.—The Berwind-White Coal Mining Co. has ordered a 4375-kv.-a. Curtis turbo-generator, which will be furnished and installed in the company's power plant by the General Electric Co.

Cresson, Penn.—The Pennsylvania Coal & Coke Corporation will install in the power plant two 345-kv.-a., 2-unit, 3-motor-generator sets and switchboards recently ordered from the General Electric Co.

Charleston, W. Va.—The mine of the Lewis Coal Co., at the mouth of Cabin Creek, which has been idle since Apr. 18, has resumed operation, giving employment to about 500 miners and mine laborers.

Fairmont, W. Va.—The Consolidation Coal Co. will equip its collieries at McRoberts, Ky., with five 10-ton 42-in. gage electric mining locomotives. The order for these machines has been placed with the General Electric Co.

Hooversville, Penn.—Washington Custer, a prominent farmer living in Shade Township, has disposed of the coal under a large tract of land to the Loyalhanna Coal & Coke Co., which is establishing a new mining town near Reitz.

Colver, Penn.—The Ebensburg Coal Co. has arranged to add to its power-plant equipment a 500-kw. rotary converter, three 185-kv.-a. and three 75-kv.-a. transformers, and switchboard apparatus. The equipment will be furnished by the General Electric Co.

Williamsburg, Ky.—The Appalachian Ry. Co., of Knoxville, Tenn., has started the actual work of surveying the line which it proposes to construct from Williamsburg, Ky., to Petros, Tenn., a distance of about 60 miles, for the purpose of giving it access to a rich coal section.

Birmingham, Ala.—The byproduct coke-oven plant of the Tennessee Coal, Iron & R.R. Co., at Corey, is now manufacturing 3000 tons of coke daily. H. M. Urban has been appointed assistant general superintendent of the byproduct coke-oven plant to succeed H. R. deHoll, who goes with the Inland Steel Co., at Chicago.

New York, N. Y.—At a recent meeting of the Executive Committee of the American Museum of Safety, it was unanimously decided that the "Scientific American" gold medal for the most efficient safety device invented during the last three years, and exhibited at the Museum, should be awarded to the Draeger Oxygen Apparatus Co.

Pittsburgh, Penn.—The Rochester & Pittsburgh Coal & Iron Co. will add to its power-plant equipment at Punxsutawney, Penn., two 300-kw. rotary converters, two 75-hp. and two 100-hp. motors, three 75-kw., six 110-kw. and one 200-kw. transformers, and switchboard apparatus. All this material has been ordered from the General Electric Co.

Hazard, Ky.—The first large operation in Perry County field is being rapidly opened up by the Kentucky Jewel Coal Co., which has leased from the Slemp Coal Co., a good-sized boundary for immediate development. The exact location of the new plant is one mile east of Hazard, and it will be designed to handle a daily output of 800 to 1000 tons.

Jackson, Ky.—The extension of the Louisville & Nashville R.R. from Jackson, up the North Fork of the Kentucky River, has opened up a heretofore entirely undeveloped and valuable coal territory.

Up to date, there are no operations in this field, but from now on it is expected to be a factor in the coal business.

Chicago, Ill.—The Consolidated Indiana Coal Co. announces that Frank Ragan has been appointed general sales agent of the company, with headquarters at 139 West Van Buren St., Chicago. Customers and the coal trade are requested to send their orders and inquiries to Mr. Ragan.

Wilkes-Barre, Penn.—During the past week the Auchincloss colliery of the D., L. & W. Coal Co. broke the colliery record for the number of tons of coal loaded for transportation. The previous record was 1156 tons, but the new one is 1226 tons of prepared coal. This is an excellent record for an experimental colliery like the Auchincloss.

Roundup, Mont.—Coal of a very fine quality has been discovered by John Davis on Horse Thief Creek. The coal seam extends over an 80-acre tract belonging to M. M. Klein, and is all very convenient for loading cars on the spur. A shaft 100 ft. in depth has already been opened, and an operating mine will be opened as rapidly as possible on the Klein and Davis properties.

Charleston, W. Va.—The New River Pocahontas Consolidated Coal Co. will equip its collieries with new electrical apparatus consisting of an 850-kv.-a., 3-unit, 4-bearing motor-generator set, a 435-kv.-a. motor-generator set, a 380-hp. motor, and an electric hoist with control equipment, air compressor and switchboard. All the apparatus will be furnished by the General Electric Co.

Hazard, Ky.—The Kentucky Jewel Coal Co. has leased about 500 acres of valuable coal land from the Slemp interests, and has started on the construction of a $50,000 plant, from which they expect to be shipping from eight hundred to a thousand tons per day, by early fall.

H. E. Bullock, who has made a success in the Jellico field, will give his personal attention to the construction and operation of the plant here. The plans, as formulated, call for a modern plant, using only the best and most scientific methods of mining.

Miike, Japan—Some Koppers coke ovens similar to those employed at Gary, Ind., have been erected at Miike by the Mitsui Busan Kaisha to deal with coal dust, which has hitherto been wasted. The capacity of the plant, says the London "Times Engineering Supplement," is 300 tons of dust at one charge, and the time of coking is 26 to 28 hr. One ton of the dust is stated to produce 10,000 cu.ft. of gas, 65 to 70% of coke, 6% of coal tar, and 1 to 1.3% of sulphate of ammonia. Part of the gas produced is to be used in large gas engines for the generation of electricity. Current will also be supplied from this source for the lighting of the towns of Omuta and Miike.

COAL TRADE REVIEWS

GENERAL REVIEW

Cancelations of orders for anthracite are being received such numbers as to cause some anxiety among the companies. There is considerable coal moving, and while there nothing as yet to indicate that any is going into storage, continuation of the prevailing unseasonable weather conlons is liable to make such a disposition necessary in the ar future. Domestic consumers have certainly effected a eat economy in fuel so far this year, but February and rch of the last two years saw a heavy consumption, and ere are still possibilities of the market assuming rather ave proportions yet. However, conditions have been even ore favorable than the most optimistic of the anthracite oducers had dared hoped for, and it is hardly possible that ere will be any real distress during the remainder of the ason. The trade is showing a direct reversal of form, and fullness more characteristic of June and July.

There seems to be plenty of bituminous coal for prompt ading in the Eastern coastwise trade, and the market has own a tendency to soften still further. Buying is limited d confined mostly to the largest consumers, small buyers pearing confident that the market will ease off still rther. The more popular grades are beginning to come rough as the pressure is released, and the prospects are nditions will shortly be more normal. There are rumors of ntracts at 15c. above last year's figures, but buyers as a e are holding off pending more settled conditions.

Eastern dealers generally are holding firm on the preling high prices, appreciating the fact that once they e off it will be difficult to restore them. In spite of their st efforts, however, slight reductions have occurred, and re will undoubtedly follow in rapid succession, unless re seasonable weather appears. There are considerable sold tonnages at some points, and buyers are showing a al lack of interest in the market. Prompt shipment is obnable in the Pittsburgh district at practically contract ces, with the exception of slack, which brings a small emium; the manufacturing demand here has been someat less than was expected.

The unseasonable weather has had a disastrous effect on the trade in Ohio, and the shortage caused by the reat flood is probably the only thing that has prevented a lent break. The domestic market is particularly weak, ile the steam grades are fairly strong, but showing a ndency to act in sympathy with the domestic. At Hampton ads the continued warm weather, good loading at the nes, and prompt movement by the railroads have softened market, and prices are again off; however, contract ces for the new year are fairly well established at 15c. r the prevailing circular. There is a good healthy dend for the steam grades in the South, while the domestics rather weak, but the mines are making record protions.

Quietness prevails throughout the Middle Western mar, small tonnages are being taken on contract, and a num- of mines are shutting down. There is less coal being ght than was ever known in January, retailers appear to heavily overstocked, and the only redeeming feature of trade is the steam business.

BOSTON, MASS.

The market continues to soften and prices are still lower. Hampton Roads there seems to be plenty of coal for mpt loading, and there is only a limited amount of buying the part of corporations and contractors who are still ind on their requirements. Pocahontas and New River reported to have sold at less than $3 f.o.b. for shipment in next fortnight or so, several of the shippers having quietly ced a moderate volume of coal. The business for the ment is confined to the largest buyers, for none of the aller plants appear to have enough confidence in either a ersal of weather conditions in February or in any higher ces than are currently quoted to justify taking on fuel more than a month or so ahead.

For inland distribution, contracts are rumored to have n closed at 15c. higher than the delivered price for last r and extending to Apr. 1, 1914. The feeling is, however, t buyers are going to be diffident about entering the market until the season is far enough advanced to show a more settled outlook.

There continues to be serious interruption in all-rail deliveries from certain districts because of floods and slow car movement. The market in that direction, therefore, shows more life than at tidewater, and is likely to be more responsive to changes in the weather. Nothing has been heard of any canvassing for contracts for 1913-1914, but season prices on bituminous all-rail will probably be out before long.

The anthracite trade shows almost a reversal of form. Dealers are getting particular over the assortment of sizes in their cargoes, and cancelations are reported. Egg is in long supply, and there is some trouble between the companies who want to ship this grade and the dealers who don't want to receive it. Shipments are not any too plentiful, that is, they would not be if we were having a normal January, but the demand from the consumer is almost nil. Retailers are laying off men and teams and there is a lassitude about the trade that is more characteristic of June and July. Premiums are not heard of now, in the face of the companies freely offering to ship on old orders during February. There is a marked change in that respect from a week ago.

Current prices at wholesale are about as follows:

Clearfields, f.o.b. mine	$1 60@$1.75
Clearfields, f.o.b. Philadelphia	2 85@ 3 00
Clearfields, f.o.b. New York	3.15@ 3 30
Cambrias and Somersets, f.o.b. mine	1 70@ 1.80
Cambrias and Somersets, f.o.b. Philadelphia	2.90@ 3 10
Cambrias and Somersets, f.o.b. New York	3.20@ 3 35
Pocahontas, New River, f.o.b. Hampton Roads	3.00 and less
Pocahontas, New River, on cars Providence	4 25@ 4 50
Pocahontas, New River, on cars Boston	4 35@ 4 53

NEW YORK

Bituminous—There has been a slight increase in the stocks at tide water, and the market has shown a further absence of strength during the week. While quotations are being normally held at last week's level, there are rumors of operators making sales at a concession of 10c. on the off grades, with the better qualities still holding firm and difficult to obtain. This easing off of the situation continues to be ascribed to the unseasonable weather conditions. Had it not been for a pronounced shortage of equipment on the Pennsylvania lines, it is probable that this slump would have attained even greater proportion. A rather unique condition prevails in transportation circles; the supply of equipment on the New York Central has seldom been known to be better, while the Pennsylvania is failing utterly to meet the demands upon them for cars.

The weather continues to be the controlling feature in the market, and an abrupt fall in temperature would doubtless bring with it a sharp advance in quotations. There is still a scarcity of labor noticeable, but the men are working much better, petty strikes are less prevalent, and on the whole production in Pennsylvania is on the increase.

We continue New York quotations on the following basis with the low-grade soft coals rather weak as noted:

	Anthracite		Bituminous	
	Circular	Individual		
Broken*	$5 00	$5 00@5 10	West Virginia, steam	$3.05@3.25
Chestnut†	5 50	6.00@6.15	Fair grades, Penna.	3.15@3.25
Pea*	2.75	3.75@4.35	Good grade, Penna.	3.30@3.40
Buckwheat**	2 75	2 75@2 80	Best miller, Penna.	3 40@3.50
Buckwheat†	2.50	2 40@2 50	Georges Creek	3.50
Rice**	2 25	2.25@2 30		
Rice†	1 95	1.85@1 95		
Barley†	1.75	1.25@1 50		

* Scranton and Lehigh. ** Scranton. † Lehigh and Schuylkill.

Anthracite—While the demand for hard coal still continues greatly in excess of the production, operators are slowly but surely losing control of the market, and providing no abnormal weather conditions appear within the next thirty days the trade will again be on a normal basis. Premiums are still being offered on some grades, although not in such a great amount, while, on the other hand, concessions below circular are readily obtainable on other sizes. Cancelations of orders seem to be increasing, while operators are continually facing the possibility of being caught with heavy consignments of demurrage coal on their hands. Such conditions, of course, have a tendency to force the market, with the re-

sult that buyers feel much easier. The smaller sizes are in practically full supply, while sellers are almost to the point of making concessions on egg in order to move it more rapidly.

Work in the mining regions continues to be interrupted by small strikes on the part of the miners. However, the companies are getting a plentiful supply of equipment for loading, and production is quite heavy.

PHILADELPHIA, PENN.

Cancelations are being received in depressing numbers, and dealers whose orders were being pushed with the large companies some weeks ago, are now tumbling over themselves to have them canceled. There is a noticeable falling off in the demand for all sizes, even pea coal, which up to a week or so ago, was in active demand, premiums being asked and freely given for reasonably prompt shipment. Stove and pea were about the only sizes for which there was any pressing demand at all, and even these are now becoming soft. Of course, there is considerable coal moving, and there is not anything as yet to indicate that the large companies are being compelled to stock, but a continuation of the present unseasonable weather is likely to pave the way for disposition of the coal into the storage yards.

However, that there is comparatively little coal in stock at the various yards, and a sudden flurry of snow, combined with a healthy fall in the thermometer, would likely bring about a condition similar to that existing a couple of months ago. Householders are economizing in their consumption of coal, hoping that the present weather will continue until spring, but this is doubtful. The last two winters in this vicinity has seen the heaviest snows, and the most strenuous weather conditions during the months of February and March, and it is not too much to say that the present light requirements will not answer later on in the season. The month of March, taking the last two years, has been as large as any of the so called winter months, in the consumption of fuel, and if it is any criterion, the present year will be the same.

There has been a marked reduction in the prices for bituminous coal, the market falling anywhere from 25 to 35c. off quotations of a week or two past, and unless there is a decided change in the weather, this price stagnation is likely to continue. Car supply at the mines seems to be fairly good, and the market apears to be in a fairly acceptable mood, although not insistent.

PITTSBURGH, PENN.

Bituminous—The market for prompt coal has eased off more, and shipment is obtainable at practically the contract prices, with the exception of slack, which frequently involves a small premium. Production is ample for all requirements, with a fair supply of labor and plenty of cars. Manufacturing demand is somewhat less than was expected, and it is inferred that the accumulating of stocks some time ago has operated to decrease the demand at this time. Regular prices remain quotable as follows: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in., $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—Under pressure of materially increased production, coke prices have declined. Prompt furnace coke has been available at lower and lower prices in the past ten days, and late last week the decline was sharp, down to $3.50, at which fairly satisfactory brands could be purchased without difficulty. The market holds at this level, but in some quarters still lower prices are expected as conditions continue unusually favorable for production. There has been scarcely any inquiry for contract coke, although there are possibly some uncovered consumers who are holding off. Occasionally cut prices are offered by producers, but in general a definite contract market has not developed under the new conditions. Foundry coke is easier and more readily obtained. We quote, with contract prices practically nominal: Prompt furnace, $3.50; contract, first half, $3.25; year, $3; prompt foundry, $4@4.25; contract foundry, $3.25@3.75, per ton at ovens.

BALTIMORE, MD.

The continued open weather conditions again proved a serious handicap to the local market and caused a marked falling off in demand with a further drop in prices. The only thing which can give a better tone to the market is a spell of severe weather, but the weather man promises no relief in this way.

The scale of prices for the week was about 10c. lower on all grades, and even then consumers were not particularly interested.

Of course, the usual supply of coal is moving under contract, and prompt deliveries are now the rule. Train movements are as good as they usually are in midsummer, and roads seem to be able to supply all equipment desired by operators. Operators are experiencing difficulty in getting sufficient miners to produce the coal in quantities to meet an easy market, and this would be much more acute should the demand suddenly increase. West Virginia companies are doing everything to divert miners to their properties in that state.

BUFFALO, N. Y.

The coal market is quiet, due almost entirely to the weather. Everybody agrees that a good snowstorm would firm prices and restore the demand in both anthracite and bituminous. The weather has also assisted the railroads in moving coal, and they have almost entirely caught up with business, so that there is now some unsold bituminous at various points for the first time in months. Certain enterprising jobbers have lately busied themselves picking up what they could of this consignment coal and getting it off the market.

The bituminous market has not broken to any extent, and if steady weather should set in at once the sag would straighten out rapidly, for the consumption is as large as ever and promises to continue. Iron furnaces are running full blast and the demand for all classes and grades of iron and steel is as active as ever. The operators are doing what they can to flood the market with coal, but are not able to get much surplus as yet.

Everybody is anxious for cold weather, but none is expected for several days. This state of things affects anthracite most, but it slows down business generally as well. Already the complaints that the railroads are confiscating coal have ceased and blockades are forgotten.

The bituminous trade is agreed that prices are at least 10c. off and not strong at that, quotations being $2.90 for select lump, $2.75 for three-quarter, $2.65 for mine-run and $2.25 for slack. Coke is tending downward, though mainly on account of excessive prices of late; quotations are based on $6 for best Connellsville 72-hour foundry. Allegheny Valley coal is quite as active and strong as Pittsburgh, at about 25c. less.

The premium on independent anthracite is about 50c. on stove and 25c. on chestnut, egg selling at circular at the mines, with jobbers adding a little for their profit. It appears that the extra prices paid for this class of coal are about at an end, which means that the large companies are pretty nearly caught up with their orders and will remain so till some actual coal weather appears. All complaints from this or that isolated district of being out of coal have disappeared.

COLUMBUS, OHIO

Mild weather has softened the coal trade in Ohio still farther and as a result quotations took another tumble. Prices are weak generally, and particularly so in the domestic grades. Dealers have large stocks on hand, and as a result are not inclined to buy to any extent now. In fact, orders for future delivery, which were placed earlier in the month, are generally being canceled.

The steam trade is still strong although quotations have sagged considerably in sympathy with domestic coal. Manufacturing establishments are taking about as large a tonnage as usual, although they are not stocking up any. Factories engaged in iron and steel lines are the best buyers of steam grades. The tonnage required by railroads is also large and the freight movement is holding up well.

Production in the various mining districts of the Buckeye State has been hampered by lack of demand and, consequently, it is estimated that it is less than 50 per cent. of normal. In the Hocking Valley the output was fairly large and somewhat above that figure. In eastern Ohio steam business is good and there was a fair production, while in other districts, which cater more to the domestic trade, the output was low

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1 75		$1 75	$1 65
¾-inch	1 50	$1 30	1 50	1.40
Nut	1 35		1.50	
Mine-run	1.20	1.15	1.25	1.20
Nut, pea and slack	1 15		1 15	1 10
Coarse slack	1.05	1 15	1.05	1.00

CLEVELAND, OHIO

The unseasonable weather had a drastic effect on the market during the past week and prices fell off from 5c. to 10c. a ton on all grades of coal. The flood that devastated the Ohio valley prevented a violent decline. A few weeks ago high premiums were being paid, but with the stringency of the car supply less noticeable, coupled with the spring-like weather, premiums have disappeared and sales organizations

are having difficulty in keeping the mines supplied with orders.

Coal men are convinced that dealers have overbought and do not look for an improvement in the domestic market until the cold weather arrives.

Wholesale quotations per short tons, f.o.b. mines, are as follows:

District	Freight rate	¼-in.lump	Mine-run	Slack
Youghiogheoy	$1 00	$1.30	$1 20	$1.00
Pittsburgh No. 8	0 90	1.10	1.00	1.00
Goshen No. 6	0 70	1 24	1.15	1.00
Coshocton	0.70	1.70	1.45	1.10

Massillon lump is quoted at $2.50 mines. Pocahontas lump and egg is sold at $2, run-of-mine $1.25, and slack 90c. at the mines. Hocking lump has dropped to $1.55, mines. Prices on furnace coke dropped to $3.25 f.o.b. ovens with about $1 added for foundry grade. Coal sales people are holding up quotations on contract business, realizing that prices will again take a decided jump upward at the opening of navigation. This will take a large tonnage off the rail market and improve conditions generally.

HAMPTON ROADS, VA.

The continued warm weather, good loading at the mines and prompt movement by the railroads have all contributed to a still further lowering of tidewater prices, $2.80 f.o.b. per long ton being offered and sales made at $2.90 to $3.05. Inland business is now being sought and some contracts have already been taken from Apr. 1 to Dec. 31. The change in the contract year has been determined upon so as to make all contracts after 1913 effective during the calendar year. The price of standard New River-Pocahontas coals on inland contracts seems to be settled at $1.25 per net ton, an advance of 15c. over this contract year.

Now that the Chesapeake & Ohio Ry. is open to the west and the bridge that caused the diversion of tonnage is again in service, the movement of Kanawha coal to tidewater has about ceased. This is offered at $2.70 per gross ton and a sale of 5000 tons was made last Monday at $2.75 less commission, about $1.25 f.o.b. mines per long ton. Local prices for the new contract year do not seem to have been settled as yet, but they will probably be $1.25 per net ton, f.o.b. mines, an advance of 15 cents.

The report that the Italian government had contracted for 200,000 tons of American coal has been confirmed and the entire tonnage will be shipped from Hampton Roads.

LOUISVILLE, KY.

The continuance of mild rainy weather in this vicinity has further depressed the market, to an unusually low point. With several weeks of quite moderate weather, and small demand for heating coal, the domestic consumption has fallen away to practically nothing. Dealers report that their supplies are all but untouched, and that their sales are hardly 25 per cent. of what they usually are at this period of the year.

The prices being quoted on nut and slack indicate pretty accurately the state of the market. Eastern Kentucky nut and slack is selling at 90c. to $1.05, according to grade; and western Kentucky is in good demand at 85c., while the Indiana variety, which is usually not wanted here, is being offered at about the same price. Eastern Kentucky block can be had for $1.75@2; lump, $1.65@1.75; round, $1.50@1.65; and mine-run, $1.25.

Indications are for colder weather, and this seems to be about the only salvation for the coal interests here. But even if the entire month of February should be genuinely wintery, this will be poor consolation for having lost practically all of the fall and early winter through a car shortage, and the month of January by unseasonable weather.

BIRMINGHAM, ALA.

The warm weather still continues and there is a growing uneasiness among the domestic dealers and operators, lest we should have no more real winter. There is a healthy demand for both steam and coking coals, and many mines are producing record outputs. The market for these grades of coal seems to broaden from day to day and the products of newly opened mines find a ready market.

Coke is the most active commodity in this district. The output at the present time is above all previous high records and bids fair to go still higher. There is an export inquiry here for approximately 300 tons per day of smelter coke and if this order is secured it will take practically all the available surplus; it is reported that the figure asked is $1, local ovens. Some foundry-coke sales have been reported as high at $4.50 ovens for spot shipment, which is the highest price received for coke in this district since the early part of 1907.

The steam coal and coke markets are being stimulated by the record number of blast furnaces now in operation in this district. The 1912 production of pig iron was considerably higher than any previous year and an additional furnace will be blown in during February.

INDIANAPOLIS, IND.

The dullness of the coal trade here is the worst ever known for January in the history of the industry. One operator who has just returned from an extensive trip, said he found retailers' yards full and much coal on the road still coming to them and that he expected to close down his mine. On mine shipments, operators can get out without a loss, but those consigning their coal cannot get cost out of it. Operators say it is too late now to recover this winter. Retailers bought heavily early in the season, stimulated by the car shortage, and are overstocked almost without exception.

The steam grades are much better than the domestic. Factories are busy; but are using 25% less fuel than last winter on account of the mild weather. Mines that can put in half time or better fom now on will be in luck. Operators are giving their attention now to selling for next season. One of the novel situations is that five cars of anthracite coal are held for demurrage at Columbus, Ind., and are offered at a bargain. Indiana prices, f.o.b. mines are:

No. 4 mine-run	$1 10	Domestic lump 5- and 6-in.	$1.65
Nos. 5 and 6 mine-run	1 00	Screenings, No. 4	0 70
No. 4 steam lump, 1½-in.	1 25	Screenings No. 5 and 6	0 60
Nut, No. 4	1.30	Washed coal, Nos. 1 & 2.	$1.75@2.00
Egg	1 40	Brazil block	2.20
Domestic lump 2½-in.	1.50		

CHICAGO

Quietness prevails in both the steam and domestic coal markets in Chicago. Several railroads operating their own mines have closed them down and a number of lines, which have been purchasing coal under a maximum and minimum contract, are now taking the minimum.

There has been an increase in the cancelation of orders for anthracite coal. Dealers say they are lacking in storage space. Smokeless mine-run is firm at $1.50@1.60, while lump and egg is selling at from $1.75@2. There has been a reduction of between 5c. and 10c. a ton in mine-run and steam lump coal of the Springfield variety. On account of a small production of lump, screenings have advanced from 5c. to 10c. a ton. Prices in the coke market are steady, but there has been a decline in the volume of sales. Gas-house coke has been cut to $5.85. Fair prices are being paid in the West for splint coal in box cars. There is comparatively little demand for Hocking Valley coal, prices remaining close to $1.75, the mines.

Prevailing prices at Chicago are:

	Sullivan Co.	Springfield	Clinton	W. Va.
4-in. lump	$2 62		$2.27	
Domestic lump		$2 32		$3.80 @ 4.05
Egg	2 52			
Steam lump	2.07 @ 2 17	2 02	2 17	
Mine-run		1 87	1.97	3.55 @ 3.65
Screenings	1.77 @ 1 87	1 62 @ 1 67	1.62	

Coke—Prices asked for coke are: Connellsville and Wise County, $6.50@6.75; byproduct, egg, stove and nut, $5.75@6; gas house, $5.85.

MINNEAPOLIS-ST. PAUL

The retailer in the Twin Cities and in the country has done a nice, steady business, and while not rushed, he is enjoying a steady trade and will make money before the winter is over. The wholesale trade is quiet, as has been the general condition ever since the record-breaking month of November. The much hoped for cold weather does not seem to make its appearance, and coal men, while trying to keep a stiff upper lip and smile, find it very difficult with the thermometer registering 50 deg. above zero.

Prices on all grades of coal, with the possible exception of hard coal, are weak. This includes soft coals at the docks, which are reported below circular, as well as Illinois and Eastern grades. Demurrage coal is to be had at low prices, this being a secondary consideration if the coal can be moved. Smokeless is sold at the docks for from 25c. to 50c. below Jan. 1 circular. Franklin County lump, egg and No. 1 nut is selling at from $1.40 to $1.50, and Carterville in the same sizes is quoted at $1.40.

DETROIT, MICH.

Bituminous—Detroit dealers and steam consumers have bought less coal in the last two weeks than over any similar period for the past two years, not even excepting the summer time. About the only thing worth featuring in the market here today is the scarcity of the slack. This perhaps is due to the floods which have made it impossible for the railroads to handle cars, thus necessitating the shutting down of some mines

The local market is quotable on about the following basis:

	W.Va. Splint	Gas	Hocking	Cambridge	Pitts. No. 8	Pocahontas	Jackson Hill
Lump	1 35		1 40			2 00	2 25
Egg	1 35		1 40			2 00	2 25
Nut	1 50		1 50			...	...
¾ lump	1 10	1 10	1 10	1 10	1 10	...	...
Mine-run	0 90	0 90	...	1 00	1 00	1 25	....
Slack	1 00	1 00	1 00	1 00	1 00	Open	...

Anthracite—The movement of anthracite is still slow and should the extremely cold weather which was promised, materialize, the supply in the local yards would soon be exhausted.

Coke—The demand for this article is falling off rapidly. Some of the local ovens are still shut down. Connellsville is being reported at $4. Solvay $4.25, and Gas House $4, f.o.b. ovens.

ST. LOUIS, MO.

There is absolutely no demand for coal either in the city proper nor in the country; several mines in the Standard field have shut down until conditions get better, and the same applies to a few operations in the Carterville district field. At no time during the past summer was the condition of the coal market any worse than it is right now.

Carterville and Franklin County lump and egg have been selling as low as $1.10 at the mines, with nut coal at $1, screenings at 75c. and mine-run at $1. These prices are below the cost and the overproduction in the field will continue to force prices down in order to move a tonnage that could be sold just as easily at 25c. per ton more if the production was under control.

The prevailing market is as follows:

	Carterville and Franklin Co	Trenton and Big Muddy	Mt. Olive	Standard
2-in. lump				$1 00
3-in. lump			$1 35	
6-in. lump	$1 20 @ 1 30		1 50	1 20
Lump and egg	1 45 @ 1 60	$2 00		
No. 1 nut	1 05 @ 1 15			
Screenings	0 75 @ 0 85			0 60
Mine-run	1 00 @ 1 10			0 90
No. 1 washed nut	1 30 @ 1 40			
No. 2 washed nut	1 40 @ 1 50			
No. 3 washed nut	1 35 @ 1 45			
No. 4 washed nut	1 00 @ 1 10			
No. 5 washed nut	0 75 @ 0 85			

OGDEN, UTAH

Real winter weather is prevailing over the territory west of the Mississippi and so far January has been a good month for the mine operators. The consumption about equals the production and there are steady shipments, from all districts.

About the middle of January, Nebraska was visited by a cold spell and dealers were able to clean up their storage coal. This has caused orders to be placed at the mines and shipments east from the Wyoming district are at a maximum.

Mines in Colorado report an abundance of orders and plenty of coal. The shortage of anthracite is noticeable in Nebraska and the dealers are compelled to handle a lot of premium coal. This has also increased the demand for the high-grade bituminous coal.

The continued cold weather has created a fair demand for slack and there are no indications of a surplus, although there are days that none can be loaded on account of the routing on the cars. Nut grade is moving nicely with none on track at the mines.

Both Utah and Wyoming prices continue strong as follows: Lump, $2.75; nut, $2.25; mine-run, $1.85. Wyoming slack brings $1, with Utah 25c. higher

PRODUCTION AND TRANSPORTATION STATISTICS

CONNELLSVILLE COKE

The "Courier" reports production and shipments in the Connellsville region for the week ended Jan. 25, as follows.

Production (tons)	Week	4 weeks	*Shipments (cars)*	Week	4 weeks
			Pittsburgh	4,303	17,322
Connellsville	229,940	1,003,675	W. of Pittsburgh	7,117	27,348
Lower Connellsville	186,342	742,300	E. of Region	870	3,613
Total	416,282	1,745,975	Total	12,290	48,283
Same period 1912	376,597	1,395,120		11,113	40,920

The Car Situation

American Ry. Association reports surpluses and shortages of coal equipment for 2 weeks ended Jan. 15 as follows:

	Surplus	Shortage	Net Surplus
New England Lines	137	173	*36
N. Y.; N. J.; Del.; Md.; Eastern Penn.	1,653	1190	463
Ohio; Ind.; Mich.; Western, Penn.	1,694	531	1,163
W. Va.; Va.; N. & S. Cal.	768	442	326
Ky.; Tenn.; Miss.; Ala.; Ga.; Fla.	538	653	*115

Same period 1912	64,719	88	64,631

*Shortage.

FOREIGN MARKETS

GREAT BRITAIN

Jan. 17—The market continues very firm in all departments. A great deal of attention is being paid to the arrangement of February stems. Quotations are approximately as follows:

Best Welsh steam	$4 68	Best Monmouthshires	$4 26
Best seconds	4 50	Seconds	4 14
Seconds	4 38	Best Cardiff smalls	3 60
Best dry coals	4 62	Seconds	3 36

The prices for Cardiff coals are f.o.b. Cardiff, Penarth, or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days —less 2½%.

British Exports—The following is a comparative statement of February stems. Quotations are approximately as 1912 in long tons:

	Year		December	
	1911	1912	1911	1912
Anthracite	2,454,523	2,547,712	221,359	230,803
Steam	47,119,017	46,539,983	4,255,301	4,210,920
Gas	10,504,172	10,559,845	910,050	829,435
Household	1,540,710	1,639,571	166,491	141,763
Other sorts	2,980,844	3,157,893	240,710	284,447
Total	64,599,266	64,445,004	5,793,911	5,697,368
Coke	1,059,879	1,026,021	115,956	97,409
Manufactured fuel	1,612,741	1,565,432	130,912	171,400
Grand total	67,271,883	67,036,457	6,040,770	5,966,177

COAL SECURITIES

COAL AGE

Vol. 3 NEW YORK, FEBRUARY 8, 1913 No. 6

Arnold Bennett, the famous English author, who recently made a short visit to the United States, has been writing his impressions of us for one of the leading monthlies. One of these articles contains the following:

"What strikes and frightens the backward European almost as much as anything else in the United States is the efficiency and fearful universality of the telephone."

Mr. Mine Operator, do you think that sentence is equally applicable to the telephone service in the average American coal mine? We think not. But if not, why not?

We'll let you answer that if you can. We've heard plenty try to give a reason but, frankly, we are still in the dark.

If you reverse the question and ask why telephones should be "fearfully universal" in and about our coal mines, every man in or out will give you a prompt and reasonable answer. But if you press the matter a little further, you'll probably find that your informer is a little hazy as to what constitutes efficiency in telephone practice.

We once heard an operator expatiating on the efficiency and dependability of his mine-telephone system. A few weeks later circumstances led us to make a trip through one of his mines and out of curiosity, we investigated the telephone system. Here is what we observed.

The mine consisted of a main slope with long right and left headings turned off at regular intervals. Some of these headings were several miles in length, and they were served with electric haulage locomotives.

The telephone system underground consisted of three phones: one at the first pair of entries, one about midway down the slope and one near the face of that roadway.

When the locomotives were at the mouths of these entries waiting on empties, the motormen were within hearing distance of these phones. When they were inside gathering trips, the phone bells were useless. If you think this is an extreme case, begin to observe if you please, how few mine phones are within hearing distance of a regular worker, who could be depended upon to hear the telephone signal bell.

In an office building the boss who can't so regulate his affairs as to be within hearing distance of his telephone every minute of the day feels justified in employing an office girl to assume such service; if he has a few assistants scattered around in adjoining rooms, he supplies each of their desks with phone extensions and push buttons and bells. He could summon any of these subordinates by simply opening a door and beckoning, but why do that when the phone saves even these few steps?

In our friend's coal mine, to summon an assistant requires the following operation: Ring, ring, ring, until someone happens to answer. Then order that someone to go to the face of one of these cross-entries (a matter of possibly one mile), as the assistant reported earlier in the day that he expected to be there. Perhaps he'll be found there, perhaps not.

In case of fire what chance would the workers at the face have if their escape depended upon some one traveling a mile to warn them?

A large coal-mine organization which has once become accustomed to an efficient telephone system would no more be able to operate without it, than a train despatcher be able to handle his trains without keeping in touch with them by wire. This comparison may seem a little exaggerated at first blush, but a little consideration will overcome such an impression.

The train despatcher has a fixed number of trains operating on a fixed schedule and passing at fixed passing points; he would not *require telegraph communication* with them if the schedules were always maintained—how often are they maintained as a matter of fact?

How often are the mine foremen and his assistants able to carry out an entire day's work according to a previously arranged schedule?

IDEAS AND SUGGESTIONS

Co-operation

By E. L. Cole

Those of us who are employed in the coal-mining industry are continually having the cry of economy dinned into our ears, until it forms a part of our very being. There is also the demand for the elimination of wasteful methods. And our superiors have provided elaborate accounting methods, so that we are at all times confronted with statements, proving that the cost of production is one that requires constant vigilance on the part of all, to insure maximum results with minimum expenditures.

But there is one phase of this problem, whereby the cost of production is enhanced, though even the most elaborate system of accounting fails to show the large losses thus sustained. This is the lack of thorough co-operation between the heads of the various departments.

Too often the men who are charged with the management of departmental work are prone to guard with zealous care, what they are pleased to term "the encroaching on their territory," by the heads of other departments. They frequently remark, in the presence of subordinates, their opinion of the offender, and there rises a wall of antagonism, high and wide, between those who are supposed to work together for the interests of their employer.

Moreover, we see the subordinates infused with a hostile feeling toward the other departments, and there is a total absence of the *esprit de corps*, with the result that there is a marked falling off in the efficiency of the entire organization.

It is not necessary for me to cite instances of this lack of coöperation, where heads of departments are prone to stand on their so called "dignity." The reader needs only to study conditions in his own department and, if he is candid, he will often be obliged to admit that the absence of discipline is but the reflex of his own attitude toward the heads and employees of other departments.

Troubles in industrial work are nearly always due to the sins of omission, or commission, of the department head who is most prone to stand on his "dignity," and who is first to take offense when he meets the head of another department "trespassing" on what he considers his "private domain."

Have you clearly and forcibly impressed on the minds of your employees that their salary, as well as that of all others, is payment for services rendered to the same employer? And that to be guilty, even in a small measure, of refusing to coöperate with your fellow employees is nothing short of larceny? Is in fact receiving money under false pretense.

* *

Concerning Conservation of Coal

By Carson W. Smith*

Has it ever been proposed that the state should tax a coal company for coal left and rendered inaccessible in a mine? Suppose for instance that some state took the notion that it was trustee to posterity for the coal within its boundary, and said to the coal-mining man:

"Now, friend, we have come to the conclusion that you can do differently and a lot better with these mines of yours. We don't like the way in which you are gouging out the best and cheapest portions of our coal, leaving so much that is totally and forever lost. We don't believe you have the right to spoil what will be so valuable and necessary in just a few years, and we are going to try to find a way so you won't want to do this.

"So we are going to tax you for what coal you don't get! That is, of course, within certain reasonable limits. If you lose coal in your mine, you are destroying this state's wealth, and so you will pay back what you have lost for us. And if you can't operate your coal mine under these conditions and make money, *then your mine never should have been opened*, and this will compel you to close down until such a time that coal will be worth more money to us and we can pay you such a price for it that you can afford to fulfill our conditions!"

The amount of coal left and ruined each year in the mines of this country must be appalling. It is certainly unfortunate, and to a large extent unnecessary. This loss, however, will continue to be excessive just as long as the present economic conditions of the coal business continue.

No man, just for the love of humanity, is going to get out coal that costs him more than he can sell it for. When he encounters such coal in his mine he is going to leave it there—and this coal generally is in such shape that its future recovery is impossible, and if it is not taken out with the rest, it is gone forever. This is good enough for the operator, as it cuts down his average cost and enables him to make more money than he otherwise would. It is good enough for the consumer, as he gets cheaper coal—for the time being.

Who was it said, "After us, the deluge!"? Is not this our attitude?

A sinking fund is good policy in most any business. Would it be amiss for the people of this state to curtail their profits to a slight degree, so that their business might be greatly prolonged? Real patriotism is not in living only for ourselves and for today—or even for our children just for tomorrow. Practical conservation, I take it, is a real patriotism, indeed. It is as intimately associated with the future welfare of the nation, as preserving the integrity of this republic. And a great many strong men have offered up their lives to the future of

*Dacono, Colo.

this United States. We, today, scarcely think of conservation as being so serious a matter.

Could a state administer successfully a law imposing a tax of 15c. a ton on all coal lost, destroyed and rendered unavailable by the operating company? Would it be impracticable, unwise and unconstitutional to do so? Possibly.

One can plainly see, however, what would be some of the results in the coal world from such a measure. First probably, the price of coal would go up. Later on certain mines would shut down. The coal production of the whole country would decrease to the resulting economic balance.

In the coal mines, operators would begin to spend money to make their mines fireproof and explosion proof and trouble proof. And they would begin to get out all the coal—within what the law considered reasonable. Instead of seeing ten million tons in a property, the owner would see fifteen million tons, and he would build accordingly. His men would live in better houses. They would work under safer conditions. They would have instructions in careful mining, and as their skill grew, so would their pay. And, above all, no longer would they work for their bread in daily danger of their lives, for disaster to them spells ruin to the company!

The price of coal would go up—and the public would pay for it. Why, God bless them, of course they would pay for it!

The Value of Discipline

By a Pennsylvania Engineer

Nearly every time we pick up a table of statistics giving the death rate per thousand tons of coal mined and the rate per thousand men employed, we are sure to see a parallel column comparing the United States unfavorably with other coal-producing countries. Among the reasons why this is so, is the fact that a more strict discipline is enforced in the foreign countries than in our own coal-mining operations. Discipline is, by all odds, one of the most important factors in the safe operation of a coal mine; and this means discipline not only for the mine workers, but also for the officials, of whatever standing they may be.

Not so very long ago, the worth of a miner was judged by the time in which he cut his coal and loaded his quota of cars for the day. Haste to finish the shift, however, nearly always entails a haste in which there are apt to be infractions of the mine rules and the mine laws which mean increased danger, not only to the offending miner, but also to his neighbors.

How often do the foremen and firebosses, in their daily examination of the workings, find little infractions of the law which may lead to serious consequences, and pass the matter over with a slight reproof? Frequently the miner is found making a cartridge with a lighted lamp on his head, instead of keeping his light five feet away. He is not discharged, as he should be, but is given a lecture and the next time probably does the same thing. The foreman excuses himself for not inflicting a more serious punishment by saying that if the man were discharged, he would find work immediately in a near-by colliery, and as men are needed in his own mine, he might as well keep him.

Often the foreman, in walking through the mine, finds something wrong with the air current, and on investigation, finds that the "nipper" or doorboy has left his place and gone in on a trip with the driver, leaving the door open, as he expected to be gone but a short time. Does the foreman discharge him? Very seldom; he needs doorboys, and the next one would probably do the same thing. So the boy is let off with a reprimand, and threatened with dismissal if the offense is repeated. Such things do not make for a good standard of discipline, and thus go far toward rendering the mines more unsafe than they would be if all rules were enforced.

Nor is the trouble wholly with the workmen. The foreman, in a hurry to go from one section to another, will ride up a slope in a mine car, instead of having the man-cars put on; or he will ride on an electric or air motor; either of which acts would be severely censured if perpetrated by a workman. And yet, how can he expect the miners to wait for the man-cars, or to walk a long, roundabout manway, when they see him travel in the mine cars?

The strict discipline existing in European mines is one of the reasons for the decreasing death rate, even though the working conditions are said to be more dangerous than in this country. We must, then, enforce strictly both the mine laws and the special rules of our collieries, and make the men, of all classes, understand that any deviation from these rules means instant dismissal.

Cutting the Price of Coal

By a Pennsylvania Inspector

We are often surprised to find that men, as intelligent as the coal operators of the present day, are continually underselling one another; in fact, cutting each other's throats. Every person interested is asking someone to explain how he can make a fair profit on his investment.

If these same operators would give the matter just one hour's thought, each and every one would arrive at the same conclusion; namely, that all coal must be sold at a standard price which will give everyone the fair profit for which they are continually clamoring. This can never be accomplished as long as coal is sold at the mine. There must be a fixed price for the different grades of the product at every market place.

If one concern has all the necessary timber on its property to operate its plant and can probably save two or three cents on props and mine ties, it is so much to its advantage, and means so much more profit on each ton of coal mined, if coal is sold at a fixed price.

Other operators are interested in steel mills. They figure that they can get their rails at a lower cost than other coal companies. This is all well and good—but instead of making that profit—the difference in cost of steel paid by them and the other company—they sell their coal just that much cheaper and the others must do likewise. Then they wonder why the price of coal is not higher.

It is all up to you, Mr. Operator. It is you who must get busy. You cannot look to some outsider to drop in and show you how to run your business. Do you realize that there would be just as much coal consumed if the prices were three or four times what they are at present? The operators must get together; they, and they alone, can remedy the low prices.

The Bering River Coal Field, Alaska

By W. R. Crane*

SYNOPSIS—The Bering River coal field is shut in by high ranges of mountains and large glaciers. It only covers 69 square miles, but the total thickness of the beds in the Carbon Mountain district is 75 ft. and in some parts of Cunningham Ridge it may be equally thick. The folding and faulting are considerable and the volatile content changes rapidly from east to west.

❖

The Bering River coal field lies north of Controller Bay and the Bering River, and extends some 20 miles in a northeasterly direction from Bering Lake on the west to the Bering Glacier on the east and south. The Martin River Glacier and the Chugach Mountains lie to the north of the field. The accompanying map gives the position of the prospected areas in which coal has been found, which is of good grade and in beds of sufficient thickness to warrant working. See Fig. 1.

Coal in Cold Storage

The coal field is practically surrounded by lofty, snow-clad mountain ranges and extensive fields of glacial ice. It is but natural then that the climatic conditions should be affected to a marked degree by the close proximity of such vast ice-bound areas. An annual precipitation, approaching 150 in., is not uncommon, and this is practically equally divided throughout the year, although the summer months are probably somewhat drier than the other seasons.

The field is practically isolated from the interior by the glaciers and rugged mountain ranges, which isolation is so complete that moose, caribou and deer are not to be found here, and the smaller animals and birds are decidedly limited in variety.

The Chugach Mountains, lying to the north of the coal field, have elevations of 6000 to 12,000 ft., and increase in height as they approach the coast, while the mountains lying within the field seldom attain a height of more than 2000 ft., although occasionally isolated peaks have elevations of 2500 to 4000 feet.

Mountains of moderate elevation rise abruptly from the flats and lowlands of the Bering River, and are cut by cañons in which both swift mountain and glacial streams are actively at work cutting the gorge deeper and wider. Erosion is much more active below timber line than above, due largely to the protection that the rock masses receive from the moss which covers the mountains.

Spruce and hemlock are abundant but seldom reach a greater elevation than 1000 ft., which is the normal timber line. Above timber, the mountains are covered with a mantle of moss and small plants, also in many places with thickets of low bushes. Many flats or parks on the summit of the mountains produce luxuriant growths of low grass, which might furnish excellent feed for animals were it not for the exceedingly wet and marshy condition of the soil.

The average temperature for this region is below 50 deg., ranging from 2 deg. to 84 deg. above zero. Were it not for the excessive rainfall, it would be possible to carry on mining operations the whole year round. While there is occasionally a heavy fall of snow, which would seriously interfere with cutting and handling timber and performing other outside operations, yet there are many seasons when the fall of snow would be of no consequence.

Only 69 Square Miles of Coal Land

The total area of the Bering River region does not exceed 430 square miles, of which 69 square miles are underlaid with coal or at least consist of coal-bearing formations. While the coal-bearing area is gradually being extended it is not probable that there will be any material additions made.

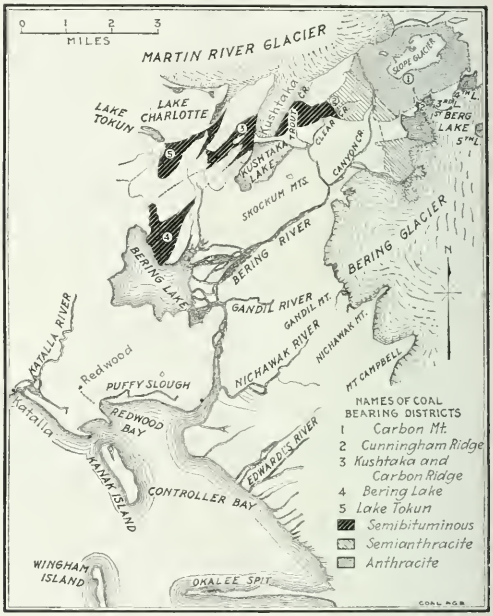

Fig. 1. Plan Showing the Bering River Coal Field and Its Relation to the Coast Line

According to Dr. G. C. Martin[1], the area containing coal can be subdivided into definite parts according to the character of the fuel found. The anthracite and semi-anthracite coal are distributed over 26.6 square miles, semibituminous over 20.2 square miles and there is an area of 21.6 square miles probably underlaid with coal, although the coal-bearing formations do not appear on the surface.

While the existence of coal in the Bering River field was known at an early date to the Indians and possibly to the Russians, definite knowledge regarding it does not seem to have become known until 1898, when R. A. Johnson, of California, learned of it from the Indians while investigating the oil resources of Yakutat Bay and the re-

*Professor of mining, the Pennsylvania State College, State College, Penn

[1] U. S. G. S., Bull. No. 335, p 65.

gion about Katalla. Considerable prospecting was done, and the Alaskan Commercial Co., now the Alaska Development Co. was formed, being interested in both oil and coal. The coal on Kushtaka Ridge was located by this company.

Heat from Igneous Rocks Has Devolatilized the Coal

For convenience of discussion, the coals of this field will be considered according to location rather than character, although the kind of coal will be carefully designated for each particular locality. The five areas into which the coals of this field may be grouped are: Carbon Mountain, Cunningham Ridge, Kushtaka and Carbon ridges, the Bering Lake district, and Lake Tokun district. The order of these fields is from east to west, which is also the order of the occurrence of the different kinds of coal; namely, anthracite, semianthracite and semibituminous.

It is somewhat difficult to explain why there should be such a wide divergence in character of coals as is found

Fig. 2. Some Badly Disturbed Coal in the Cunningham Ridge District

in the two extremes of this field, particularly if the explanation is based on supposedly greater intensity of earth movements. Dr. Martin[1] holds that the rocks of the anthracite region have been more closely folded, while those of the bituminous areas have more or less open folds, the structure being simpler.

To the writer a more plausible explanation is that the anthracite coals were close to igneous masses and in certain instances were even in actual contact with igneous intrusions now forming sills and dikes. These, though small, are evidence of the comparatively close proximity of larger masses of igneous materials. Further, there are localities in the heart of the bituminous area, which have undergone fully as extensive folding and faulting as any part of the anthracite area, and yet the coal retains its bituminous character. This matter will be referred to again under the head of occurrence of coals both in this and the Matanuska fields.

No estimate of the quantity of coal available for mining in this field will be attempted in this connection, owing to the fact that the coal beds in many localities exhibit a tendency to be quite variable in thickness and any estimate based on the assumption that a uniform bed will be maintained for a given depth or area covered by the seams will be of little value until more definite information is available.

[1] U. S. G. S. Bull. 335, p. 91

That part of the field occupied by Carbon Mountain is several hundred feet higher than the other parts. It is capped by a large mass of snow and ice, known as a "slope glacier." There is probably no part of the Bering River field which has been more thoroughly and systematically prospected.

The northern portion and the greater part of Carbon Mountain contains beds of anthracite coal, while there are a number of isolated portions in the southern extension of the mountains containing semianthracite. It is probable that coal will ultimately be discovered on all parts of the mountain, for the area is constantly being extended by careful prospecting.

It is extremely difficult to estimate the number of coal beds occurring on Carbon Mountain, owing to the shape and the exceedingly irregular surface formed by the enormous streams diverging radially from the summit and fed by the capping of ice, also due to the ever-changing dip and strike of the strata. While it is not impossible to correlate the coal beds from the top to the bottom of the mountain from data obtained through examination of outcrops, yet it would be very difficult and has not been attempted.

Seventy-five Feet of Coal on Carbon Mountain

It is not difficult, however, to obtain an approximate estimate of the aggregate thickness of coal beds occurring at or near the base of the mountain. As Canyon Creek is approximately straight, a line of sectioning could be taken paralleling that creek. Such a line would be nearly normal to the strike of the majority of the coal outcrops thus preventing the repetition of coal beds unless a fold was cross, in which case the fact would be evident from reversal of dip.

From all information available, it is safe to say that there are 65 ft. of semianthracite and 10 ft. of anthracite, or a total of 75 ft. of workable coals at present located along the lower part of the mountain and in this direction.

Maps of this mountain show a large number of outcrops, many of which are evidently on the strike of the same bed of coal, while others, which appear to be on other beds, may be upon the same, due to a change in direction of strike as a result of folding. Further, many outcrops located are of beds too small to be of any commercial value. There are, however, a number of coal beds on this mountain that range from 6 to 20 ft. in thickness, which have not been located at the base of the mountain.

Cunningham Ridge District

The Cunningham Ridge is about equally divided between the semianthracite and the semibituminous coals, the former area being at the east end of the field. The semianthracite area has undergone extensive folding, as is shown by the condition of the strata on the wall of the cañon facing Canyon Creek. See Fig. 2. From the summit to the base of the mountain the strata have been so folded and faulted that it is practically impossible to trace the separate beds continuously for even half a mile. The dip of the strata is constantly changing from north to south. Under such conditions, particularly when accompanied by cross-folding and faulting, it is practically a hopeless task to attempt to secure definite information regarding the number of workable coal beds. Conditions are, however, not so bad a mile or two to the westward, and more definite information can be secured.

Clear Creek extends in a northeasterly direction from Kushtaka Lake and cuts through the center of the productive area of the semianthracite field. Passing up this stream, non-coal-bearing formations are first crossed over, then a small extension of the semi-bituminous area is encountered, in which a 4-ft. bed of coal outcrops. Continuing up the bed of the creek, the gorge becomes deeper and the outcropping of coal beds can readily be observed. It is not, however, until an elevation of about 650 ft. is reached that coal is found in any considerable quantity. Between elevations 650 and 800 ft., and for several hundred feet along the course of the creek, extensive beds of high-grade coal occur, standing at inclinations varying from 40 deg. to 67 deg. with the horizontal.

Irregularities Which Make Estimation Difficult

Here again a serious difficulty arises, rendering the estimation of footage of coal beds very uncertain. At the locality where the largest amount of coal occurs, a fault has displaced the beds; the creek following the strike of the fault for considerable distance. The direction of displacement is not vertical but makes an angle of about 45 deg. with the vertical, thus the coal beds, while occurring on both sides of the creek, are not continuous, and one must cross and recross the stream, often going a distance of several hundred feet, up or down stream, in order to examine the outcrops.

In estimating the number of coal beds in this locality, those on one side of the creek alone should be taken into consideration, those on the other side ignored. The objection that might be raised to this method of procedure is that the bed on one side is 40 ft. thick, while that on the other side is only 17 ft. It is doubtful, however, that the 40-ft. bed will maintain this width. It has probably been thickened or massed by the movement of the strata that accompanied the faulting—a contention that seems to be borne out by examination of apparently the same bed outcropping at a point several hundred feet up the mountain and evidently in line with the strike of the 40-ft. bed.

If this is correct the coal in this locality resolves itself into practically a 17-ft. bed. Several thinner beds of coal occur at or near the source of Clear Creek and almost on the summit of the mountain. The aggregate thickness of coal beds as observed along the line of Clear Creek is therefore 21 ft., of which 4 ft. is semi-bituminous.

Passing to Trout Creek, which traverses the western portion of the Cunningham Ridge, a number of outcrops of excellent coal are to be found, which aggregate some 55 ft. in thickness.

The high ridge extending in a southwesterly direction from Monument Mountain and forming a divide between Trout and Clear Creeks, also contains a number of large outcrops, which, as in the case of the Carbon Mountain, have not been traced to a lower level. The ridge is quite narrow, is practically devoid of vegetation, and it is, therefore, an easy matter to make observation on the occurrence of existing coal beds. From north to south, seams of coal of the following thickness were noted: 3 ft., 38 ft., 31 ft. 3 in., and 3 ft., making a total thickness of 75 ft. within a distance of less than a fourth of a mile. The coal beds of the western portion of this district stand at angles varying from a few degrees even up to the vertical.

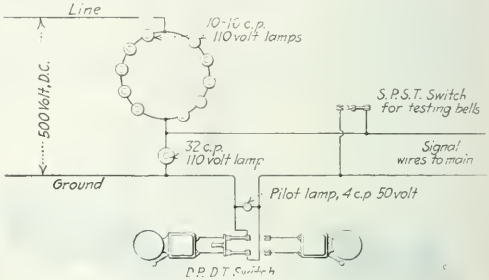
(To be continued in an early issue)

A Simple Electric Mine Signaling System

By Joseph Daniels*

The accompanying sketch shows a simple, economical and dependable system of electric signaling. The current for lighting, pumping, underground and surface haulage is 550 volts, d.c. This current is utilized for signaling purposes in the manner to be described. No. 12, B. & S. galvanized-iron wire is carried down the slopes and suspended from small porcelain knobs on plugs driven into the roof or fastened to posts on the side. These wires are also carried into each level or gangway and a double-pole switch is provided at each level to cut out the signal wires below that point.

In the engine room the current to operate the gongs is supplied by shunting the ground light of a series of ten



Layout for Signaling System

16-cp., 110-volt lamps, as indicated in the diagram. Two series of lights are in the lamp bank rheostat, thus providing for accident in case one series should burn out. Two bells, a pilot light, and a testing switch are installed on a board in front of the hoisting engineer. The bells are so arranged that either one may be used, in case the other is out of order, by simply throwing the handle of a double-throw, double-pole switch. The pilot light is connected in parallel with the bells and burns brightly at each signal, thus acting as a substitute in case the bell fails to ring. The single pole switch, connected with the signal wires to the mine, permits the engineer to test the signaling system from his station. Signals from the mine are sent by short-circuiting the wires in the slope. This is done by means of a copper spanner of ample width, so that the trip runner can close the circuit without having to get off the trip or grasp the signal wires in his hands.

The system does not require much labor, expensive apparatus or material to install, and its maintenance amounts to practically nothing. In case of any trouble in the mine, short-circuits or broken wires can be easily located and quickly repaired.

The U. S. Geological Survey classifies land as coal land only when the coal lies at what is now considered a depth minable in this country. The character of the coal determines the depth to a certain extent. The higher grade coals are allowed a maximum depth of 3000 ft., less is allowed for poorer grades. Lands underlaid with coal at a depth of 3500 or 4000 ft. are classed as "non coal" lands. The amount of coal below 3000 ft. has not yet been estimated, but it is without doubt large. The coal above this depth is estimated by the Geological Survey to be 2000 billion tons. Less than 11 billion tons have been mined. A large part of the estimated 2000 billion tons consists of comparitively low grades of lignite

Our Future in the Export Trade—II

By F. R. Wadleigh*

SYNOPSIS—The second of the series on this important subject. This installment is confined entirely to a study of British coals, methods of mining, quality, transportation and marketing conditions. Satisfactory analyses of the British product, the only serious competitor of the American fuels, are difficult to obtain.

A distance of from 20 to 30 miles is all that intervenes between the Welsh mines and the tidewater shipping ports; in fact, nearly every coal field in Great Britain is within that distance. This would seem to give the Welsh coals an immense advantage in transportation over the American product with their 300- to 400-mile haul, part of it through a mountainous country. This advantage is entirely overcome, however, by the efficiency of the American coal roads and their ability to handle immense tonnages at low costs.

South Wales Coals

There has been so much loose talk and so many incorrect and misleading statements made in the United States trade papers, regarding Welsh and Cardiff coals that it is advisable to give some information regarding them, the beds from which they are mined and the different qualities of each.

There are different kinds and grades of Welsh or "Cardiff" coals and to lump them all together for purposes of comparison, as has been frequently done, would be about the same as putting all the Pennsylvania and West Virginia products in the same class. In speaking of the Cardiff coals, it should be noted that some of those from other ports, Swansea, Newport and Port Talbot, are also of first-class quality. In addition to these there are also many other coals in Great Britain that enter the export markets and with which United States coals must come into competition, some of them being nearly equal in quality to the best Welsh product.

Let us first consider the British export tonnage and see how much of it is Welsh coal. The total exports from Great Britain, in 1911, amounted to 61,599,366 long tons, valued at $170,944,298.80, or an average of $2.616 per ton. Of this total, 16,127,000 tons were exported from Cardiff and 8,743,000 from the other three British channel ports, so that 24,900,000 tons may be taken as the annual total exports of Welsh coal, leaving out the small ports, Llanelly, Neath, etc. Of this total about 8,000,000 tons goes to countries where we can never compete, because of geographical and transportation reasons. Of the total British exports about 37 per cent. comes from South Wales.

This leaves 16,000,000 tons for the United States coals to displace, as far as they can do so, an uphill task and one that has not yet been properly started. An old Spanish proverb will apply here: "In scratching and eating, everything is in the beginning." Currents of export trade once well started, gather volume as they move and have settled channels. Our attempts on this export market have been spasmodic and unsystematic; we must overcome a bad beginning and do our best to reverse or change the trade channels.

*Consulting engineer, 1013 Bank of Commerce Bldg., Norfolk, Va.

The South Wales Coal Field—The great coal basin of South Wales is the second largest in Great Britain, containing vertical strata about 10,000 ft. in thickness and covering about 900 square miles. It is divided by Carmarthen Bay into two parts. The larger to the east into Monmouthshire is 56 miles long, and the smaller toward the Atlantic Ocean, 17 miles long, and both of them are about 12 to 16 miles across. Its general topography is not unlike that of the New River-Pocahontas field—mountainous and cut by deep valleys.

The coals in this basin vary considerably in character, from true bituminous or gas coals to anthracite. This variation usually shows from east to west; in the east, gas coals prevail, while in the middle they are semibituminous but gradually turn to anthracite in the west; it is even found that seams in the same hill may vary from bituminous to anthracite. In the total area there are 75 seams of coal, 22 of them over 2 ft. in thickness, the latter showing an aggregate of about 51 ft. The estimates of the Royal Commission of 1904-5 on Coal Supplies, gave the total available net tonnage of unmined coal, taking the limit of depth in working as 4000 ft., and the minimum workable thickness at 2 ft., as 21,372,409,604 tons.

Beds of Coal—Owing to the variations mentioned above and to the great mixture of names, many seams having different names in different localities, it is difficult to give any general characteristics of the different beds, except as applied to given localities. Most of the best grades of steam coal, however, come from the Eastern Middle section, in East Glamorgan, to the north, which is about 61 square miles in area. In this section, along the Aberdare, Rhondda and Merthyr Valleys, is mined the majority of the Welsh Admiralty coals, Nixons Navigation, Ferndale, Powell Duffryn, Corys Merthyr, Insoles Merthyr, Penrikyber, Great Western Navigation. (A complete list of coals on the Admiralty list will be found elsewhere.)

Analyses of Welsh Coals—Before making comparisons of the analyses of Welsh coals given below and those of United States coals, it must be understood that it is difficult to make any accurate and final comparisons, based on actual analysis of the coals as shipped and on trials under boilers. There are comparatively few published analyses and calorimeter tests of British coals and such as have appeared seldom give any data as to how samples were taken—whether from commercial shipments or from the seams in the mine.

The methods of making and reporting analyses also differ and in many cases a different type of calorimeter is used, making comparisons misleading; while the few comparative boiler tests that have been made between United States and Welsh coals were often under conditions unfavorable to our product or else the figures were open to doubt. Practically all of such tests have been made by private interests and the results have not been published and are only known by the parties interested.

The British government has made no such elaborate series of tests and analyses of their coals as has our government and as there is comparatively little buying on specifications in Great Britain, little information is available from either of these sources.

Class "A" is the one that includes the best Admiralty coals, due largely to its comparative smokelessness; the coals in class "B" are just as high or higher in heating value and are largely preferred to class "A" coals as they burn more freely and the small coals coke and open out in the fire. By this coking and expansion into a more or less cellular condition, better combustion results and there is little loss through the grates; they can also be burned with smaller grate area and less draft. It is these class "B" coals, which the New River and Pocahontas fuels most resemble in character, structure and in burning qualities, and it is for the reasons given above that they equal the Admiralty coals in the results obtained under boilers.

TABLE NO. 1. ANALYSES OF NINE TYPICAL SOUTH WALES COALS (EVANS)

	A	B	C	D
Fixed carbon	82 50	78 00	67 30	75.75—75.75

Moisture	1 00	1 00	1 20	1 25
Sulphur	0 85	0 75	0 85	1 75
B t.u. (calculated)	14,877	15,038	14,607	14,841—14,842

	E	F	G	H	I
Fixed carbon	70 30	66 00	85 00	89 50	87 00
Volatile	25.00	27 50	10 00	5 50	8 00
Ash	3 50	5 00	4 00	3 50	3 50
Moisture	1 20	1 50	1 00	1 50	1 50
Sulphur	0 60	1 50	0 75	0 50	0 50
B.t.u. (Calculated)	14,981	14,614	14,763	14,364	14,620

A, Cardiff Best Large; semi-bituminous steam. B, Cardiff Large, second steam. C, Best Newport Large; bituminous steam. D, Ronda No. 2 seam. E, Ronda No. 3 Seam. F, Gas Coals. G, Dry Steam. H, Anthracite. I, Bastard Anthracite.

The researches of Professor Constans and Dr. Schlapfer, of the Zurich Polytechnic, in 1909, give convincing reasons for the superiority of the coals with the higher per cent. of volatile, such as class "B" and the New River and Pocahontas coals. These researches have established the fact that coals containing about 20 per cent. volatile constituents, yield the highest temperature and best thermal efficiencies. The conclusion that coal which gives the most satisfactory results in the calorimeter, because it contains a moderate amount of gaseous constituents, should also give the most satisfactory results in practice under boilers, is confirmed by these studies and by actual extensive experiments.

TABLE NO. 2. ULTIMATE ANALYSES OF MONMOUTHSHIRE BLACK VEIN COALS

	Newport Abercarn	Mynydd	Western Valley
Carbon	84 91	82 91	83.64
Hydrogen	5 33	4 89	4 59
Oxygen	3 27	5 93	7 01
Nitrogen	1 61	1 00	1 06
Sulphur	0.57	1 11	0 71
Ash	4 31	3 12	2 23
B.t.u.	14,454	14,677	14,504
Moisture	0 80	1 04	0 76

Note:—These are hard coals and stand handling well.

TABLE NO. 3. TYPICAL ANALYSES OF SOUTH WALES AND MONMOUTHSHIRE STEAM COALS

	Fixed Carbon	Volatile	Sulphur	Ash	Moisture	B.t.u. (Calculated)
Best Admiralty Steam	83 40	12.20	0 70	2 80	0 90	14,971
Second Quality Welsh Steam	77 20	17 90	0 70	3 00	1 20	15,064
Cardiff Dry Steam	85.50	11 00	0 80	2.00	0 70	14,996
Best Monmouthshire Steam	75 50	20.50	0 80	2 20	1 00	15,197
Second Quality Monmouthshire Steam	72 80	21.20	1 30	3 50	1 20	14,871
Swansea Dry Steam	85 50	10 00	0 90	2 60	1 00	14,812

(Note: Air dried coals, selected analyses)

Professor Constans states, in summing up the results of his experiments, that from a commercial standpoint, especially where freight charges are at all heavy, short flame coals, containing from 16 to 23 per cent. volatile matter, will prove most economical, because it does not pay to transport either ashes or volatile matter that will escape unburnt.

Mining, Preparation, Screening and Loading Conditions

Most of the mines in South Wales are worked on the single or double, room-and-pillar system, modified by local conditions. Every effort is made to get the coal out in as lumpy condition as possible. Wedges are largely used for breaking down the coal, instead of explosives; the hydraulic cartridge is coming into extended use, especially where explosives are prohibited.

The coal is dumped from the mine cars on picking tables and screens, the greatest care being taken to avoid breakage; it is then passed over screens with $1\frac{3}{4}$-in. openings, that going over screen being the "large" coal, while the portion going through is divided further by screening into the following sizes:

	Inches		Inches
Nuts, through	$1\frac{3}{4}$	over	$1\frac{1}{8}$
Beans, through	$1\frac{1}{8}$	over	$\frac{5}{8}$
Peas, through	$\frac{5}{8}$	over	$\frac{3}{8}$
Duff, through	$\frac{3}{8}$		

At many collieries the small coals are washed, the nuts, beans and peas being sold for steam making or, mixed with large coals, for ships' bunkers and the duff is used in the manufacture of briquettes and coke. As to what we term run-of-mine coal, there is very little shipped or indeed taken from the mine. The British term "thro" and thro'" coal does not have exactly the same meaning as our run-of-mine. "Wro't thro'" coal is our run-of-mine, while nearly all the thro' and thro' coal is made by mixing large and small, at the docks, in proportions to suit the buyer.

It will be seen, therefore, that practically all of the Welsh coal shipped is screened coal. There are three descriptions of large coal, as follows:

Colliery Screened—Screened at the mine only.

Single Screened—Screened once at the mine and also passed over one $\frac{3}{4}$-in. screen at docks, the latter process taking out about 5 per cent. of the small coal.

Double Screened—Screened at the mine and passed over two $\frac{3}{4}$-in. screens at the docks, removing about 8 per cent. small coal.

As to difference in price, the "Single Screened" coal averages about 8c. more per ton than "Colliery Screened" and the "Double Screened" 12c. more. The British export statistics show that most of the fuel shipped to countries where we compete is large coal, which, of course, has at least one screening, over $1\frac{3}{4}$-in. screens.

TABLE NO 4. ANALYSES OF DIFFERENT WALES COALS

	Moisture	Volatile Matter	Fixed Carbon	Ash	Sulphur
Clyne Valley 3-ft Seam	Dry	29 90	65.76	4.34	0 84
Ffrochiven Steam	0.70	10.34	85.74	2 30	0 92
Glanmorwg	1.56	14.52	79 54	4 38	
Great Western Forest Coal	1 16			1 76	0.69
Cwmnant Graigola Seam		10.04	85.44	3.54	0 98

Merthyr Slantwit	0 81	17.72	73.73	7 75	2 41

All of the docks or piers at the Welsh coal-loading ports are equipped with special appliances for loading ships, most of them worked by hydraulic pressure and having various devices for preventing breakage and for screening the coal; nearly all of the hydraulic tips are equipped with anti-breakage boxes. The Lewis-Hunter coaling boxes are considered the most satisfactory, as they not only avoid breakage of the coal, but do away almost entirely with any trimming of cargoes. These boxes are filled with coal (about 12 tons), lowered into the hatchway of the ship and when the desired height is reached, the conical

bottom of the box is allowed to drop, discharging the coal by sliding in four directions. If it is desired to put the coal only on one side of the hold, the conical bottom can be secured by chains for that purpose. There are several other loading devices at the British docks, but all of them have one point in common, the avoidance of any breakage of the coal.* Of course, the speed of loading cannot compare with the records made by the United States piers, but they are able to do good work even along that line, as the following will show:

5279 tons loaded in 12½ hours
4773 tons loaded in 10 hours
6715 tons loaded in 11 hours

A record of 995 tons in one hour by four Lewis-Hunter cranes working one ship.

Welsh Coal Contract Form

This is the form generally used by the larger buyers and sellers of South Wales and Monmouthshire coals, a knowledge of which is essential information for the United States exporter of coal.

TABLE NO. 5. A TYPICAL SERIES OF ULTIMATE AND PROXIMATE ANALYSES OF THE WELSH COALS

The following analyses of Welsh coals are taken from Greenevells "Analyses of British Coals and Cokes", 1907, the method of taking samples being specified in only three instances, as noted; the others are picked mine samples and do not represent the coal as shipped, as is shown by the analyses of Naval Merthyr coal, the mine sample yielding 15,492 B.t.u. and the coal as shipped 15,199.

	Proximate				Ultimate					
Admiralty Coals	Moisture	Carbon	Volatile	Ash	Carbon	Hydrogen	Oxygen	Nitrogen	Sulphur	B.t.u.

* Calculated from analysis. † Favre and Silbermann Calorimeter, not used in the United States and giving higher results than the Mahler type

Note: Greenwell states that this collection of analyses "seems to represent mostly samples furnished by the producers" and while in some cases "fairly large quantities of coal" must have been sampled, in others "there can be little doubt that the analyses represent a picked sample.

WELSH COAL CONTRACT

(Generally adopted by the chief purchasers and sellers in South Wales and Monmouthshire)

Memorandum of Agreement entered into at.....this .....day of .....19.. between.....of.....hereinafter called the "Purchasers" and.....called the "Vendors."

1. Quantity—The Purchasers agree to buy and the Vendors agree to sell.....tons of .....Large.....Coal on the following conditions:

2. Delivery—The Purchasers will provide tonnage to take delivery of the coal from the.....to the..... in as nearly as possible equal proportions per calendar month. Such deliveries shall be into ship at one of the following docks: .....as ordered, on application to the Vendors before ship's arrival.

3. Loading—The time for loading to be mutually agreed between the Purchasers and the Vendors when each Vessel is placed on stem, and being subject in the case of steam vessels to the conditions and exceptions of Clauses 2 and 3 of the Chamber of Shipping Welsh Coal Charter, 1896, and in the case of sailing vessels to the Vendors' usual printed form of guarantee. In the event of the Purchasers and Vendors not being able to mutually arrange a stem, the Purchasers shall have the right to place a vessel on stem for the portion of the month's deliveries then due on giving seven days' notice to the Vendors, in which case the Vendors shall be allowed customary hours for loading.

4. Trimming—The Trimming shall be done by Trimmers nominated by the Vendors or their agents, and the Tariff Rates of the Port for Trimming shall be paid to the Vendors by the Purchasers in default of Payment by the Shipowners. The Vendors shall not be responsible for fire, explosion or accident in connection with the Trimming or for any act, default or negligence of the Trimmers or Foremen.

5. Wharfage—The Purchasers undertake to pay to the Vendors or the Dock Company the usual wharfage of 4c. per ton.

6. Quantity and Weight—The Purchasers shall inspect the coal in the wagons on the tip-road at the place of shipment, and any objection to quality or condition shall be raised before shipment, or be deemed to be waived. The returns of weight as ascertained at the Loading Tips by the Dock or Railway Company shall be final and conclusive for all purposes whatsoever.

7. Price—The Purchasers shall pay the Vendors the price of.....per ton for colliery screened coal.....per ton if single screened at time of shipment.....per ton if double screened at time of shipment.

8. Payment—The Purchaser shall make payment as follows:

.....

9. Strikes and Accidents—In the event of a stoppage or partial stoppage of the Vendors' Pits, or any of them, or on the Railway or Railways over which the Vendors' traffic is usually carried between any of the Vendors' Pits and the place of shipment, or at the Dock named as the place of shipment or of a suspension of work by Trimmers or Dock, Railway, or other hands connected with the working, delivery or shipment of the said coal or from any cause whatever, whether or not of the same nature, the Vendors shall not be called upon to deliver any coal during a total stoppage, and in the event of a partial stoppage the Vendor shall be entitled to a reduction in the deliveries proportionate to the reduction in their output. No liability shall attach to the Vendors for any such default of shipment, notwithstanding the fact that during such period coal may have been shipped by them. The time within which the above-named quantities are to be taken and delivered shall be extended for a period at least equal to that during which deliveries are suspended, or as otherwise arranged by mutual agreement.

10. Insolvency—In case of any default on the part of the Purchasers in making any payment on the date specified, the Vendors may suspend deliveries until such payment is made, and it shall be at their option whether they will afterward make up any deficiency in deliveries so caused; or if the Purchasers shall have been declared bankrupt, called any meeting of their creditors, or make any acknowledgment that they are unable to pay their debts in full, it shall be at the Vendors' option to consider the contract null and void.

11. Damage for Failure to Take or Deliver—Unless otherwise mutually arranged, Purchasers agree in the event of their failing to charter and stem tonnage to take each month their regular monthly quantity in accordance with the terms of this contract to pay to the Vendors as and for liquidated damages the difference between the current price on the last days of such month and the contract prices on the quantity they have so failed to take, and the Vendors agree that in the event of their declining to accept tonnage to take each month the regular monthly quantity in accordance with the terms of this contract, to pay to the Purchasers as and for liquidated damages the difference between the current price on the last day of such month and the contract price on the quantity for which they have so declined to accept tonnage.

12. War—In the event of the United Kingdom being at war with any European Powers or any prohibition being made by the British Government on the export of Welsh coal, the quantity due for delivery under this contract during the period over which such war or prohibition extends shall be cancelled.

*Some interesting descriptions of English bunkering stations will be found on pages 147, 316, 355 and 364 of Coal Age, Vol. 2.—Editor.

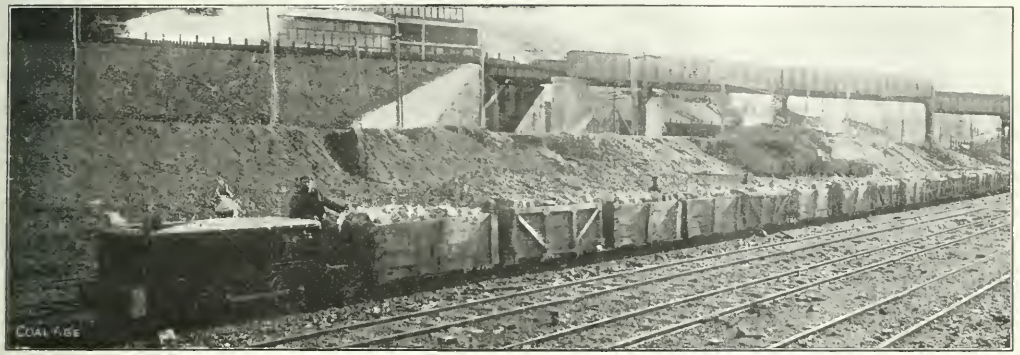
A New Gasoline Locomotive

The accompanying illustration shows an 11-ton gasoline locomotive drawing a trip of 18 four-ton cars up a ½ per cent. grade at the Prospect Colliery of the Lehigh Valley Coal Company.

This machine was built by the Vulcan Iron Works, of Wilkes-Barre, Penn. The track gage is 42 in., the wheel base 48 in., the height is 4 ft. and the width is 4 ft. 8 in. The diameter of the driving wheels is 21 in. and the tractive effort is 4000 lb. Operating at 600 r.p.m. the engine will develop 45 hp. while the speed varies from 4 to 8 miles per hour. The machine is equipped with hand-operated brake, and as may be seen in the photograph, is provided with a bell to give warning of approach. When used underground, this bell is dispensed with.



A Vulcan Gasoline Locomotive at the Prospect Colliery, Wilkes-Barre, Penn.

In the present stage of its development there can be no question as to the utility of the locomotive impelled by internal-combustion engines. It must be acknowledged, however, that these machines require a certain amount of skill on the part of the operator in order to obtain the best results, and naturally this can only be acquired through intelligent experience.

The builders of gasoline mine locomotives have all the experience of the automobile designers from which to profit as well as that of the makers of electrically operated haulage motors. They should be able, therefore, to turn out a product which, so far as reliability is concerned, is equal to any present-day automobile or power truck. And, although slight difficulties may be experienced at first in operating such motors, these will rapidly disappear as the driver gains familiarity with the machine.

One Western mine manager who recently installed gasoline locomotives in several of his mines, had serious trouble at first, in securing men of sufficient intelligence and mechanical experience to successfully operate these machines. This trouble was overcome when he secured a number of chauffeurs, who were out of employment in a near-by city, and sent these men to the mines to operate the gasoline locomotives.

⁂

According to actual tests, coals consumed in producer-gas plants develop about 2½ times the power that the same coals would develop in the ordinary steam-boiler plant.

Small Steam Turbines

When running at an economical speed, the small steam turbine is now practically equal in steam economy to the reciprocating engine of equal capacity. Due to the higher speeds employed, less floor space is used. Practically no attention is required, as the only lubricated parts are the main bearings and the governor.

The turbine shaft has a constant turning effort exerted upon it, which makes it desirable in driving small lighting sets, exciters, centrifugal pumps and blowers.

Since there is no inside lubrication, the exhaust steam is free from oil, and, therefore, may be used in an open feed-water heater and returned to the boiler, the efficiency of the thermal process being practically 100 per cent. Due to the absence of mechanical friction in the chamber in which the steam does its work, the parts here do not wear appreciably, and, therefore, the steam economy of the turbine remains practically constant.

⁂

The Mine Mule of Today

[One of our advertisers after reading Mr. Braley's verses on the mine mule, in our Jan. 25 issue, comes back with the following refrain: The effort entitles him to whatever publicity he will get.—Ed.]

That pictures Mr. Mine Mule as he once was long ago,
The poor old sinner had to work, you bet;
But now the modern mine mule, as he works all day below,
Hardly has enough to do to make him sweat.
He's as playful as a kitten and as gentle as a lamb,
And the skinner now is acting like a saint,
And you never hear him cussing—not a single little damn,
All of which may seem a story, but it ain't.

And the cause for all these changes in the labors of the mine,
Which is making Mr. Mine Mule fling his heels,
And which turns the busy skinner to a person near divine,
Is the Hyatt Roller Bearings in the wheels.
And so every day is easy for the skinner and his friend,
And they're looking "like a dividend that's fat,"
And they think that Braley's joking when he carols near the end—
"May he go where all the saintly mules are at."

British Inspector's Report, 1911

SYNOPSIS—An account of some methods of spraying in British mines and of a coal-dust explosion which occurring above ground, could not have been aided by gas. The use of electric hand-lamp lighting is on the increase. The dangers of electric shotfiring with damp detonators are exemplified and a severe outburst resulting in 3 fatalities is described. Some notes follow on the use of ropes to increase the strength of collars and on the flushing of gobs.

Thomas Mottram in his report for the Liverpool and North Wales district of Great Britain says that there are some mines at which steps are now being taken to prevent coal dust from entering the downcast. In some cases the sides of the shafts are to be enclosed between the surface and the landing. In three or four instances the coal dust made in unloading the cage and in dumping and screening the coal is collected by suction.

Tubes connected with the screens at one end suck in the dust by means of an exhauster; and a water-spraying device then douses what is thus collected. The chamber which receives the dust is provided with an outlet for clean air and another for the conduct of the water and dust to a settling tank. By this means a considerable quantity of the surface dust, which would otherwise descend the downcast, is secured and ultimately used for fuel.

Spraying Loads and Empties

Even where this system is in vogue, a considerable amount of dust still descends the downcast, it being blown from the cars in their rapid ascent to the surface. This can be obviated to a considerable extent by spraying the contents of the cars in transit or near the shaft bottom. Where this is done the comparative absence of dust at the bottom of the shaft is quite apparent. The spraying of empty cars at the screens or at some other convenient point on the surface, is also well worthy of consideration.

Portable Spray Tank

Reference is made to a portable spray tank for laying the dust in working places at Pemberton colliery, Wigan.

This 2-gal. device is only 16½x8x5¼ in., and is carried by means of a canvas sling thrown over the shoulders of the operator. It is necessary to fill the tank three times to water each working place—a length of 60 or 90 ft. of floor, roof and sides. The pump empties the tank in 8 to 10 min., according to the speed of rotation of the crank. The diameter of the nozzle is 1½ mm. (1/16 in.). The water is thrown out in a fine spray, and it takes 30 min. to water each working place.

A Coal Dust Explosion Above Ground

It may be interesting in connection with this dust problem to describe a somewhat remarkable coal-dust explosion on the surface, caused by excessive sparking of an electric motor at New Brancepeth colliery. The explosion, to which reference is made by Inspector A. D. Nicholson of the Durham district, took place in the coal-grinding house where a 25-hp. direct-current motor at 500 volts was in use for driving the machinery.

The motor was enclosed but not gas-tight, and stood on a platform about 6 ft. above the ground floor. Owing to the short circuiting of one of the armature coils much sparking resulted and this ignited the coal dust inside the motor casing causing an explosion which produced sufficient force to blow off the sheet-iron covering over the commutator end of the motor.

The flame thus produced was sufficient to explode the fine dust held in suspension within the building and the flame extended 6 ft. outside the open door of the house and for a height of 15 ft. inside. The report was heard some distance away. Some panes of glass were broken, but there was no further damage as the roof, which was partly open, was composed of corrugated iron. Fortunately the engineman was not inside the building at the time. In view of this accident, the company decided to erect the motor outside the crusher house.

Portable Electric vs. Oil Safety Lamps

In the Yorkshire district, 241,382 working people were employed in 1911 and 211,356 safety lamps were in use. A noticeable feature was the increase in the number of portable electric lamps from 69 to 922. With the approval of the late Inspector W. H. Pickering, the management of two mines introduced this type of lamp into the workings.

They give an incomparably better light than the safety lamps and in his view their general use would have the effect of reducing accidents, especially from falls of roof and from haulage. Before agreeing to the introduction of these lamps, however, he drew the attention of the management to the following points:

1. An explosion might occur in an explosive atmosphere (a) if the connection between the battery and filament was broken or (b) if both glasses were shattered.

2. If electric lamps are used, arrangements will have to be made for the periodical testing for firedamp by safety lamps or other means.

3. Objection (a) can be overcome by a proper method of locking the lamp (e.g. by a lead rivet) and a rule requiring that no lamp shall be unlocked and opened except on the surface.

4. The danger that the glass will be broken is far more remote than in the case of an oil safety lamp. It is probable that a shock which would break the outer glass would also break the thin glass of the bulb. The outer glass, however, is stronger than that of an ordinary safety lamp and is better protected. The better light given by the electric lamp enables the miner to set it in a place safe from falls or where tools cannot strike it.

5. The lamp gives such a splendid and clear light that accidents should be greatly reduced wherever these lamps are used.

6. The following conditions should be observed in using these lamps: (a) They should be locked with a lead rivet having a clear device on each face. (b) No lamps should be opened except by an authorized person and on the surface. (c) Arrangements should be made for frequent testing for firedamp by safety lamps or other means. (d) Any man ill-using a lamp, or damaging it, or having

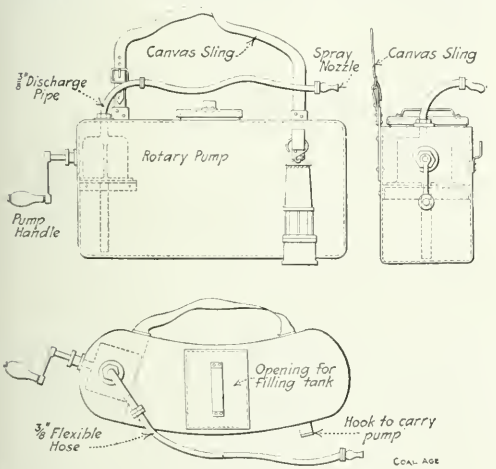
it within two feet of the swing of the tools, should be prosecuted.

Explosion of Shot After Battery is Disconnected

There is a prevalent belief that, when shots are fired by electricity, all danger in returning to a missed or hanging shot is removed if the firing cable has been disconnected from the battery.

Reference to this is made by Inspector Hugh Johnstone of the Midland and Southern district, and he says the fallacy of this idea has been proved on many occasions. One of these delayed ignitions occurred at Snowdon colliery in Kent, where 13 shots charged with Rippite and provided with No. 7 electric low-tension detonators, especially insulated for submarine work, were being fired in the bottom of a shaft then being sunk.

They were coupled together in series and connected up



A Portable Spray Used to Dampen the Ribs in a Room Prior to Shooting Down Coal

to a dynamo which was generating a current of 220 volts. The shots failed to go off and the wires were uncoupled from the cable. Three minutes afterwards, one of the shots in the middle of the series exploded, leaving the other 12 shots intact. The makers of the explosive were questioned about this failure but while they admitted that such occurrences, although rare, were unfortunately not unknown, they were unable to give any conclusive explanation.

Danger of Dampened Fuses

Mr. Johnstone says he has come across quite a number of such occurrences in which shots have exploded an appreciable time after the cable had been disconnected from the exploder and in one case after it had also been disconnected from the fuse wires.

The most feasible explanation appears to him to be that the priming charge in the detonator had become more or less damp and had been ignited but not flashed by the passage of the current. Thus it had smouldered for a time until sufficient heat was developed to fire the fulminate of mercury.

Some years ago Inspector Johnstone experimented with a number of electric powder fuses in which the priming charge had been purposely dampened, and in some cases actually moistened, by exposing them to a jet of wet steam. Although they all failed to fire on the first attempt, by repeatedly passing the current through them, the inspector succeeded in firing even those which had been moistened. It appears to him that the only way to obviate risk of accident is to prohibit any one from returning upon electrically fired hanging shots until at least 15 min. have elapsed.

An Outburst of Gas Dislodges 190 Tons of Coal

An accident of an unusual character, causing the death of three miners, John Peden, George Peden and James Jamieson, occurred at Valleyfield colliery, and is discussed by Inspector W. Walker, who has charge of the Scotland district. The sinking of both shafts had just been completed.

A cage was put in the No. 2 shaft and rapid progress was being made in the work of forming the shaft parting and driving the roadways. The guides were fixed in the No. 1 or downcast shaft, but as the sheaves of the head-frame were being erected, this shaft was not available at the time of the accident. The upcast or No. 2 shaft is 1290 ft. deep and cuts the Five Foot Seam in which the accident occurred at a depth of 1200 ft. Two levels had been turned out of the shaft in this seam, one to the north-west and the other to the south-east.

An outburst of gas occurred at the face of the south-east level in the Five Foot Seam about 300 ft. from the No. 2 shaft, displacing more than 190 tons of coal and the men were overcome and suffocated by it. There were six men on the south-east side of the pit, three in the heading nearest to the shaft and three in the face of the level, the latter being suffocated by the coal displaced by the outburst.

Draft Produced by Ascending Steam

The colliery being new and the fan incomplete, the inspector says ventilation was produced by means of induced draft caused by the discharge of exhaust and live steam into the upcast shaft. This resulted in about 7200 cu.ft. of air per min. travelling the workings and around the South side of the Five Foot Seam. The first heading which is 60 ft. away from the shaft, was 117 ft. up from the level, and the second 120 ft. further in, 60 ft. up. When measured, at 8 a.m. on the day of the accident, the face of the south-east level was 114 ft. from the second heading.

A brick wall 4 in. in thickness had been built on the low side of the road from the upcast shaft to within 10 ft. of the level face and from this point the air was carried forward by ordinary brattice cloth and on leaving the face of the level it was conducted up to the end of each of the headings by the same means. The haulage road was, therefore, the return airway.

The Cause of the Outburst.

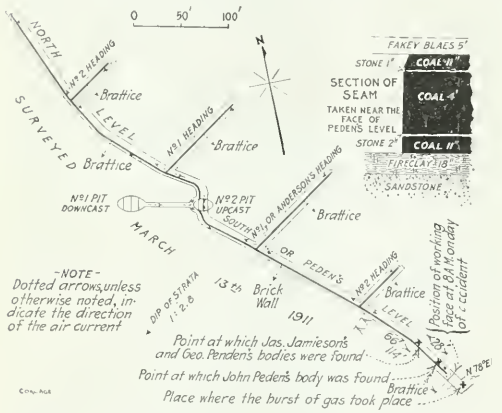
Only the south-east level was affected. At the time of the outburst three men were working in the first or outside heading, none in the second heading and three in the face of the level. When the three last mentioned were found by the rescue party from the surface, George Peden and James Jamieson were facing outby, lying

about 48 ft. back from the face; John ɔden was also lying facing downwards, about 20 ft. ıck from the original end of the level.

All three, being buried under 5 ft. of coal dust, had been smothered, but on removing John Peden's clothes it was found that he was severely blistered, due to his having been close to the face, and having experienced the full effect of the sudden expansion of the gas. When the face of the level was ultimately reached, it was discovered that a small rise fault crossed about 7 ft. in advance of the original position of the end of the heading and that the face of the level had been blown out or advanced for 12 ft. in addition to which a hole, some 30 ft. long and running parallel with the fault, had been formed on the upper side where the seam rises 1 in 1½, whereas at the shaft the inclination is 1 in 2.8. The coal near the fault was burnt, and further back it was sooty and soft.

Precautions to Prevent Outburst Accidents

After the accident the agent undertook that boreholes be kept at least 40 ft. in advance of the faces of the levels



A Fatal Outburst of Gas at a Fault Removing 190 Tons of Coal, Thereby Smothering Three Men

and headings. On one occasion when a borehole of this kind was being drilled, the rods were blown out of the hole and gas at high pressure continued to be given off for some hours.

The holes have frequently been choked with small coal. At times, this slack has been blown out in clouds of fine dust to such an extent that boring had to be discontinued until the gas blew off and the pressure decreased.

To prevent outbursts of this kind, causing loss of life, the inspector thinks it necessary, in addition to boring in advance, to have experienced men, such as firemen in charge, always on the watch for movements in the coal face. Also he advises that the same workmen be kept in such places with orders to retire if there is any sign of the coal working more easily or moving toward them. As soon as a pocket is located the face should be riddled with holes in order to liberate the gas behind it.

Burnt Coal Common in Fifeshire

Burnt coal is often found in the coal mines in Fifeshire. In the deeper measures, it is as a rule close to faults. As he points out, it is caused by the obtrusion of whin (eruptive rock) beds, which appear to have burnt the coal after it was deposited. Through movement of the surrounding strata, small parts of the coal seam have been disintegrated, and thus filled with gas at high pressure.

When the intervening solid coal between the burned area and the face of the workings becomes too weak to resist the pressure, it bursts away and the small coal pours out like running sand. This disintegrated coal containing gas appears to be in local patches.

At Valleyfield, the south-east level appears to have been driven against one of these pockets of gas and disintegrated coal, with the result that upon the face reaching within 7 ft. of the fault, the pressure overcame the resistance of the coal and blew it out with such force that the men had no chance to escape. Safety lamps had been introduced or more men would have been killed, as an explosion of gas would have followed the outburst.

Old Wire Ropes as Roof Supports

Old wire ropes are utilized at a mine in Lanarkshire, in conjunction with timber as aids to the support of the roof on a haulage road.

The seam lies from 24 to 84 ft. below the surface and it is owing to this fact that some difficulty has been experienced in its working. The stratum above the seam, at a depth of 60 to 84 ft., is fakey blaes (laminated blue shale), but nearer the surface, the roof is composed of irregular blaes, boulder and surface clays. In wet weather, owing to its becoming saturated with water, it is difficult to support.

Formerly much timber was used but its life was short and little could be withdrawn or restored. After hearing a paper read by Sam Mavor, before the Mining Institute of Scotland in 1908, describing a method of supporting roofs in Silesia by means of timber strengthened by old ropes, the management decided to give the system a trial. It has been found that not only was the saving of timber and labor considerable, but the roof of the main haulage road was much more efficiently supported. Collars or cross bars which before would have had to be renewed in six months, have already lasted over 3 years.

How the Ropes Are Fastened

The method of fixing the rope to the collars is as follows: The timber is carefully examined, and after it is decided which is the more suitable side on which to place the rope, a small piece of the thick end of the collar is flattened and a small "V" shaped notch is cut in the end of it; the rope is drawn straight and tightened along the under side of the collar to within about 12 in. of the small end, and a staple driven down over the rope to prevent its moving.

The rope being in position is further secured by the addition of staples along its length at intervals of about 20 in. The end of the rope is turned back over the end of the collar and secured on the upper side by means of other staples. The other end of the collar is left unfinished because the length which may be required is not known and the original length may have to be reduced before the collar is used. In this condition the timber is sent down the shaft. The man putting the collar in position finishes the uncompleted end in the same way as

the other, after he finds the exact length which is required.

Great care is necessary in the choice of the rope to see that only the best is used, that there are no broken wires at the time of erection and that it is in such condition that the wires are not likely to break as long as the timber remains in position, as broken wires would be dangerous to persons and animals traveling along the road.

Flushing Gravel

A portion of the Wishaw Coal Co's leasehold at Dalzell and Broomside colliery lies along the banks of the Clyde, and the greater part of the area is covered with a bed of water-bearing gravel.

The main seam, 150 ft. below the surface at this point, has been worked out into pillars known as "stoops" about 60 ft. square. Owing to the danger of rapid subsidence, breakage of the roof and flooding of the workings, a constant menace to those in the deeper seams, the owners were advised by their mining engineer, R. W. Dron, to extract the pillars and fill the waste with "redd" from the refuse heaps on the surface, by means of the flushing system.

The seam in question is 4 ft. thick, and has a strong roof and blaes floor. The dip of the strata is 1 to 8 to the south-west, and fairly regular.

A large heap of washer debris consisting of burnt shale and fireclay was at hand on the surface, and that is probably the best material for flushing, as in the absence of grit the iron pipes carrying the filling materials are not worn. Moreover the fill is not subject to spontaneous combustion.

The pipe line is carried down a borehole to the workings of the main seam; another borehole affords a passageway for the electric cables which supply power to the pump, and a third hole is used for the discharge column which returns the used water to the surface.

The material passes through cast-iron pipes to the working face. There it enters a line of wrought-iron pipe, $\frac{3}{16}$-in. thick, of the same diameter as is used for the main line.

The working face consists of four pillars with the roads between them, amounting in all to a straight line of 260 ft. to the full dip of the strata. This face was at first prepared for the flushing by a rock packwall 30 ft. wide erected on the low end, but since work has been in progress it has been found that little or no pressure falls on the wall and it is now built only about 6 ft. wide.

How the Cars Are Handled

An ingenious method of letting the full cars down the face is in operation. A bogie is attached by a clip to a single rope and passes down the face collecting the cars filled by the miners and lowering them to the haulage road.

Turf as a Fuel

In most parts of the Faroe Islands, turf is still the chief fuel used. In some places, however, coal is preferred, and its use is increasing as the supply of turf is becoming exhausted. Nowadays there is less economy than formerly in burning turf, since coal has become somewhat cheaper, and much time and labor are required to cut the turf and carry it often many miles over rough country to the homes of the people.

An Early Coke Plant

The accompanying illustration shows the surface plant of the Waverly mine of the Pittsburgh Coal Co., located at Smithtown, Penn. In view of the fact that this picture was taken in the year 1877, it is interesting from an historical standpoint. The old type of railroad cars is particularly noticeable. On the left is a train of short gondola cars, such as were used at that time.

The Waverly Plant in 1877

In the foreground, and extending back to the washery is a battery of beehive ovens, which are in the course of erection. In those days this mine was operated by the late Judge Thomas Mellon, of Pittsburgh, Penn., and J. B. Corey, of Braddock, Penn. The waterboy who stands at the right in the picture is J. B. Neel, now employed by the Pittsburgh Coal Co.

Increased Shipments of Australian Coal

The shipments of coal from Newcastle, New South Wales, during the six months ended June 30, 1912, amounted to 2,218,692 tons, valued at $5,603,833, compared with 1,846,633 tons, valued at $4,696,128, for the corresponding period in 1911. The increased shipments were principally to other parts of the Commonwealth and New Zealand. Victoria took 148,000 tons more than during the first six months of 1911, New Zealand 73,000 tons more, South Australia 19,000 tons more, Western Australia 28,000 tons more, and Tasmania and Queensland each about 10,000 tons more. The increase in the foreign trade was 53,877 tons, Chile taking 47,000 tons more and Java doubling its purchases, while the Straits Settlements took 28,000 tons less and the Philippine Islands 45,000 tons less.

Geo. Knox, in a recent article, states that it is difficult to adopt the flushing system in mines where the working operations are far advanced, particularly in those seams where the advancing system of longwall is in use and the shafts are sunk to the dip of the territory. It cannot be applied to newly opened collieries, nor to most collieries where thick seams are worked, either by retreating longwall or room and pillar. The only difficulty in the latter case will be the cost of either driving tunnels or else levels in the upper seam to the rise of the coal to provide fall for the débris [illegible]

CURRENT COAL LITERATURE

How Coal Mining Threatens the Town of Frank

The commission appointed by the Canadian Department of Mines to investigate the prospect of further falls from Turtle Mountain onto the town of Frank, Alta., included Reginald A. Daly, W. G. Miller and Geo. S. Rice. The latter is, of course, mining engineer of the U. S. Bureau of Mines.

Fear of a Second Slide

A slide, occurring on Apr. 29, 1903, killed 70 people in the town of Frank and destroyed much property, including nearly 7000 ft. of the Crows Nest Branch of the Canadian Pacific Ry. Quoting an earlier commission, which reported June 12, 1903, the commissioners say:

In their report, R. G. McConnell and R. W. Brock state that the slide was due, not to a single cause, but to a combination of causes, among which the opening up of large chambers in the mine, situated under the base of the Turtle Mountain, may have been contributory. Speaking of the North peak and shoulder of the mountain overlooking the town, they say "the caving of the rooms in the mine, after the coal has been withdrawn, perhaps long after the inhabitants of the town have lost all dread of another disaster, may precipitate it suddenly in a second destructive slide. Since this possibility must always overhang the town, it certainly seems advisable that it be moved a short distance up the valley beyond the reach of danger."

It appears that all the cross-sections striking the two main peaks of Turtle Mountain show that the slope continuously gets steeper as the peak is approached. The level of the Crows Nest River is 4155, while the North peak of Turtle Mountain is 6911 and the South peak is 7204.

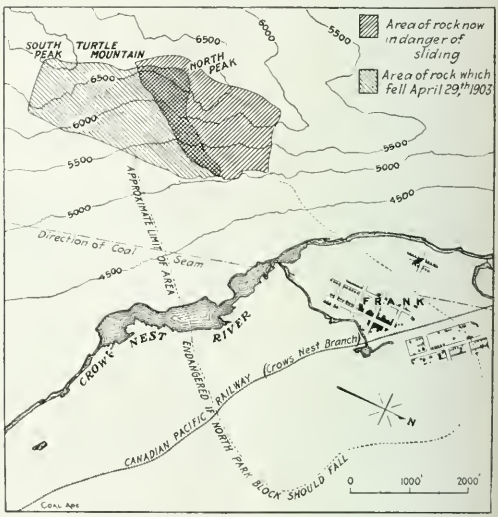
Cannot Slide on Bedding Planes

As will be seen from the cross-section accompanying this article the sloping of the measures is such as to assure that parts of the mountain could not slide into the valley by the slipping of one bed on another because the measures dip in the opposite direction with an extremely marked pitch. But the trouble arises not from the bedding planes, but from the jointing of the measures. These joints are lying at so steep an angle that if they part from any cause such as the weight of the rock, seismic, mining or other disturbances, or from the action of frost, the detached masses will freely slide and even more readily roll down into the valley.

The commissioners state that the rock, constituting the coarse rock débris in the longest talus slope eastward from a point near the South peak, is of such a character that it will rest on an angle of 30 deg. to the horizontal, but if the rock mass begins to move on a surface of that slope it will continue to slide till it reaches the foot of the mountain. That is, its angle of rest is 30 deg.

We have seen that the measures on the mountain are so disposed that they cannot slide into the valley, but if they should be broken by any means at right angles to the plane of bedding, the parts thus broken would be almost sure to be precipitated onto the town below. All that is necessary is that the plane of fracture should lie at 32 deg., or more to the horizontal.

The pieces deprived of their structural connection with the mass of the mountain would be sure to slide over the plane of fracture and descend to the valley. Bearing in mind this outside value for the limiting angle, an



Plan Showing Area of Rock Threatening to Precipitate Itself on the Town of Frank, Alberta, Can., Where a Large Slide Has Already Fallen

inspection will show the large amount of rock which could fall from Turtle Mountain.

The Weakness of Turtle Mountain

If that mountain were composed of homogeneous granite or nonjointed limestone, the foregoing calculation would have no practical value; the strength of such rock would be such as to make absurd any reference to the critical angle above defined in connection with the problem of the mountain's stability. But Turtle Mountain is peculiar in possessing a structure which forbids placing an estimate of an absolutely safe angle for the eastern slope at much greater than 30 or 35 degrees.

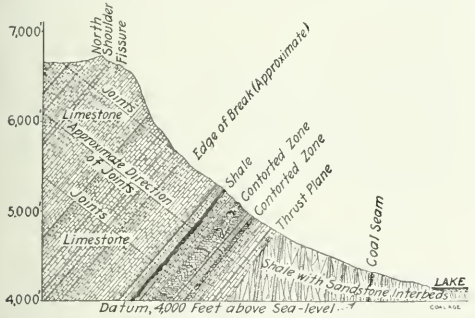
This is not meant to imply that all the rock bounded by slopes greater than about 35 deg. is in danger of sliding before the ordinary processes of erosion have lowered such slopes. Such a danger is remote according to the commission, except in a limited area where structural weakness is combined with steepness of slope in a manner to threaten disaster to the town.

A 3000-ft. Mountain on a Footing of Soft Shale

From the river flat to the lower contact of the limestone (that is, the outcrop of the thrust-plane), the mountain slope is underlain by soft shales, interrupted by coal seams and by some interbeds of sandstone. The whole is an unusually weak mass of rock; yet it forms the basal abutment which is today helping to sustain the heavy limestone forming the upper half of the mountain.

Weak as this lower member is, it might continue to hold up the entire slope if it were not for the inherent weakness of the limestone itself. The latter is composed of rapidly alternating beds of contrasted nature. Some of them are thick, massive and coherent, and, if the whole upper member were constituted of similar material, the chance for a destructive slide in the future would be greatly lessened.

But many other beds are flaggy, easily split along the bedding planes and, therefore, far less strong than the beds just mentioned. On this account alone the average strength of the whole limestone member is much below that of many, and perhaps most, of the great limestone



Cross-section of Measures, Showing Coal Seam, Weak Shale, Contorted Limestone and the Threatening North Peak

formations of British Columbia or Alberta. In addition, the total strength of the member is seriously lessened by the presence of two zones of crumpling within the mass.

These zones are diagrammatically shown in the section. It should be carefully noted that the lower edge of the rock, which fell in April, 1903, coincides with one of these contorted zones. That event actually illustrated the profound weakening of the mountain structure due to their presence. Another source of weakness is found in a band of soft shales, which breaks the continuity of the limestone.

The Limestone Is Full of Wide Joints

However, the chief reasons for concern as regards this matter of rock strength, are the heavy jointing of the limestone and the relation of the joints to the eastern slope of the mountain, the side facing the town. As is so often the case with sedimentary rocks, very abundant joints occurring in several systems are developed nearly or quite perpendicular to the bedding.

The dip of the strata is always westward, and varies from 50 deg. to 65 deg. At the North and South peaks, and for a considerable distance north of the former peak (that is, the part of the mountain opposite the town), the average dip is about 50 deg. to the west. This means that many of the joints mentioned dip directly eastward at an angle of 40 deg. The actual dips of the bedding and joints are almost ideal for the production of great intermittent slides from any mountain as steep as that under consideration.

The joints are thus of profound importance as they so seriously affect the strength of the limestone and, by their attitude, furnish potential slipping planes, which threaten to become sliding surfaces if a heavy jar or a disturbance of the basal abutment should occur. Moreover, the joints are favorable channels for the seepage of ground-water. This tends slowly to enlarge them and also to wet the rock, increasing the danger of sliding *en masse*.

Working Coal Mines a Source of Danger

The commission declares that mining in the coal seams at the foot of the mountain is likely to produce or aid in the production of a slide, thus imperiling the town of Frank and its inhabitants. The only method known to the commission that would insure against appreciable subsidence is that of hydraulic packing with sand.

The settlement, after packing with ordinary sand, is less than 5 per cent.; with granulated slag, settlement is inappreciable, and it would probably be equally imperceptible if sharp, clean sand were used. The use of loam and sandy clay, ashes or crushed shale is less successful, the settlement with such material being from 10 to 15 per cent.

Sand Flushing Not Practical

It does not appear possible to employ sand filling under ordinary commercial conditions in the Turtle Mountain district. There are no large bodies of clean sand at hand. The only available source from which material could be obtained in sufficient quantities would be the sandstone at the base of Bluff (Goat) Mountain. This would have to be quarried, crushed, transported and flushed into the mine. The cost with the high labor rates which prevail in Alberta, plus repairs, renewals and capital charges, would add not less than $1.25 per ton of coal extracted, even if done on a considerable scale. The cost of installing the necessary plant would also be great, so that the system appears commercially impossible under the competitive conditions of coal production in that district.

While the use of dry packing probably lessens the amount of subsidence, the experience with the long-wall method of mining both in America and Europe, where dry packing is employed, indicated that a settlement of 40 to 60 per cent. of the thickness of the seam must be expected. It takes several years to reach the full settlement, but any portion of such contraction might cause disastrous slides.

The only conditions under which mining should be carried on in the danger area above described are: (1) The townsite should be abandoned and compensation for the damage to the property of the Canadian Pacific Ry. assured. (2) The present entrance to No. 1 mine, which is a drift, should be abandoned and the mine should be operated by deep levels from the shaft, or from an opening at the extreme southern end of the property in the vicinity of Hillcrest. (3) Unusually heavy pillars should be left throughout the danger area, particularly in the upper levels, and not more than 50 per cent. of the coal should be extracted. (4) The excavated areas should be packed.

Edison Electric Mine Lamp

The *Engineering and Mining Journal* gives the following account of the Edison mine lamp:

The accompanying illustration shows the general features and the manner of carrying a new safety electric lamp, which is operated by an Edison storage battery of the type for the development of which Mr. Edison was recently awarded the Rathenau medal by the American Museum of Safety.

EDISON ELECTRIC LAMP AND STORAGE BATTERY

The battery is inclosed in a nickeled-steel container, from which the electrolyte cannot escape. It is claimed that the cell cannot be so over-charged, as to injure it, and charging it in the reverse direction, or leaving it in any state of charge or discharge does it no harm.

The cell must be charged, and the electrolyte replenished with distilled water, the electrolyte being changed every nine or ten months. No other attention is needed. The battery is inclosed in a locked case and a flexible cord connects it with the lamp. This cord cannot be disconnected and is covered at both ends by flexible steel armor for a part of its length. Danger of sparking by breaking at the connections is thus avoided.

The lamp itself has a tungsten filament and a parabolic reflector protected by a heavy glass lens, cushioned on gaskets. There is also a hook for attaching the lamp to the cap. The miner cannot get at the lamp without breaking a seal on the reflector.

Pittsburgh Greatest Fuel Consumer

More fuel is consumed in the city of Pittsburgh and its immediate vicinity, and more coal is shipped to and through the Pittsburgh district, than in any other district in the world, according to the U. S. Geological Survey. With a population of about one-ninth of that of Greater New York, the consumption of coal alone in Pittsburgh is nearly equal to that of the much larger city. Greater New York consumed in 1911 approximately 19,000,000 short tons, and Pittsburgh used about 16,500,000 short tons. But Pittsburgh consumes several million tons of coke and considerable quantities of natural gas, which, added to the coal consumption, gives that city a good lead over New York as a fuel consumer.

In the quantity of coal handled the comparisons are still more striking, Pittsburgh's business exceeding that of New York by nearly 50 per cent. In 1911 the total coal traffic in New York Harbor, including the city consumption, the trans-shipments to New England and up-river points, and the bunker and export trade, amounted to approximately 36,000,000 short tons, whereas the coal traffic of Pittsburgh, including rail shipments east and rail and water shipments west, amounted to nearly 53,000,000 tons.

In the total movement of coal to Pittsburgh and points east and west thereof, there was an increase in 1911 of 1,974,795 tons over 1910, all of the increase being in the shipments through or from the district. On account of the depression in the iron and steel trade, the local consumption of coal at Pittsburgh decreased about 1,250,000 tons, or from 15,600,654 tons in 1910, to 14,349,644 tons in 1911. The rail shipments to Pittsburgh decreased about 1,000,000 tons, and the water shipments about 250,000 tons. The decrease in the consumption of coke was, of course, much larger. The movements of coal both east and west, however, showed increases, western shipments increasing from 24,453,581 tons to 25,291,264 tons, all in water shipments to lower Mississippi River points, and eastern shipments, all-rail, increasing from 10,781,544 tons to 13,169,866 tons. The water shipments were the largest since 1907.

Blueprint Rack

The filing and handling of blueprints in a mine office often becomes a troublesome problem. The accompanying illustration, from *Engineering News*, Jan. 23, 1913,

A BLUEPRINT RACK

shows a rack that has proved useful in such cases. The prints are assembled in convenient groups, and bound together with softwood strips, $\frac{1}{4}$x$\frac{1}{4}$ in. in section, fastened by $\frac{3}{16}$x1-in. machine screws and wing nuts.

EDITORIALS

A Bill to Amend the Bituminous Mining Code

A bill of a proposed amendment to Secs. 3, 5 and 6, Art. 19, of the bituminous mining code, of Pennsylvania, has just been received. The bill is to be presented to the next legislature. Practically, it covers two important points, in the bituminous code, relating to the appointment of mine inspectors in the bituminous district of Pennsylvania. We give below the reading of these sections as they appear in the present law, together with the changes contemplated in the amendment. Section 3 reads as follows:

SEC. 3. The qualifications of candidates for the office of inspector shall be certified to the examining board, and shall be as follows:

The candidates shall be citizens of Pennsylvania, of temperate habits, of good repute as men of personal integrity, in good physical condition, and shall be [between the ages of thirty and fifty years: Provided, however, that any inspector appointed under the provisions of the act of May fifteen, one thousand eight hundred and ninety-three or under the provisions of this act, shall be eligible for reappointment, even if beyond fifty years of age, if in good physical condition.] The candidates shall have a knowledge of the different systems of working coal seams, and shall have had at least ten years' practical experience in bituminous mines, five years of which, immediately preceding their examination, shall have been in bituminous mines of this commonwealth, and shall also have had practical experience with explosive gas and other dangerous gases found in coal mines; and, upon examination, shall give evidence of such theoretical as well as practical knowledge and general intelligence respecting mines and mining, and the working and ventilation of mines, as will satisfy the examining board of their capability and fitness for the duties imposed upon inspectors of mines by the provisions of this act.

The amendment to this section proposes to omit the words of the section inclosed in brackets and substitute therefor the words: *"at least thirty years of age."* No other change is suggested in this section.

Section 5, of the present law, reads as follows:

"SEC. 5. The Governor shall, from the names certified to him by the Examining Board, commission one person to be inspector for each district, in pursuance of this act, whose commission shall be for a full term of four years from the fifteenth day of May following the regular examinations. (X) Each inspector appointed under the provisions of the act of May fifteen, one thousand eight hundred and ninety-three, may continue in office until May fifteen, one thousand nine hundred and thirteen.

After the passage of this act, the chief of the Department of Mines shall have the right to assign the inspectors to the districts for which, in his opinion, they are best fitted.

The proposed amendment is to insert at the point marked (*X*) the following: *"Applicants or candidates whose names have been so certified shall be chosen and commissioned in the order of rank of percentage attained at the examination held by the examining board, the higher to be first preferred over those of lower percentage, and, in case of a tie in percentage, the candidate or applicant oldest in point of service shall be preferred."*

No other change is contemplated in this section.

Section 6, of the present law, reads as follows:

"SEC. 6. When a vacancy occurs in said office of inspector, the governor shall commission, for the unexpired term, [from the names on file in the Department of Mines, a person who has received an average of at least ninety per centum. When the number of candidates who have received an average of at least ninety per centum] shall be exhausted, the governor shall cause the aforesaid examining board to meet for a special examination, and examine the persons who may present themselves for examination in accordance with section three of this article, and the board shall certify to the governor, also to the chief of the Department of Mines, the names of all applicants who have made a general average of at least ninety per centum in said examination, as provided for in section four of this article; one of whom shall be (X) commissioned by the governor, according to the provisions of section five of this article, for the office of inspector for the unexpired term. In conducting the said special examination the board shall comply with all the requirements of section three and four of this article."

There are two proposed changes in this section. The first is to substitute for the words inclosed in brackets the following: *"one from those whose names have been certified by the examining board. The choice of the one to be thus commissioned shall be made in the order of the rank of percentage attained by applicants or candidates, at examinations held by the examining board, the higher to be first preferred over those of lower percentage; and, in case of a tie in percentage, the candidate or applicant oldest in point of mining experience shall be preferred. When the number of candidates or applicants, whose names have been certified to the governor and the chief of the Department of Mines by the examining board".*

The second proposed change is to insert at the point marked (*X*) the following: *"chosen in accordance with the rank of percentage attained, at such examination, the higher to be first preferred over those of lower percentage, and, in case of tie in percentage the candidate or applicant oldest in point of mining experience to be preferred, and shall be".*

No other change is contemplated in this section.

* * * *

Referring briefly to these proposed changes, the limitation of "fifty years," provided by the new bituminous law (1911), is a wise safeguard against making eligible for appointment as mine inspectors, men of mature age who have passed the fifty mark and whose habits and opinions have quite generally become fixed. Men of this type, while possessing experience in certain fields and under certain conditions, are often prejudiced in their ideas and convictions. They have, as a rule, passed the age when they can readily adapt themselves to new conditions, which is one of the most important requirements in the qualifications of a mine inspector.

It is very proper, as the present law provides, that any mine inspector who has passed this age limit (50 years) shall be and is still eligible for reappointment to the office he has filled acceptably. His acquaintance with the conditions existing in the mines he is to inspect places him in another class from men who have had no experience as inspectors in the district. We would not, therefore, indorse the proposed amendment of Sec. 3.

The proposed amendments of Secs. 5 and 6 have, each, practically the same purpose in view; namely, to require the appointment by the governor, of that candidate who

has secured the highest percentage in the examination. According to the present law, the governor may appoint, as inspector, any one whose name appears on the certified list furnished him by the examining board.

As claimed by the advocates of this amendment, the present law places the inspector at the mercy of politicians, and has a tendency to make him part of the political machine. In support of the amendment, it is stated that the purpose of the law—the protection of life, health and property—requires that the men appointed to inspect the mines shall be free to perform this work unhampered by any political considerations and without fear of punishment, such as can be administered, by corporations, upon those who oppose their will.

These reasons appeal to the unprejudiced mind as being sound and furnishing sufficient excuse for the proposed amendment of both Secs. 5 and 6. We hope, therefore, that these two sections of the present law will be amended, in this respect.

Self Ignition of Coal

Rabid dogmatism has marked the discussion of spontaneous combustion. The advocates of the theory that iron pyrite or marcasite are the cause of this action have been unsparing of those who favor the belief that oxygenation of the coal substance is the real incendiary.

The promising suggestion and enlightening experiments of H. C. Porter, of the Bureau of Mines, that hydration may be the cause is worthy of careful consideration and he will fortify it if he can show that the coals, most subject to spontaneous ignition, heat more when exposed to hydration than coals which are not so subject.

This, M. Taffanel has shown, is true to a large degree for oxygenation. The coals of Liévin, Béthune and Lens containing 29, 14 and 12 per cent. of volatile matter respectively, on an ash-free analysis, absorbed at 60 deg., 2.90, 1.35 and 1.12 c.c. of oxygen per gram of coal. However, the coal from Nœux with 20 per cent. of volatile matter absorbed less oxygen than any of the others.

We wish to submit a working hypothesis for the consideration of our readers. It is based partly on the fact that the heat of combustion of the coal as an organic unit is almost identical with the heat which would result from the burning of its elements, omitting all that hydrogen from the calculation which may be considered as combined with oxygen to form hydrates or moisture. This fact suggests that if coal could be dissociated, the sum of the heats of the resulting chemical actions would be zero, the dissociation producing a number of calories equal to those which it absorbs.

If it be fair to argue on this basis, we must be convinced that the chemical dissociating actions which produce heat must be considerable. We know that some of the hydrocarbons will generate heat in breaking up, but whether any of them will produce enough to create the balance to which we have referred is at least doubtful.

We are inclined, therefore, to regard as significant the fact that sulphur and nitrogen are found in larger proportions in those types of coal which ignite spontaneously and that they are also components of compounds which create much heat on dissociation. It seems to take much energy to make sulphur or nitrogen mate with carbon; conversely their separation produces much heat.

The heat resulting from dissociation of a pound of cyanogen is 2273 B.t.u. and of hydrocyanic acid 1831. This assures us that at least some compounds of carbon and nitrogen are able to give out much heat on dissociation. The compounds of carbon with sulphur are perhaps fairly represented by carbon disulphide which on dissociation surrenders 1062 B.t.u. per gram of the liquid.

But these are compounds, which may not be found in coal, at least, in chemical freedom. They may be expected to be present in combination with other radicles. Most representative of the class of bodies, likely to be thus found in coal which has not been subjected to much heat, is oil of mustard, a truly organic body, $C_3H_5.NCS$, containing 826 B.t.u. per pound of the liquid. If 3 per cent. of sulphur in the coal were combined as oil of sulphur, the whole body of that compound would represent 9.3 per cent. of the mass of the coal. In many coals 3 per cent. is sulphur which is neither in a sulphate nor in a metallic sulphide and this sulphur probably forms compounds analogous to the oil we are discussing.

It is true that the oil of mustard itself is probably not to be found in coal, nor yet are any of the compounds mentioned, but it is certain that other hydrocarbons combined with sulphur and nitrogen are to be found and thermochemical inference suggests that they might be equally heat-giving on breaking up to simpler forms. Moreover, experience favors the suggestion that the sulphur, at least, will be ready to break loose from its union with organic bodies.

Hence we have suggested a chemical action which is probably most active in coals still in formation, and which is independent of oxygen. Such an action can take place in the heart of a coal pile and here it is that spontaneous combustion commences. But we do not explain by this hypothesis why coal is most subject to this action after it has been exposed to the air nor are we able to show why hydration increases the heat of the coal mass. But these are not sufficient objections to our assumption.

It is likely that hydration, dissociation and the oxygenation both of coal and pyrite all do their part and may help one another. The taking of the coal from the hill, not only oxidizes it, but removes the water which apparently is in chemical union with the coal, for otherwise its reunion would hardly be accompanied with so much heat.

This oxidizing and dehydration may possibly aid in the breaking up of the original compounds in the coal. In fact, there are reasons for thinking dehydration is more effective in American coals than oxidation because coals left in the mine, subject only to the latter, rarely take fire. Their desiccation is prevented by the subterranean moisture.

Educating the Coal User

When we recall that the early anthracite coal producer expended his money to find some means of burning anthracite in a stove, when we note with what ability the Standard Oil Co. has taken over the oiling of cars and engines, when we pass exhibitions of the gas companies in the big cities striving to show how light and heat can be more economically obtained from gas than from electricity or coal respectively, we wonder why the operator having a waste grade to sell, tries to make the market accept it only by a price differential.

SOCIOLOGICAL DEPARTMENT

A Kentucky Bathhouse

SPECIAL CORRESPONDENCE

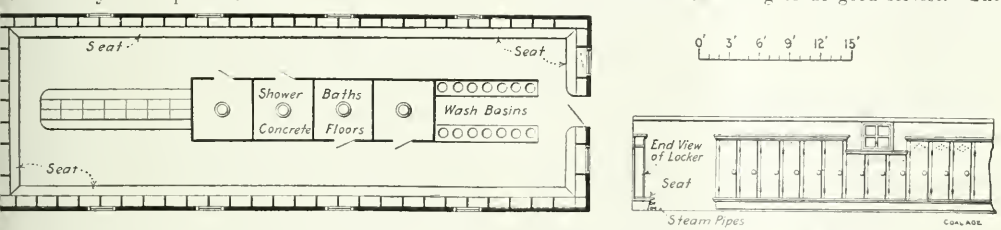
The bathhouse for the use of coal miners is not an innoation. In the older mining communities it is as much part of the equipment of the modern mine as the tipple, he machine shop and the power plant, but in Kentucky, nd especially in the mountain district, it is not often to e found.

The Stearns Coal & Lumber Co., when it attempted o improve the condition of its miners, by erecting a washhouse" for their use, did so with some misgivings. t is rather a delicate subject to approach, to suggest that ny man would feel better if he had a bath once a day, nd miners, as a class, are sensitive, especially when it the "company" which does the suggesting.

The first experiment, for it was so considered, was at line No. 4, which employs about 200 men. A simple ooden building was constructed, with 60 lockers, four owers and about a dozen basins, over which were hotnd cold-water faucets. It was heated by a stove, and ectric lighted. The water was piped from a reservoir nd heated by an old portable boiler.

steam heated and is lighted by electricity. No lockers are placed over others and all are of such height as will receive a full suit of clothes without folding. Holes are bored in the doors for ventilation. A motor-driven pump and a 10,000-gal. tank provide water during continued dry weather; at other times water will be piped from hill-side springs.

Possibly the principal beneficiary of the miner's bathhouse is the housewife; but the miner derives much comfort from it, since it permits him to leave his working clothes at the mine, where they belong, and appear on trains, in the office, at the commissary and at home in apparel befitting the well-to-do workman.



THE BATHHOUSE BUILT BY THE STEARNS COAL & LUMBER CO. AT NO. 10 MINE

The problem of maintaining the bathhouse was a erious one, for an attendant night and day was required. t was solved by charging all who used a locker 50c. er month, and all other employees at the mine 25c. per ionth "whether they needed a bath or not." There was onsiderable opposition to this at first, but the miners soon ealized the advantages and were willing to pay for them. s the arrangement stands, the "company" furnishes the uilding, equipment, water, light and fuel, and the minrs pay the other running expenses. This means of mainenance seems based on sound business principles. Luxries that cost nothing are not usually appreciated.

Ninety per Cent. of the Employees Petition for a Bathhouse

In a short time the miners at No. 10, a larger mine beonging to the above company, sent a petition, signed by o less than 90 per cent. of their number, asking for a athhouse on similar terms. The plan shown herewith ill give an idea of the one which was constructed in nswer to their request.

It is larger than that at mine No. 4, containing 100 ockers. It has four showers with concrete floors. It is

Prizes for Efficiency

The Corona Coal Co. and H. B. Swoope & Co., who operate 10 mines in Clearfield County, near Madera, on the Pennsylvania and New York Central & Hudson River railroads, recently initiated a scheme for increasing the efficiency of their employees by the giving of prizes to those who showed themselves willing to do good service. The tonnage of the combined mines is about 500,000 tons per annum.

They promise to give, about Apr. 1, fifty cash prizes, and the awards will be made by a committee to consist of the general manager, mine superintendent, engineer and mine foremen. The prizes will run from $1 to $20 and the time to be considered in the award commenced Nov. 18, 1912, and extends to the time of distributing the prizes. All employees, regardless of where they may work, are eligible for a prize, except the members of the committee. However, the mine foremen receive extra pay for the above mentioned period if they make a good record.

Open to All Employees

Without limiting the nature of services for which rewards will be made, the general manager has outlined certain possible conditions which will find favor with the committee. A miner who works faithfully every day if possible and loads as much coal when the company needs it as he reasonably can and always tries to keep his coal clean, and who endeavors to help out the mine foreman by getting him miners and in other ways, will be a suitable recipient for one of these prizes.

A cutter and his scraper who systematically keep their places cut, and who see that there is somebody to replace them if they have to be away, will be favorably considered by the committee in the making of awards. A driver who works hard and uses good judgment, making as many trips as possible, who takes good care of his mules and encourages the men whose coal he hauls, who suggests improvement in the method of hauling or gathering coal, and who helps to get miners when they are scarce, will be in line for an award of merit.

Encouragement to Work Overtime

An employee on the tipple who keeps the tipple floor clean, who helps the motorman or driver to get away quickly with his trip, who loads out a railroad car after hours so that it will not stand over, who watches for the dirty coal and hustles for the company's interest, will be remembered when the distribution of prizes is made.

Motormen, trip riders, and team drivers who make an early start in the morning and a good tonnage each hour, remembering to be careful at the same time, who get in an extra trip now and then, and who are not afraid of an extra trip in the evening, particularly if needed to finish the end of a railroad car when cars are scarce, or any other employee in the boiler house, blacksmith's shop, on the road, or in the barn, who keeps the work moving will probably be rewarded for his activities in the interest of the company.

In short, 50 cash prizes will be given to the 50 men in the employ of these two companies who are of the most value to the corporations between Nov. 18 and Apr. 1. It will be interesting to see what effect this award will have on the efficiency of the employees. It is openly admitted that it is based on the practices in vogue in the Pennsylvania R.R. and the U. S. Steel Corporation. However, it is not necessary to point out that there are certain important differences in the character of the aims.

Precautions Taken by the Frick Co.

By Thomas W. Dawson*

To warn the enginemen, machinists and others, the following notice is posted: "Employees working around engines, moving or revolving machinery, shafts, etc., are warned of the danger, and are prohibited from wearing torn clothing, loose or unbuttoned jackets, blouses, shirts, long neckties and loose sleeves. Always wear the overall jacket, tucked in the trousers or under the overall bib. Never forget to examine your clothing before commencing work." There is also the sign, "Stop this machine before oiling, wiping or repairing."

By way of safety devices, there are safety guards for all smith-shop equipment, saws, lathes, emery wheels, gears, belts, pulleys, shafting and all wood- and steel-working machinery; a locking device for handwheels on valves; safety lock for electric switches; guards for water gages; concealed setscrews; safety gaskets to be inserted in steam blowoff and feed-water connections when cleaning and repairing boilers; safety-locking device for self-dumping cages; safety chucks for drill-press spindles; safety chuck for engine lathes; safety lock for belt shifter, guards for governors and governor pulley wheels; spark arrester for charging locomotives; soap lubrication for air compressors; wagon guard and dumping platform for swing-gate mine wagons; spooling device for tail rope on haulages; stiles or protected crossings over rope and sheaves where necessary for men to pass; improved safety catch for cages; device for positively rectifying wagon catches on car hauls; self-closing hinges for shaft gates; steel gallery and runway over boilers; protecting railing of all kinds around the revolving and moving parts of all machinery, and around drum pits, sumps, waste-heat flues, etc.; safety platform for operation of electric larries; extra cages ready to replace shaft cages for use in case of accident; rubber matting around all switchboards and electrical machinery; and printed rules and regulations for the proper care of all moving parts.

"Do Not Touch" signs are used about electricity, indicating the voltage of the current; and "Do Not Pass Under" signs will be found at such places where there is danger in passing underneath structures.

Notices Underground

When coal is hoisted, you will see a sign in large letters indicating the maximum load which may be placed on the cage, and the gross weight which that rope will support. The standard signals for the hoisting and lowering of cages or trips, and the number of men permitted to ride on a cage at one time, are indicated by signs having large letters, placed at the most convenient points for observation.

We have steel doors to drop over shafts which have wood headframes or coal bins above them, in case these wood structures catch fire; pits for reception of blowoff pipes from boilers, to prevent accidents to anyone who might be passing during their blowing off; and "drags" or "dogs" on the rear end of all trips hoisted on inclines or slopes.

A thorough search is made of one man or more of each cage load which is lowered into a mine generating gas, to discover matches or smoker's articles. All safety lamps are inspected thoroughly at the lamp house each morning immediately before they are given to the employees.

DISCUSSION BY READERS

Reducing Ventilation When Firing

Letter No. 9—I have been much interested in the discussions on reducing ventilation in mines at firing time. It seems to me that it would not be right to stop the fan or reduce the ventilation when firing in a mine that is making any gas at all, for at least two good reasons: 1. The continued flow of gas into the mine would soon produce a dangerous atmosphere if the fan were to be stopped or the ventilation checked. 2. The gases produced by the firing of a large quantity of powder, at the working face, must be diluted and swept away by a sufficient current of air, which must be kept traveling.

In the use of dynamite, it often happens that one or more sticks of the charge do not explode; but, being ignited, burn with a blaze. In the use of black powder, much the same result is often produced by a shot blowing its tamping, and much of the powder being thrown out and burning in the air. These occurrences often produce an explosion, if the atmosphere in the mine is not sufficiently diluted with good, pure air. To avoid these occurrences a competent man should inspect all shots before they are fired.

THOMAS R. PIERCE.

Scranton, Penn.

❖

Letter No. 10—I have followed closely all that has been written in COAL AGE, on the subject of reducing or shutting off the air when firing in mines, and from my own experience, strengthened by the opinions and experiences of some old-time shotfirers, I am convinced that it is safer to fire shots in the mine with the fan stopped, or at least with slack ventilation, than with a strong air current.

I have noticed that a "windy shot" seldom occurs in the first rooms on a long entry where the air is generally poor and there is much room for expansion and plenty of cooling surface. But, as we shoot the rooms in regular order and approach the face of the entry, the space becomes more contracted and the ventilation stronger. In finishing up, at the head of the entry, it is often necessary to light 5 or 6 shots together. These may not all explode at once, but follow each other in quick succession. In this close confined space, the gases produced by the burning of so much powder and distilled from the coal and the fine dust thrown into the air, combine to make a highly explosive atmosphere, which is often ignited by one of the shots, producing what is called a "windy shot," or perhaps a small local explosion.

It is my opinion that if there were no air current here these gases would not explode. Gas will not burn without a certain admixture of air or oxygen. In the absence of sufficient air, flame quickly dies out. This would greatly shorten the range of flame, in blasting, and limit the amount of destruction should a windy shot occur.

It would not be necessary to stop the fan or slow it down, at the time of firing. In order to reduce the ventilation in an entry we are about to shoot, all that is necessary is to short-circuit the air by setting open the door at the mouth of the entry, or at a point outside of where the firing begins. This will leave the section we are about to shoot unventilated and accomplish the same purpose as stopping the fan. Such a question as this I think is worthy of the attention of the Federal Bureau of Mines and should be thrashed out at the Pittsburgh experiment station.

R. J. PICKETT.

Shelburn, Ind.

❖

Letter No. 11—It has been generally admitted that firing shots against a high-water gage is dangerous, but to what extent has never been thoroughly settled. The opportunities for studying the problem are limited and we must therefore depend largely on theory.

In considering the question of reducing the ventilation in a mine at firing time, in its practical bearing, and ignoring for the time the possible effect of a high water gage or pressure, we must first ask: Are shots fired in absolutely still air dangerous and, if so, why? Personally, I maintain that in the majority of cases they are dangerous and the danger is greater in a gassy mine.

The argument in favor of shooting in still air appears to be that if the ventilation is stopped there will not be enough available oxygen to support an explosion if one should start. But, let us see if such is really the case. For example, say the day shift in a mine goes off at 4 p.m. and the shotfirers going down an hour later stop the fan. Allowing them time to get to the nearest working face, perhaps an hour will elapse from the time of stopping the fan until firing of shots begins. No change could take place in the atomspheric conditions, in this time, that would warrant our saying that an explosion could not occur, the fan having been stopped? In mines generating no gas the condition of the air is practically unchanged, except for a slight reduction in pressure, owing to there being no circulation. The oxygen content of the air has not been appreciably diminished by any chemical action, in so short a time. There is, then, but one difference; namely, the air is at rest instead of in motion and there is no ventilating pressure.

Let it be assumed that this condition exists in a mine that is dry and dusty, and that three shots are fired in the face, by fuse. What will be the result? It is practically impossible for a shortfirer to cut the fuses so that these shots will explode at the same time, but they will probably follow each other in quick succession. The first shot will cause a rush of air and dust away from the face, which will probably react or rebound about the time another shot goes off; and this may be repeated, each shot throwing more dust into the air, which soon becomes thoroughly dust-laden. If, now, one of the shots happens to be overcharged and blows its tamping, producing considerable flame, the resulting conditions are ripe for a dust explosion. Such an explosion, feeding on the oxygen of the air, will seek the lines of least resistance, regardless of whether the air is still or in motion.

I believe it is unnecessary to discuss this question, in respect to mines making much gas, for the state mining laws generally prohibit the firing of shots in the presence of firedamp, which would be sure to be present in any mine making gas.

I would like to ask what mine foreman, in charge of a mine generating large quantities of gas, would dare to stop his fan for 30 min. or an hour before the shortfirers go into the mine. It would be necessary to make an examination of each place before firing a shot therein, in order to make sure that no gas had accumulated while the fan was stopped. I think few, if any, firebosses would try such a caper. One would be liable to lose his certificate, in almost any state, if he did.

Ventilation in the mines may, of course, be carried to an unreasonable extent. A strong air current may increase the tendency of the air to rush back, after a windy shot; but if a given amount of air is required, at the working face, to dilute the inflammable gases generated, the same amount or more must certainly be kept in circulation during firing time when a deficiency of oxygen would result in producing a larger amount of inflammable gas (CO) from the explosion of the powder.

The more logical thing to do is to insist on rigid shot inspection; mine the coal wherever possible; and use permissible powders, with an electrical firing system operated from the surface. If this is done it will make little difference whether the air is still or moving.

As long as coal is shot by black powder and the holes are charged as some miners see fit, with no regard to the position or depth of the hole, there will be a good chance of explosion, no matter what steps are taken in regard to the ventilation of the mine.

O. G. Sharrer.

Hanna, Wyo.

The Bellevue Mine Explosion

Referring again to the discussion of the cause of the second explosion at Bellevue, Alberta, Canada, which occurred Dec. 9, 1910, I have been hoping that there would be a further discussion of the important questions involved and which have been referred to in the Stirling-Cadman discussion, Coal Age, Oct. 5, p. 457; and my own letter, Nov. 2, p. 617.

The verdict of the jury reads in substance as follows:

> We do upon our oath say that 30 men came to their death by carbon-monoxide poisoning, and one by a combination of carbon-monoxide poisoning and a fractured skull caused by a cave of rock in chutes Nos. 76 and 78.

This evidence was based on the percussive theory as advanced by James Ashworth, mining engineer, who was called by the government to give expert evidence on this disaster. The question arises as to whether a fall of roof rock, without an explosion of gas and dust, or either, in a coal mine, could generate heat sufficient to coke the dust so as to form minute globules of coke, char the timber, blow out stoppings and do other damage, besides generating large volumes of afterdamp containing carbon monoxide. According to the expert evidence given by Mr. Ashworth, all of these effects were caused by the percussive effect produced by the heavy cave of roof rock in the chutes mentioned.

If we understand correctly, Mr. Ashworth discards the ignition of a possible accumulation of firedamp or a cloud of dust by sparks from the falling rock, and ascribes all to the percussive effect produced on the mine air by the fall of roof; assuming that the compression of the air in the mine was sufficient to generate the heat necessary for the effects just named.

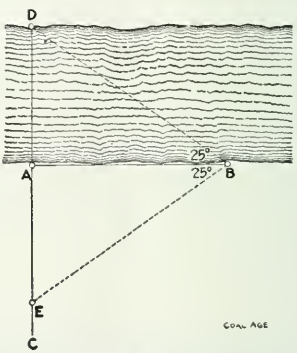
Others claimed that a body of gas and more or less dust was ignited by sparks, given out by the roof rock striking the iron chutes or in the grinding action of the roof as it fell. The discussion of these possible causes has created much interest among miners and mining men in general, throughout the Crow's Nest Pass; and we would gladly see the question further discussed.

J. W. Powell,
Mine Manager, Columbia Coal & Coke Co.
Coalmont, B. C., Canada.

Surveying Methods

Referring to the question of Mine Surveyor, Coal Age, Jan. 18, p. 113, I would like to suggest another method that has served my purpose on several occasions. This method is a very convenient one to use in a level country, although it could not be applied, in many cases, where the country is rugged and there is not sufficient room to extend the line. It possesses the advantage that it requires no technical knowledge on the part of the surveyor, or any calculation.

The method is as follows: Referring to the accompanying figure, set up the transit at *A*, on the edge of the



Simple Method of Measuring across a River

stream, and sight the telescope on some well defined object *D*, on the other side of the river. Then plunge the telescope and extend the line *DA* to *C*.

Now, deflect 90 deg. from the line *DC*, and locate a point *B* so that the line *AB* is at right angles to the line *DC*. It is not necessary to measure the distance *AB*, which can be any convenient distance. Set up the instrument at *B*, sight the point *A*; and, having first set the vernier at zero, deflect the telescope to *D*, and read the vernier. Now, sight again to *A*, with the vernier set at zero, and turn off the angle *ABE*, equal to the angle *ABD* just measured. In the figure, these angles are marked 25 deg., but may be any other angle. The point *E* must be located on the line *AC*. The distance *AE* will then be equal to the required distance *AD*; and this distance *AE* can be measured with the tape or chain.

Carbon, W. Va. Emil F. Hocke.

EXAMINATION QUESTIONS

Ventilation

(Answered by Request)

Ques.—A certain fan, at a certain mine, produces 65,000 cu.ft. of air per min., when running at 40 r.p.m.; what volume of air will this fan produce at the same mine when running at a speed of 55 r.p.m.?

Ans.—For the same power applied and the same conditions in the mine, the volume of air produced is, practically, proportional to the speed of the fan. In other words, the quantity ratio is equal to the speed ratio, therefore, calling the required volume of air x,

$$\frac{x}{65{,}000} = \frac{55}{40} = \frac{11}{8}$$

$$x = \frac{11}{8} \times 65{,}000 = 89{,}375, \text{ say } 90{,}000 \text{ cu.ft. per min.}$$

In practice, the increase of quantity is in a slightly less ratio than that of the speed. For example, the fifth power of the quantity ratio is equal to the fourth power of the speed ratio. Thus,

$$\left(\frac{x}{65{,}000}\right)^5 = \left(\frac{11}{8}\right)^4 = 1.375^4$$

$$x = 65{,}000 \sqrt[5]{1.375^4}$$

$$x = 65{,}000 \times 1.29 = 83{,}850 \text{ cu.ft. per min.}$$

Ques.—If 70,000 cu.ft. of air is passing through a fan drift per min., under a water gage of 2.1 in., what is the horsepower on the air?

Ans.—The horsepower on the air or the effective horsepower is

$$H = \frac{Qp}{33{,}000} = \frac{70{,}000\ (5.2 \times 2.1)}{33{,}000} = 23.16 \text{ hp.}$$

Ques.—If a certain power is passing 30,000 cu.ft. of air per min., in an airway 6x6 ft., what would be the size of a similar airway that will pass 40,000 cu.ft. per min., under the same power, assuming the airways are of equal length.

Ans.—In similar airways of equal length, for the same power on the air, the fifth powers of similar sides bear the same ratio to each other as the cubes of the quantities of air in circulation. In other words, the fifth power of the side ratio is equal to the cube of the quantity ratio. Therefore, calling the side of the required airway x, we have,

$$\left(\frac{x}{6}\right)^5 = \left(\frac{40{,}000}{30{,}000}\right)^3 = \left(\frac{4}{3}\right)^3 = \frac{64}{27} = 2.37$$

$$x = 6 \sqrt[5]{2.37} = 6 \times 1.188 = 7.128 \text{ ft.}$$

The size of the required airway is, therefore, 7.128 × 7.128 ft. The sectional area of this airway is 7.128 × 7.128 = 50.8 sq.ft.

Ques.—A current of 25,000 cu.ft. of air is split so that it travels in three airways subject to a common pressure. The size and length of the airways are as follows: Split A, 6x9 ft., 2100 ft. long; split B, 6x10 ft., 2400 ft. long; split C, 1x10 ft., 9000 ft. long. How will this quantity of air divide between these three splits if no regulators are employed?

Ans.—The area, perimeter and length of each of these airways are as follows:

A, $a = 6x\ 9 = 54$ sq.ft.; $o = 2\ (6 + 9) = 30$ ft.; $l = 2100$ ft.
B, $a = 6x10 = 60$ sq.ft.; $o = 2\ (6 + 10) = 32$ ft.; $l = 2400$ ft.
C, $a = 4x10 = 40$ sq.ft.; $o = 2\ (4 + 10) = 28$ ft.; $l = 9000$ ft.

Reduced, the lowest relative values are as follows:

A, $a = 27$; $o = 15$; $l = 7$
B, $a = 30$; $o = 16$; $l = 8$
C, $a = 20$; $o = 14$; $l = 30$

The relative split potentials are now found by substituting these relative values in the expression for potential,

$$N = a \sqrt{\frac{a}{lo}}$$

as follows:

A, $27 \sqrt{\frac{27}{7 \times 15}} = 27 \sqrt{\frac{9}{35}} = 27 \sqrt{0.2571} = 13.690$

B, $30 \sqrt{\frac{30}{8 \times 16}} = 30 \sqrt{\frac{15}{64}} = 30 \sqrt{0.2344} = 14.524$

C, $20 \sqrt{\frac{20}{30 \times 14}} = 20 \sqrt{\frac{1}{21}} = 20 \sqrt{0.0476} = 4.363$

Sum of potentials 32.577

The quantity of air passing in each split is proportional to the split potential, and is found as follows:

A, $Q_a = \frac{13.690}{32.577} \times 25{,}000 = 10{,}500$ cu.ft. per min.

B, $Q_b = \frac{14.524}{32.577} \times 25{,}000 = 11{,}150$ cu.ft. per min.

C, $Q_c = \frac{4.363}{32.577} \times 25{,}000 = 3{,}350$ cu.ft. per min.

Total . . . . . 25,000 cu.ft. per min.

Mensuration

Ques.—(a) What is the volume of a conical tank 8 ft. in diameter at the top, 9 ft. in diameter at the bottom and 10 ft. high? (b) How many gallons of water will this tank hold?

Ans.—(a) Calling the large diameter D, the small diameter d, and the height h, the volume of the tank is found by the following formula:

$$Vol. = \frac{0.7854\ h}{3} \times \frac{D^3 - d^3}{D - d}$$

Substituting the given values, the volume of the tank, in this case, is

$$Vol. = \frac{0.7854 \times 10}{3} \times \frac{9^3 - 8^3}{9 - 8} = 2.618\ (729 - 512)$$

$$= 2.618 \times 217 = 568.1 \text{ cu.ft.}$$

(b) The capacity of this tank in gallons is found as follows:

$$\frac{568.1 \times 1728}{231} = \text{say } 4250 \text{ gal.}$$

COAL AND COKE NEWS

Washington, D. C.

A statement made upon what appears to be good authority among Democratic members of Congress is to the effect that coal which is now dutiable under the Payne-Aldrich law will, in the forthcoming tariff reform measure, be shifted to the free list. The hearings before the committee are now finished, although briefs relating to various items are still being received.

Coal producers have not made any vigorous arguments before the committee recognizing as they apparently do the disposition to abolish the present rates, in the interest of the consumer and thereby to afford such relief as transportation conditions would permit.

It is the expressed view of Democrats that the coal section in the Canadian reciprocity bill for which practically all Democrats voted clearly committed the party to the idea of free trade in coal. They do not think that general free trade in this commodity would be more injurious to the domestic miner than free trade with Canada would have been, and while the Canadian bill did not provide for absolute free trade with that country in this item it did take a decisive step in that direction.

Another feature of the situation which has received considerable attention is the fact that the duties on various classes of manufactures are being materially cut and that under those conditions Congress ought to relieve the manufacturer of such increase in price as the coal duty necessitates. This is supposed to be particularly important to manufacturers in the Northwest.

An Important Decision

The Interstate Commerce Commission has rendered an important decision in the Louisville & Nashville coal and coke rates case. This proceeding involved the reasonableness of proposed increases on coal and coke from mines east of Middlesboro, Ky. It was sought to advance the rates on coal to the Ohio River and points south thereof 25c. per ton while the advance on coke was 30c. per ton north of the Ohio River. The Commission now finds that the defendants (the railroads) have not succeeded in establishing the reasonableness of the new rate and, therefore, the tariffs are ordered withdrawn, the present rates being continued. Incidentally the commission expresses some interesting opinions on methods of discussing the rate question and gives the following useful summary of this important controversy:

Briefly summed up the record shows, among other things, the following: (1) That the Louisville & Nashville encouraged in every proper manner the development of the mines and ovens in the St. Charles and Appalachia districts, assisting those operators in establishing a market north of the Ohio River; (2) That the present rates have been in effect nearly ten years and the advance contemplated will probably exclude the Virginia operators from the northern territory; (3) That the cost to the Louisville & Nashville for transporting coal and coke via Cincinnati is not fairly representative of the cost via that route because of substantial expenditures incident to improvements under way; (4) That via Louisville the cost to the Louisville & Nashville is materially less than via Cincinnati; (5) That according to the Louisville & Nashville's figures the cost to it equals or exceeds its revenue, while according to the commission's figures the cost is only from 71 to 82 per cents. of the revenue; (6) That these costs include all costs except return upon income account, the out-of-pocket cost being, therefore, even at the Louisville & Nashville's figures, about 60 per cent. of its revenue; (7) That the Louisville & Nashville system as a whole is prosperous, that its Cumberland Valley division as a whole is prosperous, that the portion of the Cumberland Valley division east of Middlesboro shows either a profit or a loss dependent upon the method used in the assignment of cost and revenue; (8) That the eastern half of the Cumberland Valley division is more expensive per unit of freight to operate than the western half because for ten years it has remained practically unimproved and a much more economic line could be secured from Wassiota to Appalachia; (9) That while joint rates are under investigation all of the cost and revenue figures relate only to the movement to the Ohio River; (10) That the freight traffic manager of the Louisville & Nashville admits that his road seems to have been "trimmed" by the northern lines in the matter of divisions; and (11) that beyond a few categorical answers there is no testimony tending to show the reasonableness of the increased joint rates in their entirely.

Under all the circumstances our conclusion is that the burden cast by law upon defendants to show the reasonableness of the increased rates has not been sustained and that such rates should not be allowed to become effective. We are further of opinion and find that the present rates are reasonable and should be continued for a period of two years. An order in accordance with these findings will be issued.

Look for Higher Anthracite Prices

According to reports that are being received by government officials engaged in the investigation of the coal situation, materially higher prices for anthracite coal are to be expected in the near future, unless there should be a reduction in freight rates tending to offset them. As to future demand it is apparently positively assured while, according to information received by the bureau of mines production is about reaching its maximum capacity—a point from which it is certain shortly to recede. This prospect in connection with coal prices is likely to be seriously discussed in connection with the reports to Congress regarding the coal situation that are now in process of preparation.

PENNSYLVANIA

Anthracite

Scranton—It was announced here, Feb. 3, that following a meeting of the directors held in New York, the Erie Railroad Co. has divorced all relations with its coal holdings. Henceforth they will be operated as two separate corporations. The headquarters of the coal department, now located in New York, will be removed to Dunmore, where the offices of the Pennsylvania Coal Co. are now located. F. D. Underwood, president of the Erie, retires as president of all the coal companies that are subsidiary to it. He is succeeded by Captain W. A. May, vice-president and general manager of the coal companies.

Treverton—Treverton and Shamokin locals of the United Mine Workers have adopted resolutions to work on days that colliery employees, who are killed, are buried and to give the widow $150. If a breaker boy is killed, the parents will receive $50.

Taylor—As a part of the campaign that has been waged for months in the interest of a 100% organization of mine workers throughout the anthracite field, about 6500 employees of the Lackawanna Coal Co., at eight of its collieries in Scranton and Taylor, quit Feb. 1. They refused to work with nonunion men, engineers being included in this list, the miners insisting that they should belong to the organization.

Pottsville—Two large collieries of the Reading Coal Mining Co. are crippled as a result of the strike of 2200 of their men. The reason is said to be that certain of the employees refused to wear union buttons.

Bituminous

Connellsville—A scarcity of labor has been serious in the eastern Tennessee field since the holidays and, as a consequence, the car supply in that section is exceptionally good. The full output is not being loaded at any of the mines.

It is said that many miners in the Tennessee-Kentucky field left that region shortly before Christmas, owing to the scarcity of cars and the consequent slack work and came to the Connellsville region.

Greensburg—The U. S. Weather Bureau is notifying mine owners throughout the country that it will inform them, if they so desire, of the times when it would be advisable to take extra precautions to prevent explosions and mine disasters. The weather bureau declares that when there is a marked fall in atmospheric pressure the chances for mine explosions are greatly increased.

Carrolltown—Mine Inspector Monteith is conducting an investigation into the explosion in mine No. 25, of the Pennsylvania Coal & Coke Corporation, in which Ferdinand Behe and Paul Steffus, both of this place, were killed, Jan. 23.

WEST VIRGINIA

Bluefield—The visit of D. A. Thomas, head of the Cambrian Syndicate, and one of the most prominent men in the coal trade, has aroused much interest and discussion among coal men here as well as elsewhere. Those who are in a position to know best believe that the interests represented by Mr. Thomas are about to take over the ownership of a considerable portion of the New River-Pocahontas coal fields and that the deal, whatever it is, is already consummated.

Boomer—A vigorous membership campaign has been waged during the past month by the Boomer local of the United Mine Workers. As a result the membership roll has been increased by 3500. At Boomer from 8000 to 10,000 miners are employed in the various mines, who have never had any trouble with the Kanawaha Coal Operators' Association. The union believes that if the Paint and Cabin Creek sections were unionized, the operators in those districts would have no trouble.

Charleston—Delegate W. W. Wertz, of Kanawha, has introduced a bill in the House, changing the present system of privately-employed guards, and prescribing the appointment of special police by the governor.

ALABAMA

Birmingham—A number of the largest coal operators in the district have announced wage increases effective in the near future. Included in these are the Tennessee Coal, Iron & R.R. Co., Pratt Consolidated Coal Co., Alabama Fuel & Iron Co., Eldorado Coal Co., Little Cahaba Coal Co., Blocton Cahaba Coal Co., and others.

The properties of the Southern Iron & Steel o., bankrupt, were sold on Jan. 31 to the bondholders who will reorganize under the name of the Standard Steel Co. James Bowron, trustee of the bankrupt concern, will be president of the new company.

TENNESSEE

Knoxville—Kentucky operators are interested in the mee ing of the Southern Appalachian Coal Operators' Association, which is to be held Feb. 11, at Knoxville. Several addresses of unusual interest are on the program, among them, probably one by Dr. Joseph A. Holmes, of Washington, D. C., head of the U. S. Bureau of Mines.

The association, while an organization now only in its third year, numbers among its members operators who expect during the current calendar year to mine between six and seven million tons of coal, which is much the largest tonnage it has ever enrolled before.

KENTUCKY

Louisville—The slowness of the domestic demand has given rise during the current season to somewhat extensive resort on the part of some operators to the practice of consigning unsold coal to the various markets to their own account. An agent is sent on to sell it or some dealer handles it for them, and, in event of failure to accomplish this, the coal is thrown on the market as demurrage coal. The practice is often followed by tieing up of railroad equipment for an unduly long time, and the demoralization of the market.

OHIO

St. Clairsville—Fully 3000 men are out of work as the result of the car shortage. Mines which have box-car loaders are able to operate in full; on the other hand, few mines in Belmont County which cannot load box cars are operating in full. The shortage of flats and gondolas on the railroads has reached a climax during the past two weeks.

Bridgeport—President John Moore, of the Ohio Mine Workers, has arrived to take up the strike of the 400 miners at the Crescent mine of the Lorain Coal & Dock Co. The miners claimed that they were being cheated by the scales. Mr. Moore will also look into other strikes in Belmont County, involving 1500 men.

Coshocton—At a recent meeting of the board of trade of Coshocton, strong resolutions were adopted opposing the proposed anti-screen law, pending in the Ohio General Assembly. It is said that the law, if enacted, would be "inimical to the best public interests of our community."

The resolutions call attention to the fact that Professor Edward Orton, of the department of geology of the Ohio State University, is opposed to the bill.

INDIANA

Terre Haute—On account of high waters, 450 miners are idle in the Clinton field. The Chicago & Eastern Illinois R.R. has been compelled to abandon its mine trains and the men will be compelled to remain idle until the water subsides.

The entire area of the great coal fields west of this city is covered with water.

ILLINOIS

Lincoln—Two miners were killed, two injured and 34 had a narrow escape from being buried alive recently by a huge fall of slate at the Latham mine, near Lincoln.

Benton—The strike of the miners at the Benton Coal Co.'s mine here, which lasted for over a week, ended when the charter of the Miners' Local was revoked by the state organization. The strike was caused by the coal company fining the employees for refusing to work one day in December last, and the miners' state officials upheld the mining company.

COLORADO

Boulder—The House of Representatives has adopted the Ardourel resolution calling for the appointment of a joint committee from both branches of the legislature to investigate the labor conditions in the north Colorado coal fields. The resolution now awaits the action of the senate.

FOREIGN NEWS

England—English coal trade is extremely unsettled, owing to the fact that it is feared that the miners will cease operations in March.

Alaska—Officials of the Department of the Interior were at Anna, Ill., Jan. 25, to investigate the Hartline coal claims in the Controller Bay region of Alaska. They are in the same section as the Cunningham claims, the title to which has been invalidated by that department.

PERSONALS

H. L. Findlay has been appointed general sales manager of the Youghiogheny & Ohio Coal Co., Cleveland, Ohio, to take effect Feb. 1.

F. R. Wadleigh has opened an office at 1013 Bank of Commerce Building, Norfolk, Va., as consulting engineer. He will specialize on mining reports, purchase and use of railway fuel, coal markets, both here and abroad, handling and analysis of fuel. Mr. Wadleigh has had a rather unusual experience in certain branches of the coal industry, which places him in a position to speak authoritatively on these.

BOOK REVIEW

SIXTEENTH BIENNIAL REPORT OF STATE MINE INSPECTORS TO THE GOVERNOR OF THE STATE OF IOWA. 110 pp., including index; 6x9 in. Cloth bound.

There are only three mines using mules and these are all in Appanoose County. Iowa is one of the safest mining districts in the United States. There are few which can show an accident rate lower than 1.85 per thousand men employed, as Iowa did in the year ending June 30, 1912. The year before, the loss was 2.13. The best record was in 1905, when it was 1.4, and the worst in 1902, when it was 4.2.

The mines are for the most part small. For the first fiscal year of the two considered, only 242 mines were working; the tonnage was 7,729,674, or about 32,000 tons to each mine, that is about 125 tons per day. In the second fiscal year, the number of mines working increased to 260, and the tonnage fell to 6,820,828, but the mines were idle for 60 days, owing to a strike, and after that the work was quite slow for a whole month.

This report covers the coal-mining industry in Iowa for the two years ending June 30, 1912. Marked features in Iowa mines are the frequent use of longwall and the rare use of mules. Laboriously totaling the record, we find that 90 mines have longwall workings and 190 are worked on the room-and-pillar system. The former method of mining is used in eleven counties, well scattered over the state, and of these Appanoose is the chief, 38 mines being worked by longwall in that county and 34 having rooms and pillars.

GOB FIRES, ETC., MET WITH IN COAL MINES. By Arthur Brealey. Certificated mine manager. 55 pp., 5¾x8¾, 5 ill. Chronicle Printing & Publishing Co., Ltd. Leatherette boards. 1912. Price, 1s.

This pamphlet makes no great pretensions, and this fact makes us little disposed to criticise it severely. It is written in a somewhat disjointed and obscure style, does not contain anything which is at once new and true, and contains quite a few misstatements.

We miss many interesting and valuable features of gob-fire fighting. There is, for instance, no reference to the

French method of mudding coal to extinguish fires. There is no discussion as to the best method of approaching a mine fire, nor is anything said about using animals to guard against carbon-monoxide poisoning. The author has nothing to say about drowning the fire with carbonic or sulphuric dioxide.

He believes that an exhausting fan is to be avoided, because it draws gas out of the coal and says that "if a piece of coal is inclosed in a vacuum, a high temperature can be procured very quickly, thus assimulating it to coal left in the gob and inclosed in a space containing a warm atmosphere, the oxygen being used by the coal absorbing it and also by the surrounding strata producing a warm atmosphere similar to that of a vacuum." It is obvious that had we quoted this at the head of the review, no further criticism would have been necessary.

For instance, we read "Water will boil in a vacuum at 67 deg. F." After this statement, which, by the way, places the temperature too high, the author states inconsequentially that "the above facts show that any substance will burn at a very low temperature if the air pressure be sufficiently reduced." This is neither true nor apropos of anything which precedes. We are not surprised, therefore, to find that the author is capable of announcing that the expansion of the gases on the fall of the barometer "causes a rise of the temperature of the goaves."

CONSTRUCTION NEWS

Danville, Ill.—The new mine of the Bunsen Coal Co. will be located ½ mile west of this city. The company has over 25,000 acres of land in this vicinity. Clay Lynch, formerly of the Connellsville region, is general manager.

Johnstown, Penn.—M. Sheeley & Sons, the well known contractors, have landed the contract for 1900 ft. of tunnel work and a lot of shaft work at a mine being opened by the Loyalhanna Coal Co., in Shade Township, Somerset County.

Youngstown, Ohio—The Republic Iron & Steel Co. will build a new coking plant on 15 acres purchased between the Canfield branch of the Pennsylvania R.R. and the Lake Erie & Eastern right-of-way. The plant will have a 1000-ton capacity.

Somerset, Penn.—The Quemahoning Creek Coal Co. is rushing work on a new opening at their operations at Harrison. It is expected that when this second opening has been completed the number of men as well as the output will be trebled.

Bessemer, Ala.—A large sum of money will be expended this year by the Tennessee Coal & Iron Co. in developing the mines at Potter, on Red Mountain. Several hundred miners will be employed at this mine when working with a full force and full time.

Washington, Penn.—The opening up and development of untouched coal fields of Washington and Greene Counties is forecast in the report that the Pennsylvania R.R. is at work preparing to make an extension of its lines from northern Washington County south into Greene County. It is likely that work will be begun on the new extension within a few months.

Connellsville, Penn.—The contract for the boiler house to be erected at Trotter works of the H. C. Frick Coke Co. is to be let this month. The structure is to be of brick, steel and concrete, and to have a length of 118 ft., with ends 43 and 75 ft. wide. The height is to be 35 ft.

The new structure is to be built over the old one without stopping operations in the latter.

Connellsville, Penn.—Two contracts have been awarded for new coke-oven plants in this section. One plant of 100 ovens is to be built in the Ligonier Valley, on 300 acres of upper Connellsville coal land.

The other will consist of 200 ovens, to be built near Du Bois, Penn., by the Sykesville Coke Co. The ovens are to be of the rectangular type with mechanical pushers. The plans for this plant have been completed and it is to be built this summer.

St. Louis, Mo.—According to dispatches from New York, a syndicate has been formed to build byproduct coke plants in different portions of the country. These plants are to use adjacent coals for coking them. It is proposed to build plants suitable for different localities, and no special type of oven will be used.

The concern will establish one plant at St. Louis, with an annual coal consumption of over 400,000 tons. Another, at Newark Bay, N. J., will have an annual consumption of 200,000 tons.

Charleroi, Penn.—Contracts are to be awarded in a short time for important extensions to the little coal road owned by the Pittsburgh Coal Co., known as the Montour railroad, which will connect that road with the Bessemer & Lake Erie R.R., near Homestead. In all, 40 miles of new road will be built. Cost, $4,000,000.

Kosmosdale, Ky.—The St. Bernard Mining Co., one of the largest of the western Kentucky operators, has just closed a five-year contract for the full supply of the Kosmos Portland Cement Co., of Kosmosdale, Ky. The company's requirements average about 3000 tons a month. A former five-year contract between the two companies has just expired.

NEW INCORPORATIONS

Cincinnati, Ohio—The C. G. Blake Coal Co.; to change its name to the C. C. Blake Co.

Arvonia, Va.—National Slate Corporation; capital stock, $25,000; to develop slate property.

Hamilton, Ohio—The Hamilton-Otto Coke Co.; capital stock, $700,000. Incorporators: J. C. Thomas and others.

Richmond, Va.—Maryland Coal Corporation; increased capital from $250,000 to $600,000 for continued development of its properties.

Spokane, Wash.—British Columbia Coal Co.; capital stock, $500,000. Incorporators: Henry Rising, managing editor of the "Spokane Chronicle," and J. H. Tilsley.

Cambridge, Ohio—The Economic Coal Co.; capital stock, $10,000; to deal in coal and coke. Incorporators: C. B. McCoy, J. L. Secrest, J. A. Thrasher, Homer Witten and F. W. Tobin.

Cleveland, Ohio—The Albert E. Ward Coal Co.; capital stock, $5000; to mine and deal in coal. Incorporators: Albert E. Ward, C. V. Ward, M. W. Shetter, Fred J. Axel, and J. Stacel.

Cushing, Okla.—The W. T. Fields Oil, Gas, Coal & Investment Co.; capital stock, $25,000. Incorporators: W. T. Fields, Guthrie; William W. Cuthbertson, El Reno and Pete Hanraty, McAlester.

Salt Lake City, Utah—Thomas Knox Coal Co.; capital stock, $10,000; shares $100 each. A. R. Thomas, president; Athol Rawlins, vice-president; George S. Knox, secretary and treasurer.

Fairmont, W. Va.—Milan Coal & Coke Co.; to develop coal lands in Harts Creek district, of Lincoln County, West Virginia; capital stock, $100,000. Incorporators: Milan N. Glumicich, Julius Hoffman, Marvin L. Linn, Thomas W. Powell and Richard Hoffman, all of Fairmont, W. Va.

Clarksburg, W. Va.—Francois Coal & Coke Co.; to develop coal lands, manufacture lumber, coke, and drill for oil and gas in Harrison County, West Virginia; capital stock, $100,000. Incorporators: V. E. Gocke, J. M. Francois, J. C. Williams, E. J. Francois and E. L. Spraker, all of Clarksburg, W. Va.

Roundup, Mont.—Articles of incorporation were filed Jan. 9 by the McCleary Coal Co., which will have a capitalization of $500,000. V. C. McCleary is secretary. Active work will be started on a spur which will be built from the main line of the Milwaukee, up Carpenter Creek to the mine, a distance of about five miles. Work will also be started at the mine early in the spring, and they expect to be able to load 300 tons of coal daily.

INDUSTRIAL NEWS

Rivesville, W. Va.—According to reports, active preparations are being made to develop the Pittsburgh seam, along the western side of the Monongahela River.

Plains, Penn.—M. J. Healey has concluded negotiations for the transfer of his interests in the Stark holdings, recently purchased by the Madeira Hill Co., to that concern.

Fairmont, W. Va.—The National Consolidated Coal Co. will develop a large tract of coal in Barbour County, West Virginia. It is proposed to erect coke ovens and enter that trade as well.

Cleveland, Ohio—The largest purely gravity coal-handling plant in this city is now in practically complete operation at

the yards of the Cuyahoga Coal Co. The bins have a capacity of 3000 tons.

San Francisco, Calif.—The Taylor-Wharton Iron & Steel Co. announce that they have moved their Western sales office from 203 Mills Building, San Francisco, Calif., to 504 Newhouse Building, Salt Lake City, Utah.

Prescott, Iowa—An 8-in. seam of bituminous coal has been struck during the past week at a depth of 104 ft. The drillers are still going down in the hope that they will strike the second seam which they believe to be close.

Connellsville, Penn.—The mines of the Latrobe-Connellsville Coke Co., near Latrobe, are partially flooded from old workings which take surface drainage. The company has found it necessary to order a pump installed in the mine.

Morgantown, Ky.—G. L. Drury, J. A. Watkins, C. E. Sullivan and J. C. Haney, of Union County, Ky., have purchased the West Aberdeen Coal Co.'s property and are now repairing the mines with a view to putting them in operation.

Lovington, Ill.—Up to last week the Lovington mine has been taking on new men almost every day, until the entire works are now nearly full. All told, the company has now employed about 145 men. They are hoisting from 500 to 700 tons of coal a day.

Washington, Ind.—Judge Ogden has appointed John Dosch, a real-estate dealer, as receiver of the Riverside Coal Co., owning one of the largest mines in this section. The receivership was brought about by trouble existing between the miners and operators.

Pittsburg, Kan.—State Mine Inspector Leon Bessen has ordered mine No. 6 of the Dixie Coal Co. to be closed down, owing to the failure of the company to make certain alteration in the equipment. The mine is the largest in the district and employs 300 men.

Waynesburg, Penn.—E. F. Baily has just completed the sale of 1000 acres of coal located in Braxton County, West Virginia, to some Greene County business men. The sale included both the Pittsburgh and Freeport seams. The consideration has not been made public.

Whitesburg, Ky.—It is announced that an eastern syndicate has purchased the Sam J. Wright and John Osborne tracts of coal and mineral land near that city, consisting of about 1200 acres. Early development is planned, in connection with which a four-mile branch will be built.

Middlesboro, Ky.—It is reported that a company composed of West Virginia mining men has obtained control of the Mary Moore coal property in that vicinity, which has been idle for some time, and will shortly reopen the mines for operation. Ray Moss, of Middlesboro, will act as manager for the company.

Camden, Ark.— A fluid extracted from lignite coal, which is mined near here, is being successfully used for tanning purposes. The discovery was made by Dr. Geo. W. Kimball, who has offered to sell his patent to the Morris Packing Co., for $20,000, with the stipulation that the company install a tanning plant here.

Sycamore, Kan.—A 5-ft. bed of anthracite coal has been discovered by a test drill, 7 miles from Independence. Experts declare that the coal is first class in quality. The anthracite coal was struck at a depth of 800 ft. Additional ore drills have been ordered to test the field further and ascertain its extent.

Fairmont, W. Va.—The holdings of the Southwestern Coal Co., consisting of 8000 acres of land, are to be transferred to the Excelsior-West Virginia Colliery Co., which has just been incorporated with a capital stock of $2,000,000. The land will be developed at once. The principal offices of the company will be in this city.

Fayetteville, W. Va.—The Marsh Fork Splint & Gas Coal Co. began loading coal from their new mine, near Jarrolds Valley, a few weeks ago. They are just out of the strike zone, the men seem well satisfied and indications bid fair to make this one of the most important operations in this section of the country.

Norfolk, Va.—The Norfolk & Western has just placed an order for 40 more Mallet locomotives and 2250 cars while the Virginian is now receiving the 7000 coal cars ordered last fall and the delivery of the 2000 cars ordered by the Chesapeake & Ohio will soon begin. The ordering of the additional equipment is assurance that the railroads look for a most prosperous coal year in both domestic and export business.

St. Louis, Mo.—James Campbell, a local capitalist, and others, are reported organizing a company, with capital $5,000,000, to build byproduct coke plants in various cities, including St. Louis. The local plant, it is proposed, shall have a capacity of 1000 tons of coal per day, with plans that will permit expansion. Everything pertaining to the proposed corporation as yet is somewhat indefinite.

Birmingham, Ala.—Between four hundred and five hundred men will be put to work Monday in the Searles mines, Tuscoloosa County. Harry Coffin, trustee of the Alabama Consolidated Coal & Iron Co., with permission of Referee in Bankruptcy Dryer, has made a contract with the Tennessee Coal, Iron & Railway Co. for 1000 tons of coal daily. The coal will be used in making coke at Corey.

Fairmont, W. Va.—Filing of 87 coal deeds with the county clerk brought a big coal deal to light recently. Eighty-six of these deeds conveyed various parcels of the Sewickley or Mapletown coal vein underlying parcels of land in Paw Paw, Lincoln and Fairmont districts to the Southwestern Coal Co. from the individual owners, and the other conveyed the tract from the Southwestern company to E. H. Thompson, of Chicago. It is said the coal would not be worked, but was bought by Mr. Thompson as an investment.

Waynesburg, Penn.—E. F. Bailey, of Cumberland Township, has just completed a sale of 1000 acres of coal, situated in Braxton County, W. Va., to a party of business men in the eastern part of the county. The coal comprises the Pittsburgh and Freeport veins. Since Greene County coal is passing into the hands of operators, the eyes of investors are being turned toward West Virginia, where coal may still be had at prices which may double themselves in a short time if the present rate of advancement is maintained.

Chicago, Ill.—The Link-Belt Co., of Philadelphia and Chicago, designers and manufacturers of coal-tipple equipments and other conveying machinery, announce that hereafter the contract work in the West Virginia and Virginia coal fields will be in charge of their engineer, F. F. Waechter, replacing A. Kauffman, who has been transferred to the Chicago plant.

Mr. Waechter has been in the company's employ for the last 15 years, having spent a great part of his time in the engineering department, where he held the position of chief draftsman. The last two years he has spent in the sales department. This combination of experience fits him admirably for his new duties in the coal field.

Pittsburgh, Penn.—Orenstein-Arthur Koppel Co., general offices, Machesney Building, Pittsburgh, Penn.; works, Koppel, Penn., advise that their general manager, A. Reiche, is now in Berlin, Germany, where the head office of this company is located, in consultation with the executive officials regarding the extensive improvements to be made during the coming year at their American plant, Koppel, Penn. It is of interest to know that the entire executive department of the American organization, which is now located in the Machesney Building, in Pittsburgh, is to be moved to their plant, at Koppel. They are having a new office building erected, which will be two stories high, and will cover a plot 100x160 ft. This shows the tendency of the larger manufacturers toward avoiding the heavy expense of the rents in cities and getting closer to their mechanical and operating departments.

Development of the telephone

The telephone, though but a bit over 37 years of age, and therefore still young, has probably developed more in that short time than any of its humanity-helping contemporaries. In fact, writers have termed the development of the telephone a "romance of science." The story of this romance has been put forward in what is perhaps the most understandable and, at the same time, the most interesting way, in the exhibit of historical and modern telephone apparatus and electrical supplies recently inaugurated at New York by the Western Electric Co. The exhibit is in three sections.

The historical section shows the development of the telephone from its earliest stages up to the present time. The smoked-glass records of sound waves, made by Alexander Graham Bell, in 1874, using the human ear as a transmitting diaphragm, and thus proving that diaphragms would transmit sound waves; parts of Bell's original telephone of 1876, mounted to make a complete model, and numerous instruments showing the gradual improvement in design, are exhibited to great advantage in large glass cabinets with placards, giving a description of each article. Included in the historical collection, which is composed partly of apparatus loaned by the American Telephone & Telegraph Co., and partly of the Western Electric apparatus, are the switchboard used by Mr. Bell in opening the New York-Chicago line in 1892, and the receivers and transmitters used at the opening of the New York-Denver line in 1911.

The modern apparatus section contains switchboards, magneto and central battery, each switchboard having wired to it a number of telephone sets, so that service demonstrations may be made to visitors.

COAL TRADE REVIEWS

GENERAL REVIEW

It is generally conceded by all that the hard-coal trade has passed the high point for the season, and is now definitely on the decline. Premium coals have almost entirely disappeared and concessions on various sizes are being freely offered. Some operators are attempting to enforce restrictions as to allotments of various sizes, but consumers are showing an independence of any such regulation on their orders. Middlemen who contracted heavily at high prices over February are being forced to sell at liberal concessions below contract prices.

There is a general slump apparent in the Eastern coastwise trade. Shippers are pressed by cars standing in the yards, with the result that they are eager to make sales, and it is evident that there will have to be a curtailment in mining, or the trade will shortly be demoralized. Only a few contracts are being closed; prices are off, and the trade is finding it difficult to contract as buyers appear confident that quotations will ultimately reach the low level of last year. Consumers of Pittsburgh coal are, as a rule, taking full allotments on their contracts, although some are asking for curtailment in shipments; spot prices are down to the contract level, and operators are actively seeking business. The car and labor supply are sufficient to meet all requirements, but mining is only under a moderate pressure. Ordinarily, such a winter as the present one would make the marketing of coal difficult if not impossible, and Eastern dealers generally are surprised at the ease with which the heavy tonnages are being moved; however, prices are weak and unsteady, and operators are finding it difficult to contract.

The Ohio market is showing more strength but is still far from normal for this period. Domestic continues the weak feature in the market, with steam still showing a tendency to act in sympathy with it; cars are plentiful and production is down to a lower point than at any time during the season. There are some forced sales at reduced prices to avoid demurrage on speculative coal, and the general tendency is toward lower prices; however, producers are holding firm for higher quotations on contracts. Dumping at Hampton Roads is heavier than usual and close to the record, but the market is weak, due to heavy accumulations, as a result of a good car supply and warm weather. There is still a good healthy tone to steam in the Southern market, although domestic has weakened and operators are finding it difficult to dispose of their output.

An abrupt change in weather conditions has avoided what would certainly have developed into a complete demoralization of the Middle Western trade had it not appeared. Immense tonnages of unsold coal were standing on track and it is difficult to say what would have been the result had the same unseasonable weather continued. Prices still rule low, and operators are finding it difficult to contract at reasonable figures, but it is expected that the zero weather will effect a rapid change in the existing conditions. The improvement is confined mostly to domestic grades, but it is also having a stimulating effect on the steam sizes. In the Rocky Mountain region and on the Pacific Coast severe weather has been prevailing, and there were temporary fears of a coal famine, but the situation appears to be well in hand now.

BOSTON, MASS.

The slump is apparent in every direction. The shippers of the Southern coals are pressed with cars standing and so eager are they to make sales that prices are now down to the level of last summer; $2.70 has been the current price for nearly a week, f.o.b. Hampton Roads, for Pocahontas and New River. The off-shore market seems a little better than along the coast, but there will have to be a restriction in mining or things will be demoralized. The Pennsylvania grades are off to $2.70@2.80 f.o.b. New York, and even Georges Creek is beginning to come down freely on orders, both at Philadelphia and New York as well as at Baltimore.

A week ago there was talk of contracts, but the agencies realize now that it would be next to impossible to close a season's business at $2.85@3 when the market is 15@25c. less than that for current shipment. Some business is rumored to have been closed, but the volume is relatively small. Buyers are confident prices will rule at least as low as last year, and February is too early to get them interested, in view of present conditions.

The market all-rail is as dull as at tidewater. Prices for spot coal are not much in excess of $1.25 at the mines for the ordinary grades and purchases are small and less frequent. Some of the railroads which were down to two and three days' supply several weeks ago are now apparently well stocked and there is no life to the situation. Car supply is improving, and practically all the mines are enjoying a reasonably good allotment.

Current quotations at wholesale are as follows:

Clearfields, f.o.b. mine	$1 25@$1 40
Clearfields, f.o.b. Philadelphia	2 50@ 2 65
Clearfields, f.o.b. New York	2.75@ 2 95
Cambrias and Somersets, f.o.b. mine	1.40@ 1.60
Pocahontas, New River, f.o.b. Hampton Roads	2.60@ 2 70
Pocahontas, New River, on cars Providence	3.90@ 4 10
Pocahontas, New River, on cars Boston	3 95@ 4 10

NEW YORK

Bituminous—A fall in temperature the last of the preceding week which continued over the first of the current one, had a somewhat steadying effect on the local market, but did not entirely check the decline which the trade has been experiencing over the last few weeks. But even though prices have fallen off, there is a slight increase in the demand and some of the operators are of the opinion that the market is in a stronger position. As a reason for this belief, they state that, owing to the high price level prevailing in the spot market over the last few weeks, shippers generally have been curtailing allotments on contracts in order to take the greatest posible advantage of the high quotations for prompt coal. Now that this demand has been partially satisfied, thus causing an easing off in prices, consumers having contracts are finding their supplies at an unusually low point.

The railroads are again beginning to appear in the market after having been out over the last two or three weeks. The heavy buying on their part has been one of the best features in the trade, this season, and the new inquiries from them will do as much to steady up the market as anything that could occur, with the possible exception of an abrupt change in weather conditions. This latter has been so entirely adverse to a heavy consumption, that it is rather remarkable that the soft-coal market has held so well as it has.

We quote the local market as follows; with bituminous prices somewhat reduced, but quite strong at the new level:

	Anthracite		Bituminous	
	Circular	Individual		
Broken*	$5 00	$4 50	West Virginia, steam	$2 80
Chestnut†	5.50	5 45	Fair grades, Penna	$2 90@2 95
Pea*	2 75	$3.75@4 10	Good grade, Penna	2.90@3 00
Buckwheat**	2 75	2.25@2.70	Best miller, Penna	3.00@3 05
Buckwheat†	2 50	2 00@2 40	Georges Creek	3.25@3.30
Rice**	2 25	1 80@1.95		
Rice†	1.95	1.50@1.65		
Barley†	1 75	1 20@1 70		

* Scranton and Lehigh. ** Scranton † Lehigh and Schuykill.

Anthracite—While weather conditions have experienced an abrupt change locally, it has not as yet been of sufficient duration or severity to effect any difference in the hard-coal situation. The result is that prices have slumped off still further, orders are quite scarce, and the trade is at an unusually low ebb. There is some slight demand for stove and pea, and chestnut is becoming noticeahly easier; egg is so plentiful, that concessions are readily obtained on it, and consumers generally are becoming particular about sizes and grades. Cancelations are coming in at a rate that is alarming the companies and new orders are almost impossible to obtain.

It is evident that the speculators stand to lose heavily the coming season. In view of the shortage of some 6,000,000 tons in production, many of these anticipated an acute famine in hard coal during the winter and contracted liberally for February tonnages at relatively high prices. Consumption has been so low, due to the unseasonable weather, that the heavy demand failed to materialize, with the result that quotations are low and the speculators will be forced to sell this high-priced product at circular or lower.

PHILADELPHIA, PENN.

A slight fall of snow, followed by a comparatively low thermometer, stimulated the retail coal market, but unfortunately, it centered on the two sizes which were already short of the current demand, that is stove and pea. During the previous week, these sizes had been slightly easier, but the cooler weather, tightened them up again. Egg and nut are in a comparatively easy supply, orders being filled with promptness, but the dealers are still short on stove and pea.

Tidewater business still continues good, and while it is understood there are some cancelations, large numbers of barges are going out weekly, consigned to down east points, although it is admitted that the trade in the east is taking as little as possible of egg size. This is used almost exclusively in large residences, and assuming that it is purchased in large quantities, the supplies now on hand, due to the unseasonable weather, have been ample so far this winter, and unless conditions change, there is likely to be a surplus of this grade until the spring or opening prices are announced. It is a fact that egg is invariably active, only when prices are the lowest, in the spring, some dealers at that time taking almost their entire requirements.

Complaints are heard that, inasmuch as the supply of coal is easier, prices should recede or be reduced. Considerable coal was brought in this city, for which the dealers paid quite handsome premiums, but it is doubtful if the householder paid any advance over the current prices. The individual operators, finding it impossible to market their egg coal at current figures, are conceding anywhere from 25 to 30c. per ton to move it, and in some cases, are breaking it down at the mines into the smaller sizes, for which there is still a ready market.

PITTSBURGH, PENN.

Bituminous—Mining is being conducted under only moderate pressure. Car supply is adequate and so is labor, while demand is less than was expected. Contract consumers are taking full shipments as a rule, but there are cases of requests for curtailment in shipments, owing to accumulation of stocks. Prompt demand is relatively light, and some of the operators are rather actively seeking such orders, though, as a rule, not at the expense of prices, which recently dropped, for prompt coal, to the contract level. In exceptional cases it is possible the contract prices have been shaded slightly on small prompt lots, but generally speaking, the market is firm. This is for mine-run and screened coal. Slack continues to command a good premium above the circular or general price for the season, 90c., and is rather readily sold at $1.10.

There is more sounding of the market on contract coal for the year beginning Apr. 1, and some buyers evidently have hopes of breaking the regular prices, but thus far there has been practically no encouragement for this position. Regular contract prices are as follows: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in., $1.55 per ton at mine, Pittsburgh district.

Connellsville Coke—The coke market has been soft since the decline noted a week ago, and prices are quotable still lower. There has been an almost entire absence of demand for both prompt and contract coke. This has been partly the cause of the market weakening, but of equal moment has been the increased production since the celebration of the various holidays was completed. In the past three weeks the output has averaged about 425,000 tons weekly, against 400,000 tons maintained for many weeks previous. Sales of prompt furnace coke have been made in the past week at $3.25, and while $3.50 is asked by many operators the price seems to be entirely nominal. There has been scarcely any negotiation for contract coke, and the full measure of the decline is not disclosed, but enough is known to make it quite certain that $3.50, formerly the minimum asking price, is entirely out of the question, and $3.25 would doubtless be shaded for many good brands. Foundry coke has also declined, but not so markedly as regards price, the change rather being that better grades of coke can now be secured. For many weeks really standard foundry coke was out of the market. We quote: Prompt furnace, $3.25; contract furnace, $3.10@3.20; prompt foundry, $3.50@3.75; contract foundry, $3.25@3.50, per ton at ovens.

BALTIMORE, MD.

A sharp break in prices occurred during the week, occasioned by the prolonged open weather. Operators reported sales at prices from 50c. to 60c. lower than were obtained 10 days or two weeks ago; some offered low-grade fuel as low as $1 per ton, and found consumers were not overanxious to enter the market even at these low quotations. The market is weaker than it has been for three or four weeks, and does not show any signs of improvement, especially in spot business. There has not been such a mild January, according to reports issued by the weather bureau, for nearly eighty years. Naturally such weather would affect the anthracite trade the most, but the bituminous dealer, too, has found the demand gradually falling off until but little or no coal is moving except on contracts.

The only activity is in contracting; one of the largest companies has closed up three contracts during the week at prices from 10c. to 15c. higher than the old quotations. It is expected that contracts will be closed spasmodically until the general renewals which will take place two months hence. There is a slight shortage of labor and some little complaint was heard of the car supply during the week, but it is not causing the trouble that it would were the demand for fuel greater.

BUFFALO, N. Y.

The anthracite shippers are agreed that the mild winter has been a good thing for them, as otherwise the demand for coal would have been so far in excess of the supply that the situation would have been acute. As it is the anthracite supply is now about up to the demand.

Ordinarily such a winter would have obliged the bituminous trade to use every possible means to sell coal at a profit Prices are, of course, what they were a month ago, though it is difficult to quote accurately just now, as buyers and sellers are far apart. There are many rumors of coal offering at sacrifice prices, but at the same time jobbers are expressing surprise that their sales are going through so well. Even the railroads, which bought considerable high-priced coal during December, are generally taking it without grumbling. Sellers are finding it difficult to contract because of prevailing low prices. The car situation is easier than it has been for some time, as all the railroads have to contend with is some high water and landslides. Quotations are weak and unsteady on the following basis: $2.75 for Pittsburgh select lump; $2.65 for three-quarter; $2.50 for mine-run and $2.40 for slack. In some instances slack is so much stronger than sizes that it sells on a par with mine-run. The price of coke is about as formerly, being based on $6 for best Connellsville foundry. Allegheny Valley coal is quite as strong and active as Pittsburgh, at about 25c. less.

The sellers of independent anthracite are getting little premium now, and will get none at all soon, if warm weather continues. The Buffalo retail anthracite trestles are running only about half as strong as they usually do in midwinter, and orders from outside are no longer urgent.

COLUMBUS, OHIO

While steam trade is holding up well, it is sharing in the general weakness which has taken possession of the market. Manufacturing plants are taking large tonnages, although they are not inclined to stock up for the future, only taking what is temporarily needed. There is now no complaint from a lack of cars, they being plentiful in every section and shipments are coming out promptly. The high waters, which interfered with the movement from West Virginia, have not subsided and a considerable tonnage is coming from that state.

The first day of the low temperature caused a rush of telegrams asking to start shipments on orders placed previously. Production has been lower than at any time during the winter, most of the mining districts reporting between 40 and 50 per cent. of normal. In the strictly domestic fields the production was even below those figures. In the Pomeroy Bend district most of mines have been placed in commission and a considerable output is reported. Consumers have a fair supply and unless continued winter weather comes the retail business will be slack from this time on; retail prices have weakened materially.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1 50		$1 65	$1 50
4-inch	1 35	$1 20	1 40	1 30
Nut	1 50		1 50	
Mine-run	1 20	1 10	1 25	1 15
Nut, pea and slack	1 15		1 00	1 05
Coarse slack	1 05	1 00	1 05	0 95

CLEVELAND, OHIO

The large speculative movement of coal to this district had a tendency to reduce prices during the past week. Shippers continue to report a scarcity of orders and in many cases, unconsigned coal is being held at the mines. Some operators have shipped large quantities for distribution in the city retail trade, and this has weakened the market and companies have been forced to sell their product at reduced prices to avoid demurrage.

Shippers of Pittsburgh No. 8 coal report a general curtailment of railroad fuel. Orders to discontinue shipments

temporarily were received from the Pennsylvania, Baltimore & Ohio, Lake Shore & Michigan Southern and the Ann Arbor railroads. Shippers, however, are assured of a resumption of fuel shipments as soon as the present accumulation is cleared away.

Wholesale quotations per short ton f.o.b. cars at the mines are as follows:

District.	Freight rate	¾-in lump	Mine-run	Slack
Youghiogheny	$1.00	$1 40	$1 30	$0 95
Pittsburgh No. 8	0.90	1 20	1.10	1 00
Goshen No. 6	0.70	1.35	1.25	1 05
Coshocton	0.70	1.70	1 45	1 05

Pocahontas lump and egg is quoted at $2, run-of-mine $1.25, and slack 90c., f.o.b. mines. Massillon $2.50 and Hocking $1.50 mines. Furnace coke is bringing $3.50 f.o.b. ovens, while foundry grades are going at $4 for spot shipment. While the prices for spot coal are below normal, shippers are quoting high prices on contract business, believing that the market will improve in the near future.

Railroad equipment is arriving with regularity especially in the Youghiogheny field; in fact, cars are too plentiful for the good of the market. Some difficulty is reported in receiving exactly the class of equipment wanted, but shippers believe this condition will gradually improve.

HAMPTON ROADS, VA.

The spot market is rather weak just now, owing to the temporary accumulation of coal at tidewater; the Virginian Railway has about 56,000 tons at its terminal today with about 45,000 tons more along the line, while the Norfolk & Western also has quite a large tonnage here and the Chesapeake & Ohio about 38,000 tons at Newport News. This accumulation of coal, caused by heavy loading at the mines, quick movement and abnormal weather conditions, has brought quotations down to $2.90 to $3 f.o.b. with few buyers even for the best grades.

The dumping at the piers has been heavier than usual, close to the record figures and there has been no scarcity of bottoms. During January the Norfolk & Western dumped 484,843 tons at Lamberts Point, the Virginian Railway 260,544 tons at Sewalls Point and the Chesapeake & Ohio 243,571 tons at Newport News. The week's exports of coal have shown a slight increase over the preceding week; January exports were 173,706 tons as compared with 109,325 tons in the same month last year.

Two new tidewater agencies have been established here. The United States Coal Co., a new concern, handling New River and Pocahontas coals and the Flat Top Fuel Co., operating and owning properties in the Pocahontas fields. The latter is an old company, owned by the Thomas-Cooper interests, but has not been in the tidewater market. A new sales agency has also been chartered, the West Virginia Coal Co., with headquarters at Richmond, Va. They are to handle New River and Kanawha coals, and will be a factor in tidewater business.

BIRMINGHAM, ALA.

The market on domestic coals has weakened considerably during the current week and mines producing this grade are finding it a hard task to dispose of their output; prices have eased off to some extent. The much-longed-for cold weather has not arrived and many of the dealers still have good stocks in their yards. Not much more winter is expected and it is probable that considerable domestic coal will be thrown into the steam trade during the next few weeks. Fortunately, there is a healthy demand for steam grades and any surplus is not likely to materially effect prices until well in the spring, when automatic reductions are made on all grades.

Domestic coke is less active, the market on this product being directly subject to conditions controlling the domestic coal situation.

LOUISVILLE, KY.

The first day of February brought with it the beginning of about the only really cold snap of the present winter and gave some strength to the trade. Some of the more pessimistic have taken the ground that the present cold wave, unless quite prolonged, is not likely to benefit operators to any extent. They believe that the retailers will take advantage of the stimulated demand to get rid of the stocks laid in during December and earlier, and chance the possibility of a late spring, rather than buy in any considerable quantities at this time.

Owing to the conditions outlined, the domestic market has been really no market at all. The only quotations made to the trade on high-grade Jellico and other good domestic coal, are in the neighborhood of $2.25, with second-grades from $1.50@2, and there have been practically no sales at these figures. Steam coal is scarce, and the market stiff. Eastern Kentucky nut and slack is quoted at 80c.@$1; No. 2 run-of-mine, $1@1.15, and straight run-of-mine, $1.25.

INDIANAPOLIS, IND.

About the only change in the situation here this week is a spell of cold weather that took the temperature down around zero and greatly increased sales of domestic grades, adding also to the steam consumption. But buyers are well stocked and will not be in the market to any material extent until their piles have been reduced; mines caught up some time ago with the heavy demand of November and early December, caused by buyers trying to get all the coal possible.

Factories are busier than they have been for years, but the mild weather of the first two months of winter has resulted in a comparatively light consumption. Prices at the mines are at the summer level. Operators are making, or trying to make, contracts for next winter, the earliest in the year they have ever done this.

DETROIT, MICH.

Owing to this uncertainty, and after an investigation covering a period of about three months, which has been extended into a number of other cities, a special committee of the city's common council has submitted its report recommending the establishment of a municipal coal yard as the means of regulating the local prices on hard coal. The committee announces that in other cities, less accessible to the mining regions than Detroit, hard coal is being sold at $7.50 per ton while local consumers have had to pay from $8 to $9.

It is feared that the balance of the season will continue to show an over supply of domestic coal, and that there will be no demand, in this market, for that kind of fuel.

	W. Va. Splint	Gas	Hocking	Cambridge	Pitts. No. 8	Pocahontas	Jackson Hill.
Lump	1.50		$1.50			$2.00	$2 25
Egg	1.50		1.50			2.00	2 25
Nut	1 40		1 50				
1¼-in. lump	1 25						
¾ lump	1 10	$1 10	1 10	$1.10	$1.10		
Mine-run	1 00	1 00	1.00	1.00	1.00	1.25	
Slack	1.05	1.05	1 05	1.05	1.05	1.25	

CHICAGO

With the advent of zero weather, Chicago coal dealers are anticipating a change in business conditions that will bring better prices and a greater volume of sales.

There has been such a slump in the local market that a curtailment in production has been advocated on almost every hand. As a result of this, a number of mine operators in Illinois and Indiana have been planning to close down two or three days each week until conditions improve. The storage space of retail dealers has been taxed to capacity, but the forecast for continued low temperatures is expected to result in a comparatively buoyant market.

An index of recent conditions is seen in the statement that at a distributing point in northwestern Illinois a few days ago, 250 cars were awaiting reconsignment orders, with no demand for the coal. So far as anthracite is concerned, egg and chestnut are abundant. Prices of steam-lump and mine-run have weakened to some extent, but there has been some advance in screenings.

Prevailing prices in Chicago are:

	Springfield	Franklin Co.	Clinton	W. Va.
Domestic lump	$2 07@2 17	$2.45@2 55	$2.27	
Egg		2 45@2 55		3 55@3.80
Steam lump	2.02		2 17	
Mine-run	1 97	2 20@2 30	1 97	3.30@3.55
Screenings	1.67	1 90@2.05	1.62	

Coke—Connellsville and Wise County, $6.50@6.75; by-product, egg, stove and nut, $5.75@6; gas house, $5.85.

MINNEAPOLIS, ST. PAUL

The long-sought-for cold spell has at last made its appearance and while it is too late in making its appearance to save prices, yet it will clean up the market in general.

The soft-coal situation remains practically the same as heretofore, much coal is in demurrage and is being sold at any old price. One case is shown of a car of the best Illinois grade of coal taken in by a city council in a southern Minnesota town for the freight and railroad charges, but when the books were balanced they showed the shipper owed the buyer $8.

ST. LOUIS, MO.

The cold wave helped local conditions considerably. If this had not occurred to move the coal, it is hard to say what would have become of the hundreds of cars at the different points. At the different railroad centers in the South and in Illinois, Iowa and Missouri, it is estimated there were between 3000 and 5000 cars, of unsold coal, and because of this, there has been practically no market, as a general thing. It has been a case of everybody trying to get as much as

they could, but taking what they were offered. This applies to the high-grade field, both Franklin County and Carterville, with the former in perhaps a more precarious condition than the latter.

In the Mount Olive district prices are being maintained by curtailing the output and keeping the mines working on a short schedule. In the Standard field coal has been going for less than the cost of production, and many mines have shut down until the market gets better. As a rule, the selling price in all districts has been below the cost of production, and in many instances mines have suspended operations, except in the Standard field. The present cold wave, if it lasts long enough, may bring about a condition that will enable these operations to start up within a few days.

In anthracite, chestnut is still scarce, but the other sizes are moving freely, and as a matter of fact, are coming in too fast. Smokeless business is just holding its own at the present time, and the demand for coke is exceedingly good, ranging from $5.25 to $5.50 on the better grades of gas house and byproduct.

OGDEN, UTAH

The car shortage and congestion that has prevailed on the Denver & Rio Grande railroad has been somewhat relieved, although traffic conditions are far from normal. The mines in Utah tributary to the Rio Grande have suffered greatly, and at present are not able to work full time, due to the shortage. In Wyoming the Union Pacific is able to furnish sufficient cars to keep the mines running full time. Box cars are scarce and a large percentage of the commercial coal must be loaded in open equipment; again the railroad places instructions that certain cars must go East or West.

In the Northwest there are no large stocks of coal on hand and shipments during February should continue normal, providing the usual weather conditions prevail.

Both Utah and Wyoming prices continue strong as follows: Lump, $2.75; nut, $2.25; mine-run, $1.85. Wyoming slack brings $1, with Utah 25c. higher.

PORTLAND, ORE.

After two weeks of cold weather the temperature is again higher through all parts of the Pacific Northwest and the worst of winter is believed to be over. A great deal of snow fell during January in the mountainous sections and in many instances traffic was badly crippled. The Great Northern and Northern Pacific lines through the Cascades, have been more or less tied up for the greater part of three weeks, but on the Columbia River, out of Portland, they have been open as usual. There has been no advance in coal prices this winter and there is little probability of any now. The volume of business has been fair.

SAN FRANCISCO

For the past month there has been an exceptional cold snap, and the supply of coal in wholesale yards is practically nil. Owing to large bunkering engagements in the north there is but little Wellington available for this market; in fact, the deliveries of this coal here were only 24,537 tons in the past four months. Tonnage en route from Australia is small, probably not to exceed 12,000 tons for arrival during the next three months. There is one steamer cargo of Japanese house coal on the way, due to arrive the end of this month, and it will be much needed when it comes in.

Whilst nominally rates remain unchanged, in many cases dealers are charging consumers $13 in place of $12, the regular price.

PRODUCTION AND TRANSPORTATION STATISTICS

Pennsylvania Railroad

Statement of coal and coke carried on the P. R.R. Co.'s lines east of Pittsburgh and Erie during December and the 12 months, with the increase or decrease over the same period last year, in short tons:

	December	Difference	12 Months	Difference
Anthracite	1,036,717	— 178,088	10,312,348	—1,641,801
Bituminous	4,271,702	+ 290,216	46,434,187	+4,011,742
Coke	1,242,882	+ 331,911	13,371,345	+2,732,238
Total	6,551,301	+ 444,039	70,117,880	+5,102,179

Baltimore & Ohio R.R.

Coal tonnage moved over the B. & O. R.R. and affiliated lines during December, 1912, was 2,648,429, as compared with 2,468,943 for December, 1911; coke tonnages for same periods were 416,296 and 313,821, respectively, making gross of 3,064,725 tons in 1912 as compared with 2,782,764 in 1911.

CONNELLSVILLE COKE

The "Courier" reports production and shipments in the Connellsville region for the week ended Feb. 1, as follows:

Production (tons)	Week	5 weeks	*Shipments (cars)*	Week	5 weeks
Connellsville	233,550	1,237,225	Pittsburgh	4,445	21,767
Lower Connellsv'le	189,203	931,503	W. of Pittsburgh	7,136	34,484
			E. of Region	901	4,483
Total	422,753	2,168,728	Total	12,482	60,734
Same period 1912	360,153	1,755,273	Same period 1912	10,623	51,543

NORFOLK & WESTERN RY.

The following is a statement of tonnages shipped over this road from mines in West Virginia and the commercial and company coal, for the month of December, in short tons:

Field	Shipped	Tipple	Total	Commercial	Company
Pocahontas	1,038,432	17,364	1,055,796	993,357	121,246
Tug River	167,355	3,824	171,179	137,786	33,393
Thacker	222,188	6,979	229,167	165,923	63,244
Kenova	71,032	086	71,118	65,025	6,093
Clinch Valley				104,531	6,890
	1,499,007	28,253	1,527,260	1,466,622	230,866

Shipments of coke, entirely from the Pocahontas field, were 100,848.

Norfolk & Western Ry.

The following is a comparative statement of the coal and coke shipments over the lines of the N. & W. Ry. for the month of December and the 12 months of the years 1911-12, in short tons:

	December		12 Months	
Destination	1911	1912	1911	1912
Coal				
Tidewater, foreign	101,118	84,083	995,400	1,343,311
Tidewater, coastwise	293,850	258,216	3,084,674	3,583,283
Domestic	1,413,644	1,355,189	15,363,913	17,716,575
Coke				
Tidewater, foreign	5,713		75,867	52,762
Domestic	116,988	134,763	1,434,985	1,416,856
Total	1,931,313	1,832,251	20,954,839	24,112,787

LAKE COAL SHIPMENTS

Coal passing through Sault Ste. Marie Canals for the full season of navigation was, in short tons:

	1911	1912	Changes
Anthracite	2,060,209	2,142,485	+82,276
Bituminous	13,272,667	12,789,109	—483,557
Total	15,332,876	14,931,594	—401,282

Total shipments of coal from Lake Erie ports for the Lake trade and steamship consumption for three seasons past, in short tons:

	1910	1911	1912
Pittsburgh district	11,911,900	10,611,941	11,300,000
Ohio	4,297,300	4,019,544	4,676,000
West Virginia	6,629,500	7,151,200	7,360,000
Total	22,838,700	21,782,685	23,336,000

In 1912 the Pittsburgh district furnished 48.4%; Ohio, 20%, and West Virginia, 31.6% of the total.

VIRGINIAN RAILWAY

The total shipments of coal over this road for December of 1912 were 317,405 net tons, as compared with 316,564 for the month previous.

FOREIGN MARKETS

GREAT BRITAIN

Jan. 24—Market conditions show irregularity for prompt shipment, on account of delay to tonnage caused by stormy weather. Colliery owners appear to be heavily booked "on paper," and for forward shipments quotations are steadily upheld:

Best Welsh steam	$4 56	Best Monmouthshires	$4 20
Best seconds	4 32	Seconds	4 08
Seconds	4 32	Best Cardiff smalls	3 60
Best dry coals	4 62	Seconds	3 36

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days —less 2½%.

FINANCIAL DEPARTMENT

The Four States Coal and Coke Co.

At a special meeting of the stockholders, held on Jan. 18, the preferred stock of the company was increased from $1,500,000 to $2,500,000 of which increase $250,000 is to be issued at once for additional working capital. The company has been organized slightly over two years, and for the year ending June 30, 1912, is eleventh in production in the state of West Virginia, and at the present rate of production will be fifth during the coming year.

It is the judgment of the management that by the installation of two additional plants the earnings will be at least 15%, based on the present selling price of coal and the average cost for the past two years. As of May 1, 1913, after deducting all operating and fixed charges, the earnings are estimated at 6% on the preferred stock and about 7% on the common.

Reports have recently been made on the properties of the company by Dr. I. C. White, State Geologist of West Virginia, and W. H. Coverdale, Consulting Engineer, of No. 66 Broadway, New York City. Mr. Coverdale's report reads in part as follows:

The Four States Coal & Coke Company owns 37,000 acres of coal seams, of which 6110 acres of low sulphur Pittsburgh coal are located in Marion County, West Virginia and on which are located the Annabelle mines.

Annabelle is a shaft mine operated by air with a past life of only two years, as it was opened late in 1910. It produced 189,579 net tons during the year ending June 30, 1911, and 390,521 tons during the year ending June 30, 1912. This mine is now developed to the point where it can produce its normal tonnage of 750,000 tons.

Dorothy and Sarita are drift mines, electrically operated. Dorothy has been shipping coal for six years, and Sarita for three. Together, they produced about 300,000 tons during the year ending June 30, 1910; about 578,000 tons for 1911, and 534,819 tons in 1912.

After the additional preferred stock referred to shall be issued, balance sheet of the company, which follows, will be in all other respects as per report of certified public accountant under date of Oct. 31, 1912.

Assets:			
Cash in banks and at works		$300,748	
Accounts receivable		118,733	
Supplies on hand and coal not billed		31,794	
Development and equipment of mines.			
Annabelle	$1,061,716

Dr. I. C. White estimates the value of the Four States property to be at least $9,125,760; and sound value after full depreciation is charged off to date may be taken as $10,185,669.

By setting aside 5c. per ton for a sinking fund, it will return to the investors the total amount of the bonds, preferred stock and common stock, when 70% of the present coal is mined out and the total investment returned to the stockholders. The remaining 30% left unmined will be worth much more than the total value of the property at the present time, on account of the increase in value of coal lands from time to time.

SUMMARY OF ACREAGE, TONNAGE AND VALUES

	Acres Coal	Acres Surface	Available Tonnage	Total Value Including Equipment
Annabelle Mines,				
Pittsburg	6,109.975	666 279	62,264,922	
Sewickley	249.730		2,356,192	
Dorothy and Sarita Mines	31,454.000	86.455	194,279,451	$9,125,760
Totals	37,813.705	752.734	258,900,565	

For the period of twenty-two months from Oct. 1, 1910 to July 31, 1912, profits after deducting administrative expense, taxes and sinking fund show as follows:

	Net Profits
Nine months ending June 30, 1911 (Production 409,830 tons)	$118,836.51
Thirteen months ending July 31, 1912 (Production 955,376 tons)	257,715.84

Total production for twenty-two months 1,365,206 tons
Average net profit per ton 28 cents equal to $376,552.35

The average net price received for coal in December, 1912 is 0.1386c. per ton in excess of the price for twenty-two months which increase, based upon the same cost of production as in the twenty-two months referred to with mines in full operation and producing their normal output of 1,500,000 tons per annum would show a profit as follows:

1,500,000 tons @ $0.4186		$627,900 00
Less:		
Interest on bonds issued	$182,500.00	
Dividend on preferred stock	105,000 00	
		287,500 00
Estimated net profit after paying interest on boods and dividends on preferred stock		$340,400.00

COAL SECURITIES

Lehigh Coal & Navigation Co.—Regular quarterly No. 137 of $1, payable Feb. 28 to holders of record Jan. 31.

PRICES OF MINING SUPPLIES

THE MARKET IN GENERAL

The edge of the boom is off. This does not mean that business conditions are deplorable or anything of the kind, but it does mean that, while trade was booming in October, November and December and merchants were competing with one another in placing their orders with jobbers and manufacturers, they have now settled down to a regular rate of business. Every manufacturer in the country, practically, has as much business as he can do, and orders on his books for months ahead, but new orders since the first of the year have come in rather slowly. This is by no means unusual. January is generally considered to be an excellent time for inventory, and many large concerns are taking stock and making preparations for another year's business.

Fundamental conditions appear to be unusually sound. There are numerous investigations going on in federal, state and municipal government. In fact, there seems to be an epidemic of them, and while some facts are brought out that are not at all to the liking of the projectors, still to the country at large it is doing a great deal of good. There are, however, not as many unsavory disclosures being made as was the case during the life insurance investigation in 1905 and 1906, which was followed by several years of depression. The open winter that has permitted outside construction work has aided some lines of trade, but for winter specialties there has been a decided lack of orders.

The steel market is steady and firm without any advances compared with last month, few orders being placed yet, with numerous contracts on the books of manufacturers.

Railways continue to plan large expenditures during the year, and the amount of money paid out in developments would be larger if it were possible to sell bond issues at more advantageous terms. Perhaps this method of doing things will be better in the end, for the Southern Ry. has just spent for improvements, out of surplus earnings, the sum of $5,000,000, and the Pennsylvania Line will probably spend about $16,000,000 for new freight equipment. Most pressing of all the needs of the railways are new yards at strategic points and large terminals at all points. The necessity for these will grow rather than diminish, and the demand seems to increase in all proportions to the amount of traffic.

LABOR

An important advance in wages was made by the Interborough Rapid Transit Co. of New York, which followed the advance made last month by the Public Service Ry. which operates in Newark, and in addition, the New York Operating Co. established a company store where employees may secure food, provisions, and other necessities at considerably lower prices than at ordinary stores in the city.

There is a very good demand for miners in Pennsylvania and West Virginia, and agencies for the most part are able to supply this demand at about $2.85 per day with transportation paid to New York by the employing company. Surface laborers when obtained from New York agencies are paid $1.80 per day and the same rate is demanded for other rough laborers.

Firemen on the railways now have grievances, and the Brotherhood of Local Firemen is now taking a vote regarding a strike. Both the employers and employees express themselves as willing to submit to arbitration, but differ over the form of arbitration being made.

Immigration has not shown up in the expected volume, and unless immigrants come into the country more rapidly in the next two months than they have, present indications show that there will be a dearth of labor this summer.

The new scale of wages announced by the Carnegie Steel Co. calls for a payment of 17½c. per hr. to common laborers in Allegheny County, Penn.

IRON AND STEEL PRODUCTS

A diminution in the volume of orders received by mills and selling agencies since the first of the year has been almost universally reported. No strenuous efforts have been made to book a large amount of business, but there is a noticeable hesitancy among men of large affairs to place orders for future delivery. As far as present contracts are concerned, there is no uneasiness, for all of the mills have as much work as they can do for three months to come, at least, and many of them have sold up until August.

Railway buying is of fair volume, and a recent inquiry sent out by the Pennsylvania R.R. for 16,000 cars indicates the confidence of this corporation in the continuance of this present era of prosperity. Other railroads have purchased freely, not only of cars but of rails, and these consumers have been the real mainstay of the market.

Building operations all over the country are not as active as it was hoped, and while the amount of building in 1912 aggregated a fair total, in New York, in particular, the outlook is not especially bright; for one reason, funds are not available for large operations, and furthermore building operations seem to have gone forward on too generous a scale for several years. This latter, however, is an opinion held by only a part of the community, while others firmly believe that building operations in the last few years have been on a very much restricted plan, and in the near future a marked expansion will take place.

The demand for scrap iron and steel is no better, and the amount of old material coming on the market is large. Prices are low, compared with quotations for iron, and this is especially disturbing, as many believe the scrap market is the most valuable index to the iron situation.

Steel Rails—New orders have been few. Some of the Western roads are inquiring for a large tonnage later in the year, but these cannot be taken by any of the Western mills and it is doubtful if the Eastern mills can make deliveries before July. Southern mills are shipping direct, and will do so for at least four months to come. The demand for standard sections has been very light and no large orders, either for domestic or foreign business, are reported.

Quotations continue unchanged as follows: Standard sections, 50 to 100 lb. per yd., 1.25c. per lb.; 40 to 50 lb., 1.21c.; 12 lb., 1.25c. Relaying rails in Chicago of standard sections are held at $24 per ton.

Track Supplies—The railroads in the West are specifying heavily on old contracts for all classes of track fastenings, and much work has gone forward by the railroads during the winter which would ordinarily be postponed until spring. This results in a scarcity of fastenings at mills, and quite a little delay is experienced in securing shipments. In Pittsburgh track bolts with square nuts are held at 2.05c., and splice bars at 1.50c. per lb.; spikes at 1.90c. for very large lots and spikes of large size. There has been a particularly active demand for small spikes, and these are sold as high as 2.25@2.40c. per lb. In Chicago, angle bars and splice bars are 1.50c.; track bolts with square nuts, 2.40@2.50c.; tie plates, $32@35 per net ton.

Structural Materials—Mills rolling structural shapes have had a large volume of business from the railroads, which was made up of plates and all kinds of shapes and some bridge work. The demand for cars has, of course, stimulated the inquiry for plates, and in addition there is a good deal of interest in the market for plates for shipbuilding work, and some large aqueduct work is prospected, which may, later in the year, call for a good tonnage of this material. The biggest piece of work in sight for the structural mill is the New York Subway, the interest in which was revived late in the month when there were reports that contracts would be signed. If these contracts go through, it will mean a great deal of structural work in New York City, and stimulate some business on the outskirts, which otherwise would not take place for several months. Structural shapes in Pittsburgh are 1.50 to 1.55c. for future delivery, and 1.75c. for prompt. In Chicago, quotations for future can be had at 1.68 to 1.78c., while prompt commands 1.88 to 1.93c. Plates are held at 1.55 to 1.60c. in Pittsburgh for future delivery, and 1.75 to 1.80c. for fairly prompt shipment. In Chicago, plates are 1.68 to 1.73c. for future shipment, and 1.88 to 1.93c. for fairly prompt shipment.

Pipe—This is practically the only line in which business booked during January shows an excess over that for December. All the mills in and around the Pittsburgh district report phenomenally heavy business. There is one inquiry in the market for 180 miles of 12-in. pipe, and the leading fuel company in Pittsburgh has sent out an inquiry for over 8000 tons of tubing and casing. New discounts on pipe are firmly held, and the demand for small sizes, particularly those formerly known as merchant sizes, is excellent. Discounts are as follows: Steel pipe, ½-in., large lots from mill, black, 77%

from list; galvanized, 66⅔%; ¾- to 3-in., black, 80%; galvanized, 71½%; 2½- to 6-in. black, 79%; galvanized, 70½%. Based on these discounts, the net prices of pipe per foot are as follows in carload lots Pittsburgh:

Size, inches	Cents Black	Cents Galvanized
⅜	2.30	3.40
1	3.40	4.85
1¼	4.60	6.55
1½	5.50	7.70
2	7.40	10.30
2½	11.50	16.70
3	15.40	21.75

Sheets—The leading interest making black and galvanized sheets has advanced its quotation $2 per ton, and the new prices which are established are the maximum of the prices demanded for prompt shipment from independent sources for the last few weeks. Even at the higher prices, mills are securing some fairly good orders, and the sheet trade is more active than any other branch of the steel industry, with the exception of pipe. Not so much complaint is heard regarding deliveries, but makers are still from 12 to 16 weeks behind on their orders, and this will increase rather than diminish, for the sheet trade opens in the spring, and large orders placed during the winter are heavily specified against at that time.

The following table gives the price of sheets in Pittsburgh and also the price of small lots from store in Chicago:

	Cents per pound — Pittsburgh Black	Pittsburgh Galv.	Chicago Black	Chicago Galv.
Nos. 22 to 24	2.20	2.90	2.66	3.60
Nos. 25 and 26	2.25	3.10	2.70	3.65
No. 27	2.20	3.25	2.75	3.90
No. 28	2.25	3.40	2.90	4.15

WIRE PRODUCTS

Wire—Painted barb wire in large lots Pittsburgh is $1.75. and galvanized $2.15. Annealed fence wire in carload and larger lots is sold in Pittsburgh at $1.55, and galvanized at $1.05. In Chicago, annealed fence wire is $1.73; galvanized, $2.13. The supply of woven wire fencing is not at all large, and the mills are rushed to keep up with their specifications. Barbed wire in Chicago is $1.93 base, and galvanized, $2.33. All of these prices are per 100 lb.

Wire Rope—Net prices of the sizes in most general use are quoted f.o.b. Pittsburgh: 2 in., 57@76c. per ft., 1¼ in., 23@32c. per ft.; ¾ in., 10@13c. per ft. All of these prices are for large lots.

Telegraph Wire—The demand for telegraph wire has been large. For lots in fair size, the wire measured in Birmingham wire gage, prices are as follows: "Extra Size Best," Nos. 6 to 9 4¾c.; Nos. 10 and 11, 4¼c.; No. 12, 4¼c.; No. 14, 5¼c.; "Best Best," Nos. 6 to 9, 3¾c.; Nos. 10 and 11, 3¼c.; No. 12, 3¼c.; No. 14, 4c. Actual freight is allowed from basic points where it does not exceed 25c. per 100 pounds.

Copper Wire—The condition of the copper market is unsatisfactory to the holders of metal, and prices have declined within the last month. Copper wire which was sold at 18¼c. per lb. a month ago can now be had at 17¼c. Even at this concession, there is little or no demand.

MINE SUPPLIES

Bar Iron and Steel—Jobbers in New York and Chicago are demanding from $1@2 more a ton for refined iron and steel. The consumption is unusually large.

Quotations from jobbers' store, either New York or Chicago, are as follows:

Refined iron:	Per lb
1 to 1¾ in., round and square	2.15c.
1¾ to 4 in. x ¼ to 1 in.	2.15c.
1¾ to 4 in. x ¼ in. to — in.	2.35c.
Norway bars	3.60c.
Soft steel:	
¾ to 3 in., round and square	2.10c.
1 to 6 in. x ¼ to 1 in.	2.10c.
1 to 6 in. x ¼ and — in.	2.25c.
Rods—¾ and — in.	2.20c.
Bands—1¼ to 6x— in. to No. 8	2.40c.
Beams and channels—3 to 15 in.	2.25c.

Nails—The demand is fair, and the fact that prices advanced means that most of the orders for the time being have been taken. Consumers will not order from the mills, and are permitting their present stocks to run down. The minimum price to largest trade, in carload lots and over, is $1.75 Pittsburgh. In Chicago, carload lots to retailers are 1.98; less than carload lots, $2.03. In New York, wire nails from store are $2.05 per keg base. Cut nails are quoted at $1.70@1.75 in Pittsburgh and $2.05 New York. These prices are per 100 lb.

Packing—The demand for packing has been only fair, and while prices are high, there seems to be plenty of stock at the following unchanged quotations: Asbestos wick and rope, 13c. per lb.; sheet rubber, 11@13c.; pure gum rubber, 40@45c.; red sheet packing, 40@50c.; cotton packing, 16@25c.; jute, 5@6c.; Russian packing, 9@10c.

Brattice Cloth—Agents selling brattice cloth are unable to secure a stock in their warehouses, and mining companies are buying more freely, although they feel that present prices are too high. This is denied by those in close touch with the situation who point out that the world wide demand for all kinds of hemp products is phenomenal, and besides if there were anything artificial in the situation, it would have shown itself long before this in increased stocks, as prices have been high for at least eight months. Some buyers are purchasing more freely, not only because they have to, but for the reason that they think no lower prices will rule for some time, and there may be some difficulty in securing supplies.

Chain—Stocks of chain are not at all large, and consumers are buying freely. Prevailing prices are not high considering the rapid advance in the price of other steel products. Prevailing quotations per 100 lb., f.o.b. Pittsburgh, are as follows:

— in.	$7 50
¼ in.	4 95
— in.	3 95
⅜ in.	3 40
— in.	3 20
½ and — in	3 00
⅝ and — in.	2 90
⅝ and — in	2 80
¾ and — in.	2 70
1 to 1¼ in.	2 60
Extras for BB	
— in.	1 50
¼ in.	1 50
— in. and larger	1 25
Extras for BBB	
— and ¼ in.	2c.
— and larger	1.75c.

CONCRETE AGGREGATES

Portland Cement—Manufacturers of Portland cement are much pleased with the situation, prices are firm, and no concessions are made from the existing level of $1.30 per bbl. at the mill. This corresponds to a price of $1.58 in New York and Pittsburgh, with an allowance of 40c. for bags returned when shipped in cloth bags, or no allowance when wooden bbl. are used. Stocks at the mills are exceptionally small, probably smaller than any time since 1903, when there was a marked shortage of cement. Few of the mills are getting any large portion of the increase in price, and, in fact, most of them are tied up with long-time contracts which run well into February By early summer, however, all of these old contracts will have been filled, and the mills will commence to make all shipments on the basis of 90c. per bbl. in bulk.

Bars, Concrete Reinforcing—Shipments are being made a little more freely, and there is a larger stock at the warehouses. Contractors, however, have been able to use concrete most of the winter, and the supply has not increased as rapidly as was hoped.

Quotations are $1 per ton higher as follows:

PITTSBURGH PRICES IN CENTS PER POUND

	Mill Shipments	Warehouse Stock
¾-in. and large	1.50@1.55	2.00@2.10
½-in.	1.55@2.15	2.05@2.15
⅜-in.	1.60@1.70	2.10@2.20
¼-in.	1.70@1.80	2.25@2.35

Triangular Mesh—Makers of this material report a very good volume of business, considering the winter months, and, moreover, the fact that they can make shipments promptly has aided them to a marked degree.

From mill in De Kalb, Ill., quotations are 18c. per 100 lb higher. Prices are as follows per 100 sq.ft., f.o.b. Pittsburgh district, for less than carload lots and lots of more than 10,000 sq.ft.:

No. 4	$1.23	No. 32	$2 62
No. 23	2.05	No. 36	1.05
No. 26	1.42	No. 40	3.25
No. 28	1.97	No. 41	2 48

MISCELLANEOUS

Kentucky Mule Market—Reports from Louisville, Ky., and Nashville, Tenn., are to the effect that prices of mules continue high, good mules bringing from $175 to $180 and some very good stock has been disposed of at considerably higher figures. Matched and mated teams sell at around $500. Most sales have been exceptionally well attended, and practically all of the offerings have been cleaned up. The farmers of southern Kentucky who are raising mules are being paid anywhere from $110 to $160, but at the low figures, farmers are quietly dropping out of the market, and refusing to make sales.

Castings, Gray Iron—Foundries are making more of an effort to secure orders than they were a month ago, and prices are somewhat cheaper on particularly large orders. For the general run of orders, however, quotations are established as follows: Building castings, 1.75@2.25c. per lb.; rough castings, such as are used for footings, manhole covers, and similar work, 1.75@2c. per lb.; castings for machinery, lock gates and similar work, 2½@4c. per lb., depending on the size of the order and the intricacy of the pattern.

COAL AGE

Vol. 3 NEW YORK, FEBRUARY 15, 1913 No. 7

There are many different ways of performing most any task, no matter how simple, but there is generally one way that is far superior to any of the others; often the best way is not the one adopted.

The cycle of operations carried out by some coal-mine managers when they decide to purchase new mine equipment, should convince any one that the last statement above is not extravagant.

If a man does not know himself what he wants, it ought to be reasonably evident that no one else can know, and yet every day mining men buy machinery under just such conditions and then cuss the maker thereof ever after. There is only one satisfactory way to purchase mine equipment—require your office force to prepare plans and specifications to cover the exact machine wanted (when we say exact, we mean exact) and then be sure that the machine furnished is precisely the one specified.

But, objects someone, that would require the services of an engineer, and we have worked out a plan that relieves us of that expense. When we need a new hoisting engine, coal washer or what not, we get up a circular letter giving in a general way our requirements and then let the various manufacturers prepare plans and estimates of what they recommend; from these we choose the one that looks the best to us.

US. No engineer within forty miles. Get on the other side of the fence and see what these manufacturers are up against. Most mine equipment is such that each piece of machinery has to be built special, and if complete and intelligent data are not at hand, the manufacturer has about as much chance of furnishing a suitable machine as a tailor would have of fitting a man whom he had never seen and whose order contained only a picture of the would-be customer and a note stating that he wished the suit to be brown.

Under such conditions the purchaser is furnished with proposals that cover wide variations in design and price, and these proposals are soon followed by the salesmen of the various companies competing for the business. When the decision is finally reached, it often occurs that the manufacturer who offered the lowest-priced machine, through the highest-priced salesman, carried off theprize.

What is the result?

1. Some six or seven manufacturers have prepared, at considerable expense, plans and specifications for which they receive no compensation. Frequently, the more conscientious ones send their own engineers to the mine to pick up the missing links; however, if the final plans are not passed on by an engineer in the employ of the purchaser, this work is never noticed.

2. One manufacturer has succeeded in selling a machine which will not give satisfaction and eventually his reputation as a builder will suffer because of its performance. You've heard the proverb about "give a dog a bad name;" well, he's the dog.

3. A purchaser has received a machine which will do everything except produce dividends and general satisfaction.

These facts cause us to believe that if some of the more promising of our young mining engineers, who are now earning their livelihood by time keeping and similar occupations, should be allowed to carry on investigations covering present and future requirements in mine equipment, the pay rolls of both the coal-mine operators and the manufacturers of machinery would eventually absorb the young engineers' salaries and still have room for the usual current charges.

Coal Mining Investments

By Eli T. Conner

Men in all ages have felt and responded to the lure of the "mines." The fascination of winning from Nature's store of wealth a great prize, by some "lucky strike," has always attracted the layman as well as those who are well informed in mining matters. Were it not for this optimism—the belief of the *prospector* in ultimate success that will bring him wealth; of the *operator*, in the turn of the market that will convert apparent failure into a profitable venture—the wonderful expansion in the mining activities of recent years would not have been witnessed.

Were mining ventures susceptible of the accurate forecast that is possible in most other lines of business, they would lose some of their attractions; and the well known risks would deter many from making similar investments. On account of the risks and uncertainties of coal mining, much larger profits are necessary and legitimate in *that* industry than in other well-established enterprises.

It is important, however, in all mining investments, to remember that each ton of mineral extracted requires a proportionate depletion charge; so that by the time the whole deposit is removed the entire capitalization will have been amortized, as regards the value of the mineral deposit. This fundamental principle is often lost sight of and, in consequence, many disappointments result.

Coal operators too often put off charging to their monthly or annual cost, an item for the depletion of coal reserves. This should be done as regularly, if not as often, as the actual payroll outlay; because, if it is not regularly shown, the operator is deceiving himself as to his actual cost of production; and when the margin between operating expense and net price realized is as narrow as it has been during recent years in bituminous mining, an apparent profit may really represent instead, an actual loss.

The amortization charge should not only provide for the ultimate extinction of the capital account, in respect to coal reserves, but should preferably include an item that will cover certain possible mining risks, such as floods, fires, explosions, faults, creeps or caveins, labor strikes, car shortage, shrinkage of shipments and other interruptions to regular production and losses. Lastly, but quite as important, the industry should bear its fair proportion of compensation to workmen who may be injured in the discharge of their duties, or to the families of any who may be killed by unavoidable accident.

Reference to these matters incident to coal mining, need not be taken as indicating that, when properly conducted, coal mining is relatively a less stable and profitable investment than the average business venture, in normal times. In considering a coal-mining proposition, however, it is not enough to know that coal exists under certain lands. To insure success, it is absolutely essential to ascertain the quantity and quality of the coal and to compare the facts ascertained, with the same facts in regard to other coals supplying the same market and with which the property to be developed must compete.

The cost of building and equipping a plant of economic capacity together with the cost of the coal lands will constitute the capital to be invested. The cost of producing the expected daily capacity, including depreciation and depletion, must be offset by the proposed daily tonnage and the average price per ton that may be realized for the product. It is also necessary to consider well the labor conditions in the region where the property is located; so that when all of these elements are carefully estimated the amount of capitalization necessary can be determined.

The mistake is often made that the cost of development is underestimated (at times perhaps intentionally, in order to get the work started); and the attempt is made later to make up the deficiency from the earnings. While there are some instances of this being successfully accomplished, it is hazardous to attempt to conduct a business on an insufficient working capital; as any interruption, such as is liable to occur in mining, may result in wrecking the project. On the other hand, it is almost as great a mistake to provide too much money for a given project, as this tends to extravagance on the part of the construction engineer, whose tendency is naturally toward incorporating features that may be desirable from an engineering point of view but are not justified from a commercial standpoint.

In addition to the matters mentioned, it is essential that the market conditions, transportation facilities, freight rates, etc., be well considered to insure a fair competitive chance for the disposal of the output. I have thus tried to make clear that to estimate correctly the value of a mining venture requires painstaking study and careful weighing of many factors any one of which, if ignored, may seriously cripple the scheme. After the project is launched, it should be evident to anybody that men trained by education and experience should be put in charge as officers, superintendents and managers. It seems unnecessary to make this statement but for the fact that so many instances are known of manufacturers, druggists, doctors, lawyers, preachers and others equally uninformed, are constantly venturing into mining investments without competent advice and attempting to direct and manage the operations, with the usual result of partial or complete failure.

It is almost unaccountable why men of good business acumen in their own lines, will essay to go into a business as complex and exacting in its requirements for success as coal mining; or allow themselves to be persuaded by some smooth-talking seller of so called mining securities, into purchasing stock that if subjected to the most elementary analysis by experienced mining men would be found wanting in the essentials of a paying proposition. The only explanation for this credulity is the gambling spirit, which most men possess to a greater or less extent. The willingness to "take a chance" in a mining venture is found in many women also, who fall easy victims to the glittering prospects held out by the vendor of insecure mining securities.

The points to be investigated *before* making an investment in coal mining seem so obvious that it appears needless to emphasize them. Nevertheless, many instances are daily occurring that show the gullibility of uninformed investors, in their readiness to buy worthless mining stocks; and it is hoped this article may both benefit meritorious projects and help to expose worthless ones. Do not wait until part or all of the investment is made before fully investigating the project. *Do it first.*

Central Washer of the Ala. F. & I. Co.—I

By Edw. H. Coxe*

Synopsis—The first of a series of two articles on this interesting plant. A description of the extensive holdings of the company are given here and some preliminary remarks on the methods of washing.

This company was organized in 1906 by the late Henry F. DeBardalaben, one of the pioneers of mining and furnace building in the Birmingham district. Their coal holdings consist of 24,660 acres in the Cahaba field, lying about 20 miles south of Birmingham, Ala.; 12,660 acres of this is in what is known as the Henry Ellen Basin, 10,000 acres of which surround their Margaret opera-

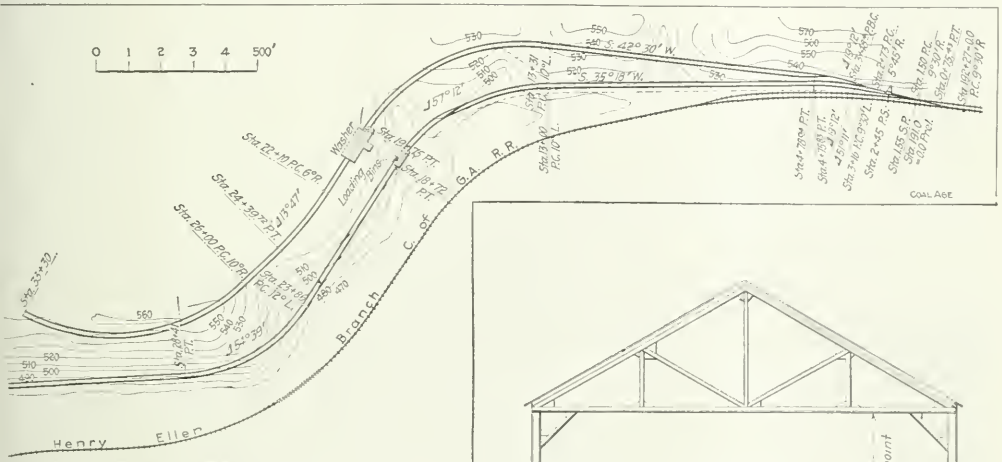

Fig. 1. Track Arrangement at the Washer, at Colgate

tions, which are mining the Harkness seam, the bottom workable coal of the Cahaba measures. These mines, three in number, opened in 1906, produce 2500 tons per day. Their Acmar mine has about 2600 acres and was opened in 1911; it is working the Mammoth seam, which is about the middle of the Cahaba measures, and produces about 1800 tons per day. At their Acton mines, opened in 1907, they have 6000 acres. The Helena seam, one of the highest grade coals in the state, is mined; it is next to the top seam in the Cahaba measures, and production at the two mines is 1000 tons a day. Large holdings in the Water-Works and the Scottsville basins are, as yet, undeveloped.

In addition they own 2500 acres of red-ore land in Shade's Valley, across Red Mountain from Birmingham, which are also undeveloped, but which test borings show to be underlaid with 8½ to 9 ft. of self-fluxing ore, carry-

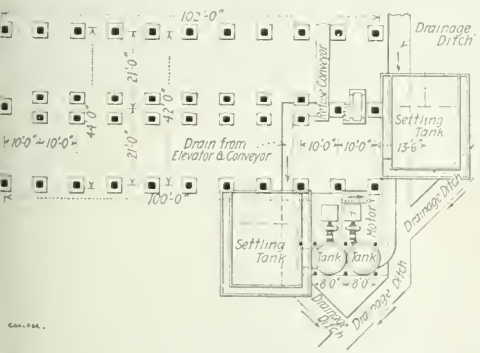

Fig. 2. General Foundation Plan of Washer

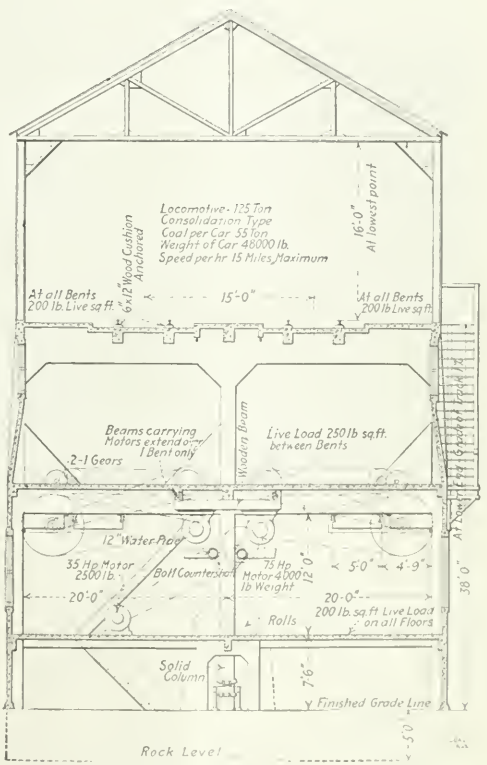

Fig. 3. Ideal Cross-section of Washer

ing 36 to 38 per cent. metallic iron, and 2500 acres of brown-ore land in Franklin County.

All the operations, including the central washer, are on the Central of Georgia Ry., except the Acton mines, which are on the Louisville & Nashville R.R. The officers of the company are J. M. Overton, president, Nashville, Tenn.; Charles F. DeBardelaben, vice-president and general manager; Overton Fullton, secretary and treasurer, Birmingham, Ala., and I. C. Delony, general superintendent, Margaret, Alabama.

The coal at all the operations is screened over shaking screens with 4-in. perforations, the lump being handing. It was built in 1911 by the American Concentrator Co. The main washer building, bins and tanks are of reinforced concrete, except the shed over the unloading platform, which is a steel frame covered with corrugated iron, and the belt galleries and shed over the washed-coal bins which are frame.

The map, Fig. 1, shows the general track arrangement at the washer, all cars being handled altogether by gravity. The loaded cars from the mines are placed at the south end of the tracks, the coal from the Margaret mines on one track and that from Acmar mine on the other. The loads are dropped over the bins and unloaded,

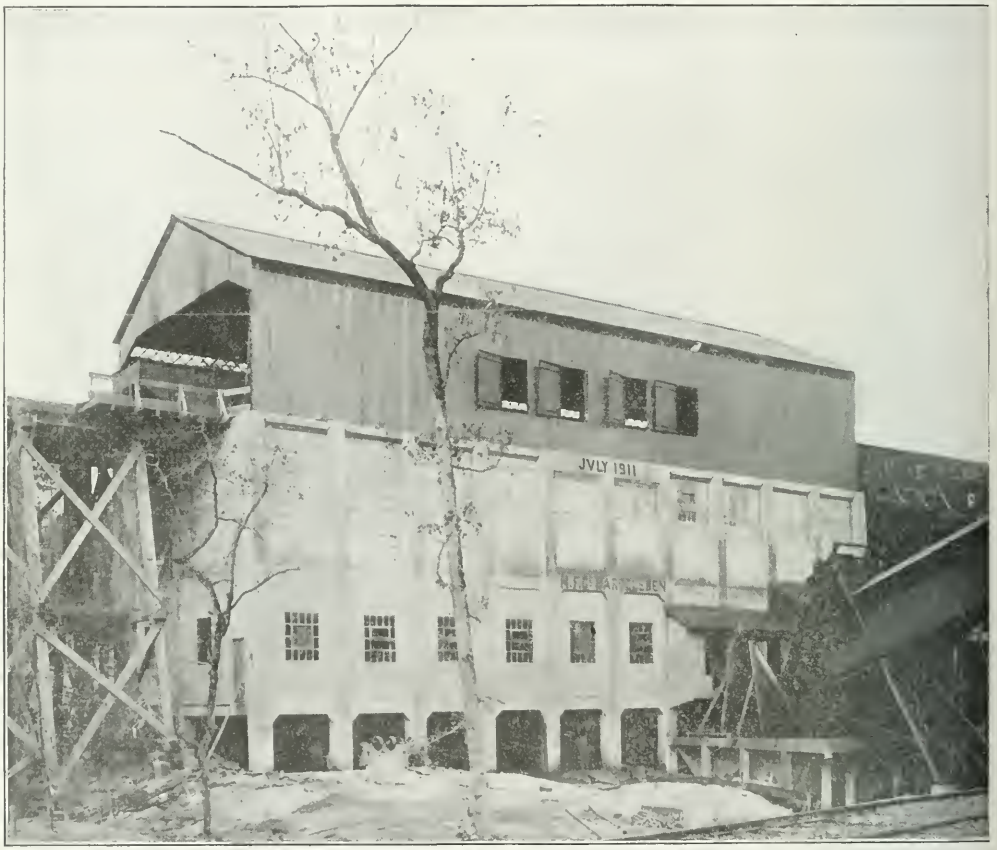

Fig. 4. Complete View of the Washer, Looking North, Showing Trestle

picked after passing over the screens. What passes through the 4-in. screen in carried over a 2-in. screen, the nut and slack being loaded and washed separately, after which they are again mixed; that at Acton is washed at a small local washer, and that from the Margaret and Acmar mines is sent to the central washer for treatment.

The Central Coal Washer

This washer is located at Colgate station, 2½ miles from the Acmar mine and 7 miles from the Margaret mines, from which points coal is shipped to it for washafter which the empties run to the switchback at the point marked A on the map, and thence under the washed-coal loading bins; after being loaded there, they run to the storage yard ready to be removed by the railroad company. The coal from the two operations is kept separate throughout. The photograph, Fig. 4, of the complete plant, looking north, shows on the left the loaded-car trestle approach to the washer. On the extreme right is shown the empty cars leaving the washer, below which are other empties which, having passed through the switchback, are approaching the washed-coal bin, the building on the right. Between it and the washer

building are shown the two washed-coal inclined belt conveyors.

A foundation plan of the washer is given in Fig. 2. This shows the supports for the columns carrying the jigs and bins, also the location of the refuse conveyor, settling tanks, water tanks and circulating pumps. The refuse is carried to the conveyor by another cross belt conveyor between the two center rows of supports. These two rows of supports are arched together just below the jig floor line supporting one row of pillars from there up. A cross-section of the washer is given in Fig. 3, and Fig. 5 is a view of the jig floor taken before the curtain walls were put in, showing jigs, line shaft and sprocket drives for refuse elevators. It will be seen from these that there are two sets of tracks, jigs, settling tanks and washed-coal elevators, so that the treatment and loading of the coal from each of the two operations is kept entirely separate.

By referring again to Fig. 4, it will be seen that the main washer building consists of four floors, the top or corrugated-iron section being the raw-coal dumping floor, where eight cars (three of each kind of slack and two of each kind of nut) can be dumped at one time, four cars on each track. Under this are the bins, eight in number, four under each track, three for slack and one for nut; these were figured for 100 tons capacity each, but will actually hold 150 tons. Directly under the bins is the jig floor, and under this are the washed-coal sluiceways and refuse cross-conveyor belt. On the jig floor are the two rows of jigs, 10 on each side, six for slack 2-in. and under, and four for nut from 2 in. to 4 in. in size, the capacity of the whole being intended for 250 tons per hour, though they have washed 3500 tons in a 10-hour day.

The coal is dropped directly to the top of the jigs through round pipes or feeders. From the jigs it is sluiced, nut and slack together, to the two settling tanks from which it is lifted by short perforated bucket elevators and discharged onto two 24-in. inclined-belt conveyors, 190 and 220 ft. long, respectively, which discharge into the washed-coal bins.

The jigs are arranged in pairs and the refuse discharged by automatic slate gates which drop it into bins or tanks under each pair of jigs. From there it is lifted by short bucket elevators, one for each pair of jigs, and discharged onto the cross-horizontal belt conveyor running under the floor and from which it is discharged onto the final refuse 22-in. belt conveyor 1050 ft., run-

ning at a slight elevation, which discharges over a ridge west of the washer where it is washed down the hill. A photograph of this last mentioned conveyor is shown in Fig. 7.

The water is pumped from Black Creek by an Alberger, single-stage, centrifugal pump through the condenser to a well or cistern. From here it is picked up by two De Laval single-stage centrifugal pumps, running at 1800 r.p.m., driven by 35-hp. General Electric induction motors, and having a capacity of 2300 gal. per minute.

The boiler plant consists of two batteries, each of two Sterling water-tube boilers, the total rated horsepower being 1000. These run two General Electric, turbine-driven, horizontal, 500-kw., 3-phase, 60-cycle, 2300-volt A.C. generators, which supply power for the whole washing plant, as well as the pumping and ventilating at the

FIG. 7. A 22-IN. BELT CONVEYOR 1050 FT. LONG

Acmar and Margaret mines; they will also furnish power for hoisting at the Margaret mines, where they are now installing a General Electric, 350-hp., 2300-volt, water rheostat, induction-motor gear, connected to the drum-shaft by cut-steel herring-bone gears.

An interior of the power house, showing switchboard, one generator and one exciter is shown in Fig. 6. The power for operating the jigs is furnished by two General Electric, 75-hp., 900-r.p.m., 2300-volt, induction motors, belt-connected, by toggle-clutch pullies to the two line shafts. Each jig is belted through tight and loose pullies to the line shaft, so that any one jig can be cut out at any time without disturbing any other operations. The washed-coal elevators are driven by cut-steel sprockets from the line shafts. The refuse conveyor is driven 100 ft. per minute by a General Electric, 25-hp. induction motor. The speed of the washed-coal conveyor is 450 ft. per minute.

The American concentrator type of jig consists of a fine mesh, stationary screen over the front half of the jig tank with a square wooden plunger which acts as a valve, the water being introduced on the upper side and drawn into the tank on the up stroke. This type of plunger was unsatisfactory, being difficult to keep in repair and the maintenance cost was also high. Hence a cast-iron circular plunger was designed especially for the work, with eccentrics running in oil, the oil casing being of cast iron bolted to the top of the plunger. Detail of this plunger is shown in Fig. 8. This plunger is giving excellent results, the wear being almost entirely eliminated.

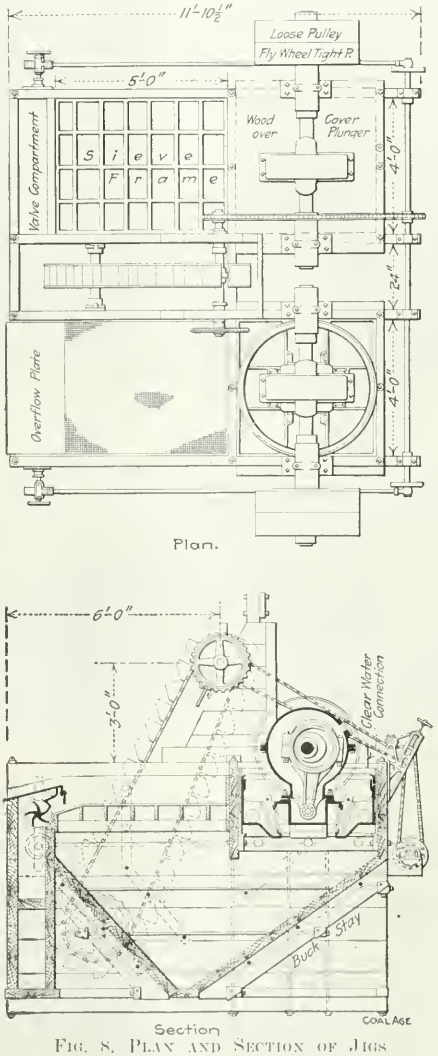

FIG. 8. PLAN AND SECTION OF JIGS

A crusher and rewashing jig with independent motor drive were provided for rewashing the refuse to save the fine coal lost in the primary washing, but the refuse is only 5 per cent. good coal and the rewashing of the refuse was abandoned, not being considered worth the cost and annoyance it entailed.

The custom of whitewashing the surface of loaded coal wagons has been inaugurated in Germany as a security against coal pilfering during transportation. Where the experiment has been tried it is said to have been successful.

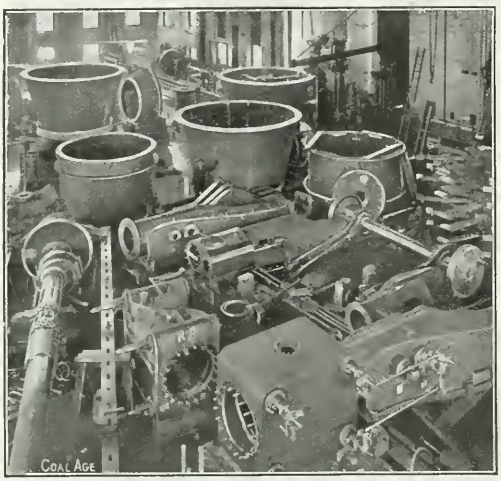
A Large Steam Mine Hoist

By L. F. Mitten

SYNOPSIS—The drums of this machine are conical, 10 to 14 ft. in diameter and 8 ft. long, weighing 40 tons each. The valve gear is so arranged that the engines may be started on the throttle, but when up to speed, the steam is used expansively.

The Delaware, Lackawanna & Western R.R. Co., coal-mining department, is now installing at the Loomis colliery, Plymouth, Penn., two pairs of 34x48-in. first-motion, link-reversing, heavy-duty, Corliss-type hoisting engines, which were built by the Vulcan Iron Works, of Wilkes-Barre, Penn. Engines of this kind are, to a certain extent, an innovation in the anthracite region, and a description of them will, no doubt, be of general interest.



Hoist on Assembling Floor. Note Man beside Hoisting Drum

The engines are equipped with two conical drums, each tapering from 14 ft. to 10 ft. in diameter, and are spirally grooved for 1½-in. wire rope. One drum is securely keyed to the engine shaft, while the other is brass bushed and driven by a toothed clutch-wheel, to allow for changing for different levels. The engines are reversed by an independent steam cylinder, while the brakes on each drum are also operated by this same type of mechanism.

In addition to the steam brakes auxiliary hand brakes are provided. The engines are equipped with tail cross-heads provided with guards. Sheet-steel crank or splash shields are also furnished, which cover entirely the crank disk.

The arrangement of throttles is also different from the general practice as followed in the coal regions. On top of each cylinder is placed a vertical throttle-valve, surmounted by a steam separator. These valves are operated simultaneously by a cross shaft.

In the overhead steam pipe is mounted an auxiliary throttle, which is used in emergency. The valve motion is of full Corliss type, provided with dash pots. The cylinders are fitted with Vulcan improved releasing-valve gear. The actuating forces of the catches are a combination of hand-adjusted springs and gravity. The trips or releasing motion instead of being controlled by the ordinary type of Corliss governor, are operated from the throttle lever.

The first two or three revolutions of the engines are with a long cutoff, the throttle being only partially opened. A complete advance of the throttle lever, after the engines have gotten up to their full speed, throws into gear the trip motion, and the engines use steam expansively for the balance of the hoist. The cylinders are also fitted with a bypass arrangement, allowing the engineer to lower a load under compression. A foot treadle is conveniently located for this service.

These engines are to handle 100 cars per hour in a vertical shaft. Each hoist will be used for raising coal from lower levels up into the tower by means of self-dumping cages. The maximum depth of shaft at present is 900 ft., but this will ultimately be increased to about 1575 ft. The cages weigh approximately 13,000 lb. each, the empty car 3000 lb. and the coal 8000 lb.

We illustrate the conical drums that are used on these engines. As previously stated, they are 10 ft. to 14 ft. in diameter, and have a face of about 8 ft. Some idea as to their size can be formed by comparison with the man who stands alongside. Each section of these drums, together with its spider, weighs approximately 40 tons.

Coal Mining in Southern Shantung

The most successful coal mine in all Shantung Province is that of the Shangtung Chung Hsing Mining Co., a Chinese concern operating in the vicinity of Yi-Hsien, southern Shantung. In fact, these mines seem to have been the only ones operated in Shantung at a profit. The capital of this concern is $2,450,000 gold. The company is operating eight shafts and has just equipped its newest operation with modern machinery.

The machinery for this mine was supplied entirely by German manufacturers, who advanced a loan of 80,000 marks (about $19,000) to the company in connection with the installation of the machinery. The plant includes 10 boilers, pumps, elevators, electric machinery and cars. The company operates 27 miles of railway in connection with the mine, and for the construction and equipment of this railway German capital and materials were used.

Previous to the construction of the Tientsin-Pukow Ry., the company's products were shipped via the Grand Canal, but now practically all of its coal is shipped over this railroad. The company states that shipping over the canal costs 3c. Mexican a ton-mile, while shipping over the railroad costs but 2c. The coal, which sells at the mine for $2.25 gold a ton, is a first-class bituminous.

The chief engineer and the first assistant of this company are Cantonese who were trained at Tong Shan in Chihli. They have had no foreign assistance in the construction and operation of the company's plant. The chief engineer receivers $120 gold a month and his assistant one-half this sum. All of the labor in the mine is on a contract basis, the native miner making an average daily wage of about 10c. gold. There are about 800 men employed on the company's premises.

Compressed Air Trouble in English Mine

By Frank Richards*

SYNOPSIS—Extracts from a recent letter describing, briefly, trouble experienced in transmitting power by compressed air long distances, in an English coal mine. Pressure drop quoted as being 80 per cent. The situation carefully analyzed on assumed conditions. The importance of high initial pressure and ample pipe capacity clearly demonstrated. The pipe capacity does not increase in the same ratio as the diameter of the pipe. Large pressure drop may be economical in certain work. It does not always indicate loss of power.

I am pleased to lay before the readers of Coal Age the essential portions of an interesting letter recently received from the manager of a large English coal mine. The writer says:

We have at this colliery a large compressed-air installation. The compressor consists of a cross-compound condensing steam engine and a two-stage air compressor with a capacity of 9000 cu.ft. of free air per minute. We have about 13 miles of pipe, which comprises two mains, each 4 miles long; two mains, each 2 miles long; and various lengths of tappings, making a total of about 13 miles.

The air pressure, at the compressor situated on the surface, is 52 lb. gage, while at the two ends of the 4-mile mains (especially in the winter time, or in cold weather), the pressure varies from 10 to 14 lb. gage, which shows a loss of from 73 to 80 per cent. As the entire colliery depends on compressed air for driving the hauling engines and pumps (not coal cutters), this great loss is an important item. If you can suggest a way to reduce this loss of power it will be welcome information.

The shaft is 1690 ft. deep. Would covering the pipes leading down the shaft, with some nonconducting material, such as boiler covering, be of any use? The temperature of the air leaving the compressor is 250 deg. and at the shaft bottom it is only 90 deg. F.

A Suggested Analysis

In answer to the question asked in this letter, allow me to say nothing could be gained by covering the pipes. When air is transmitted to such distances, it invariably attains, more or less closely, the temperature of the surroundings. This is quite plainly the case here where the temperature of the air, in going only a third of a mile or so down the shaft, has fallen 160 deg. F.

It would seem, at once, that this is a case of too low initial pressure, very common in English mining practice, and an insufficient pipe capacity. It is much to be regretted that no information is given regarding the size of the pipes, which is a most important particular.

In the absence of any statement to the contrary, we may assume, at first, that the pipes are without leakage, which may or may not be the case. Air pipes with proper attention are less likely to leak than steam pipes; but often they do leak more, because the air leak does not sizzle and drip and compel attention, as do steam leaks. That air-pipe lines may be made tight is attested by the many long pipe lines in use and kept at full pressure in switch and signal service; and by the many-jointed and valved air-brake pipes, in service on trains.

We would, in the present case, shut off everything, at the extremities of the lines or wherever the air is used; and pump up to maximum pressure, at the compressor; and observe how this pressure holds. If the pressure continuously drops there are, of course, leaks and these must be found and stopped. If the pipe is properly laid at first, there should be no leaks and none are likely to develop later. But leaks, however small, will grow bigger and become more and more difficult to stop. It is unfortunate for anyone who has to do with compressed air to assume that leaks are a legitimate part of the game. On the contrary, they show a poor installation.

Pipe Capacities

The Johnson formula, for the flow of air in pipes, which is quite generally used, for sea level, with a slight change of the constant, is as follows:

$$p_1^2 - p_2^2 = \frac{V^2 l}{2000\, d^5} \qquad (A)$$

Here, V is the volume of free air, in cubic feet per minute; l is the length of pipe, in feet; d the diameter of the pipe, in inches; p_1 the initial absolute pressure (gage pressure + 14.7, for sea level); and p_2 terminal absolute pressure.

The formula (A) may be transformed as follows, according to the purpose for which it may be used:

$$l = \frac{2000\, d^5\, (p_1^2 - p_2^2)}{V^2} \qquad (B)$$

$$V = \sqrt{\frac{2000\, d^5\, (p_1^2 - p_2^2)}{l}} \qquad (C)$$

$$d = \sqrt[5]{\frac{V^2 l}{2000\, (p_1^2 - p_2^2)}} \qquad (D)$$

In the case before us, the absolute pressure, at the compressor, is 52 + 14.7 = 66.7 lb. per sq.in.; and the pressure at the end is, say 14 + 14.7 = 28.7 lb. per sq.in., the difference or drop being 66.7 — 28.7 = 38 lb. This terminal pressure, by the way, is 43 per cent. of the initial pressure, and the percentage of pressure "loss" is only 57, instead of 80 per cent., as stated.

We are told that there are two 4-mile lines; and we may assume that each transmits about one-half of the air, so as to enable us to estimate the possible conditions. Say, then, that we have a 9-in. pipe (which we are aware is not a common commercial size), 4 miles long, transmitting, say 4500 cu.ft. of free air per minute, at the initial pressure of 66.7 lb. absolute.

By formula A, we have,

$$p_1^2 - p_2^2 = \frac{4500^2 \times 4 \times 5280}{2000 \times 9^5} = 3621$$

which gives the difference between the squares of the initial and terminal absolute pressures. But, $66.7^2 = 4449$, and $4449 - 3621 = 828$; and $\sqrt{828} = 28.7$, which is, therefore, the terminal absolute pressure. This shows a drop of 66.7 — 28.7 = 38 lb.

Noting the above result, obtained from formula A, taking the initial pressure at 52 lb. gage; let us now assume that the initial pressure was, say 100 lb. gage, or 100 + 14.7 = 114.7 absolute; and observe the difference. Now, since $114.7^2 = 13{,}156$, we have 13,156 — 3621 = 9535; and $\sqrt{9535} = 97.65$, which is then the terminal absolute pressure. The pressure drop in this case is 114.7 — 97.65 = say 17 lb.

*Ingersoll-Rand Co., New York City.

This shows clearly what an increase of initial pressure will do toward reducing the pressure drop, in transmission. Without giving further figures, it may be stated that if, in the last case, the pipe had been 10 instead of 9 in. in diameter, the theoretical terminal absolute pressure would have been 105 instead of 97.65 lb., and the drop would then be only 114.7 — 105 = 9.7 lb. Thus, by adopting a suitable diameter of pipe the pressure drop, in transmission, may be whatever we choose.

Relative Capacities of Small Pipes

In many installations where the *mains* are of sufficient size, there is still a considerable final drop of pressure in branches and extensions that are too small. It is not sufficient to have the sum of the sectional areas of the smaller pipes equal to that of the main pipe that supplies them. The pipe areas are, of course, directly as the squares of the diameters. For example, a 2-in. pipe has one-fourth the area of a 4-in. pipe; but, for the same pressure drop, four 2-in. pipes, though having the same total area, will transmit much less air than the single 4-in. pipe, because of the greater rubbing surface of the former. If the four 2-in. pipes were required to transmit the same quantity of air, per unit of time, the pressure drop would have to be much greater.

It has been found, in practice, that the square root of the fifth power of the diameter approximates the relation of pipe capacities for delivering air. For example, as stated previously, a pipe of one-half the diameter of another has only one-fourth the area of the larger pipe; but it will not transmit one-fourth as much air, under the same pressure drop. For the same pressure drop, the ratio of air volume, in this case, will be

$$\frac{V_1}{V_2} = \sqrt{\left(\frac{1}{2}\right)^5} = \sqrt{\frac{1}{32}} = \sqrt{0.03125} = 0.176$$

Then, to transmit the same volume of free air, under the same drop of pressure, will require $\frac{1}{0.176} = 5.65$ of the smaller pipes. Or, say a pipe of twice the diameter of another will transmit 5.65 times the volume of air, with the same pressure drop, for any given distance and initial pressure. This difference becomes greater as the difference in pipe diameters increases. A pipe of only one-fourth the diameter of another will transmit not $\frac{1}{16}$, but $\sqrt{\left(\frac{1}{4}\right)^5} = \frac{1}{32}$ of the air volume, for the same initial pressure, pressure drop and distance.

Air Saved by Pressure Loss

It must not be supposed, however, that this drop of pressure, in transmission, always, means a loss of power. That will depend on the way in which the air is used in doing its work, after transmission. There might be cases where the pressure drop outlined in the above letter would mean a gain in actual power or a saving in air consumption, rather than the reverse; and, in that case, the loss of pressure mentioned might prove to be the most economical feature of the proposition.

The wasteful habit of the ordinary steam pump when driven by compressed air is notorious. Not only is the air used without cutoff for expansion while doing its work, and there are excessive clearances to fill; but, at the end of the stroke, the entire cylinder will fill with air at a pressure perhaps considerably above the required working pressure, equalizing the pressure in the pipe line. The greater this excess of pipe pressure, therefore, over that required for the pump, the greater will be the loss of air.

It is always desirable to transmit air at high pressures, for the sake of pipe-line cost, if long distances are to be traversed. While the air is at a high pressure, the opportunity is presented for draining the air, so that the later freezing of exhausts must be minimized. If the air is to be used at high pressure, as usually it should be, it ought to be used expansively and reheated, if possible. The various types of rock drills now in use call for pressures approximating 100 lb. gage, in order to develop the highest efficiency in the drills.

The indications are that, in the above colliery, the pumps and the haulage apparatus mentioned would be amply supplied, so far as pressure is concerned, if a 20-lb. pressure could be maintained. If the air were to be used at that pressure but reached the work, at a pressure considerably higher; pressure reducers should be employed at that point; and after reducing the pressure, the air should be reheated as near to the work as possible. In this case, the pipe line mentioned serves as a pressure reducer; but it seems to overdo the business. It is also, to a certain extent, a reheater; as the air, notwithstanding the drop in pressure, will generally reach the point where the work is to be performed, at a temperature close to that of its surroundings.

We may say that the case in hand is a bad one and cannot be improved without redesigning and reconstructing the entire system, the cost of which would probably be prohibitive. Leaks should be sought and stopped. With two-stage compression, the delivery pressure should approximate 100 lb. gage, or, say, at least, not less than 80 lb. gage. In the present case, however, this would prove of little advantage, unless arrangements were made to use the air economically. It seems quite evident that the "loss" of pressure, in transmission, in this colliery, is only an item that is by no means the chief element of inefficiency.

Survey Spads

For a number of years the standard spad for underground surveying was a horseshoe nail with the head flattened and punched or slotted to receive the plumb-bob cord. The *Engineering and Mining Journal* states that a few years ago, a substitute was proposed consisting of a wire nail with a triangular file-cut halfway through the rim of the head, the nail being inclined when driven, so as to bring the notch on the upper edge of the head. Considerable experience with both types has brought out the following points:

(1) The wire nail is stronger and better resists chance blows or blasting, if set near the face.

(2) It is cheaper and easier to make.

(3) It makes the plumb-bob easier to hang in the first place, but slower to adjust for height.

(4) It is more accurate. Any one size of plumb-bob cord can occupy but one position, whereas in a hole the cord can climb the side and be off-center by a small fraction of an inch.

(5) It is not suitable when it must be set in a position difficult to reach. In such cases, it is customary, with the old-style spad, to hang a permanent loop of cord down to a point within easy access. This is not possible with the wire nail.

The Gas and Oil Well Problem

By R. Dawson Hall

SYNOPSIS—The Bureau of Mines called a conference of those interested in the drilling of gas and oil wells through coal beds. The Federal authorities opened the discussion but did not try to influence the decision of the meeting. However they presented some extremely helpful suggestions.

It was my amiable intention to praise the admirable suggestions made by the engineers of the Bureau of Mines in relation to the protection of mines from gas and oil wells. Unfortunately, I was enjoined to say that the Bureau really had no suggestions, nor even any working hypotheses; that all which was said at the Pittsburgh conference was intended simply as a quickener of interest to awaken discussion. It was darkly hinted that the Bureau secreted its judgment "*in petto*," so to speak; everything was unauthorized and inchoate.

The Attitude of the Bureau

I confess that I could hardly credit that G. S. Rice and O. P. Hood did not really feel their solutions were the best which they could devise, and any attempt to shake their confidence in the cures suggested met with their spirited, though courteous dissent. It did not appear that they were presenting merely the consensus of ideas urged at the various ex-parte conferences. The suggestions did not seem a composite of jarring interests, but rather the personal preferences of those presenting them.

Naturally the Bureau does not desire to appear to be coercive and would not like to have its working hypotheses used as expert testimony in a court of law. Moreover there are only too many worthy people who desire to see a pallid, limp institution, rather than a Bureau of fearless initiative. In fact, in this country little is less free than our governmental bureaus.

The Representatives Present

The meeting was held in the auditorium of the Western Pennsylvania Society of Engineers in the Oliver Building, Pittsburgh, Penn., commencing Friday morning, Feb. 7 at 10 a.m. W. E. Fohl was made presiding officer and O. P. Wood, secretary. The meeting was not largely attended, but was fairly representative, and those present were of sufficient importance in their various fields to make their judgment felt widely. A few may be mentioned:

E. J. Taylor, Pittsburgh, Penn., chief engineer, Pittsburgh Coal Co.; W. C. Neill, Pittsburgh, Penn., attorney, Manufacturers Light & Heat Co.; F. W. DeWolf, Urbana, Ill., director State Geological Survey; Richard R. Hice, Beaver, Penn., state geologist; A. P. Cameron, Irwin, Penn., general superintendent, Westmoreland Coal Co.; A. C. Beeson, Pittsburgh, Penn., chief engineer, Wm. A. Weldin, Pittsburgh, Penn., assistant chief engineer, Pittsburgh-Buffalo Co.; B. H. Canon, Pittsburgh, Penn., United Coal Co.; George W. Schluederberg, Pittsburgh, Penn., general manager, Pittsburgh Coal Co.; A. J. Moorshead, St. Louis, Mo., president, Madison Coal Corporation, representing Illinois Coal Operators' Association; E. B. Moore, Fairmont, W. Va., chief engineer, Consolidation Coal Co.; John W. Boileau, Pittsburgh, Penn., coal operator, David Young, Freeport, Penn., state mine inspector, and George S. Rice, chief mining engineer; O. P. Hood, chief mechanical engineer; H. M. Wilson, engineer in charge, and Irving C. Allen, petroleum chemist, all of the United State Bureau of Mines, Pittsburgh, Penn.

A paper was read by G. S. Rice entitled "Gas and Oil Wells in Coal Fields." The most novel feature in this paper was its reference—I had almost said its "advocacy" of the withdrawal of coal around gas wells. But it did not arouse any discussion because neither this paper nor the one which followed, nor even the preamble of the third paper, was presented for criticism.

Why Leave Well Pillars?

The proposal that coal around wells should be extracted has some merit as a suggestion, but as presented it cannot be regarded as without serious objection. The parent of the idea—for Mr. Rice acknowledges that he suggested it—calls attention to the success with which pillars have been drawn around shafts by the longwall process both in England and America.

But I may be pardoned if I call attention to an essential difference in the plans presented. The workings around such shafts proceeded from the axis of the shaft as a center, but the illustration of Mr. Rice exhibited a well in a room from which the pillars were being extracted back toward the borehole. Thus the well lay in a piece of rock unsupported at one end. Even before fracture would take place, the borehole would be tilted out of plumb and a partial breakage of the rock might distort the hole so that gas or oil tubing would be broken.

Where Well Pillars Might Be Extracted

There is a method of action providing strains more closely analogous to those sustained by a pillarless shaft in longwall. A plan known as the "double-entry system" in America, and I believe as the "wicket" system in England consists of rooms driven from two headings to meet at the center line between them. A hole sunk on that center line would be free from warping provided that the ribs were withdrawn to the right and left, beginning at the room where the hole was located.

The plan would be successful only where it is arranged that the borehole will be at the center of excavation at all times prior to final collapse. One cannot feel confident that even with careful scheming such a result could be attained, unless the privilege to drill were immensely restricted.

Even though the discussion did not take up this essential consideration on the ground that it formed no part of the proposed legislation, E. B. Moore, chief engineer of the Fairmont division of the Consolidation Coal Co., declared himself unchanged in his views on the importance of pillars.

To Fight Legislation with Legislation

A paper followed by L. M. Jones on "Some Troubles Experienced by Mines Resulting from Proximity to Gas and Oil Wells." This paper reviewed the unfortunate experiences which have already occurred. It can only be said that they justify the Bureau in taking up this subject. What do the stand-patters want? Are they anxious that the mining public wait and learn their lesson from a disaster of a magnitude equal to that at Monongah or Harwick, before any preventive action is taken?

A third paper by O. P. Hood and A. S. Heggem made

"Suggestions for Laws and Regulations in the Matter of Boreholes Passing Through Workable Seams of Coal." The actual draft of law with which that paper concluded was read clause by clause and criticized carefully till the close of the meeting shortly after noon on Saturday, the 8th.

The Attitude to the Proposed Department

Richard R. Hice opposed the suggested creation of any more departments in the various states. He thought there were already too many. O. P. Hood conceded that all the services of state geologist, mining and fuel-well inspector might be grouped under one and the same head. F. W. DeWolfe speaking for Illinois, regarded it well not to put the authority in the hands of the mine inspectors because many parts of his state, underlaid by unworked coal, were being drilled for gas and oil. The inspectors already appointed could not supervise these drillings. G. W. Schluederberg favored leaving the matter to the Department of Mines.

Discussing notification to parties interested before locating a borehole, it seemed generally conceded that a certain period of notice—a week or ten days—should be sufficient. In the event of the coal operator failing to arrange to be present or represented in that time, his absence should not act as a stay to prevent location and license. It was suggested that the mine owner, fuel-well inspector and mine inspector should not be the only persons notified, but that the lessor of the coal and of the oil right was entitled to a notification and hearing.

To Reduce Surveying Inaccuracies

It was asserted that the demand for an accurate survey was deficient in several points. It calls for a connection with two property lines. This gives an assurance that the meridian of the survey can be accurately determined if the corners of the property are obvious and undisputed, and if the survey is correct. But from experience, it is unlikely that either need will be fulfilled. Fuel-well surveying, with some noteworthy exceptions, is grievously inaccurate, and land lines are in nearly every case indeterminate.

Consequently, it was suggested that all surveys be made to connect with the U. S. Geological monuments, or with certain arbitrary monuments set in new fields in cases of "wildcatting." There is a strong objection to reliance on a survey connected by long lines from some distant monument, no matter how permanent it may be or how carefully recorded.

Essential, it seems to me, is a requirement that all surveys be carefully duplicated along separate lines, not only because a competent surveyor will thereby discover his error, but because a novice and ignorant practitioner can be unmasked infallibly by a careful traverse of his survey. A diligent traverser at headquarters working in dubious cases could make it extremely unpleasant for such a man and his employers.

Are Churn and Diamond Drill Holes a Menace?

Exception was taken, and I believe rightly, to the requirements that "any borehole drilled for gas, oil or other mineral shall be drilled at least 20 ft. below any workable seam of coal which may be penetrated," and be double cased and mudded and so forth. This would include churn and diamond drillings, and only for the inadequate reason that gas or oil might be struck.

Surely the gas and oil inspector ought to be the judge of the matter. It should not be required that such test holes be extended 20 ft. beyond their needed length. Water and elevator wells possibly should so extend to protect the pipe from breakage when mining reaches the well but test holes if immediately plugged and filled should be safe, and made free from all such unreasonable requirements.

The Clay Packing

The proposition advanced by G. S. Rice and O. P. Hood that above the workable coal and for a certain distance thereunder, two casings should be provided and the space between them filled with clay is as sane and sound a proposition as has yet been heard. Fault can be found with it but criticise it freely as you will, it is based on correct prineiples:

The scheme as outlined is probably insufficient; it is hard to place the clay and difficult to retain it in place; the plan has not been submitted to test and sufficient emphasis has not been laid on the ductility of the casing or of the tubes within the well, and the method involves a larger hole than has been hitherto provided. These are important objections it is true, but as an indication of the right lines for future progress, no better suggestions have so far been made.

Make no question but that all the specifications of all the coal companies have been worse than useless as have been the orders of the court. How can any number of casings laboriously placed and diligently concreted be expected to resist the movements of millions of tons of rock. Our final "caves" frequently involve not less than a million tons, and often five million tons tilt over in one body. Against this we oppose a miserable pipe stem incapable of upholding an axial load of a few hundred tons.

The Elastic Casing

It has always been marevelous that such a false protection received almost the unanimous approval of the coal-mining fraternity, and Mr. Hood is to be congratulated that he is leading what, at first sight, appears to be a forlorn hope against it. Yet his ideas are sure to succeed for nothing is more certain than that casings should be elastic.

What chance has a casing with its joints imbedded in concrete or cement mortar, with that material hanging doggedly to the roughnesses and recesses of the borehole, when the rock to which it thus adheres falls, subsides or take a tilt?

Surely none whatever, but if the pipe rested on supports from the surface or stood on the unyielding measures below, without restraint from the environing walls, it could be relied upon to slide up and down the hole as the movement of the measures rendered that motion necessary, provided always that the distortion of the hole did not suffice to bind the pipe.

It is true that the concrete has been provided to keep corrosive waters from destroying the casing. This it may do in some instances. As Mr. Hood pointed out, the rapidity of the corrosion is a function of the frequency with which the corrosive waters are replenished and cement mortar or concrete may well serve to reduce the frequency of that change, even when porous and filled with air holes.

Imperfections in Cement Mortar

But it is notoriously hard to keep airbubbles and resulting voids out of concrete, even when the material is deposited in large bulk and the air is given a vent by a shovel, a paddle or some form of tamping tool. In the depths of the well, the only hope is that the increased pressure will make the air bubbles smaller.

The quantity of air introduced with cement mortar in a deep well must be larger because as it falls down the annular space, the air has less chance of escape. It may be reduced in quantity by the use of a lowered pipe by which the mortar is conveyed in an almost continuous stream to the point of deposit. It is impossible to make this continuous, however, and some air must enter.

But there is probably a solution of this difficulty. The clay in the alternative clay filling could be ground somewhat coarsely so that there would be plenty of granular material for settlement. The pressure of the water in the hole would probably serve to make a complete fill.

Vented Pipe Lines

The suggestions presented by the bureau officials laid particular emphasis on the providing of a vent around the pipes. It was stated that it was customary to convey gas from sands of low pressure between the casing and the outermost gas tube. Should the gas traveling this pipe be closed off, a heavy gas pressure would soon result. This gas is likely to escape from the casing if that pipe should be corroded or torn apart. Of course a gas company might leave all manner of instructions forbidding the shutting off of the gas from the line without opening a vent to the surface but such instructions might well be forgotten or disobeyed.

The gas and oil men who showed all through the meeting a disposition which does them no little credit seemed at this point prepared for opposition. The representative of the gas interests near Fairmont, W. Va., stated that there were 11 sands making gas in that section. He said that this involved the placing of a great number of pipes in the well as the pressures from the different strata did not permit of the use of a single tube. He concluded by saying that the hole would be rendered so large, if a vent were provided, that a heavy burden would be put on the gas companies.

Mr. Hood answered his criticisms with much justice stating that perhaps the gas men demanded too much from one hole. If there are so many profitable sands, the necessary steps for their safe tapping should be provided and if it could not be done satisfactorily by one hole, two could be drilled in close proximity.

Plugging Abandoned Wells

The question of abandonment was warmly debated. It was thought by some of the coal men that it was impossible to plug a gas well satisfactorily if the rock pressure was extremely high. A well having a negligible gas flow may develop a rock pressure of 1000 or 1200 lb. per sq.in. Such a well is hard to plug even with lead.

As Mr. Hice pointed out, a lead plug, however tight, may fail to keep back the gas by reason of leakage through the strata as the plug cannot be made sufficiently long to prevent such by-passing of the gas. The consensus of opinion seemed to favor the idea that the method of plugging should be settled by the inspector.

(To be continued in the next issue)

The Bohunk

Written Expressly for Coal Age.

By Berton Braley

[In several coal-mining camps the term "bohunk" is applied to the men of any race, who live in herds, speak no English, and have no independence, no pride, no desire apparently, to be human beings. In short, the lowest class of European Labor is the Bohunk.]

We never loved the Bohunk an' I guess we never will,
He ain't the sort of person you kin cheer for,
He hasn't got no decency ner self respect, ner skill
An' a job at any price is what he's here for.
He lives in dirt an' squalor, sleepin' seven to a bed,
In a tumble-down old shack that was a cabin,
An' work an' sleep an' eatin' is the thoughts that fill his head,
While his favorite amusement is a stabbin'.

We do not love the bohunk,
We never liked his style,
He hasn't got no winnin' ways,
He don't know how to smile,
He often pays to git his job,
A fact that's plain for seein',
But we don't like the bohunk, for
He ain't a human bein'!

The husky guy from Tuscany is just as good as us,
The proper sort of Finn is all the candy,
An' the Frenchy an' the German an' the Spanish an' the Russ,
You take 'em as a rule an' they are dandy.
But the Bohunk is a dummy an' a rummy an' a clam,
He's a lowly beast of burden like a mule is,
An' I'd rather be a comrade of a native of Siam
Or the chum of any yellow brand of coolies.

We do not love the Bohunk,
Which doubtless is a sin,
It ain't the ugly face of him
Ner the color of his skin,
But he doesn't love his feller man
Ner yet his feller woman,
An' he ain't a decent animal
Ner yet a decent human!

The bohunk takes his money an' he sends it over sea,
He never goes an' spends it where he makes it,
He comes to get his wages in this country of the free,
An' when the land has paid him—why he shakes it!
An' though he joins the union, he's a crooked scab at heart,
There ain't a single soul he seems to care for,
I kin like a decent *nigger*—but I found out at the start
That the Bohunk I ain't any love to spare for!

We do not love the Bohunk,
No matter what his race,
We never want to shake his hand,
We want to break his face,
For when all is said an' spoken,
It is plain for any seein'
That the Bohunk may have feelin's,
But he ain't a human bein'!

CURRENT COAL LITERATURE

Motor Truck Coal Shoveler*

A mechanical shoveler mounted on a motor truck and suitable for loading coal at a storage pile is described in Glückauf, Dec. 14, 1912, by O. Dobbelstein, a mine assessor, of Essen, Germany. It is built by the Pohling Aktien Gesellschaft, of Cologne, Germany.

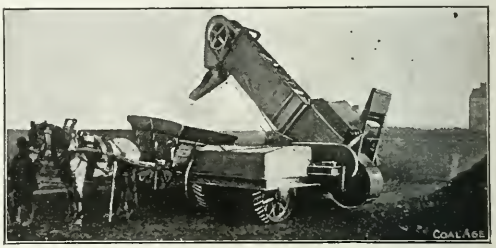
The shoveler is mounted on a strong platform truck having wheels of wide tread roughened as is customary for traction-motor service. The machine proper consists of an inclined bucket conveyor which is supplied with coal by a mechanically operated shovel. This is shown in the cut, lifted clear of the ground into the discharging position. The coal is dumped by a chute into a railroad car, wagon or dump cart.

The truck, conveyor and shovel proper are driven by a benzine or electric motor situated at the front end of the truck. This is covered by a hood, but even that is concealed in the illustration by the side boards of the conveyor. A differential gear acts upon the rear driving axle, and the front axle of the truck as in automobiles has a knuckle joint.

Shovel Actuated as by a Man

The shovel is actuated by a crank drive which causes it to move in a manner similar to that of a hand shovel. It is first slowly crowded into the pile close to the ground, then it rises and throws the coal backward into the conveyor. The scoop is not fixed solidly in its frame but is so arranged that when it emerges from the pile it tilts back and so retains the coal which would otherwise spill at its edges.

The conveyor, with shovel and drive, is mounted on a carriage which can be moved at right angles to the path of the truck, so that as removal of the coal progresses, the shoveling outfit can be shifted to the extent of about 40 inches.



A Motor Truck with a Shoveling Attachment and a Conveyor for Loading Wagons with Coal

Where the shovel is to be moved long distances and the ground which it must traverse is irregular, the conveyor which is 17½ ft. high, may be swung around till lengthwise of the truck. The gage of the vehicle is about 5 ft. 6 in.; the wheel pressure behind is 2.2 tons and in front 2.9 tons.

The consumption of power by the motors averages from 12 to 15 hp. with a maximum of 20 hp. The shoveler costs about $5000 and will handle from 39 to 65 cu.yd. per hour.

Why Proximate Coal Analyses Differ†

By A. C. Fieldner‡

SYNOPSIS—Proximate analyses of coal samples of identical composition may vary greatly even when made by chemists of undoubted ability and according to recognized standards. Thus the moisture content found may vary with the chemist, and the ash percentage of two determinations of one coal may vary 1 per cent. The content of fixed carbon and volatile matter found by two chemists with identical samples may differ by 4 per cent. If samples can be taken which accurately represent the coal in the bed, the sulphur percentage as determined by two chemists will usually agree within 0.05 per cent. Oxidation is the cause of errors in the moisture determination. Inequality of the heat applied, in the ascertaining of fixed carbon, volatile matter and ash, occasion the irregularities found in estimating their percentages.

In recent years, chemical and physical tests have come into use in connection with the mining and utilization of coal. Within certain limits these tests are useful, not only in establishing the fuel value, but in directing the coal into the market for which it is best adapted, and of maintaining the standard of the output to meet the requirements of this market.

Proximate Analyses of the Same Coal Vary

The growing practice of buying on specifications demands accuracy and strict uniformity in the methods of sampling and analysis. Chemists who make only occasional examinations of coal do not, as a rule, realize the empirical nature of the proximate analysis, and while they may obtain concordant results, as far as their own laboratories are concerned, their determinations may not agree with those obtained in another laboratory.

These discrepancies, which are more likely to occur in some determinations like those of volatile matter or of fixed carbon, tend to discredit the whole analysis in the eyes of those engineers who are not familiar with the difficulties peculiar to each individual determination. The object of this paper is to call attention to the fact that some constituents may be determined much more accurately than others, and to present some experimental

*Abstracted by E. P. Buffet, from the German.

†Part of paper entitled "Accuracy and Limitations of Coal Analysis," read before the Coal Mining Institute of America, at the winter meeting, Dec. 19, 1912.

‡Bureau of Mines, Pittsburgh, Penn.

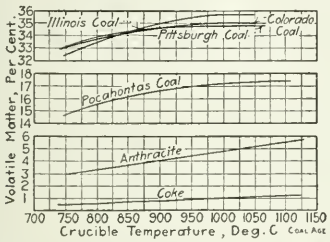
data bearing on the variations which are likely to occur in good laboratory practice.

Tests Vary with Nature of Service to Be Rendered

Coal is used principally for fuel purposes; hence its value, other things being equal, is proportional to its calorific power. The different kinds of coal, however, vary greatly in character, so much so that each has its own particular field of usefulness. For instance, a Pittsburgh steam coal cannot be burned efficiently in an anthracite furnace, nor can a coal high in sulphur or phosphorus be used for the manufacture of foundry coke.

Certain other tests, then, are also required, and for this purpose, we have the conventional proximate analysis and the sulphur or phosphorus determinations. While these tests may be sufficient for most industrial purposes, it is desirable at times to know the elementary composition of the coal as shown in an ultimate analysis, and to ascertain its clinkering properties as indicated in the relative fusibility of the ash. No doubt other tests more suitable for individual needs will come into use as the chemist learns what coal really is.

For fuel purposes the constituents of coal may be grouped into the following three classes: 1. Water or moisture. 2. The mineral impurities which remain in a



Curves Showing Variation of Volatile Matter with Temperature

somewhat altered condition, as ash on burning the coal. 3. The organic or combustible matter, which, like the original vegetable matter, is composed mainly of the elements carbon, hydrogen, oxygen and nitrogen.

The Empirical Substitute for a True Moisture Determination

Moisture may be accurately determined in an inorganic substance like iron ore by drying the material at a temperature slightly above the boiling point of water and noting the loss in weight. The same method when applied to coal is complicated by the oxidizing tendencies of the organic compounds, and the possibility of loss of some water of composition at the temperature of drying.

The present methods of analytical chemistry do not distinguish with certainty between added moisture, that is water which is simply mechanically held by the coal particles, and water which may be in some unstable chemical combination in the coal substance. The usual method of drying a pulverized sample for one hour at 105° C. (221° F.) is, therefore, somewhat arbitrary, and to secure uniform results a strict adherence to a standard method of procedure is necessary.

In the Bureau of Mines method[1] the moisture is determined in two stages: (1) The coarse sample received by the laboratory is pulverized to ¼-in. size and then air-dried at 30° to 35° C. (86° to 95° F.). The loss in weight, which is called the air-drying loss, includes all the superficial and a large portion of the loosely retained moisture.

(2) The air-dried sample is then pulverized in a closed ball mill to avoid loss of moisture, mixed and sampled down to a small, powdered sample in which the residual moisture is determined, by heating 1 gram for 1 hour at 105° C. (221° F.) in an oven through which dry air is being circulated. By this method duplicate results in the same powdered sample seldom vary more than 0.15 per cent.

Intrinsic and Extraneous Ash

Ash is the incombustible residue left on burning coal. It is derived from the mineral impurities in the fuel and is largely composed of silica, alumina, lime and iron compounds, together with smaller quantities of magnesia, titanium and alkali compounds. The silica, alumina and titanium are derived from sand, clay, shale and slate; the iron oxide mainly from iron pyrite; and the lime and magnesia from their corresponding carbonates and sulphates.

The ash-forming constituents of coal may be classified in two groups:

1. Mineral matter present in an intimate mixture with the coal substance, derived either from the vegetable structure or from earthy matter intermixed as silt during the process of coal formation.

2. Mineral matter occurring in the form of thin bands and nodules of shale, bone and pyrites; in this class are also the fragments of roof and floor that become mixed with the coal in mining.

Mineral matter from the first source cannot be removed by washing; it is sometimes called the "intrinsic ash" of the coal. Mineral matter of the second class, sometimes called "extraneous ash," may be removed by washing, screening and picking. In the laboratory a similar separation can be made by the float-and-sink test.

Coal has a specific gravity somewhat less than 1.35; the impurities are heavier; hence a separation may be made by placing the coal, crushed to a suitable size, in a solution of calcium or zinc chloride of 1.35 specific gravity. The coal will float, while the shale, bone, pyrite, etc., will sink. In this way the possibility of improving the quality of coal by washing can be determined.

Presence of Carbonates and Pyrite Make Ash Determination Variable

The determination of ash, although one of the simplest operations, is also beset with certain difficulties, which lead to disagreement between different laboratories, more especially with coals containing notable quantities of calcium carbonate and iron pyrites.

On ignition the calcium carbonate is decomposed, and carbon dioxide driven off, either partially or completely, depending on the duration and temperature of ignition. The iron pyrite is changed to ferric oxide, while more or less of the sulphur combines with the lime to form $CaSO_4$.

For example, in certain experiments with Illinois coals, which contained notable quantities of calcium carbonate and sulphur, 14 per cent. ash was obtained by ignition to constant weight at a low-red, and 13 per cent. ash was obtained by ignition at a bright-red heat. To secure con-

[1] Stanton, F. M., and Fieldner, A. C., "Methods of Mining Coal and Coke." Technical paper 8, Bureau of Mines.

cordant results a standard temperature should be adopted. If this is done duplicate determinations on the same powdered sample will agree to within 0.2 per cent.

Usually More Ash in Coal Than Any Analysis Will Show

Coal ash, as determined, usually weighs less than the mineral matter from which it is produced. This is due mainly to the loss of volatile constituents during ignition; the shale and clay will lose their water of composition; the carbonates will be more or less decomposed, giving off carbon dioxide, and the iron pyrites will be changed to ferric oxide, giving off sulphur.

Several methods have been proposed to compute the weight of original mineral matter in the coal, by adding corrections to the weight of ash obtained by ignition. These methods are, however, too complicated and uncertain in their general application to all classes of coal to be used in technical work.

The Percentages Described as "Volatile Matter" and "Fixed Carbon"

The volatile matter and fixed carbon represent the relative proportions of gaseous and solid combustible matter which may be obtained from the coal by heating it in a closed vessel. This is done by heating, for exactly seven minutes, a finely powdered sample in a small, covered platinum crucible, supported in the flame of a bunsen or Meker burner. The volatile matter consists mainly of the combustible gases—hydrogen, carbon monoxide, methane and other hydrocarbons—and some noncombustible gases as carbon dioxide and water vapor. The volatile matter does not include that part of the water present in the coal which can be driven off as moisture at 105° C. (221° F.) or lower.

The residue of coke left in the crucible after deducting the ash is reported as "fixed carbon." That term does not represent the total carbon in the coal, as a portion of this element is driven out in combination with hydrogen in the volatile matter; furthermore, fixed carbon is not pure carbon, but still contains several tenths per cent. of each of the three elements, carbon, hydrogen and oxygen; from 0.4 to 1.0 per cent. of nitrogen; and about half the sulphur which was in the coal.

It should be clearly understood that the terms "volatile matter" or "volatile combustible matter" and "fixed carbon" do not represent any definite compounds which existed in the coal before heating. The method of determination is purely arbitrary, and variations in temperature and rate of heating will cause variations amounting to several per cent. Even with a strict adherence to the method recommended by the American Chemical Society, variations of 3 and 4 per cent. in both the volatile matter and fixed carbon may occur in different laboratories.

Variations of 3 per Cent. Which Are Not Errors

One of the most prominent factors in causing variations is the temperature at which the crucible is heated. This is especially pronounced in anthracite and semibituminous coal. It is not improbable that one laboratory would report 4 per cent. and another 7 per cent. volatile matter on the same sample of anthracite, or 14 per cent. and 17 per cent., respectively, on the same sample of Pocahontas coal. These different percentages of volatile matter were actually produced by different conditions of heat treatment. Caution must therefore be observed in making comparisons of the volatile matter and fixed carbon in proximate analyses made in different laboratories. Even determinations made at the same laboratory by the same analyst may vary to the extent of 0.5 per cent.

Recently a series of experiments were made at the Pittsburgh station of the Bureau of Mines to provide data on which to base a temperature specification at which the most uniform analytical results could be obtained.* A series of determinations at temperatures varying from 750° C. (1382° F.) to 1100° C. (2012° F.) were made on five different types of coal and one sample of foundry coke. These determinations were made in a 30 c.c. platinum crucible, which was heated in an electric furnace under uniform conditions. Oxidation was prevented by passing nitrogen into the crucible. The results obtained are illustrated in the accompanying figure and set forth in detail in the table.

It will be seen that more volatile matter is obtained at the higher temperature, although the ratio between temperature and volatile matter varies in the different coals tested. The curve for anthracite is remarkable in that it is practically a straight line. Those for the three bituminous coals become horizontal at about 950° C. (1742° F.). The Pocahontas curve retains a slight upward inclination even at the higher temperatures.

From the analytical standpoint, 950° to 1000° C.

*Fieldner, A. C., and Hall, A. E. Influence of temperature on the determination of volatile matter in coal. Eighth International Congress of Applied Chemistry, vol. X, p. 139 (1912).

(1742° to 1832° F.) appears to be the best temperature for the determination of volatile matter, as slight variations in temperature on the upper end of the curve produce less deviation in results.

Sulphur Determination Correct to 0.05 per Cent.

Sulphur is usually determined in connection with the proximate analysis. It is classified with the impurities and undesirable constituents of coal, although it usually exists in a combustible form and contributes to the heating value. Commonly sulphur is present as iron pyrite, either in brassy lumps and bands or in very fine particles uniformly distributed throughout the coal. Sulphur may also occur in combination with iron and lime as sulphates and in combination with the coal substance as organic compounds.

Duplicate determinations by the "Eschka" method on the same powdered sample will usually agree to within 0.05 per cent. Where much sulphur is present in visible form, as pyrites, difficulty is experienced in obtaining a representative powdered sample from the coarse aggregate, and somewhat greater errors, due to inaccuracies in sampling, may occur.

(To be continued)

Ventilating Mammoth and Skidmore Beds

By H. M. Crankshaw*

The Mammoth bed is customarily worked from the Skidmore bed by rock chutes spaced at 120-ft. centers. Air tunnels are driven from the Skidmore bed up to the Mammoth, every 360 ft., at which point a crosscut is also made between the gangway and airway in the Skidmore.

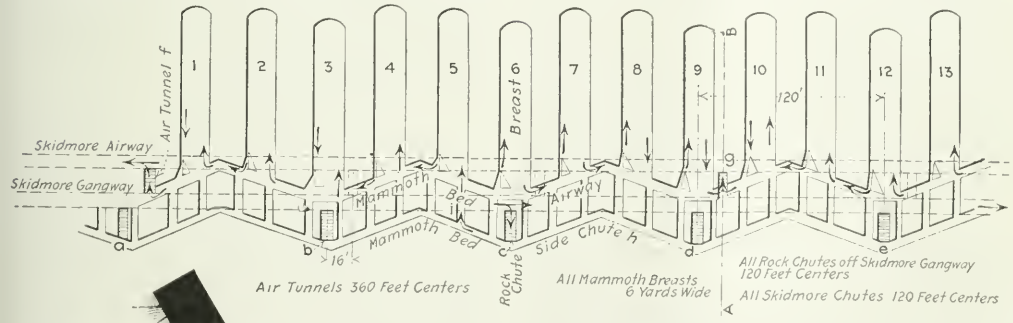
We can arrange to split the air passing through the live workings by taking it up through a rock chute and passing it up and down the chambers and through the airway connecting them till the next air tunnel is reached. At this point, the air returns to the Skidmore airway.

In the accompanying plan the rock chutes from the gangway in the Skidmore to the side chute in the Mammoth are marked *a, b, c, d* and *e*. The air tunnels from the airway in the Skidmore to the airway in the Mammoth are *f* and *g*. It is obvious that all the rock chutes from the gangway will not be needed as intakes but all the tunnels from the airway will act as returns.

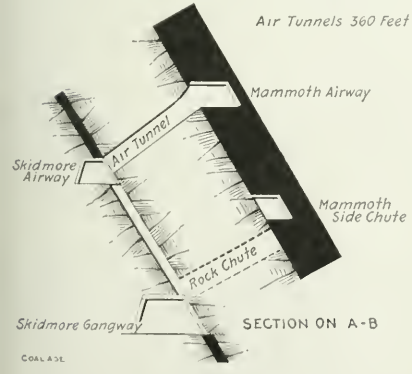
For example, consider the section between air tunnels *f* and *g*, as shown by the arrows, the air travels up the rock chute *c*, up the side chute or slant *h* and the traveling way *i*, reaching the second slant chute or airway. Here the air is split. Part goes up breast No. 5 and part to the right along the airway. That traveling up the breast returns after reaching the face and passes along the airway ventilating successively breasts Nos. 4, 3, 2 and 1. Eventually it returns to the Skidmore airway by the air tunnel *f*.

The other split passes up to the faces of breasts Nos. 6, 7, 8 and 9 respectively and descends by air tunnel *g* to the airway in the Skidmore. In this way, there are never more than five breasts on one air split, so if one breast makes gas freely, it can be isolated with the other breasts on that split without shutting down the whole gangway.

Also when breasts Nos. 1 to 5 are worked out, a cement stopping can be placed in air tunnel *f* and the whole



How the Mammoth Bed Can Be Ventilated by Splits from the Skidmore Headings



section can be entirely abandoned, thus saving the cost of maintaining extensive airways, chutes, etc. It is also possible to work any section separately or as desired, and the same system applies equally well to any size of breasts or any system of chutes we may care to use.

*District superintendent, Lehigh Coal & Navigation Co., Lansford, Penn.

Note—Abstract of article read at meeting of Panther Valley Mining Institute, Dec. 7, 1912.

The important points to be kept in mind during the manufacture of briquettes are: (1) The percentage of moisture should be kept as low as possible. (2) The binding agent should not add largely to the percentage of ash. When possible only organic substances should be used in binding materials, as the use of inorganic substances adds to the incombustible part of the briquette and correspondingly decreases the calorific power. (3) For domestic purposes the shape of the briquette should be modified to suit the demands of the consumer.

Regulation of Boreholes through Coal

By O. P. Hood* and A. S. Heggem†

SYNOPSIS—A rough draft of a bill to cover the relations between mine owners and oil and gas operators. The objects sought in the regulations governing the wells themselves are: To supply a free vent for all gas escaping from the packers, a casing which is free to slide past the measures in case of any movement of the same, the protection of the casing by a coating of clay, impervious to corrosive waters and plastic enough to remain uncracked after deformation and capable of transmitting side pressures in such a way that the strain on the inner casing may not be local in character.

The following suggestions are an attempt to harmonize as far as possible the information and advice which has so far been available to the bureau. Suggestions have come from those interested in the safety of miners; those interested in mining operations and the boring of gas and oil wells; and those interested in geology and the conservation of the coal, gas, oil and other mineral resources of the country. There has been no attempt to put these suggestions in proper legal phrases nor to make them entirely complete, but only to frame them so as to form a basis for discussion and further suggestion at this conference. It is hoped that as a result of this consideration, suitable laws may be suggested to the various states which will make mining more safe and prevent mineral waste.

Appointment of Gas- and Oil-well Inspectors

It seemed to be the general opinion that some form of inspection is necessary in order to make operative any laws which may be enacted, and which required specific methods or results. It is, therefore, suggested that there be a chief inspector of gas and oil wells; that he have sufficient help of a permanent and temporary character to meet the exigencies of the well-drilling business and that these officers shall have certain duties prescribed.

Licenses Required before Drilling

In order that it may be possible to locate a well, with accuracy, which goes through a workable coal seam, and which may at some time be within a mine area, it seems desirable to require a license to drill, this license depending upon the filing of proper maps and records. In case a location is proposed which may be detrimental to a coal mine, from the standpoint of either safety to the miner, or economy in the working of the mine, a conference between the three parties interested in such location is provided, these parties being the mine owner, the well owner and the miner, as represented by the state mine inspector.

The gas- and oil-well inspector is given power to change the proposed location within reasonable limits in order to insure a safe and equitable condition. It is also required that the inspector shall keep records of his office, so that at any subsequent time it may be possible for a mine operator to locate abandoned wells with accuracy. He should not be obliged to proceed in ignorance of their existence.

Abandonment of Wells

In order that the wells shall be properly plugged when they are abandoned, it has been suggested that the well driller shall furnish a bond which is to be returned to him when the plugging has been properly done. The inspector is required to supervise this plugging, so that a record becomes available of the method employed and the satisfactory accomplishment of this operation.

In making a provision, that wells which have suspended operation shall be maintained in a safe condition by the well owner, it is believed that formal abandonment will naturally follow rather than neglect.

What Is a Workable Coal Seam?

These suggestions cover only those wells which are put down through workable coal seams. A definition of this term "workable coal seam" is so difficult that it has not been attempted, and the responsibility for a reasonable interpretation of this phrase is placed on the state geologist whenever the matter becomes one of dispute. It is believed that some such official would interpret this phrase in view of the intention of this act, namely, to protect the miner while working seams of coal that may be used during the reasonable life of any well. It is not the intent to require special protection for all seams of coal which are physically workable. The exploitation of some of these will probably not be attempted before the well is abandoned and plugged.

Survey Requirements

It is believed that the location of a borehole should be so accurately determined that it could at any time be relocated, even after all surface indications have disappeared; and for this purpose it seems necessary to have the survey made by competent persons and reference made to established boundaries. These must be located by reference to at least three monuments or reference points. It is also desirable that all maps should be on the same scale.

In order that gas may not be drawn into the ventilating system of any mine, a minimum distance from a mine opening has been provided, and a similar minimum distance to those buildings which are vital to safety in the operation of a mine, so that in case of fire, of either wells or mine buildings, the risk shall not be increased.

Location Relative to Haulage Ways

It seems evident that a borehole should not go through any mine haulage or airway, and in order to insure this a distance of 15 ft. from such mine haulage or airway is required. It is believed that if pillars are considered necessary about such a borehole that the supporting power of the haulage-way ribs will be sufficient, as it seems to be generally admitted that such a pillar does not serve the purpose of keeping out gas which may leak around the casing.

*Mechanical engineer, Bureau of Mines, Pittsburgh, Penn.
†Petroleum expert, Bureau of Mines, Pittsburgh, Penn.

Note—A paper read before a conference called to determine proper legislation covering the drilling of gas and oil wells in the coal regions, held at Pittsburgh, Feb. 7 and 8. The full title is "Suggestions for Laws and Regulations in the Matter of Boreholes Passing through Workable Seams of Coal."

In requiring casing from surface water, it is believed hat after the casing which goes through the coal seam s properly placed and packed as required that the one sed for excluding the surface water may be withdrawn. The double casing which is required through any coal eam is deemed necessary because should a mine be pened, the operation might be fraught with much danger if the casing had been exposed to corrosion or if the ipe were injured by a movement of the measures. In rder that the casing might be allowed a certain amount f play in conforming to the side strains resulting from uch movements, it is required that they be extended into he floor a sufficient distance, that they be surrounded y a clay pack and that the second casing shall be brought nto play through the pressure of a similar clay pack.

The Clay Filler

Clay was thought to be a more desirable material for acking than cement. It would not under strain be so ikely to develop cracks through which corrosive water night enter if the outer casing was penetrated. Moreover it was felt that the use of clay would prevent the ocalizing of stresses on the second casing in case of a novement of the measures. A hard connection would ransmit the stresses in such a manner that the casings ould have to break, not being able to bend. Clay is beieved to be of such a nature that it will prevent leakage f gas even if the casings are deformed by a movement f the strata.

The second casing, which is provided through any coal eam, may extend downward to any depth, but in the vent that it is stopped 10 ft. below the first casing, when is cemented in place, this cement does not extend to he first or outer casing. This facilitates the drawing f the outer casing when the well is abandoned.

Where the casings pass through a mine excavation, a urther mechanical protection is provided by a suitable all and clay pack surrounding the casing, with the inent of preserving it from mechanical injury and corroion. Where such a casing passes through an inaccessible ine excavation a similar protection is attempted by aplying a cement covering held within an outer metal tube cting as a form.

The Free Vent to the Atmosphere

In the arrangement of casings and casing head, it is roposed to require a free vent to the atmosphere from point in the wall below any of the casing used and to emand that this vent shall be maintained by openings hich cannot be readily closed by ignorant or malicious ersons.

Where oil is allowed to rise within a casing above the oor of a mine, as it may during the disuse of a well, may find its way past the several casing seats and into ie mine, so that it seems necessary to keep the level of ny such oil below the mine floor.

How a Well Should Be Plugged

In suggesting a plugging method, it has been attempted keep the requirement as simple and as general as posble. The method is based on the theories that while clay one may make a good stopping, it is also apt to flow and ot be maintained where it is believed to be. Also, that ement mortar or concrete is apt to be porous, to deterorate in oil, and to form a plug of doubtful tightness.

It has, however, the quality of probably staying where it is put. To combine these two qualities, it is suggested that there be a body of cement on each plug and that a length of clay filling shall be placed above and below the cement, so that if there is any movement of fluids through the cement, the clay will be carried into small openings and eventually close them. It also seems desirable that there be a hard, solid portion through any coal seam, so that if struck by mining tools it is immediately disclosed.

We submit the following suggestions for laws and regulatons to control the drilling and abandoning of boreholes passing through workable seams of coal:

OFFICERS

Method of Appointment—A chief inspector of gas and oil wells shall be appointed by the governor from an eligible list of men who have passed a satisfactory examination showing technical fitness for the position.

Salary—The yearly salary of the chief inspector of gas and oil wells shall be —— dollars. Necessary traveling expenses to the amount of —— shall be borne by the state and an office equipped with suitable filing arrangements provided.

Assistants—Assistant inspectors of gas and oil wells, subject to the authority of the chief inspector, may be appointed by the governor.

Deputies—Competent men may in an emergency be deputized by the chief inspector to perform the duties of the position in the field, but an appeal from their decisions may be made to the chief inspector. Deputies may receive not over —— dollars per day and actual expenses not exceeding —— dollars per day.

DUTIES

Location—It shall be the duty of the inspector to receive applications for permission to drill boreholes and issue a license to drill to persons who comply with the law.

The inspector shall receive and file maps, giving the location of boreholes; shall determine the sufficiency of such maps, and shall cause a new survey of such location in case the maps shall be deemed insufficient.

It shall be the duty of the inspector or his assistant to examine the maps accompanying applications for permission to drill boreholes, and where the location is in the vicinity of a mine, he shall immediately proceed to the site and notify the district mine inspector and the coal operator to state whether the location on the map accompanying the application to drill is such as will interfere with the safe and economical operation of the mine.

The inspector shall issue a license when the proposed location of a borehole is such as not to interfere with the safe and economical operation of a mine, as determined by the mine owner, state mine inspector and himself. To this end he shall have the power to move the location of a proposed hole as hereafter specified.

After hearing and duly weighing the evidence he shall permit the borehole to be drilled at such point as will in his judgment permit the safe and economical operation of the mine.

Records—It shall be the duty of the inspector to keep a complete record and prepare for publication a yearly report of the number of wells drilled in his district together with their location; date of completion; depth; production; date of abandonment and name of owner.

Supervision—It shall be the duty of the inspector to examine each well in his district at frequent intervals, giving special attention to all wells containing gas in quantity which may be, in case of leakage, a menace to a mine, and to see that all the provisions of this act are observed and strictly carried out.

Complaints—He shall receive and investigate all complaints as to injury, present or impending, due to a lack of precaution on the part of any well owner or mine operator, and if he finds the complaints against the latter well founded he shall lay the facts before the state mine inspector.

Plugging Wells—Upon receiving notice of intention to abandon a well the inspector or his assistant shall proceed to such well and satisfy himself that the provisions of this act referring to plugging wells are complied with. He shall join the owner in making affidavit to the manner in which the well has been plugged.

Violations—If the inspector discovers any well being drilled, operated or plugged contrary to the requirements of this act, he shall order the workmen engaged upon such well to cease work at once and until the law is complied with.

Enforcement of Laws—To enable the inspector to perform the duties imposed upon him by this act, he shall have the right at all times to approach and examine any well in his district, and with the authority of the state mine inspector, enter any mine affected, and upon the discovery of any violation of this article or upon being informed of such violation, he shall institute proceedings against the person or persons at fault, under the provisions of the law provided for such cases.

In case of failure of the owner to properly plug an abandoned well, it shall be the duty of the inspector to have the work properly performed by contract and assess the cost against the well owner.

Penalties—There shall be adequate penalties provided to aid in obtaining the safer conditions here proposed.

LOCATION

Application—Any person (firm or corporation) purposing to drill a borehole through a workable seam of coal shall make application in writing to the chief inspector of gas and oil wells for permission so to do, and he shall not commence drilling until such permission, in writing, has been received by him. In case of dispute the state geologist shall determine whether a seam of coal is workable within the intent of this act.

Survey and Maps—Accompanying the application for permission to drill such borehole there shall be submitted a map showing the location of the proposed borehole with reference by course and distance to the boundaries.

Said map must be made on a scale of 200 ft. to one inch, and shall be based on surveys made by surveyors or engineers of recognized standing, and certified to by the surveyor or engineer making the same.

In case the inspector finds the map insufficient to enable him to locate the proposed well with accuracy, he shall require that another survey and map be made before permission to drill is granted.

If the original map is found to be correct the cost of the second survey and map shall be borne by the state.

Bond—Any person (firm or corporation) purposing to drill a borehole through any workable seam of coal shall be required to give bond in the amount of —— dollars to insure that the drilling and abandoning of such borehole shall be in accordance with the provisions of this act.

Distance from Buildings, etc.—No borehole penetrating a gas- or oil-bearing formation shall be located within 300 ft. of a shaft or entrance to a coal mine not definitely abandoned or sealed nor within 100 ft. of any mine shafthouse, boiler or engine house, or mine fan. No borehole shall be located to reach the coal bed within 15 ft. of any mine haulage way or airway.

License—Should the proposed borehole be so located as not to interfere with the safe and economical operation of any mine and the previous requirements of this act be complied with, a license shall be granted and said person (firm or corporation) may proceed to drill such borehole in accordance with the further provisions of this act.

PROTECTION OF COAL MEASURES

Casing from Surface Water—Any borehole penetrating any workable seam of coal shall be cased by the owner of the borehole with a suitable casing (conductor or drive pipe) so as to shut off all surface water from entering the coal seam.

Casing Through Any Coal Seam—Any borehole, drilled for gas, oil or other mineral shall be drilled to a point at least 20 ft. below any workable seam of coal which may be penetrated ,and receive a metal casing not less than ¼ in. in thickness and an outside diameter 4 in. less than the borehole. This casing shall be concentrically seated on the bottom of the hole and shall extend to the surface and shall be known as the first casing.

A second inner casing 4 in. less in diameter shall extend at least 10 ft. below the first casing and be seated in 1 to 2 cement mortar 9 ft. in depth. The inside of the second casing shall be open to the atmosphere its full length.

The intervening spaces between the second and the first casings and between the first casing and the borehole or outer wall shall be filled with puddled clay to a height 30 ft. above the coal seam.

Casing Through Accessible Mine Excavation—Casings which pass through a mine excavation shall be protected by a wall of concrete or of masonry or brick laid in cement mortar, extending from 2 ft. below the mine floor to the mine roof. Between the first casing and the wall thus constructed there shall be left an annular space of not less than 2 in., which must be filled with puddled clay. This work shall be done by the well owner.

Casings which are exposed by mining operations shall be covered as above by the mine operator.

Casing Through Inaccessible Mine Excavation—Where a borehole passes through an inaccessible mine excavation the outer casing shall be protected by cement mortar held within a metal tube 4 in. greater in diameter than the casing and extending from 4 ft. below the mine floor to 4 ft. above the mine roof or cave.

Casing to Exclude Water—Before drilling a borehole into a gas- or oil-bearing formation a string of casing shall be so set as to exclude all water from the lower borehole.

Tubing a Gas Well—To conduct gas from a gas-well tubing shall be inserted with a suitable packer located below the inner casing and in such manner as to prevent the escape of gas except through the tubing.

The inner casing shall be left open to the atmosphere throughout its full length.

Tubing an Oil Well—To conduct oil from an oil well, tubing shall be inserted and extend from the oil-bearing formation to the top of the well.

The inner casing shall be left open to the atmosphere throughout its full length.

Should gas be liberated in the well in sufficient volume to have commercial value it may be shut in by means of a packer placed below the inner casing and be conducted from the well through tubing inserted into the well parallel to the oil tubing.

Casing Heads—Casing heads must have at least one opening to the atmosphere to which a valve or plug cannot be attached, so as to insure ample vent in case of leakage into casing spaces.

Completion of Well—When a borehole has been drilled and put into operation the owner shall file with the inspector a statement of the total depth of the hole, the sizes and lengths of casing used and remaining in the hole, the depth and thickness of all coal seams penetrated and whether oil, gas or water is obtained.

Suspended Operation—When for any cause a borehole which passes through a workable seam of coal shall cease temporarily to be operated the inner string of casing shall be maintained open to the atmosphere. Should oil tend to rise in the well above the bottom of the first or outermost casing passing through the workable coal seam, such oil shall be pumped out by the owner and its level maintained below the bottom of this casing.

ABANDONMENT OF WELL

Notice of Intention—When any oil or gas well is to be abandoned the owner shall notify the chief inspector in writing of such intent to abandon and proceed with plugging methods only after complete arrangements for inspection shall have been made and permission granted.

Method of Plugging—In abandoning a well it must be entirely filled from bottom to surface. The lower hole must first be filled to a point 5 ft. above the lowest gas- or oil-bearing formation with sand, clay or rock sediment. Above each formation supplying gas, oil or water and immediately below any workable seam of coal there shall be a plug as hereafter described, and each well shall have not less than three such plugs whatever the formation.

This plug shall consist of 25 ft. of cement mortar made of 1 part portland cement and two parts of sand properly mixed and placed with a bottom dump bailer upon 5 ft. of clay resting on a seasoned wood plug 2 ft. long and of the same diameter as the hole. Five feet of clay shall also be placed on top of the cement section. The space between the plugs here called for must be filled solidly with puddled clay, sand or rock sediment, cement mortar or concrete. The filling shall be complete up to the bottom of a casing before such casing can be drawn and the filling shall continue length by length as the casing is withdrawn, using cement, mortar or concrete when passing through coal seams.

Log of Method of Plugging—When a borehole has been plugged an affidavit stating the method followed, the materials used, and the distances occupied by each material shall be certified to by the gas- and oil-well inspector and filed with the oil-well inspector and a duplicate with the county recorder.

Release of Bond—After, and not until these several requirements have been met, any bond which may have been given by the owner shall be returned.

Fees—Shall fees be charged for license and inspection?

EDITORIALS

Tax Valuations of Coal Property

At a recent meeting of the Mining and Metallurgical Society of America (New York Section), the subject for discussion was "Systems of Mine Taxation."

Interesting descriptions of methods of valuing mineral property in many different states and countries were brought out in the discussions of the principal paper of the evening, by J. R. Finlay; who, it will be remembered, was retained by the State of Michigan in 1911 to appraise the mineral properties of the state for this purpose.

This subject of taxation is being agitated in nearly all mineral-bearing states and countries, and the general public has come to believe that in the past, injustice has been done other property owners by reason of the valuation of mineral lands being too low.

There is, undoubtedly, ground for this feeling, as there are many instances known where the valuation of mineral property is relatively much below an equitable basis, as compared with other taxable real estate, and on the other hand, there are instances of excessive values when all the factors that make up the worth of mineral land are considered.

The subject of the taxable value of coal lands in Luzerne County, Penn., has recently been in the courts on an appeal by the Lehigh Valley Coal Co., from the assessment of 1907 on its Franklin colliery. Many other appeals are pending, but it was agreed by the County Commissioners and the Taxpayers Association to make a test case and apply the decision to other cases, not formally tried.

The trial of this case was long and tedious, and it is unnecessary to follow the details, but the striking feature brought out in the evidence is the wide difference between the expert mining engineers representing the two sides.

The average of the estimates of five engineers representing the company was $750 per acre, and of five engineers representing the county was about $3050 per acre. These two sets of engineers used the same maps, etc., to get at the content of the property. These figures are here quoted to bring out the fact that no logical method of determining the real value of coal-bearing lands for taxation purposes, appears to have been developed or adopted anywhere.

In most counties of Pennsylvania, and we believe in other states also, valuations are largely matters of compromise between the local assessor and the corporation representatives, subsequently revised by the county commissioners.

As a result, many instances of great inequality, entirely unjustified by the geologic or mining conditions of adjacent properties, are known.

We believe the time is ripe for the adoption of common-sense systematic methods of arriving at values for the purposes under discussion, and suggest a method not by any means new; but seldom considered by taxing authorities.

Appraisal of such property, in our opinion, should be based on the probable proportion of the original content of coal that can be *won and prepared into a marketable product.*

Under this method, the holders of the coal properties are to be considered as land owners, offering their lands for lease on a royalty basis; that is, on the basis of a fixed royalty per ton, of each size of coal, to be paid as the coal is mined. By this method, the calculated value of the lands as a present asset, is the present value of the money which, compounded at interest, will ultimately pay to the land owner or lessor the royalties (dividends or profits) receivable from the coal yet remaining to be mined therefrom.

In calculating the present worth, it is assumed that 5 per cent. is a reasonable interest for investments of this character.

We believe this is a fair method of valuation for the reason that rates of royalty for coal lying in beds of known thickness and quality are, in the older mining regions, well established; in fact, far better established than the valuation of the lands on an acreage basis, or a basis of future profits from operation. This method necessitates an approximate estimate of the date of ultimate exhaustion of the tract under consideration, which determines the annuity period.

The particular point we make is that mineral lands should be valued as a *present asset,* not speculatively, as would appear to be the case in the testimony of the engineers for the commissioners in the Luzerne County suit.

Weather Bureau Mine Service

Referring to the circular recently sent out by the U. S. Weather Bureau, from its several stations in the coal-mining districts of the country, notifying the mine operators of each district that if they so desire, information will be given them promptly, from time to time, of weather changes that are liable to affect conditions in the mines, a contemporary comments on the possible value of this service to mining.

Dr. Holmes, director of the U. S. Bureau of Mines, is quoted as expressing the fear that the warnings themselves may add to the risks and dangers in mines where gases occur in dangerous quantities. The investigations of the past two years, by the Bureau of Mines, are said not to have given conclusive results as to the influence of weather conditions, especially barometric pressure, on the condition of the mine atmosphere.

In the same connection, Dr. Holmes is quoted as using the old argument that such warnings may tend to make miners and operators less careful during the periods in which no warnings are given. He adds, however: "If they should serve to make miners and operators more careful at the time of danger, they will serve a good purpose, in gaseous mines."

COAL AGE referred to this mine service offered by the

Weather Bureau, in an editorial, Jan. 25, in which it expressed the hope that the service, being a responsible one, would be appreciated by those mine officials having no barometer at the shaft.

Mining men differ, to some extent, on the supposed influence of weather conditions on the atmosphere in the mines. It is sometimes stated that the indications of the barometer are too tardy to be of any value in giving warning of the change in conditions in the mine. For several years past, we have made a careful study of the relation existing between the indications of the barometer and the appearance of gas in mines generating gas, especially in mines having large abandoned areas.

We have barometric charts showing the changes of the barometer continuously during the past six years. During a portion of this time, we received reports from firebosses in different mines, in the same locality where the barometric readings were taken; and these showed continually that the indications of the barometer preceded the change in condition in the mine, from two to three hours.

In regard to the Weather Bureau's proffered service, we can endorse the statement of Dr. Holmes that "the value of the service will depend on the way in which it is used." We do not doubt for a moment that such warnings promptly given should prove of great value to the intelligent mine official; and if such warnings are freely offered to operators, they should be held the more responsible for not having availed themselves of the opportunity of forestalling a dangerous condition in the mine. In each case, the action to be taken after the warning is received will depend on the particular conditions existing in the mine, and this can be determined only by the officials in charge.

The Danger of the Outside Driver

The outside-wheel locomotive, either electric or gasoline, where connecting rods are not employed, is a fruitful source of minor accidents about mines. On these machines the brake mechanism between the drivers forms a possible foothold for the trip brakeman. In attempting to step aboard the moving motor, should this man's foot slip, it is almost certain to be caught and crushed by the rear wheel. Many of the crippled and one-footed men to be seen about the collieries can trace their misfortune to this cause.

It appears to be utterly useless for the management of any mine to forbid men from getting aboard the locomotives in this way. So long as the opportunity is there, and the man wishes to get upon the machine, the temptation to do so from the side is well-nigh irresistible.

So numerous have been the accidents from this cause that some companies refuse to buy any new motors of this type, while the machines which they already possess having outside wheels have been guarded by an auxiliary plate or sheet of steel, which is hinged at the top of the motor frame and secured at the bottom by two or three bolts. This plate completely incloses both driving wheels and brake mechanism and presents no projections whatever, that can possibly serve as a foothold.

If the outside-wheel locomotive possesses sufficient advantage over those of other types to warrant its manufacture or purchase, in the interest of humanity and our brakemen's feet, let us house in its dangerous drivers, and just so far as we are able, render it impossible for anyone to get caught beneath them even though such a misfortune might be only the logical outcome of a man's own carelessness, negligence or willful disobedience.

Conditions Favorable to the Coal Industry

In many parts of the United States the chief bugaboo of the coal industry has been oil and gas. The supplies of these natural fuels have been growing less each year, and as a consequence their price in the market has advanced materially.

The benefit to the industry brought about by this change has not been confined entirely to the Western states. Plants at various Eastern points, which for many years have been burning oil as fuel—notably at such places as Worcester, Mass., and Allentown, Penn.—have been compelled to return to the use of coal, owing to the fact that the oil producer will not contract with these consumers for a further supply of fuel oil.

The rapid dwindling of the natural-gas supply in most parts of the United States has already caused many manufacturers, who have been depending on gas for fuel, to install producer-gas plants. All of these conditions are tending to the betterment of the coal industry through bringing about an increased coal consumption. Adding to this favorable situation the improvement which prevails in our export business, which latter trade amounted to $78,000,000 last year, it does appear that the owners of coal mines should view the future with optimism.

British Indian Efficiency Methods

Resting during working hours and eliminating waste of time by reducing distances traversed are two principles carried to their conclusions in British India. J. R. R. Wilson, at the recent meeting of the National Association of Colliery Managers (Yorkshire, England, branch), stated that 24-hr. shifts are quite common in the Raniganj coal field. "Of course, the men are not working all the time; they eat, sleep and work at will. The system probably arises from the fact that numbers of them live a long way off and they do not care to and could not perhaps make the journey every day. Sleeping in the mines is quite common, both on the part of the piece-worker and of the day hand."

Reduction Gears

As turbines inherently involve high rotative speeds, many of their applications necessitate some means of transmitting their power at greatly reduced velocity. For this purpose a reduction gear provided with a floating frame so supported as to equalize tooth pressures, has been devised for large capacities.

An official test of a 6000-hp. set has shown an efficiency of 98½ per cent. over a wide range in load.

The reduction gear was primarily intended for marine practice, to permit the turbine and propeller to be operated at their most efficient speeds, but has been adopted for driving large direct-current generators, and may be used to interpolate between the high and low relative speeds of any two movers.

SOCIOLOGICAL DEPARTMENT

How the H. C. Frick Co. Eliminates Accidents at Its Mines

By Thomas W. Dawson*

The company has originated a device for automatically controlling high-pressure air compressors and has applied for a patent on the mechanism. When the temperature of the discharge air in the pipe reaches a predetermined point, showing that the air is being excessively compressed, it acts on the thermometer and the recording device, thus closing an electric circuit and energizing a solenoid. This in turn moves over a tripping device, which opens the pilot valve, releasing the steam pressure on one side of the regulating piston. Thereby the valve on the steam feed pipe is automatically closed, shutting off the flow of the steam to the compressor, thus stopping it and preventing an explosion.

Protection against Shaft Accidents

At all shafts where men are hoisted, the engines are equipped with an automatic device, which acts directly on the engine, cutting off the steam and applying the brakes, making it impossible to hoist the cage beyond a safety point.

At the bottom of shafts which have sumps, it is frequently necessary to remove fine coal which falls from the dumping platform above. During this removal, the cages are hoisted to a clearance height, and iron pins are placed in holes in the guides and on these the cage rests, making it impossible for the engineer or others to lower it into the sump. These pins are always in place, being attached to the guides by chains which prevent the removal of the pins when not in use.

There is a device installed at surface landings of all shafts to prevent gates from being opened when the cage is not in position at the landing. When the cage is at the right height, it serves as a fulcrum, so that the gate latch may be opened. This device also controls a spring switch on the track leading to the cage at the surface landing, which opens when the cage is in position, and is closed at all other times.

All hoisting compartments of shafts are lined at the cage ends. This provision with that of safety gates prevents workmen from being caught during the movement of the cage.

Inspections in Triplicate

All cages and safety catches are periodically inspected, tested, and a written report made of the inspection. In no case, is a hoisting rope kept in service longer than two and one-half years, even though apparently safe and in good condition.

Frequent inspection of air shafts must be made to keep them open and free at all times from ice and other obstructions. A fireboss must make this examination, and travel either up or down such shaft once each day, the mine foreman once each two weeks, and the superintendent once a month. It has been the practice for some years to pass exhaust or live steam into the air compartments of such shafts during the winter months, to prevent ice from forming therein.

More Air Provided than Law Requires

Article No. 2 of the general rules of the company states that: "Mines generating explosive gas must have, at the intake, not less than 500 cu.ft. of air per minute, per person employed in the mine, and so distributed that there will be sufficient volume in circulation in and around the working places, to give not less than 300 cu.ft. of air per minute, per person employed in each split.

No mine shall have at the intake less than 300 cu.ft. of air per minute, per person employed, and sufficient volume shall be supplied in and around working places to give, at least 150 cu.ft. per minute, per person employed in that split. This rule provides increased air at working faces and at the intake, above that required by the state mining law.

These measurements of air supplied are carefully made and reported to the general office once each week. Local officials, at mines which generate gas, are required to keep air up to the working places, and to such other places where explosive gas might be encountered.

On all ventilating fans can be found the Bristol recording and "U" gages, and these are kept in good and operating condition. At a number of the larger and more recent plants, the ventilating fan is operated by two engines, one on each side of the same and each of them is powerful enough to operate the fan in case of failure of one or the other.

Here is installed a system of piping, with valves, by means of which either engine, or both, can, in case of accident be stopped immediately by the attendant should he be in either engine house. All ventilating systems in the mines are ascensional.

Clowes' Hydrogen Lamp

We do not rely on the ordinary safety lamp for the detection of gas. The Clowes' hydrogen-test lamp is used in all mines generating methane. This will detect a very much smaller percentage of gas than can be discovered when watching the indications of an ordinary safety lamp. Samples of air are taken in gaseous mines and sent in copper cans to the company's laboratory where they are analyzed. A detailed report is filled out by the party obtaining the sample, who is usually a mine foreman, his assistant or a fireboss.

The results of the analyses are reported to the general office and to the mine, and if there should be a percentage of explosive gas which might have been de-

*Assistant chief engineer, H. C. Frick Coke Company, Scottdale, Penn.

Note—Abstract from paper entitled "Welfare, H. C. Frick Coke Company," read before the winter meeting of the Coal Mining Institute of America. Continued from our issue of Feb. 8, 1913, page 230.

tected by the Clowes' lamp, the party making the test and reporting no gas is required to explain, and perhaps to hand in his resignation. In this way, all the underground officials are trained to make careful investigations.

Boreholes are frequently drilled from the surface to release any dangerous accumulations of explosive gas in the gob where these cannot be removed by the mine ventilation. Shotfirers have been employed to do all blasting and they are required to inspect all places where shots have been fired to see that there is no fire or other danger thereafter. Only the safest permissible explosives are used, and all tamping is done with clay.

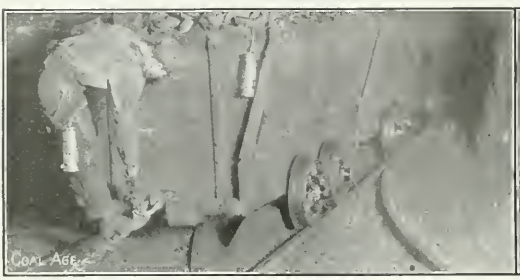
All safety-lamp mines must be examined on Sundays, holidays and lay-off days, and all mines which have been idle for more than two consecutive days are examined before operations are renewed.

In the larger mines, wherever safety lamps are used, any other workman can at once note the clearance side of the heading when passing a moving trip.

All underground trips controlled by motors, steam engines or other mechanical means must carry front and rear lights. Underground signal systems on all haulages are standardized. All apparatus in connection with these signals is kept in good working order. On electric haulage you will see the block system, similar to that used in the operation of street cars in our towns and cities.

Timbering Provisions

Systematic timbering systems are devised and strictly followed. Printed regulations cover the system of timbering in rooms, headings and rib and pillar drawing, and are worked out to suit conditions at the various mines. Timber is not set without caps or crossbars as safety depends so much on their use and only when it is so set will it bear its full share of the load which it



Ordinary Method of Releasing Chain of a Haulage Rope by Use of Foot

Frick Method of Detaching Haulage Rope without Risk to Trip Runner

auxiliary escapeways are provided. In some instances these are stair shafts from the surface to the mine, located in the active working sections. These shafts are also arranged so that they will aid ventilation. In other instances, means of escape are provided by having connections between mines which are closed by double iron doors. Frequent examinations are made to make sure that these doors are always in condition for use in case of necessity.

Where coal dust is a menace to safety, a system of pipes and a supply of water under sufficient head and all necessary appliances are provided to dampen thoroughly the floor, sides and roof of all parts of dry mines.

Means of Avoiding Accidents from Cars

When a trip of loaded wagons has been hauled to the shaft bottom, the rope rider, at most mines, releases the rope or chain by using his foot to remove the slack so that the pin attaching the chain may be extracted. This dangerous practice has been eliminated by a simple device which disengages the chain as soon as it is given slack.

At the bottom of steep headings safety switches are provided, so that in case of a runaway, the trip is derailed before it can reach the main headings, the landing or possibly the shaft bottom, with a consequent accident and even loss of life.

Brakes are provided for mine cars, eliminating the use of sprags where braking is necessary. The wide or clearance side of all headings in the mine is indicated by a wide whitewashed strip so that the driver, brakeman or is intended to support. A post extractor is furnished so that timber can be withdrawn in safety and a long hook is provided for the recovery of timber when making a "fall."

Boreholes for Pipes

Another point of technical interest is that high-pressure air lines for underground haulage are placed in boreholes from the surface to the mine, thus eliminating accidents from the bursting of these high-pressure pipes. Also, in a number of cases steam lines are placed in special boreholes drilled for the purpose, and water discharged from main pumping stations to the surface by way of boreholes.

On compressed-air haulages, at the charging stations, there is protection provided to the engineman, so that he cannot be injured while attaching or detaching the supply pipe of the locomotive.

All the mines of the H. C. Frick Coke Co. have complete mine telephone systems. Phones are located at the various landings, shaft bottom, mine foreman's office, connecting with the superintendent's office on the outside, where a connection can also be made with the general office at Scottdale. Thus in case of accident, immediate attention or assistance can be obtained.

(To be continued in an early issue)

In gaseous mines the coal seams should be worked out systematically and completely in order to bring about a uniform subsidence of the strata, thus preventing the accumulation of gas in reservoirs.

DISCUSSION BY READERS

Reducing Ventilation When Firing

Letter No. 12—After reading Mr. McAllister's letters, in recent numbers of COAL AGE, I was inclined to think that he was not serious, or, at least, that he had greatly exaggerated his statements or is himself mistaken as to the facts observed. Not one man in a thousand has had the opportunity of making tests such as as he has described; or would have the nerve to experiment with his employer's property in such a reckless manner.

During the 30 years I have worked in the mines I have had ample opportunities of studying the different conditions that exist. I worked as shotfirer in a very gaseous mine, in the north of England, where my instructions were that not a shot was to be fired if the lamps showed the faintest trace of gas at the working face. This often occurred, and the only remedy was to increase the circulation so that the air would dilute and sweep away the gas. Since it is well known that marsh gas (CH_4) will only explode when mixed with a certain amount of air, someone might say: "Stop the fan and let the place fill with gas, and then fire the shots." It is safe to say that such argument would not appeal to many practical mining men.

Mr. Waterman (Letter No. 6) states that the advocates of reducing the ventilation at firing time "have been, for the most part, content with recounting their personal experiences." I would like to ask, what better proof can be found than that of "personal experience." This discussion arose from the personal experience of Mr. McAllister; and if any good is to be derived from the discussion, it will be through the personal experiences of others, either confirming or disproving the theory he advances. Many practical men, myself included, have a high regard for theory where it can be applied to everyday practice.

Referring again to Mr. McAllister's experience, I call to mind an explosion that occurred in our mine, caused by a single shot; and there was not a trace of gas in the mine. The explosion killed 20 men and destroyed all the overcasts and many stoppings, besides doing other damage. Although we did not stop the fan when firing, after that occurrence; but adopted the use of permissible explosives and fired as before with the full current of air in circulation, there were no more explosions in the four years following. But, suppose, instead, we had adopted the practice of slowing down the fan and had put doors on the upcast shaft, no more explosions occurring, we would have concluded that such practice was correct and that it prevented other explosions.

The practice of slowing down the fan, or stopping it altogether when firing, may possibly work in some mines, but it can never become a general thing.

This is a subject that should receive the close attention of all our expert mining men, who should strive to prove or disprove the correctness of the theory. But until shown to be wrong, the old practice of running the fan at the normal velocity when firing, should be continued. If Mr. McAllister, however, has not converted a single man to his belief, he has still the satisfaction of knowing that he has called attention to a subject that is worthy of discussion.

THOMAS HOGARTH.

Heilwood, Penn.

Letter No. 13—We are operating a pick mine and, at times, have some very heavy shooting. It is our custom to run the fan at a speed of from 35 to 40 r.p.m., during working hours. The other evening, my duties required me to go into the mine, at shooting time. Having been much interested in this discussion, it occurred to me to speed up the fan to 50 r.p.m. before going down, which I did.

Upon going below, I met one of the shotfirers, and asked him the question: Considering your own safety and the safety of the property, do you prefer to slow down the fan, or to increase its speed when firing? Not knowing that I had speeded the fan before coming down, he replied: "When I am shooting I want the fan to run about the same as it is running now. This is a good air." I might add the speeding of the fan, in that case, gave no trouble.

I believe it is important, however, to regulate the air according to certain conditions, as they exist in the mine. For example, a new mine that is just being opened has a comparatively small air space; and the number of shots fired is correspondingly small. The volume of the workings and the number of shots fired increase with the development of the mine. At the present time, in our mine, we are firing from 250 to 300 shots, in about 95 minutes. Many mines fire a larger number of shots in less time. It seems to me that it is of the utmost importance to give more time for firing, so that the air current will be able to handle the large volume of smoke and gases produced by the firing of the shots. I believe mine accidents will be reduced by this method more than by reducing the ventilation.

AN INDIANA FIREBOSS.

Linton, Ind.

Letter No. 14—As bearing on the question of reducing the ventilation when firing in a mine, my attention has been drawn to a statement of Mr. Verner, COAL AGE, Jan. 11, p. 75. In speaking of electrical firing, in mines Mr. Verner refers to the concentration of a strong dust-laden current returning toward the face, where a single shot has been fired. He adds, that this concentration of dust-laden air, which he styles "draft concentration," is minimized or fully eliminated when a large number of shots is fired at one time.

Mr. Verner concludes his obscure reasoning with the statement that, assuming each of the 100 shots fired simultaneously produces an equal effect, the "draft concentration" affecting each shot would be less than, say 10 per cent. of the effect produced by the firing of a single shot. No attempt is made, however, to explain the reason for this "dangerous draft."

Except in steeply-pitching seams and under extreme conditions of temperature, a velocity due to an air column, in an entry, could not exceed, say 800 ft. per min., as a simple calculation would show. But, even assuming a draft of high velocity returning toward the face, following the blast, it is hard to see how the firing of a large number of shots at one time will reduce this draft, so that the heat and flame produced will be less liable to ignite a dust cloud than when a single shot is fired.

Stopping or reducing the ventilation in a mine, at the time of firing, may or may not reduce the chances of a dust explosion in a large mine generating little or no gas. However, this is not proven by the bare unsupported statement of a theory. When a man starts to propound a theory for the guidance of practical mining men, he should make clear the facts on which his theory is based, so that others than he can judge whether or not his conclusions are correct.

LEONARD L. QUISENBERRY.

Johns, Ala.

Letter No. 15—The discussion on reducing ventilation when firing has been of great interest to me and I consider it of much importance in practical mining.

I fail to see any reasonable ground for reducing the air current to a low ebb when firing shots in mines. I consider it of far more importance to adopt measures that will prevent the ignition of gas and dust, than to consider how the violence of an explosion once started, may be diminished.

Mr. McAllister certainly had a remarkable experience and is to be congratulated that he is still among the living. In my estimation, a man would be taking desperate chances to place 25 lb. of blasting powder in a pile and cover it up with fine coal dust and ignite that pile together with 27 shots, at the same time; and withal remain in the mine to await the explosion. Not only would I never attempt such an experiment, but I certainly would not remain in the mine in a safety hole, as no hole inside the mine could be considered safe under those conditions. The result, in this case, has proved the truth of the old saying: "It is always the unexpected that happens." Certainly an explosion might have been expected under the conditions Mr. McAllister has described.

Willian Scaife has estimated that a pound of powder has a potential energy of 500 ft.-tons, and that this energy expended on the air, in a 10x10-ft. airway, would produce a velocity of 346 miles an hour. This estimate, if true, easily explains how tipples have been weakened, fan houses destroyed and loaded cars of over two tons weight hurled through the air like feathers in a breeze. In my opinion a mine is never safe unless it is thoroughly ventilated by an adequate supply of pure air to dilute and render harmless the obnoxious gases generated.

In the Crows Nest Pass mines of British Columbia, at Fernie, Morrissey and Michel, should the ventilation be reduced to a low ebb, the gases generated would fill the entry a long distance back from the face, in a few minutes, and make it impossible for a shotlighter to approach the working face to fire a shot, even with a safety lamp. Again, the seams here often pitch 40 and 60 deg. and generate explosive gas to such an extent that the head of the pitch where the shot is to be fired would become dangerously charged with firedamp, immediately upon the current being reduced.

The object of reducing the current is apparently to obtain a low oxygen content in the mine air. It would seem to me, however, that the atmosphere of the mine would supply enough oxygen, for a long time after the air has ceased to flow, to defeat this plan or render it effective for the purpose in view. This would be especially true in a large mine generating little or no gas. In the samples of mine air, given as explosive by G. A. Burrell, COAL AGE, Jan. 18, p. 106, one of the samples contained only 17.49 per cent. of oxygen, which, I believe, is lower than what could be, or is commonly realized at the working face.

In closing, I wish to refer to the excellent article of R. T. Rhys, COAL AGE, May 11, 1912, p. 1004, in which he classifies all the principal explosions that occurred in Iowa, from the year 1892 to date; comparing those that occurred under reduced ventilation when the fan was slowed down, with those that occurred under the normal ventilation of the mine. From the records of these explosions, I am sure that the claim that reducing ventilation at firing time reduces the force of the explosion is not supported, but the records are decidedly against such a theory. I shall watch with interest the further discussion of this subject, which must prove of much value in mining.

J. W. POWELL, Mine Manager,
Columbia Coal & Coke Co.

Coalmont, B. C., Canada.

Seven Shifts a Week

Personally I cannot agree with the Colorado Engineer, COAL AGE, Jan. 18, p. 88, who considers seven shifts a week a "fallacy." I have had some experience as mine superintendent, mine manager, etc.; and I want to say that the man who expects to be successful, working a limited number of shifts or hours for the present-day corporations, will certainly be disappointed.

There was a time, before the large companies came into existence, that six shifts a week were sufficient; but, today, with our large plants and valuable machinery to be carefully gone over, repaired and inspected, it is necessary for the superintendent, master mechanic and mine manager, to be on the job almost day and night; and often he must live, eat and sleep with the job. When that is necessary, the job will be better off and so will the man who contentedly adapts himself to the conditions and stays with the work.

I have been on the job, at times, forty-eight and sixty hours, without seeing home or bed; and when the job was done and my tonnage thereby increased by little improvements made, here and there, which would not have been made had I been at home or enjoying a season of recreation, I always feel amply repaid for the extra hours of toil.

My opinion is that living with the job will never hurt anybody as long as they are ambitious and determined to make good. Seven or even ten shifts a week cannot hurt such men. But the man who limits his time, watches the clock, and neglects business for ease and pleasure, will soon be reduced from a monthly wage to day's pay; and placed in the class in which he rightly belongs.

MINE FOREMAN.

Collinsville, Ill.

INQUIRIES OF GENERAL INTEREST

Weir Measurements

I have built a weir 6 ft. 6 in. long, in a stream in which there is a considerable velocity of approach and in which it is impossible to secure a forebay of any size.

I would like to ask: (a) What means do you recommend for obtaining the velocity of approach? (b) What formula do you prefer for the calculation of the quantity of water passing through the weir?

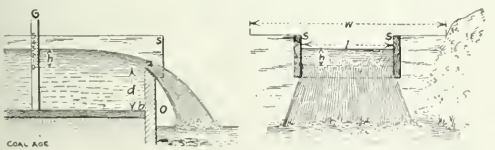
I have read the height of the water on the weir at two points, one 3 ft. and the other 8 ft. upstream. Could the difference of the readings at these two points be used to calculate the velocity of approach according to the formula $v = \sqrt{2gh}$?

W. B. T.

Canmore, Alberta, Canada.

The formula suggested by our correspondent could not be used for calculating the velocity of approach. The formula $v = \sqrt{2gh}$ gives the velocity due to any height h when a body falls from rest, or when the initial velocity is zero. But, even assuming that $h = h_1 - h_2$, which is probably the meaning of our correspondent, the formula would give only the increase in velocity between the two points at which the measurements were taken. It would not give the velocity of approach. What is required is the *average* velocity of approach, which cannot be calculated by the above formula, even if the actual head were known.

There are two or three essential points that must be observed in order to obtain accurate weir measurements.



Longitudinal Cross-section and Front View of Weir, Showing Important Dimensions

First, it is desirable to reduce, as far as possible, the velocity of approach. In order to do this, the area of cross-section of the flow of water through the weir represented by $h \times l$ (see accompanying figure) should be small with respect to the total area of cross-section of the stream, represented by $w\ (h + d)$. To obtain good results, the depth d of the bottom of the weir below the crest a, over which the water flows, should not be less than twice the head h; and the length of the weir l, say not greater than one-third of the width of the stream w. With these limiting dimensions, the area of the cross-section of the weir will not exceed one-ninth of the cross-section of the stream; and, as a result, the velocity of approach will not exceed one-ninth of the velocity through the weir.

It is important, also, that the back of the weir, ab, shall be vertical. The cross-section of the weir must, of course, be regular throughout; the sides, also, of the weir $s\ s$ must be vertical and extended a short distance beyond the crest over which the water flows. The purpose of extending the sides is to prevent the rapid expansion of the stream of water, until it has passed beyond the point where such expansion would influence the velocity of the flow over the crest. It is always important that the weir should be so arranged that there will be no vacuum formed in the space o in front of the weir and under the waterfall. If this space is closed, the falling water has a tendency to reduce the pressure at o which would increase the flow of water over the weir; and this increased flow would not be accounted for in the formula.

There are different methods of measuring the height h, which is assumed as approximately the velocity head of the water flowing over the crest a. A simple method is to erect a vertical gage G, in the weir, say from 6 to 8 ft. upstream from the crest a, making the zero of the gage correspond exactly with the elevation of the crest a. The reading of the gage at the surface of the water will then be the required height h, which must be measured in feet. The gage must be thin and arranged so as to prevent the formation of ripples at the surface of the water; it must present no appreciable obstruction to the flow of water through the weir.

Except in a still-water basin, the water reaches the point where its height h is measured, with a certain velocity called the "velocity of approach." It is ordinarily impracticable to measure the head to which this velocity is due, or the head to perfectly still water upstream. Moreover, as stated previously, the velocity of approach is the actual average velocity of the stream, allowing for friction and other obstructions. Experiments have shown that when the velocity of approach does not exceed 1 ft. per sec., the discharge calculated for the height h will show an error not exceeding 2 per cent. of the actual discharge.

Ignoring the velocity of approach, or taking the measured height h as the head creating the velocity of the water flowing over the weir, the flow of water may be calculated very approximately by the formula

$$q = 3.1 l h \sqrt{h}$$

When it is necessary, in any given case, to consider the velocity of approach, divide the quantity of water, as calculated by this formula, by the area of cross-section of the weir, which is l times h; or this velocity may be calculated independently by the formula

$$v = 3\sqrt{h}$$

derived from the preceding formula.

The head due to this velocity of approach, or the additional head, is then calculated thus,

$$h_1 = \frac{v^2}{2g} = \frac{(3\sqrt{h})^2}{2 \times 32.16} = 0.14\,h$$

This head h_1, due to the velocity of approach, must be added to the measured head h to obtain the total head

creating the flow of water over the crest. Calling this total head H, we have

$$H = h + h_1 = h + 0.14\,h = 1.14\,h$$

The quantity of water passing over the weir is then found by substituting this total calculated head for the measured head h in the previous formula; thus,

$$Q = 3.1\,l\,H\sqrt{H} = 3.65\,l\,h\sqrt{h}$$

This last formula is practically correct for finding the approximate flow of water over a weir constructed according to the diagram shown in the accompanying figure, when the measured height of the surface of the water in the weir, above the crest, is h, in feet, and the length of the weir is l, in feet, assuming that the weir complies with the other conditions mentioned. The quantity of water thus found is given in cubic feet per second.

Does Carbon Monoxide Support Combustion?

In reading up on the subject of carbon monoxide, I find a conflict of opinion regarding this gas. Some books state that carbon monoxide supports combustion, while others state that it does not. Will you kindly state somewhat fully the opinion you hold in regard to this question?

M. D. Cooper.

Ellsworth, Penn.

The following quotation from "Mine Gases and Explosions," p. 62, will make our answer clearer:

> In a broad sense, combustion is any chemical reaction accompanied with the evolution of heat and often with the production of light or flame or both. Combustion always involves at least two substances, one of which is the combustible and the other the supporter of combustion, the latter being generally a gas.

Carbon monoxide is a product of the incomplete combustion of carbon in oxygen. Since the combustion of the carbon is incomplete, in this case, it is possible to carry it farther, in an atmosphere that will supply the needed oxygen; and, as a result, carbon dioxide will be produced. It is clear that the carbon monoxide is, here, the combustible, because it is susceptible of further oxidation. It is not, in this case, the supporter of combustion.

The only reason we can suggest for the statement being made that carbon monoxide is a supporter of combustion, is that the idea probably has grown out of the fact that lamps continue to burn in an atmosphere of this gas. The gas is not an extinctive gas, as is carbon dioxide, because the presence of this gas in air does not depress or extinguish the flame; but the combustion of the gas itself in contact with the flame increases the heat of the latter, causing it to burn brighter and with greater intensity. A lamp will not burn in an atmosphere of pure carbon monoxide, since there is then no available oxygen to carry on the combustion.

From this reasoning, it is clear that carbon monoxide cannot, in any sense, be considered a supporter of combustion, except a reaction takes place in which the carbon monoxide gives up its oxygen to another substance, in which case, it could be said to support the combustion of that substance. In all other cases in which this gas is concerned and combustion ensues, the gas is the combustible and not the supporter of combustion.

Relative Size of Intake and Return Airways

I would like to ask: Which should have the largest sectional area, the main-intake or the main-return airway of a mine, and why? The textbooks all say the return airway should have the greater sectional area, owing to the expansion of the air and gases in the mine.

In my opinion, the relative size of the intake and return airways should be determined by considering which of these airways is the haulage road. I believe it is of greater importance that the haulage road should be the larger of the two. There is scarcely an hour of the day when the haulway is not more or less blocked by trips of loaded cars, which greatly obstruct the flow of air along the road.

Besides, when the haulage road is used as a traveling-way, extra width should be provided, so that men or animals can safely pass the loaded cars. For this reason, it seems to me, that considering both the ventilation of the mine and the safety of the men, the haulage road should always be the larger of these two airways.

J. Bennett.

Lock No. 3, Penn.

The question presented by our correspondent is one that is frequently asked in mining examinations, and the answer generally given is: The return airway is the larger of the two, for the reason first stated. There is no doubt, however, but that there is much truth in the remarks offered by our correspondent in reference to the need of a large haulage road.

This is a case, as frequently happens, where the answers given to examination questions are too theoretical and ignore the practical requirements in the mine. We might add, however, that while it is well to refer to the necessity of a large sectional area for haulage purposes, it is also important and absolutely necessary that the sectional area of the return airways shall be amply sufficient to allow the increased volume of the return air and gases to travel out of the mine at a moderate velocity. This is very essential, particularly in a gaseous mine. We are glad attention has been drawn to this point, as the answers to all examination questions should cover both theory and practice.

Height of Flame Cap and Percentage of Gas

The following formulas are given, Coal Age, Vol. 1, p. 1020, for calculating the percentage of gas from the height of flame cap:

Unbonneted Davy, $Percentage = \sqrt[3]{36\,h}$

Bonneted Davy, $Percentage = \sqrt[3]{70\,h}$

Please give a formula for calculating the height of a flame cap when using a Wolf lamp.

Fireboss.

Brucetón, Penn.

There is no formula for calculating the percentages of gas from the height of the flame cap, in the use of the Wolf lamp. The volatile nature of the oil burned in the Wolf lamp makes the height of the flame cap vary according to the length of time the lamp has been exposed to the gas.

EXAMINATION QUESTIONS

Air and Mine Gases

(Answered by Request and Suggested)

Ques.—Find the weight of 1 cu.ft. of dry air, at a temperature of 70 deg. F. when the barometer is 29.5 inches.

Ans.—The weight of 1 cu.ft. of dry air is calculated thus:

$$w = \frac{1.3273 \times 29.5}{460 + 70} = 0.0738 \text{ lb.}$$

Ques.—Find the weight of 1 cu.ft. of air fully saturated at a temperature of 65 deg. F. and a barometric pressure of 29 in. The tension of the water vapor, at this temperature (65 deg. F.) is 0.6176 in. of mercury.

Ans.—The weight of 1 cu.ft. of saturated air at the given temperature and pressure is calculated thus:

$$w = \frac{1.3273\ (29.0 - 0.3765 \times 0.6176)}{460 + 65} = 0.0727 \text{ lb.}$$

Ques.—How many gallons of water are carried out of the mine per minute by an air current of 100,000 cu.ft. per min., assuming the temperature of the return air is 70 deg. F., at which temperature the tension of the water vapor is 0.36 lb. per square inch?

Ans.—The weight of water vapor in this return air is

$$w = \frac{0.6235 \times 0.36}{0.37\ (460 + 70)} \times 100{,}000 = 114.46 \text{ lb.}$$

Taking the weight of water as $8\frac{1}{3}$ lb. per gal., the number of gallons of water carried in the return current, in this case, is $114.46 \div 8\frac{1}{3} = 13.735$ gal. per min., or nearly half a barrel of water each minute.

Ques.—Find the weight of 1 cu.ft. of marsh gas, at a temperature of 60 deg. F. and a barometric pressure of 28.6 in.; taking the specific gravity of the gas as 0.559.

Ans.—The weight of 1 cu.ft. of gas is found by multiplying the weight of 1 cu.ft. of dry air, at the same temperature and pressure, by the specific gravity of the gas. It is calculated thus:

$$w = \frac{1.3273 \times 28.6}{460 + 60} \times 0.559 = 0.0408 \text{ lb.}$$

Ques.—Write the chemical equation expressing the complete combustion of marsh gas in oxygen, and state what volume of carbon dioxide is produced in the explosion of 100 cu.ft. of marsh gas.

Ans.—The chemical equation expressing the reaction is

$$CH_4 + 2\,O_2 = CO_2 + 2\,H_2O$$

The coefficient of each term, in this equation, represents the relative volume of the gas concerned in the combustion. Thus, one volume of marsh gas (CH_4) consumes two volumes of oxygen ($2\,O_2$) and produces one volume of carbon dioxide (CO_2) and two volumes of water vapor ($2\,H_2O$). Therefore, 100 cu.ft. of marsh gas will produce 100 cu.ft. of carbon dioxide and 200 cu.ft. of water vapor.

Ques.—How would you proceed to remove firedamp from a section of a mine after an explosion; what dangers would you expect, and how would you overcome them?

Ans.—Before attempting to remove any considerable accumulation of firedamp, the men on the return of the air must be notified and withdrawn from that section of the mine. Under certain conditions where roof falls are imminent, all of the men in that section of the mine should be promptly withdrawn. Guard all approaches to the district by stationing reliable men to prevent anyone from entering that portion of the mine. Select only experienced men, and provide each man with a good safety lamp that has been previously examined. Arrange to increase the circulation in the affected district, as the conditions may require. Approach the trouble from the intake side, and avoid as far as possible being trapped in the gas. Erect the necessary brattices so as to deflect the current of air upon the gas. Allow sufficient time for the air current to sweep away the gas, making occasional tests to ascertain the progress of the work.

The dangers are: The possible ignition of the gas by a defective lamp or otherwise. A possible fall of roof may drive the gas back upon the men, and envelop them in an explosive atmosphere. If poisonous gases are present the men may be overcome by the gas. To avoid these dangers the work must be conducted, as explained, from the intake side, with safety lamps, by experienced men; and ample time must be given for the removal of the gas. The best type of safety lamp must be used.

Ques.—While examining for gas near the roof, if the safety lamp is extinguished without giving any of the characteristic indications of firedamp; what inference would you draw and what would be an approximate composition of the gas?

Ans.—It is possible for the lamp to be extinguished by a body of pure marsh gas (CH_4) given off at the roof; but in that case, the lamp flame, if carefully observed, should give some indication of the gas before being extinguished. Again, it is possible for the lamp to be extinguished by blackdamp, issuing freely from the roof strata and coming probably from an overlying seam that has been previously worked out and abandoned.

It is very probable, however, that the gas in question is a mixture of carbon dioxide (CO_2) and marsh gas (CH_4). Under certain conditions where these gases mix in the strata without being diluted with air, there is produced a firedamp mixture lighter than air but containing sufficient carbon dioxide to make the mixture extinctive. This mixture of carbon dioxide and marsh gas has been termed "flashdamp," for the reason that when a lamp is first elevated into the gas the pure air contained in the combustion chamber of the lamp dilutes the gas, which gives a distinct cap to the flame. But this cap appears for a moment only and is gone, owing to the lamp filling with the undiluted gas, which dims and may extinguish the flame if the lamp is not promptly withdrawn. It is this brief appearance of the cap that has given the mixture the name "flashdamp." By the addition of air the mixture becomes highly explosive, as the proportion of carbon dioxide is insufficient to prevent explosion.

COAL AND COKE NEWS

Washington, D. C.

Orders issued by the Interstate Commerce Commission on Saturday, Feb. 8, have canceled the advanced coal rates which it had been intended by the Atchison, Topeka & Santa Fé R.R. to put into effect from Colorado coal-producing regions to points in Kansas, Oklahoma & Texas. Under the new orders, however, coal rates are allowed to be established from the Walsenburg fields at a figure 10c. higher than the rates from the Cañon City field to the same points in the three states named. This new adjustment will go into effect on Mar. 12.

The commission is following the general policy of keeping coal rates down so far as possible practically everywhere. While it probably has not been more extreme in this matter than it has in regard to other advances on commodities of miscellaneous character, it is a fact that the general policy planned by the commission contemplates the keeping down of rates on staple products which are presumed to have a direct relationship to the cost of living.

In the case of coal it has been strongly desired by the administration that so far as possible everything should be done to keep the product moving steadily to market. That there has been success in this regard is claimed by some to be shown in the fact that the coal-car shortage up to Feb. 1 is reported to the commission to have increased by 1211, notwithstanding that there was an idle-car surplus of 37,260 on the same date, which was an increase of very nearly 9000 cars, as compared with the middle of January.

An advance in coal rates, it is supposed by some members of the commission, would prevent coal from moving to market quite as actively as would otherwise be the case. It is probable that the question of the attitude of the new administration on the freight-rate question generally and particularly with regard to rates on coal and other staples will be one of the first business problems that has to be met after Mr. Wilson is inaugurated.

A New Record of Output

According to information received here by Government authorities, a new record has been set for anthracite shipments in the first month of the year. The shipments in January amounted to 6,336,419 tons, an increase of 572,723 tons over January, 1912. The former record, made in January, 1903, was 5,964,950 tons, or 371,469 tons less than were shipped last month.

The immediate effect of this is shown by an increase of nearly 35,000 tons in the amount of coal on hand at tidewater shipping ports in the last month. On Dec. 31, 1912, there were 340,637 tons on hand. On Jan. 31, 1913, this amount had increased to 375,566 tons.

The Threatened Strike

The threatening developments in the controversy between the railroads and the firemen are causing considerable anxiety in administrative circles because of their dangerous charter and particularly on account of the possibility of their intensifying the coal shortage should matters come to an actual breach.

The fact that Commissioner of Labor Neill, although reappointed by President Taft, has not been confirmed by the Senate is an additional aggravation. If arbitration should be attempted under the Erdman act, the only man available for the service in the Bureau of Labor would be the present chief clerk, G. W. Hanger, who is not considered sufficiently familiar with the task to handle it successfully.

The criticism to which the Erdman act is now being subjected in the present controversy has greatly weakened the demand that that act be so extended as to permit Federal arbitration in cases involving coal-mine controversies.

PENNSYLVANIA

Anthracite

Scranton—Although the colliery engineers employed by the D. L. & W. Coal Co., in the Scranton district, have joined the miners' union, after a one day's strike at eight collieries of the company, it is said that in many instances the engineers will not have to take the oath of allegiance which would call upon them to quit work in case of mine strikes. The engineers have long hesitated about joining the miners' union because of their eligibility under the company's pension rule, which would be canceled if they went on strike or left the employ of the company.

Archbald—Employees at the White Oak Colliery of the D. & H. Co., in Archbald, have gone on strike, alleging that the company is unfair in the distribution of cars, and that certain men are being discriminated against. It is claimed by the miners that contractors in headings and gangways are working six or more men, and that these contractors are being openly favored in the number of cars furnished them.

Ashland—Following a conference of officers of the union and officials of the Reading Coal & Iron Co., 75 miners on strike for over a week because of a checking out system recenly inaugurated, agreed to return to work at Bast Colliery. Instead of the check system obliging all men to report at the colliery office nightly, forcing many of them to walk a long distance out of their way, the company has agreed to place peg-boards at all openings to the mine.

Williamstown—The Williamstown colliery resumed work Jan. 30, after an idleness of one week. The one miner who refused to join the union has quit and the men have returned to work.

Shamokin—Enterprise colliery employees have resolved that they will not work with men who refuse to pay dues to the United Mine Workers' organization. It is feared that a strike may result.

Coal stripping operations are to be started soon at the Alaska Colliery of the Reading Coal & Iron Co., at Shamokin. Two 18-ton locomotives and a 70-ton steam shovel are on the ground ready to begin work.

Hazleton—The boys at the White Ash breaker of the Lehigh Coal & Navigation Co., at Hazleton, have been given a 15 per cent. increase, putting them on equal terms with the No. 6 breaker boys.

Nanticoke—In order to do away with any inconvenience and delay in sending its officers and engineers to the different collieries, the D. L. & W. Coal Co. has installed a new auto bus which will run between Nanticoke and Kingston.

Wilkes-Barre—In addition to the elaborate provisions for rescue and first-aid work now in force in the anthracite mines, the Lehigh Valley Coal Co. is preparing for service a mine-rescue car, which can be rushed at a moment's notice to any colliery in case of accident. This car consists of a remodeled passenger car equipped with oxygen breathing apparatus and every kind of first-aid equipment. It has six Draeger helmet outfits, with the necessary auxiliary equipment, pulmotors, stretchers, blankets, splints, bandages, etc. It will be used as a hospital and ambulance combined, and rushed on call to any colliery where an accident has occurred, by special train service, and manned by a crew of trained helmet men.

Pottsville—To stop annoyance resulting from the numerous petty strikes, the Reading Co. has adopted a new policy. Where such strikes are called the operations shall remain idle until the operators get ready to resume. This rule has gone into effect in several parts of the anthracite region.

Bituminous

Punxsutawney—The Lindsey Coal Mining Co. has bought 250 acres of coal land of the Berwind-White Co., near Punxsutawney, and will make a new opening at once on the Bellwood-Punxsutawney branch of the Pennsylvania R.R. It is expected that this opening will tap nearly 1000 acres and will lead to the mining of nearly a million tons of coal.

WEST VIRGINIA

Bluefield—Twenty-one miners of the Houston Coal & Coke Co. have been arrested by Mine Inspector Nicholson on the charge that they have been shooting off the solid. Twenty of the men were fined $10 each and one was fined $30. It is learned that if this practice is not stopped Mr. Nicholson intends to have the mine foremen prosecuted for allowing the men to make use of this dangerous method.

Charleston—Much interest has been attracted by the introduction of a bill in the House of Delegates, which will

ake the mine owners responsible for deeds of violence committed by guards employed by them.

Reports are current that the town of Acme has been shot o by the striking Eskdale miners. Some rumors say that 500 ots were fired. It is claimed that conditions on Cabin Creek re as bad as they ever were. The mine-guard system is inaming the miners to a pitch where a serious outbreak may ome at any time.

KENTUCKY

Basketts—The breaking of the hoisting cable in the mine f the Pittsburgh Coal Co., at Basketts, Ky., recently imrisoned the entire working force in the mine for four hours. he cage started to fall when the cable broke, but it was topped by the safety catches, and no one was injured. The ccident occurred at 2 o'clock in the afternoon, and it was before the cage was put in working condition.

Whitesburg—It is announced by the Consolidation Coal o. that coal shipments from its plant at McRoberts will soon e doubled, reaching something like sixty cars a day, most f which goes to Northwestern points. The company's mines Jenkins, in the same field, are also making large increases their capacity, and will cut a large figure in swelling the ompany's output.

OHIO

Columbus—The Colonial Coal & Supply Co. has asked the hio Public Utilities Commission to collect $15.70 from the ocking Valley and the Chicago and Erie Ry. companies. The oal company claims that there was a shortage in weight on car of coal shipped from Pomeroy to a customer in Lima. he railroad companies are charged with being negligent in he transportation of the coal resulting in the loss.

A hearing was held recently before the Ohio senate committee on mining, on the anti-screen bill pending in the Ohio gislature. Operators who spoke were C. L. Cassingham, resident of the Coshon Coal Co., of Cleveland; E. M. Poston, the New York Coal Co., Columbus; Edward Johnson, presient of the Lorain, Coal & Dock Co., Columbus. All of the perators were opposed to the bill as unjust in every respect. number of representatives from the miners' union appeared favor of the bill.

INDIANA

Indianapolis—The supreme court of Indianapolis has reersed the decision of the appellate court and the Greene unty circuit court and holds that coal in the ground and ld is taxable although it is not connected with an open al mine This decision was handed down in the case of the reene County officials against the Lattas Creek Coal Co.

The court thinks that after a farmer has sold the coal der his property he should no longer be compelled to pay xes on it. These taxes should be paid by the persons who ught and own it.

Fort Branch—Two shotfirers were recently killed in an plosion in the mine of the Fort Branch Coal Mining Co., by "windy shot" caused from the clay placed around the arge not being packed tightly enough. Horace Dewees and illiam Bush were the names of the men, who went into the ine after the otner men had left, in order to shoot down al for the next day's work. The first shot caused their ath. The mine-rescue car from Evansville, Ind., was sent r, but no great damage was done to the mine, and the bodies ere removed by volunteers from among the miners employed the company.

ILLINOIS

Lincoln—A pocket of gas was set off, Feb. 1, by the lamp an electrician in the Latham coal mine. Two miners were lled and thirty were imprisoned. Three hundred were in e mine.

MISSOURI

Rolla—The State Bureau of Geology and Mines has just sued a report showing that the annual coal production for e state of Missouri reaches 4,000,000 tons. The productive ams vary from 18 in. to 5 ft. in thickness.

NORTH DAKOTA

Grand Forks—Thousands of tons of coal are being conmed in North Dakota by fires which are burning in undeloped mines. It is expected that action will be taken by e state legislature to halt this destruction of the nation's sources.

FOREIGN NEWS

Nagasaki, Japan—One hundred and fifty coal miners were tombed, Feb. 6, by an explosion in a colliery near Fukooka. tle hope is entertained for their rescue.

PERSONALS

General Superintendent Thomas R. Evans, of the Parrish Coal Co., has tendered his resignation.

D. A. Thomas, who has been visiting various coal properties in this country, and whose home address is Cambrian Building, Cardiff, Wales, sailed for home Feb. 11.

Chas. Dorrance, hitherto fuel engiher of the Lehigh Coal & Navigation Co., has been made chief mining engineer for the same company, having superintendence of the mining and mechanical departments.

Judge George Gray has appointed Charles P. Neill, United States Commissioner of Labor, as referee in three cases which the Board of Conciliation was unable to settle.

Clinton Neyhart, weighmaster at No. 3 D. & H. Colliery, has been appointed outside foreman at the Boston Colliery of the same company, to succeed William Steevers, who was transferred to No. 2 Colliery.

It has been announced that T. K. Jenkins, formerly purchasing agent of the Durham Coal & Iron Co., at Chattanooga, Tenn., has been appointed chief clerk to the assistant to the president of the Davis Coal & Coke Co.

Robert W. Johnson, for 10 years sales manager of the Ottumwa Box Car Loader Co., has accepted the general managership of the United States Coal Co., at Kemmerer, Wyo. This company has a plant with a daily output of 2500 tons.

E. T. James, superintendent of shops of the Lehigh Coal & Navigation Co., has resigned to become an assistant of Charles A. Straw, his former chief. His place is to be filled by Joseph Williams, hitherto general foreman of shops. Albert Leonarz is made assistant master mechanic in charge of the electrical department.

At the annual meeting of the stockholders of the Red Ash Coal Co., Woodward Leavenworth, John N. Conyngham, William H. Conyngham, G. Frederick Parrish and Edgar R. Reets were elected directors. The officers elected are: Woodward Leavenworth, president; G. Frederick Parrish, vice-president and treasurer; Walter Roberts, secretary.

OBITUARY

John Fritz, mechanical and mining engineer, born in Londonderry Township, Chester County, Penn., Aug. 21, 1822, died at his home in Bethlehem, Penn., Feb. 13, 1913.

His early boyhood was spent upon his father's farm, where he received what education the local school afforded. At the age of 16, Mr. Fritz became an apprentice in a machine shop; later on entering the employ of the Moore & Hoover Iron Works. It was here that he perceived the immense possibilities in the iron industry.

From the Moore & Hoover Iron Works he went with the Morristown Iron Works and later the Cambria Iron Works, at Johnstwn, Penn. While here he revolutionized the iron-rail industry, securing a better product with four-fold greater capacity of the mill, thus enabling American manufacturers to compete with those of foreign countries.

About this time he perfected blast-furnace practice. In July, 1860, he began service with the Bethlehem Iron Co. as general superintendent and chief engineer. While here he greatly assisted in perfecting the bessemer process of steel manufacture, and also in remodeling and improving the Siemen-Martin openhearth process.

Turning his attention to the production of steel plates and structural shapes, he designed mills and rolls superior to any then on the market. When the problem of making armor plate arose, he originated the solid steel plate, the superiority of which still remains unquestioned.

He took a great interest in Lehigh University and recently presented that institution with a laboratory.

The engineering profession has lost one of its great members—one who was associated with all of the principal engineering societies both in this country and abroad, which vied with each other in doing him honor. Engineers and scientific men throughout the entire world will mourn the loss of "Uncle" John Fritz, as he was familiarly called, whose name will be forever associated with the growth and development of the American steel industry.

BOOK REVIEW

BOOK OF STANDARDS. National Tube Co., Pittsburgh, Penn. 559 pp.; 4x6½ in.; leather bound, about ⅝ in. thick. Price, $2.

This is strictly a handbook devoted to pipe and allied products. Much valuable information bearing on subjects which may appear to be but remotely connected with the main theme of the work are concisely treated. Among these might be mentioned the Pitot tube, the Venturi meter, the mechanical properties of solid and tubular beams, boiler incrustation and corrosion, the properties of saturated steam, etc., etc.

Not the least valuable part of the contents is a glossary of terms used in the pipe and fitting trade. To the man unfamiliar with these and particularly to the technical student or recent graduate, this glossary alone is worth the price of the volume.

The compilers of this work express themselves as being of the opinion that it contains a greater amount of information in regard to tubular products than any other similar work of this character. We think that we can honestly concur with them in this belief.

ANNUAL REPORT, DEPARTMENT OF PUBLIC WORKS OF THE PROVINCE OF ALBERTA. 1911. 242 pp., 6½x10. Paper.

This pamphlet, as its title suggests, contains more than mining reports. It covers bridges, ferries, roads, architecture, building, steam boilers and telephones. The mining section is spread over 95 pages. It states that whereas in 1910 there was one life lost for 49,783 tons of coal mined; in 1911, 242,080 tons were extracted for each fatality.

It seems to be easier in Alberta to secure conviction of violators of the mining code than in the United States. Seven persons were fined an aggregate of $110, and paid costs amounting to $31.25. One case was dismissed. Two managers, three firebosses and two miners were convicted. All prosecutions were instituted by the mining department.

The Bellevue explosion is detailed at some length in this report. The inspector states that telephones are being installed in nearly all the mines in accordance with the suggestion of the coroner's jury, impaneled after that disaster. An arrangement is being made to ventilate the completed sections of the Bellevue mines by frequent openings to the surface, and instructions have been given the West Canadian Collieries Co., Ltd., that no further pillars may be drawn until a sufficient number of crop holes have been made where these pillars are to be extracted.

The examination questions for mine managers, "pit" bosses and firebosses are given in full, as are also the wages for all employees. Outside workers labor 10 to 12 hours, and those underground for 8 hours only.

CONSTRUCTION NEWS

Fall River, Mass.—The Fall River Gas Works Co. is making plans for a $500,000 coal gas works at Birch and Bay Sts.

Earlington, Ky.—The St. Bernard Mining Co. has installed at its coke ovens a 20-in. rubber belt conveyor for carrying coal to the washer.

Rankin, Ill.—The new $12,000 coal dock of the L. E. & W. has been completed. It is built entirely of steel and is run by a 12-hp. gasoline engine.

Centralia, Ill.—Chicago capitalists have secured a large acreage of coal land in the Zeigler district and will put up a modern colliery during the summer.

Albion, Mich.—Albion's coal mine will soon be in operation, provided high water does not interfere with the work. The shaft has been sunk 66 ft. and is now within 6 ft. of the coal.

Honesdale, Penn.—The D. & H. Co. are soon to build a washery between Honesdale and Waymart for the purpose of cleaning up the coal and culm dumps along the line of the old gravity road.

Holt, Ala.—The Central Iron Co. has broken ground for 20 more ovens, thereby increasing its byproduct plant capacity 50 per cent. The company recently completed a blast furnace at a cost of $325,000.

Schafer, N. D.—Beds of lignite will form the foundation for the new line of the Great Northern Ry. through this section. In some places the track will be built on a continuous seam of lignite. Most of this fuel which has been blasted out will be wasted.

Monongahela, Penn.—A corps of engineers under the direction of George B. Eaton is making surveys of the Charleroi coal properties sold recently to the Carnegie Coal Co. As soon as the surveys have been completed work of improvement will begin.

Uniontown, Penn.—Engineers for the W. A. Stone Coal & Coke Co. have been making surveys on the company's property near Maidsville Landing, on the west side of the river. It is stated that the surveys are preliminary to the opening of mines. The company owns 350 acres at that point.

Whitesburg, Ky.—It is announced that an eastern syndicate has bought the Sam J. Wright and John Osborne tracts of coal and mineral land, consisting of about 1200 acres. Early development is planned. A 4-mile branch railroad from the main line of the Lexington & Eastern will be constructed at once.

Battle Creek, Mich.—The big 10,000-ton coal pocket at the Commonwealth Power Co.'s plant has been completed. The coal stored in this pocket will be kept under water in order to avoid fire and explosion hazards. The sidetrack, which is being constructed to the plant by the Michigan Central, has not yet been completed.

Altoona, Penn.—Actual work has been started to transform the old Wopsy road into the Altoona-Northern line. The new road will extend from Altoona to Patton, a distance of 20 miles. The line will be designed for both steam and electric power and will carry passengers by day and coal by night. At Patton connections will be made with the Northern Cambria Ry. The company is capitalized at $750,000.

Mobile, Ala.—Information has been received that the first barge of the New Orleans & Mobile Transportation Co. will be launched about Mar. 15. The announcement is received with great satisfaction by those who are interested in the Warrior coal fields. Boats of the company will make points between Mobile and New Orleans wherever tonnage is offered in sufficient quantity to warrant. The company was organized for the purpose of developing the Warrior coal field.

NEW INCORPORATIONS

Toronto, Can.—The North Alberta Coal Co.; capital stock, $2,000,000.

Louisville, Ky.—The Purity Coal Co.; capital stock, $8000. Incorporators: A. H. Gardener, R. H. Tydings and J. T. Gardener.

Little Rock, Ark.—The Arkansas Anthracite Coal Co.; capital stock, $100,000. Incorporators: W. H. Barrett, T. M. Barrett and W. H. Barrett, Jr.

Greensburg, Penn.—The Greensburg Coal & Coke Co.; capital stock, $200,000. Incorporators: Alexander Coulter, H. W. Coulter, W. A. Coulter and Margaret Coulter.

Danville, Ill.—The Two Rivers Coal Co.; capital stock, $100,000; general coal and lumber business. Incorporators: R. H. Sherwood, W. C. Hartshorn and J. W. Hegler.

Chattanooga, Tenn.—The Paint Rock Consolidated Coal Co.; capital stock, $50,000. Incorporators: J. R. Barnes, H. B. Bonney, W. B. Garvin, J. E. Patton and G. M. Price.

Mann, W. Va.—The Kistler-Schuler Coal Co.; capital stock, $50,000; to develop coal properties. Incorporators: J. F Kistler, Grace Kistler, E. J. Schuler, J. F. Schuler and S. A. Schuler.

Cambridge, Ohio—The Economic Coal Co.; capital stock, $10,000; to mine and deal in coal. Incorporators: C. B. McCoy, J. L. Secrest, J. A. Thrasher, Homer Whitten and F. W. Tobin.

Charleston, W. Va.—The California & West Virginia Lumber & Mining Co.; capital stock, $3,000,000; to produce lumber mine and market coal, iron and other minerals and ores, together with oil.

New York, N. Y.—Plans have been completed for the consolidation of the Burns Brothers and the Curtis-Blaisdell Co. The new firm will be known as the Burns Brothers and will be capitalized at $2,000,000.

Fairmont, W. Va.—The Ross Coal Co. capital stock, $75,000; to carry on a coal mining and real estate business. Incorporators: C. E. Hutchinson, C. H. Jenkins, E. C. Curry, R. A. Johnson, and H. M. Pierpont.

Charleston, W. Va.—The Argyle Coal Co.; capital stock, $50,000; to do a general coal and mining business and deal in

real estate. Incorporators: W. H. Thurmond, T. H. Hooper, E. J. Payne, G. M. Jones, and A. W. McDonald.

Ashland, Ky.—The Elk Horn Fuel Co.; capital stock, $150,000; to do a general mining business and acquire real estate and mineral lands. Incorporators: R. D. Davis, Jr., J. S Hager, K. M. Fitzgerald, Thomas Boggess, Jr., and W. P. Wheeler.

Canal Fulton, Ohio—The Fulton Pit Car Co., of Canal Fulton, Ohio, has been incorporated with a capital stock of $100,000 to manufacture mine cars and deal in iron and steel products. The incorporators are E. J. Nichler, E. E. Shilling, C. A. Vanderhoof, A. H. McCadden and George Fellmeth.

INDUSTRIAL NEWS

Elys, Ky.—The Camp Coal Co. has increased its output to 200 tons per day. H. N. Camp is general manager.

Pueblo, Colo.—The Royal George coal mine is now working on a larger scale than ever and is employing several hundred people.

Clinton, Ind.—Now that the waters of the Wabash are receding it is the hope of the management of the Lyford mines that work can soon be resumed.

Waynesburg, Penn.—Dr. J. C. McClenathan has purchased the West Aberdeen Coal Co.'s property and is now repairing mines with a view to putting them in operation.

Connellsville, Penn.—The Mahoning plant of the Cambria Steel Co. has been sold to J. M. Gray and K. K. Kramer, of Connellsville. The 82 ovens will be fired within two weeks.

Pekin, Ill.—Coal has been found on the farm owned by George W. Cunningham, 4 miles north of here. The quantity of the find is not known, but men are at work to determine it.

Providence, R. I.—At the annual meeting of the Portsmouth Coal Co., which was formerly the Rhode Island Coal Co., the stockholders voted to continue the development of the property.

Pittsburgh, Kan.—The Missouri, Kansas & Texas R.R. Co. has just completed taking options on coal leases on 20,000 acres of land in Grant Township, on the west border of Crawford County.

Jasper, Ala.—The gas development in Walker County is assuming greater proportions. The Pennsylvania Gas & Oil Co. has enlarged its working capacity and is beginning to bore for gas and oil in additional fields.

Kansas City, Mo.—The possibilities of large coal deposits as yet untouched in the Ozark regions will be investigated by a party of Eastern capitalists. Recent small finds have been made in the country near Gretna, Branson and Hollister.

Saline, Ia.—Drilling operations have been resumed after a suspension of about 8 months. In case anything valuable is found a company will furnish funds for further testing. In case a general field is indicated by the test drilling a shaft will be sunk.

Bartlesville, Okla.—A coal company, recently formed in Wann by B. W. Mizer and D. W. Bunnell, has leased a tract of land 2 miles south of town and has begun operating their mine. The seam crops out at a creek, is of good quality and is 15 in. thick.

Connellsville, Penn.—J. E. Barnes, of Pittsburgh, has secured options on 2500 acres of coal land in Whitely Township at $400 an acre. It has been reported that he secured the options for the Pittsburgh Coke & Coal Co. The options extend for 90 days.

Chicago, Ill.—The strength of the Colorado Fuel & Iron preferred stock, which has advanced to 155, is taken in some quarters to foreshadow a substantial payment on accumulated back dividends. This year's earnings are at about the same rate as last year's.

Moline, Ill.—The old Sackville coal mine which was abandoned some years ago is to be reopened. There is plenty of coal, left in the field and good management is all that is needed to make it a paying project. It has been secured by Sievers & Sommerson.

Petersburg, Ind.—The miners at the Hammond coal mine have found a vein of lead or bismuth embedded in the center of a 6-ft. seam of coal. The vein is about 3 in thick, but no estimate can be made as to how far it runs. Samples have been sent to the assay office.

Cañon City, Colo.—The coal mines of Fremont County are in a prosperous condition and are working better than they have for months. One mine official states that there are sufficient orders now booked by the Victor American Fuel Co. to the mines and putting them in operation.

Lewis, W. Va.—Owing to the abandonment of the Lynch mine the Consolidation Coal Co. has removed its store to the Two Lick mine. The Lynch mine was opened in 1878. It was first made a modern mine by the Hutchinson Coal Co. and was then sold to the Consolidation company.

McRoberts, Ky.—The Consolidation Coal Co. announces that this plant will double its capacity. They expect to ship from 20 to 25 cars a day. The plant at Jenkins is also expected to make an increase. Thousands of men are now employed at the mines at McRoberts and Jenkins.

Tuscaloosa, Ala.—Certain Florida men have purchased 320 acres of coal land at Shira's Station. This land contains two fine seams of coal which is considered to be the best in the country. The purchasers expect to ship much of the coal which they mine. The property is situated near the Warrior River.

Steamboat Springs, Colo.—Graders on the Moffat Road extension have struck sufficient coal to last the road for years, 12 miles below here. The seam is 4 ft. in thickness and the coal is being thrown over the dump by the graders. M. A. Wogan, the Denver contractor, has charge of the construction work.

Cheyenne, Wyo.—John Skinner and son have been working all winter opening a seam of coal which they discovered on Badwater. They expect to get into the best coal within a few days and are contemplating putting it on the market as soon as they have the mine sufficiently developed to warrant hauling the coal to town.

Waynesboro, Penn.—Dr. J. C. McClenathan has purchased from W. F. Patterson 1500 acres of coal land located in Monroe County, Ohio. The amount involved in the transaction was $100,000. The new owner has not given out any plans he may have in regard to the property but it is understood that he bought it as a speculation.

Howe, Okla.—It is stated on good authority that the Southwestern Tennessee Iron & Coal Co. has purchased all the mines of the Rock Island R.R. from Hartford to McAlester. This means the opening of new mines and the working of the old ones, together with a demand for men. The properties or leases are valued at $3,000,000.

Connellsville, Penn.—A company of eastern capitalists who own about 7000 acres of mineral land in the vicinity of Kingwood have been drilling test holes on their property. Results show that the land is underlaid with a seam of excellent steaming coal varying in thickness from 54 to 62 inches. Analysis shows this coal to be of superior quality to that of the Humbert field.

Cincinnati, Ohio—Arrangements are being completed for the issuance of $10,000,000 convertible 6 per cent. notes by the Consolidation Coal Co. This new financing has become necessary owing to the great growth of the company. Of this issue $6,000,000 is to be sold at once and the proceeds used to continue the development of the company's coal lands in Kentucky, and otherwise enlarging facilities.

Racine, Wis.—The Racine Gas & Electric Co. of Racine, Wisconsin, have placed an order with the Roberts and Schaefer Co. for a large coal-dock bridge for the storing of coal at Racine and the handling of same mechanically. Contract price approximately $75,000

This company has also secured a contract this week from the Alpine Coal Co., Ottumwa, Iowa, for a complete coal mining plant at the point

Colorado Springs, Colo.—Alex Patterson has opened up what is said to be the finest bed of lignite ever discovered in this state. This strike confirms the belief of the experts that the land immediately north of here is underlaid by coal deposits.

Patterson has opened up a seam 11 ft. thick, which apparently extends over several hundred acres, at a depth of 371 ft. The value of the find is estimated at $1,000,000.

Columbus, Ohio—The Kilbourne & Jacobs Mfg. Co., of Columbus, Ohio, in the annual report recently issued shows a fine year in every respect. The company is preparing to put on the market a new kind of mine car which is intended for slope mining. At the annual meeting James Kilbourne was elected president, Felix A Jacobs, first vice-president, James R. Kilbourne, 2d vice-president and general manager, F W Hubbar, secretary Frank C Eaton, treasurer and Joseph B. Potter auditor Lincoln Kilbourne was elected assistant general manager

COAL TRADE REVIEWS

GENERAL REVIEW

The continual rather cold or stormy weather over the last two weeks has had a mildly stimulating affect on the demand for hard coal. This has not materially aided the situation, however, as this demand has been concentrated entirely on one or two sizes already in short supply; these are pea and stove, the only two grades for which there is any sustained demand, and the former is the only one which now brings a ready premium. Substantial concessions on the regular circular are easily obtainable, and the individuals are creating a market by their usual methods of price cutting. All sales departments are actively seeking orders. The current month will no doubt see the smallest production in the anthracite field since May of last year, at which time the suspension in mining was brought to a close.

Contracting is the only feature of interest in bituminous circles at the present time. It is rumored that a considerable volume of the Eastern contracts are being closed at a small advance over last year's figures, and with the usual protection being guaranteed against a declining market. This applies more particularly to the Coastwise situation, few all-rail contracts having been placed so far, most operators apparently waiting action by the larger producers. In spite of the abrupt change in weather conditions, there is little demand except on contract. The movement is rather light, and prices low, with buyers showing no interest whatever in the market; there are, however, fair tonnages moving on contract.

The market in the Pittsburg district is now feeling the effect of the long period of mild weather, which greatly increased the production at the mines, and at the same time curtailed consumption; there is little active negotiating on season contracts, buyers evidently doubtful if the new prices will be maintained. At Buffalo the abrupt drop in temperature occurred at the crucial stage, and turned what might otherwise have been a disastrous slump into a fairly active market.

The change in weather conditions also brought an immediate increase in the orders for domestic coal in Ohio. This, together with the heavy steam consumption, has materially stimulated the market, although not sufficient to affect prices. The indications are for a thoroughly good business the balance of the season, and the operators are optimistic. The feature of the Southern market is a rumor to the effect that there will be a general advance on the Cahaba domestic grades, to take effect March 1. There is a tendency in this district to shade prices on the steam sizes in order to secure good business, but otherwise quotations will remain unchanged.

Colder weather has caused an increased consumption, and a rather unsettled feeling in the Middlewestern trade; however, the heavy overproduction is still tending to keep prices down. In the Northwest cold weather has made a decided change for the better, although the domestic grades continue weak. The dealer's stocks are still quite heavy, and some cancelations of orders are coming in, while others are being held up.

BOSTON, MASS.

A week of continuous cold has served to steady the market, but neither bituminous nor anthracite can be said to be at all active. Sales are few and prices are no higher than a week ago; it is simply that the downward tendency has been checked for the time being. There is ample coal at the Hampton Roads piers and what transportation reports is loaded promptly; a liberal share is going off-shore.

Contract business has already been closed in considerable volume, but only by two or three of the Southern shippers. The prices are understood to be slightly in advance of the figures for 1912 but as usual protection is guaranteed against a declining market. It is the usual straining to get business covered. Meanwhile, spot coal, Pocahontas and New River, is being sold down to $2.70 f.o.b. and even less.

All-rail there is nothing new. Buyers generally have lost interest in the current market, if indeed there can be said to be any, and prices are on last summer's level. There are the usual signs of campaigning for contracts but little is heard of actual sales being made. Most of the operators are marking time to see what position is to be taken by the larger producing companies. Cars are in much better supply and the movement is so good that cancelations, rather than orders, are the rule just now.

Individual hard-coal operators had a taste of lucrative business for a few months but now they are offering coal broadcast at prices well under the company circular. Not much of it is likely to reach New England, however, for the rates on company transportation are likely to exclude outside shipments at market freights. On Long Island Sound the margin between the company rate of 40@45c. and the market rate of 45@50c. is so small that some individual coal is still being received, but mostly on old purchases. All-rail anthracite is almost certain to be stirred up more or less by offerings of independent coal right through the season. The sales departments of all the companies are actively out for orders now and February is sure to be the lightest month for tonnage since May. Egg is still the long size, and stove and pea are again coming into supply so that free shipments of those sizes are beginning to be made.

Current wholesale quotations are about as follows:

Clearfields, f.o.b. mine	$1 20@$1.35
Clearfields, f.o.b. Philadelphia	2 45@ 2 60
Clearfields, f.o.b. New York	2 75@ 2 90
Cambrias, Somersets, f.o.b. mines	1 30@ 1 45
Cambrias, Somersets, f.o.b. Philadelphia	2 55@ 2 70
Cambrias, Somersets, f.o.b. New York	2 85@ 3 00
Pocahontas, New River, f.o.b. Hampton Roads	2 70 and less
Pocahontas, New River, on cars Providence	3 85@ 4 00
Pocahontas, New River, on cars Boston	3 90@ 4 10

NEW YORK

Bituminous—In spite of a week of severe winter weather the soft-coal market has fallen off still further. Prices on all grades have receded sharply, the off qualities suffering particularly. Conditions now, however, are only about what was ultimately to have been expected in view of the abnormally open winter up to the first of the current month. As a result of this, production in the mining regions was greatly facilitated, while on the other hand consumption was correspondingly curtailed. Consumers have naturally accumulated substantial surpluses, and in the face of these conditions a reversal of form was inevitable. The abrupt change in weather conditions had a steadying influence on the trade, and while essentially weak it cannot by any means be considered down to a low level.

There is little or no activity in contracting for the new year. Because of the unsettled conditions in the spot market, consumers are holding off in the hope that the present slump will see prices forced to a low level; such a condition would, of course, have a detrimental effect on contract figures. Prices on both the hard and soft coal have suffered a more or less general reduction on all grades, and the market is now quotable on the following basis:

	Anthracite		Bituminous
	Circular	Individual	
Broken*	$4.50	5.00	West Virginia, steam $2.65@2.75
Egg	5.25	4.75	Fair grades, Penna... 2.75@2.85
Chestnut†	5.25	5.25	Good grade, Penna.... 2.90@3.00
Pea*	3.50	3.75	Best miller, Penna.... 3.05@3.15
Buckwheat**	2.75	3.70	Georges Creek..... 3.25@3.30
Buckwheat†	2.45	2.55	
Rice**	2.25	2.25	
Rice†	1.95	1.80	
Barley†	1.75	1.10	

* Scranton and Lehigh. ** Scranton. † Lehigh and Schuylkill.

Anthracite—The advent of more seasonable weather conditions failed to have any very stimulating affects on the hard-coal market. All sizes are in free supply and can be obtained in any required tonnages promptly. Egg is quite long, and concessions under the circular are being freely offered; nut is in fairly good demand, while stove and pea are the two short grades in the market, the latter being the only one to command a ready premium. Buckwheat is plentiful, while the same applies to barley, but there is a fairly persistent demand for rice.

There is but little doubt that substantial surpluses have been accumulated, and many dealers will not require any additional shipments until after the summer reduction in the circular goes into effect Apr. 1. The week of cold weather the first of the month helped the speculative coal to a cer-

tain extent, but it was not of sufficient duration to do more than check the slump, temporarily. Operators agree that nothing less than two or three weeks of continuous severe weather will save the situation for them.

PHILADELPHIA, PENN.

There has been a continuous run of cold weather for the last week or ten days, but while it has stimulated trade to a certain extent, the demand has been concentrated on sizes which were already short. The demand for egg coal seems to have fallen off altogether, and some dealers report that chestnut is rapidly going the way of egg. Stove and pea coal seem to be the only sizes for which there is any sustained demand, and for these the dealers are having to depend on current receipts. From now on until the spring or opening prices are announced, there is hardly likely to be any great movement of the egg and chestnut sizes, and it is understood that some of the large companies are putting some of the former size into stock.

The individuals are creating a market by their usual methods—quoting prices which dealers cannot very well overlook. This has been continuing for several weeks now, and it is only by working the lever of stove and pea that the large companies are able to work off any of the egg size at all. Of course, the production of the stove and pea sizes is limited, and with the demand as it is, there is some little premium pea coming to the market that is disposed of without trouble, but stove is at circular, and likely to remain there. The steam market is not particularly good, although it is understood that there is a fairly good movement of buckwheat. This grade is gradually falling into the domestic class, large quantities being used for both ranges and furnaces in the smaller residences.

The bituminous market is anything but favorable at the present time. Prices as well as the demand are off, although the figures secured now compare more than favorably with those being received late in the fall of 1912, but the operators do not seem at all pleased with the situation. Complaints are general that this branch of the trade has been infected with the apathetic condition of the anthracite trade, and a cure for one will bring the other back to normal.

PITTSBURGH, PENN.

Bituminous—The market has continued rather dull, and is feeling the effects of the open weather so long prevalent, encouraging production and curtailing consumption below expectations. The prompt market is dull, except that there is slightly improved demand from retail dealers. While there are inquiries against contracts to begin Apr. 1, there is little active negotiating, and buyers are evidently in doubt whether the advanced prices for the season will be maintained. The prompt market in the past few weeks has been on the contract basis, except for slack, which commanded premiums, although for prompt shipment it has now dropped to the contract level. We continue to quote: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in., $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—The prompt coke market continues to slump, and contract coke, while not definitely quotable in the absence of sales or active negotiations, may be considered as having declined equally. In the past few days standard grades of furnace coke for prompt shipment have sold at $2.50, and it is doubtful if above that figure has been obtained within a week, while it is possible the price has been shaded. The total turnover has been very light. This makes a total decline in prompt furnace coke of fully $1.50, all occurring in less than 30 days. Contract coke, while not closely quotable, can hardly be considered as above prompt, which would make a decline in contract of $1, since $3.50 was the minimum quotation on first-half, and was actually obtained in two or three instances. We quote: Prompt furnace, $2.50; contract furnace (nominal), $2.50; prompt foundry $3; contract foundry, $3@3.25, per ton at ovens. The slump in prices has now reached such proportions that curtailment in production will undoubtedly occur. This will be particularly with respect to off grades, which found a market during the scarcity, but can hardly be sold now at any figure.

BALTIMORE, MD.

In spite of a decided change in weather conditions during the week, there was but little demand for fuel, except on contracts. Prices were weak, steam coal being quoted around $1@1.10, while run-of-mine sold at 90c., with but few consumers interested. The movement from the mines to tidewater was light due to a lack of cars. A number of additional contracts were renewed during the week, at an advance from 8 to 10 per cent. in the price as compared with last year.

B. Nicoll & Co., selling agents for the Pittsburgh Terminal R.R. & C. Co., recently forwarded their first shipment of Pittsburgh gas coal to Spain. Early in the week, 6700 tons were loaded on the "Volnay," destined for Valencia, Spain, and about 6000 tons will be shipped this month. The coal is from the new mines opened by the Pittsburgh Terminal R.R. & C. Co., located on the West Side Belt R.R., in the Pittsburgh district.

BUFFALO, N. Y.

The sudden cold turn on the opening of February saved the local bituminous market from a bad slump. Prices had become weak and there was report, as usual at such times, of considerable coal offering at sacrifice prices, but the temperature dropped 40 deg. at the crucial point and the market began to right itself. The railroads, which had been delivering coal at a rapid rate also fell down at this time, which further strengthened the market. In a short time coal began to pile up at terminal points, especially if destined for Canada; embargoes were issued against several trunk roads and the Grand Trunk embargoed itself by refusing coal. The last active Lake Erie ferry began to freeze up with 600 cars of coal waiting for it, and Canadian coal consumers became anxious, especially after it began to snow.

It would be hard for bituminous prices to go down after such conditions had set in and it is quite possible that the market may stiffen up soon. This uncertain condition of the market creates some uneasiness as to the prices likely to be obtained for spring contracts; predictions differ 15c. to 20c., and it is quite possible that as much variation as that may be the case. It is known that contracts already let have varied more as a rule than usual. Pittsburgh lump is quotable at $2.75, three-quarter at $2.65, mine-run at $2.50 and slack at $2.40, with best Connellsville foundry coke down to $5.50. There is no change in cannel or the smithing coals, as they are not commonly affected by the fluctuations of ordinary bituminous.

The demand for anthracite has been easy of late, on account of the mild weather and the return of snow has not firmed it up much. Retailers say that a great part of the supply bought early is still unused and there is now talk of a short winter, even though February is severe, so that buying is not likely to be heavy, unless the cold weather runs quite late, as it did last year.

COLUMBUS, OHIO

Lower temperatures which prevailed during the past week were almost immediately reflected upon the coal trade in Ohio by a large run of orders for domestic grades. This, coupled with the larger steam tonnage required, stiffened the market perceptibly, but not sufficiently to advance the price list. Coal men are content that prices did not go lower and believe that there are indications of a better trade from this time on.

Dealers who had rather large stocks during the winter months and were unable to dispose of them are now placing orders with the operators and jobbers and are asking for immediate delivery Factories are also taking more fuel and the large apartment houses and office buildings are buying better. Operators believe that prices will remain at the present level until late in the summer as it is too late for rush of orders to have any great effect upon quotations.

Operations in the various mining districts of the state have been more active during the week. The Hocking Valley probably received the greatest benefit although an increase is reported from eastern Ohio and the Pomeroy Bend. The indications are very bright for an active lake season during the present year and the larger shippers are making preparations accordingly.

Operators are preparing for a good Lake trade, despite the soft winter weather which has prevailed so far in the Northwest. The supply on the docks is not large, and as a result shipments via the Lakes will probably be heavy. Arrangements are already being made for chartering vessels, and it looks like there will be a scarcity of bottoms.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawah
Domestic lump	$1 50	....	$1.65	$1 50
3-inch	1.30	$1.20	1.35	1.30
Nut	1.45	....	1.35	....
Mine-run	1.20	1.05	1.20	1.15
Nut, pea and slack	1.10	..	1.10	1.05
Coarse slack	1.00	0.95	1.00	0.90

CLEVELAND, OHIO

The sudden change to winter weather put new life in the coal trade here, and prices on slack advanced 5 to 10c. a ton. The final arrival of real winter caused a feeling of comfort to shippers, and they look for a strong market during the balance of February. While reports indicate that all

manufacturing plants are operating full capacity, line trade and the spot demand have slightly diminished and shipments are largely made on contract business.

The transportation of coal has been remarkably good since the first of the year and consumers report deliveries arriving with a good degree of promptness.

Coal men are in the market for all available vessel-tonnage for the coming season of navigation on the Great Lakes; 1,000,000 tons is already under contract for delivery to principal Lake Michigan Ports at 35c. per ton, which is an advance of 5c. over last season's rate. Contracts are made subject to price adjustment, but with the demand for ore and grain tonnage, vesselmen believe that 35c. will be the established price this year. Vessel men are satisfied with the 30c. rate to Lake Superior and have placed approximately 5,000,000 tons under contract for shipment to the head of the Lakes.

Quotations per short ton f.o.b. mines are as follows:

District.	Freight rate	¾-in.lump	Mine-run	Slack
Youghiogheny	$1.00	$1 40	$1 30	$1.00
Pittsburgh No. 8	0.90	1 20	1 10	1.05
Goshen No. 6	0.70	1 35	1 25	1.15
Coshocton	0.70	1 75	1.50	1.15

BIRMINGHAM, ALA.

The most interesting feature of the current week is the rumor that several of the mines producing Cahaba domestic coal will increase their prices beginning with the month of March. Some of the leading companies are now quoting $2.50 f.o.b. mines, for March and April shipment as against $2.25 for the same months in 1912. This is an increase of 25c. per ton and if adhered to during the remainder of the year, it will place the maximum price for the winter months at $3.25.

Some winter has appeared, but it has not stimulated the market except in retail trade. A slight weakness is apparent in the steam market, there being a tendency to shade prices in order to hook desirable business. The coke market is unchanged.

LOUISVILLE, KY.

There is ample production of coal at the mines, plenty of cars available, and there are no impediments to traffic, but the temperature is such that the average citizen does not find it necessary to heat his residence and the wheels of industry are threatened with paralysis by reason of a lack of demand.

As a consequence of this condition, summer prices are prevailing, insofar as any quotations at all are to be had. However, many operators have practically withdrawn from the market, believing it to be useless to attempt to sell coal by cutting the prices, especially in view of the possibility of more severe weather later on. Some Indiana coal is coming into this market for steam consumption, because of the vastly reduced output of these grades in all sections of Kentucky.

The Monongahela River Consolidated Coal & Coke Co. reports that business has been fairly active on domestic grades, although this demand is merely the accumulation of an abnormally light run of orders during the high-water period. This company has recently put into effect a price of 8½c. a bushel on Pittsburgh, a substantial reduction from the price of 10c., which has prevailed through the winter.

DETROIT, MICH.

Bituminous—The unexpected cold weather has made a decided change in the local coal situation. Domestic trade still seems to be the weakest factor. Retailers' stocks are heavy and they are not inclined to place new orders while those for delivery the early part of January are being canceled or held up. However there does not seem to be the amount of domestic on track that there was a week ago which has a tendency to strengthen the market. The demand from many factories is holding up well and railroads are also taking large tonnage.

Prices for mine-run and slack are probably the strongest points in the market. Most of the West Virginia districts report less than 50 per cent. of normal capacity while in strictly domestic fields the production was even lower.

The prevailing market prices for today are as follows:

	W.Va. Splint	Gas	Hocking	Cambridge	Ohio No. 8	Pocahontas	Jackson Hill
Domestic lump	$1.65		$1.80			$2 00	$2.25
Egg	1.65		1 80			2.00	2.25
Nut	1 35		1.50			...	...
¾ lump	1 10	$1 15	1 15	$1 15	$1.15	...	...
Mine-run	1 00	1 00	1.00	1 05	1.05	1 35	
Slack	Open	Open	1 05	1.05	1.05	Open	

Anthracite—The demand for hard coal has been unusually heavy. The cold weather has drained the supplies of all the large wholesalers, so that the consumers are again demanding great quantities. The premium is now about 25c. above circular, but should these conditions continue for some time dealers will be paying more than a dollar above circular again.

MINNEAPOLIS—ST. PAUL

A careful estimate of stocks of anthracite at the head of the lakes up to and including Dec. 13, after the last boat was in, shows the following figures: Egg, 88,000 tons; stove 67,500 tons; nut 85,000 tons; pea 8000 tons. The stove and nut is practically all gone and the pea is reduced to about 400 tons. About 50,000 tons of egg are on the docks and some companies are thinking of getting a stone crusher and reducing the egg to smaller sizes as this grade can only be used in furnaces. Some Twin-City shippers are receiving some nut and stove direct from the mines all-rail, but it comes slow owing to shortage of cars in the east.

Arrangements for making Minneapolis the head of navigation on the Mississippi River are working into a reality. With the completion of river improvements and the establishment of adequate steamboat facilities, followed by the operation of a line of freight-carrying barges, there will be a reduction in cost of transportation of fully one-third. It now costs $2 to bring hard coal from the mines to Eastern loading ports. There it is loaded and carried to the head of the Lakes for 35c., and the railroads charge a $1.25 rate to the twin cities. With steamboats coming here, the coal could be loaded on boats at Pittsburgh and brought here via the Ohio and Mississippi River route for $2, if the charge for conveying the coal from the mines to Pittsburgh by rail does not exceed 50c. per ton. A company incorporated in South Dakota has been formed by Minneapolis capitalists under the name of the Star & Crescent Navigation Co.; it is capitalized for $2,500,000.

ST. LOUIS, MO.

With some slightly colder weather, causing an increase in the consumption of coal, the market still remains in an unsettled state. Under ordinary conditions, the local trade should be in fine shape, but the overproduction in the Illinois field keeps the price below cost. The only sizes that are standing up are the small steam grades. The ice in the river has put the ferries out of commission and everything is moving via the bridges; traffic is consequently much congested. Standard mine-run has sold as low as 80c. and lump 87½c., while Carterville lump and egg have sold at $1.10, with nut at $1.

The prevailing prices, however, are:

	Carterville and Franklin Co.	Trenton and Big Muddy	Mt. Olive	Standard
2-in. lump				$0 95
3-in. lump			$1.25	
6-in. lump	$1 25		1.40	1 15
Lump and egg	$1.45 @ 1 60	$2 00		
No. 1 nut	1 25			
Screenings	0 90			0.60
Mine-run	1 20			0.85
No. 1 washed nut	1.50			
No. 2 washed nut	1.40			
No. 3 washed nut	1.35			
No. 4 washed nut	1.35			
No. 5 washed nut	1.00			

OGDEN, UTAH

Shipments continued good from both the Wyoming and Utah mines during January, except for the shortage of equipment on the Rio Grande railroad which to date has not been entirely relieved. This condition has continued for practically two months and has greatly diminished the shipments from the Utah mines. Idaho, Washington and Oregon are short on Utah coals and the operators anticipate good business during February and March on account of this shortage.

The Nebraska and Kansas market has not recovered from the extensive shipment in the later part of December and January and at present consignments into this territory are at a minimum. The railroad could not be persuaded to remove the east routing placed on the cars until the mines had accumulated a great number of loaded cars drawing demurrage at Rock Springs. Then, after the Eastern market had been flooded, they removed the embargo and allowed the cars to be billed west. However, the damage was done and there is nothing for the mines to do but wait until this over supply has been partially consumed.

There has been an over-production of slack and some of the larger operators have reduced the price to several large consumers which if continued will place the slack market in bad shape. Both Utah and Wyoming prices continue as follows: Lump, $2.75; nut, $2.25; mine-run, $1.85. Wyoming slack brings $1, with Utah 25c. higher.

The box-car situation on the Union Pacific Railroad has been somewhat relieved, and a good portion of the equip-

ment sent to the mines for loading is closed. The mines in Utah are still bothered with a car shortage, although the situation is slightly relieved, and no doubt in a short time there will be sufficient equipment available. The officials of the Denver & Rio Grande Railroad have succeeded in overcoming the congestion along the line, and coal is now moving in reasonable time.

SPOKANE, WASH.

Fear of a coal famine in Spokane and the Inland Empire has been alarming the citizens here for the past two weeks, on account of the conditions of the railroads in the mountains, but the local coal dealers state that although they have been running close for the past month, conditions are now improved to such an extent that there is no further cause for alarm. There is no advance in the price of coal, quotations continuing as follows:

	Crows Nest	Wyoming Northern	Wyoming Southern	Utah	Montana	Roslyn
Lump	....	$6 45	$7 20	$7 20	....	....
Lump and egg	....	....	....	....	$6.35	....
Furnace	$6.00	....	....	....	....	....
Egg	....	5 95	6.85	6.85	....	....
Mine-run	5.00	....	....	....	....	$5 00
Nut	4 50	....	....	....	....	....
Screened domestic	....	....	....	....	....	6.25

PRODUCTION AND TRANSPORTATION STATISTICS

SAN FRANCISCO, CALIF.

The total deliveries of coal by sea into this port for year 1912 aggregated 374,556 tons, of which quantity 135,438 tons was the domestic product, consisting of 110,299 tons of Pocohontas for the U. S. Navy, and 25,139 of steam coal from the State of Washington, for use on the Pacific Coast Co.'s steamers. Imports from British Columbia were 149,830 tons, and from Australia, 89,288 tons.

THE CAR SITUATION

American Ry. Association reports surpluses and shortages of coal equipment for two weeks ended Feb. 1 as follows:

	Surplus	Shortage	Surplus or Shortage
New England Lines	49	233	184
N. Y., N. J.; Del.; Maryland; Eastern Penn.	1,676	1406	**270**

CONNELLSVILLE COKE

The "Courier" reports production and shipments in the Connellsville region for the week ended Feb. 8, as follows:

Production (tons)	Week	6 weeks	*Shipments (cars)*	Week	6 weeks
			Pittsburgh	4,344	21,666
Connellsville	225,207	1,228,882	W. of Pittsburgh	6,825	34,173
Lower Connellsv'le	182,162	924,462	E. of Region	871	4,484
Total	407,369	2,153,344	Total	12,040	60,323
Same period 1912	354,569	2,109,842	Same period 1912	10,590	62,133

FOREIGN MARKETS

GREAT BRITAIN

Jan. 31—The market is weak in places for spot loading, due to tonnage being delayed by stormy weather. For forward loading quotations are on a firm basis. Prices are approximately as follows:

Best Welsh steam	$4.56	Best Monmouthshires	$4 20
Best seconds	4 44	Seconds	4 08
Seconds	4.32	Best Cardiff smalls	3 60
Best dry coals	4 62	Seconds	3.36

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days —less 2½%.

Spanish Imports of coal for 11 months to Nov. 30, 1912 were 2,118,948 tons as compared with 1,834,315 tons for same period the year previous. Coke imports over same periods were 327,325 and 293,841 tons respectively. Practically all imports are from Great Britain.

COAL SECURITIES

The following table gives the range of various active coal securities and dividends paid during the week ending Feb. 8:

Nova Scotia Steel & Coal Co.

The following is an abstract from the general manager's report for the fiscal year ended Dec. 31, 1911:

The company controls for periods of from 2 to 10 years, 8 large steamers, totalling about 42,000 tons dead weight, chartered sometime ago. Several additional steamers will be required to move the ore and coal tonnage of 1912. Two steamers of about 13,000 tons deadweight capacity each were put in the service in May last. These boats are under contract for 10 years, the hire paid being based on a certain percentage of the cost of the vessels. One of these boats landed 37,560 tons of ore in Philadelphia during August; The total tonnage carried by the fleet was in the vicinity of 1,000,000 tons, of which more than one-half was iron ore.

Iron-ore mining at Wabana passed through a period of transition, due to the substitution of submarine for surface mining; the quantity mined, however, was nearly 25,000 tons more than during 1910, but owing to the severe weather during December, and other causes, the actual shipments were less than would have been the case under normal conditions. It is expected that 1912 will show a substantial increase in shipments.

The main haulage slope at Wabana was driven 1835 ft., while levels east and west of the main slopes have been driven 2335 ft., opening up a considerable amount of productive territory. In all, more than 5000 ft. of slopes, crosscuts, rises and levels have been driven in the submarine ore territory during the year. No serious difficulties were encountered, and exploration and development work done has further increased the quantity of proven ore in this property.

OUTPUT OF CALENDAR YEARS (IN TONS)

	Coal	Wab. Ore	Coke	Pig Iron	Steel In.	Steel Billets	Bars, etc

Maryland-Georges Creek Coal Co.—This company was incorporated in Maryland in September, 1912, and has a paid-up capital of $1,500,000. It has recently floated a large bond issue which is secured by 2470 acres owned in fee, 661 acres of coal without surface and 41 acres of surface, a total of 3172 acres located in the Maryland-Georges Creek coal basin, nine miles from Cumberland, Md. The mortgage also covers mining plant, miners' houses, etc., charged on the books at $120,000 along with $80,000 for other equipment. The sinking fund is 10c. per ton of mine-run coal and 5c. a ton on all clay mined with a minimum for 1913 of $10,000; 1914, of $15,000; 1915, of $20,000; 1916, $25,000; 1917 to 1931, $33,000 per year, and 1932, $35,000 to retire bonds at not to exceed $105 and interest.

COAL AGE

Vol. 3 NEW YORK, FEBRUARY 22, 1913 No. 8

It might as well be understood that the "good old days" are gone for good. The "good old days" of careless haste, enormous profit, sinful waste, are dead and done and have been cast out on the cultn heap of the past.

New times are here, new days, new ways, and "forward" we must turn our gaze—set forth upon a modern track and never think of turning back. If there are bills which must be paid for blunders that our fathers made, we might as well make up our minds to pay them. We need our skill and common sense, our tact and our experience, and now's the time for coal men to display them.

The labor problem is ours to face at almost every time and place, and ancient force and brutal power are *not* the methods of the hour. We cannot trample underfoot with ruthless strength and iron boot the mighty hosts of labor. The man who mines the good black coal is *not* a blind and brainless mole, but human, with a *mind* and *soul*—a brother and a neighbor.

Yes, we must deal with discontent because of ways our fathers went, because they somehow wouldn't see the lesson of humanity. It's not by guns and high stockade that wage agreements can be made; it's not by guards and strong redoubt that peace and calm are brought about. But we must keep our passions cool and give the gentle golden rule some practical expression, and meet the men who toil and sweat for all the tonnage that we get, with just and fair concession.

The "good old days," thank God! are done, a better time has just begun, a time for which we've striven; a time to heal each wound and sore; a time to love our brother more, forgive—and be forgiven. We have our problems grim and great, our legacy of wrong and hate, but we shall reach a nobler state, with less of toil and sorrow. The bitter past is dead and gone, and progress still goes marching on to greet that bright and rosy dawn—The Dawn of a Tomorrow!

Berton Braley

Post Timbering at the Working Face

By J. T. Beard

In considering methods of reducing mine accidents there is no subject of greater importance than that of timbering the working face. More than one-half of the fatal accidents in mines are due to falls of roof and coal, as the direct result of either a lack of proper timber or faulty methods or systems of timbering. Mine officials throughout the country have expressed their willingness and desire to coöperate with mine inspectors and mine legislators, in an effort to secure greater uniformity of remedial action in respect to determining and adopting the most efficient methods and systems of mining.

An Outline of The Next Question for General Discussion

Aside from the knowledge and skill required in the placing of mine posts in a working place, it is the miner's own neglect that, in the large majority of cases, is responsible for his injury. There is an old saying: "Time and tide wait for no man"; and none the less true is it that *a falling roof never waits for a miner to load out his coal before setting a post or two, needed to make his place safe.*

Few miners—a small percentage only—learn the lessons their procrastination should teach them; and a still smaller number can ever be expected to profit by the misfortunes of their fellows. This habitual disregard of safety is, therefore, an element of human nature that must be recognized as ever present, and one that it will be needless to dwell upon at any considerable length, in the present discussion. Instead of wasting time and valuable space in a fruitless attempt to enlarge upon the well known failings of men, let us have the practical suggestions of practical men, setting forth ways and means of improving conditions as they now exist at the face, and advocating the adoption of systems that shall tend to eliminate the human factor, which is so largely responsible for the daily recurrence of fatal mine accidents.

There are many intelligent miners today who have but an imperfect knowledge of the simple rudiments and principles of post timbering. They make no study of the nature of the roof under which they work, or its mode of action. They regard faults and dislocations in the strata, only in the sense that these cut out the coal and make the work of mining more laborious, not to say necessarily more dangerous. Many miners set a post in a mine, as they would shore up a building that was liable to fall. It does not once occur to them that this same mine post, aside from the slight support it affords to the roof slate, acts or should act as a silent but faithful monitor of impending danger, to a careful and observant miner.

What is the real province of a mine post; where, when and how should the post be set; what advantages are to be gained by systematic timbering; do you advocate systematic timbering under all conditions in mines; what arguments can be urged for and against systematic timbering; should a miner be compelled to timber his own place and be held responsible for the proper performance of this work, or should special timbermen be employed for the purpose; should the bark of mine timber be removed before it is sent into the mine; when should mine timber be cut and how should it be stored; what methods, if any, should be employed for its preservation? These are some of the practical questions that can be discussed with profit, with a view to increased safety and economy in the operation of mines.

On the other hand, there are many theoretical questions of equal importance, such as the relative diameter and length of mine posts, to secure the greatest efficiency in service; the calculation of the load a mine post can properly be expected to support; the crushing strength of mine timber; the effect of seasoning, and other like questions. Owing to the growing scarcity of timber in mining regions, the use of steel timber in mines, and its preservation from the corroding action of mine water, are questions of growing importance.

It is the plan of Coal Age to confine each of these discussions to one month, except it should be found advisable to extend this time, in any case, owing to the interest manifested and the importance of the matter discussed. It is, therefore, important that all who are seeking to improve methods and systems in mining coal should take part in the discussion as early in the month as possible.

A Modern Mine Ventilating Plant

By U. U. Carr*

SYNOPSIS—This plant was built with the ideas of efficiency and economy predominating in the design. The rope transmission between motors and fan is a departure from ordinary practice and one which possesses many advantages over the customary and time-honored belt drive. The arrangement of sheaves and clutches to obtain operation from either motor independent of the other is also particularly worthy of notice.

The pre-eminent ideas governing the design of the ventilating equipment of the Monongahela River Consolidated Coal & Coke Co.'s Crescent Mine, located near California, Washington County, Penn., were to provide against interruption of service, and to secure a permanent, fire-proof construction that would endure throughout the life of the mine, combined with the highest possible efficiency of the fan.

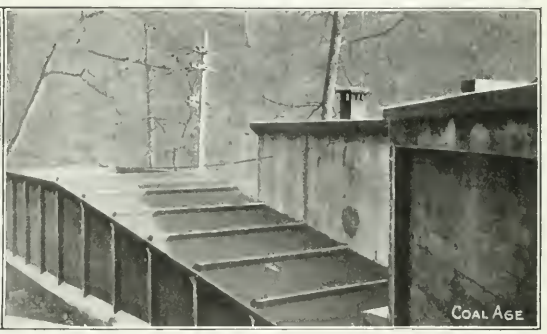
The desirability of continuous operation is easily appreciated and, in emphasis of the importance of permanent construction, it may be said that with an output of 6000 tons daily the estimated life of this mine is 35 years.

Cost of power is apparently often disregarded or passed over with the thought that the generation of a few extra horsepower will show no appreciable increase in the expense of operation, but the fact remains that every horsepower generated, represents an expenditure of money.

In the case of this installation, each per cent. increase in efficiency means a saving of approximately four horsepower, or say $100 annually; an amount justifying a considerable outlay, tending to increase the efficiency.

For the fulfillment of the above conditions, several innovations were employed. Chief among these may be mentioned the duplication of the driving machinery, self-closing steel explosion doors, reinforced-concrete construction, extra large airways and an evase chimney of unusual strength.

General View of Fan House



Evase Chimney, Showing Pilasters

Position of Fan and House

The center line of the fan drift intersects the main airway at an angle, and the fan and motor house are removed from the direct force of any explosion occurring in the main airway. The explosion doors are located in the side of the fan drift, directly in line with the main air course.

These air ways are lined with concrete through the faulty strata overlying the coal near the outcrop. For this work, plank forms were used on the side walls, and Hy-Rib sheets bent to the proper radius were used as forms for the segmental arch roof. After the concrete arch was placed on these sheets, the under side was plastered; the Hy-Rib sheets forming the steel reinforcement for the arch.

The minimum thickness of concrete on the side walls was fixed at 6 in., and where the space to be filled was much greater than this, cyclopean masonry was employed. The haunches of the arches were cut into the rock, and the space above packed with broken stone in the usual manner.

The concrete airways and fan drifts are proportioned to carry the output of the fan with a maximum velocity of 1500 ft. per min., at which speed the frictional losses in them are negligible.

The fan drifts are constructed entirely of reinforced concrete and were poured in plank forms. The side walls are 6 in. thick, stiffened with pilasters and reinforced with vertical and horizontal sets of $\frac{3}{8}$-in. diameter bars, spaced 18 in. centers and wired together at each intersection.

A flat slab, 4 in. thick reinforced with $\frac{3}{8}$-in. diameter bars spaced 10-in. centers, forms the roof over the fan drifts. To reduce the span of the roof slab, reinforced-concrete beams were arranged crosswise and along the center line of the structure, so as to not interfere with the drainage of water from the roof.

These beams rest on the pilasters of the side walls and project upwards from the roof, leaving the interior free of obstructions. The roof slab was finished with a $\frac{1}{4}$-in. coat of cement plaster, waterproofed with Trus-Con waterproofing paste, afterwards heavily coated with asphalt paint.

Location and Construction of Explosion Doors

The explosion doors, located in the side of the fan drift facing the main airway, cover an opening equal to and coinciding with the projected area of this pas-

*410 Barclay Ave., Pittsburgh, Penn.

sage. While the impossibility of constructing a door that would withstand the force of a severe explosion without damage was well understood, the intention was to provide a device which, if not completely wrecked, would automatically close and thus restore the ventilation.

Manifestly the size of the opening (15 ft. by 17 ft. 10 in.) rendered the use of single or double doors impracticable on account of their inertness to the explosive force and their momentum when in motion.

In the design adopted, sixteen overlapping doors were used, each one capable of opening or closing independently of the others. These were made of $\frac{3}{16}$-in. steel plates, hung on 2¼-in. diameter axles by means of 2¼x⅞-in wrought-iron hinges, which extend the full

Explosion-door Frame and Pit Mouth during Erection

width of the plate. The doors are further stiffened by a 3x2x¼-in. angle, riveted along the lower edge and aranged to lap on the upper edge of the door below.

The frame supporting the door axles consists of five vertical 12-in. I-beams tied together by a 12-in. channel at the top and a plate and angle at the bottom. The door axles extend the full width of the opening and pass through holes drilled in the webs of the beams.

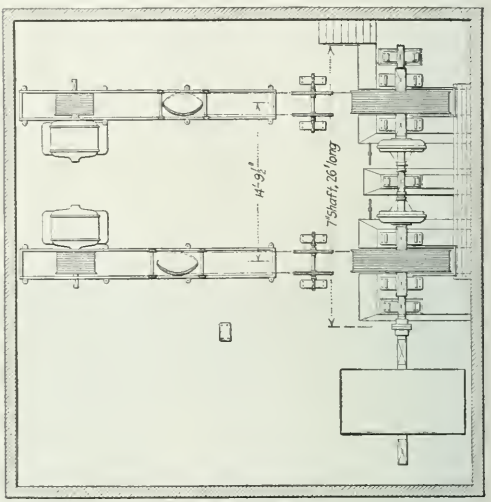
The concrete was built around this frame, and is so interlocked with it, that it can be displaced only by the destruction of the walls. The axis of the hinge, being located near the tops of the doors and two inches from the vertical plane, causes them to close against the I-beam frame, by gravity, where they are tightly held by atmospheric pressure.

In this connection it may be said that for this mine it was not considered necessary to have a reversible fan. It, therefore, was designed primarily for exhausting and no provisions were made for operating it as a blower.

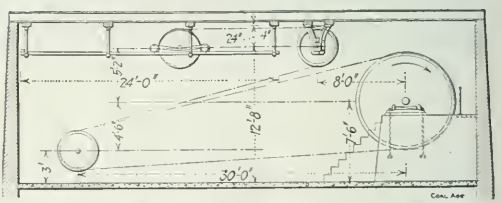
Type and Size of Fan

The fan is a double inlet "Sirocco" type, manufactured by the American Blower Co., and was designed to deliver 350,000 cu.ft. of air at 157 r.p.m. against a 5-in. water gage. The wheel is 13 ft. in diameter and 6 ft. 9 in. wide, driven by a central hub, mounted on a shaft 10 in. in diameter, which is reduced to 8 in. in diameter at the Journals.

The fan shaft extends into the motor house and is



Plan of Fan Drive



Side Elevation of Fan Drive, Showing Important Dimensions

carried in three adjustable bearings, one mounted on a concrete pedestal within the house itself, while the other two rest on bridges in the fan inlets. These bridges are of unique design, being constructed of ½-in. steel plate, so disposed as to offer a minimum resistance to the flow of air through the inlets.

Only the inlet cones and upper half of the fan casing are steel plate; the lower half and the evase chimney are of concrete construction.

Theoretically, the maximum water gage effect and efficiency of an exhaust fan would be realized were it possible to extend the chimney with an increasing area to that point, where the velocity of the air discharged would be zero. This, of course, is impossible and subject to practical limitations, but that chimneys of greater length than those usually employed, would result in increased efficiency, is not doubted.

The chimney in this case is about 40 ft. long from the point of cutoff to the end of the evase portion. For practical reasons it was placed in a horizontal position, representing the usual vertical arrangement of chimney and casing rotated through an angle of 90 deg. Beyond the evase portion, the bottom is inclined upward and the discharge opening made horizontal, so that the outflow of air is not appreciably affected by the direction of the wind.

That portion of the stack below the ground line is made of plain concrete, poured in plank forms. The remainder of the stack is constructed of Hy-Rib sheets supported on a steel frame and plastered with cement mortar.

The frame consists of 4-in. I-beam posts spaced about 6-ft. centers, tied together at the top and bottom with angles. The latter were used mainly to facilitate erection, rather than as a necessary member of the frame. The cover is carried on 6-in. I-beams which rest on the posts, and the Hy-Rib sheets are secured to the inner sides of the beams by steel clips made for that purpose.

To carry the plaster coat, strips of metal lath were stretched over the projecting beams and fastened on either side to the Hy-Rib sheets. This gives the appearance of small pilasters on the wall, and encloses the steel beams in concrete. On the sides of the chimney the finished concrete is 2 in. thick, while the roof slab is 2½ in. thick.

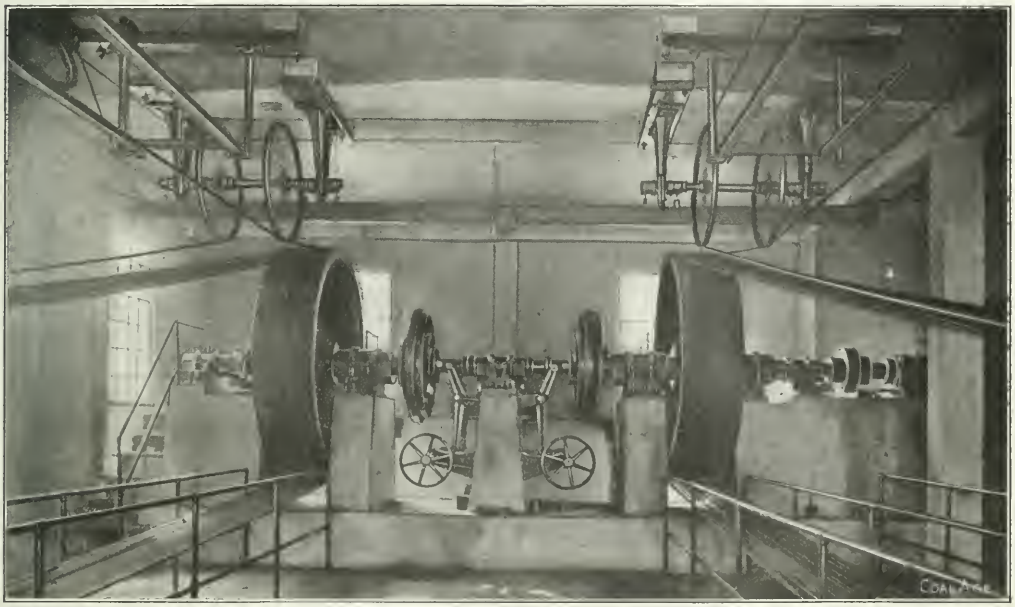
Power Transmission to the Fan

The fan is driven by manilla rope transmission from two Allis-Chalmers Co.'s 300-hp., 450-r.p.m., 2300-volt, 60-cycle, three-phase-wound rotor, variable-speed, induction motors. These are of the three-bearing type with extended sub-base; speed variation being accomplished by means of resistance in the secondary circuits.

The stacks of grid resistance for each motor are inclosed with expanded metal and provided with a face plate controller. The switch board equipment consists of two indicating wattmeters, one recording wattmeter, and two triple-pole automatic oil switches with low voltage release and inverse time limit overload relays.

With the exception of the incoming lines, which are carried in the ceiling, all wiring for the motors is placed in conduits under the floor. Current for lighting is furnished by a 110-volt transformer from the high-tension line, the wiring being run in small pipes.

To provide for increased ventilation in an emergency, the rope sheaves are proportioned to operate the fan at normal speed with a motor speed of 400 r.p.m., so that full motor speed would run the fan at 172 r.p.m., or ten per cent. above normal.



The Twin Rope Drives and Clutches

The rope transmissions are the Dodge Manufacturing Co.'s American or single rope system, each carrying sixteen wraps of 1-in. manila rope, and are duplicates in every particular.

The motor sheaves are 12 in., and the driven sheaves 107 in. in diameter. These latter are mounted on hollow or quill shafts through which a 7-in. jack shaft passes. The jack shaft is rigidly connected to the fan axle with a flanged coupling and is engaged by 18-in. Dodge patent split friction clutches bolted to flanges on the ends of the quill shafts and operated by handwheel and pinion.

The quill and jack shafts are supported independently in adjustable bearings, resting on concrete pedestals, which are joined by a continuous concrete footing to prevent uneven settling.

The motors are set 30 ft. centers from the jack shaft, which gives sufficient room to operate the tension carriages inside the building. The winding sheaves and tension carriage tracks are placed directly above the driving ropes, and are bolted to timbers which are in turn secured by anchor bolts to concrete leveling pads on the under side of the roof. With this arrangement, extreme accuracy in setting the anchor bolts is avoided and the alignment of sheaves and tracks greatly facilitated.

Pipe hand railings are provided around the sheaves and ropes while the clutches are protected by expanded metal guards.

Either drive can be thrown in or out without changing the speed of the fan, in fact the sheaves and clutches on the quill shafts being split, one drive could be dismantled without interfering with the operation of the other.

The ropes run exceedingly smoothly and are practically noiseless, and in addition when worn out their replacement is a matter of small expense.

Size and Construction of Motor House

The motor house proper is 30 ft. wide by 45 ft. long, with an irregular addition to its width where it joins the fan drift and chimney. It is also of concrete construction.

The roof slab is $5\frac{1}{2}$ in. thick, reinforced with $\frac{1}{2}$-in. and $\frac{5}{8}$-in. steel bars, and has a rise of 8 in. at the center. Reinforced concrete beams projecting above the roof and resting on columns carry this slab and leave the clear height under the roof unobstructed for the accomodation of the rope drives.

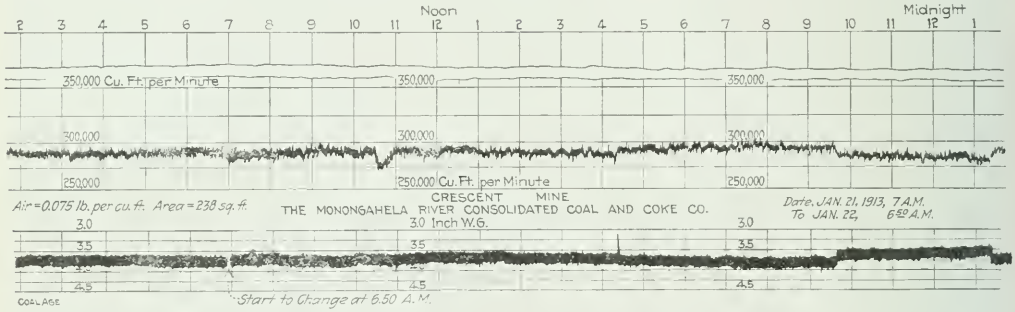
The concrete columns, ten in number, are 12x12 in., reinforced with four $\frac{5}{8}$-in bars. Plank forms were used for the columns, beams and roof slab but the motor house walls are constructed of Hy-Rib sheets, placed horizontally and plastered with cement mortar and are 2 in. thick.

The ends of the Hy-Rib sheets are secured in grooves in the columns, and are also attached to 3x3x$\frac{1}{4}$-in. angle posts, which are set in the concrete and support the door and window frames. A surface coat of cement plaster, waterproofed with Trus-Con waterproofing paste was applied to the sides and roof of the motor house. The latter was also heavily coated with asphalt paint.

The foundation walls under the motor house are of plain concrete as are those under the sides of the fan drift. Trussed Concrete Steel Co.'s standard reinforcing and waterproofing materials were used throughout the work.

In addition to the usual water manometer required by law, the fan is equipped with a Hydro Manufacturing Co.'s recording gage, which indicates both the pressure and the volume of the air delivered. The recording pens of this instrument are attached to floats resting on water and move up or down by the action of the air on Pitot tubes stationed in the main airway. This instrument is quite sensitive and faithfully records any variation in conditions.

The fan when running at 147.4 r.p.m. will deliver 322,470 cu.ft. of air at 4.97 in. water gage. Its mechanical efficiency is remarkably high, ranging between 79 and 83 per cent.



Hydro Chart, Record of Fan Performance for 24 Hours

Mining Steep Seams in South Wales

At the southern outcrop of the South Wales coal field, the seams are usually steep, having a dip of from 17 to 27 deg. Shafts are not common in this field; instead, advantage is taken of the outcropping and the seam is followed inward and downward with a pair of main slopes. This method permits quick travel, provides plenty of fuel available for power, and water gives less difficulty than if a vertical shaft crossed the measures. Large pillars are left along the main slopes for protection against caves, also as the mine deepens substantial pillars are left against the outcrop to prevent the percolation of surface water.

Where more than one seam is to be worked, connection is made by cross-measure headings driven horizontally and the coal taken out through the seam in which the slopes have been driven. Often an inferior seam unfit for working, is chosen for the main haulway, simply because it has a good roof.

The Park Slip modification of longwall mining is used. Level headings are driven every 100 or 110 yd. Ventilation is secured by driving a roadway, about 50 yd. distant from the slope, through the block of coal to the level above; an airway is then driven from this crosscut, parallel to the level heading which leaves a rib of coal 22 yd. wide between, which is cut through every 25 yd. for ventilation, thus forming pillars 25x22 yd. along the upper side of the level. These are allowed to stand until the level is worked out.

Gas and Oil Wells in Coal Fields

By George S. Rice*

SYNOPSIS—Much pressure has been brought to bear on the Bureau of Mines to induce it to call a conference on the proper methods of drilling and casing gas and oil wells in coal fields and on the legislation needed for the regulation of the same. The author here suggests tentatively the discontinuance of the practice of leaving pillars around wells, and the protection of boreholes by other means. He questions whether a return of the measures to their original condition is not sufficient when wells are abandoned. His scheme for protecting wells through goaves is submitted to the consideration of the public.

The problems of gas or oil wells extending through or near coal mines, and through the future coal reserves, has gradually become more and more serious, not only on account of the danger to the miner, but also because there has been an increasing loss of coal in pillars left around the wells. There will be a further loss in the future unless means are found which, while giving safety to the miner, will enable the coal to be extracted.

Drilling Has Made Property of Doubtful Value

A prominent engineer told the writer recently that he had been obliged to report unfavorably to his client upon the purchase of a certain tract of coal land which he was examining, on account of the numerous oil and gas wells on the property, which would seriously interfere with mining operations.

Fortunately so far there has not been a large loss of life in mines through explosions or fires caused by leakages of gas from wells, but there are a number of cases on record in which lives have been lost, and the possibility of occurrence of disasters has been present in a number of instances.

One special case, which has been much referred to, is that of the Middleton and Enterprise mines, near Fairmont, W. Va., where natural gas under high pressure leaked from a well and entered the two adjoining mines, leading to local explosions in each mine, and to the death of three miners. Fortunately the entrance of gas into the mine occurred at night when but few men were in the workings; and fortunately also, the company which owned the mines had taken most excellent precautions to keep the coaldust wet, and the explosions were thus limited in extent.

This case is particularly interesting because the well was surrounded by a pillar 100 ft. wide, and there was also a coal barrier between the two mines 100 ft. thick. Therefore the gas entered the mines, not through the coal, but through the floor and along a line 2300 ft. in length, according to Mr. Tarleton, general superintendent of the company, who presented a paper on the subject, which appeared in the *Transactions* of the West Virginia Mining Institute for 1911.

Mine Fires from Gas Wells

Wells are constantly being drilled in the coal fields of this country, and are numerous in the coal basins of Pennsylvania, West Virginia, Ohio, Indiana, Illinois and Kansas. In Pennsylvania and West Virginia, mines not infrequently strike uncharted and abandoned wells.

In many cases these have been found filled with gas, and in some instances the gas has been lighted. Recently a serious fire was caused in a mine in the vicinity of Pittsburgh, by gas which ignited when an unknown well was struck in mining operations.

Fortunately this fire was not attended by an explosion, but it led to the mine being shut down for two weeks, and the bureau's engineers and rescue crew had to be called upon to investigate behind the fire stoppings. In a number of cases where wells have been encountered, explosions have been but narrowly escaped.

It would therefore appear that the industry hitherto has been more lucky than far-seeing, in not taking precautions to make secure and to record the location of abandoned holes, which, while not giving gas in commercial quantities, make sufficient to render them serious menaces to mining.

The Need for Satisfactory Legislation

The dangers which threaten have frequently been pointed out by I. C. White, of West Virginia, president of the Association of State Geologists. In a recent meeting of this association, a committee was appointed to confer with the director of the Bureau of Mines on this subject. Director Holmes also received requests from others to take up the question with a view to formulating suggestions which might lead to uniformity of oil- and gas-well legislation in the various states in which gas or oil is found in the coal fields.

Hitherto the legislation on gas and oil wells in all states except Ohio and Indiana, has dealt with the subject only from the standpoint of protecting the wells from one another. The Ohio laws, and to a lesser extent the Indiana laws, take some cognizance of the dangers to mining in the vicinity, but they are considered inadequate.

The Preliminary Conferences

As a preliminary to this general meeting, it was thought advisable to have conferences with those interested in the questions involved; consequently a meeting was held a few weeks ago with some of the coal operators who had had experience in dealing with gas and oil wells through mines. Then followed a conference with representatives of the gas-well interests; and more recently the problem was discussed with a number of state geologists, representing several of the leading coal-mining states in which gas and oil wells have become or are becoming an important factor.

Following these preliminary meetings, the members of the staff of the Bureau of Mines who had been charged by the director with this investigation prepared a tentative outline of rules and regulations which might serve as a basis for possible legislation on the subject of oil and gas wells, passing through coal measures.

These were formulated to harmonize as far as possible with the ideas presented in the several preliminary conferences with the different interests, taking into consideration that it would be wise to have such rules and regu-

*Mining engineer, Bureau of Mines.

Note—A paper delivered before the conference to suggest legislation covering the drilling of gas and oil wells in coal fields, Feb. 7, 1913.

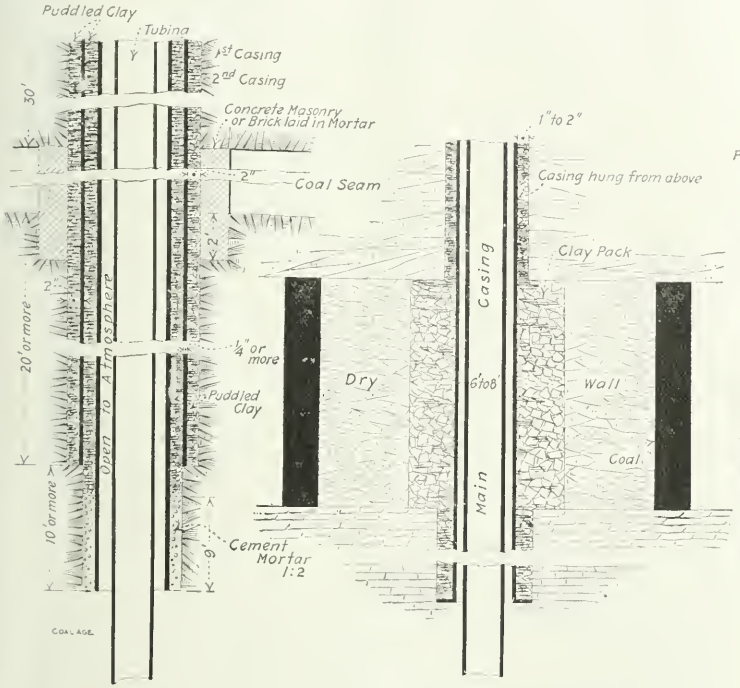
lations of a general character suitable for forming a basis for possible legislation in each of the states.

There are several features which have been discussed at considerable length in the preliminary conferences which have not been incorporated in the rules and regulations, as it was felt that it would not be wise to do so. The Bureau thought that certain questions should be left for gradual development, and in certain cases, should be left to private agreement between the parties at interest. These questions are as follows:

Pillar Is Not a Stopping But a Support

In the preliminary conferences it was unanimously conceded that pillars of coal of any reasonable size did not prevent leakage of gas into the mine when there were defects in the well casings, but that they served as supports to the overlying strata to prevent fracturing or breakage of the well casing anywhere from the coal seam upward to the surface.

Looking at it from this point of view, the question of



Suggested Method of Casing Well through Accessible Coal Seam, Hood and Haggem Plan

Suggested Method of Casing Well Where Pillar Is Withdrawn as Described on Pages 294 and 295

Suggested Plan of Casing Well through Inaccessible Coal Seam, Hood and Haggem Method

Size of Coal Pillars That Should Surround Gas and Oil Wells

It has been found from investigations and inquiry that the pillars which have been left around gas wells in Pennsylvania and West Virginia vary from 40 ft. diameter or 40 ft. square, to 200 ft. in diameter or 200 ft. square, the well being at the center of the circle or square. Inquiry has been made as to the underlying reasons by which the size of these pillars was determined, but it was found that the choice of size did not have a scientific basis. The various sizes of pillars merely represented the opinions of the parties concerned, or compromises made between interested parties. The courts in rendering decisions, would appear to have determined arbitrarily the size of pillars which must be left in certain cases. Presumably the size determined in each specific case represented the consensus of the testimony presented.

size of pillar surrounding the well is a problem similar to that which has arisen as to the proper size of pillar to be left surrounding a mine shaft. Investigation by the bureau has not disclosed any uniform system of determining the size of a shaft pillar, but there have been a number of empiric formulas used by mining engineers in the various mining countries. They are usually based on the distance of the coal bed from the surface.

The ratio in diameter of the pillar to depth from the surface in such formulas varied from $\frac{1}{4}$ to 1 up to $\frac{1}{2}$ to 1, that is, under the first ratio if the coal is 400 ft. below the surface, the pillar would be 100 ft.; in the latter ratio, the pillar diameter would be 200 feet.

Empiric Formulas for Barrier and Shaft Pillars

A formula used for barrier pillars in the anthracite district, by a number of prominent companies, and approved by one of the state mine inspectors, takes into ac-

count the thickness of the coal. The formula is as follows:

> The width of the barrier pillar is equal to the thickness of workings multiplied by 1 per cent. of the depth below natural drainage level, plus the thickness of the workings × 5.

If, for example, a seam was 9 ft. thick and 300 ft. below drainage level, the thickness of the barrier pillar would be $(9 \times 3) + (9 \times 5) = 72$ ft. The drainage level presumably is at or near the surface. While apparently this formula is chiefly for protection against inrushes of water, it is manifest that the effect of crushing is also involved, for if the pillar was crushed it would not furnish the necessary protection.

The Coal and Metal Miners' pocketbook offers this formula for shaft pillars deeper than 100 ft., namely, radius of shaft pillars equals $3 \times \sqrt{D \times t}$, where D equals depth of shaft and t equals thickness of seam. For example, in a shaft 900 ft. deep and the coal bed 8 ft. thick, the radius of pillar figures 255 ft., or diameter 510 feet.

The necessity for protecting a shaft is doubtless greater than for a gas or oil well. It is the means of egress, and it is not simply the protection of the shaft itself that must be considered, but also the support of the surrounding buildings, including the engine and boiler plant; hence there is greater need to have large pillars surrounding shafts than around wells.

The Fracture May Pass over the Pillar

It is manifest that the varying character of the strata in different districts affects the determination of the size of mine pillars to adopt for oil or gas wells—that is, assuming that it is necessary to prevent any movement of the measures surrounding the casing all the way to the surface. If the roof over the coal bed breaks easily, the fracture will probably extend upward in more or less vertical planes; on the other hand, where the roof is strong, sandstone or limestone, and the fall occurs on only one side of the well first, which is usually the case, there is a possibility that there may be a considerable pull toward that side which may carry the break diagonally upward, so that the plane of fracture may intersect the line of the well before it reaches the surface, in which case there might be danger of rupturing the casing, or at least swinging it out of line.

Inequality of Strength of Pillar

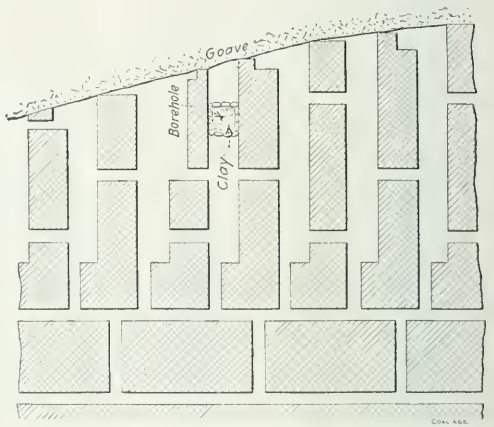
It was pointed out by S. A. Taylor in the first preliminary conferences, that where the cleavage of the coal was very marked, as in the Pittsburgh coal seam, a pillar should not be square but should be rectangular in order to get equal strength, that is, that the pillar should be longer across the faces, or parallel with the butts.

The Consolidation Coal Co., in the Fairmont district, is considering the necessity of leaving pillars 200 ft. square, surrounding the wells. It is easy, however, to realize how serious this requirement may be when the wells are close together, either from the standpoint of laying out the mine, or from the loss of coal in the pillars. This brings up the question whether or not it is necessary to retain the pillar permanently.

Extraction of Coal Surrounding a Well

I suggested in the preliminary conferences that it might be possible to dispense with a coal pillar around an oil or gas well provided an artificial pillar was substituted. This proposal is not quite so radical as it might seem at first. The coal surrounding shafts has been extracted without detriment in some of the longwall mines in Great Britain, and in one longwall mine in northern Illinois.

Where this plan has been employed, the section from which the coal has been excavated is carefully packed with broken rock and dirt, as is usually done in "longwall advancing," so that the movement downward is



Proposed Method of Protected Well Where Coal Is About To Be Entirely Withdrawn

very gradual and even, the strata all the way to the surface subsiding equally, and without damage to the surface buildings, provided the longwall face advances regularly. The final surface subsidence where the goave has been well filled with dry packing, is about 50 per cent. of the thickness of the excavation; that is, in a bed of coal 6 ft. thick the subsidence would be about 3 feet.

A Method Suggested Where No Pillars Are Left

To suit the room-and-pillar conditions, I suggest the following plan: That a room be laid out so that the drillhole will be approximately in the center of same; in drilling the well, the hole to be made 2 or 3 in. larger in diameter than the outer casing which is to be inserted, so that there is a space of from 1 to 2 in. surrounding that pipe.

Let us suppose this outer casing is to go 30 ft. below the coal bed, then the larger hole will be drilled an additional distance equal to the thickness of the seam, below where the shoe of the casing is to hang. The casing will then be lowered and hung from cross-beam supports at the surface, the ends of which are to be placed on piers so as to make these supports permanent.

These cross-beams should be steel channels or girders, 9 to 10 ft. or more in length, and of sufficient strength to hold the weight of the casing. Before lowering this pipe a gasket of rubber or canvas is to be fastened just above the shoe around the outside, so as to fit against the

rock or shale when the casing has been lowered to place and hung from the beam supports.

A grouting of clay will be run in between the casing and the sides of hole so as to completely fill the space from the gasket to the surface. This is to allow an opportunity for the casing to slide freely, either at the bottom or the top if the coal is excavated and the ground subsides.

After the casing has been put in and grouted with clay, the drilling and putting down of the inner casing will proceed in the usual manner. If subsidence of the ground occurs the arrangements spoken of will be equivalent to an expansion joint in a steam line. The inner casings and the gas tube being rigid and fixed below, when the subsidence takes place they will merely project that much further above the surface of the ground, and will not be affected by the subsidence.

It is, of course, assumed that a space will always be left open to the top between the outer casing and the next inner casing, so that if there are any gas leaks they will be enabled to pass unobstructed to the surface, in accordance with the plan employed in recent wells where by agreement with the coal companies various precautions have been taken.

Precautions When the Well Is Reached

When the room above mentioned has reached the well, the casing should be protected from contact with moving cars and from the violence of blasts by the use of the necessary post timber; and further, if the roof is very poor, a timber cog should be carefully built around the well and packed tightly with clay. When the rooms in the vicinity have reached their proper distance, before withdrawing the pillars, clay should be brought from the surface (any ordinary clay will do) placed around the well casing, and tightly packed so as to make a cylinder from 6 to 8 ft. in diameter. It will not be necessary to withdraw any of the timber to do this.

The space surrounding this clay cylinder back to the ribs should be filled with mine waste obtained from lifting the bottom, or from fallen roof rock. When the ribs have been drawn back to a point opposite the artificial pillars, a thin curtain wall can be retained on either rib, merely to hold the gob in place.

The purpose of the "gobbing" will be to allow the roof to be dropped evenly, as the packed clay around the hole will prevent undue pressure at any point, thus preventing distortion of the casing. Since above and below the coal bed the casing is surrounded with a layer of clay, it will either allow the roof to slip down without injury to the casing, or if the whole strata above goes down and grips the casing, the latter will slide further down into the hole, which has been previously drilled large enough to receive it.

With such a plan properly carried out, I can see no serious risk in not leaving a coal pillar, for even if a break of the outer casing occurred, which does not seem likely, at all times there is a vent to the surface between the inner and outer casing.

If abandoned wells are properly plugged from bottom to top, there would seem to be no need for other special precautions for deeper coal beds. It is manifest that in the great majority of cases these coal beds will not be worked for many years to come, perhaps 25 or 50, or as much as 100 years. It is also clear that no casing would resist corrosion for such extended periods, therefore it is believed that the project of restoring the strata to practically the same strength and impermeability as originally found will be the best method.

Abandoned Wells Should Be Plugged to the Surface

It was further agreed by the geologists that the simplest and safest way of handling abandoned wells through coal mines will be to plug them tightly all the way from the bottom to the surface. If holes are plugged so that there is no leakage of gas, there would seem to be no danger in laying out a mine, or in the working of same, without paying attention to an abandoned well, beyond approaching it carefully, and testing to see whether there is any sign of leakage of gas.

Drilling Gas Wells through Inaccessible Mine Workings

The question has arisen in several cases as to the protection from leakage of a gas well drilled through an inaccessible mine opening or excavation, as, for example, where pillars have been pulled. In the case of such leakage there would be danger of the goave filling with gas, which would escape into the active mine workings.

I will not attempt to discuss the relative merits of the two sides to the controversy, but as the courts have held that the parties possessing the gas ownership have the right to drill, it is necessary to consider how this can be done with a minimum amount of danger.

All have conceded the necessity of having at least one outer protective casing open at the top to the atmosphere, but in the event that acid mine water may corrode it, additional protection is necessary. One plan proposed by Mr. McCloy, of the Philadelphia Company, is to make the hole large enough to insert an outer pipe opposite the coal bed and fill between it and the casing with cement. This plan seems to be an excellent one.

The Protective Cone in Abandoned Workings

I offer an alternative scheme which might be used when the mine excavation is not too much filled with débris, and in some cases might be used to supplement the previously described method. The plan is: When the drill has entered the excavated space and drilled through any loose rock to the bottom, to fill the space with crushed rock or gravel, sand and cement, thoroughly mixed by a concrete mixer.

This is to be put in rapidly and will, if of proper consistency, form a conical heap with the apex at the top of the open space. A conical bit or tool fixed on the end of the string of tools will then be immediately lowered and used to spread out the top of the cone. More concrete must then be put in and again spread out by the conical tool.

The concrete should then be allowed to set, following which a hole will be drilled through it by the usual method. This hole may be a small one. Then liquid cement will be run in and forced under pressure to fill the interstices.

After this has set it is anticipated that there will be a strong concrete column through the mine excavation, which will be practically impervious to the mine water, and through which a hole of full size can be drilled as through a solid rock stratum, the casings being inserted in the usual manner.

The Gas and Oil Well Problem

By R. Dawson Hall

SYNOPSIS—Some reasons for urging the elastic casing as a necessity were presented at the recent conference on gas and oil wells passing through coal. A committee was formed to discuss the proposed legislation. It has been decided to proceed in a more leisurely and cautious manner in framing a code than was at first suggested.

In this article, I purpose to continue the remarks on the Pittsburgh fuel-well conference contained in the previous issue.

It was urged at the meeting that the recommendations of the Bureau did not furnish a sufficient guarantee of elasticity, though it must be granted that the provision for this quality has rarely if ever been even considered in previous discussions. It was pointed out that the space between casings was only two inches on either side, and even this was much reduced at couplings.

Some sketches here reproduced were presented to the meeting to aid in the presentation of this view of the subject. Fig. 1 shows a rock beam over an excavation. The roof in bending tends to break at *A*, *B* and *C*. *A* and

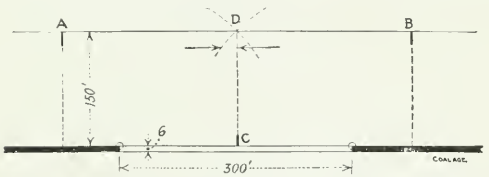


Fig. 1. Roof Which Has Failed by Bending Begins To Resist by Arching

B are points on the surface over the pillars, and *C* is the center point on the underside of the roof beam.

These breaks do not extend, at least at once, for the full depth or height of the rock mass, and it may be added that it is not asserted that the breaks over the pillars are vertical; there are some reasons for thinking they are not. For the present purpose, the matter is not material.

How Roof Will Warp

These breaks tend to divide the roof which we have in question into disturbed and unaffected areas. The latter shows in sectional elevation as a pair of rectangles. These rectangles tend to revolve on the edges of the coal pillars, which are here supposed to be completely resistant. This action produces a thrust between the rectangles at *D*, see Fig. 1. The bending is thus arrested until some part of the roof mass gives.

One action which may take place and the most probable of all, is a horizontal shear along one of the many weak measures, or less probably between two bodies of rock having a smooth bed between them. If the coal is 6 ft. thick and the opening is 300 ft., the final slope of the strata in case of complete subsidence and a complete break, will be 6 ft. in 150 ft. If the measures are 150 ft. thick, the aggregate of shear along the shearing planes must be 6 ft. in order that a body of rock which originally was rectangular may become a rhomboid.

It must be remembered, however, that if this slipping along bedding planes were uniform from coal to surface there would be little or no injury to a bore hole drilled through any part of the measures. The strain would arise wholly from actions prior to the shearing, which are in themselves severe enough. There is good reason to believe, however, that most of the readjustment takes place at favoring bedding planes, which are rendered free to slide past one another by reason of the new-found freedom caused by ruptures from tension.

How Shears Are Eased in Practice

O. P. Hood, the mechanical engineer of the Bureau, in reply, declared that there was rarely any such thing in actual practice as the shearing of pipe or iron by natural forces, that shearing could hardly be attained in a laboratory or a mill and that what actually took place was a reverse bending with curves of small radius.

This criticism is perfectly just and might be supple-

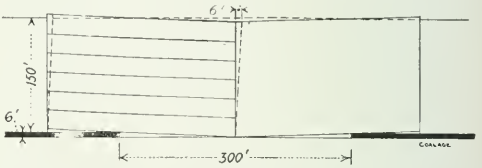

Fig. 2. Roof in Previous Figure Breaks Down Completely as the Measures Slide Past Each Other

mented by the statement that the principal shearing distortions would occur at beds of coal, clay and shale, and would be distributed over some distance. Still making all allowances, the fact that measures readjust their shape as much as 6 or more feet is extremely suggestive of deformations.

Of course, the angle of warp is further reduced when the floor rises, the coal crushes and gob is left in the mine. On the other hand there is an increase of movement when the coal is thicker and the roof beam of greater depth and is in proportion, other things being equal to these factors.

The Action of Unbroken Roof

It was pointed out also how extreme might be the motion of a borehole before breakage took place. If a lath is placed over two supports and the position marked by two tacks *A* and *B*, as in Fig. 3, on being loaded it is drawn down between the supports and the tacks moved to *A'* and *B'*. A similar action takes place in a modified degree with the mine roof and the new angle assumed by *A* and *B*, to wit, *A'* and *B'* shows the nature of the tilt which a vertical hole might receive.

At the same time a tack in mid span is lowered vertically and is still plumb, regardless of the amount of lowering. This is why a borehole in the location shown in Fig. 4 would be subject to minimum distortion.

It was suggested that the hole should be lined with a

Note—Continued from the issue of Feb. 15.

thin coating of cement of an internal diameter 8 in. larger than that of the casing. This cement could be kept in place by some extremely light pipe, possibly spiral riveted. The space between this pipe and the interior casing could be filled with clay.

The Difficulties in Abandonment

R. C. Johnson spoke on the possibilities of cement grouting under pressure for the filling of crevices in broken rock. The use of cement in this connection is described in Vol. 1, pp. 639 and 674, and the German system can be found in the *Engineering and Mining Journal*, Vol. 95, p. 363. There is little question but what such grouting would serve on abandonment of wells to stop natural crevices and those caused by the shooting of the hole, but it may be added that the pressures in a well 3000 ft. deep are even greater than Mr. Johnson has ever employed. The whole objection is to the cost of such work and that might not be prohibitive.

The difficulties involved in the abandoning of fuel wells caused some of the coal operators to favor the insertion of a 2-in. line extending 10 ft. above the surface and bent over with elbows. It is easy to see that the perpetual use of an unprotected vent pipe as part of an abandoned well is fraught with much danger and could only be

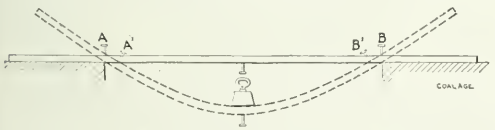

Fig. 3. Tacks Move between Supports and Tilt Out of Plumb When Lath Sags

justified where efficient plugging was impossible or where the measures above the fuel sands were so creviced as to make the escape of gas dangerous.

The Workable Seam

Mr. DeWolf frequently brought up the question as to what coal seams should be protected. He urged that drillers could not well form an estimate of the thickness of the coal beds through which they passed and would be less likely to find workable beds if the protection of such as they found would be likely to involve the expenditure of much money.

He thought the drillers should be compelled to protect, by double casings, all the productive coal measures whether coal was known to be contained in them or not. It was easy to see that the definition of "workable seams" had a larger meaning in Mr. DeWolf's vocabulary than in that of the Bureau. The engineers of that body declared a "workable seam" to be one likely to be exploited during the life of the well.

All other seams were to be protected by the precautions in abandonment. This seems a fair decision. Extremely remote protection afforded at great expense is not true conservation but waste. If beds are to be protected for long periods of time before mining has commenced concrete casing seems to be preferable wherever the oil can be prevented from attacking it.

Where the concrete is thick, it is probable that there is a limit to the corrosion, the face of the mass becoming glassy and impervious. But unless the quantity of material is large and dense, this action will not prevent corrosion. Moreover concrete is destroyed by oil and if any length of cement-protected casing is attacked by oil and salt water in turn, the casing will be inevitably destroyed.

The Difficulty in Placing the Clay

Opposed to these disadvantages, clay seems to be free from corrosion by salt water or oil. If deposited as a slime it would contain few air bubbles. Mr. Rice, however, doubted whether, if clay were comminuted so as to form a slime, it would settle at all in a coherent manner in a hole where the water is not filtered off.

Mr. Hood and Mr. Heggem urged that it would so settle if the water were made acid and instanced filling pipes with the loess of Louisiana, but while it is possible that the salt in the wells would be enough to cause the

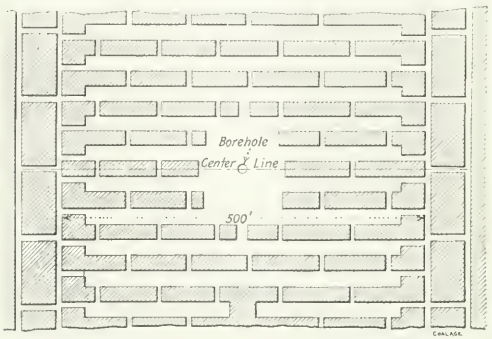

Fig. 4. The Only Location for a Fuel Well Where Coal Pillar May Be Withdrawn without Distortion

deposition of a cloud-like flocculence, the most acid of waters would be unlikely to produce the equivalent of a puddled clay. As Mr. Rice observed, it would coat the casings but not fill the spaces between them.

The keynote of the meeting was haste. It was represented that legislation should be secured before the legislatures ceased their sessions. It came as a surprise when H. M. Wilson, engineer in charge of the Bureau of Mines, stated that there was no hurry and that a committee meeting in March would meet the situation. It is too late to formulate or pass a well-considered measure. Possibly a bill regulating the surveying of wells could and should be immediately passed but the other matters have been so little discussed, and are understood in their entirety by so few that hurry is undesirable.

It might be added that on Thursday, Feb. 13, the committeemen named by the chair met and appointed a few of the final committee, the selection of the remainder being left for the individual committeemen, acting through and for organizations representing coal, oil and gas interests.

The coal committeeman was G. W. Schluerderberg; the representative of the bureau, G. S. Rice; Frank DeWolf is committeeman for the state geologists; J. B. Corrin and E. E. Crocker will represent the gas and oil interests, and David Young, the mine inspectors.

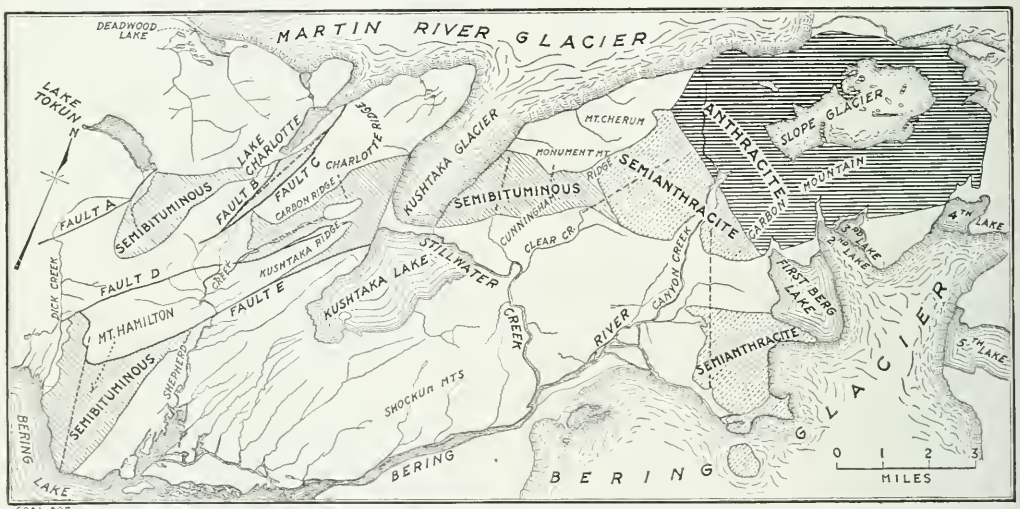
The next meeting was arranged for March, and is to be held in Pittsburgh. The presiding officer, W. E. Fohl and the secretary, O. P. Hood, are to be ex-officio members.

The Soft Coals of the Bering Field

By W. R. Crane*

SYNOPSIS—The coals of the Kushtaka and Carbon ridges are thicker in aggregate than the anthracite coals to the east and may reach in all 188 ft., four beds ranging from 25 to 32 ft. Proceeding further to the east, a reduction in aggregate thickness is discovered, the Bering Lake district having 76 ft. and the Lake Tokun body only 30 ft. In some cases the coal is so fragmentary as to appear briquetted in the bed, and this condition extends into the body of the hill. But little of all the Bering River field will find its way into market in its natural condition. Coking or briquetting will be necessary before it is sold. The second of a series of articles by W. R. Crane.

The district named after the Kushtaka and Carbon ridges lies wholly within the semibituminous coal area. these beds is such as to place them parallel with those on the eastern slope of the ridge. The thickness of these beds is as follows: 17 ft., 13 ft. 6 in., 8 ft., 20 ft., and 19 ft. 6 in., making an aggregate of over 70 ft., which if added to the total thickness of beds on the eastern slope of the ridges make a total thickness of over 150 ft. of workable coal.



The Bering River Coal Field in Alaska, Showing the Change in the Nature of the Coal Beds from Northeast to Southwest

The outcrops of the coal beds occur along the streams separating the two ridges, on the slopes of the latter, and to a limited extent on the tops of the ridges themselves.

Eastern Half Has 150 ft. of Semibituminous Coal

A large number of coal beds of moderate size have been located on the eastern slopes of the Kushtaka and Carbon ridges, but owing to the dense thickets of salmon brush, willows and alders, as well as a thick covering of moss, many of the outcrops are concealed. However, over 80 ft. of coal has been measured on the lake side or the eastern slopes of these ridges, and it is not improbable that many other workable beds still remain to be uncovered.

Five coal beds outcrop on the top of the extremely narrow prong of Carbon Ridge. The dip and strike of

Western Half Has 188 ft. of Semibituminous Coal

There are abundant outcrops of excellent coal on the western slope of Kushtaka ridge and the southern extension of Carbon ridge, but owing to the distance between them and the extreme folding and faulting that they have undergone, it is hazardous to attempt to correlate with any degree of accuracy and equally difficult to estimate the number and thickness of the separate beds. A statement as to the number and thickness of the various beds will, however, serve to give an idea of the size of the coal beds that have been located.

Beginning with the extreme southern extension of this district on Carbon Creek and proceeding northward, the following thickness of coal beds was noted: 18 in., 10 ft., 9 ft. 4 in., 30 ft., 32 ft., 24 ft., 30 ft., 12 ft. 6 in., 25 ft., 14 ft., and many others impossible to measure with any degree of accuracy owing to excessive folding. The aggregate thickness of the beds measured is 188 ft.

Two Localities So Crumpled that Strip-pit Mining Will Be Required

There are two localities in this district, namely, west of the narrow ridge extending southeastward from Carbon ridge and west of the northernmost extension of Kushtaka ridge, where folding and faulting have caused such extreme changes in the coal beds as to render them

*Professor of mining, Pennsylvania State College, State College, Penn.

totally unfit for working except by open cut, but fortunately such areas are very limited in extent.

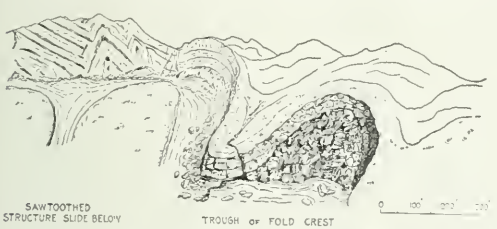
The coal beds at these points have been forced back upon themselves by the close folding of the inclosing rocks until in many cases the rock strata have been crowded out and the coal massed together in huge pockets. Erosion has removed the overlying rocks and exposed large bodies of badly crushed coal. See the illustration below.

Another more or less isolated coal-bearing area, which may be considered as belonging to this district, lies on the western slope of Carbon ridge and also on the like slope of Charlotte ridge. This area lies between two extensive fault planes forming a long narrow strip of land practically separated from the adjoining districts except for narrow extensions of the Kushtaka and Carbon ridges touching it on the east and a similar extension of the Tokun district connecting with it on the west.

No attempt has been made to correlate the coal beds lying within this area, but the following outcrops have been located: 20 ft. 6 in. of coal at the extreme southern extension of the area and 16 ft. at a point about halfway up Lake Charlotte.

Bering Lake District

The Bering Lake district comprises an isolated area lying directly to the east of Bering Lake and including



Section on West Wall of Canon, Canyon Creek, Showing Folded Strata

most of the highland between the lake and Shepard Creek. To the northward the district splits into two prongs, one extending toward Lake Tokun on the north, the other toward the Kushtaka and Carbon ridges district to the northeastward.

The coals of this district are wholly semibituminous and where not too badly broken are of fairly good grade. As the strike of the majority of the coal beds is east and west, a north and south line would serve very well along which to estimate their number and thickness. Beginning at Poul's Point and proceeding northward the following thickness of coal beds was noted: 9 ft., 7 ft. 6 in., 2 ft. 4 in., 6 ft. 10 in., 1 ft., 9 ft., 17 ft., 10 ft. 6 in., 7 ft., 3 ft. 6 in., etc., giving an aggregate thickness of over 76 feet.

Powers and Falls Creeks Are Not Only Contorted, but Have Many Shale Partings

The coal beds on Falls Creek, in the northern extension of this district, have been badly folded and faulted, so much so that it is extremely difficult to secure reliable information regarding their thickness and extent. Further, the coals of both Powers and Falls Creeks tend to be dirty, containing numerous shale partings.

The coal beds on a narrow ridge, the southern extension of Mount Hamilton, stand at high inclinations; one in particular, the 17-ft. bed mentioned above and occurring at a considerable elevation, stands practically on end. This bed measures 17 ft. at the summit of the ridge, but pinches out in depth, as shown by the outcrops on the side of the mountain, until it narrows to 6 ft. some 300 ft. below.

The coal bed at the McDonald mine is somewhat irregular and is claimed to be a detached mass of the original bed. If this is the case the line of displacement should readily be seen, but I am not aware of its existence.

Lake Tokun District

This area of semibituminous coal lies to the southeast of Lake Tokun, and on Tokun Creek. The locations of the outcrops of coal beds have been made principally along the gorge of the creek. The precipitous walls of the cañon of Tokun Creek afford an excellent opportunity to locate outcrops and while a number of fair-sized outcrops have been found, many others are so badly disturbed and broken by rock movements as to be practically worthless.

The following measurements were taken along the course of the creek, beginning with the uppermost and proceeding downward toward Lake Tokun: 8 ft. 10 in., 9 ft. 5 ft., 6 ft. 6 in., etc., making total thickness of approximately 30 feet.

Powdered Coal Sometimes Briquetted in the Bed by Pressure

The physical condition of the coals of the Bering River field is such as to render mining both difficult and wasteful. From one end of the field to the other extreme rock movements have broken the coal badly while in certain localities the coal has been crushed almost to powder, although it stands fairly well in the face at the outcrops owing to the high pressure to which it has been subjected.

There is little likelihood, as is often expressed, that the badly crushed condition of the coal is of a superficial nature only, and will disappear beyond the weathered zone. Sufficient work has been done in the nature of drifts and tunnels driven into the coal beds for distances up to 700 ft., to demonstrate that while the coal is not as soft as at the outcrops yet the fractured condition exists and practically the same degree of breakage is ex-

A = anthracite. S-A = semi-anthracite. S-B = semi-bituminous

perienced in mining and handling as at a distance of only a few feet from the exposures on the surface.

THE CRUSHING OF THE COAL HAS LESSENED ITS VALUE

Obviously the anthracite coals will be affected to a much greater extent by breakage and disintegration than the bituminous coals, and their commercial value will be reduced in proportion to the sizes that can be delivered to the consumer. A certain reduction in size is advantageous but beyond that the result is an economic loss.

Sizes including pea coal and below are often of necessity, placed on the market in competition with bituminous coals for steaming purposes and at a cost below that of production.

With the bituminous and to a less extent with the semi-anthracite coals the reduction in size is of less importance although it is a serious matter even with these coals, particularly from the standpoint of waste in mining and handling. With coking coals, aside from waste and the cost of cleaning, if necessary, there is little disadvantage in a certain amount of breakage, as reduction must ultimately be resorted to.

Much work has been done by the United States Geological Survey in determining the constituents and heat value of the coals of the Bering River field. At the foot of the foregoing page, the analyses of coals taken from the various districts are listed in the order followed in this description.

The ash content of these coals is very high so that extra care will be required in mining and there may be much expense incurred in preparation. It is not improbable but that in certain localities it may be found necessary to leave several inches of coal on the bottom to prevent too extensive mixing of the coal with waste.

As a whole, the bituminous coals of the Bering River field cannot be used without being first converted into coke. Likewise the anthracite and semianthracite must, for the most part, be rendered acceptable to the market by briquetting.

A Test of Carborite Bits

The old adage concerning the "the test of the pudding," is as applicable to coal mining as to anything else. Many devices are constantly being placed before the country which appear to possess good qualities. None of these, however, secure general adoption, unless they "make good" under actual conditions of service.

The Carborite Steel Bit Co., of St. Louis, Mo., has placed upon the market a new bit for use in chain coal-cutting machines, a test of which was recently made by R. Xeeson, mine manager, O'Gara Coal Co. mine No. 4, at Harrisburg, Ill. The results obtained are here given:

Two machines were selected in as nearly the same physical condition as possible. One of these was supplied with ordinary bits, while in the other Carborite cutters were placed. These machines were then operated for 13 days in adjacent territory, so as to subject them to cutting conditions as nearly identical as possible, the bits in both machines being sharpened only when necessary. Records were kept of the voltage and amperage of the current and of the tonnage produced by each machine.

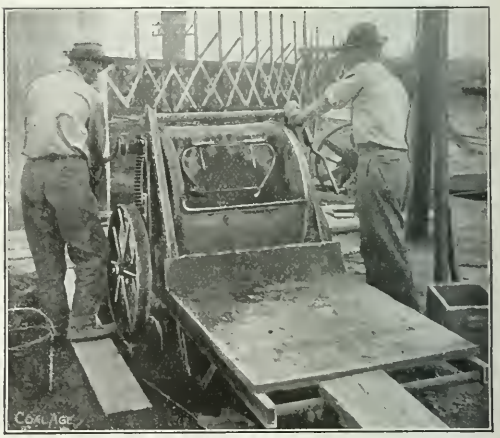
The Carborite bits operated 13 days with 12 sharpenings, producing 3546 tons of coal, or slightly less than 273 tons per sharpening. The average voltage was 250, while the amperage ran from 35 to 45. The machine worked free at all times and without any breakdowns.

The ordinary or standard bits tested against these, operated the 13 days with 36 sharpenings, producing 3120 tons of coal, or approximately 84½ tons per sharpening. The voltage recorded was 250, the same as before, but the amperage ran from 65 to 75. During the time of testing, this machine also suffered four breakdowns—three chain failures and one burn-out.

It is to be regretted that the test was not carried a step further, and the two types of bits exchanged between the two machines and the work continued for another equal period of time. Had the records then been as much in favor of the new bit as before, it would have removed all suspicion that the results might, in part at least, have been due to the condition of the machine rather than the excellence of the cutters.

A Hand Mixer for Concreting

Supplementing the series of articles now appearing in COAL AGE on colliery concreting, we show in the accompanying illustration an ingenious hand mixer. This machine is comparatively inexpensive and of such size that it could be readily mounted on mine-car trucks and run through any part of the mine.



VIEW OF SMALL CONCRETE HAND MIXER

It is a well known fact that ordinary hand mixing is not only exorbitant in cost but also uncertain in results. For the small jobs that are almost incessantly developing around the surface plant or in the mine itself, few companies feel justified in going to the expense of a complicated power-driven mixing machine, and such would also be cumbersome to handle under certain conditions.

The machine shown herewith turns slowly and easily, weighs only 1000 lb., and, as before mentioned, is self-contained so that it could be readily taken down the slope or shaft without dismounting. The manufacturers, T. L. Smith & Co., Milwaukee, Wis., claim that only three turns are required for a perfect mixture, the capacity of each batch is 2½ cu.ft., and the daily capacity of the machine, 25 to 30 cubic yards.

Central Washer of the Ala. F. & I. Co.—II

By Edw. H. Coxe*

SYNOPSIS—The second and concluding installment on this subject, in which a description of the mines and methods of working are given. Considerable water is encountered and a comparatively large drainage equipment is in use.

The main washer building, in the early stages of construction, is shown in Fig. 1, and the washed-coal bins in Fig. 3.

The separation in washing is made on a 1.37 specific gravity. The average analysis of the Margaret raw coal as brought to the washer shows 25 per cent. ash, which is reduced by washing to 7 per cent., as compared with 18 and 10½ per cent. for the Acmar coal. The washed coal contains 3 per cent. of sink heavier than 1.37 sp.gr., the balance of the ash being in chemical combination with the coal.

There is, in connection with the washer, a small machine shop, equipped with a lathe having a 24-in. swing, a sharpener, drill press and forge. In this shop all the light repair work for all the mines, as well as the washer, is done, that can be handled. The total number of men employed at this washer, including superintendent, electrician, engineer, etc., is thirty. These are housed in thirteen 4-room and one 6-room house, weather boarded and ceiled, with 16-ft. square rooms. The houses are fenced and each one has ample ground surrounding it for a good garden.

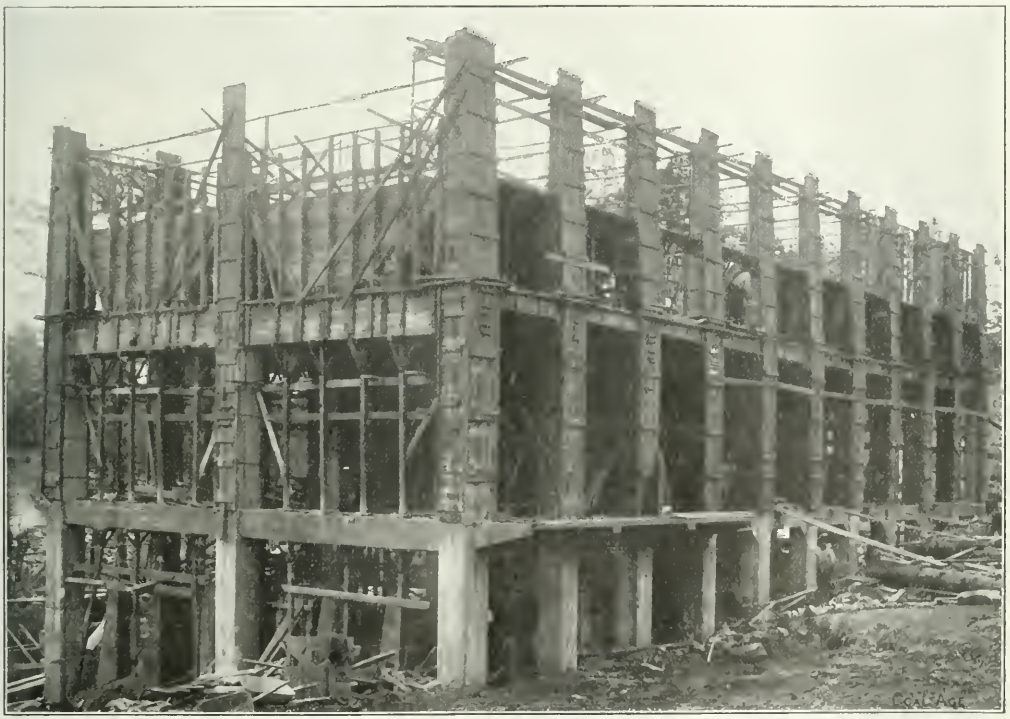


Fig. 1. The Main Washer Building of the Alabama Fuel & Iron Co., in Process of Construction

The Acmar Mine

As stated before, this mine is on the Mammoth seam and it has an average daily output of 1800 tons. The slate roof is about 30 ft. thick and is one of the best mine roofs I have ever seen.

The upper bench, which separates readily from both the rash parting and the roof, is shot out on the solid by shearing ahead of the cutting shots, advancing about 12 ft.; then the parting, which is soft, is shoveled off into the gob, and the bottom bench of coal is shot up. Monobel, manufactured by the du Pont Co., is used exclusively for blasting. The mine was opened on the outcrop, the slope following the seam at right angles to the strike; the pitch at the outcrop is about 29 per cent., which decreases gradually, till near the face it is only a trifle over 1 per cent.

Near the face of the slope is a fault. This is not a regular displacement, but is in the nature of a wave or wrinkle, the coal rising abruptly about 6 ft., without de-

*1026 Glen Iris Ave., Birmingham, Ala.

creasing in thickness; then rising gradually for about 80 ft., and at the present face indications are that it will again assume the slight normal dip. The headings are driven on a slight up-grade to be self-draining. On the right of the slope the pitch steepens, causing the headings to come closer together, and on the left the reverse obtains. Every eighth room an 80-ft. solid block of coal is left in.

Mine Is Ventilated by a Sirocco Fan

The mine is ventilated by a 6x3-ft. single-inlet, steel-incased, Sirocco exhaust fan, running 218 r.p.m., belt-connected to a General Electric 50-hp. induction motor, running 895 r.p.m. The main slope is the main intake and the manway the return. Each heading is furnished with a separate split of air, the return from the right side being overcasted over the slope, and the manway being undercasted across the left-hand headings.

The main pump station in the mine is between the third and fourth right headings and all the water made above this point is drained directly to this sump. The pump here is an electric-driven Alberger, two-stage centrifugal, working against a head of 270 ft., and having a capacity of 500 gal. per min. Below this and pumping to it, is another Alberger electric driven, single-stage, 500 gal. per min. capacity pump, rated for 125-ft. head. The sinking pump is an electric-driven Aldrich, triplex, portable, 120 gal. per min. capacity pump, rated for a 270-ft. head.

Considerable firedamp is given off, but it is carried out and rendered harmless by ample ventilation. This is naturally a damp mine, water dripping over the coal everywhere, so that there is absolutely no dry dust and humidifying is entirely unnecessary, even in winter. The slope is single track and laid with 60-lb. rails. In the rooms are laid 16-lb. steel rails on one side and 3x4-in. wood rails on the other, the latter being used to help hold the loaded cars coming out of the rooms.

Fig. 3. View Showing the Washed-coal Bins

Iron-frame, wood mine cars of 4800 lb. capacity, having side bumpers and swinging end gates, are used, the couplings consisting of a link and two clevises. Eight cars to the trip are hauled out of the slope by a Hardie-

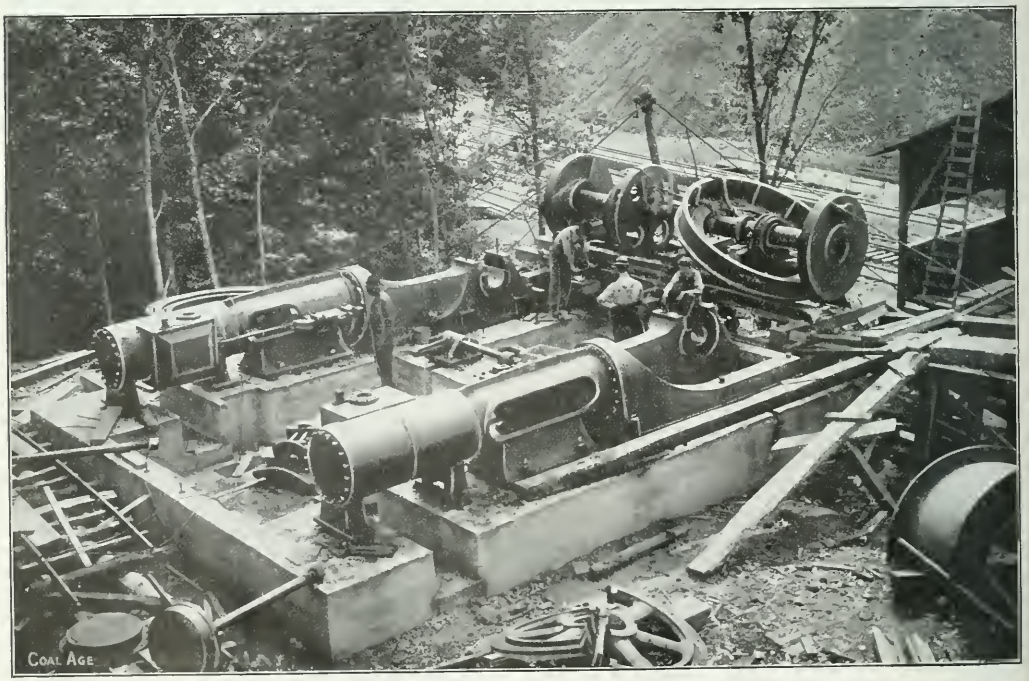

Fig. 2. The 28x48-in. First-motion Hardie-Tynes Hoist Being Erected

Tynes duplex, 28x48-in., first motion hoisting engine, having a single 8-ft. drum; steam for this is furnished by two 200-hp. Walton, Chattanooga, Tenn., boilers, having one stack 60 in. in diameter 120 ft. high. Fig. 2 is a photograph of the hoisting engines being erected, the end of the tipple showing on the right. In this picture will be seen a large pile of coal stored across the tracks, which was obtained while driving the slope before the railroad was built. There is an electric-driven auxiliary hoist, consisting of a 75-hp. General Electric induction motor, geared to a 4-ft. drum, for driving the slope and turning new headings in the mine.

Screening the Coal

The tipple is on a direct line with the slope track, and when a trip is landed, the cars are handled by gravity over a Phillips crossover dump, then over a switchback to the empty track, where they are attached to the rope and dropped down the slope. Fig. 4 is a photograph of the tipple and yard under construction, the former being of frame. The screens were built by the Montgomery Washer Co., of Birmingham, and consist of two parts, working in opposite directions, to equalize vibration. The upper section has 6x16 ft. of screening surface, with 4-in. perforations, and the lower one is the same size with 2-in. perforations. The lump coal from the upper screen passes over a 36x16-ft. traveling picking belt, where it is hand picked before dropping into the railroad car for shipment. The other two sizes over and through the 2-in. perforations are loaded separately and shipped to the washer. All the machinery at this plant is electrically operated, except the main hoist, by power from the washer generating plant.

William J. Hand is superintendent of this mine, and W. J. Lovejoy, mine foreman; 150 miners and 50 day hands are employed. All the employees are housed in company houses, 150 in number, mostly 4-room, and of the same construction and dimensions as those at the washer, except a few larger ones for the mine and office officials. There is also a commodious company commissary, operated for the convenience of the employees, where they can buy all the necessities as cheap or cheaper than can be done elsewhere. The inside of this building measures 100x40 ft., in addition to which is an ice house and well equipped meat market.

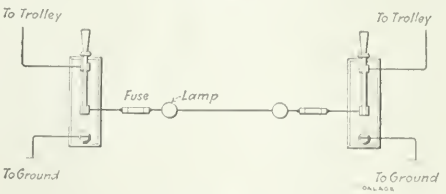
Signal Lights for Single Track

By C. J. Fuetter*

A number of mines are using electric haulage motors which, for some reasons, must pass over the same track for a certain distance. In such mines it is almost necessary to provide some arrangement so that only one motor at a time will have the right-of-way on this portion of track. Some mines have telephone systems, but these are not effective for the purpose.

The safest and most economical arrangement is to have an electric-lamp signal as shown in the accompanying figure. This consists of two lights of the proper voltage, connected in series, two single-pole double-throw switches, two fuses and enough of No. 14 B. & S. rubber-covered copper wire to be strung the full length of that particular place in the track. Suppose both switches to be in the upward position, giving a live wire but no return, and consequently no light. Then, the motorman to arrive at the signal light first, will throw the switch downward and light up the system, giving him the right-of-way. When he reaches the other end, he throws the switch downward, darkening the lights, showing that the section is clear.

The next motorman will repeat the same operation to get his right-of-way, with this difference, that instead of throwing the switches downward, he will throw them upward. Under no conditions must a motorman change the switches in any way when the lights are bright, as somebody else has right-of-way. Should the signal get out of order, no light can be obtained. In that case no motorman should enter the single track before signal is again in working condition.



Wiring Diagram for Block Signal

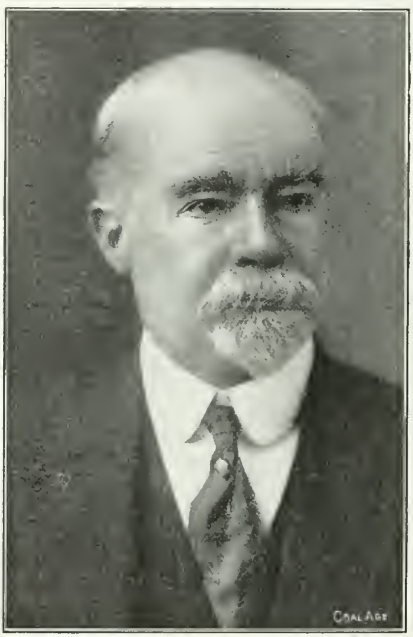
WHO'S WHO—IN COAL MINING

The legislature of Pennsylvania, which is credited with doing nothing without a political motive and whose politics is said to be swayed continually by the lure of the dollar, has managed to keep its mining and geological departments, among some others, remarkably free from graft. Geology is a study which attracts men who are not of a domineering or acquisitive nature, and to whom politics for its own sake or for hope of reward is utterly repellant. The ability of the geologist is rarely developed by men whose minds are diverted by their personal interests.

J. P. Leslie, for many years state geologist of Pennsylvania, chose men who were enthusiasts like himself. As one recalls the names of the men who were young enough to have a career after their service closed, one cannot recall a single instance of a man who failed to make good in his after life, and to justify the confidence Leslie placed in him.

They have all become elder brethren in the mining industry, doing far more than their share to stir its inner life and mold its later progress. It has been said that every Pennsylvanian is a geologist. The general interest in the strata of the hills and valleys of that state has been continually fostered by the able monographs of the second geological survey.

Among the *protégés* of J. P. Leslie, should we not rather say his stalwart supporters, was William Griffith, the eldest child of Andrew J. and Jemima (Sax) Griffith. He was educated in the public and private schools of West Pittston, Penn., and at Lehigh University. He taught school for one term in New Albany, Bradford County, Penn., and on holidays and Saturdays he surveyed near-by farms.



WILLIAM GRIFFITH

In 1878 he went West and secured a position as transitman and assistant engineer for the Union Pacific Railroad Co., for which he surveyed and supervised the construction of railroads in Nebraska, Idaho, Montana, Utah and Colorado. He returned East at the Christmas season of 1880, and became division engineer for the Lehigh Valley R.R., residing at Bethlehem, Penn. Two years later he became an assistant geologist on the Geological Survey of Pennsylvania, being located successively at Pottsville, Hazleton and Bernice, and mapping the Schuylkill, Lehigh and Bernice coal measures.

From 1884 to 1886, inclusive, he was engaged in private engineering practice at Pittston, Penn. During 1887 and 1888, as assistant state geologist, he had in charge the completion of the geological survey of the Wyoming & Lackawanna coal fields.

After this work was finished, he opened an office in Scranton as consulting mining engineer and geologist. Since that time he has prepared numerous economic geological reports, many of which have appeared in print and had extensive circulation in Canada, England and Holland, and some have been translated into German and French for circulation in Europe.

Among the most notable articles from his pen was an extended monograph entitled "Anthracite Coal with Estimates of Reserved Supply." This appeared in the "Bond Record" of New York and attracted widespread attention in business and financial circles. In 1892, Governor Pattison appointed him a member of a commission to inquire into the possibilities of utilizing the waste in mining anthracite.

In 1895, he purchased a tract of anthracite at Wyoming, Penn., organizing and becoming president of the Wyoming Coal and Land Co., which operated a colliery for a number of years until it was sold to the Lehigh Valley Coal Co.

In 1897 and 1898, he investigated and rendered a report on the anthracite deposits of northern Peru, both on the Pacific slope and on the head waters of the Amazon River. From 1906 to 1908 he examined and reported on the coal resources of the Matanuska valley in Alaska, being the first to recognize the high-grade character and coking qualities of the Matanuska coal. In fact, he manufactured on the ground the first coke ever made in Alaska. At one time or another he has visited all parts of the United States and Canada, including the more distant parts of the latter dominion, Vancouver and Queen Charlotte Islands.

In 1908 he was appointed by the Court of Northumberland County, Penn., a member of a commission to fix the taxable value of all the coal lands in that county. In 1910, with Eli T. Conner, he was appointed by the advisory committee to the city of Scranton to investigate the risks to which the city was exposed by the extensive mining work being prosecuted beneath it, and the report made was published by the Bureau of Mines.

EDITORIALS

Use of Explosives in Mines

It is entirely proper that explosives used in mining coal should be subjected to rigid tests. The only wonder is that the movement in this direction in the United States was so long delayed. The safety of our underground workers and the preservation of our mining property make it incumbent that the inquiry be extended indefinitely.

The advent of a flameless explosive would be welcomed by the whole industry; however, this is asking a great deal of the manufacturers of permitted powders. It is quite generally realized that even the best of our permitted explosives fall short in this respect under the crucial test of actual use. There is no doubt but that the present products have been improved until they more nearly approach the ideal than was ever the case when we used any and all powders with indifference as to their safety qualities.

The experience of Great Britain in the matter of testing explosives for use in underground work is of interest to the industry in this country. During recent years the British have formulated one Coal Mines Order after another, until legislation on this subject in that country is quite complete.

A survey of the most recent British acts shows among other things the following requirements: The storage of explosives underground is prohibited, and the workman must bring his remaining stock out at the end of his shift, or deliver it personally to the workman succeeding him in his room or entry. The mine owner must provide facilities on the surface for storing the powder. For use below, the explosives must be in cartridges in a secure case or canister, in which it must be kept until required for charging shot holes. If the explosive contains nitroglycerin, proper warming pans have to be provided.

Detonators are under the control of the mine manager, or some specially appointed person. When issued to shotlighters, the latter must keep the detonators in a locked case separate from any other explosive until about to be used.

Concerning the charging and firing of shots, the British rules are somewhat exacting. A shotlighter must see that all persons in the vicinity take proper shelter before firing, and the hole may be fired only by means of an efficient magneto, electrical apparatus or a fuse complying with stated conditions. In case a shot misses fire, careful search for the detonators and charge must be made; if they are not found, the coal must be loaded under the supervision of the person firing the shot, or one of the mine officials. After being loaded, this coal is sent to the surface in specially marked cars.

Only permitted explosives may be used in seams in which gas has been found within the previous three months, "in such quantity as to be indicative of danger." In mines not naturally wet throughout, the use of permitted explosives is required in "any road or any dry and dusty part of the workings, or any shaft or drift communicating therewith which is in process of being sunk, deepened or enlarged."

The wages of the appointed shotlighter must not depend on the amount of coal to be gotten, and no person shall be qualified for appointment as a shotfirer, unless he has obtained the requisite certificates as to his ability to make accurate tests for inflammable gas, and as to his eyesight. Before firing, the shotlighter must examine the place where the shot is to be fired and all contiguous places within a radius of 20 yd. for the presence of inflammable gas; and, also, he must examine the floor, roof and sides within a 5-yd. radius, for coal dust, and render all dust harmless that may be within such area.

It might be well for coal operators in this country to follow the example set by European nations in this matter of providing stringent regulations concerning the use of explosives in coal mines. A few states have taken steps in this direction, but the movement should be more general and the laws more uniform in character.

Reducing Ventilation When Firing

With this issue closes a discussion that has been at once interesting and profitable, in breaking down or at least *forcing a passage* through one of the high walls of prejudice surrounding the practice of coal mining.

Although the discussion has in no wise proved the truth of the claim that "greater safety is assured by reducing ventilation when firing," it has clearly pointed the way to a new field of investigation that promises developments that may lead ultimately to a practical solution of the mine-explosion problem, which thus far has successfully baffled both science and practice in their efforts to discover its hidden secrets.

Mining practice has dealt with the problem of the prevention of explosions of gas and dust in mines, by diluting the explosive atmosphere with air—the very element on which the explosion depends—much as a child's appetite for sweets is broken by an overdose of the same.

Recently, suggestions of a variety of different methods of treatment are being offered. Many of these, as wet zones, stone-dust zones, the Taffanel barrier, etc., have been tried with varying results. And now comes the latest suggestion—the depletion of the oxygen content of the air, by diluting the mine atmosphere with extinctive gases.

The Harger suggestion of doing this "by introducing the waste gases of the furnaces, into the intake air current" has not been taken seriously by practical men, because of the known poisonous character of these gases; and even could this element of danger be eliminated, there would still remain the difficulty of rightly gaging the percentage of gas necessary to prevent ignition and which would not be inimical to life. The margin is a narrow one.

The question of reducing the circulation of air in the mine when firing, by closing the discharge opening at the

mouth of the upcast shaft, has appealed to many practical men as a good suggestion, applicable to all but gaseous mines; where according to general opinion, such a proposition could not be considered, owing to the rapid accumulation of dangerous quantities of firedamp.

It has been rightly urged by a number of our correspondents that this question should receive the earnest attention of the federal Bureau of Mines, and that a series of suitable experiments should be undertaken to ascertain what, if any, advantage may be gained by this practice, and to what conditions it is applicable. We heartily commend this suggestion and hope that the Bureau of Mines will be able, soon, to throw some light upon this subject about which there is so much speculation.

Importance of Rail Bonds

The unfortunate property of electricity of taking the line of least resistance has been the cause of many urban troubles. Electrolysis and the deterioration of concrete are prominent among these. However, until the recent experiences at the mines of the St. Bernard Mining Co., in Kentucky, detailed by C. J. Norwood, the state geologist and chief inspector of mines of that state, the danger of stray electrical fields at collieries was not made clear.

Efficient bonds and adequate returns may, from now onward, assume an entirely new aspect. They may be regarded not merely as good investments; but as essentials, the use of which is to be enforced by laws and regulations.

If a permissible explosive had not been used at the mine in question, the men who were present at the premature explosions recorded would have been killed and their deaths would have been wrongly charged to their carelessness. Fortunately, the flame of the explosive was so short that the men could state what occurred.

In all three cases, the copper needle was in the hole when the cartridge exploded. In two cases, the powder had been in the hole for some time and had not been ignited. The presence of the copper needle seemed necessary to conduct the electricity. This raises the question whether in mines where extensive electrification has taken place, it is well to use metal and especially copper needles without some kind of protecting insulation.

W. C. Waddell, an electrical engineer, ascertained that a fair average of the current required to fire the permissible powder under investigation would be 25 volts and 0.30 ampère and to fire black powder 0.35 ampère. As Professor Dates obtained voltages of 25 volts between an air pipe and the lower dirt band and several of 12 volts between that parting and the mine floor, it is easy to see how an explosion could arise, especially if the needle tended to convey the current between two pyritiferous masses in one dirt band or from one dirt band to another. It was shown by H. B. Dates' experiments that the dirt and sulphur bands carried nearly twice as high a voltage as the cleaner coal of the seam.

Conclusions must be drawn with due conservatism, but it may be necessary in some instances not only to provide good bonds but a shorter return to the surface than is afforded by the mine tracks. As the resistance of mineral bodies, likely to be encountered, is apparently not known, it is impossible to form an estimate of their relative conductivity compared with iron. Moreover, much work remains to be done to ascertain the ampèrage by which powders may be exploded.

Too High an Efficiency

In our Feb. 1 number, we printed an editorial calling attention to the remarkable performances accredited to some mine fans, no approach to which has ever been attained in any careful or scientific laboratory test. In this issue we print an article describing a recent fan installation. This states that the efficiency ranges between 79 and 83 per cent.

We cannot but believe that the men making the test from which these efficiencies have been derived were deceived in securing their own data and that the real performance of the fan was considerably below the figures named.

In making the above statement, we do not wish to be misunderstood as casting any reflection whatever upon the veracity or accuracy of the observers; neither are we inclined to question the reliability of the Hydro-gage used, as the basic principle of this instrument is the Pitot tube, the accuracy of which has been firmly established.

If one will observe the flow of water in any stream, he will notice that the swiftest part of the current may or may not be in the center, but the movement close to the edge is quite different from both maximum and average velocity. Furthermore, that the only sure method of determining the average rate of flow, with any current meter, is by making a complete traverse of the entire cross-sectional area of the stream.

Coming back to the efficiency of the fan in question, we are much disposed to doubt that the velocity of the air at the point or points of measurement represented a correct average of the rate of flow across the entire heading or airway. And, if this did not represent the true average, the capacity or performance of the fan as reckoned from it would necessarily be erroneous.

Simultaneous Shot Firing

As to the advisability of firing shots simultaneously, in a coal mine, experienced mining men in the United States are divided in their opinions. The question was disposed of with considerable finality in Great Britain by the most recent Explosives Order. The British rule bearing on this problem provides that "Except in driving a stone drift, or in sinking pits, two or more shots shall not be fired in the same place simultaneously." In stone drifts the number of shots that may be fired at one time shall not exceed three, unless fired electrically in series.

In the United States, a number of mining companies have adopted the simultaneous-shotfiring plan, exploding all shots by electricity from the surface, after every man has been withdrawn from the workings. The officials at the mines where this plan is followed vouch for the success of the scheme, claiming that falls of roof are not increased thereby.

It may be suggested as a safeguard in firing simultaneously by electricity that the current should be thrown in, once only. When the switch is thrown a second time there is likelihood of a blownout shot occurring when the mine atmosphere has just been filled with gas and dust. A Western mine was severely damaged some years ago when this latter plan was followed.

SOCIOLOGICAL DEPARTMENT

A Winter First Aid Meet

By J. G. Smyth*

An interesting series of meetings was held under the auspices of the Miners' Y. M. C. A., of Jenkins, Ky., during the week beginning Jan. 20, 1913.

P. C. Dix, state secretary of Louisville, Ky., was present, and the Industrial Department of the International Committee of the Y. M. C. A. was represented by Peter Roberts, who is author of a system of teaching English to foreigners, which enables them to discuss mining subjects after a few lessons, and of books on the immigration problem, especially in relation to mining.

ing officer. Mr. Dix introduced as the first speaker D. J. Price, who gave a history of the mine-safety work of the U. S. Bureau of Mines.

J. R. Fleming then described the large first-aid meeting held in Pittsburgh in 1910, illustrating his remarks with moving pictures.

The Assimilation of the Foreigner

The concluding speaker of the evening was Dr. Peter Roberts, who, in a forceful address, proved to his listeners the economic value of the foreigners who are daily arriving at our shores, and the place they have and will have in developing the natural resources of our land. He

Gathering at First-aid Meeting Held in the Miners' Y. M. C. A., Jenkins, Ky., Jan. 21

D. J. Price, J. Henson and J. R. Fleming, of car No. 7, which has been located at Jenkins for three weeks, also gave their assistance. During their stay, they have instructed six distinct classes, of nine men each, in the use of the helmets and pulmotor in mine-rescue work. They have also given about 60 men a course of first-aid training.

Almost a Week of Safety Planning

Although a preliminary lecture, illustrated with moving pictures, was given at the Burdine Y. M. C. A. on Monday, Jan. 20, by J. R. Fleming, the meetings really opened with a dinner and conference at the home of W. N. Ewald, secretary of the Jenkins Y. M. C. A.

The first session of the institute was held on Wednesday, Jan. 22, with State Secretary P. C. Dix as presid-

*Manager, Consolidation Coal Co., Kentucky Division, Jenkins, Ky.

clearly brought out the fact that immigrants do not reach their maximum efficiency until thoroughly assimilated into our civilization, or until they have become naturalized citizens of our country.

On Thursday night, J. R. Fleming gave an interesting and instructive lecture on mine safety, which was illustrated by stereoptican slides and motion pictures, taken by the U. S. Bureau of Mines.

Doctor Roberts addressed this meeting, dwelling principally on the part the Y. M. C. A. is taking in educational work among working men, and made a plea for the attendance of the men in and about Jenkins at the educational classes to be conducted by the Y. M. C. A. at that town.

The week culminated in a first-aid contest, the teams competing being taken from the various mines in and about Jenkins, and including two teams from the engineering department.

Six men from each of the seven mines constituted the teams, the personnel of which was as follows:

Mine 201
Tom Thomas (Captain)
John C. Yates
M. D. Ramsey
L. D. Mann
Lester Schrum

Mine 202
Charles Smith (Captain)
M. F. Eskew
Fred Hemphill
Harry Smith
W. A. Perry

Mine 203
R. P. Jenkins (Captain)
M. C. Penix
S. S. Wright
R. S. Gunther
Tom Patton

Mine 204
L. Tomlinson (Captain)
Joe Rickett
P. B. Dent
Tom Cummings
C. Bowling

Mine 205
George Christopher (Captain)
J. B. Williams
Melbourne Boggs
R. W. Smith
James Sisk
David Campbell

Mine 206
John Huston (Captain)
Ed. Garret
Jim Short
J. A. Roberts
Steve Jones

Mine 207
J. H. Johnson (Captain)
J. S. Creech
George Rodick
R. F. DeBusk
Paris Smith
W. H. Smith

Engineering Dept., lower division
L. L. Holmes (Captain)
W. H. Robinson
J. C. Metger
Lawrence Malone
A. B. Walter
W. L. McLane

Engineering Dept., upper division
C. G. Evans (Captain)
Paris Fitzpatrick
A. J. Baldwin
Frank Fisher
C. W. Rhodes
J. C. Fi-man

The list of 15 problems had been furnished the men, the first of the week for practice, and from these 15, the following four problems were selected, which were only given to captains of the various teams at the time that the problem was to be demonstrated.

No. 1 Burns on the face, neck, ears, breast, arms and hands. Burned completely from waist up
No. 2 Bad cut on top of head on right side, severe bleeding, broken left collar bone, right leg broken below knee with bone stuck out on right side.
No. 3 One-man event. Man overcome by gas, found with broken right arm below elbow. Perform one-man shoulder lift and carry to place of safety.
No. 4 Man found lying on back over electric wire, unconscious with bad burn on back. Artificial respiration.

Three impartial judges were chosen. About 800 people were present, the number being limited by the accommodations. Special trains were run from the different mines to Jenkins to accommodate the people interested in their particular teams. The first prize was won by the lower division of the Engineering Department, second prize by team of mine 204, and third prize by team of mine 205. J. B. Williams, of mine 205, won the one-man event.

On Friday afternoon, for the benefit of the teachers in the Jenkins schools and for those who will instruct the class in English, which is to be conducted under the auspices of the Y. M. C. A., Doctor Roberts gave a demonstration of his method of teaching English to foreigners. A crowd of about 30 aliens of varied nationalities was gathered in the assembly room of the new office building of the Consolidation Coal Co., and although by careful examination all were eliminated who had any knowledge of English, yet in about 45 min., Doctor Roberts proved conclusively that he had the foreigners not only using but also thoroughly understanding the first lesson.

All the meetings were held in the large auditorium of the temporary Y. M. C. A. building at Jenkins, and at each meeting, the capacity of the hall was taxed. It was decided in a conference to form classes in English for foreigners and in arithmetic and mine work for miners.

MINE RESCUE CAR NO. 7 AND CLASSES OF CONSOLIDATION COAL CO. EMPLOYEES AT JENKINS, KY.

PETER ROBERTS, AUTHOR OF SYSTEM FOR TEACHING ENGLISH TO ALIENS, INSTRUCTING A CLASS OF FOREIGNERS IN "MINE TALK," FOR CONSOLIDATION COAL CO.

DISCUSSION BY READERS

Reducing Ventilation When Firing

Letter No. 16—The discussion, thus far, seems to have been confined more to the questioning of certain statements of facts, rather than to the ascertaining of the reason for such facts. The experiences recorded in the letters of Mr. McAllister apparently contradict all we have been taught in relation to the prevention of explosions. It has always been considered important to keep the mines free from accumulations of explosive gas, by means of an ample air current, which we have been taught serves two purposes: (1) The pressure causing the circulation of air acts to oppose the expansion of the gases generated in the mines. (2) The air current dilutes, renders harmless and carries away these gases.

One naturally concludes from this teaching that when circulation ceases, the gases held back by the ventilating pressure expand and fill the working places of the mine, forming with the air explosive mixtures of firedamp. That this teaching and conclusion are true, and that an explosion would occur if such firedamp mixtures came in contact with flame or become otherwise ignited, is unquestionable. That an explosion did not occur, in the experiments of Mr. McAllister, is sufficient indication that these conditions favoring an explosion did not exist.

We observe Mr. McAllister states that when the fan was stopped there was still an air current of 30,000 cu.ft. per min. passing in the mine, produced by natural ventilation. He rightly regards this as a dangerous condition, because such a current, even in an ample airway, would have a velocity sufficient to carry dangerous quantities of coal dust in suspension in the air, besides supplying the danger zone in the mine with a large quantity of oxygen, which is the supporter of combustion. There were thus present the two elements regarded by all mining men as the most potent in the propagation of an explosion. The danger in this case was overcome, as stated, by sealing up the upcast shaft with heavy doors, which stopped this natural circulation.

It may be assumed that as long as the temperatures producing the natural air column in the mine remained unchanged, the pressure producing the natural circulation still existed. The outlet being closed, the condition in the mine would be the same as when a forced fan is working on a closed drift or mine. The pressure would be maintained and would be, perhaps, more effective in preventing the expansion of the gases than when the air was in motion.

If this reasoning is correct, the mine at the time of the experiment presented the following conditions: (1) A constant pressure opposing the expansion of the gases and thus far acting to prevent an explosion. (2) A limited supply of oxygen, the quantity being determined by the capacity of the airways in the danger zone. (3) The absence, to a greater or lesser extent, of coal dust in the mine atmosphere, owing to the lack of circulation of air.

I believe such conditions must have an important bearing on the limitation and prevention of an explosion. While the experience of Mr. McAllister is unique, I do not consider it contradictory or inconsistent with the conditions known to be characteristic of explosions. He seemingly succeeded in turning an element of danger into a factor of safety, which was possible to do in his case, because the pressure was maintained while the circulation was stopped. On the other hand, had the circulation been stopped by sealing up the intake opening instead of the return opening, I believe we will all agree that the experiment would have resulted disastrously.

Coal mining has no greater problem demanding a solution than that of the prevention of explosions—the king of terrors underground. I am inclined to think that experiments should be conducted along the lines suggested by this discussion, to prove the efficacy of the proposition and to show its limitations in practice, or to expose the error of such a method.

I. C. Parfitt.

Jerome, Penn.

✲

Letter No. 17—Referring to the discussion on reducing ventilation when firing, I would say that while there have been some points advanced in favor of such practice, and these were seemingly supported by experience and the results reported were good, the arguments are not strong enough to induce me to abandon the old-school practice. Like the man from Missouri, I think enough has been said against the system and I can add but little.

In case a mine is generating explosive gas, it would be very unsafe to stop the ventilating fan or reduce its speed. When the shots are fired after all the men, except the shotfirers, are out of the mine; or when a number of shots are fired at one time on a single entry, I am in favor of having the shotfirers begin firing on the return end of the air current and advance with their work against the air. By so doing, the smoke and gases will not be carried past any place yet to be shot; and this eliminates the chances of flame being projected into what might be a dangerously explosive atmosphere. The shotfirer thus always has a clear atmosphere for his work and can make the proper test for gas and feel satisfied with his examination; whereas, if the places were full of smoke and gas, he would be doubtful in making the necessary examination before firing the shot.

When this system is strictly carried out, with an air current sufficient to keep the split or mine in a healthy condition; or, in a dusty mine, if the place where a shot is to be fired is well watered for a distance back from the face, say 25 or 30 yd., the chance of an explosion taking place will be reduced to such an extent that I would feel much safer in the mine while shotfiring was in progress, than if the speed of the fan were to be reduced or the fan shut down.

For example, I will cite one case, that of the Harwick mine explosion, in 1904, when 179 men were k[illed].

The air current in the mine was nearly shut off by the freezing up of the airshaft, and very little air was traveling through the mine, especially in that portion of the mine where the explosion took place; here the air current was hardly perceptible. I think this instance may serve, at least, to offset similar ones that have been given in favor of reducing the ventilation when firing.

F. W. CUNNINGHAM.
Mine Inspector, 21st Bituminous Dist.
Charleroi, Penn.

❖

Letter No. 18—The question of reducing the ventilation in a mine, at the time of firing shots, is so foreign to the average mining man's belief, that at first glance it seems absurd. There are mines where this experiment can never be tried, for the reason that the miners would leave their places in a hurry the moment they discovered the fan had been slowed down.

To reduce or shut down the ventilation, in any mine producing a large amount of gas at the working face, would be to court disaster. On the other hand, former Mine Inspector Verner and others have called attention to this subject, for some time; and this, together with the experiences described by Mr. McAllister, in his recent letters in COAL AGE, has placed this subject beyond the category of mere conjecture. If there is any truth in the theory, its practical application must be ascertained and the conditions clearly demonstrated.

More or less of the same theory has been recently strenuously advocated by Prof. Harger, in a series of lectures, in England. Prof. Harger contends that the lowering of the oxygen content in the mine atmosphere, will reduce the liability to explosion. While I am unable to believe that the arguments advanced apply to mines generating gas freely, I can see that the theory may have an important application in mines subject to the dangers of a coal-dust explosion. A coal-dust explosion is merely a rapid form of combustion and must require a large amount of oxygen to propagate the explosive wave. Under these conditions, it is reasonable to believe that the chance of a dust explosion will be naturally lessened by reducing the supply of oxygen.

While it may be shown, later, that the same argument can be applied likewise to a gas explosion, I fear such a conclusion would surely lead to disaster. My opinion now is that, in a mine free from gas but liable to dust explosion, greater safety may be secured by reducing or entirely stopping the ventilation when firing shots. I do not, however, accept this theory as a panacea for all the ills of coal mining.

JAMES HOLDEN, Supt.,
Princeton Coal & Land Co., Ltd.
Princeton, B. C., Canada.

❖

Letter No. 19—I have read with great interest the discussion of the question of reducing ventilation in mines when firing. I am employed, every afternoon, in the work of inspecting shots. I note some writers favor reducing the ventilation, while others would increase it, at firing time.

My opinion is that when conditions will permit, the ventilation should be entirely stopped before firing is begun; that is to say, provided there is a proper system of shot inspection maintained in the mine. Every hole should be examined by a competent person to ascertain that it is properly placed and cleaned out before it is charged. Only permissible powder should be used in blasting and the holes should be tamped with wet clay.

I believe in electric firing when everybody is out of the mine. I do not believe in the employment of shotfirers who must make their rounds, firing one or two shots at a time, when all the men have left the mine but themselves. If the mine is not safe for the men, it is not safe for the shotfirers; and what is more dangerous still, the mine air is often heated and loaded with coal dust, which makes it ready for an explosion to occur upon the slightest mistake of a shotfirer.

We have in our mines one of the best systems of firing possible. Each afternoon, the firebosses, carrying the electric detonators in a leather bag, visit every working place, examine each hole to be fired, see that the place is well sprinkled with water, make up the necessary charge of powder and see that it is put to the back of the hole and the hole properly tamped with wet wood pulp, which we use for tamping.

All electric currents are turned off at the end of each shift. The wiremen then go around, couple up the shots, put in the switches and return to the surface. The fan is then stopped for 30 min., before firing, and remains so for a few minutes after the shots have been fired. After starting the fan again and giving time for the air to clear, in the mine, the wiremen go below to examine for fire and take out the switches.

We fire, in this way, from 150 to 200 shots, at the end of each shift; and I have never yet found the least evidence of any trouble having occurred, when making my morning examination as fireboss.

WILLIAM ROTHWELL, Fireboss.
Castle Gate, Utah.

❖

Letter No. 20—In regard to reducing ventilation when firing shots in a mine, I would say at once and without any qualification that I consider such a proposition a retrograde step. It is a parallel to the suggestions of Dr. Harger, as expressed in his recent book on the "Prevention of Explosions and Mine Fires."

Assuming, however, that the shots are to be fired in the working places and not on the roadways, the danger of explosion would be less, owing to the coarseness of the dust at the face. Also, whether we consider a longwall face or a bratticed room, the air current is seldom a serious obstacle to the expansion of the gases produced in firing.

In a mine generating firedamp, I cannot imagine that any sane man would advocate closing off the ventilation either wholly or in part, at any time. The Mines Regulation Act (Canada) and the mining laws of most states require the maintenance of a current of air sufficient to dilute, render harmless and carry away the gases generated in the mine. If this rule is to be disregarded, mine officials would be at liberty to adopt the "Harger theory," and reduce the oxygen content of the air current to 17 per cent., and introduce, say 1¼ per cent. of carbon dioxide into the air current.

In my own experience, I have never had charge of a mine where it was possible to shut down the ventilating current without causing an immediate accumulation of firedamp in the workings. Besides the accumulation of firedamp, the shutting down of the ventilation would

introduce another danger; namely, large quantities of carbon-monoxide gas, produced by firing in a dust-laden atmosphere and a limited supply of air, would accumulate in the rooms and chambers to an extent that might prove fatal to the shotfirers should they have to return to a room where shots had been fired.

The reading of some of the letters, especially those of Mr. McAllister leads one to conclude that the mine air, in the cases mentioned, must have contained a low percentage of oxygen. It would be interesting to know the exact composition of the air in the mine at various points, at the time indicated in Mr. McAllister's letters. To make the investigation complete, an analysis of the coal should also be given to show the inert dirt contained in the seam, and which probably played an important part in preventing an explosion.

In closing, permit me to say that the whole proposition of reducing ventilation in mines, at firing time, appeals to me only as an excuse for reckless blasting. Although the theory seems to have some support, from the instances given, the details are insufficient to be conclusive.

JAMES ASHWORTH,
Mining Engineer.

Vancouver, B. C., Canada.

Oxygen Supply as Affecting Mine Explosions

The discussion on reducing ventilation when firing naturally draws attention to the oxygen supply necessary to support combustion in mines where coal dust or firedamp abounds.

In mines where the coal is blasted, the explosion of a large quantity of powder, at one time, undoubtedly has a tendency to decrease the percentage of oxygen in the mine air, at the working face. This is due, not to the consumption of the oxygen of the air by the powder in explosion, as the powder is supposed to contain its own oxygen supply; but the large quantities of carbon dioxide produced by the explosion of the powder naturally reduce the percentage of oxygen in the mine air in the immediate vicinity.

At present, authorities differ as to the reduction of oxygen percentage that is necessary to prevent the ignition and explosion of otherwise explosive mixtures. Dr. J. Harger, England, states that *comparative* safety in mines may be obtained by a reduction of from 1 to 2 per cent. in the oxygen content of the air and the introduction of about ¾ per cent. of carbon dioxide; and adds that *absolute* safety will be secured by a reduction of 3½ per cent. in the oxygen content and the introduction of from ½ to 1 per cent. of carbon dioxide.

G. A. Burrell, chemist of the Bureau of Mines, gives, as a result of his laboratory experiments, a much larger percentage of reduction in the oxygen content of air as necessary to prevent the ignition of an explosive firedamp mixture. In fact, Mr. Burrell's figures are, approximately, double those of Mr. Harger (COAL AGE, Jan. 18, p. 105). The oxygen content given by Mr. Burrell as necessary to prevent the ignition of firedamp, would not probably support human life. In commenting upon the results of his experiments, Mr. Burrell states (p. 106): "If all conditions are identical the mixture will explode less violently and less completely in proportion to the decrease of oxygen percentage."

Mine air always contains less oxygen than outside air. The deficiency of oxygen, in the air that is traveling through the mine, may vary from 0.1 to 0.2 per cent. or even more, while at advancing faces, under ordinary conditions, the deficiency may reach 2 per cent. or even more in extreme cases.

It is to be sincerely hoped that more uniformity of results will be obtained by future experiments. If it is true that, under certain conditions possible in mining, the deficiency of oxygen may amount to 2 or more per cent., it might be assumed that in such workings an explosion of gas would be practically impossible, according to Doctor Harger's figures, inasmuch as we may be reasonably sure that from ½ to 1 per cent. of carbon dioxide will also be found at the face of such workings. It is in this connection we are to look for whatever benefits may be derived from reducing the ventilation at the time of firing in mines, since, by reducing the air supply, the oxygen percentage will be decreased and the carbon-dioxide percentage increased.

Experience shows that mine explosions frequently originate on the first of the air and the explosive wave travels toward the intake or fresh air. While this fact is significant, it is true that there are frequent exceptions to the rule. If the recoil of a violent explosion extends inby from the point or origin, there is generally found little evidence of flame, particularly in territories where shots have recently been fired.

Investigations of a few dust explosions in the Pittsburg (Kansas) field proved that, in every case, the explosion originated on the first of the air and traveled toward the intake. The significant feature, in this connection, was that the dust on the intake was not as dry as that at the working faces. It is the general practice in this field to change the direction of the air current whenever the section on the first of the air is giving trouble. By this change, the troublesome sections of the mine are placed on the last of the air, and the trouble ceases.

While I am fully aware of the danger that might arise, in gaseous mines, if the circulation were to be materially reduced at the time of firing shots, I am still of the opinion that, in a dusty mine, there is a benefit to be derived from limiting the oxygen supply at the time of firing, as described in the letters of Mr. McAllister, recently published in COAL AGE.

I wish to heartily endorse the suggestion that has been made that the Bureau of Mines, which is well equipped for carrying on extensive experiments, should undertake the experiments necessary to prove or disprove the theory that greater safety is obtained by the reduction of the circulation of air at the time of firing shots, in mines, under different conditions.

Although, it is true that cutting off or reducing the ventilation, in an experimental mine, might not produce a mine atmosphere precisely similar to that found in a regular working mine, where the air becomes diluted with a noticeable percentage of carbon dioxide very quickly after the ventilation is reduced. In this connection, we will be glad to afford opportunity to any representative of the Bureau of Mines to obtain samples of the air, in mines where the fan is entirely stopped for from 30 min. to 1 hr. before firing shots.

C. W. WATERMAN,
Genl. Supt., The Fleming Coal Co.

Pittsburg, Kan.

EXAMINATION QUESTIONS

Rescue Work and Appliances

Ques.—How would you proceed to enter a mine after an explosion, and how would you conduct the rescue operations?

Ans.—Much will depend on the extent and violence of the explosion. The first step is to ascertain what damage, if any, has been done to the mine openings and the ventilating apparatus. Any damage to the fan or fan drifts should be promptly repaired, or temporary arrangements should be made for producing the necessary ventilating current in the mine. Observe if the air current is taking the same direction as usual, or if it has been reversed by the explosion.

It is important in entering the mine to follow the fresh air current, and the above observations are generally of importance, even though rescue apparatus is available and a trained rescue corps is at hand ready to enter the mine by any available opening. There is generally more hope of rescue by following the air, but this course may be modified by the conditions existing in any particular mine.

In the absence of an organized rescue corps, an immediate call should be sent out for volunteers and, from these, experienced men should be selected and a rescue party organized under the leadership of a competent miner who is thoroughly acquainted with the mine and the conditions existing in the workings. The party should be equipped with approved safety lamps and tools, such as picks, axes and hammers, necessary for the work.

Upon entering the mine, careful tests should be made of the mine air, to ascertain what poisonous qualities it may have aside from its explosive condition. For this purpose, the rescue party should carry with them, in addition to safety lamps, caged mice or birds, and constantly observe how these are affected by the atmosphere of the mine.

The aim of this first rescue party is to make as rapid advance as possible; exploring, as they go, every nook and corner where it is possible someone may still have survived the explosion. Only such work of repairing doors and stoppings and erecting brattices should be performed, at this time, as is necessary to conduct the air current forward so as to make it possible to explore the rooms and headings.

A second party should be organized, at the surface, to follow the first party and supply them with whatever is needful to expedite the work of rescue. As survivors are found, they should be promptly treated by first-aid methods and removed from the mine.

Ques.—Would you allow any class of workmen to enter a return airway contaminated by gases coming from a mine fire; and, if so, for what purpose would you allow them to enter?

Ans.—No one but the most experienced miners should be permitted to enter a return airway, under these conditions and, then, only when protected with an approved form of rescue apparatus that will permit the wearer to live surrounded by a poisonous atmosphere. Such a return airway should be entered only for the purpose of rescue or for the performance of such work as is absolutely necessary for the extinction of the fire or preventing its spread.

Ques.—If the safety lamp gives no indication of the presence of gas, is this fact proof that the atmosphere is safe to enter?

Ans.—No. The atmosphere, in a mine, may be poisonous to that extent as to be instantly fatal, owing to the presence of carbon monoxide in the air. The percentage of the gas present may be so small that the gas will escape detection on the lamp. Its presence can only be ascertained by the blood test; or by observing the effect of the gas on small caged animals, such as mice or birds. These small animals are much more quickly affected by this gas than is the human system. Their action will therefore serve as a warning for men to vacate the place and seek fresh air.

Ques.—How would you determine which of two different kinds of rescue apparatus is the better for given conditions in the mine?

Ans.—Before entering the mine the wearer should test each apparatus in the smoke room and find out which is the most suitable to him. The conditions in the mine, however, largely determine which type should be worn. If the conditions within the mine are known and no irritating gases are likely to be met, I would prefer the Fluess apparatus; but if fires have to be contended with I prefer one of the helmet type.

Ques.—Suppose you were wearing a rescue apparatus while hurrying into a mine to save a man; and you suddenly felt as though you could not get your breath, under normal working conditions. What would probably be the cause and what would you do?

Ans.—As the apparatus is regulated to give 122 cu.in of oxygen per minute, which is the amount necessary under normal working conditions, it is probable that by hurrying more was required and this supply of oxygen, therefore, was not sufficient; and he found that he could not breathe. To overcome this condition sit down and rest until the supply of oxygen is again sufficient. Then be careful not to exert yourself more than is required to perform the work.

Ques.—How would you test a rescue apparatus before giving it to a man to wear?

Ans.—Make sure that the apparatus is properly charged. The apparatus should be tested to see that it is giving off the required amount of oxygen per minute, and to see that the pressure on the intake tube and the vacuum on the return tube is not, in either case, greater than 3.94 in. water gage. Be careful to note also, that all connections are air-tight.

Before going into a mine, the man should be required to put on the apparatus and go into a room filled with the fumes of burning sulphur. This will detect any leakage in the apparatus.

COAL AND COKE NEWS

Washington, D. C.

The action of Attorney-General Wickersham in filing a new suit on Feb. 13 against the Delaware, Lackawanna & Western Ry. Co. and the Delaware, Lackawanna & Western Coal Co. under the Sherman anti-trust law had been expected for some time past. J. C. MacReynolds, counsel for the Government in this suit, explains the purpose of the action as that of securing from the Court a judgment on the question whether persons in control of a railroad company can organize among themselves a corporation which continues under their management and through the form of a contract escape the prohibitions of the commodities clause of the Interstate Commerce law, while it was also intended to apply the Sherman act so as to restrict railroads to the business of common carriers by preventing them from entering into contracts or arrangements tending to interfere with the performance of their duties under such contracts.

Attorney-General Wickersham in outlining the object of the suit says:

The purpose of the railroad company and those who controlled it in organizing the defendant coal company was to use the latter as a mere instrumentality for retaining under their direction and for their profit the business of selling coal theretofore carried on by the railroad; and under the agreement of Aug. 2, 1909, this purpose has been carried into fruition.

They have always constituted its dominant stockholders and probably always will. They elect its officers, determine its policies, and, moreover, they may take away its sold business upon six months' notice. If its conduct should fail to meet their approval, it may be deprived of all benefits under the sales contract and its business quickly destroyed. In such event a similar subterfuge could be organized and the profits of the entire business still be secured to the stockholders of the railroad.

The arrangement under which the defendant companies are operating in no proper or legal sense destroys the interest which the railroad company has in the output of the mines which it owns and operates or in the coal which it purchases from others before the same starts in the course of interstate or foreign transportation, but during the entire course of such transportation the carrier has an interest therein within the true meaning of the statute.

The two companies are but the instrumentalities of the same group of stockholders; the arrangements and contracts between them are but devices to avoid the prohibitions of the Interstate act, and operations under them are more damaging to the public than those under the old plan prior to August, 1909.

They have enabled the coal company to acquire a monopoly of the sales of coal produced along the defendant railroad, and through the exclusive use of the instrumentalities leased by the latter, and otherwise this monopoly will be continued.

Having secured for itself a monopoly, the defendant railroad successfully undertook to transfer this to the coal company, and, unless prevented, such monopoly will continue to the great detriment of the public.

Furthermore the contract between defendants necessarily hinders the railroad from freely fixing its rates for transporting coal according to recognized and legitimate standards, and introduces a factor into the determination of questions relating thereto which may not be considered consistently with the rights of the public, and which necessarily tends to keep such rates unduly high. For since under the contract the railroad company receives for its coal at the mines a percentage of the price at New York harbor, which price is largely determined by the freight rates, it follows that the higher the freight rate from the mines to New York harbor the higher the price received by the railroad company at the mines, and, on the other hand, as the freight rate decreases such price decreases.

The contract is thus not only a barrier against any reduction in the railroad company's freight rates to New York, however justified by the conditions, but is an inducement to higher rates regardless of any change in the cost or character of the service. It is in undue, unreasonable and unlawful restraint of interstate and foreign trade and commerce.

Municipal Coal Mines

Mr. Taylor, of Colorado has offered the following bill for the establishment of a "municipal coal mine."

That the following-described coal land or so much thereof as the city of Grand Junction, Colorado, may apply for within six months after the approval of this Act, is thereby granted to said city as a source of coal supply for the use of said city and for the use therein of the inhabitants and industries thereof, to wit:

In section ten, the east half of the east half.

In section eleven, the southwest quarter and the southwest quarter of the southeast quarter, the west half of the northwest quarter and the southeast quarter of the northwest quarter.

In section fourteen, the north half of the northwest quarter and northwest quarter of the northeast quarter.

And in section fifteen, the northeast quarter of the northeast quarter, all in township one north, range one east, of the Ute meridian, containing six hundred and forty acres, more or less, upon the following conditions, that is to say: That said city shall, within two years from the approval of this Act, open a workable vein of coal upon said land and shall continuously thereafter develop and operate a practical coal mine thereon for the purpose aforesaid; shall not assign or transfer said land or any interest therein; shall comply with such rules and regulations as may from time to time be prescribed by the United States Bureau of Mines and approved by the Secretary of the Interior. . . . . .

Mr. Taylor has also continued this same policy in a general way by offering the following measure:

That the Secretary of the Interior is hereby authorized, in his discretion, to patent lands of the United States classified as coal lands within any State or Territory to any city or incorporated town therein, duly authorized in this behalf, as a source of coal supply for the use of such city or town and for the use therein of the inhabitants and industries thereof, the lands so patented to be conveniently situated with reference to such city or town. Every such patent shall include not to exceed six hundred and forty acres for each city and one hundred and sixty acres for each town. It shall be appropriately conditioned to provide for prompt and continuous development of the coal, the prevention of any assignment or transfer of the land, the safeguarding of the health and safety of laborers mining or handling the coal, the prevention of undue waste of mineral resources, and the securing of full reports and publicity as to the mining and disposal of coal mined under the patent, including costs of construction, of maintenance, and of operation, use for municipal purposes, sales, and receipts from sales, all in such manner and form and at such times as the Secretary of the Interior may by rules and regulations prescribe.

PENNSYLVANIA

The mine inspectors' examination in the bituminous region of Pennsylvania will occur in March. The examinations for mine foreman, assistant mine foreman and firebosses, in the bituminous districts of the state, will take place in April. The dates of these examinations will be announced later.

Anthracite

Wilkes-Barre—The Bliss colliery was idle Feb. 4 as a result of the smashing of the cage. Work was resumed, however, the following day.

Questions of importance to the Miners' Union were considered Feb. 12, when the members of the three anthracite district boards met. The call was issued Feb. 11. President White attended.

In addition to the provisions for rescue and first-aid work now in force in the anthracite coal mines, the Lehigh Valley Coal Co. is now putting into service a mine-rescue car which can be rushed at a moment's notice to any colliery in case of accident. This car consists of a remodelled passenger car equipped with oxygen breathing apparatus and several kinds of first-aid equipment.

Scranton—The Scranton school board has gone to court in an effort to force the Scranton Coal Co. to furnish them with maps showing the underground condition at the corner of Washington and Vine Sts., where the board is contemplating the erection of a new school building, and about which they have been unable to obtain any information from the coal company.

Bituminous

Harrisburg—Senator Sensenich, of Westmoreland County, has presented a bill aimed to take the appointment of mine inspectors in the bituminous region out of politics. It makes specific provision that the Governor must appoint inspectors in the order of rank of percentage. The candidates making the highest mark must be appointed first. This bill has been endorsed by several coal operators, while others oppose it. The present law gives the Governor the option of appointing as inspector any man passing the examination with an average over 90 per cent.

Beulah—The Beulah Coal Co. has filed suit in the United States District Court against the Pennsylvania R.R. Co. to recover $50,000. The coal company alleges that the Pennsylvania company illegally discriminated against them in awarding and distributing of coal cars to their mines in the Clearfield district.

Indiana—Six thousand acres, including practically all of the unsold coal in Green township, this county, has been optioned by Elmer E. Davis, of Johnstown, representing Philadelphia capitalists. In the tract is a solid block of 2000 acres near Pine Flats, which was obtained at $70 an acre. The options expire May 1.

WEST VIRGINIA

Charleston—Manufacturers of South Carolina have united in a complaint to the Interstate Commerce Commission of alleged excessive and unreasonable freight rates on coal from West Virginia fields to cities in South Carolina. The petition is directed against the Norfolk & Western and its connecting lines.

Bluefield—An appropriation of $70,000 will be made for the purpose of establishing a mine-rescue station at Norton. A rescue car will be stationed there and will have easy access to mines in the West Virginia fields.

Bridgeport—Arrangements have been completed for the transfer of 1500 men and 22 locals from this district of the United Mine Workers to District No. 3, which centers about Mansfield. Mar. 29 has been set as the date for the district convention, and New Philadelphia as the place for meeting. The action taken will then be ratified. The reason for the transfer is said to be that the miners involved do not work the Pittsburgh No. 8 vein, which is worked by the miners of the eastern portion of the district. As a result, difficulty in adjusting the scale is always arising.

Tiltonville—Work has been resumed at the Red Mud mine north of Martin's Ferry after a ten days' strike. A mass meeting was held and the members voted to abide by the order issued by John Moore, president of the Ohio miners, and return to their work.

MARYLAND

Baltimore—Announcement has been made of the establishment of a joint new coal rate by the New York Central & Western Maryland R.R., from the Pittsburgh district to Baltimore piers. For the first time in the history of the Pittsburgh coal industry, competition with other coal fields is thus made possible in seaboard coal markets. This action also opened to Pittsburgh the growing coal export trade.

TENNESSEE

Knoxville—The fourth annual banquet of the Southern Appalachian Coal Operators' Association was held in Knoxville, Tenn., on the evening of Feb. 11, at the Colonial Hotel, with a fine attendance. Col. James R. Wooldridge, of Wooldridge, Tenn., presided as toastmaster.

KENTUCKY

Lexington—The recent order of the Interstate Commerce Commission suspending railroad schedules providing for cancellation of point rates for the transportation of coal from Kentucky and West Virginia mines to Wisconsin points via the Pere Marquette R.R. has been attacked in a brief filed by the Chesapeake & Ohio Ry. Co. The company contends that no public necessity exists for the establishment or continuance of a through route from the fields indicated to northwestern territory via Toledo and the Michigan lake lines. The commission is asked to vacate its order, and to permit the company to haul its coal over its own lines to Chicago.

OHIO

Columbus—Fire of unknown origin destroyed the offices and yards of the Murray City Coal Co. and the Hocking Valley Ry. tracks, Columbus, early Saturday morning, Feb. 15.

General Mine Inspector John C. Davies has appointed Thomas E. Grogan, of Cardington, Ohio, as district mine inspector in Belmont County to succeed Thomas Hennessy, who resigned on account of ill health.

INDIANA

Indianapolis—The coal-mine operators of Indiana are greatly interested in the proposed transportation of coal from the Indiana and Illinois coal mines to Chicago by pipe line. This scheme is said to be well under way by Chicago financiers. The plan is to pump the coal by hydraulic power, which it is claimed can be done at a cost impossible for the railroads to meet.

Isham Randolph, engineer, the expert behind the project, is emphatic in declaring the plan perfectly feasible, and that coal could be delivered in Chicago cheaper than at present and that the new process will revolutionize the coal-carrying trade. It is said that the right-of-way for the pipe line and branches has been quietly obtained.

Bloomfield—The Summit coal mine, one of the oldest in the Greene County field, has been flooded ten days or more, and all efforts to lower the water have proved futile. The mine is on low ground, and it is believed water from some abandoned mine is pouring into the Summit. The owners have almost decided to abandon the place, which means a loss of several thousand dollars worth of mining machinery, to say nothing of the unmined coal and the miners' loss for lack of employment.

Petersburg—The Ingle Coal & Coke Co. is taking leases on hundreds of acres of coal land in the vicinity of Augusta, Pike County. They are paying $20 an acre for the coal. The Ingle company is now operating seven mines along the Southern R.R., and employs seven hundred miners.

MISSOURI

Kansas City—An order has been granted by United States District Judge McPherson, in the Federal Court, restraining the Chicago, Burlington & Quincy R.R. from tearing up seven miles of track on the spur known as the Adair County R.R., which runs seven miles northeast from Youngstown to the property of the Great Northern Fuel Co., at Novinger. It is claimed that the absence of a railroad there would make the Great Northern property worthless.

COLORADO

Denver—The itinerary of the Denver Rescue Car No. 2 is given as follows:

Town	Arrive	Leave
Frederick (mail Segundo), Colo.....	Feb. 23	Mar. 1
Madrid, N. M. (Alberquergue & Cerillos Coal Co.)	Mar. 2	Mar. 8
Carthage, N. M. (Carthage Fuel Co.)...	Mar. 9	Mar. 15
Gallup, N. M. (Diamond Coal Co.) (Victor-American Fuel Co.).....	Mar. 16	Apr. 5

FOREIGN NEWS

Brussels, Belgium—King Albert has stepped into the breach in an effort to avert the general strike which has been called to go into effect throughout Belgium in April. The King has advised the cabinet to make concessions to the Labor Party and Socialists. The 200,000 Belgian miners who have grievances are anxious to go out.

PERSONALS

A. F. Harper has been transferred as resident engineer of the Woodward Iron Co.'s coal mines from Dolomite, Ala., to Mulga, Ala.

King J. Ellicott has assumed active management of the Operator's Coal Co., taking the place recently made vacant by the resignation of E. O. Hoover.

J. Q. Clarke has severed his connection with the Pittsburgh Coal Co. as assistant sales manager at Buffalo, and has opened an office there on his own account under the name of the Monongahela-Youghiogheny Coal Co.

In the latter part of May President John Moore, of the Ohio mine workers, expects to leave for Europe to attend the International Mining Contest. During his absence Vice-President John Valenka, of Bridgeport, will be in charge of the state organization.

Wemyss Jackson has been appointed general sales agent of the Consolidated Indiana Coal Co., with headquarters at 139 West Van Buren St., Chicago. Mr. Jackson is to be in general charge of the sale of coal in place of Frank Ragan, who at his request, is appointed district sales agent, with headquarters at 403 Terminal Traction Building, Indianapolis, Ind.

TRADE CATALOGS

THE ALBERGER PUMP & CONDENSER CO., 140 Cedar St., New York City. The Hammond water meter. 8 p., 8½x11 in., ill.

CONSTRUCTION NEWS

Akron, Mich.—Tracks are being laid by the Handy Bros. Mining Co., of Bay City, to a point near here, where two coal shafts will soon be sunk.

Wilkes-Barre, Penn.—The D. and H. company is contemplating erecting a washery some time in the near future between Honesdale and Waymart.

Philadelphia, Penn.—The Keystone State Construction Co. has secured a permit for a coal trestle 22x220 ft. on the east side of Broad street south of Sedgley avenue, for the Pennsylvania Railroad; cost, $12,500.

Fort Wayne, Ind.—Kendallville business men have a

proposition to establish a factory for the manufacture of peat fuel from bogs. It is the desire to establish a factory with a capacity of 50 tons per day.

Shamokin, Penn.—Local mining engineers of the Reading Coal & Iron Co. today completed plans for the sinking of a new shaft at the Sterling colliery. The company is also preparing other plans for the greatest improvements in the history of collieries in this region.

Waynesburg, Penn.—Engineers are making the location for new mines and coke plants about a mile above the Poland Coal Co.'s new works up Dunkard Creek, new developments are to be made by the Henderson and Kennedy interests of Pittsburgh. About 400 coke ovens are to be built at once.

Shenandoah, Penn.—Plans for the breaker to be built for the Locust Mountain Coal Co., which will operate the new Girard Estate lease, are nearing completion and materials and machinery will be brought in February so that construction can be commenced about April 1. A 6000-ft. drainage tunnel will be started about the first of March.

Scranton, Penn.—The Minooka Coal Co. has leased from the Delaware & Hudson Co. a tract of land containing more than 70 acres, situated South of Minooka Park. The location is known as the old Corey Tract.

It is the intention of the Minooka company to erect a $25,000 breaker on this site. The company also expects to mine more than 200,000 tons of coal from the land, and this product will be prepared at the new breaker.

St. Louis, Mo.—A byproduct coke oven and recovery plant is to be erected by the Laclede Gas Light Co. on a 200-acre tract of land at the junction of the River Desteres with the Mississippi. The cost is to be approximately $5,000,000, and the plant will have a capacity of 250,000 tons annually.

In connection with the coke-oven plant, the company will build an additional water-gas plant, power stations, pumping stations, and machinery for handling the 500,000 tons of coal that will be consumed every year for the manufacture of coke and the byproducts.

Ironton, Ohio—It is reported that the Semet Solvay Co., of Syracuse, N. Y., is negotiating with the Rogers-Brown Co. for the installation of a coke plant similar to their million dollar plant at Ashland, Ky., for supplying coke for the local furnaces. The Ashland plant has a capacity of about 700 tons daily, and a plant of similar capacity would supply coke for the furnaces of this city. It is also stated that the Rogers Brown Co. will erect a large blast furnace at Ashland. Should another coking plant be installed here, it will prevent the frequent coke shortages at the furnaces.

Brownsville, W. Va.—A contract has been let to R. J. McFadden by the Hitchman Coal Co. for the sinking of a new shaft to connect with the new coal which that firm owns at the Glendale mine. The contract price is said to be about $10,000, and it is aimed to complete the work by the 1st of May.

The new opening will be made on the Bell property, on Little Grave Creek. It is said that a new uptodate structural-steel tipple will be erected upon the completion of the new shaft. The mine will be equippd with the most modern machinery, and will have one of the largest outputs in this section of the state.

NEW INCORPORATIONS

Paris, Ohio—The Caney Cannel Coal Co.; capital stock, $1000. Incorporators: P. J. Johnson, Wm. Kenney and F. M. Farres.

Mayo, Ohio—The Hampton Timber Coal and Land Co.; capital stock, $25,000. Incorporators: B. M. Craft, John M. Allen and C. C. Craft.

Pittsburgh, Penn.—The Buffalo Creek Coal Co.; capital stock, $25,000; to operate in Butler and Armstrong Counties. Incorporators: C. A. Ross, C. B. Clark, C. L. Glass, C. E. Meyer and G. M. Bilger.

Greensburg, Penn.—A charter was granted the Greensburg Coal & Coke Co. at Harrisburg Saturday, $200,000. The new company will operate a tract of about 600 acres of coal north and west of this city.

Pittsburgh, Penn.—A special meeting of the stockholders of the Wellsley Oil Co. will be held Mar. 27 for the purpose of voting on a proposed decrease in the capital stock of the company from $500,000 to $5000.

Boston, Mass.—The Belmont-Monroe Coal Mining Co.; capital stock, $1,000,000. Promoters: William B. Crowther, James O. Evans, Pittsburgh, Penn., C. L. Andrews, L. L. Coleman and R. S. Buzzell, Augusta.

Montgomery, Ala.—Papers have been filed reporting the incorporation of the Syracuaga Ice and Coal Co. of Talladega County; capital stock, $15,000. Incorporators: F. W. Ledbetter, A. B. Parker, and Ethel Ledbetter.

Fairmont, W. Va.—The Mineral Fuel Co.; capital stock, $1,200,000; to develop coal and other mineral lands in Letcher County. Incorporators: A. B. Young, G. M. Alexander, Brooke Fleming, Jr., J. O. Watson and Walter Miller.

Vaughan, W. Va.—The Lewis Land & Coal Co.; capital stock, $400,000; to develop mineral land and deal in real estate in Nicholas County. Incorporators: E. W. Knight, G. S. Couch, Jr., F. F. Brown, A. W. McDonald, and O. P. Fitzgerald.

Wheeling, W. Va.—The Washington Oil & Gas Co.; capital stock, $15,000; to acquire real estate and explore for gas, coal and other minerals. Incorporators: B. E. Thompson, R. J. Desch, Geo. Haid, R. S. Magie, J. R. Rowan and J. E. Hughes.

Wilmington, Del.—The Coal Savings & Smoke Consuming Co., $1,000,000. To establish foundries for the purpose of manufacturing coal saving devices and install the same on stoves, etc. Incorporators: R. Boyd Cooling, Clarence J. Jacobs, Harry W. Davis, all of Wilmington, Del.

Pittsburgh, Penn.—Alberta Development Co.; to deal in all kinds of mineral lands in the state of New Mexico and elsewhere. Capital stock, $300,000: Incorporators: Preston B. Ewing, Thomas H. McKay, E. W. Ewing, and J. Albert McKay, of Pittsburgh and Lloyd L. Little, of Emsworth, Penn.

Connellsville, Penn.—The Northumberland Coal & Coke Co., operating three miles south of Somerset, will apply for a charter on Feb. 25. The incorporators are R. C. Fiss and James Christian, of Shamokin; E. G. Jones and V. S. Truckenmiller, of Watsontown, Penn. and E. H. Mayer of Somerset. The company has opened mines on the Frank Walter and Robert C. Bittner farms in Milford Township. W. H. Mayer has charge.

Hartford, Conn.—The Schniewind Coke Oven Co., of Hartford, has been formed to manufacture illuminating gas and coke and use the by products. Capital stock, $500,000. Incorporators: Robert C. Metcalfe, of Newark, N. J., and Alvan Waldo Hyde and Charles Welles Gross, of Hartford.

Allen, Ky.—The Mayo-Hampton Timber, Coal & Land Co. has been organized by B. M. Craft and others, with a capital stock of $25,000. The company proposes to acquire timber and coal lands for development.

INDUSTRIAL NEWS

Easton, Penn.—The Easton Coal & Coke Co. will occupy a site at Belmont and McKeen streets. Frank McInerney is president.

Fairmont, W. Va.—The Consolidation Coal Co., will equip its collieries at McRoberts, Ky., with five 10-ton 42-inch gage electric mining locomotives.

Indiana, Penn.—The Armerford Coal Mining Co. have opened coal developments on Blacklick Creek, on the site of the old John R. Wilson farm.

Huntington, W. Va.—Twelve mines are now operating on the Buffalo extension of the G. V. Ry. above Logan and put out something like a hundred cars of coal daily.

Waynesburg, Penn.—Attorney G. C. Drake has purchased 50 acres of coal land in Gilmore township at $160 per acre. The tract was formerly known as the John D. Russell farm.

Marshall, Mich.—While sinking a shaft at the Sheridan township mine, coal was struck at a depth of 72 ft. The seam is 5½ ft. thick, and the operators believe that the strike will prove profitable.

Punxsutawney, Penn.—W. S. Blaisdell expects to be shipping coal from the mines which are just being opened on Williams Run, near No. 6 mine, of the Anita Coal Mining Co. about midway between Punxsutawney and Horatio.

Morgantown, Ky.—G. L. Drury, C. E. Sullivan, J. C. Haney, of Union County, have purchased the West Aberdeen Coal Co.'s property, and are now repairing the mines to be put in to operation.

Philadelphia, Penn.—Colonel T. Coleman du Pont, the powder manufacturer, with many diversified interests, has effected a merger of six bituminous coal companies with an annual output of more than 10,000,000 tons a year. The capital is $6,000,000.

Derby, England—John Davis & Son (Derby), Limited, of All Saints' Works, Derby, England, and care of Messrs. J. F

McCoy Co., of 157 Chambers St., New York, have been granted letters patent by the U. S. Patent Office for their "Davis-Biram" anemometer.

Pittsburgh, Penn.—At a special meeting of the stockholders of the four States Coal & Coke Co., the first stock of the company was increased from one and a half million to two and a half million dollars. This concern was the 11th in production in West Virginia for 1912.

Carrolltown, Penn.—It is reported that the Logan Coal Co. is negotiating for the purchase of a 150-acre coal tract near the operation of the Black Diamond company at this place. It is reported that John Hayes and William Mardemer of this place may take over the mine.

Grafton, W. Va.—The Preston Fuel Co. is owner of about 5000 acres of coal land at Independence and is opening up the same. A shaft is to be sunk to a depth of 210 ft. and a steel tipple will be built. The work is in charge of R. B. Stewart, superintendent and manager.

Huntington, W. Va.—A deal involving $500,000 and the transfer of a tract of valuable coal and timber land in Logan County was closed recently. Six thousand six hundred acres on Buffalo Creek were sold by Huntington and Charleston capitalists to the Buffalo Coal & Coke Co.

Connellsville, Penn.—The Knickerbocker Fuel Co., with mines at Hooversville, Somerset County is a new firm in that field. The company expects to mine 600,000 tons during 1913. Officers Jas. A. Hill, New York, president Frank M. Graff, Blairsville, treasurer, Telford Lewis, Johnstown, secretary.

Waynesboro, Penn.—J. E. Barnes, of Pittsburgh, has secured options on 2500 acres of coal land in Whitley township, at $400 an acre. It is reported that he secured the option for the Pittsburgh Coal & Coke Co., and that the option extends for 90 days.

Waynesburg, Penn.—J. B. F. Rinehart of this place closed a deal recently with Justice W. S. Mankey, of East Waynesburg, whereby he was granted title to the Pittsburgh vein of coal underlying a tract of land containing a little over 100 acres, situated near Nineveh, Morris township, the price per acre being $125.

Summerset, Penn.—Captain Sanner, L. G. Lambert and J. Shaver have listed their options on a tract of 6000 acres of coal in this county. The option price was $50 an acre. The purchasers of the tract have not been made known, but it has been given out that the men holding the option have sold out to a firm which will develop the tract.

Tuscaloosa, Ala.—A. S. Costellono and associates from Jacksonville, Fla., have purchased 320 acres of coal land at Shira's Station near Tuscaloosa, on the Tuscaloosa Mineral L. & N. Railroad from Miss Margaret Miller and Messrs. John T. Bradford and C. M. Peterson. Purchasers expect to ship much of the coal which they will soon mine.

Windsor, Mo.—The Brownington Coal Co. expects to begin operation soon on a large scale. They have been stripping some coal for the past several weeks with teams and scrapers, but expect that their new 95,000-lb. steam shovel will soon be on the ground. They have a fine 4-ft. seam of coal near the surface, the depth ranging from 9 to 13 feet.

Connellsville, Penn.—Announcement has been made that the Pennsylvania Coal & Coke Co. is prepared to fire up 1000 ovens in the Allegheny Mountain coking region. Greene County coal will probably be used. The ovens have a capacity of about 12,000 tons per month Byproduct ovens will also be built at Midland to run on this coal which is floated down the river in barges.

St. Louis, Mo.—Dr. J. C. Parrish, representing the Audrain Coal Co. of Vandalia, Mo., announced the closing of a deal with the Laclede-Christy Clay Products Co., of St. Louis, by which about 300 acres of coal lands in northeast Missouri, overlying a rich vein of fire clay are transferred. For the present the fire clay will be shipped to the St. Louis factory of the company.

Newark, N. J.—The H. W. Johns-Manville Co. announce the removal of its Newark office to 239 Halsey St. Its new office and salesroom is located on the ground floor of a modern building right in the heart of the city's business center. With a floor area of 4000 sq.ft., ample space is afforded for the display of a varied line of J-M asbestos roofings, packings, pipe coverings, etc.

Colorado Springs, Colo.—Alexander Patterson has exposed a body of coal one mile north of Pikeview on the land owned by Dorr, Flosson & Meridan. The value of new seam is estimated at several hundred thousand dollars. A shaft 14x7 ft. was in the course of construction when this bed was struck at a depth of 371 ft. Mr. Patterson says that he will arrange to extract 1000 tones a day.

Des Moines, Ia.—The Madison coal mine at Twentieth street and Hickman avenue sustained a $3000 loss when the engine house and boiler room wher destroyed by fire. The origin of the fire, which was discovered by Carl Miller, night watchman, is unknown. The loss is partly covered by insurance. Repairs were begun at once and the company will continue operations.

Salt Lake City, Utah—By the middle of February the Spring Valley Coal Co. expects to have its coal upon the market of the West. This is the enterprise brought into being by the Jesse Knight interests of Provo, and a wide market for the coal is being prepared by Lewis M. Cannon, the general sales agent for the company. The company has equipped the mines for a daily coal production of 2000 tons.

Pineville, Ky.—The Continental Coal Corporation has recently sold, at its offices in Pineville, Ky., all of the standing oak and poplar on 10,000 acres of its coal properties in Bell and Knox Counties, in this state, to Carr Bros., of Nashville, Tenn. The purchasers propose to erect on Straight Creek a large mill for the immediate working up of the timber in that vicinity. It is estimated that it will take several years to go over all of the timber purchased.

Reynoldsville, Penn.—Two years ago the McConnell Coal Co., of Reynoldsville, secured the mining rights of the Dennison and Ross tracts above Coal Glen, consisting of about 300 acres of coal and established a colliery on the tract. This mine has developed into a large producer. A few weeks ago the McConnell coal interests secured a large tract near Sugar Hill and a force of men is now putting in drifts and equipment for the development of the tract. A new tipple is being erected.

Clarksburg, W. Va.—W. W. Fowler, owner of the Calvert Coal & Coke Co. and the Calvert Coal Mining Co., has purchased two mines now in operation and producing 600 tons of Kanawha splint coal daily. Mr. Fowler took over the entire holdings of the Ceste-Kanawha Coal Co. and the Ceste-Kanawha Merchandise Co. The acquisition of the two splint mines gives Mr. Fowler's company the advantage of being the only company in West Virginia producing the four best varieties of coal mined in the state.

New York, N. Y.—The sales of the Western Electric Co. will be between 71 and 72 millions for the year 1912, which is slightly more than in 1906, the previous largest year in the company's business. The increase has been in American sales ontside of the Bell System, which have increased about 100% over 1906, and in European sales, which were the largest in the company's history. The results have been accomplished by an energetic selling campaign in the face of increased and increasing competition.

Harbourville, Ky.—Local coal operators, among them W. M., S. H. and J. R. Jones, have acquired a valuable coal acreage on the outskirts of Hazard, Perry county, and will install one of the largest mining plants in that newly opened district. The mines will be electrically equipped and the company will seek a franchise from the town of Hazard for operating an electric-lighting plant. In the event arrangements are made, the same power plant will be used to operate the mines and furnish the town with electricity.

Stoyestown, Penn.—Owners of a tract of about 6000 acres of coal land lying between Stoyestown and Shanksville have been notified that options taken about three months ago will be lifted and that the money, $50 an acre, will be received by the owners probably within a week. The company making the purchase is not known, but the agent who has been working in the field is A. G. Smith, of Lehigh County. The options were taken by Capt. Sanner, L. G. Lambert, and Joseph Shaver, all Somerset County men. Deal will mean the transfer of about $300,000.

Chicago, Ill.—The Western Electric Co. has recently placed upon the market a new dry battery to be known as the red label blue bell battery. It is designed for intermittent service requiring high efficiency and rapid recuperation. This new battery is a result of careful development work extending over a long period.

The Red Label battery is of the high initial amperage and low internal resistance type, giving 25 amperes on short-circuit. These characteristics together with its powers of rapid recovery after use, insure its long life and usefulness wherever this general type of battery is required.

Medford, Ore.—Experiments on the Sunnyside coal mined about three miles from Medford have demonstrated that it will produce illuminating gas and it is probable that it will be used by the Medford Gas Co. in place of crude oil, which is now shipped from California.

F. W. Topkin, of El Paso, Texas, is experimenting with this coal and finds that it will have valuable byproducts in the way of tar and asphaltum and as it is not of a sufficiently high grade to ship will be useful for gas companies.

COAL TRADE REVIEWS

GENERAL REVIEW

In spite of the changed weather conditions, the expected improvement in the hard-coal trade has failed to materialize. Production at the mines is heavy, perhaps close to any previous high record and the coal is being readily absorbed, but there is an absence of snap in the market and indications are strongly in favor of the situation becoming worse. There are rumors of concessions of from 25 to 50c. being offered on individual egg and chestnut, while even stove is selling at less than the circular; such conditions obviously make it difficult for the companies to maintain their regular circulars. Dealers are hoping for a continuation of low temperatures so that they will be able to dispose of their surplus egg and chestnut.

The Coastwise bituminous trade is a shade firmer, but all shippers have coal they are anxious to dispose of, and receipts are not being absorbed very readily. The market is characterized by a feeling of indecision and none seem to be able to formulate an opinion as to which way it will go; at present it is down to approximately a summer basis, and it is quite difficult to arouse any interest among the buyers. Only a few season prices have been announced so far, and contracting seems to be reserved for a later period. On inland contracts considerable business is being done, operators getting a slight advance over last year's figures. There also seems to be more activity there in the spot market, particularly in the North, where the movement on the railroads is quite uncertain; the Canadian trade is divided between a fear of both a surplus and a shortage because of the great uncertainty in the movement. There is little interest being displayed in contracts in the Pittsburgh district and contract prices are being slightly shaded on spot business; there is considerable inquiry, however, and prices are as good or better than formerly.

There is more activity in the Ohio field due to the lower temperature and the increased domestic demand; the movement is also slow and uncertain and shippers are convinced that the railroads are not prepared to do much in the face of adverse conditions, should these materialize. A considerable tonnage is being produced, dealers are busy and insisting upon immediate shipments, with the result that the downward tendency in prices has been checked and producers are holding firm at nominal quotations. In the South the weather continues favorable to a good domestic consumption, stocks are being depleted, and there is a good healthy demand generally. While the trade has not by any means been satisfactory so far this season, because of the unseasonable weather, stocks are rather low, and there is a fairly strong buying movement.

The cold weather in the Middle West has materially reduced stocks in the retailers hands and resulted in a rather concerted buying movement. The demand is unusual and all shipments are being readily absorbed. The Far Western market is in a doubtful condition, due to the impending change in the season; many dealers are putting in stop orders and will not again be interested in the market until next season.

BOSTON, MASS.

The New England market continues practically unchanged from a week ago. Bituminous is perhaps a shade firmer on account of the seasonable weather, but all the shippers have coal they are anxious to sell and the receipts at the piers have not been absorbed very readily. There is not so much doing on contracts as might be supposed; the uncertainty over transportation rates coastwise, is helping to put off closing business at season rates.

Water freights are firm at 95c.@$1 on large vessels, Hampton Roads to Boston. On Long Island Sound barge rates for New York loading are down to 45@50 cents.

Pennsylvania coals are dull and season prices are not yet announced on any but a few of the more popular grades. Those are asking from 5@10c. more than last year, but it is doubtful if they can command it in view of the light demand that will probably prevail between now and September. The Georges Creek shippers have as yet made no announcement, but they are expected to be out for comprehensive business within a short time. There is a general air of indecision about the bituminous market just at this time and all hands seem to be wondering what moves to make.

All-rail there is little doing. Even fuel contracts seem to be reserved for a later time and the trade is so nearly on a summer basis that it is difficult arousing any interest on the part of buyers. Then, too, most steam plants are carrying over considerable stocks of what they have called their "reserve" during the winter months.

Anthracite trade from now until April will depend wholly on the weather. If the present cold spell continues there will be some orders for Eastern shipment, but if warm weather sets in soon it will be dull, indeed. Dealers are hoping for seasonable temperatures so they can work off the surplus supplies of egg and chestnut they took on earlier in order to secure stove. Some of the New York companies have receded from the 15c. advance on company barge freight, New York to Boston, and are making efforts to sell on the old 50@55c. basis. It will be interesting to see what attitude the same companies take Apr. 1. Pea size is still in short supply.

Wholesale quotations are about as follows:

Clearfields, f.o.b. mine	$1 20@$1 40
Clearfields, f.o.b. Philadelphia	2 45@ 2 65
Clearfields, f.o.b. New York	2 75@ 2 95
Cambrias, Somersets, f.o.b mines	1 30@ 1 55
Cambrias, Somersets, f.o.b. Philadelphia	2 55@ 2 80
Cambias, Somersets, f.o.b. New York	2 85@ 3 10
Georges Creeks, f.o.b. Philadelphia	2 87@ 3 10
Pocahontas, New River, f.o.b. Hampton Roads	2 70@ 2 80
Pocahontas, New River, on cars Boston	3 85@ 4 10

NEW YORK

Anthracite—The cold weather has been holding out more or less continually throughout the month and has resulted in an active business in the local retail trade. Conditions have also been favorable for a large distribution, and this branch of the business has been quite prosperous over the last two or three weeks. This prosperity has not, however, extended to the wholesale end. Practically all sizes are in easy supply with egg quite heavy. Premium coal is entirely unheard of, and with the individual cutting prices, the large companies are experiencing a great deal of difficulty in moving certain grades at circular; they are already putting some of these into storage, although this has not by any means become general yet.

Had it not been for the recent stretch of cold weather, it is difficult to say what condition the trade would have been in at this time. Production has been quite heavy at the mines, there being a plentiful car supply, while the petty strikes, which so seriously interfered with the output during last month, have not been so much in evidence. As a result shipments have been quite large and these, added to the reserve stocks accumulated by many dealers on speculation, make an enormous tonnage that the market has not been able to absorb.

New York quotations remain practically unchanged from last week. Price variations are noticeable both up and down, but average prices continue as before. We quote the nominal market as follows, with consignments possibly a little more difficult to obtain, and quotations a trifle firmer:

	Anthracite		Bituminous	
	Circular	Individual		
Broken*	$5 00	4 75	West Virginia, steam	$2 65@2 75
Egg	5 25	4 90	Fair grades, Penna	2 75@2 85
Stove	5 25	5 25	Good grade, Penna.	2 90@3 00
Chestnut†	5 50	5 50	Best miller, Penna.	3 05@3 15
Pea*	3 50	3 75	Georges Creek	3 25@3 30
Buckwheat**	2 75	2 50		
Buckwheat†	2 45	2 35		
Rice**	2 25	2 25		
Rice†	1 95	1 90		
Barley†	1 75	1 20		

* Scranton and Lehigh. ** Scranton. † Lehigh and Schuykill.

Bituminous—The soft-coal market at this point continues off, and weak, in spite of almost three weeks of practically continuous low temperatures. While this has resulted in an active retail trade, it has not helped the large wholesalers. Large stocks have accumulated at tide which the companies are finding it almost impossible to move. Some of these have been standing for so long, that demurrage charges are piling up on them, and among these are some high priced coals.

For prompt delivery, the market is uncertain and irregular, with prices fluctuating a great deal, according to the urgency of the demand from the consumer. As a whole, quotations are off from last week for spot coal and buyers are displaying an entire absence of interest in the market. Much the same condition applies to contracting, although there has been some slight evidence of activity in this branch; only tentative figures have so far been advanced, and the market cannot, as yet, be said to be quotable. There are rumors of the operators holding out for from 10 to 20c. above last year's figures, but there is nothing definite of anything being closed at these prices, and it is highly improbable that they will be able to maintain this level for the season.

PHILADELPHIA, PENN.

Notwithstanding the changed weather conditions, the expected improvement did not materialize in the local market. Although there is considerable coal moving, and the output of stove, chestnut and pea seems to be readily absorbed, yet there is an unmistakable lack of snap in the trade, and this seems likely to continue, or grow even worse, unless unusual conditions prevail.

The reported strike of the firemen on all the roads leading into this city has not taken hold of either the dealer or the public as might be expected. It would undoubtedly bring about a distressing condition, if continued for any length of time, but there has been no apparent activity manifested so far. The papers are not giving any undue prominence to this matter, which undoubtedly has its effect on the public at large, but scare heads of a strike which would result in an almost complete tie-up of any additional supplies, would likely cause considerable commotion, and this would not apply to the anthracite business alone.

Taking the trade as a whole, it is inclined to be rather dull. Current gossip hints at cuts of anywhere from 25c. to 50c. per ton on the individual egg and chestnut coal, and stove is reported to be selling at less than circular. This is a condition that has to be met at this season, although earlier than usual this year, and with the added output of individual coal that has been turned loose on the market, owing to the recent decision of the Supreme Court, it makes rough sledding for the large companies who uphold the prices on their circulars.

The bituminous market does not seem to improve in any respect, and coals that were being offered at from $1.60@1.65 are now selling at anywhere from 25c. to 35c. less, and current reports indicate no immediate improvements.

PITTSBURGH, PENN.

Bituminous—Demand for prompt coal has improved, and especially the demand for slack. There is considerably more inquiry, and sales are more numerous, with prices fully as good as formerly, and in some instances better, while slack is quotably higher. Slack was rarely bringing above the circular price of 90c., but in the past week it has occasionally brought $1.10, and $1 has been done even on desirable tonnages. There is little interest in contracts. For prompt lots shading of the regular contract prices is altogether exceptional, while prompt slack, as indicated, is quotable at $1@1.10. Contract prices remain as follows: Slack, 90c.; nut and slack, $1.05; nut, $1.25; mine-run, $1.30; ¾-in., $1.40; 1¼-in., $1.55, per ton at mine, Pittsburgh district.

Connellsville Coke—The coke market is beginning to show slight signs of a reaction after its precipitate decline in the past few weeks. Last week saw new low prices for prompt coke, $2.25 being reached, though probably on indifferent grade, since $2.50 has been obtained for standard grades in several instances. While there has been no negotiating of importance on contracts, it would appear in the circumstances that about $2.25 would represent the closing basis were buyers and sellers able to get together on common ground. There is curtailment of production, both by some of the standard operators running only four or five days, as well as by some operations, those making inferior cokes, being forced to blow out ovens. The consensus of opinion in the trade is that the situation will have to be righted by this means, there having been coke produced in the past few months of such quality that it cannot be marketed at any price in normal times when consumers can choose. The using up of stock coke will have its influence also. Consumption all along the line is as heavy as ever. We quote: Prompt furnace, $2.25@2.50; contract (nominal), $2.25; prompt foundry, $3; contract foundry, $3@3.25, per ton at ovens.

BALTIMORE, MD.

Except for some contracting at an advance over last year's figures, the Baltimore market has been devoid of interest during the week. It is generally believed that practically all contracts will call for an advance of from 10 to 15c.

During the remainder of February, many contracts will be closed up here, but the majority of them will not be renewed until the latter part of March or around the first of April.

The supply of fuel at the present time is sufficient, but the demand is lacking. Consumers appear to be entirely out of the market so far as spot business is concerned. Consumers who wanted low-grade coal during the week had no trouble in getting it around $1 per ton and even less.

The cold weather brought about a slight improvement in the demand for anthracite, but the market was by no means active, as many households were well stocked. West Virginia mines are still facing an acute labor shortage.

BUFFALO, N. Y.

For some time the Grand Trunk has been struggling with more coal than it could move. Occasionally it would take a large tonnage and seem to be out of its difficulties; then it would refuse everything again and allow the coal to accumulate at East Buffalo and Black Rock; it is reported that the East Buffalo yards are full of coal trains, made up for the Grand Trunk, ready to run over to it the moment it will take anything. Of late the Canadian Pacific has been taking so much coal that was routed over the Grand Trunk that it is also occasionally blocked.

The Canadian trade has been divided between an oversupply and a fear that the stocks would run out before the roads were back to normal conditions again; at last accounts there was still a surplus, but the demand was improving rapidly. Buffalo has not suffered in that way; in former years it was used as a dumping ground, but the local dealers became tired of having the market ruined by consignment coal and refused to handle it. Car service charges did the rest.

There is a heavy demand for bituminous and, if the production is not allowed to run away with the trade there is a good margin of profit in sight for both operator and jobber right along. It is generally conceded that this is going to be a good bituminous year, if only because of the necessity for readjusting wages again next year; some jobbers are already making calculations based on a shutdown at that time.

There is a disposition to accept the figures of the Pittsburgh Coal Co. as a basis of quotations here, merely adding the freight rate of $1.25 to those prices as follows: Pittsburgh select lump, $2.80; three-quarter, $2.65; mine-run, $2.55; slack, $2.15, with Allegheny Valley 15@25c. lower. Coke is still declining, chiefly on account of having gone too high. Best Connellsville is quotable at $5.50.

The anthracite trade is strong, but the excitement is gone. The cold weather has insured a heavy consumption and it is not quite late enough in the season for consumers to consider the possibility of being stuck with some of their stock. Only chestnut is at all scarce; the independents are getting a small margin on it. The Lehigh Valley Co. has begun to load its surplus egg into vessels, having loaded some two cargoes already.

COLUMBUS, OHIO

More activity developed in the coal trade in Ohio during the past week, due to lower temperatures which stimulated the domestic demand. Dealers in Hocking Valley coal were busy and insisting upon immediate shipment, with the net result that a considerable tonnage was produced.

One of the best features of the trade is the good demand from steam users. Factories are good buyers, and since the general industrial prosperity continues, are taking a larger tonnage than ever. Then there is a good demand from apartment houses and office buildings for steam sizes. Taking it all in all the trade is in excellent condition, and a complete recovery from the dullness of the past few weeks has taken place.

Retail business has been active and dealers are busy making deliveries. Some small advances have been made in quotations, but not sufficient to shut off buying in the least. The icy condition of the streets has interfered with deliveries.

Production in various Ohio fields has been rather good. In the Hocking Valley the output is estimated at about 85 per cent. of usual, and the same is reported from the Pomeroy Bend district; in eastern Ohio the output has been about 75 per cent. Little or no complaint has been heard of the lack of cars, although there is a shortage of motive power on some of the roads touching the coal regions.

Quotations in the Ohio fields are as follows:

	Hocking	Pittsburgh	Pomeroy	Kanawha
Domestic lump	$1.50	.....	$1.50	$1.50
¾-inch	1.35	$1.20	1.40	1.30
Nut	1.50	.....	1.25	....
Mine-run	1.20	1.05	1.15	1.15
Nut, pea and slack	1.10	.....	1.15	1.00
Coarse slack	1.00	0.95	0.90	0.90

CLEVELAND, OHIO

The situation in this district has improved to a large degree and prices continue to advance. The movement is slow and uncertain, and shippers are convinced that Northern carriers are not fortified against abnormal conditions. The trouble is most noticeable on shipments from the Youghiogheny district to points in this territory. This condition has caused considerable of a hardship to shippers and consumers; in many cases deliveries are 72 hr. overdue and public service and large manufacturing plants report their storage supply running dangerously low. All shippers are wire-tracing coal en route and have impressed upon the railroad people the necessity of better movement.

Mines in the Youghiogheny and Pittsburgh No. 8 district did not operate over 80% this week on account of the scarcity of railroad equipment, and operators are not assured of an increased supply for the present.

Wholesale quotations per net ton f.o.b. cars at the mines are as follows:

District.	Freight rate	¾-in.lump	Mine-run	Slack
Youghiogheny	$1.00	$1.40	$1.30	$1.10
Pittsburgh No. 8	0.90	1.20	1.10	1.15
Goshen No. 6	0.70	1.35	1.25	1.30
Coshocton	0.70	1.55	1.35	1.30

Massillon domestic lump is quoted at $2.50 f.o.b. mines. Pocahontas lump and egg is selling at $2, run-of-mine $1.25, and slack $1.10. Hocking lump advanced from $1.50 to $1.60 mines. The coke market has weakened considerably, furnace coke has dropped to $2.50 f.o.b. ovens; about 75c. is added for the foundry grades.

The downward tendency of prices has been checked and producers of Youghiogheny coal are firm in their quotations on contract business for the ensuing year. Inch and a quarter lump is quoted at $1.55; three-quarter, $1.40; run-of-mine, $1.30, and slack, 90c., f.o.b. cars at the mines. Consumers do not seem to be overanxious to sign at these figures, but shippers claim they will not experience any difficulty in contracting for their entire production at these prices. The demand for Youghiogheny gas coal increases as the lake season approaches.

BIRMINGHAM, ALA.

There has been no material change in the local market during the current week. The weather continues to be gratifying to retailers, who are fast depleting their stocks. Incidentally, this condition is pleasing to producers of domestic coal who would surely have found trouble in inducing the dealers to stock up early had they not been able to dispose of the supplies on hand.

Many of the mines are having more or less trouble with water, but such trouble is not out of the ordinary at this season of the year. The foundry coke market has softened slightly, and while prices have not been reduced, orders are now being taken by the ovens with the promise of immediate shipment. Domestic nut coke can be had more freely, although prices remain very firm.

LOUISVILLE, KY.

A few operating companies and sales agents report some light and cautious storage on the part of dealers whose fall purchases were not sufficient to carry them through the months of November and December, during which time the car shortage was at its worst, and leave a surplus for the rest of the winter. The comparatively few dealers in this class have fared rather well, altogether, inasmuch as they have disposed of their stock coal at the regular winter prices, and are now enabled to supply their trade with coal purchased at phenomenally low figures, considering the date.

The best grades of block are quoted at $2, while the second and lower qualities shade down to as low as $1.50, especially in western Kentucky. Lump and block from the eastern Kentucky district is 10 or 15c. lower than the prices indicated for block, with a poor demand; for the best grades of round, prices vary from $1.20 to $1.40. Straight mine-run is quoted at $1.10, and No. 2 at $1. Nut and slack are in active demand, at prices ranging all the way from 75c. to $1 and a little better, for the best grades, depending upon location and other factors, and from 60 to 75c. on second grades. A few sales are reported of Indiana screenings, as usual when the supply is inadequate on this side of the river; the sales agents of the river companies state they could dispose of practically their entire stocks of steam coal at good prices if they cared to do so at this time.

KNOXVILLE, TENN.

The last half of January and the first of February have been characterized by little or no demand for domestic grades, and what was promising to be one of the most prosperous winters in the history of the Kentucky-Tennessee field has been turned into a most unsatisfactory one, so far as the last four weeks are concerned. However, that retailers have no stocks is revealed by the fact that a few cold days in succession quickly brought some orders for immediate delivery.

The demand for steam, especially the smaller sizes, has held up well, but they are not as high as they were 30 days ago. The active steel and iron market in the South assures a fairly good demand for steam, as considerable is used in making coke, thus relieving the commercial market, but the trade is taxed to take care of grades that ordinarily would be marketed as domestic coal.

INDIANAPOLIS, IND.

The cold weather has lasted about two weeks, with the temperature hovering not far from zero. Necessarily it has helped the coal trade by reducing stocks in the dealers' yards and among the larger users in factory districts where large piles are kept in reserve. The retail yards were well loaded before the cold snap came, sales having been quite restricted in January.

The optimists, both among operators and dealers, believe there is still to be some winter weather, and that retailers who stocked up heavily in October and November will be able to clear their yards. The smaller dealers who did not load up with coal in the fall, when cars were scarce and prices stiff, have been benefiting by the situation since the first of the year, buying at summer schedule practically and underselling the larger dealers 50c. to $1 a ton. There is no trouble now about cars, the mines being promptly supplied.

The following represents closely the Indiana f.o.b. mine prices, Indianapolis f.o.b. prices being 50c. higher, to cover freight:

No. 4 mine-run	$1.15	Domestic lump 5- and 6-in.	$1 65
Nos. 5 and 6 mine-run	1.05	Screenings, No. 4	0 80
No. 4 steam lump, 1½-in.	1 30	Screenings No. 5 and 6	0 70
Nut, No. 4	1.40	Washed coal, Nos. 1 & 2	$1.75@2 00
Egg	1.45	Brazil block	2 20
Domestic lump 2½-in.	1.50		

DETROIT, MICH.

Bituminous—Conditions at Detroit and in the southern part of the state have shown a marked improvement during the past week, owing to the cold weather that has recently set in. Steam trade still remains the strong feature at this time, and the domestic line has taken a decided increase in sales also in the past week. Operators in the south are beginning to make much larger shipments on steam coal, while the dealers on the other hand are getting rid of domestic stocks in a more satisfactory manner. The domestic line has improved to such a great extent that the retailers are now disposing of a great deal more fuel than was predicted they would.

	W.Va. Splint	Gas	Hocking	Cambridge	Pitts. No. 8	Pocahontas	Jackson Hill
Domestic lump	$1.50	....	....	....	....	$1 75	$2.00
Egg	1.50	....	....	....	....	1.75	2.00
Nut	1.40	....	$1.50	....	....	....	....
1½-in. lump	1.25	....	....	....	....	....	....
¾-in. lump	1.15	$1.15	1 20	$1 20	$1.20	....	....
Mine-run	1.05	1 05	1 00	1.00	1.00	1.25	....
Slack	1.00	1.00	1.00	1.00	1 00	1.10	....

Anthracite—The demand for this product is unusually heavy, and shipments do not seem as free as heretofore. Some of the operators are now charging a 60c. premium on all sizes, but if the weather should moderate, Detroit will be oversupplied with this grade.

Coke—All the ovens are working to their utmost capacity, and the demand is unusual for domestic coke. Quotations are advancing, and the product is bringing a top-notch price for this time of year. There seems to be a scarcity of Connellsville in this market, and it is being quoted at $4.50 per ton, with Semet Solvay at $4.25, and gashouse at $4 per ton f.o.b. ovens.

CHICAGO

There has been an unusual demand in the Chicago market for coal, and regular shipments from the mines are being readily absorbed. There is continued strength in the steam trade. So far as smokeless coal is concerned, the demand is so heavy that dealers find it difficult to supply the trade. The market on mine-run is quotable all the way from $1.25@1.40, f.o.b. the mines. The anthracite situation is stronger, while the coke market is slack.

Prevailing prices in Chicago are:

	Sullivan Co.	Springfield	Clinton	W. Va.
Domestic lump	$2 47 @ 2.37	$2.07 @ 2.32	$2.27	....
Egg	2 47	....	....	$3.95
Steam lump	$2 12 @ 2.37	1 92 @ 1 97	2 17	....
Mine-run	....	1 97	1 97	3.30
Screenings	1.67 @ 1 72	1 57 @ 1 62	1 67	....

Prevailing prices for coke are: Connellsville and Wise County, $6@6.25; by-product egg, stove, nut and gas house, $5.75@5.85.

ST. LOUIS, MO.

Continued spring weather has left its mark on the trade during the past ten days; it has resulted in the closing down of many mines in the Carterville and Franklin County fields and others in the Standard and Inner District, and some of these operations claim that they will not resume work until some time next August or September.

In both the Carterville and Franklin County fields, as well as the Standard, coal is being sold below the cost of production. How long some of the operators can hold out with this policy is a question, and it begins to look as if some of the St. Louis shippers were skating on thin ice.

The prevailing prices, however, are:

	Carterville and Franklin Co.	Trenton and Big Muddy	Mt. Olive	Standard
2-in. lump				$0.90 @ 0 95
3-in. lump			$1.25	
6-in. lump	$1 25		1.35	1.00 @ 1.10
Lump and egg	1 25	$2 00		
No. 1 nut	0 85			
Screenings	1 10			0.60 @ 0 65
Mine-run	1 20			
No. 1 washed nut	1 35			
No. 2 washed nut	1.30			
No. 3 washed nut	1 25			
No. 4 washed nut	1 20			
No. 5 washed nut	1 10			

Coke is strong at $5.25 and up, and some smokeless is offered, but there is little moving.

MINNEAPOLIS—ST. PAUL

While the weather in the past two weeks has helped considerably in forcing the consumption of coal, it has not been of great benefit to the wholesale trade as far as demand and prices are concerned. The dealers in the country are benefitted to a certain extent, but they have not been able to clean up stocks and consequently there has been no occasion to order any coal. It is thought that a large percentage of the dealers in the Northwest will not be able to clean up their bins this winter and all grades of coal including anthracite will be carried over.

Prices on the various grades are hard to quote as the different mines in the different localities vary a great deal. Mines which have no contracts have flooded the territory with coal at low prices, while those that have, are only running part time and are in most cases, asking a fair price. Dock prices are steady, owing to the low stocks at Milwaukee and the head-of-the-lake points. Nearly all of the docks are swept clean and only here and there can be found any coal to speak of that is not under contract.

In the Twin Cities hard-coal stocks are low, especially in the nut size. One car of nut was received on track recently which had been passed at the docks through a stone crusher and before it could be switched onto the side track there was a line-up of from 15 to 20 dealers waiting to get at it.

OGDEN, UTAH

The market in the Intermountain territory is in a doubtful position. While there are no indications of an early spring, most of the dealers expect the demand for domestic coal to break soon, and they hesitate to get much in transit. A large number of small dealers who entered the market in the fall have discontinued shipments entirely, and will not again be in the market until next season.

The mines in Wyoming and Utah have caught up on all unfilled orders and have their salesmen out looking for business. Nut and slack coal are hard to dispose of, and quite a number of loaded cars are accumulating at the mines. The larger producers of the steam grades are now unloading at the mines, as there is practically no market for these grades. Nut should commence moving in the near future, as it is an excellent summer coal for use in ranges and small heating stoves.

FOREIGN MARKETS

GREAT BRITAIN

Feb. 7—Steam-coal market conditions are quiet and easy, on account of tonnage delays. Substantial reductions can be obtained by buyers who are in a position to nominate spot tonnage. For forward loading, sellers are holding firmly for higher figures. Quotations are approximately as follows:

Best Welsh steam	$4 38@4 50	Best Monmouthshires	$4.08@4.14
Best seconds	4 20@4.32	Seconds	4 02@4 08
Seconds	4 08@4 20	Best Cardiff smalls	3 60@3 66
Best dry coals	4.20@4.38	Seconds	3.18@3 42

The prices for Cardiff coals are f.o.b. Cardiff, Penarth or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days—less 2½%.

GERMAN EMPIRE

The following is a statement of the German production, imports and exports during November, 1912:

	Production	Imports	Exports
Coal	14,805,443	1,002,271	2,551,839
Lignite	7,558,561	676,065	5,629
Coke	2,596,768	50,130	505,844
Briquettes	2,119,594	21,443	242,008

PRODUCTION AND TRANSPORTATION STATISTICS

CHESAPEAKE & OHIO RY.

The following is a comparative statement of the coal and coke traffic over the lines of the C. & O. Ry., for December, and the six months ending Dec. 31, 1911-12, in short tons:

	December		Six Months	
Destination	1911	1912	1911	1912
Tidewater	367,310	223,833	1,970,464	1,690,591
East	200,434	251,819	1,069,625	1,215,205
West	937,038	724,867	5,735,565	4,917,470
Total	1,504,782	1,200,519	8,775,654	7,853,266
Coke	17,557	23,544	110,597	134,936
From Connections				
Bituminous	23,204	65,984	117,326	241,000
Antracite	3,338	1,541	18,749	6,971

NORFOLK & WESTERN RY.

The following is a statement of tonnages shipped over this road from mines in West Virginia and the commercial and company coal, for the month of January, in short tons:

Field	Shipped	Tipple	Total	Commercial	Company
Pocahontas	1,262,869	18,579	1,281,448	1,216,218	124,213
Tug River	191,896	4,021	195,917	158,209	37,708
Thacker	277,018	6,944	283,962	217,555	66,407
Kenova	78,371	5,620	83,991	72,573	11,418
Clinch Valley				156,189	9,384
	1,810,154	35,164	1,845,518	1,820,744	249,130

Shipments of coke, entirely from the Pocahontas field, were 117,305.

COAL SECURITIES

The following table gives the range of various active coal securities and dividends paid during the week ending Feb. 15:

Stocks	Week's Range High	Low	Last	Year's Range High	Low
American Coal Products			94	94	94
American Coal Products Pref			109¼	109¼	109¼

Colorado Fuel & Iron Co.—Dividend on preferred of 35% (on account accumulated dividends) payable Mar. 20, to holders of record Mar. 1.

COAL AGE

Vol. 3 NEW YORK, MARCH 1, 1913 No. 9

ALL the nations that have died have perished through privilege. Never before have men grasped such powerful levers against the snags of special benefit as at present. There is no parallel in history for the deep hatred of injustice that exists in human hearts today.

Recall the golden age of Pericles. Greece leads civilization; Athens is pre-eminent, mistress of the world. In no other nation had the gods raised philosophy, morals and physical courage to such heights. Men said: Does not intellect govern the earth? How can Greek supremacy fail? Other civilizations have faded and gone out, but with such a constellation of genius how can Greek progress falter?

Yet it did. An aristocracy held as private property the soil and all the avenues of production. The community was divided into mutually hating classes—those who possessed special privileges and those who toiled in poverty. The inevitable happened. Greece fell from her exalted independent station in the world, and now, through the perspective of time, we can see how impossible it was for this proud people to continue their glory.

From a similar cause came the downfall of imperial Rome. Of 450,000 citizens, only 2000 possessed anything of real value. Eleven Italians owned the Province of Africa. The French Revolution resulted from a like condition, where only one per cent. of the nation's population constituted the privileged class.

The lesson is plain: We people of the United States have become a world power. Individuals here have built up greater fortunes than were ever dreamed of in ages past. A privileged class has come with our rapid development. And, in opposition to these more fortunate citizens, we have our discontented masses who live in semi-poverty. In many places, industrial slavery exists; class hates class; discord and bitterness prevail.

Many employers today are of the newer school. They have seen the handwriting on the wall and want to do what is fair by their men, but the latter have been fooled so often they are suspicious of every move. Humane motives are questioned. Distrust is everywhere evident. Labor has discovered its power and is determined to force a state where we shall associate in a condition of greater equality.

Some employers are pulling for shore. A greater number are sitting tight, drifting they know not where. A few of the more charitable and more intelligent ones, however, are trying to steer the social craft, realizing that the success of their mining operations is dependent on something more than ideal physical conditions and modern mechanical equipment at their properties. They recognize that a satisfied body of workmen—which means regular production—is just as essential as good ventilation or efficient haulage.

Whether we follow the way of Greece and Rome depends on whether special privilege is eliminated by reason or expelled by force. No man need bend his ear to the ground to hear the rumble of the approaching storm. Labor matters in the coal industry, as in most other lines of business, are unsettled. The anthracite field today is a hotbed of strife, notwithstanding the contracts recently signed. Conditions in West Virginia border on civil war.

It is a time to come out in the open and advocate a square deal all around. Half the troubles of our present mine managers are inherited from their arbitrary, all-sufficient predecessors, who invariably placed the corporation before the individual. Too many of us converse in whispers and tremble lest the truth be spoken aloud. What we need is not more education, but rather an injection of humanity mixed with equal parts courage and patriotism.

At no time on this planet has a nation made social gains that have not been lost. However, there has never been a *real* democracy before. We started right by going after the biggest culprits first, but we must not forget the corner grocer who gives short weight, the milk-dealer who sells one-third water, or the labor union that says: "I have no responsibility; a contract only binds the other fellow." An age of real permanent progress cannot come until we sweep clean from top to bottom. Might as well try to make our mines safe by eliminating big disasters only. They draw the bold headlines in the papers, but it's the little falls of roof we do not hear about which make our death toll so great.

A 6000 Horsepower Steam Hoist

By Frank H. Kneeland

SYNOPSIS—A tandem frictional rope steam hoisting engine which hauls the output of 48 collieries up Mahanoy Plane. In the design of this machine no means were neglected to make it as reliable as possible.

The trend of modern steam engineering has been almost universally toward efficiency. It is only in exceptional cases when it is desired to accomplish special results, that the consumption of steam is made a secondary consideration.

The Lesson of Previous Installations

All the previous experience (extending over a period of something like 40 years) of the Reading Ry. Co. operating this plane has gone to prove that the cost of a failure of the plane engine could by no means be measured by the expense of the necessary repairs. In the design of the present machine, therefore, neither time, pains nor expense was spared to make it as reliable as possible.

The engine is designed to hoist an unbalanced load of 190 long tons, up a plane 2500 ft. long with an 18% maximum grade, at a piston speed of 600 ft. per minute. Under test it has already hoisted 161 tons of unbalanced load at a piston speed of 450 ft. per minute, and a rope speed of 2250 ft. per minute, developing an indicated horsepower of 5100. At various other times 190 tons have been hoisted.

Weigh House and Engineer's Room at Top of Mahanoy Plane

Certain uses to which the steam engine has been adapted have required the development of special forms and devices in order to accomplish the desired results wherein the consumption of steam per horsepower-hour is to all intents and purposes a negligible quantity. Perhaps the best example of this is a modern steam fire engine, which must be light, rapid and reliable in action.

Another instance of a machine wherein reliability is of much more importance than great efficiency, is to be found in hoisting engines which handle a large amount of material and are required to operate over long periods of time without shutdown or repairs.

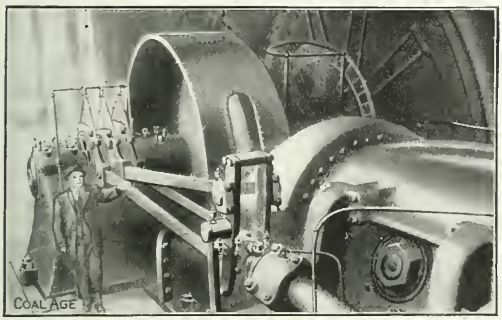
A good example of this latter type of engine is to be found at the Mahanoy Plane, near Pottsville, Penn. An idea of the importance of reliability in this installation may be gained from the fact that the output of 48 collieries located in the Mahanoy and Shamokin valleys is here hoisted to the top of Broad Mountain, from whence it is transported to tidewater by the Philadelphia & Reading Ry. Co.

The engine was designed by John Wood, superintendent of shops and machinery of the Philadelphia & Reading Coal & Iron Co., and built jointly by the Reading Iron Co., Scott Foundry Dept. and the Pottsville Shops of the Philadelphia & Reading Coal & Iron Co. It is of the heavy rolling-mill type with piston slide valves, located on the outside of the engines. These valves are operated by the ordinary Stevenson link reversing motion from eccentrics driven by a return crank from the main crankpin of the engine.

Each of the two simple cylinders is 54 in. in diameter with a 72-in. stroke. The piston rods, which are hollow medium high carbon forged steel, are 11 in. in diameter. These pass through the pistons, forming tail rods

10 in. in diameter, while the hole through the center is 4 in. in diameter. The crosshead or wristpins are 11 in. in diameter and 16¼ in. long, while the crankpins are 16x16 in. with a 6-in. hole through the center. These are of forged steel also.

The hollow medium high carbon forged steel crankshaft is 17 ft. 8 in. long, and is 32 in. square for a distance of 3 ft. 8 in. between the friction rollers. To a square section of this size the driving and idler drums



View in Engine Room. Note Comparative Size of Man

are securely clamped in halves to their respective shafts. The main bearings are 26 in. in diameter and 18 in. long. A hole 11 in. in diameter runs through the entire length of this shaft.

A shaft similar to the crankshaft, except that it is 14 ft. 8½ in. long and carries no crank, is placed 20 ft. 6 in. from the crankshaft. This carries the idler or what might be termed the auxiliary drum.

Inside of each main journal box on each of the main shafts is mounted a friction roller 10 ft. 3 in. in diameter with a 10-in. machine-finished face. This arrangement places a friction roller on each side of both drums.

Midway between the main shafts is located a roller shaft on which is mounted two friction rollers 10 ft. 3 in. in diameter whose faces meet those of the four rollers on the main shafts. This system of rollers can be adjusted to relieve the pressure on the main journals caused by the rope tending to pull the drums together.

The system of hoisting is an endless-rope friction system not dissimilar to the American type of rope transmission. There are two steel built-up rope drums, one of which only is driven by the engine, the other being simply an idler to carry the rope. The rope leads from one track of the plane and makes eight laps around both drums, then to a rendering sheave 17 ft. 2 in. diameter (which is the distance between the center lines of the two plane tracks) and thence down the plane. By this arrangement sufficient rope friction is obtained by eight half laps on the driving drum.

The driving and idler drums are 19 ft. in diameter and 29½ and 33 in. wide respectively. The driving drum is equipped with eight and the idler drum with nine wrought-iron differential rings 18 ft. 4½ in. in internal diameter, each grooved to receive the 2⅝-in. hoisting rope. These rings are not shrunk or fastened to the driving drum, as sufficient friction exists between the eight rings and the driving drum to hoist the load.

The main rope is 2⅝ in. in diameter, made of cast steel and composed of six strands of 19 wires each, upon a wire-rope core. To each end of this large cable is fastened a barney, which travels upon a track of a lesser gage than the railroad cars.

View at Bottom of Plane, Barney Just Taking Hold of Load

View down Plane from Landing

A 1½-in. tail rope passing around a sheave upon a movable carriage connects the two barneys. To this tail sheave carriage is fastened another cable which passes over a back balance, keeping the rope tight at all times.

Upon reaching the bottom of the plane, the barney passes into a pit under the track, where the above mentioned movable carriage is located. The loaded cars are then run by gravity to a point in advance of this barney pit. The engine is started slowly and the barney comes in contact with and pushes against the rear bumper of the rear car, forcing the entire trip up the plane.

The hoist house is located at the head of the plane in such a position that the operator can at all times see the entire length of the incline and, therefore, has a view of the car landing. No brake is provided upon the engine,

and the only levers which the operator is required to handle are the throttle and reverse, which with a distance of 15 ft. between the usual stopping place and the head sheave provides ample means for stopping the hoist. Each cylinder of the engine is provided with a throttle 13½ in. in diameter, both being controlled by the single hand lever. The reverse is operated by a 12-in., horizontal auxiliary, steam cylinder, in conjunction with an 11-in. cataract or oil cylinder, both having an 18-in. stroke. Proper lubrication of all bearings is obtained by a continuous gravity oiling and filtering system.

The Steam Plant

The steam plant consists of eight Stirling boilers, with an aggregate capacity of 2060 rated horsepower. These are fired by improved Cox automatic stokers, the improvement consisting in driving the chain grate from the rear sprocket, thus keeping the upper part of the chain always tight. A loop system of steam piping is employed, the pipe being 12 in. and 16 in. in diameter. They discharge into a steam drum 34 in. in diameter, and about 40 ft. long, which supplies the engine with steam through suitable piping. This steam drum furnishes a storage space, and reduces the pulsation of steam in the pipe connected with the boilers to a considerable extent, thus avoiding a fruitful source of priming. As an additional safeguard against the possibility of a water slug, each engine cylinder is provided with 6-in. water relief valves.

The boiler stokers above referred to burn rice coal, with an air pressure of approximately one-inch water gage, which is furnished by a suitable blast fan. Steam pressure is carried at 125 lb. The ashes are disposed of by means of a scraper line, which conveys them to a point outside of the boiler house, where they are elevated to a bin and then deposited in railroad cars for disposal.

Weight frequently expresses more than lineal dimensions. An idea of the massiveness and solidity of this hoist may be gained from the fact that the weight of the engines and drums as a whole is 500 tons, while that of the main shaft with its drum alone is approximately 90 tons.

As was stated above, the output of 48 collieries passes over this plane. This means a daily average of about 1100 cars in 12 hours. During the month of January, in 25 working days, or a total of 304 hours, 19,874 cars were hoisted.

The Electric Mining Lamp

Special Correspondence

The official statistics of the Prussian government show that 308 out of 341 explosions occurring between 1901 and 1911 in Prussian mines were due directly to the use or rather the abuse of the so called miners' safety lamps. It is needless to say that the Prussian government is particularly strict in its regulation of mining lamps, and in prescribing the precautions to be observed in their installation, maintenance and handling.

The lamps mostly in use—burning benzine or naphtha—can only be called safety lamps when in the hands of old, experienced miners, who are aware of their dangers and consequently know how to handle them with the necessary care. They cannot be regarded as furnishing any absolute immunity from an explosion. They have the advantage that they warn the miner of the presence of gas and put him on his guard if he is intelligent enough to recognize the warning and careful enough to heed it when it is given.

The use of the safety lamp has been approved up to the present time, not so much because it justified its title but because it was the best lamp available. About 10 years ago, efforts were made to introduce electric mining lamps with small accumulators, but the cell rapidly deteriorated and the lamps were heavy and clumsily made. Recent lamps have overcome these difficulties, and the new electric lamps radiate a stronger and brighter light than the old benzine or naphtha lamps.

Among these the Ceag lamp deserves mention. It is made by the C. E. A. G. Co., of Dortmund, Germany, and the American rights are held by the Mannesmann Light Co. of America, with offices at 55 John St., New York City. In an international competition given by the British department of internal affairs known as the Home Office, this lamp was awarded first prize. It is the lamp exclusively used in the most dangerous mining sections in Hamm, Westphalia and also in the mines of England, France and Belgium.

The oil and benzine lamp is the right type of light to entrust to firebosses and foremen. It would be well to give it also to rib bosses but to hand it to every man, regardless of his experience is to put fellow workers of such men in unnecessary jeopardy.

A Successful Scraper Line

The accompanying illustration shows 1500 ft. of Rivetless chain at the washery of the Susquehanna Coal Co., Nanticoke, Penn., which has been conveying from 1600 to 1700 tons of wet culm and coal per day for the past five months without any delay from breakdowns.

The Scraper Line As It Appears in Operation

This conveyor consists of a double line of 9 in. pitch chain of the type known as double outside pin drive. It passes over idlers at the loading point and is propelled by sprockets at the head of the incline. It is driven by the 150-hp. motor, which also operates the washery.

This line displaced one of almost identical capacity, but which had an annoying faculty for breaking down, thus causing delays averaging about 10 per cent. of the time. As stated above, no annoyance from this cause has thus far been experienced since its installation several months ago.

A New Electrically Driven Hoist

EDITORIAL CORRESPONDENCE

SYNOPSIS—A hoist with two 10-ft. drums driven through cut steel herringbone gears by a 700-hp. alternating-current motor. Several other features are embodied in the construction of this machine that are not found in the ordinary hoist.

The concentration of power in central stations in various mining districts and its distribution by means of high voltage alternating currents has rendered it advantageous to operate hoists from these lines without making use of a rotary converter or motor-generator set. Hoists thus operated are, however, exceptional, although the advantages attendant upon their use are immediately manifest.

The Vulcan Iron Works, of Wilkes-Barre, Penn., have recently built a hoist of this description for the Woodward Iron Co., of Woodward, Ala. This machine is intended for hoisting cars from a slope, the length of which is approximately 1800 ft., and its inclination about 30 deg. from the horizontal. The gross weight of the cars to be hoisted is 63,600 lb., and the lineal speed of travel is 1800 ft. per minute.

Traveling upon an auxiliary track and attached to the hoist by a two-part rope so that its travel is one-half that of the cars is a counterbalance weighing 15,000 lb. The hoist is provided with two drums each 10 ft. in diameter, which are grooved to coil 1800 ft. of 1½-in. wire rope in two layers. The motor has a full load speed of 290 r.p.m., and the power is transmitted to the drum shaft by means of single reduction cast-steel machine-cut gears of the herringbone type.

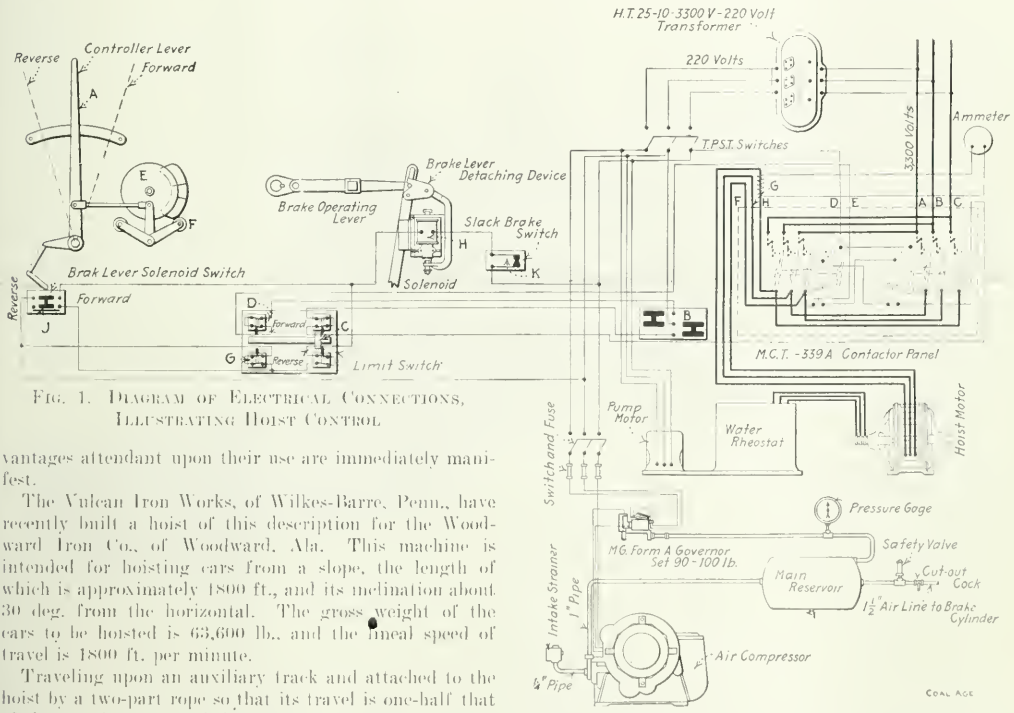


FIG. 1. DIAGRAM OF ELECTRICAL CONNECTIONS, ILLUSTRATING HOIST CONTROL

THE MOTOR AND ITS CONTROL

The hoist is driven by a General Electric variable-speed, polar-wound rotor, 700 hp., 10-pole, 3300-volt, three-phase, 25-cycle induction motor, which is connected to the countershaft of the hoist by means of a flexible coupling of the flange and rubber-buffer variety.

The speed of the motor is varied and controlled by cutting resistance into and out of the rotor circuit. This is done by means of a liquid rheostat of the rising and falling weir type. The rate at which the water level may be raised, and, therefore, the rate of acceleration of the motor, can be made independent of the weir, so that automatic acceleration can be obtained, while the lowering of the weir for the retarding of the motor can be done quite rapidly. Each drum is equipped with an extra heavy band brake, one being operated by hand and the other by means of a weighted air cylinder. The weighted brake is of the floating lever type, which permits of the band being only partially applied or set up tight as may be desired. It is possible, therefore, to regulate the pressure on the band, allowing the drum to revolve as slowly as may be wished.

Operating in conjunction with this drum brake, there is a smaller brake on the counter shaft, and both are applied simultaneously. This removes all undue shock or stress due to the inertia of the rapidly moving parts in case the emergency is suddenly thrown on. There is, therefore, no danger of stripping or other injury to the gears from this contingency.

GUARDING AGAINST ACCIDENTS AND OVERWINDS

The means employed to guard against accidents and overwinds upon this hoist are unique and well worthy of attention. That they may be better understood, reference should be made to Fig. 1. We will suppose that the ma-

chine is at rest preparatory to a hoist. The controller lever *A* is moved to its forward position, thus through a shaft closing the circuit in the master switch *B*, which starts the hoist. A further movement reduces the resistance in the liquid rheostat causing the hoist to accelerate in motion.

The traveling nut *C* on the limit switch has a movement corresponding to that of the load being hoisted. Near the landing point, this nut forces apart the contacts *D*, which are connected to contactors and opens them. Simultaneously the cam *E*, which is geared to the drum, has returned the controller lever *A* to its central or off position.

The hoist is now running from momentum, but at an adjustable, predetermined point the nut *C* opens up the switch *G*. This breaks the circuit to the solenoid *H*, allowing its core to fall and disconnect the brake-operating lever from the engineer's lever. This allows the weighted valve in the cylinder controlling the brake to shut off the air supply and exhaust that which is already in the cylinder, thus allowing the weighted brake to come into action bringing the hoist to rest.

Of course, under ordinary circumstances, the operator would have shut off the current and applied the brake through the medium of the air cylinder by hand and none of the emergency devices described as operating above would have come into play. The solenoid is provided solely for case of accident or overwind.

How the Engineer Regains Control of Machine

If an overwind has occurred and the switches *D* and *G* are both open, to again gain control of his machine, the operator moves a lever (which is the air-brake lever and is not shown), to the on position, then throws the controller lever *A* to the first contact in the reverse direction. This closes the main contactors through the controller switch *B*.

At the same time this has short-circuited the limit switch *G* through the switch *J*, thus reënergizing the solenoid *H* and raising its core again giving the engineer control of the brake which may now be released. In case the overwind is with a loaded cage, the machine would now start to reverse; if with an empty cage, the motor would be slightly energized and would sustain the load.

When the brake wears sufficiently to alloy the brake weight to settle to the limit of its travel, the slack brake switch *K* will be opened and the brake cannot be released until the necessary tightening adjustments are made.

As soon as the hoist starts in motion after an overwind, or other accident calling the emergency apparatus into action, the contacts on the limit switch are automatically reset by the nut *C* during its return movement.

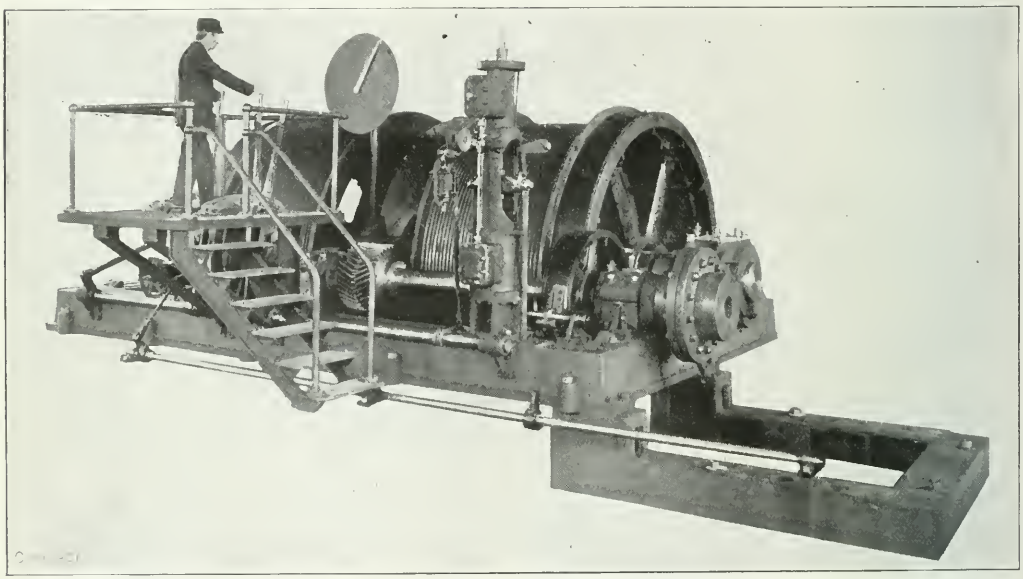

Fig. 2. The Hoist, Showing Bedplate for Motor in Place. Part of Gear Cover Removed, Showing Herringbone Pinion

Any hoist driven by an alternating-current motor cannot ordinarily be made to run too fast, even when lowering a load. The motor then tends to generate current into the line, at the same time it tends to keep in step electrically with the generators from which it draws its supply. This hoist cannot be run in either direction without current on the motor.

As stated above, the line circuit to this machine is 3300 volts. The control circuit is of 220 volts, both are 25 cycle. Air for operating the brake is provided by a General Electric 24½-cu.ft. electric driven auxiliary air compressor, while the resistance employed is a General Electric liquid rheostat.

Number and Position of Control Levers

There are in all three levers employed for the control of this machine. These are all located in a convenient quadrant on the operator's platform, which is elevated at

such a height that he may easily see over the top of the hoisting drums.

The bedplates and pedestals on this machine are both heavy in design and free from sharp angles and projections. The base for the motor is securely bolted to that of the hoist, and the whole may be set up as one unit.

Whatever other impressions may be received by the

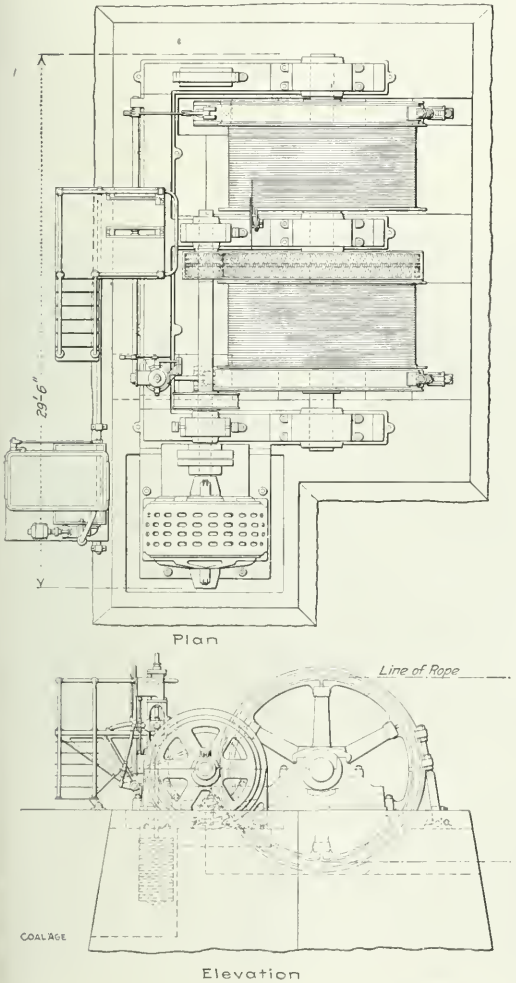

Fig. 3. Plan and Elevation of Hoist and Motor

man who sees this hoist, the idea that will first force itself upon his mind, and probably remain with him the longest, is that the machine was designed and built "for business."

The massiveness and solidity in the design, together with the obvious care and attention that have been given, even to what might be considered unimportant details, give this machine the appearance of one which should stand up indefinitely under any operating conditions to which such a hoist might legitimately be subjected.

Karl F. Schoew

A circular letter, dated Feb. 20, 1913, announces the candidacy of Karl F. Schoew, for the position of chief of the Department of Mines, in West Virginia. The present incumbent of the office, John Laing, has served the state during the past four years. Mr. Laing's term of office expires June 30, 1913. It has been known for some time by Mr. Laing's intimate friends that he does not desire and would not accept an appointment to the office for another term. During his incumbency, Mr. Laing has brought the Department to a high state of efficiency, in which work he has had the unqualified and earnest support of the twelve district mine inspectors, who constitute the present efficient mine-inspection force of West Virginia.

Karl F. Schoew, at present mine inspector for the 1st district, having served the state in that capacity for a term of four years, now desires to succeed his chief. Mr. Schoew has had a practical mining experience of 23 years, 15 of which have been devoted to mining engineering. His work during the past four years, as district mine inspector, has been performed with credit to himself and the department, and has earned for him the unqualified indorsement of all the operators in his district.

As every inspector knows, the work of mine inspection requires more than a thorough mining knowledge and experience on the part of the inspector; he must possess good judgment and tact in dealing with the numberless complicated questions that arise constantly and which are submitted to the mine inspector for his decision. The fact that harmony has prevailed in the first district speaks well for the ability of Mr. Schoew in this respect.

Mr. Schoew reports that during his term of office not a man has been burned or killed by a gas or coal explosion through carelessness. Mr. Schoew makes this statement more in a spirit of thankfulness, realizing that much of the credit for this must be ascribed to good fortune rather than that it should be regarded as the result wholly of good management and efficiency on his part.

Mr. Schoew has the success of the mining industry at heart, and thoroughly indorses the policy followed by Mr. Laing during his term of office. He believes that this policy of educating the miner, which has been followed throughout the state and which has received the hearty indorsement of both inspectors and operators, has reduced the loss of life and increased the value of mining property and contributed more to the success of the industry in the state than any other factor. It is Mr. Schoew's hope that the harmony and prosperity that has existed in the 1st district and, largely, elsewhere in the state can be further advanced by the promotion of good will and a proper use of diplomacy in the treatment of all questions that arise.

During Mr. Schoew's residence in West Virginia, he has lived both in the northern and southern portions of the state, which fact makes him thoroughly familiar with mining conditions in both these fields. If Mr. Schoew is successful in securing the appointment as chief of the Department of Mines in West Virginia, he will receive the hearty cooperation of Coal Age, in every effort to promote education and raise the standard of mining, which is our constant aim and purpose in respect to every mining state and district.

A Large Capacity Electric Hoist

By W. H. Easton*

SYNOPSIS—The difficulties incident to the application of electricity for hoisting purposes are too well known to require comment here. These seem to have been successfully overcome, in the case of the Coalwood hoist, where it is proposed to handle 5000 tons per day of 8 hr. from a depth of 650 ft. Reserve power for overcoming the excessive initial starting load is provided for by means of a flywheel, and perfect control is assured throughout the hoist.

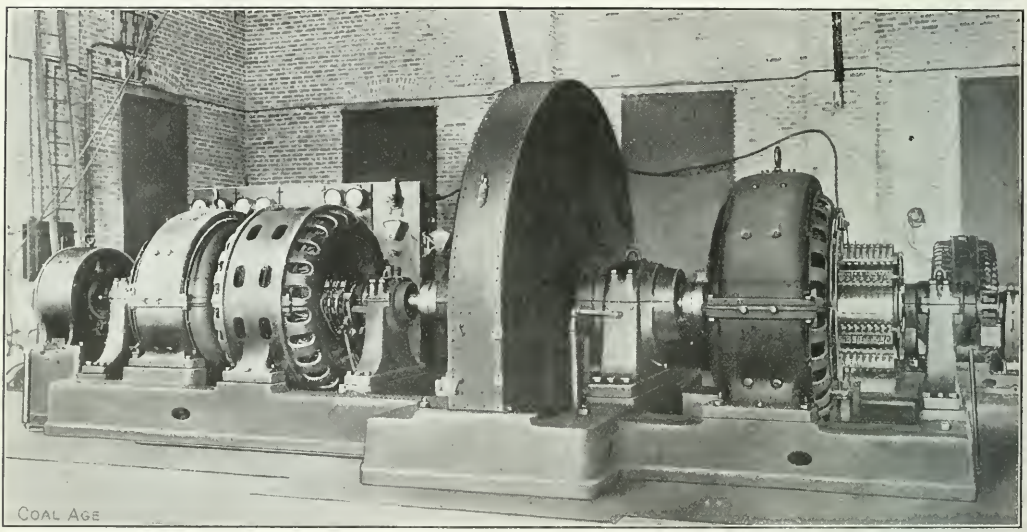
The interesting announcement has just been made that the Virginia-Pocahontas Coal Co. has ordered from the Ottumwa Iron Works and the Westinghouse Electric & Mfg. Co. what will be one of the largest, if not the largest, coal-mine hoists in this country for their new mine at Coalwood, W. Va. This hoist will raise 5000 tons of coal in 8 hr., from a depth of 650 ft. The hoist motor will exert a maximum horsepower of 2200 during each normal hoist.

Those familiar with small electric hoists will ask at once: How can so large a machine be controlled with the necessary ease and certainty? Will there not be a tremendous waste of energy in resistance when the motor is started at slow speed? How can the generating and transmission lines stand the heavy peaks, drawn from the line in starting?

For a hoist of this capacity, patterned after the ordinary installation, in which the hoist motor receives its power directly from the transmission line and is controlled through resistance, the points raised by these questions might prove serious obstacles. But they present none for the Coalwood installation, as it is controlled, by means of a small lever, with perfect ease and complete accuracy. The loss of energy at low speeds is small; in spite of the fact that the hoist will develop 2200 hp. on starting, at no time can more than 700 hp. be drawn from the main transmission lines. These results are unusual and the principles by which they are obtained are worthy of particular note.

Description of the Coalwood Hoist

The Coalwood hoist will be operated by the Westinghouse Flywheel Equalizer System. In this system the current from the transmission line is not received directly by the hoist motor, but by a flywheel motor-generator set, consisting of an alternating-current motor, a direct-current generator, and a heavy flywheel, all mounted on the same shaft. The hoist motor is a direct-current machine and receives its energy from the generator of the flywheel set. The illustrations herewith show the motor-generator set and the hoists of the Cleveland Cliffs Iron Co., which operate on the same principle and constitute what is at present the largest electric hoist of this type in operation in America.



Westinghouse Motor-generator Set, with 25,000-lb. Flywheel, for Cleveland-Cliffs Hoist

The alternating-current motor, of course, drives the direct-current generator and flywheel by the energy it receives from the line. It is so arranged that, whenever there is a demand for power in excess of the average, it will *slow down* automatically, thereby permitting the flywheel to aid in driving the generator. When the heavy demand for power ceases, the motor speeds up automatically, and in doing so restores the expended energy to the flywheel. So nicely are the conditions balanced that when hoisting steadily at the rate of 5000 tons a day, with peaks of 2200 hp. at each hoist, there is not more than 700 hp. drawn from the supply line.

*Pittsburgh, Penn.

The hoist motor is controlled by adjusting the voltage of the generator by means of a field rheostat. This rheostat is small and light and wastes but little current, but by moving its lever, the hoist motor can be run at any speed from zero to maximum in either direction. Acceleration and retardation limits are provided, which, together with the ease of control, reduce the possibility of accident to the minimum, and probably below anything that has been accomplished with steam hoists.

Method of Maintaining Reserve Power

This motor is of the slip-ring type and the three phases are connected to three stationary plates, in earthenware pots filled with a solution of carbonate of soda. Above these plates are movable electrodes, connected together electrically; these electrodes are nearly balanced by an adjustable counterweight and can be raised and lowered by a small motor. This latter receives its current from series transformers in the main line to the main alternating-current motor.

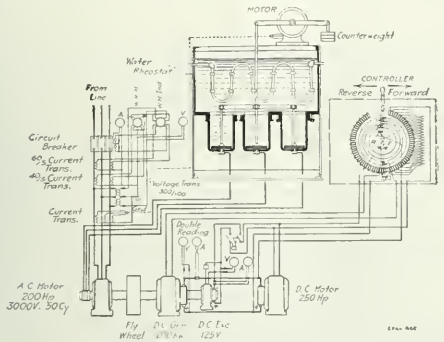


Diagram of Westinghouse Flywheel Equalizer Hoisting System

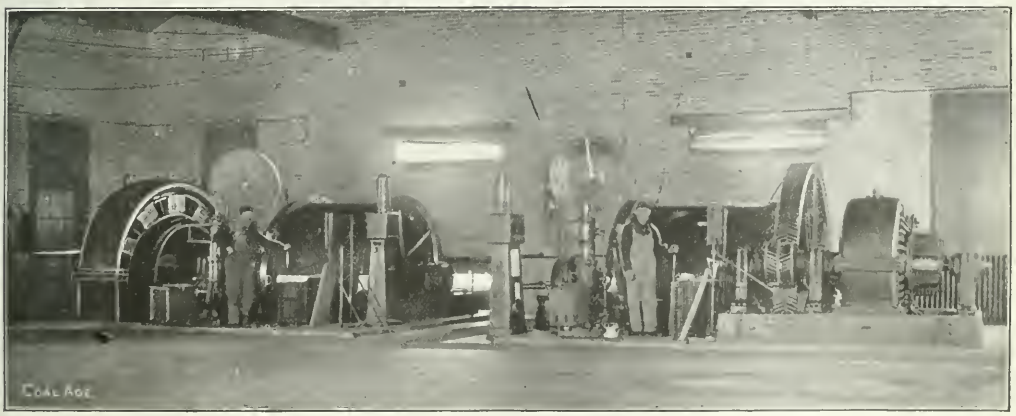
When, on account of an excessive demand for power by the hoist motor, the main alternating-current motor receives more current than that for which the system is adjusted, the current in the small motor also increases, and the movable plates are raised, thus introducing resistance into the rotor circuit of the main motor, reducing its speed and bringing the flywheel into action. When the current to the main motor falls below the adjusted value, the movable electrodes fall, thereby permitting the speed of the flywheel set to increase to normal.

This system has been used in a number of installations and has proved eminently satisfactory. It overcomes many difficulties which would be unsurmountable with steam hoists or with direct-driven electric hoists and enables the mine operator to use hoists of practically unlimited size with a high degree of economy and perfect ease of control.

In the Cleveland Cliffs installation the main hoist motor has a maximum capacity of 1000 hp. It can raise a net load of 10,000 lb. from a depth of 1000 ft. at the rate of 1500 ft. a minute, and can make 40 trips an hour. When the hoist is working steadily at this rate, the alternating-current motor of the flywheel motor-generator set draws not over 365 hp. from the line and its variation in speed is about 15 per cent.

Generator Ratings

Standard ratings of Westinghouse alternating-current turbo-generators are based on two different methods of determining capacity. First, a rating with guarantees covering performance at normal loads and at certain overloads, momentary peak loads being within the guaranteed overload capacity. Second, a rating at the maximum safe operating capacity of the machine, with no guaranteed overload capacity.



Main Cleveland Cliffs Hoist of 1000 hp. and Auxiliary of 400 hp. on the Right

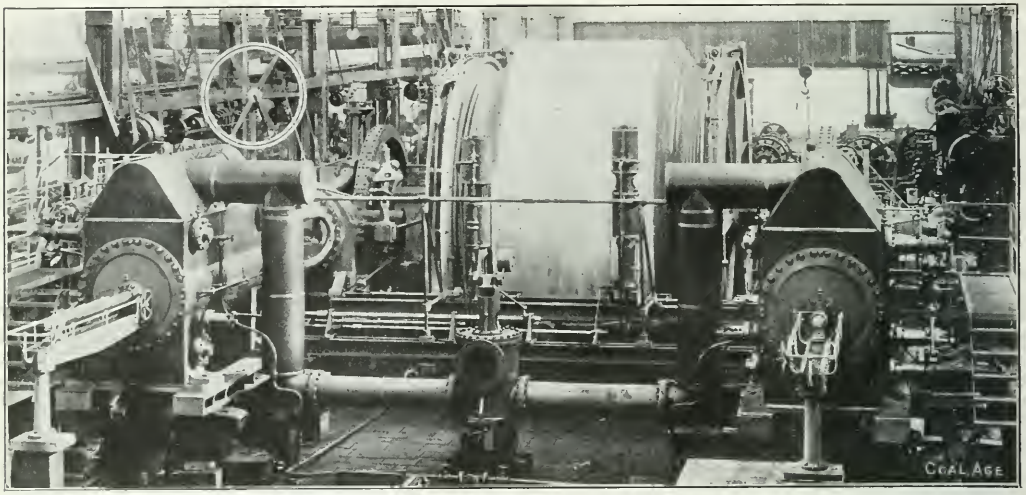
The maximum rating basis is proving to be a highly desirable one, the tendency being to install units of such capacity that as the load on the station varies, additional machines can be cut in or out, and the remaining units operated continuously at or near their maximum rating and efficiency.

It is the simplest to use in making or comparing guarantees, as well as the most satisfactory, from the central-station operator's standpoint, when once it is thoroughly understood.

A Hoisting and Haulage Plant in India

SYNOPSIS—Description of both a hoisting and haulage plant of large capacity. The hoisting engine is designed for a depth of 3700 ft. and has 42-in. cylinders and a stroke of 7 ft. It is equipped with a Gott overwinding device, which has proved particularly effective.

The question of overwind prevention is now receiving considerable attention, and the particulars of a plant constructed for mines in India will be of interest. The information has been specially secured for this journal, and relates to a 5500-hp. corliss winding engine and a 100-h.hp. electric haulage gear, the former being constructed for use at a gold mine and the latter for a coal operation.



THE 5500-HP. CORLISS HOIST SET UP IN THE SHOPS FOR TESTING

The corliss winding engine is one of two, both constructed exactly alike as regards size and design, to wind from the same vertical shaft, which has a depth of 3700 ft. The total weight of the engine is 275 tons; it occupies a space of 20 sq.yd., and the speed of winding is 3000 ft. per min., using superheated steam at 120 lb. pressure per square inch. The unbalanced load is 15.5 tons. The cylinders are 42 in. in diameter, with a 7-ft. stroke, and the valve gear is of the improved corliss type, placed on the outer side of the engine.

The valve spindles have spherical metallic packings, the end pressure of the valves being balanced by springs, while the eccentric shafts for operating the valve gear are connected to the crank pins by drag links. Possessing separate liners the cylinders are steam jacketed, each body being cast separately from the two end pieces which carry the valve chambers. The pistons are fitted with metallic packing rings, the outward pressure of which is adjustable, and the piston rods have a diameter of 8 in., being fitted with United States metallic packing. The crossheads are of steel with cast-iron adjustable slippers, the method of attaching the piston rods to the crossheads constituting a special feature. Each rod passes through a steel plate, and heavy nuts on the rod—one on either side of the plate—secure it in position. The plate is bolted to the crosshead by four bolts, a method which retains the advantage of being able to adjust the distance between the centers of the piston and crosshead with ease, when connecting or disconnecting the crosshead from the piston rod.

The guides are of circular form, 41 in. diameter; the beds are of massive design, of what is known as the "Mammoth" type; the drum-shaft bearings, which are cast with the beds, have the steps lined with special metal and are 21 in. in diameter and 33 in. long; the connecting rods have screw and wedge adjustment at both ends; the drum shaft is 25 in. in diameter, having an overall length of 27 ft., and disk brakes are provided, operated from the driver's platform by foot, handwheel and screw.

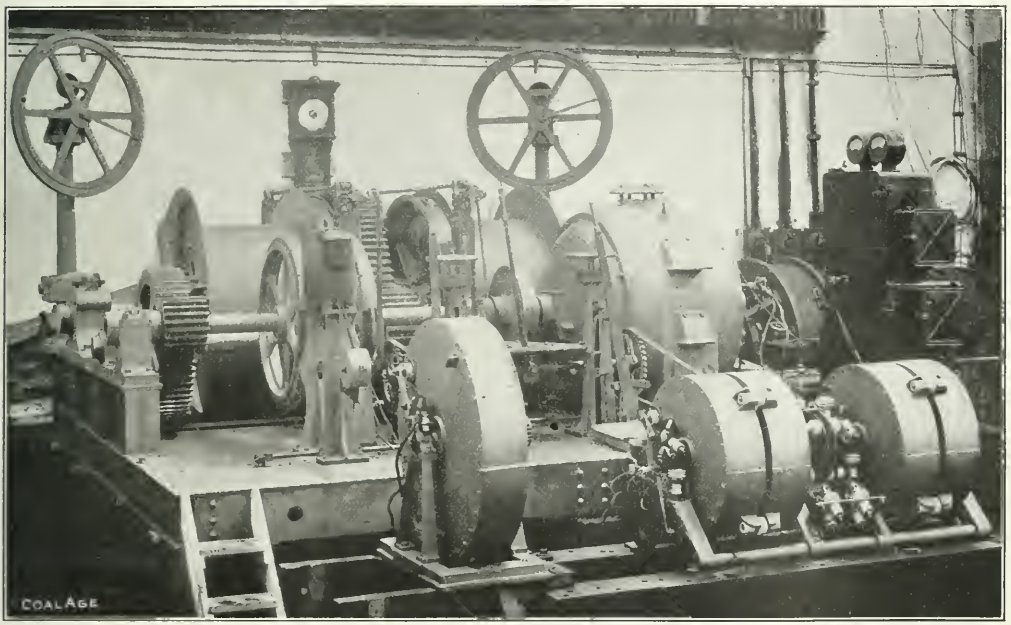
A special feature in the design of the crank disks is that they are each made in two pieces. These disks are 9 ft. 2 in. in diameter, with center hub separate and having a flange cast on one end of it. The disk itself is bored to fit the hub to which it is keyed, and is also bolted to the flange, which makes it very secure and reduces the weight and overall dimensions of the drum shaft for transport. The drum is of the cylindro-conical type, of cast iron, built in sections, the conical part grooved for 1¾-in. diameter rope, the cylindrical part—which is 20 ft. in diameter and 8 ft. 9 in. wide—being plain. Two small internal drums, fitted inside the main drum, carry spare rope, which can be played out as required.

Two main brakes of the suspended curved post type, have power applied to both ends of the posts. They are operated by a steam-brake engine, the brakes being put on by means of a weight and held off by steam, which can

also be put on the top side of the brake-engine piston, if extra pressure is required. The brakes are adjusted automatically as the blocks wear. Reversing the engine is done by means of a steam reversing gear, having an oil locking and controlling cylinders. The main steam valve is 18½ in. in diameter and of the single-beat type, the valve being balanced by a steam piston which makes it easy to operate. On the left-hand side of the engine is placed the driver's platform, with all the operating levers.

The governor is of the spring-loaded, high-speed type, and is very powerful. During acceleration, the engine takes steam up to about seven-eighths of the stroke, but when nearing full speed the governor begins to open, operates the cutoff gear and controlls the speed of the engine. Special attention is given to the lubrication and all steam cylinders and cylinder jackets are drained by means of steam traps.

The engine is fitted with Gott's controlling gear for preventing overspeed, overwind or starting in the wrong direction. In case of overspeed, in any part of the wind, the gear automatically shuts off steam and applies the brakes. It also operates in the same way if, on nearing the surface, the driver has not reduced speed sufficient to land the cage safely, or if the driver starts his wind in the wrong direction; that is, if he is taking the cage into the headgear instead of down the shaft, the brakes are automatically applied and the steam is shut off as before.



Detailed View of the 100-b.hp., Electrically Driven Haulage Gear

Electric Hauling Gear

Coming now to the description of the 100-b.hp., electrically driven, double-drum hauling gear, for the Indian coal mine, the conditions of service are to bring a full set of loaded tubs a distance of 4000 ft. without the help of a descending set of empty tubs (although normally the tubs will run in balance) at an average speed of six miles per hour. The incline is 1 in 5½, with steeper sections up to 1 in 3. One trip comprises 12 tubs, each weighing 6 cwt. and carrying 12 cwt. of coal; occasionally some of the tubs may be loaded with 20 cwt. of rock.

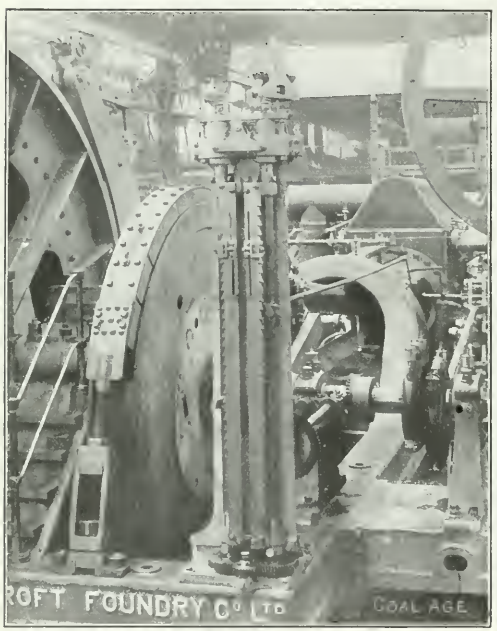
The drums are 4 ft. in diameter by 2 ft. 9 in. wide, each capable of holding 4500 ft. of ⅞-in. rope. The drum centers are of cast steel bushed with gunmetal, the sides being of mild-steel plates in halves bolted to the drum centers and stiffened by steel channels. Lagging for taking the rope is of cast iron in halves, strongly ribbed and bolted to the drum sides by 1⅛-in. bolts, half of which pass right through the drum from one side to the other.

The brake rings are of cast iron, in halves, bolted to the drum sides, the clutches being of the cast-steel jaw type, the moving portion sliding on the hexagons formed on the drum shaft, operated by hand levers on the driver's platform; the drum shaft itself is of Siemens Martin steel, 9 in. in diameter, the outer bearings being 7 in. in diameter by 12 in. long. The countershaft is 5¼ in. in diameter. Each drum is provided with a strong brake of the post type, capable of holding the full load. Each brake can be operated independently by foot levers or by a handwheel and screw on the driver's platform, the latter being an extension of the bedframe and covered with chequered plate. This bedframe is built of mild-steel channels, having machined facings for the bearings and joggles to prevent lateral movement of the same, the side frames being of sufficient

height to raise the drums and gearing above the bottom of the bedframe.

Gearing is double reduction, motor speed 360 r.p.m. and drum speed 40 r.p.m. While the pinion on the motor shaft is of compressed paper, the other pinion and wheels are of cast steel having straight machine cut teeth. On to the extension of the motor shaft a brake operated by hand is fitted, and can be used in case of necessity. A magnetic brake is also fitted on the same shaft, and is automatically lifted off when the current is switched on to the motor, being again applied when the current is interrupted. The position of the tubs on the haulage road is given by a dial-type indicator for each drum.

The engine is driven by a Sandycroft-Hunt Cascade induction motor of the two-speed, pipe ventilated type, the machine being capable of giving a continuous output of



Gott Overwind Prevention Gear in Position

100 b.hp. when running at a speed of 360 r.p.m., or 65 b.hp. at 240 r.p.m. Efficiency at the higher speed is 90 per cent., at the second speed 88 per cent.

The motor, which is controlled by two liquid switches of the Sandycroft patent inclosed type, is wound for a three-phase circuit of 2000 volts, 25 cycles. As the motor has to work in a hot, saturated return mine air, the insulation of the machine has been specially impregnated, and it is capable of giving the output stated continuously, the temperature rise not exceeding 60° F. Further, it can give at either speed an overload of 25 per cent. for two hours immediately following the full-load current—the temperature rise not exceeding 80 deg. F.

The lever mounted on the driver's platform operates the reversing switch by means of a side motion, and when moved backwards it operates a four-phase liquid switch, which is connected to the secondary stator tappings. If it is desired to increase the speed of the winder to its maximum the second lever is brought into operation. This lever operates, by means of a chain, the liquid switch in the rotor circuit, and is connected to the three slip rings.

The magnetic brake is provided in addition to the hand brakes and this comes into operation on the opening of the static circuit or the failure of the supply, or by means of an emergency button in series with a no-volt release. Referring to the photograph, it will be seen that the switch gear is entirely protected by means of a wrought-iron case, containing a double-pole isolating switch.

The Armies of Peace

By Berton Braley

Written expressly for "Coal Age"

No band precedes them on parade, no uniform they wear,
But armed with shovel, fuse and pick the underworld they dare.
They war against the inky dark, the overhanging shale
And all the perils that may mark a miner's burrowed trail.
Each day they seek the pit again to make the seam pay toll,
The armies that go underground to give the world its coal.

They face the ever-lurking damp, that strikes when all seems well
And turns the many workings to a fierce and flaming hell.
They take their chance with cheerful mien in dust and wet and mirk,
They are not heroes to themselves—just workmen at their work.
And so they go about their task—to shoot and cut and hole,
The armies that go underground to give the world its coal.

They mine the gleaming anthracite to meet the need of men
(Forests of ancient ages which are brought to light again).
They mine the soft bituminous, a million boilers burn,
Which keeps the wheels of industry forever on the turn.
Of all the life we live today they are the very soul,
The armies that go underground to give the world its coal.

Our trains that thunder over land, on rails of shining steel;
Our ships that travel over seas, on swift and steady keel.
The fire that warms our houses and the light that keeps them bright
Are spoils of all the battles that these peaceful soldiers light.
So let the trump of triumph sound, they stand on honor's roll,
These armies that go underground to give the world its coal.

A Gasoline Hoist at a Coal Mine

SYNOPSIS—It is ordinarily taken for granted that steam and electricity are the only forms of power that it is advisable to use for stationary work at coal mines. This article describes one of the exceptions to this rule, gasoline being so far ahead of these other sources of power supply that there was no hesitancy in its adoption.

Although small hoists operated by internal-combustion engines have been in use for a number of years at some of the Western metal mines, an installation of this character in the center of a coal-mining region is decidedly an innovation. The Lehigh Valley Coal Co. has recently installed such a hoist at its Blackwood Colliery, near Pottsville, Penn., the machine being designed and built by the Vulcan Iron Works, of Wilkes-Barre.

THE HOIST HOUSE, LOCATED IN A LONELY PLACE IN THE WOODS

The above named coal company was desirous of sinking a proving hole at a point which was a considerable distance away from their power house or any source of electrical supply. A careful investigation was, therefore, made of the cost of hoists embodying each of the three sources of power, namely, steam, electricity and gasoline.

This comparison was so far in favor of the gasoline hoist when used in this isolated position, that there was no hesitancy in making its adoption.

The machine was designed for the following service: Single-car trips are handled on a slope approximately 500 ft. long at an inclination of 40 deg. from the horizontal. The gross weight of car and coal is 4000 lb., and the cars are handled at a rope speed of 200 ft. per minute.

Aside from the motive power, the hoist is not materially different from those designed to be operated by electric motors. As will be seen from the photograph, the machine is self-contained, and may be readily transported from place to place. The drum is loose on the shaft, is driven by a band friction clutch, and controlled by the usual type of brake, operated by hand.

The driving engine is of the four-cylinder type, with a rated capacity of 25 hp., having cylinders 5 in. in diameter, with a stroke of 6 in. It is equipped with a speed-regulating governor, magneto, battery, intake and overflow water pipes, water circulating pump and intake and exhaust manifolds.

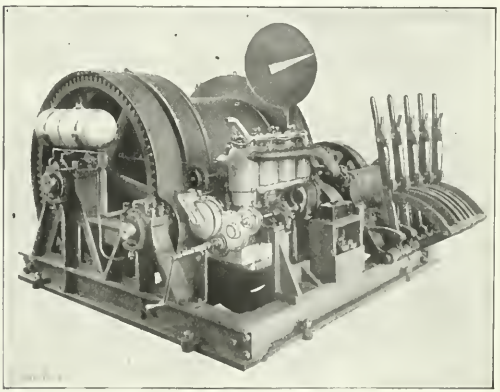
Owing to the conditions under which this machine operates, it is, of course, necessary to change the direction of rotation of the drum, and reversing gears are, therefore, provided for this purpose.

Although the cost of operation of a hoist of this type may be somewhat higher than that of an electrically driven machine of equal capacity the ease and cheapness with which it may be transported and set up more than offsets this when employed in an isolated position.

There is also the advantage that the fuel is easily transported and the danger from fire is probably less than with a steam operated hoist, all of the gasoline except what is in the tank on the machine being stored at some point outside of the hoist house, preferably in an underground vault or tank.

One of the principal difficulties experienced with hoists of this type which have been built heretofore has been that the torque was low in starting. In this particular machine, however, the capacity of the engine is sufficiently great to equal this condition.

This machine has been in operation for some time, and has, thus far, given entire satisfaction. It has, of course, its peculiarities with which the operator must become familiar, and which require decidedly different treatment from either a steam engine or an electric motor.



GASOLINE HOIST, SHOWING ENGINE, FUEL TANK, CONTROL LEVERS, ETC.

For instance, as the cylinders are water-jacketed, it is necessary to carefully drain this part of the apparatus and remove all water therefrom before leaving the hoist at night in cold weather; otherwise, the jacket would be liable to freeze and ruin the engine. This, of course, is one of the details of successful operation, but one which, nevertheless, is different from that of the ordinary motive power usually employed, and which, in winter at least, must not be neglected.

The internal-combustion engine is no longer either an experiment or an uncertainty. It is with us to stay, and, if properly handled, is fully as reliable as a steam engine, if not more so. Of course, it looks like "carrying coals to Newcastle" to employ an expensive liquid fuel at a coal mine, but in an instance like the one above described, where the position in which the machine is to be used is remote from any source of power supply, and, to a certain extent, temporary, the advantages attendant upon the use of this type of engine are self-evident.

An Important Advance in Coal Storage

By William E. Hamilton*

SYNOPSIS—The elimination of breakage in the handling and marketing of anthracite coal is one of the serious problems of the hard-coal operator. Immense savings have been effected by numerous ingenious devices for reducing the severity of handling, with the consequent increase in the percentage of lower-priced grades. This article describes a storage plant of large capacity and embodying some novel and original appliances for the reduction of breakage in both storing and reloading coal.

It is estimated by A. D. W. Smith, of Wilkes-Barre, Penn., and William Griffiths, of Scranton, who have made investigations for the U. S. Geological Survey, that the anthracite coal will be exhausted in 104 years. It will therefore continue to increase in value, and this fact will necessitate more economical systems of handling.

The features to be desired in a plant to store and rehandle anthracite coal are the following:

The least breakage of the coal.
Lowest operating cost.
Low first-cost, per ton of storage capacity.
Least amount of labor employed.
Least amount of machinery involved.
Simplicity, and consequent freedom from breakdowns.
Greatest storage capacity.
Greatest strength in construction.
Protection against fire, either accidental or incendiary.
Protection against the weather.

The system herein described consists of cylindrical tanks, having conical roofs and floors. In the center of each tank is a hollow tower, containing a spiral chute, and a pivoted bucket conveyor, which operates in connection with the chute and a track hopper. Although the plan is new, the details have been heretofore tested and proved. It is a combination of old and well known ideas and principles, and its simplicity insures its successful operation.

The first aim is to reduce the loss in value of the coal, caused by degradation. This is an item, which, on a tonnage basis, often amounts to more than the cost of operation, and the cost of interest on plant investment, combined.† A great deal of machinery, costly to install and operate, expensive to maintain, and destructive to the coal (through its chipping and flaking by abrasion), is dispensed with by this method of handling.

The number of transfers and the fall of the coal at these points has been reduced to a minimum. The rolling or sliding of the product upon itself is also *less*, by reason of the form of the retainer. (See Fig. 1.) The coal is carried on pivoted buckets, traveling on self-oiling wheels. A conveyor such as this, is 50 per cent. more durable and consumes less power than the scraper type.

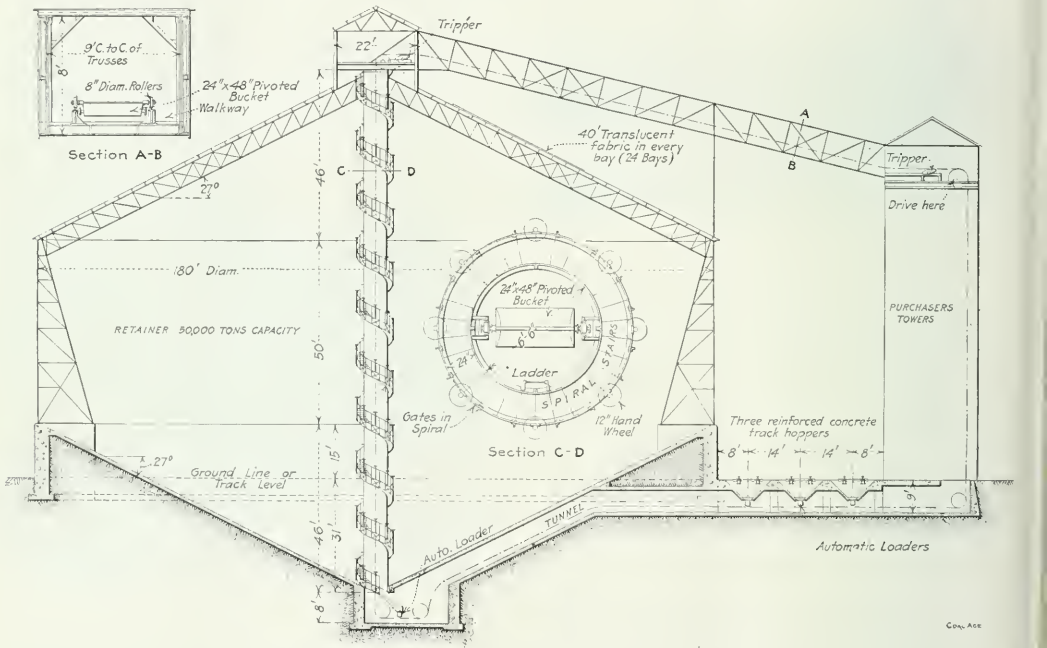


Fig. 1. Cross-section of a Single Unit, Showing Some Details

*Engineer with the Jeffrey Mfg. Co., Columbus, Ohio.

†C. Dorrance, now chief engineer of the Lehigh Coal & Navigation Co., states that an increase of 1 per cent. in the steam sizes means an annual loss of $75,000 to his company. See "Coal Age," bottom of second column, page 659, and also erratum, page 683, Vol. 2.—Editor.

Method of Operation

The coal is received from the mines in cars which are "spotted" over the track hoppers. From these it is carried by wheeled bucket conveyor to the top of the retainers or tanks, where it is discharged into the large hopper of a covered spiral chute. It glides down and fills this chute and then sliding gates are opened successively, which allow the coal to flow out into the retainer or tank.

The spiral chute has a capacity greater than that of the bucket conveyor, and may always be kept full; the angle of inclination insures of the coal sliding, and there is no "internal movement" or "working" of coal within the chute, such as would cause grinding or abrasion. The coal moves down the chute *en masse*, sliding on the smooth surfaces, and not grinding on other coal. The flow through the gates is regulated so as to keep the spiral chute filled, this being shown by its height in the hopper at the top of the tower. The buckets, after discharging into this hopper, travel on guides, down through the center of the hollow tower, and through the coils of the spiral chute. Passing out of the retainer at the bottom, they return under the track hoppers and are again filled and passed on to their discharge.

Facilities for Storing the Coal

At the beginning of the operation of storing, all gates of the spiral chute are closed, except the lowest one, and the coal flows out of this and fills the lower part of the retainer. As soon as the coal has reached its level of repose in the tank, this gate is closed and the next higher opened. The gate-controlled openings are large, and there are eight to each spiral turn, so that the difference in height between one gate and the next is very small, in fact, the top of one gate is higher than the bottom of the one next above it, so there is no falling of the coal. (See diagram.)

The gates are opened and closed, one after another, until the storage retainer is entirely filled, and the coal reaches the top of the tank in a conical pile, of which the hollow tower is the center, and the steel wall of the retainer is the circumference. In this construction the strains occasioned by this great weight of coal are equally distributed on the outer wall of the retainer.

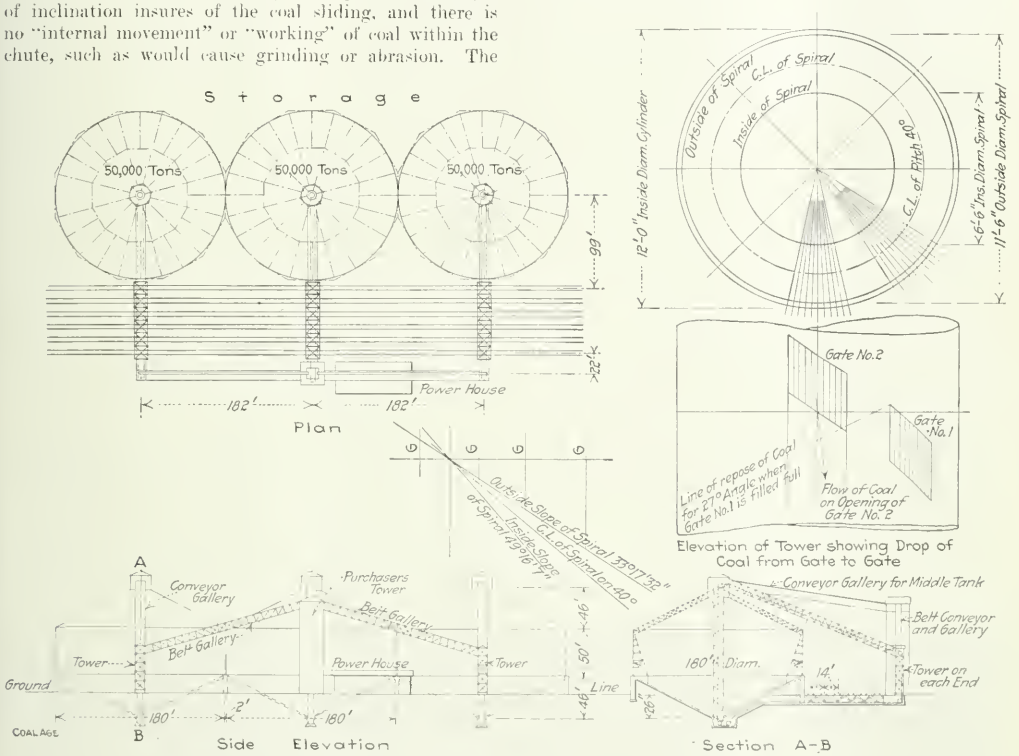

Fig. 2. General Plan of Three Units and Diagrams Showing Maximum Fall of Coal

Reclaiming

In reloading (out of storage), the preceding operation is reversed. Beginning at the top, the gates in the spiral are opened successively as they are uncovered by the lowering of the coal in the retainer; thus the coal is drawn from the top of the pile, and never from the bottom under pressure of overlying coal. The only labor required is for opening and closing the gates, and even this can be done mechanically.

The travel of the coal is retarded by the turns of the spiral, so that the pressure at the bottom of the chute where the coal passes into the pivoted buckets, is only slightly greater than at the top, whereas, if this chute were vertical, straight and smooth, when full of coal, there would be a pressure of 2000 lb. per sq.ft. at the bot-

tom, for each 50 ft. of height. The weight of coal in the spiral chute is practically uniform at every turn, as it is not carried by the coal at the point of discharge; in reloading (out of storage), there is none moved under pressure.

In this plan of "piping" the coal from the top of the pile, it is taken out of the center so that the pressure on the wall of the retainer is reduced equally in all directions, and it is uniform at all time and stages of both operations—like the pressure of water in a tank. The "internal working" of a pile of coal when drawn off from the bottom is apparent. A cone-shaped depression forms at the top and throughout the pile one piece of coal is grinding against another, chipping, flaking and breaking off the edges into particles too small to be of much commercial value.

Plants for the storage and recovery of anthracite coal involve the expenditure of a considerable amount of money. Only a few covered plants have been built, in fact, little advance has been made in this work in comparison with the general progress and improvement in other arts and industries.

From records kept at a number of plants, through several years of operation, the fact is disclosed that neither the first cost nor the operating expense is the principal thing to be considered. The loss in value of the coal from its "degradation" is a cost greater than any other. This degradation has not been materially reduced in late years, as the plants which have been installed have followed the original scheme of storing the coal in conical or rectangular piles and drawing it off either by tunnels, under the great pressure and weight of the overlying coal or by conveyors scraping against the side of the coal pile.

The system herein described provides protection against fire either accidental or incendiary, as no sparks nor flying embers can get into the inclosure; also in case of labor troubles, strikes and riots, there are no doors or other openings that give access to the coal where combustible material can be piled and fires started.

The circular tank or retainer is the strongest construction known. Likewise the capacity is greater than that of any other geometrical form of building, with the exception of a sphere; it also affords the greatest possible storage capacity for the amount of material entering into its construction.

The German Coal Industry

The activity in mining and industrial enterprises in Germany continues unabated. Despite the coal miners' strike of last March and other impediments such as the chronic shortness of railroad cars, political unrest, etc., the production of coal in Germany has come up to 177,094,917 tons in 1912, as against 160,742,000 tons in 1911. Prussia alone produced 167,267,860 tons, of which 93,798,000 tons must be credited to the Dortmund district, while the administrative district of Breslau, comprising Upper and Lower Silesia participated with 17,272,579 tons. The production of coke amounted to 29,141,070 tons, also an increase over 1911, while 5,332,651 tons of coal briquettes were manufactured.

The production of brown coal or lignite likewise shows an increase, to wit, 82,339,588 tons in 1912, as against 73,516,789 tons in 1911. The production of lignite briquettes amounted to 19,058,000 tons.

By the Way

Many foxes grow gray, but few grow good.

One man's story is no story—hear both sides.

Little minds, like weak liquors, are soonest soured.

He who strikes with his tongue must ward with his head.

To believe a thing impossible is the one sure way to make it so.

We are judged, not by our intentions, but by the result of our actions.

We will walk a long time behind a wild goose before we find an ostrich feather.

Wise men are instructed by reason, the ignorant by necessity and beasts by nature.

It is said that Chamberstown, Chambersville and Pottsville, Penn., were all named after the same man.

The man who starts out with the intention of doing no more than his part is apt to be satisfied with doing only a part of that.

A state mine inspector of long experience in gaseous mines characterizes a nonreversible fan operating at a coal mine, as a railway passenger train minus the air-brake equipment. This is too practical an illustration to let slip.

Press reports state that Josiah Van Kirk Thompson, the Pennsylvania coal and coke operator, recently paid $1,000,000 for a divorce. We believe this establishes a new high record and it is worthy of note that coal men can head the list in more than one way.

Morgan Kingston, a Nottinghamshire (England) miner, has signed a contract with Andreas Dippel, of the Chicago Opera Co., to appear as the latter's principal tenor, beginning October, 1913. Kingston was a miner for eleven years, but has been under the care of some of Europe's ablest vocal instructors during the past three years.

The vote registered at a certain Western coal camp in 1910 was: Republican, 40; Democrats, 278. Two years later the vote was: Republican, 304; Democrats, 32. In explanation it is stated that the superintendent changed his politics during the intervening two years. Why such a man should waste his time bossing a mine is more than we can understand.

Curious happenings are recorded even in England. A Nottinghamshire collier sold his wife for 24c. The man was drinking and his wife tried to persuade him to go home. Friends joined their entreaties to hers and this so incensed him that turning to one of them he shouted: "Does tha' want 'er Tha' can 'ave 'er for a 'bob." The offer was promptly accepted and the woman "changed hands." The husband has since repented his sorry bargain, but his wife prefers the new order, and is obdurate and apparently content. The husband has invoked the aid of the guardians of the peace, but in that quarter has met with little sympathy. The woman's husband and present owner are "old friends."

In the discussion of an interesting paper on the "Structure of the Northern Anthracite Basin," presented by N. H. Darton, geologist of the U. S. Bureau of Mines, at the November meeting of the New York Section of the American Institute of Mining Engineers, the question was asked as to the quality of coal that is being mined at present in the anthracite fields. Mr. Darton replied that the operators are endeavoring to conserve the coal fields in that region and are shipping as low a quality of coal as the market will take. He stated further that if the market demands high-grade coal it can be delivered, as there still remain millions of tons yet unmined.

A Monitor Gravity Plane at Penn-Mary

By R. Dawson Hall

SYNOPSIS—No. 7 mine of the Penn-Mary Coal Co. dumps its coal near the drift mouths into a bin. The coal is loaded as required into a large car or monitor holding 15 gross tons, which, running to the bottom of the plane, draws an empty monitor up the hill to take its place. The coal on reaching a bin at the foot of the hill is discharged, and is allowed to fall thence at will into railroad cars.

The Penn-Mary Coal Co. is most successfully operating a monitor gravity plane at its No. 7 mine. The cars after leaving either of the openings pass over automatic scales. One front wheel operating on a lever sets these scales in operation, and the corresponding rear wheel throws the scale out of gear. The weight of the load in the car is automatically registered on a paper tape, as shown in the illustration. The upper printed figures in Fig. 1 represent thousands; thus 3 in the upper part of the diagram denotes 3000 lb.; the lower figures represent hundredweights. It will be seen that the arrow lies between 3200 and 3100 lb. and that the actual weight of the car evidently approximates 3120 lb. because the scale divisions each correspond to 25 lb.

Reducing Weigh Scale Worries

The figures written cursively on the diagram are those placed there by the weighman or clerk and were copied from the check numbers taken off the cars as they passed over the scale. It would not, of course, be necessary to employ a weighman. The check numbers could be placed in order on a file and by reading the values on the tape and the check numbers on the file in due order, the tonnage corresponding to each check number could be ascertained at the end of the day.

erated successfully by unintelligent men, they are sure to be extensively introduced at all tipple scales. They are made by the Streeter-Amet Weighing & Recording Co., of Chicago, Ill.

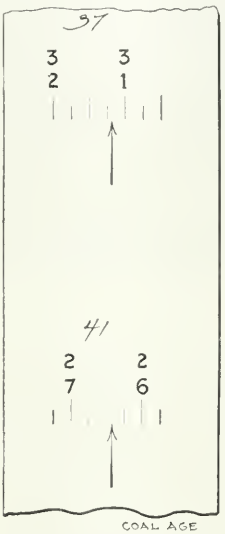

Fig. 1. Record of Coal Tonnage of Individual Cars

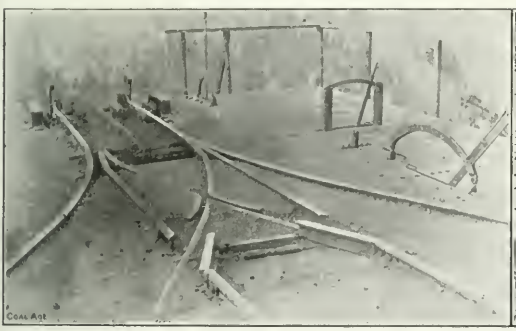

Fig. 2. The Switches over the Upper Bin, Permitting Rapid Dumping of Coal

Fig. 3. An Entrance to No. 7 Mine, Showing Iron-rail Timbers and a Baldwin-Westinghouse Motor

The system is most expeditious, gives satisfactory results and a permanent, unanswerable record, and the Penn Mary Coal Co. is well satisfied with its operation. They do not, however, leave the recording of the check numbers till evening, but note them on the tape as the cars are dumped. Scales of this type have had a far larger application to railroad work than to mining, but because they are automatic, rapid and accurate and can be op-

A Time-saving Tipple Switch

The coal after being weighed passes in the car to the upper bin. A clever arrangement of switches has been devised by H. P. Dowler, the manager of the company. It will be noted that both rails of the straight track leading to the dump are broken so as to form latches. These portions of the rail are connected by spiral springs. When the loaded car is pushed forward, the rails are forced out

Fig. 4. The Monitor Gravity Plane at Penn Mary No. 7, Heilwood, Penn.

into line and the car passes on a solid track. As soon as it has passed, the track is broken and is so disposed that empty cars can pass back on a rail just below the loaded track, either to the right or left.

As the grade of the plane was excessively steep, a simple kickback dump was necessary to save the expense of high trestling which would have been involved had a crossover dump been installed. The switches for the load track and the two empty tracks are all together and are controlled by one and the same lever and are set so close to the dump that the operation of the parting is simple and rapid. This is necessary as the cars are small and have to be handled with rapidity if a large tonnage is to be obtained. By setting the rails in solid concrete, the switch rails are made so stiff that it is impossible for them to get out of alignment. Thus derailments are avoided. The immediate track grades leading to the tipple and away from it, are 2 per cent.

The bin at the head of the plane holds 43 tons and dumps into a monitor with a rated capacity of 12 long tons. It is customary, however, to load it with about 15 tons. The box of this large car—one is almost moved to term it a traveling bin—is 12 ft. long and the height of its upper edge is 7 ft. 10 in. clear of the 60-lb. rail on which it runs. Its length is 15 ft. over all, the wheel base 4 ft. and the gage 4 ft. 8½ in. There is only one switch on the plane and that is near the top. Under the upper bin, the monitors occupy in turn the same rails, but they are switched to a separate track at the parting, to which reference has just been made, and each dumps always into its own portion of the lower bin.

The monitor has three hoppers and these are raised by winches which are held in place by pawls. They can be so arranged that a rod projecting from the end of the car and striking a bumper will release all the pawls at one time and dump the monitor almost instantaneously. This, however, has not been placed up to the present date on the Penn-Mary monitor.

Spotting the Railroad Cars

The monitors dump into a large bin holding about 50 tons and having three chutes discharging endwise into

Fig. 5. Monitor over Lower Bin

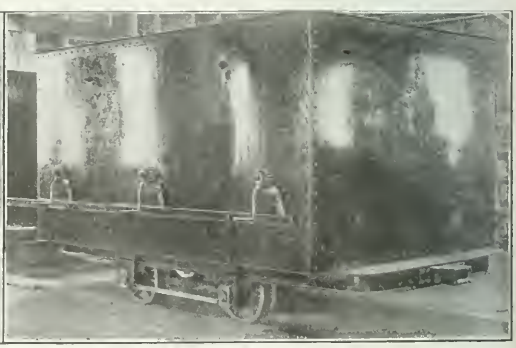

Fig. 6. Car Equipped for Automatic Dumping

the railroad cars below them. These chutes are controlled from a dumping platform by the long levers shown in Fig. 7. In order to reduce the labor needed, the railroad tracks are set at a grade of 2 per cent. and the cars are controlled by the use of a Fairmount Machinery Co.'s car retarder, which enables one man to spot the car within a few inches of the desired place. The man in Fig. 7 has his hand on the controlling lever of

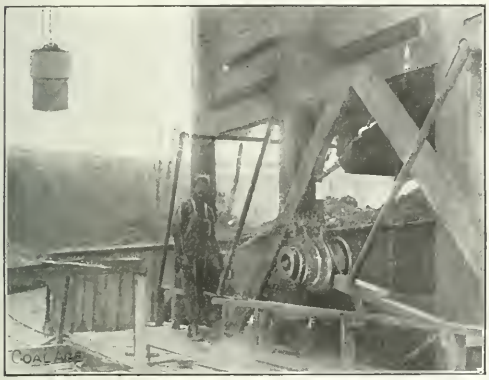

Fig. 7. The Car Retarder and Dumping Levers

this device. By gently lifting on this controller, he permits the car to travel forward as desired.

The grades near the top of the plane are from 20 to 25 per cent. At the steepest point the grade is 38 per cent. The approach to the tipple is, however, only about 8 per cent. This easy grade at the foot involves allowing the monitors to travel at some speed. At the same time they must be under such control that they can be stopped at any point on their travel. This is done without difficulty with the two sheaves shown in Fig. 8. This photo-

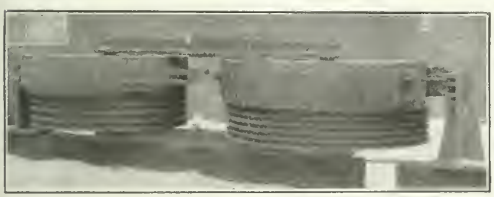

Fig. 8. The Figure-of-Eight Sheave Wheels and Brake

graph was taken in the factory as it was impossible to get a good view of the machine in position.

How the Monitors Are Controlled

The rope winds in the form of a figure-of-eight between the two sheaves and thus has sufficient turns to make a firm contact, so that it is prevented from slipping under the most untoward circumstances. The brake band being cast integral with the sheave wheels absolutely restrains both them and the rope, when the brake is applied. The bands are 18 in. wide and there is only one to each sheave, and as this is on one side only, it would tend to throw the bearing out of line. Attempts have been made to correct this by putting brakes above and below each sheave. This puts the lower bands in an undesirable position.

Consequently, a single band is preferable and in order to avoid the possibility of breaking the wheel or of wearing the bearing by excessive unsupported strain, the band in this machine is reinforced by being connected with four arms to another bearing on the same shaft. This keeps the wheels true and safe under any load the checker can throw onto them. In fact, the monitor system has been rendered so reliable that grades of 70 per cent. have been fitted out and operated with entire success.

At Penn-Mary No. 4, a mine recently worked out, monitors controlled by figure-of-eight sheaves were in use from 1906 to 1912. The outfit was slightly smaller than that now in operation at No. 7, but it handled 322,947 tons in that length of time and cost only $4 a year for renewals. The only parts to be renewed were the brake blocks. No repairs were needed.

Lessening Friction of Fan

No. 7 mine is ventilated by an 8-ft. disk fan with Hyatt roller bearings. There has been no test made to

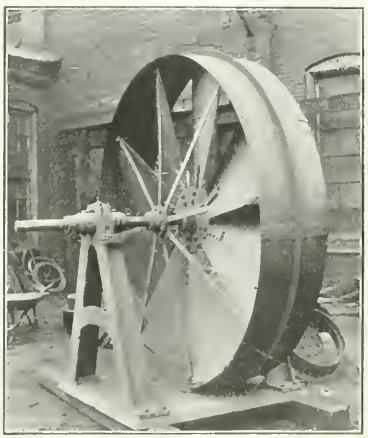

Fig. 9. An 8-ft. J. C. Stine Fan with Hyatt Roller Bearings

determine the saving effected by the use of this antifriction device, but the Penn-Mary Coal Co. is expecting to equip another of its fans in a short while with the same improvement as it is sure that the economy effected in the use of roller bearings fully justifies their use. The fan installed will be replaced by a larger one of the same type when more air is needed. It is rotated by a 71½-hp., shunt-wound, 590-r.p.m., 220-volt motor which takes a full load current of 28.7 amperes. The tracks running up the side of the plane, Fig. 1, is for the transportation of supplies. A Lidgerwood hoist electrically driven is kept at the head of the plane for that purpose.

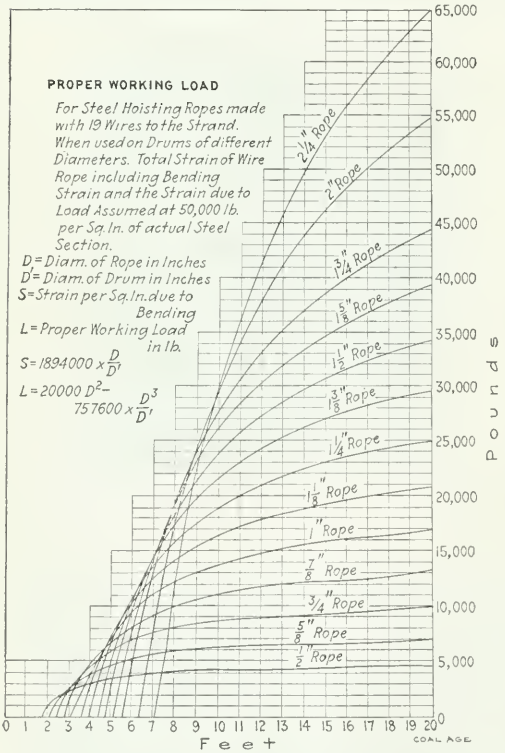
The monitors, figure-of-eight sheaves and the fan mentioned were supplied by J. C. Stine, of Tyrone, Penn. H. P. Bowler is general manager, M. H. Kallaway assistant and J. T. Hoover chief engineer.

Steel Hoisting Ropes

By George L. Phillips*

The agent through which the power developed by the hoisting engine is transferred to the cage with its car of coal anywhere from 50 to 2000 ft. down at the shaft bottom, is the wire hoisting rope, and upon its quality and power of transmission rests the efficiency of the hoisting apparatus.

Steel hoisting ropes are used at all shafts, those best suited to the work having six strands of 19 wires each, of medium steel and having an ultimate strength of from 60,000 to 70,000 lb., the working or safe load being obtained by employing a factor of safety of not less than five. The character and quality of the steel, as well as the lay of the strands, play an important part in the life of the rope, the continuous bending and straining to which it is subjected making it necessary to look closely after these details. A poor steel rope becomes brittle as a result of continuous bending, over a sheave which is perhaps just a trifle too small, and the individual wires soon begin to break.



Safe Working Loads for Steel Hoisting Ropes

Given the proper kind of rope, as above stated, and with reasonable care as to the kind of oil or lubricant used (one part of linseed oil to one part of lamp black being a good preservative) and the right kind of judgment in the selection of pulleys and sheaves, and the maximum of efficiency can be obtained.

We herewith submit a diagram of the safe loads that can be carried by ropes of a given diameter over sheaves of a given size. The abscissas are sheave diameters in feet and the ordinates safe loads in pounds. Along the curved lines will be found the diameter of rope in inches.

For instance, should we desire to ascertain the safe working load for 2-in. rope on a 12-ft. drum; we find by tracing up the 12 line until it intersects the 2-in. line, that the corresponding ordinate gives 38,000 lb. Where the 2-in. line crosses the 2¼-in. line will be the minimum size of sheave for a 2-in. rope.

*205 South Main Ave., Scranton, Penn.

Production of Coal

Seventeenth Bituminous District (Pennsylvania)

Following is the production of coal in the 17th bituminous district of Pennsylvania, for 1912, showing the tonnage of each mine in the district, and its distribution in the counties:

Company or Operator	Short Tons
Pittsburgh Terminal Railroad and Coal Co.	2,360,163
Pittsburgh Coal Company	1,937,974
New York and Cleveland Gas Coal Company	371,283
Crescent Coal Company	317,401
Pittsburgh-Buffalo Company	275,224
Youghiogheny and Ohio Coal Company	250,803
Monongahela River Consolidated Coal and Coke Company	250,783
Mans Williams Coal Company	28,561
Ollett Brothers	21,452
Paul Coal Company	14,491
Sorg Brothers	11,419
Vogel and Weinman	7,484
Samson and Hormel	7,482
W. S. B. Hays	6,950
Weinman Brothers	5,894
Steele and Scott	5,350
James T. Fox	3,725
Bureau of Mines	3,674
Shearn Brothers	3,423
John Peterman	3,223
Production by Counties	
Allegheny County	5,729,361
Washington County	157,428
Total	5,886,789

Record of Charleroi District, 1912

Last year's coal production in the twenty-first inspection district of Pennsylvania while 3 per cent. (213,322 tons) larger than the year before, would have increased still more had it not been for the freezing of the Monongahela River in the months of January and February, which caused navigation to be suspended for about three weeks. Furthermore, there was another suspension of equal duration in the month of April pending the signing of the scale by the United Mine Workers of America and the operators. The labor shortage also resulted in a further restriction of output.

There were 22 fatal accidents in the mines, 13 less than in 1911. This is a decrease of 37 per cent. They can be classified and compared with those in 1911 as follows:

CAUSES OF DEATH, CHARLEROI DISTRICT

Causes	Per cent. 1911	Per cent. 1912
Falls of coal	11.42	18.18
Falls of drawslate	34.28	13.63
Falls of roof	11.43	9.10
Electricity	11.43	13.63
Mine cars	28.57	36.36
Miscellaneous	2.86 (blasts)	9.10
	100.00	100.00

It will be noticed that accidents from falls have materially decreased, but there has been an increase in accidents from mine cars owing to the large steel cars used in two of the largest mines. Of 6735 persons employed at the mines only 240 are between the ages of 16 and 21 years. The majority of these young men are 19 years old. The number employed above ground between 14 and 21 years of age is 91. None of the mines used compressed-air mining machines. By hand picks, 1,787,697 tons were mined; electric machines undercut the balance of 5,141,536 tons.

EDITORIALS

Hoist Evolution

The methods employed for raising coal from the mines have probably been as numerous and varied as those devised for its transportation upon the surface.

To begin with, baskets or boxes were strapped upon the backs of carriers, usually women, who toiled laboriously up and down ladders or crude stairways. Then came the windlass and rope with a bucket attached to the end; next the winch or sweep mill, to which a horse, mule or ox could be hitched, the bucket being slowly raised by the animal walking endlessly round and round.

Finally, with the utilization of steam and the development of the steam engine, this machine was quickly adapted to the hoisting of coal, which service, until very recent years at least, it has performed to the almost entire exclusion of all other devices.

Within a comparatively short time, however, the electric hoist has come into extensive use and has proved itself as reliable and satisfactory as the time-honored steam engine. Its employment obviates the necessity of providing a boiler plant at each mine, and allows the complete centralization of power, which is always conducive to economy.

The electric hoist possesses other advantages over the steam engine, chief among which might be mentioned its adaptability to distant control. With a motor-driven machine it is quite possible, even convenient from the electrical standpoint, to place the operator near the point where the load hoisted is discharged into the bin or chute. He is thus enabled to watch all that goes on in the dumping process. And, although this arrangement will probably in no wise increase the efficiency of the hoist or affect in any way the number of horsepower-hours necessary to raise or prepare a ton of coal, it will undoubtedly have an influence upon the regularity of hoisting operations and will reduce the liability to hoisting accidents.

⁂

Lonely Virtue

The Director of the Bureau of Mines appeared before the Committee on Public Buildings and Grounds, and made the following statement. It is sent to us for publication, and we will not give it a lowly place, but quote it in our editorial columns, for we know our subscribers will want to read it.

What is more we will not edit it as one of our distinguished contemporaries did, before putting it into circulation, and we will not write the words "contributed to" in place of the bolder word "yielded" in the quotation we make. "The work," says Doctor Holmes, "such as we have been able to do in our present location within the past year, has *yielded* a reduction in the annual loss of life of not less than 500, but the great loss is still a discredit to the nation."

This gasconade reminds us of the Andalusian peasant, who, as Washington Irving records, declared, "When I draw my sword, the earth trembles" (tiembla la tierra). We can forgive a little self-esteem in a bureau doing good work like the Bureau of Mines; we can condone a trifle of excess self-adulation in a body seeking to establish itself and needing funds to make such establishment possible; we can excuse some exaggeration, remembering that a diplomat has been described as an honest man who makes misstatements for the good of the commonwealth; but to rob our philanthropic companies, which have spent their millions for safety, of the honor due them, to overlook the original work all over the country, and to remember only the propaganda of foreign experiments which, as far as safety is concerned, has replaced original research in the Bureau of Mines, is ungenerous and unfair.

We hope Doctor Holmes will get his appropriation of a half million of dollars. The Bureau needs it and its members deserve it, but we also hope the claim that the Bureau alone is the cause for the growth in mine safety will never be made good, no matter however faithfully its attachés serve the nation. The mining public will do its part, no matter how severely its Bureau may misrepresent its actions.

⁂

To Regulate the World's Output of Coal

The Miners' Federation of Great Britain has recently made public the report of the International Miners' Congress, which was held at Amsterdam, Holland, July 12, to formulate, if possible, an international rule to regulate the world's output of coal.

The British miners are now voting on the question of only working five eight-hour days each week, which is so far reported as follows: For, 231,711; against, 171,270.

The American report did not make any recommendations, merely giving statistics of American production. After the vote of the English miners has been carefully considered, the International Committee will probably draft a plan which, in their judgment, will be best adapted to regulate the world's output of coal.

It should be remembered, however, that even if a five-days-a-week working policy were adopted in all coal-producing countries, the output, if limited at all, would be so only temporarily. Such a plan could not permanently regulate the supply of coal. New mines would be opened as fast as needed.

If, however, the miners should appoint an international committee having power to recommend at any time a reduction of working days to four, three, or even two per week, for a prescribed period, the production of coal might be regulated as desired. This latter statement, of course, assumes that the unions in the different countries would be able to enforce or carry out the recommendation of the international committee

If such a bold plan on the part of the coal miners in all countries could be consummated, the various governments would then have on their hands a trust of such vital importance as to justify their closest attention. New evidence is being brought forward every day that labor will have to be regulated by federal control precisely as we now attempt to regulate industrial corporations that have become too dangerous for public welfare.

Mine Telephones Made Compulsory

A law that becomes operative Apr. 1 in Great Britain compels all mines to have telephones installed when the point of entrance is more than 1000 ft. distant from the workings.

Legislation having the same object in view would not be out of place in the United States. There is no device more urgently needed, in case of trouble underground, than the mine telephone. In a few years any mine unequipped with a complete telephone service will be looked upon with the same misgivings as are aroused by a commercial enterprise lacking such service today.

Railless Coal Transportation

It is rather surprising to find such a well informed publication as the *Wall Street Journal* giving credence to the somewhat visionary plan of transporting coal by pipelines. In a recent issue, however, it publishes a telegram to the *Manufacturers' Record,* from a "drainage engineer" in Chicago, which reads: "Developed a project for transporting coal hydraulically for 96 miles, divided into six equal sections. Pipe 18 in. in diameter; 6 ft. per second; resulting economy very great." Whether the proposition is "developed" on the ground or only in the brain of the inventor, is not stated, but we venture to believe that it has not yet outgrown the latter embryo stage.

The idea apparently originated from watching the results of dredge pumps working in Lake Michigan, where material up to 6 in. in diameter is pumped half a mile. Perhaps it was thought that this was a new departure in the science of engineering, when as a matter of fact it has long been recognized as a standard method of handling material, within certain limits. That these limits have a radius of 96 miles remains for the inventors to prove.

It is hardly to be presumed that they expect to transport anything other than the finest sizes; obviously, the largest lump would be reduced to an almost impalpable powder at the end of its 96-mile jaunt in the restricted confines of an 18-in. pipeline. In fact, innumerable physical conditions might be cited, any one of which would show the utter absurdity of the scheme. For instance, it is doubtful if the inventors have considered the mere detail of wear and tear on the pipeline. This question was first brought into prominence on the mammoth fill made by the Chicago, Milwaukee & Puget Sound Ry. near North Bend, Wash., which was accomplished by hydraulicking. In the sluiceways, sheet-iron, cast-iron and even steel plates were worn away with surprising rapidity, and it finally became necessary to resort to removable wooden blocks.

It has long been conceded that enormous losses are involved in the handling and various processes to which coal is subjected before it is resolved into actual power. But we do not believe this new solution to be worthy of serious consideration. The more conservative engineers are, however, beginning to regard long-distance electrical transmission as a fruitful field for investigations along this line, and the next few years will doubtless see a more general adoption of this method. Already the Lehigh Coal & Navigation Co. has a large installation of this character under construction, which will transmit power over a radius of 175 miles. We recommend this method to the consideration of the "pipeline" promoters.

How Our Plants Are Built

It is a healthful exercise for a mine superintendent to look around his plant and determine just how many of the features in his operation are the result of his own devising. The number of these is not large. Most of his improvements arose from the prompting of a catalog, a technical journal, a government bulletin, of a sales agent or of someone whom he happened to meet or who strolled into his plant.

His vaunted operation is based on other men's ideas, and his work has been largely that of an adapter, not of an inventor. This being the case, why do we not put ourselves in the way of learning more? Why do we stay in one place till the new idea is forced upon us? We will learn it sooner or later, but if we grasp it and adopt it now, we shall receive enough profit from its use to pay for its installation and for our search after it, long before we would otherwise have been brought face to face with it, had we waited till it traveled our way. We shall make such an improvement before long; why not now?

The bituminous coal field has undergone a different development from the anthracite because its problems have been slightly different. The minds of its superintendents, engineers and manufacturers have been concentrated on these peculiar difficulties, and machinery has been devised to meet these problems. The bituminous region has like questions to solve but in a minor degree. They are overshadowed by other difficulties and have therefore received only casual attention. Consequently, when the bituminous mine manager goes to the anthracite region, he learns how the hard-coal operator has solved many of the problems which also vex him—problems on which he has not concentrated all thought and energy, but which are nevertheless of great importance in the conduct of soft-coal mines. We mention as examples, the matter of sizing and cleaning coal and disposing of waste.

The Coal Mining Institute of America is going to hold its summer meeting at Wilkes-Barre, Penn. There will be an excellent opportunity to see the great anthracite industry at its best and in the most intimate way. It seems fitting that every member of the Institute should be present. We wonder why the operators do not insist on every member going instead of granting a grudging permission to a few. We can almost as readily understand the purpose of a manager who discourages the reading of technical papers or of publications of the Bureau of Mines as we can the intent of one who does not lend every encouragement to those desiring to view practice in other fields.

DISCUSSION BY READERS

Seven Shifts a Week

I am not sure whether it is wise to sympathize with "Mine Foreman," Collinsville, Ill., COAL AGE, Feb. 15, p. 272. The idea of being on the job "almost day and night"; "living, eating and sleeping" on the job; working "48 and 60" hr. (2 to 2½ days) without going home and making "from 7 to 10 shifts a week" is beyond the average human capacity for endurance.

A man might as well be in the penitentiary at once. We may assume from his letter that this man works for a large company and should have assistants. If *he* has brains, he should be able to share the responsibility with his assistants, provided they are not mere imitations of himself. Perhaps their brains have been numbed by the continual grind of work.

I am heartily in accord with the previous article by a Colorado engineer, COAL AGE, Jan. 18, p. 88, in which he describes seven shifts a week as "a fallacy." Statistics have shown that men are more efficient working six shifts a week, instead of seven. The man who takes his rest day every week is the man who is ready for emergencies when they arise.

The man of initiative and the man of ideas is not ordinarily the man who sleeps with his job; but rather the man, who, when the day's work is over, takes up some hobby or other occupation apart from his day's work. This is the man who systematizes his work so that it can generally be accomplished on the regular working days or nights, as the case may be.

There is unquestionably some necessary work that must be performed on Sundays; but the extra "Sunday job" should be made the exception and not the rule. I will guarantee that if the Collinsville "Mine Foreman" will follow this suggestion, and use the six shifts a week to the best advantage, he will prove a more useful and valuable man to his company. In closing, I may express the hope that no calamity of any kind will occur that would make me dependent on the service that this man would be able to offer, as I could scarcely expect any bright ideas or help from him.

STATE MINE INSPECTOR.

————, Illinois.

Allegheny Valley Price Quotations

A number of local operators are desirous of having Punxsutawney price quotations listed separately in COAL AGE, instead of including them in the general Allegheny prices as you do. Will you kindly advise us why you do not do this.

J. G. STEINER.

Knoxdale, Penn.

It appears that the old difficulty in regard to quotations on coal produced in the territory between Buffalo and Pittsburgh has come to the surface again. The plea is that "our coal is so much better than the run of it in the Allegheny Valley and neighboring territory that we ought to be taken out of the list and given a special price in the market quotations." On the face of it, this always appears just and proper, for no doubt the coal in question is above the average.

The trouble is there are others in the business in the same territory who also would like to obtain help in booming their coal. Some of them are entitled to it while others are not, and the worst of it is that there are also certain mine owners who have high-grade coal coming from one mine and quite a different grade from one or more others. Ask any old Allegheny Valley operator about it and he will say that he knows of certain concerns, with a limited amount of really good coal and a lot of poorer grades, who are selling the good fuel four or five times over. The consumer comes to know which mine's output suits him best and he always asks for that coal.

The fact is that in the Allegheny Valley and vicinity there are grades and grades, all of them varying according to some geological condition. All that the public is likely to find out is that such a mine has the reputation of producing good coal, while another does not enjoy that distinction. Now and then there is a jobber or consumer who claims to be so well acquainted with the different coals that he can recognize at sight the mine any coal comes from, but this is subject to doubt in most cases.

It is, therefore, quite out of the question to quote special prices in a general district, unless some mine or mines turn out a very distinctive sort of coal, such as smithing or cannel. There are mines which are known to be better than others, but the producers will not agree as to which they are. There are so many operators who hold their coal above its actual grade that any effort to distinguish between ordinary coals in a single district, for the purposes of quotation in print, is certain to lead to endless disputes. The writer speaks from experience.

"BUFFALO."

[These remarks are well justified. The Allegheny Valley operators mine coals from several different beds, the Upper and Lower Freeports, the Lower Kittanning and the Brookville. In some sections of the East only one bed, the Pittsburgh, is mined, so there is no uncertainty as to the seam from which the seller receives his coal. Of all the beds in the Allegheny Valley region, the Lower Freeport is the best. The Upper Freeport and Lower Kittanning are of about equal value and the Brookville will run the whole gamut from the best to the worst, so varied is its quality. The Lower Kittanning varies considerably from place to place; sometimes it has much bone in the roof coal and sometimes but little. In dips, it is apt to be streaked with sulphur, but it is also, in a few places, extremely dirty on sharp ridges. Most of the large companies are mining both beds of coal and some were at one time dumping them into the same cars, so that they themselves did not know the actual value of the coal they were shipping.—EDITOR.]

Oxygen Supply and Mine Explosions

The recent discussion on reducing ventilation when firing has proved both instructive and suggestive as showing the effect of a limited supply of oxygen in restricting combustion and preventing mine explosions. This seems to me one of the most serious and important subjects connected with coal mining and one calling for the most careful consideration.

The rapidity and intensity of all forms of combustion depend on the amount of oxygen available to support the combustion. Both gas and coal-dust explosions are but forms of very rapid and violent combustion, and there can be little doubt, therefore, that the violence of the explosion can be controlled, to the extent that we are able to regulate the supply of oxygen.

In case the ventilation in a mine has been stopped and no air is moving, there is still sufficient oxygen present, in the mine atmosphere, to support a gas or coal-dust explosion when the first shots are fired. As the firing proceeds, however, where gas or dust is present much of this available oxygen is consumed by the combustion of the gas or dust. Now, if no more air is allowed to enter the mine, during the time the shots are being fired, there can be little doubt but that the chances for an explosion will be lessened; and if an explosion should then occur, its violence and extent would not be as great as if a large volume of air was in circulation.

Again, when the dust is stirred up and blown into the air by the concussion of the shots, it will settle much quicker in still air than when there is a strong air current passing, which holds it in suspension. This soon produces a dusty atmosphere that is readily fired by the flame of a heavy or windy shot should such a shot occur.

If we can take as correct the figures of Dr. J. Harger, which he presented recently to the Society of Chemical Industry, at Liverpool, England, it is surprising what a slight reduction in the oxygen content of the air is necessary to produce a marked effect on combustion. According to these figures, a reduction of from 1 to 2 per cent. in oxygen, together with an addition of from ½ to ¾ per cent. of carbon dioxide, will render a firedamp mixture nonexplosive. This statement is said to apply also to an explosive atmosphere formed of coal dust suspended in the mine air.

Dr. J. S. Haldane, in his description of the Haldane flame test for oxygen, states that the light of a candle or lamp is diminished 30 per cent., by a decrease of 1 per cent. in the oxygen content of the atmosphere. This might be taken as indicating that the flame of the lamp or candle would be wholly extinguished when the oxygen was depleted 3¾ per cent.

REES H. BEDDOW,
State Mine Inspector.

Gallup, N. M.

The Bellevue Mine Explosion Controversy

Referring to the request of J. W. Powell, COAL AGE, Feb. 8, p. 232, that the question as to the actual cause of the second Bellevue mine explosion be further discussed, I would suggest that Mr. Powell give the readers of COAL AGE his own theory accounting for the explosion. In doing this, I would suggest that he give particular attention to the following points:

1. Name the places in the mine where there was evidence of coking or cindering of the dust, or of any abnormal heat.

2. State the place where, in his opinion, No. 2 explosion had its origin. The origin of this explosion, according to Messrs. Stirling and Cadman, was between the third and fourth cross-pitches above No. 73 chute.

3. State what evidence of firedamp, if any, was found at this point.

4. State if it is not a fact that the timber work at the foot of this chute was not blown away.

5. State if this is not proof positive that an explosion of firedamp did not originate at this point.

6. Explain why Mr. Stirling's evidence at the inquiry does not agree with the place mentioned in his paper as being the point of origin of the explosion.

7. State if the pillars were not intact between chutes Nos. 70 and 71 and were there not stoppings in all the crosscuts between these chutes, excepting the top crosscut.

8. State what pillars were being worked between chutes Nos. 71 and 88.

9. State if it is not a fact that no firedamp was found in the fourth cross-pitch between chutes Nos. 71 and 75 according to the examination by Bovio & Cardell, who made a special investigation of the old workings in this part of the mine, before the disaster occurred.

10. Explain the probable effect on the mine, if a body of firedamp such as that assumed by Messrs. Stirling, Heathcote and Cadman to have accumulated here had been ignited by sparks caused by a fall of roof.

11. Where, in your inspection of the mine, did you find the strongest indications of heat, after the second disaster.

12. State which of the high-pressure, air-charging stations were plugged up by your rescue party, and to what extent it was injured.

13. State in what condition you found chutes Nos. 52 and 53, as regards abnormal heat and débris, especially in the cross-pitches on the south side of the chutes.

14. State which chute or chutes were used for dumping and carrying the coal gotten at the south end of the fifth cross-pitch, to the main gangway; and describe the condition of this chute after the disaster.

15. State if you or any other person, to your knowledge, found any traces of flame or coking on the pillars between chutes Nos. 45 and 82.

16. State if Messrs. Stirling and Cadman do not eliminate coal dust from taking any part in the propagation of the flame, in this explosion.

17. State in what condition you found No. 5 cross-pitch, between chutes Nos. 45 and 61, and the main gangway between these points, after the second disaster.

If Mr. Powell will answer these questions in order, I will reply at as early a date as possible. I believe this will help to settle definitely any points at issue as to the real cause of the explosion.

JAMES ASHWORTH,
Mining Engineer.

Vancouver, B. C., Canada.

Explanation

The following letter received from W. M. Thornton, in reference to his article, "Gas Ignition by Electric Sparks," COAL AGE, Vol. 2, pp. 685, 722 and 796, is self explanatory.

In reply to your letter of the 6th inst., in regard to the size of conductors used in my gas-ignition tests, I would say that the same size of conductor was used throughout; viz., iron, 0.075 in.; copper, 0.065 in.; nickel, 0.05 in., except where I have definitely specified otherwise.

You will probably notice some criticism from the chemists to the effect that small quantities of impurities in the gases would influence the result. This, in my opinion, is quite beside the mark; for the value of the results, as a general electrical survey of the ground covered, is not affected by a change of even a few per cent., in any of the constituents, before dilution with air. I have reason to believe that my analyses were well within that limit.

W. M. THORNTON,
Professor of Electrical Engineering, Armstrong College.
Newcastle-upon-Tyne, England.

INQUIRIES OF GENERAL INTEREST

Bending Stress in a Hoisting Rope

Please explain fully what is meant by bending stress, in reference to wire ropes; and state how this affects the safe working load. Will the use of a sheave of larger diameter reduce the bending stress, and how may the required diameter of a head sheave in hoisting be calculated?

MINING ENGINEER.

Pittsburgh, Penn.

The term bending stress, as its name implies, is the greatest stress produced in any of the fibers or wires of a rope, due to its being bent over a sheave or pulley. When a rope is bent over a sheave, the result is the same as in the bending of a loaded beam (Fig. 1). As in the beam the fibers are compressed on one side of a neutral

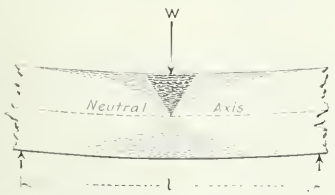


FIG. 1. SHOWING EFFECT OF BENDING ON THE FIBERS OF A HEAVILY LOADED BEAM

axis and extended on the other side of that axis, so when a rope is bent over a sheave some of the wires are compressed while the others are extended. The extension or compression is greatest in the outer fibers of the rope.

A rope is no stronger than its weakest fiber and, for this reason, the bending stress in a rope is always calculated for its ultimate fiber, which is at the outer surface or circumference of the rope. This stress in the outer fiber of the rope, caused by bending, is calculated from a basis of the *modulus of elasticity*, $E = 30{,}000{,}000$ lb. per sq.in., for steel.

The modulus of elasticity expresses the degree of elasticity of the material. For example, a certain force will produce a certain stretch or elongation in a rod of given material and cross-section. The force divided by the area of cross-section is the *unit force;* and the elongation divided by the length of the rod is the *unit elongation*. The modulus of elasticity E is the ratio of the unit force f, to the unit elongation l. Thus,

$$E = \frac{f}{l}; \text{ and } f = El$$

The bending stress must always be considered as a part of the working load and therefore decreases the net working load or the load hoisted. In the use of a sheave of too small diameter, the bending stress in the rope may often equal or even exceed the load hoisted. It is, therefore, of the utmost importance to calculate this stress and add it to the load hoisted, including friction, in order to find the total load on the rope. If this exceeds the safe working load for the rope, a sheave of larger diameter should be used, so as to reduce the bending stress.

In the case of a rope bent over a sheave (Fig. 2), it can be shown that the elongation of the outer fiber of the rope per unit of length, or the unit elongation, is equal to the ratio of the diameter d of the rope, to the diameter

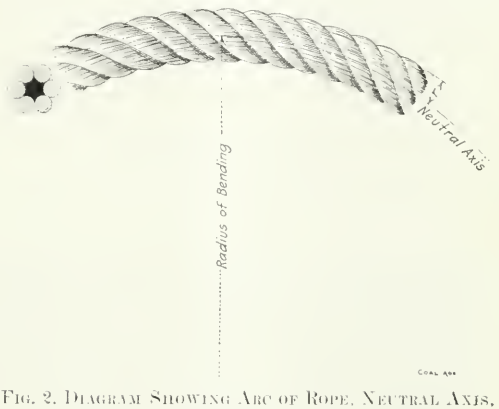

FIG. 2. DIAGRAM SHOWING ARC OF ROPE, NEUTRAL AXIS, RADIUS OF BENDING AND RADIUS OF ROPE

D of the sheave; or $l = \frac{d}{D}$; which gives for the unit bending stress

$$f = E\frac{d}{D}$$

An example will make this clear.

Let it be required to find the smallest diameter of sheave that will be required to hoist a load of 8 tons, including friction, from a shaft 400 ft. deep, using a factor of safety of five.

The first step is to find the diameter of a 6-strand, 19-wire, extra-strong cast-steel hoisting rope, which is calculated for this load, as follows:

$$d = \sqrt{\frac{5 \times 8 \times 2000}{39 \times 2000 - 5\,(1.58 \times 400)}} = 1.03, \textit{ say } 1 \textit{ in.}$$

A 1-in. wire rope weighs 1.58 lb. per lineal foot, and the weight of the rope hanging in the shaft is, therefore, $1.58 \times 400 = 632$ lb. The total load on the rope at the beginning of the hoist, including friction, is then $8 \times 2000 + 632 =$ say 16,630 lb., or 8.315 tons.

For a 6-strand, 19-wire, extra-strong cast-steel hoisting rope, the minimum diameter D of sheave, in inches, is found by dividing the cube of the diameter d of the rope in inches, by the load L on the rope in tons, and multiplying this result by 100, thus:

$$D = 400\frac{d^3}{L} = \frac{400 \times 1^3}{8.315} = 48+, \textit{ say } 50 \textit{ in.}$$

The above formula is based on a value for the modulus of elasticity for steel, $E = 30{,}000{,}000$ lb. per sq.in.

EXAMINATION QUESTIONS

Pertaining to Hoisting

Ques.—What are the essential qualifications of a competent hoisting engineer at a coal mine?

Ans.—The hoisting engineer at a mine must be honest, sober and industrious. He must be prompt in the performance of his duties; observant of small details; quick to answer all signals and must exercise care and judgment in the handling of his engine. He must be intelligent, able to read, write and speak the English language; familiar with the theory of steam and the steam engine and have had sufficient experience to understand the care of boilers and the requirements of firing, to obtain the best results in the generation of steam. He must be able to detect anything wrong in the running of his engine and to make the necessary alterations and repairs.

Ques.—In ordinary coal-mining practice, what style of rope is best adapted to hoisting?

Ans.—A 6-strand, 19-wire, extra-strong cast-steel rope will generally give the best service. The 19-wire ropes (19 wires in each strand, making a total of $6 \times 19 = 114$ wires) are more pliable, because the wires are smaller and, for this reason, they are better adapted to hoisting than the 7-wire ropes (7 wires in a strand, making a total of $7 \times 6 = 42$ wires). For very deep hoisting, plow-steel ropes are often used, on account of their greater tensile strength.

Ques.—Find the diameter of an extra-strong cast-steel, 6-strand, 19-wire rope, for a safe working load of 10 tons.

Ans.—The breaking load of a 1-in., 6-strand, 19-wire, extra-strong cast-steel rope is 39 tons. In ordinary mining practice, it is customary to use a factor of safety of 5. Then, since the strength of ropes varies as the squares of their diameters, the required diameter of rope, for a working load of $L = 10$ tons, may be calculated as follows, using a factor of safety $f = 5$:

$$d = \sqrt{\frac{fL}{39}} = \sqrt{\frac{5 \times 10}{39}} = 1.13 \text{ in.}$$

Therefore, assuming a factor of safety of 5, an extra-strong, cast-steel, 6-strand, 19-wire hoisting rope, 1⅛ in. in diameter, will have a safe working strength of 10 tons.

Ques.—Find the safe working load of a ¾-in., extra-strong, cast-steel hoisting rope having 6 strands and 19 wires.

Ans.—Using the same factor of safety as in the previous question and reversing the formula, the safe working load, in this case is,

$$L = 39\frac{d^2}{f} = \frac{39 \times 0.75^2}{5} = 4.38 \text{ tons}$$

Ques.—What load will be exerted to break the axle of a head sheave when the load on the hoisting rope is 10 tons, including friction; and the rope leading from the winding drum to the head sheave makes an angle of 50 deg. with the horizontal?

Ans.—In this case, the stress in each branch of the hoisting rope is 10 tons (20,000 lb.). If the shaft is vertical, the angle the rope will make in passing over the sheave, or the angle between the two branches of the rope, will be $90 - 50 = 40$ deg. Referring to the accompanying figure, the relation of the forces acting on

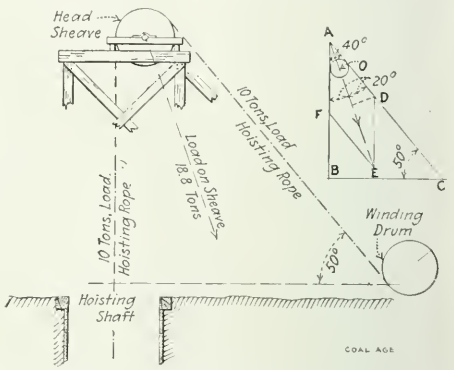

Diagram Showing the Direction and Intensity of the Load on Head Sheave in Hoisting

the sheave and the resulting load on the axle is clearly shown in the small diagram at the right. The center of the sheave being at O, the two branches of the rope are extended to meet at A, and the angle BAC is $90 - 50 = 40$ deg. The parallelogram of forces is represented by the figure, $ADEF$. Since the load on each branch of the rope is the same, $AD = AF$ and the sides of the parallelogram of forces are all equal. The diagonal AE represents the direction and intensity of the resulting load on the axle of the sheave. This load is calculated thus:

$$L = 2\ W\ cos\ \tfrac{1}{2}\ (90° - 50°) = 2 \times 10\ cos\ 20° = 20 \times 0.94 = 18.8\ tons$$

Ques.—Calculate the diameter of an extra-strong, cast-steel, 6-strand, 19-wire rope required for hoisting in a shaft 650 ft. deep. The mine cars weigh 1600 lb. and have a capacity of one ton, each; the weight of the cage is 2400 lb. Allow one-tenth of the total load hoisted, for friction.

Ans.—The load hoisted at one time is coal, 2000 lb.; car, 1600 lb.; cage, 2400 lb.; total, 6000 lb. Allowing one-tenth for friction, the load on the rope is $6000 + 600 = 6600$ lb. Using here a factor of safety of 6 and making allowance in the calculation for the weight of the rope hanging in the shaft, the depth of the shaft being 650 ft.; the required diameter of the rope for this load will be

$$d = \sqrt{\frac{6 \times 6600}{39 \times 2000 - 6\ (1.58 \times 650)}} = 0.74, \text{ say } \tfrac{3}{4} \text{ in}$$

The constant 1.58 is the weight, in pounds per foot, of a 1-in. rope.

SOCIOLOGICAL DEPARTMENT

Safety the First Consideration

By Peter Westleigh*
